TMS320DM814x DaVinci Digital Video Processors

Technical Reference Manual

Literature Number: SPRUGZ8D
14 November 2011–Revised April 2013

Contents

Preface **130**

1 Chip Level Resources **131**

1.1 ARM® Cortex™-A8 Microprocessor Unit (MPU) Subsystem Overview 132
1.1.1 ARM Cortex-A8 RISC Processor 132
1.1.2 Embedded Trace Module (ETM) 133
1.1.3 ARM Cortex-A8 Interrupt Controller (AINTC) 133
1.1.4 ARM Cortex-A8 PLL (PLL_ARM) 133
1.1.5 ARM MPU Interconnect 133
1.2 Media Controller Subsystem 134
1.2.1 Dual Cortex-M3 MPU Subsystem Overview 134
1.2.2 Dual Cortex-M3 MPU Subsystem Integration 135
1.2.3 Dual Cortex-M3 MPU Subsystem Functional Description 138
1.2.4 Shared Cache 140
1.2.5 Shared Cache MMU 140
1.2.6 L2 MMU 141
1.2.7 Registers 142
1.3 C674x DSP 155
1.3.1 Introduction 155
1.3.2 TMS320C674x Megamodule 157
1.3.3 Memory Map 161
1.3.4 Advanced Event Triggering (AET) 161
1.4 HD Video Coprocessor Subsystem 161
1.4.1 HDVICP2 Overview 161
1.4.2 ICONTs 163
1.4.3 vDMA 163
1.4.4 iME3 163
1.4.5 iPE3 163
1.4.6 MC3 163
1.4.7 CALC3 164
1.4.8 iLF3 164
1.4.9 ECD3 164
1.4.10 SL2 Interface 164
1.4.11 Message Bus 164
1.4.12 HDVICP2 Local Interconnect 164
1.4.13 MailBox 164
1.4.14 HDVICP2 System Control 164
1.5 System MMU 166
1.5.1 MMU Overview 166
1.5.2 MMU Integration 166
1.5.3 MMU Functional Description 167
1.5.4 MMU Low-level Programming Models 180
1.5.5 MMU Registers 183
1.6 SGX530 Graphics Subsystem 196
1.6.1 SGX Overview 196
1.6.2 SGX Integration 199

Copyright © 2011–2013, Texas Instruments Incorporated

1.6.3 SGX Functional Description 201
1.6.4 SGX Register Manual 203
1.7 Device Interrupts and EDMA Events 218
1.7.1 Interrupt Controllers 218
1.7.2 Interrupt Requests to Cortex-A8 MPU INTC 219
1.7.3 Interrupt Requests to C674x INTC 222
1.7.4 Interrupt Requests to Media Controller INTC 226
1.7.5 EDMA Channel Synchronization Events 230
1.8 Inter-Processor Communication 233
1.8.1 Reset Requirements 233
1.8.2 Features 233
1.8.3 Overview and Strategy 234
1.8.4 IPC Component Configuration 237
1.9 Mailbox 238
1.9.1 Overview 238
1.9.2 System Mailbox Integration 238
1.9.3 Functional Description 240
1.9.4 Programming Guide 244
1.9.5 Mailbox Registers 248
1.10 Spinlock 268
1.10.1 Overview 268
1.10.2 Integration 269
1.10.3 Functional Description 270
1.10.4 Programming Guide 272
1.10.5 Spinlock Registers 274
1.11 Error Location Module 278
1.11.1 Error Location Module Overview 278
1.11.2 ELM Integration 279
1.11.3 ELM Functional Description 280
1.11.4 ELM Basic Programming Model 283
1.11.5 ELM Registers 290
1.12 Bus Interconnect 302
1.12.1 Interconnect Overview 302
1.12.2 L3 Interconnect 306
1.12.3 L4 Interconnects 384

2 Power, Reset, and Clock Management (PRCM) Module 438

2.1 Introduction 439
2.1.1 Device Power-Management Architecture Building Blocks 439
2.1.2 Module-Level Clock Management 440
2.1.3 Clock Domain 443
2.1.4 Power Management 445
2.2 Power Reset Clock Management Structure 448
2.2.1 Introduction 448
2.3 Clock Generation and Management 450
2.3.1 Types of Clocks 450
2.3.2 Clock Structure 450
2.3.3 Main PLL Clock Structure 453
2.3.4 USB PLL Clock Structure 455
2.3.5 DDR PLL Clock Structure 456
2.3.6 SERDES and Ethernet Clock Structure 456
2.3.7 Video PLL Clock Structure 457
2.3.8 Audio PLL Clock Structure 459
2.3.9 Timer Clock Structure 462

Copyright © 2011–2013, Texas Instruments Incorporated

2.3.10 Device Clocking from External Sources 464
2.3.11 Clock Output Pin 465
2.4 Oscillator 466
2.5 DPLLS 467
2.5.1 DPLLS Frequency Range 468
2.5.2 DPLLS Fractional M-divider Programming 468
2.5.3 DPLLS Clock Functions 468
2.5.4 DPLLS Frequency Factors 469
2.6 DPLLLJ 469
2.6.1 DPLLLJ Fractional M-divider Programming 471
2.6.2 DPLLLJ Clock Functions 471
2.6.3 DPLLLJ Frequency Range (MHz) 472
2.6.4 DPLLLJ Frequency Factors 472
2.6.5 Mode of Operations 472
2.6.6 BYPASS Mode 473
2.6.7 M2 & N2 Change On-the-Fly 474
2.6.8 Gating and Power Down of Output Clocks 474
2.6.9 M2PWDNZ / CLKDCOLDOPWDNZ bits 474
2.6.10 Connected Outputs of DPLLS 475
2.6.11 Connected Outputs of DPLLLJ 475
2.7 Reset Management 475
2.7.1 Overview 475
2.7.2 Reset Concepts and Definitions 475
2.7.3 Power On Reset (PORz) 477
2.7.4 External Warm Reset (RESETz) 477
2.7.5 Emulation Cold Reset (ICEPICK POR) 477
2.7.6 Emulation Warm Reset 477
2.7.7 Reset Requestor 477
2.7.8 Software Controlled Reset 477
2.7.9 Test Reset (TRSTz) 477
2.7.10 Reset Priority 478
2.7.11 Reset Characteristics 478
2.7.12 Trace Functionality Across Reset 478
2.7.13 Reset Isolation 479
2.7.14 Reset Output ($\overline{\text{RSTOUT_WD_OUT}}$) 479
2.7.15 Power-on-Reset (PORz) Sequence 480
2.7.16 RESETz Sequence 480
2.7.17 Power-Up/Down Sequence 481
2.7.18 IO State 481
2.7.19 MPU Subsystem POR Sequence 481
2.7.20 MPU Subsystem Warm Sequence 482
2.7.21 HDVICP Power-On Reset Sequence 483
2.7.22 HDVICP Software Warm Reset Sequence 485
2.7.23 C674x DSP Power-On Reset Sequence 485
2.7.24 C674x DSP Warm Reset Sequence 486
2.7.25 Media Controller Power-On Reset Sequence 486
2.7.26 Media Controller Warm Reset Sequence 488
2.8 Voltage and Power Domains 488
2.8.1 Voltage Domains 489
2.8.2 Power Domains 490
2.8.3 Device Modules and Power Management Attribute List 491
2.8.4 Power Domain Power-Down Sequence 491
2.8.5 Power Domain Power-Up Sequence 491

2.9 Voltage Management Functional Description 493
2.9.1 Overview 493
2.9.2 Internal LDOs Control 494
2.10 PRCM Registers 494
2.10.1 PLLSS Registers 496
2.10.2 PRM_DEVICE Registers 683
2.10.3 CM_DEVICE Registers 686
2.10.4 OCP_SOCKET_PRM Registers 688
2.10.5 CM_DPLL Registers 690
2.10.6 CM_ACTIVE Registers 710
2.10.7 CM_DEFAULT Registers 712
2.10.8 CM_HDVICP Registers 720
2.10.9 CM_ISP Registers 724
2.10.10 CM_DSS Registers 728
2.10.11 CM_SGX Registers 732
2.10.12 PRM_ACTIVE Registers 735
2.10.13 PRM_DEFAULT Registers 740
2.10.14 PRM_HDVICP Registers 745
2.10.15 PRM_ISP Registers 750
2.10.16 PRM_DSS Registers 754
2.10.17 PRM_SGX Registers 759
2.10.18 CM_ALWON Registers 764
2.10.19 PRM_ALWON Registers 828

3 Control Module 831

3.1 Control Module 832
3.1.1 MMR_LOCK Register (Locked/Unlocked States) 832
3.1.2 Pin Multiplexing (Pin Mux) 833
3.1.3 BOOT Status 834
3.1.4 DSP / EDMA Memory Management Unit Configuration 834
3.1.5 Interrupt and DMA Controller Crossbars 834
3.1.6 Device Level Peripheral Configuration 835
3.1.7 Reset Isolation 835
3.2 CONTROL_MODULE Registers 836
3.2.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h] 842
3.2.2 CONTROL_HWINFO Register (offset = 4h) [reset = 0h] 843
3.2.3 CONTROL_SYSCONFIG Register (offset = 10h) [reset = 0h] 844
3.2.4 CONTROL_STATUS Register (offset = 40h) [reset = 0h] 845
3.2.5 BOOTSTAT Register (offset = 44h) [reset = 0h] 847
3.2.6 DSPBOOTADDR Register (offset = 48h) [reset = 800000h] 848
3.2.7 MMR_LOCK0 Register (offset = 60h) [reset = 1A1C8144h] 849
3.2.8 MMR_LOCK1 Register (offset = 64h) [reset = FDF45530h] 850
3.2.9 MMR_LOCK2 Register (offset = 68h) [reset = 1AE6E320h] 851
3.2.10 MMR_LOCK3 Register (offset = 6Ch) [reset = 2FFA927Ch] 852
3.2.11 MMR_LOCK4 Register (offset = 70h) [reset = 143F832Ch] 853
3.2.12 CONTROL_SEC_CTRL Register (offset = 100h) [reset = 1Bh] 854
3.2.13 DEVOSC Register (offset = 468h) [reset = 0h] 855
3.2.14 AUXOSC Register (offset = 46Ch) [reset = 2h] 856
3.2.15 PCIE_CFG Register (offset = 480h) [reset = 0h] 857
3.2.16 DEVICE_ID Register (offset = 600h) [reset = B8F202Eh] 858
3.2.17 DEV_FEATURE Register (offset = 604h) [reset = 0h] 859
3.2.18 INIT_PRIORITY_0 Register (offset = 608h) [reset = 0h] 861
3.2.19 INIT_PRIORITY_1 Register (offset = 60Ch) [reset = 0h] 862
3.2.20 MMU_CFG Register (offset = 610h) [reset = 80h] 863

Copyright © 2011–2013, Texas Instruments Incorporated

3.2.21 TPTC_CFG Register (offset = 614h) [reset = AAh] 864
3.2.22 DSP_IDLE_CFG Register (offset = 61Ch) [reset = 28h] 865
3.2.23 USB_CTRL0 Register (offset = 620h) [reset = 3C006007h] 866
3.2.24 USB_STS0 Register (offset = 624h) [reset = 0h] 868
3.2.25 USB_CTRL1 Register (offset = 628h) [reset = 3C006007h] 869
3.2.26 USB_STS1 Register (offset = 62Ch) [reset = 0h] 871
3.2.27 MAC_ID0_LO Register (offset = 630h) [reset = 0h] 872
3.2.28 MAC_ID0_HI Register (offset = 634h) [reset = 0h] 873
3.2.29 MAC_ID1_LO Register (offset = 638h) [reset = 0h] 874
3.2.30 MAC_ID1_HI Register (offset = 63Ch) [reset = 0h] 875
3.2.31 SW_REVISION Register (offset = 640h) [reset = 0h] 876
3.2.32 DCAN_RAMINIT Register (offset = 644h) [reset = 0h] 877
3.2.33 AUD_CTRL Register (offset = 64Ch) [reset = 0h] 878
3.2.34 GMII_SEL Register (offset = 650h) [reset = 0h] 879
3.2.35 OCMEM_PWRDN Register (offset = 654h) [reset = 0h] 880
3.2.36 MEDIA_CONTROLLER_MEM_PWRDN Register (offset = 65Ch) [reset = 0h] 881
3.2.37 SD_DAC_CTRL Register (offset = 670h) [reset = 18800C6h] 882
3.2.38 SD_DAC0_CAL Register (offset = 674h) [reset = 0h] 884
3.2.39 SD_DAC1_CAL Register (offset = 678h) [reset = 0h] 885
3.2.40 SD_DAC0_REGCTRL Register (offset = 67Ch) [reset = 0h] 886
3.2.41 SD_DAC0_REGSTATUS Register (offset = 680h) [reset = 0h] 887
3.2.42 SD_DAC1_REGCTRL Register (offset = 684h) [reset = 0h] 888
3.2.43 SD_DAC1_REGSTATUS Register (offset = 688h) [reset = 0h] 889
3.2.44 EMIF_CLK_GATE Register (offset = 694h) [reset = 0h] 890
3.2.45 SMRT_CTRL Register (offset = 6A0h) [reset = 0h] 891
3.2.46 ARM_CORTEX_A8_HW_DBG_SEL Register (offset = 6A4h) [reset = 0h] 892
3.2.47 ARM_CORTEX_A8_HW_DBG_INFO Register (offset = 6A8h) [reset = 0h] 893
3.2.48 PRCM_DEBUG_ALWON_DEFAULT Register (offset = 6B0h) [reset = 3F7B0010h] 894
3.2.49 PRCM_DEBUG_PD_DOMAIN_STATUS Register (offset = 6B4h) [reset = 871C7180h] 896
3.2.50 PCIE_PLLCFG0 Register (offset = 6D8h) [reset = 40007000h] 899
3.2.51 PCIE_PLLCFG1 Register (offset = 6DCh) [reset = 0h] 901
3.2.52 PCIE_PLLCFG2 Register (offset = 6E0h) [reset = 0h] 902
3.2.53 PCIE_PLLCFG3 Register (offset = 6E4h) [reset = 4000000h] 903
3.2.54 PCIE_PLLCFG4 Register (offset = 6E8h) [reset = 0h] 905
3.2.55 PCIE_PLLSTATUS Register (offset = 6ECh) [reset = 0h] 907
3.2.56 PCIE_RXSTATUS Register (offset = 6F0h) [reset = 0h] 908
3.2.57 PCIE_TXSTATUS Register (offset = 6F4h) [reset = 0h] 909
3.2.58 SATA_PLLCFG0 Register (offset = 720h) [reset = C0007160h] 910
3.2.59 SATA_PLLCFG1 Register (offset = 724h) [reset = 812C0000h] 911
3.2.60 SATA_PLLCFG2 Register (offset = 728h) [reset = 0h] 912
3.2.61 SATA_PLLCFG3 Register (offset = 72Ch) [reset = 4000000h] 913
3.2.62 SATA_PLLCFG4 Register (offset = 730h) [reset = 0h] 916
3.2.63 SATA_TXSTATUS Register (offset = 73Ch) [reset = 0h] 918
3.2.64 SATA_TESTCFG Register (offset = 740h) [reset = 0h] 919
3.2.65 VDD_MPU_OPP_050 Register (offset = 770h) [reset = 0h] 920
3.2.66 VDD_MPU_OPP_100 Register (offset = 774h) [reset = 0h] 921
3.2.67 VDD_MPU_OPP_120 Register (offset = 778h) [reset = 0h] 922
3.2.68 VDD_MPU_OPP_166 Register (offset = 77Ch) [reset = 0h] 923
3.2.69 VDD_C674x_DSP_OPP_050 Register (offset = 788h) [reset = 0h] 924

5 DCAN Controller Area Network 1052
5.1 Overview 1053
5.1.1 Features 1053
5.1.2 Functional Description 1053
5.2 CAN Operation 1055
5.2.1 CAN Module Initialization 1055
5.2.2 CAN Message Transfer (Normal Operation) 1057
5.2.3 Test Modes 1058
5.3 Dual Clock Source 1061
5.4 Interrupt Functionality 1062
5.4.1 Message Object Interrupts 1062
5.4.2 Status Change Interrupts 1062
5.4.3 Error Interrupts 1063
5.5 Local Power-Down Mode 1064
5.5.1 Entering Local Power-Down Mode 1064
5.5.2 Wakeup From Local Power Down 1064
5.6 Parity Check Mechanism 1066
5.6.1 Behavior on Parity Error 1066
5.6.2 Parity Testing 1066
5.7 Debug/Suspend Mode 1067
5.8 Configuration of Message Objects 1067
5.8.1 Configuration of a Transmit Object for Data Frames 1068
5.8.2 Configuration of a Transmit Object for Remote Frames 1068
5.8.3 Configuration of a Single Receive Object for Data Frames 1068
5.8.4 Configuration of a Single Receive Object for Remote Frames 1069
5.8.5 Configuration of a FIFO Buffer 1069
5.9 Message Handling 1070
5.9.1 Message Handler Overview 1070
5.9.2 Receive/Transmit Priority 1070
5.9.3 Transmission of Messages in Event Driven CAN Communication 1070
5.9.4 Updating a Transmit Object 1071
5.9.5 Changing a Transmit Object 1071
5.9.6 Acceptance Filtering of Received Messages 1072
5.9.7 Reception of Data Frames 1072
5.9.8 Reception of Remote Frames 1072
5.9.9 Reading Received Messages 1072
5.9.10 Requesting New Data for a Receive Object 1073
5.9.11 Storing Received Messages in FIFO Buffers 1073
5.9.12 Reading From a FIFO Buffer 1073
5.10 CAN Bit Timing 1075
5.10.1 Bit Time and Bit Rate 1075
5.10.2 DCAN Bit Timing Registers 1080
5.11 Message Interface Register Sets 1083
5.11.1 Message Interface Register Sets 1 and 2 1083
5.11.2 IF3 Register Set 1084
5.12 Message RAM 1085
5.12.1 Structure of Message Objects 1086
5.12.2 Addressing Message Objects in RAM 1088
5.12.3 Message RAM Representation in Debug/Suspend Mode 1089
5.12.4 Message RAM Representation in Direct Access Mode 1090

6 DMM/TILER 1132
6.1 Introduction 1133
6.1.1 Overview 1133
6.1.2 Features 1134
6.1.3 Functional Block Diagram 1134
6.1.4 Terminologies and Acronyms Used in this Document 1135
6.2 Architecture 1136
6.2.1 DMM Functional Description 1136
6.2.2 TILER Functional Description 1147
6.3 Use Case 1171
6.3.1 DMM Basic Register Setup 1171
6.3.2 Simple LUT Bypass Use Case: Arrangement of Video Buffers 1172
6.3.3 LUT Refill Using the PAT Refill Engines 1174
6.3.4 Address Management Using LISA Sections 1181
6.4 DMM/TILER Registers 1186
6.4.1 DMM Revision Register: DMM_REVISION 1186
6.4.2 DMM Clock Management Configuration: DMM_SYSCONFIG 1187
6.4.3 LISA Configuration Locking Register: DMM_LISA_LOCK 1187
6.4.4 DMM LISA MAP Registers: DMM_LISA_MAP_0-DMM_LISA_MAP_3 1188
6.4.5 DMM TILER Orientation Registers: DMM_TILER_OR0-DMM_TILER_OR1 1189
6.4.6 DMM PAT Configuration Register: DMM_PAT_CONFIG 1189
6.4.7 DMM PAT View Registers: DMM_PAT_VIEW_0-DMM_PAT_VIEW_2 1190
6.4.8 DMM View Map Registers: DMM_PAT_VIEW_MAP_0-DMM_PAT_VIEW_MAP_4 1191
6.4.9 DMM PAT View Mapping Base Address Register: DMM_PAT_VIEW_MAP_BASE 1192
6.4.10 DMM PAT End of Interrupt Register: DMM_PAT_IRQ_EOI 1192
6.4.11 DMM PAT Raw Interrupt Status Register: DMM_PAT_IRQSTATUS_RAW 1194
6.4.12 DMM PAT Interrupt Status Register: DMM_PAT_IRQSTATUS 1196
6.4.13 DMM PAT Interrupt Enable Register: DMM_PAT_IRQENABLE_SET 1198
6.4.14 DMM PAT Interrupt Disable Register: DMM_PAT_IRQENABLE_CLR 1200
6.4.15 DMM PAT Status Registers: DMM_PAT_STATUS_0-DMM_PAT_STATUS_3 1202
6.4.16 DMM PAT Descriptor Registers: DMM_PAT_DESCR_0-DMM_PAT_DESCR_3 1203
6.4.17 DMM PAT Area Geometry Registers: DMM_PAT_AREA_0-DMM_PAT_AREA_3 1203
6.4.18 DMM PAT Control Registers: DMM_PAT_CTRL_0-DMM_PAT_CTRL_3 1204
6.4.19 DMM PAT Area Entry Data Registers: DMM_PAT_DATA_0-DMM_PAT_DATA_3 1204
6.4.20 DMM PEG Priority Registers: DMM_PEG_PRIO_0-DMM_PEG_PRIO_1 1205
6.4.21 DMM PEG Priority Registers for PAT: DMM_PEG_PRIO_PAT 1205
7 DDR2 and DDR3 Memory Controller 1206
7.1 Introduction 1207
7.1.1 Purpose of the Peripheral 1207
7.1.2 Features Supported 1207
7.1.3 Features Not Supported 1207
7.2 Architecture 1207
7.2.1 Signal Descriptions 1209
7.2.2 Memory Map 1210
7.2.3 Clock Control 1210
7.2.4 DDR2/DDR3 Memory Controller Subsytem Overview 1210
7.2.5 Address Mapping 1214
7.2.6 Performance Management 1218
7.2.7 Performance Counter Usage 1221

9-40. CPSW Port 0 Transmit FIFO Control Register (P0_TX_IN_CTL) Field Descriptions 1506
9-41. CPSW Port 0 VLAN Register (P0_PORT_VLAN) Field Descriptions 1507
9-42. CPSW Port 0 TX Header Priority to Switch Priority Mapping Register (P0_TX_PRI_MAP) Field Descriptions 1507
9-43. CPSW CPDMA TX (Port 0 RX) Packet Priority to Header Priority Mapping Register (CPDMA_TX_PRI_MAP) Field Descriptions 1508
9-44. CPSW CPDMA RX (Port 0 TX) Switch Priority to DMA Channel Mapping Register (CPDMA_RX_CH_MAP) Field Descriptions 1509
9-45. CPSW Port 1 Maximum FIFO Blocks Register (P1_MAX_BLKS) Field Descriptions 1510
9-46. CPSW Port 1 FIFO Block Usage Count (Read Only) Register (P1_BLK_CNT) Field Descriptions 1510
9-47. CPSW Port 1 Transmit FIFO Control Register (P1_TX_IN_CTL) Field Descriptions 1511
9-48. CPSW Port 1 VLAN Register (P1_PORT_VLAN) Field Descriptions 1511
9-49. CPSW Port 1 TX Header Priority to Switch Pri Mapping Register (P1_TX_PRI_MAP) Field Descriptions 1512
9-50. CPSW_3G Port 1 Time Sync Control Register (P1_TS_CTL) Field Descriptions 1513
9-51. CPSW_3G Port 1 Time Sync Sequence ID and LTYPE Register (P1_TS_SEQ_LTYPE) Field Descriptions 1514
9-52. CPSW_3G Port 1 Time Sync VLAN2 and VLAN2 Register (P1_TS_VLAN) Field Descriptions 1514
9-53. CPSW CPGMAC_SL1 Source Address Low Register (SL1_SA_LO) Field Descriptions 1515
9-54. CPSW CPGMAC_SL1 Source Address High Register (SL1_SA_HI) Field Descriptions 1515
9-55. CPSW Port 1 Transmit Queue Send Percentages Register (P1_SEND_PERCENT) Field Descriptions .. 1516
9-56. CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKS) Field Descriptions 1517
9-57. CPSW Port 2 FIFO Block Usage Count (Read Only) Register (P2_BLK_CNT) Field Descriptions 1517
9-58. CPSW Port 2 Transmit FIFO Control Register (P2_TX_IN_CTL) Field Descriptions 1518
9-59. CPSW Port 2 VLAN Register (P2_PORT_VLAN) Field Descriptions 1518
9-60. CPSW Port 2 TX Header Priority to Switch Priority Mapping Register (P2_TX_PRI_MAP) Field Descriptions 1519
9-61. CPSW_3GF Port 2 Time Sync Control Register (P2_TS_CTL) Field Descriptions 1520
9-62. Port 2 Time Sync Sequence ID and LTYPE Register (P2_TS_SEQ_LTYPE) Field Descriptions 1521
9-63. CPSW_3GF Port 2 Time Sync VLAN2 and VLAN2 Register (P2_TS_VLAN) Field Descriptions 1521
9-64. CPSW CPGMAC_SL2 Source Address Low Register (SL2_SA_LO) Field Descriptions 1522
9-65. CPGMAC_SL2 Source Address High Register (SL2_SA_HI) Field Descriptions 1522
9-66. Port 2 Transmit Queue Send Percentages Register (P2_SEND_PERCENT) Field Descriptions 1523
9-67. CPDMA_REGS TX Identification and Version Register (TX_IDVER) Field Descriptions 1524
9-68. CPDMA_REGS TX Control Register (TX_CONTROL) Field Descriptions 1524
9-69. CPDMA_REGS TX Teardown Register (TX_TEARDOWN) Field Descriptions 1524
9-70. CPDMA_REGS RX Identification and Version Register (RX_IDVER) Field Descriptions 1525
9-71. CPDMA_REGS RX Control Register (RX_CONTROL) Field Descriptions 1525
9-72. CPDMA_REGS RX Teardown Register (RX_TEARDOWN) Field Descriptions 1525
9-73. CPDMA_REGS Software Reset Register (SOFT_RESET) Field Descriptions 1526
9-74. CPDMA_REGS Control Register (DMACONTROL) Field Descriptions 1526
9-75. CPDMA_REGS Status Register (DMASTATUS) Field Descriptions 1528
9-76. CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET) Field Descriptions 1529
9-77. CPDMA_REGS Emulation Control Register (EMCONTROL) Field Descriptions 1529
9-78. CPDMA_REGS Transmit Priority Rate Registers Field Descriptions 1529
9-79. CPDMA_INT TX Interrupt Status (raw value) Register (TX_INTSTAT_RAW) Field Descriptions 1530
9-80. CPDMA_INT TX Interrupt Status (masked value) Register (TX_INTSTAT_MASKED) Field Descriptions. 1530
9-81. CPDMA_INT TX Interrupt Mask Set Register (TX _INTMASK_SET) Field Descriptions 1531
9-82. CPDMA_INT TX Interrupt Mask Clear Register (TX_INTMASK_CLEAR) Field Descriptions 1531
9-83. CPDMA_INT Input Vector (CPDMA_IN_VECTOR) Field Descriptions 1532
9-84. CPDMA_INT End Of Interrupt Vector (CPDMA_EOI_VECTOR) Field Descriptions 1532

1.1 ARM® Cortex™-A8 Microprocessor Unit (MPU) Subsystem Overview

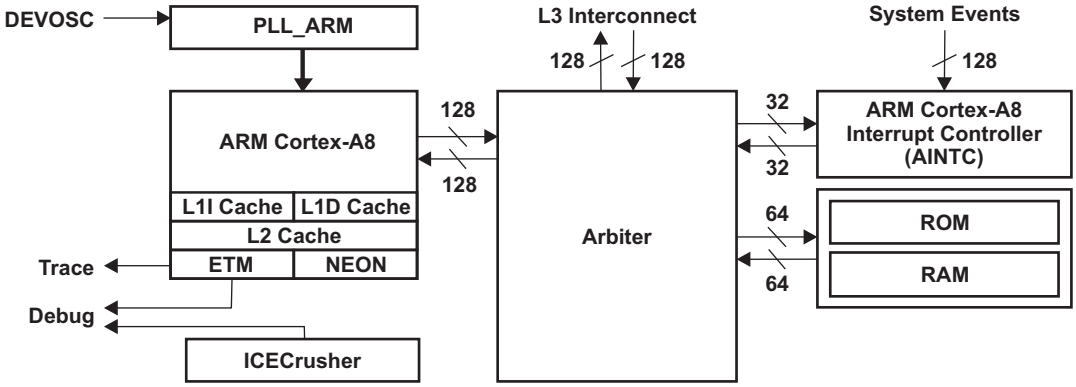
The ARM® Cortex™-A8 Subsystem is designed to allow the ARM Cortex-A8 master control of the device. In general, the ARM Cortex-A8 is responsible for configuration and control of the various subsystems, peripherals, and external memories.

The ARM Cortex-A8 Subsystem includes the following features:

- ARM Cortex-A8 RISC processor:
  - ARMv7 ISA plus Thumb2™, JazelleX™, and Media Extensions
  - Neon™ Floating-Point Unit
  - Enhanced Memory Management Unit (MMU)
  - Little Endian
  - 32K-Byte L1 Instruction Cache
  - 32K-Byte L1 Data Cache
  - 256K-Byte L2 Cache with ECC
- CoreSight Embedded Trace Module (ETM)
- ARM Cortex-A8 Interrupt Controller (AINTC)
- Embedded PLL Controller (PLL_ARM)
- Internal RAM
- Internal ROM

Figure 1-1 shows the ARM Cortex-A8 Subsystem for the device.

Figure 1-1. ARM Cortex-A8 Subsystem



1.1.1 ARM Cortex-A8 RISC Processor

The ARM Cortex-A8 processor is a member of ARM Cortex family of general-purpose microprocessors. This processor is targeted at multi-tasking applications where full memory management, high performance, low die size, and low power are all important. The ARM Cortex-A8 processor supports the ARM debug architecture and includes logic to assist in both hardware and software debug. The ARM Cortex-A8 processor has a Harvard architecture and provides a complete high-performance subsystem, including:

- ARM Cortex-A8 Integer Core
- Superscalar ARMv7 Instruction Set
- Thumb-2 Instruction Set
- Jazelle RCT Acceleration
- CP14 Debug Coprocessor
- CP15 System Control Coprocessor
- NEON™ 64-/128-bit Hybrid SIMD Engine for Multimedia
- Enhanced VFPv3 Floating-Point Coprocessor

Copyright © 2011–2013, Texas Instruments Incorporated

- Enhanced Memory Management Unit (MMU)
- Separate Level-1 Instruction and Data Caches
- Integrated Level-2 Cache
- 128-bit Interconnect with Level 3 Fast (L3) System Memories and Peripherals
- Embedded Trace Module (ETM).

1.1.2 Embedded Trace Module (ETM)

To support real-time trace, the ARM Cortex-A8 processor provides an interface to enable connection of an embedded trace module (ETM). The ETM consists of two parts:

- The Trace port which provides real-time trace capability for the ARM Cortex-A8.
- Triggering facilities that provide trigger resources, which include address and data comparators, counter, and sequencers.

The ARM Cortex-A8 trace port is not pinned out and is, instead, only connected to the system-level Embedded Trace Buffer (ETB). The ETB has a 32KB buffer memory. ETB enabled debug tools are required to read/interpret the captured trace data.

1.1.3 ARM Cortex-A8 Interrupt Controller (AINTC)

The ARM Cortex-A8 subsystem contains an interrupt controller (AINTC) that prioritizes all service requests from the system peripherals and generates either IRQ or FIQ to the ARM Cortex-A8 processor.

1.1.4 ARM Cortex-A8 PLL (PLL_ARM)

The ARM Cortex-A8 subsystem contains an embedded PLL Controller (PLL_ARM) for generating the subsystem's clocks from the device Clock input.

1.1.5 ARM MPU Interconnect

The ARM Cortex-A8 processor is connected through the arbiter to the L3 interconnect port. The L3 interconnect port is 128-bits wide and provides access to the other device modules.

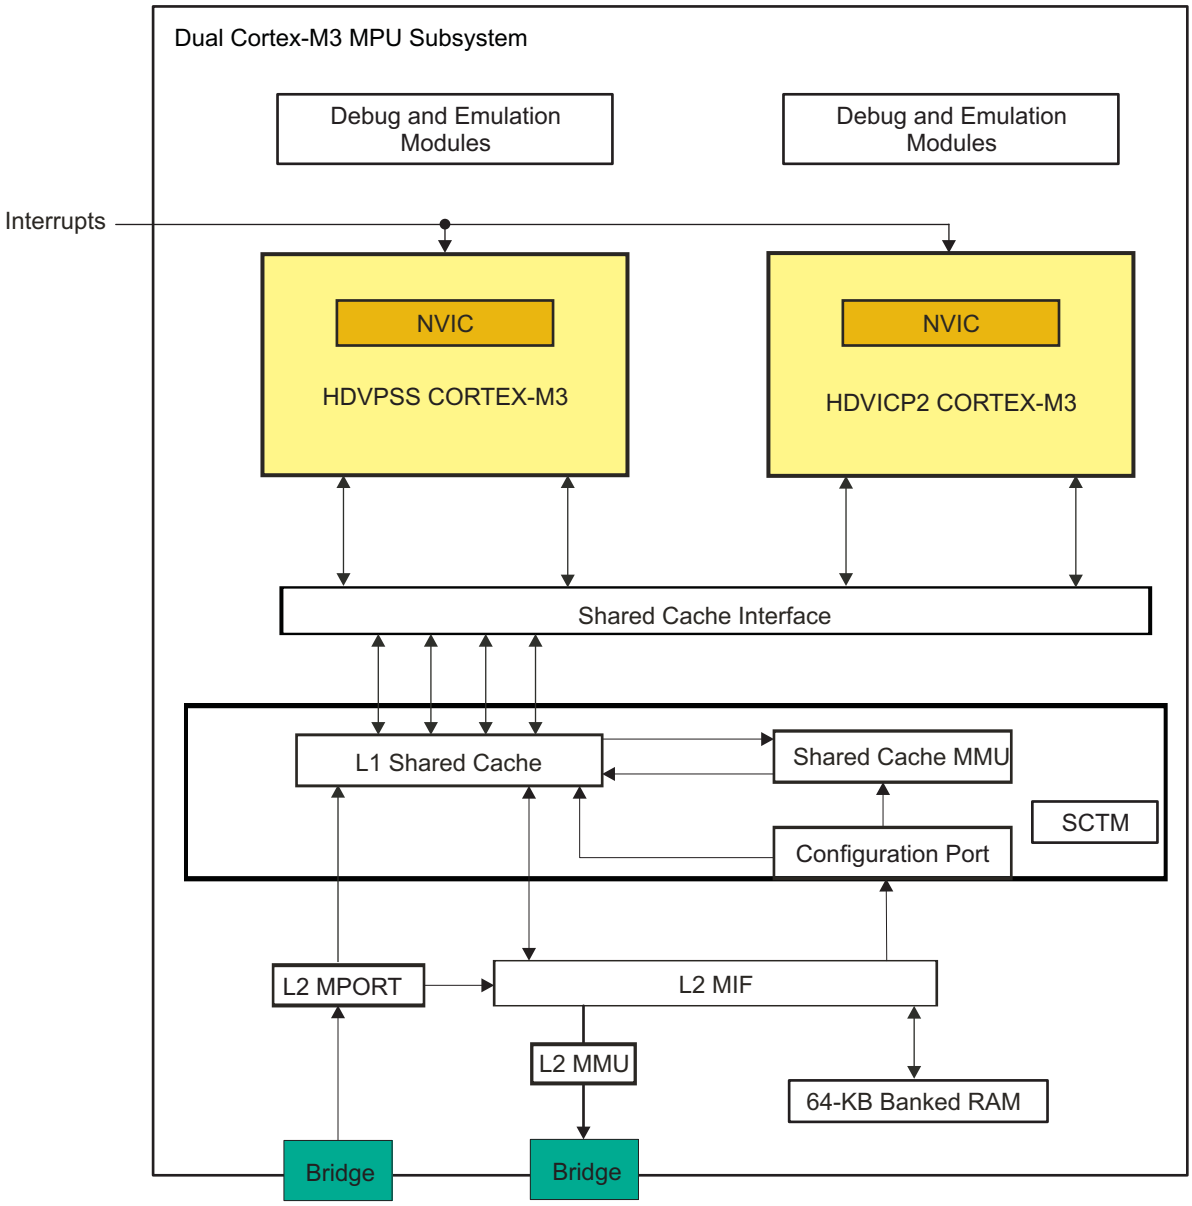
1.2 Media Controller Subsystem

1.2.1 Dual Cortex-M3 MPU Subsystem Overview

1.2.1.1 Introduction

The Dual Cortex™-M3 MPU subsystem controls and manages the HDVPSS and HDVICP2 subsystems. It contains two ARM® Cortex-M3 processors (CPUs) that share a common L1 cache - Shared cache. Figure 1-2 is a high-level block diagram of the dual Cortex-M3 MPU subsystem.

Figure 1-2. Dual Cortex-M3 MPU Subsystem Overview



1.2.1.2 Features

The dual Cortex-M3 MPU subsystem integrates the following:

- Two ARM Cortex-M3 microprocessor:
  - ARMv7-M and Thumb®-2 instruction set architecture

Copyright © 2011–2013, Texas Instruments Incorporated

  - Hardware division and single-cycle multiplication computational acceleration
  - Integrated nested vector interrupt controller (NVIC)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Shared cache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- L2 MIF (Master Interface) – splitter for access to memory or configuration port
- Configuration port - used for shared cache maintenance and shared cache MMU configuration
- Shared cache
  - 32KB divided into 16 banks
  - 4-way
  - Cache configuration – lock/freeze/preload
  - Internal MMU (memory management unit):
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- SCTM - Counter Timer Module
- Banked RAM memory
- Emulation/debug: Emulation feature embedded in Cortex-M3
- L2 MMU: 32 entries with walking table logic
- Power management

1.2.2 Dual Cortex-M3 MPU Subsystem Integration

Figure 1-3 shows the signals that interface with other modules.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-3. Dual Cortex-M3 MPU Subsystem Integration Overview

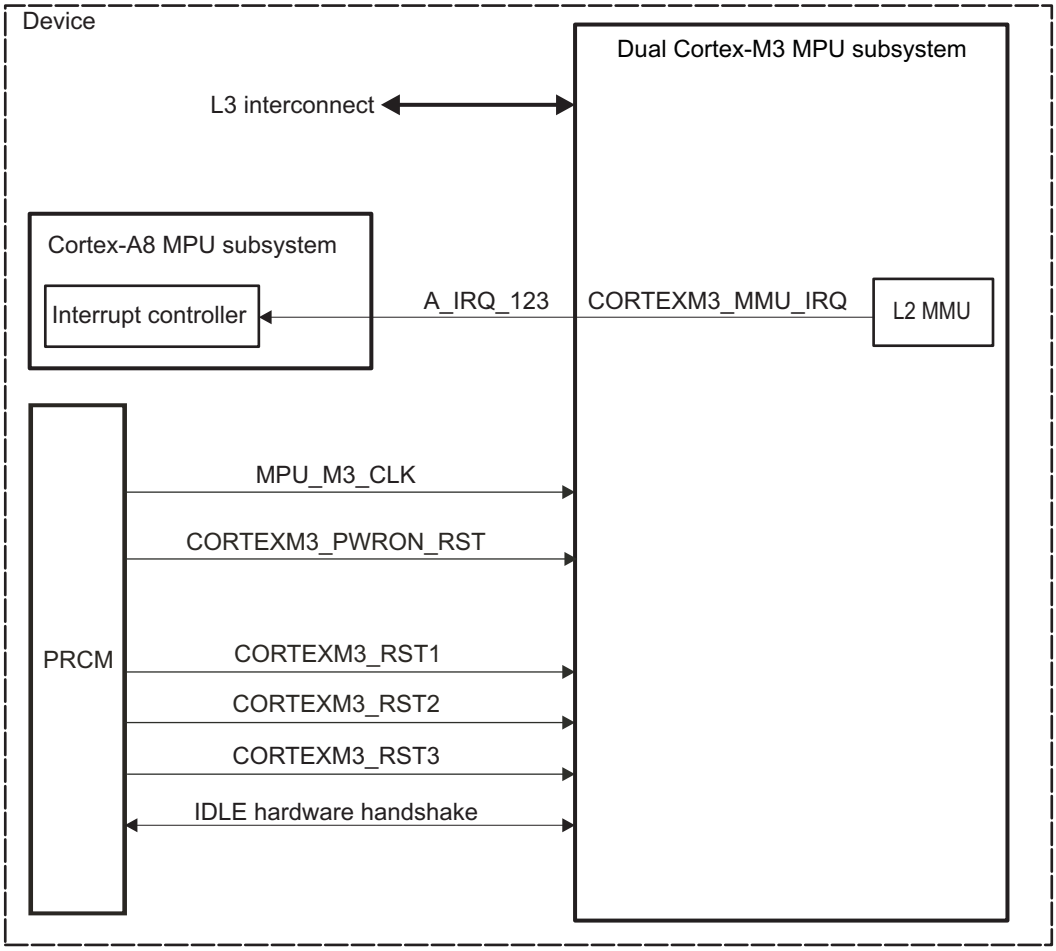


Table 1-1 and Table 1-4 summarize the integration of the module in the device.

Table 1-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
CORTEXM3	PD_ALWAYS_ON	L3

Table 1-2. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
L2MMU	CORTEXM3_MMU_IRQ	A_IRQ_123	Cortex-A8 MPU INTC	L2 MMU Fault Interrupt

Table 1-3. Clocks

Module Instance	Source Signal Name	Destination Signal Name	Source	Description
CORTEXM3	MPU_M3_CLK	MPU_M3_CLK	PRCM module	Interface and Functional Clock

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-4. Resets

Module Instance	Source Signal Name	Destination Signal Name	Source	Description
CORTEXM3	CORTEXM3_PWRON_RST	CORTEXM3_PWRON_RST	PRCM module	Power-on reset, used to reset the whole Media Controller Subsystem
	CORTEXM3_RST1	CORTEXM3_RST1	PRCM module	Reset signal to the HDVPSS
	CORTEXM3_RST2	CORTEXM3_RST2	PRCM module	Reset signal to the HDVICP2
	CORTEXM3_RST3	CORTEXM3_RST3	PRCM module	Reset signal to the shared cache and L2 MMU

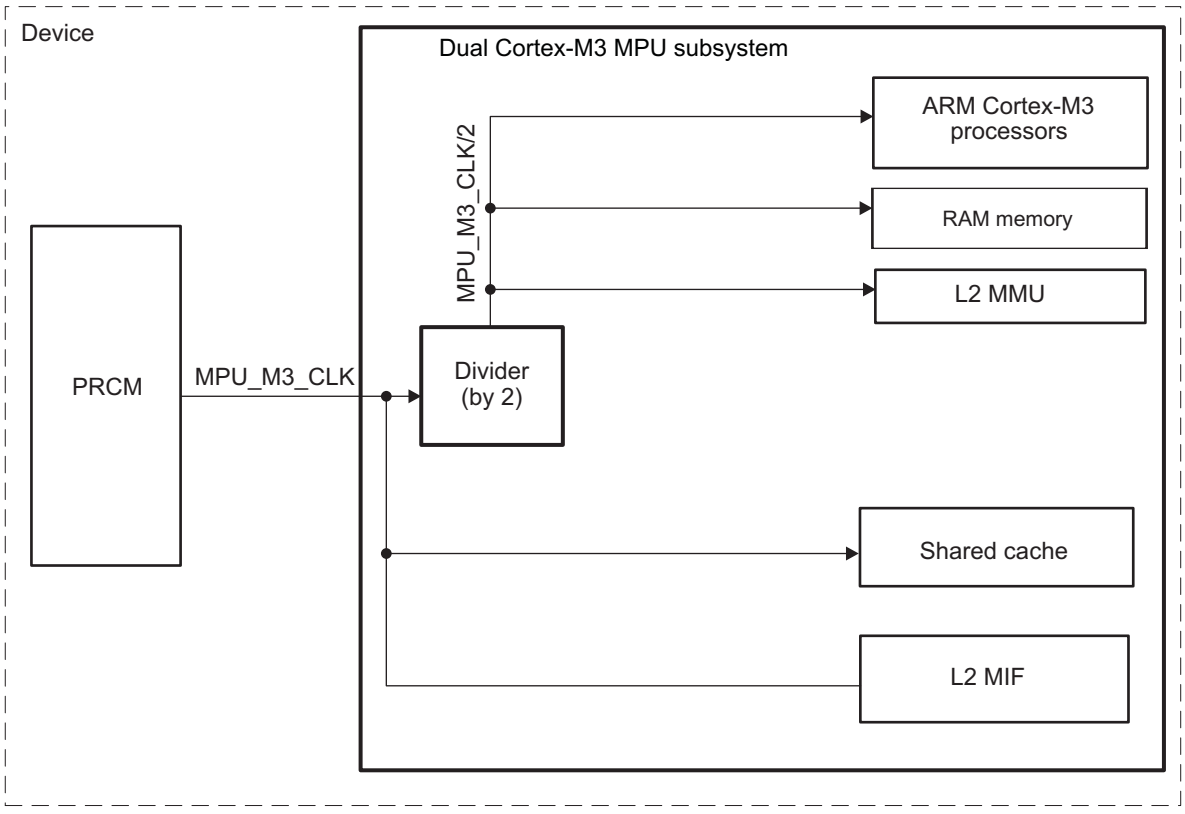
1.2.2.1 Dual Cortex-M3 MPU Subsystem Clock and Reset Distribution

1.2.2.1.1 Clock Distribution

The dual Cortex-M3 subsystem receives only one clock, MPU_M3_CLK, which is divided in two for each ARM Cortex-M3 processor, RAM memory and the L2 MMU module. The shared cache and the L2 MIF are directly clocked by the MPU_M3_CLK, without any division.

Figure 1-4 shows the clocking scheme of the MPU subsystem.

Figure 1-4. Dual Cortex-M3 MPU Subsystem Clocking Scheme



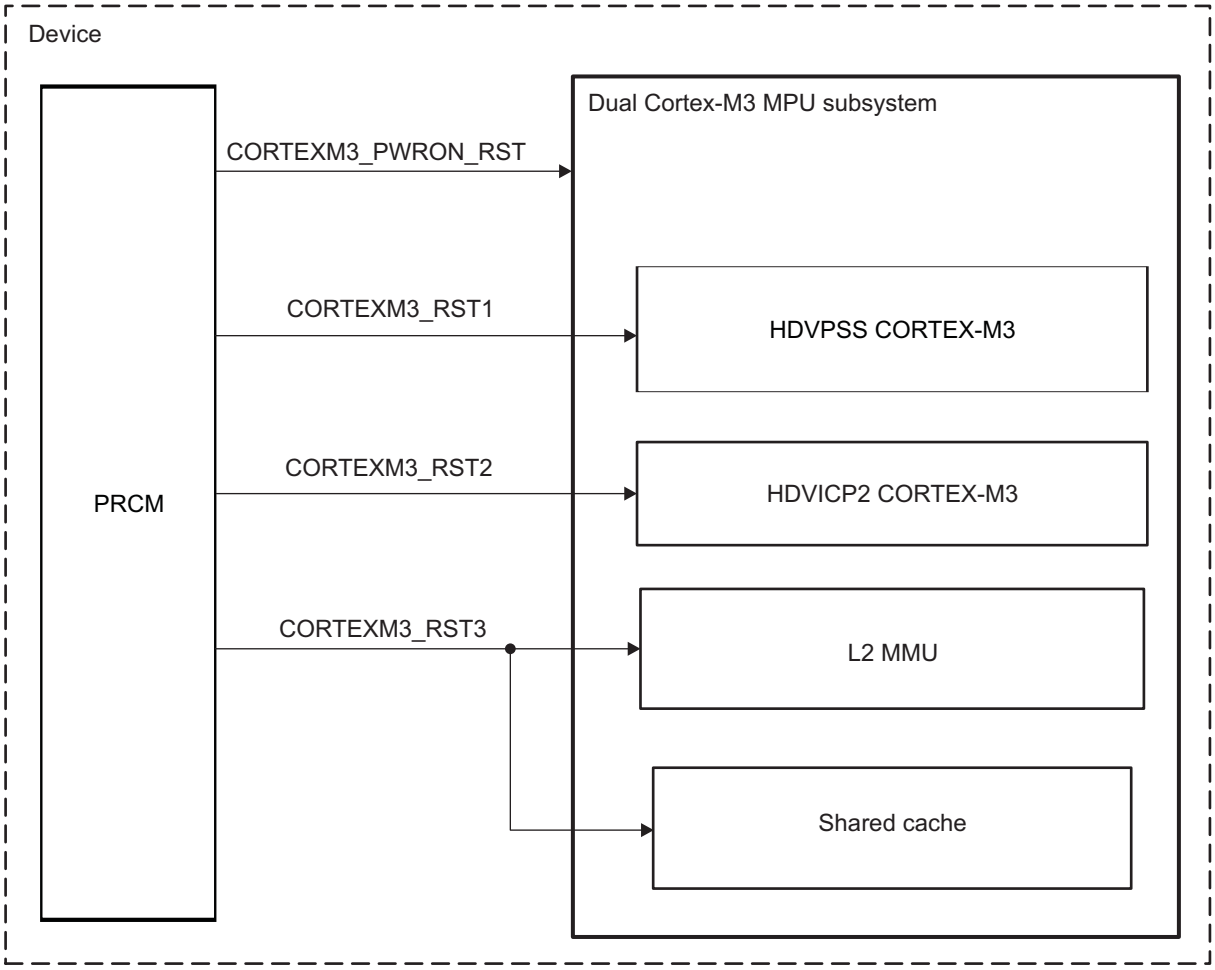
1.2.2.1.2 Reset Distribution

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two ARM Cortex-M3 processors and the rest of the dual Cortex-M3 MPU subsystem be reset independently. These three reset signals are: CORTEXM3_RST1, CORTEXM3_RST2, and CORTEXM3_RST3.

Figure 1-5 shows the reset scheme of the MPU subsystem.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-5. Dual Cortex-M3 MPU Subsystem Reset Scheme



1.2.3 Dual Cortex-M3 MPU Subsystem Functional Description

1.2.3.1 Dual Cortex-M3 MPU Subsystem Block Diagram

The dual Cortex-M3 MPU subsystem integrates the following group of submodules:

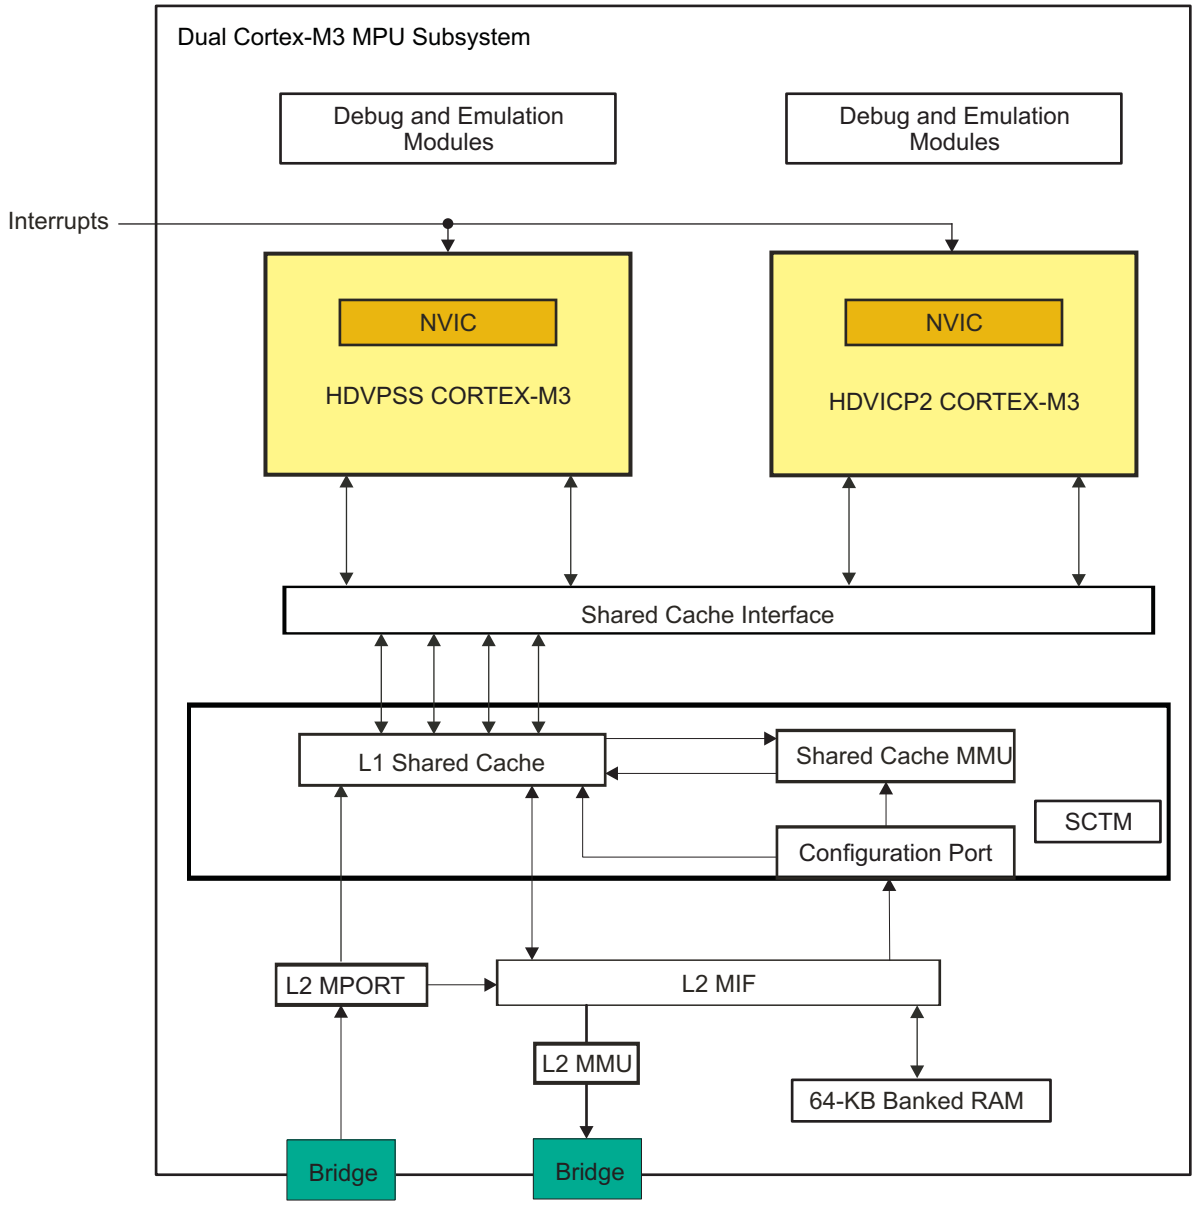
- Two ARM Cortex-M3 processors: Two cores, one core dedicated to HDVPSS and the other core dedicated to HDVICP2. For a description of the ARM Cortex-M3 processor, see the ARM Cortex-M3 Technical Reference Manual, available through your TI representative.
- Interrupt controller (NVIC): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M3 receives the same interrupts except for a few internal interrupts.
- Shared cache interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the ARM Cortex-M3 processors (two for each processor).The instruction and data connections from each ARM Cortex-M3 are multiplexed, but the ARM Cortex-M3 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cache ability is provided through the MMU inside the cache.
- Shared cache: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- Shared cache MMU: Provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the shared cache MMU is done only under privilege mode. The shared cache MMU can be programmed by the Cortex-A8 MPU subsystem through the Cortex-M3 slave port.

Copyright © 2011–2013, Texas Instruments Incorporated

- SCTM: Counter Timer Module, embedded in the Shared cache. Interconnect configuration port: Ca-che maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the shared cache MMU. Interconnect accesses are generated from the L2 MIF.
- L2 MMU: Provides address translation for all the accesses done from the Cortex-M3 to the level 3 (L3) interconnect. The L2 MMU can be programmed by the Cortex-A8 MPU subsystem through the Cortex-M3 slave port.
- L3 interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the dual Cortex-M3 MPU subsystem, see the Memory Map section of the device data manual.
- Banked RAM memory. The address range of the on-chip banked RAM memory is from 0x5502 0000 to 0x5503 FFFF.

Figure 1-6 shows the block diagram of the dual Cortex-M3 MPU subsystem.

Figure 1-6. Dual Cortex-M3 MPU Subsystem



Copyright © 2011–2013, Texas Instruments Incorporated

1.2.4 Shared Cache

Table 1-5 describes the shared cache configuration in the dual Cortex-M3 MPU subsystem platform.

Table 1-5. Shared Cache Configuration

Parameter	Value
Way	4
Size	32KB
Bank Elements	32b
Bank Number	16
Slave Interface Data Size	32b
Master Interface Data Size	64b
Line size	256b
MMU lookup	Included
Number of slaves	4
Number of masters	1
Number of fill/prefetch buffers	4 prefetch buffers
Slave Types	Shared cache interface

Shared cache allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

1.2.5 Shared Cache MMU

The MMU for the shared cache provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Table 1-6 describes the MMU configuration in the dual Cortex-M3 MPU subsystem.

Table 1-6. Shared Cache MMU Configuration

Parameter	Harware Configurable
Number of large pages	4 entries
Size of large pages	32MB or 512MB
Number of medium pages	2 entries
Size of medium pages	128KB or 256KB
Number of small pages	10 entries
Size of small pages	4KB or 16KB
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of unicache maintenance interfaces	3
Size of entry address	32-bit

Copyright © 2011–2013, Texas Instruments Incorporated

1.2.6 L2 MMU

An additional MMU provides address translation for the accesses done from the dual Cortex-M3 MPU subsystem to the L3 interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with ARMv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion
- 2-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16MB, 1MB, 64KB, 4KB)
- Page table alignment on 128-byte boundary for ARM11™ compatibility

The configuration of the MMU can be done from one of the Cortex-M3 cores or from the L3 interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access. When an MMU fault occurs, an interrupt is generated. This interrupt is connected to the Cortex-M3 cores, but it is generated outside of the dual Cortex-M3 MPU subsystem and is connected to the dual Cortex™-A8 MPU subsystem. When an MMU fault occurs, no other access can be done through the L2 MMU; the current faulty access is stalled, thereby stalling one or both Cortex-M3 cores. The dual Cortex-A8 MPU that received the MMU fault must clean up the fault to resume the execution of the code (or reset Cortex-M3).

CACHE_MMU_MMUCONFIG	RW	MMU Configuration Register		0000 0CB8h

1.2.7.1 Configuration Registers (CACHE_CFG)

The Configuration Registers (CACHE_CFG) is described in docato-extra-info-title Configuration Registers (CACHE_CFG) Field DescriptionsTable 1-8 .

Table 1-8. Configuration Registers (CACHE_CFG) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Reserved	R	0
4	Reserved	Reserved	R	0
3	Reserved	Reserved	R	0
2	Reserved	Reserved	R	0
1	BYPASS	bypass cache	RW	0
		0x0: everything is non-cacheable		
		0x1: everything is cacheable		
0	Reserved	Reserved	R	0

1.2.7.2 Interrupt Register (CACHE_INT)

The Interrupt Register (CACHE_INT) is described in Table 1-9.

Table 1-9. Interrupt Register (CACHE_INT) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:9	Reserved	Reserved	R	0
8:5	PORT	slave interface number that has recorded an error	RW W1toClr	0
4	READ	interface read response error	RW W1toClr	0
3	WRITE	interface write response error	RW W1toClr	0
2	MAINT	maintenance is completed	RW W1toClr	0
1	PAGEFAULT	AMMU page fault	RW W1toClr	0
0	CONFIG	configuration error	RW W1toClr	0

1.2.7.3 Interface Configuration Register (CACHE_OCP)

The Interface Configuration Register (CACHE_OCP) is described in Table 1-10.

Table 1-10. Interface Configuration Register (CACHE_OCP) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:6	Reserved	Reserved	R	0
5	CLEANBUF	clean write and prefetch buffers in cache	RW	0
		0x0: do not clean		
		0x1: clean		

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-10. Interface Configuration Register (CACHE_OCP) Field Descriptions (continued)

Bits	Field Name	Description	Type	Reset
4	PREFETCH	always prefetch data	RW	0
		0x0: follow MMU policies		
		0x1: always prefetch		
3	CACHED	follow cacheable sideband signals	RW	1
		0x0: reads always not allocated, writes write through if cached		
		0x1: slave sideband signals determine policy		
2	WRALLOCATE	follow write allocate sideband signals	RW	0
		0x0: no writes are allocated independent to sideband		
		0x1: follow sideband		
1	WRBUFFER	write throughs and write back no allocate are buffered	RW	0
		0x0: write throughs and write back no allocated are not buffered		
		0x1: write throughs and write back no allocated are buffered		
0	WRAP	OCP wrap mode (critical word first)	RW	0
		0x0: disabled		
		0x1: enabled		

1.2.7.4 Maintenance Configuration Register (CACHE_MAINT)

The Maintenance Configuration Register (CACHE_MAINT) is described in Table 1-11.

Table 1-11. Maintenance Configuration Register (CACHE_MAINT) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:6	Reserved	Reserved	R	0
5	INTERRUPT	generate interrupt when maintenance operation is complete	RW	0
		0x0: do not generate interrupt		
		0x1: generate interrupt		
4	INVALIDATE	invalidate lines in region defined by maintenance start/end addresses	RW	0
		0x0: do nothing		
		0x1: invalidate		
3	CLEAN	evict dirty lines in region defined by maintenance start/end addresses	RW	0
		0x0: do nothing		
		0x1: clean		
2	UNLOCK	unlock region defined by maintenance start/end addresses	RW	0
		0x0: do nothing		
		0x1: unlock		
1	LOCK	lock region defined by maintenance start/end addresses	RW	0
		0x0: do nothing		
		0x1: lock

Table 1-11. Maintenance Configuration Register (CACHE_MAINT) Field Descriptions (continued)

Bits	Field Name	Description	Type	Reset
0	PRELOAD	preload region defined by maintenance start/end addresses	RW	0
		0x0: do nothing		
		0x1: preload		

1.2.7.5 Maintenance Start Configuration Register (CACHE_MTSTART)

The Maintenance Start Configuration Register (CACHE_MTSTART) is described in Table 1-12.

Table 1-12. Maintenance Start Configuration Register (CACHE_MTSTART) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	START_ADDR	start address of maintenance operations, reset to 0 when finished	RW	0

1.2.7.6 Maintenance End Configuration Register (CACHE_MTEND)

The Maintenance End Configuration Register (CACHE_MTEND) is described in Table 1-13.

Table 1-13. Maintenance End Configuration Register (CACHE_MTEND) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	END_ADDR	end address of maintenance operations, reset to 0 when finished	RW	0

1.2.7.7 Cache Test Address Register (CACHE_CTADDR)

The Cache Test Address Register (CACHE_CTADDR) is described in Table 1-14.

Table 1-14. Cache Test Address Register (CACHE_CTADDR) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	ADDRESS	address of cache visibility when read CTDATA register, autoincrements	RW	0

1.2.7.8 Cache Test Data Register (CACHE_CTDATA)

The Cache Test Data Register (CACHE_CTDATA) is described in Table 1-15.

Table 1-15. Cache Test Data Register (CACHE_CTDATA) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	DATA	cache data at address of CTADDR register, CTADDR autoincrements each time CTDATA is read	RW	0

1.2.7.9 Counter Timer Control Register (CACHE_SCTM_CTCNTL)

he Counter Timer Control Register (CACHE_SCTM_CTCNTL) is described in Table 1-16.

Table 1-16. Counter Timer Control Register (CACHE_SCTM_CTCNTL) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:26	NUMSTM	Number of timers that can export via STM	R	0
25:18	NUMINPT	Number of event input signals	R	1Fh

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-16. Counter Timer Control Register (CACHE_SCTM_CTCNTL) Field Descriptions (continued)

Bits	Field Name	Description	Type	Reset
17:13	NUMTIMR	Number of timers in the module	R	2
12:7	NUMCNTR	Number of counters in the module	R	8
6:3	REVISION	Revision ID of SCTM	R	TI internal data
2:1	IDLEMODE	Idle mode control	RW	2
		0x0: Force Idle mode		
		0x1: Ths SCTM will acknoledge the idle request, but never transition to the idle state		
		0x2: Ths SCTM uses the smart idle protocol. This is the default mode		
		0x3: Since the SCTM does not support internal wakeup, this mode is identical to smart_idle		
0	ENBL	SCTM global enable	RW	0
		0x0: Ths mode is disable. Only the configuration interface is functional. All other logic is reset		
		0x1: The module is enabled and individual counter/timers can be configured		

1.2.7.10 Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL)

The Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL) is described in Table 1-17.

Table 1-17. Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:11	Reserved	Reserved	R	0
10	XPORTACT	Indicates if a frame is currently being written to the STM	R	0
9:5	NUMXPORT	The total number of counters designated for export. This will be used as the count in the CSM and CCM headers. The value written should be the total number of counters designated for export -1	RW	0
4	CCMXPORT	SW control of CCM message export	RW	0
3	CCMVAIL	SCTM supports CCM export	R	0
2	CSMXPORT	SW control of CSM message export	RW	0
1	SENDOVR	Send overflow data in CSM frame	RW	1
0	ENBL	STM global enable	RW	0
		Read 0x0: The STM function of the SCTM is disabled		
		Read 0x1: The STM function of the SCTM is enabled		

1.2.7.11 Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID)

The Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID) is described in Table 1-18.

Table 1-18. Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:7	Reserved	Reserved	R	0

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-18. Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID) Field Descriptions (continued)

Bits	Field Name	Description	Type	Reset
6:0	MASTID	HW Master ID for this module.	RW	0

1.2.7.12 Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL)

The Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL) is described in Table 1-19.

Table 1-19. Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Reserved	R	0
15:0	INTERVAL	Periodic export interval	RW	0

1.2.7.13 Counter Timer STM Count Select Register 0(CACHE_SCTM_CTSTMSEL0)

The Counter Timer STM Count Select Register 0(CACHE_SCTM_CTSTMSEL0) is described in Table 1-20.

Table 1-20. Counter Timer STM Count Select Register 0(CACHE_SCTM_CTSTMSEL0) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	COUNTSEL	The counter selection bit-field	RW	0

1.2.7.14 Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i)

The Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i) is described in Table 1-21.

Table 1-21. Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	INTERVAL	Interval match value for the timers in the SCTM	RW	0

1.2.7.15 Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM)

The Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM) is described in Table 1-22.

Table 1-22. Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:3	Reserved	Reserved	R	0
2:0	NUMEVT	Number of input selectors for debug events	R	0

1.2.7.16 Counter Timer Global Enable Register 0(CACHE_SCTM_CTGNBL0)

The Counter Timer Global Enable Register 0(CACHE_SCTM_CTGNBL0) is described in Table 1-23.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-23. Counter Timer Global Enable Register 0(CACHE_SCTM_CTGNBL0) Field Description

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved	R	0
7:0	ENABLE	The counter enable bit-field	RW	0

1.2.7.17 Counter Timer Global Reset Register 0(CACHE_SCTM_CTGRST0)

The Counter Timer Global Reset Register 0(CACHE_SCTM_CTGRST0) is described in Table 1-24.

Table 1-24. Counter Timer Global Reset Register 0(CACHE_SCTM_CTGRST0) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved	R	0
7:0	RESET	The counter reset bit-field	RW	0

1.2.7.18 Counter Timer Control Register 0-31(CACHE_SCTM_CTCRWT_i)

he Counter Timer Control Register 0-31(CACHE_SCTM_CTCRWT_i) is described in Table 1-25.

Table 1-25. Counter Timer Control Register 0-31(CACHE_SCTM_CTCRWT_i) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:21	Reserved	Reserved	R	0
20:16	INPSEL	Counter Timer input selection	RW	0
15:11	Reserved	Reserved	R	0
10	RESTART	Restart the timer after an interval match	RW	0
9	DBG	Signal debug logic on interval match	RW	0
8	INT	Generate interrupt on interval match	RW	0
7	Reserved	Reserved	R	0
6	OVRFLW	Counter has wrapped since it was last read	R	0
5	IDLE	Counter ignores processor IDLE state	RW	0
4	FREE	Counter ignores processor debug halt state	RW	0
3	DURMODE	Counter is in duration or occurrence mode	RW	0
2	CHAIN	Counter is chained to an adjacent counter	RW	0
1	RESET	Counter reset control	RW	0
0	ENBL	Counter enable control	RW	0

1.2.7.19 Counter Timer Count Register 0-31(CACHE_SCTM_CTCNTR_k)

The Counter Timer Count Register 0-31(CACHE_SCTM_CTCNTR_k) is described in Table 1-26.

Table 1-26. Counter Timer Count Register 0-31(CACHE_SCTM_CTCNTR_k) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:0	COUNT	Counter value	R	0

1.2.7.20 Large Page Address

The Maintenance Configuration Register (CACHE_MAINT) is described in Table 1-27.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-27. Maintenance Configuration Register (CACHE_MAINT) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:28	ADDRESS	logical source address	RW	0
27:0	Reserved	Reserved	R	0

1.2.7.21 Large Page Translated Address (CACHE_MMU_LARGE_XLTE_l)

The Large Page Translated Address (CACHE_MMU_LARGE_XLTE_l) is described in Table 1-28.

Table 1-28. Large Page Translated Address (CACHE_MMU_LARGE_XLTE_l) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:28	ADDRESS	logical Destination address or translated address	RW	0
27:0	Reserved	Reserved	R	0

1.2.7.22 Large Page Policy(CACHE_MMU_LARGE_POLY_l)

The Large Page Policy(CACHE_MMU_LARGE_POLY_l) is described in Table 1-29.

Table 1-29. Large Page Policy(CACHE_MMU_LARGE_POLY_l) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:24	Reserved	Reserved	R	0
23	L2_WR_POLICY	L2 write policy	RW	0

1.2.7.35 MMU Configuration Register (CACHE_MMU_MMUCONFIG)

The MMU Configuration Register (CACHE_MMU_MMUCONFIG) is described in Table 1-42.

Table 1-42. MMU Configuration Register (CACHE_MMU_MMUCONFIG) Field Descriptions

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Reserved	R	0
1	PRIVILEDGE	Privilege bit. once this bit is set, only global flush, debugger, or hardware reset can clear	RW	0
		0x0: CPU can access everything		
		0x1: CPU can only access maintenance, and DMA can		
		not access MMU at all		
0	Reserved	Reserved	R	0

1.3 C674x DSP

1.3.1 Introduction

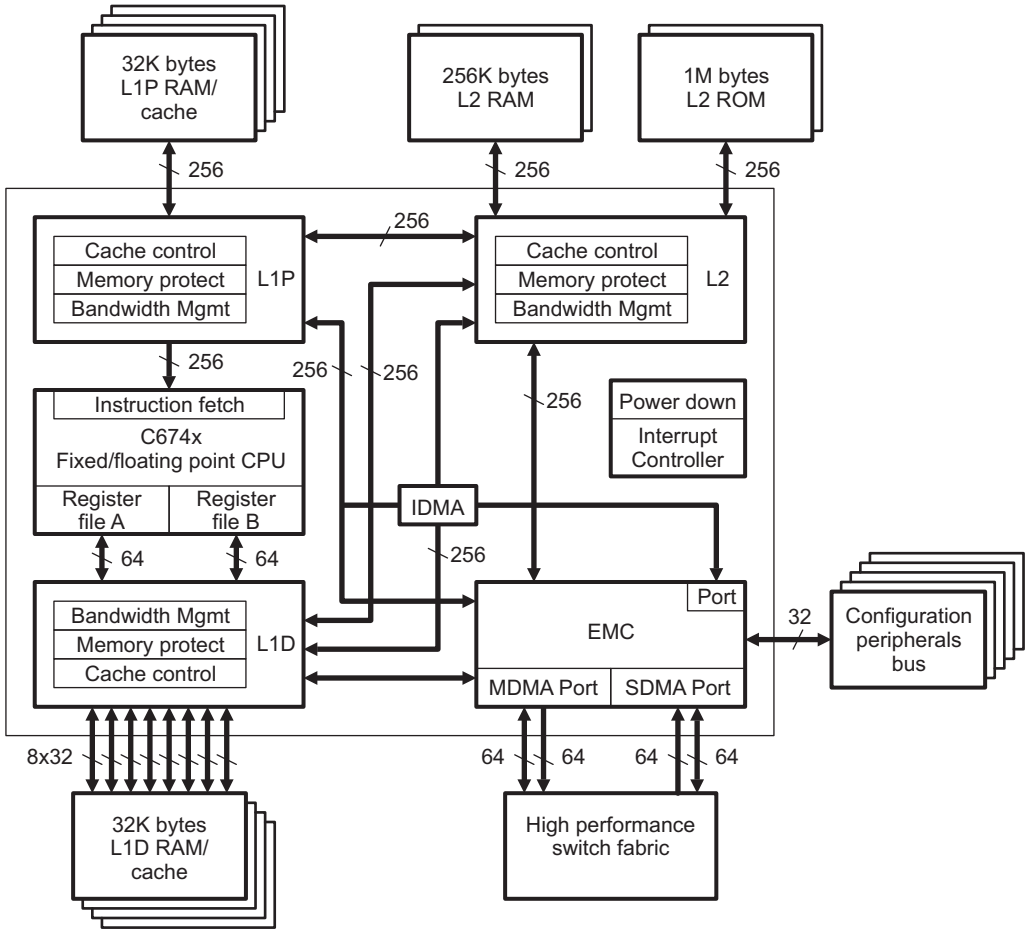
The DSP subsystem (Figure 1-7) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). This chapter provides an overview of the DSP subsystem and the following considerations associated with it:

- Memory mapping
- Interrupts
- Power management

Copyright © 2011–2013, Texas Instruments Incorporated

For more information on the TMS320C674x megamodule, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5), the *TMS320C674x DSP CPU and Instruction Set Reference Guide* (SPRUFE8), and the *TMS320C674x DSP Cache User's Guide* (SPRUG82).

Figure 1-7. TMS320C674x Megamodule Block Diagram



Copyright © 2011–2013, Texas Instruments Incorporated

1.3.2 TMS320C674x Megamodule

The C674x megamodule (Figure 1-7) consists of the following components:

- TMS320C674x CPU
- Internal memory controllers:
  - Level 1 program memory controller (PMC)
  - Level 1 data memory controller (DMC)
  - Level 2 unified memory controller (UMC)
  - Extended memory controller (EMC)
  - Internal direct memory access (IDMA) controller
- Internal peripherals:
  - Interrupt controller (INTC)
  - Power-down controller (PDC)
  - Bandwidth manager (BWM)
- Advanced event triggering (AET)

For more information about each of these controllers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.2.1 Internal Memory Controllers

The C674x megamodule implements a two-level internal cache-based memory architecture with external memory support. Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). L1 memory is accessible to the CPU without stalls. Level 2 memory (L2) can also be split into L2 RAM (normal addressable on-chip memory) and L2 cache for caching external memory locations. The internal direct memory access controller (IDMA) manages DMA among the L1P, L1D, and L2 memories.

1.3.2.2 Internal Peripherals

The C674x megamodule includes the following internal peripherals:

- DSP interrupt controller (INTC)
- DSP power-down controller (PDC)
- Bandwidth manager (BWM)
- Internal DMA (IDMA) controller

This section briefly describes the INTC, PDC, BWM, and IDMA controller. For more information on these internal peripherals, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.2.2.1 Interrupt Controller (INTC)

The C674x megamodule includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps DSP device events to 12 CPU interrupts. All DSP device events are listed in Table 1-43. The INTC is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

Table 1-43. DSP Interrupt Map

Event	Interrupt Name	Source

1.3.2.2.1.1 Interrupt Controller Registers

For more information on the DSP interrupt controller (INTC) registers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.2.2.1.2 NMI Interrupt

In addition to the interrupts listed in Table 1-43, the DSP also supports a special interrupt that behaves more like an exception, non-maskable interrupt (NMI). The NMI interrupt is controlled by two registers in the System Configuration Module, the chip signal register (CHIPSIG) and the chip signal clear register (CHIPSIG_CLR).

The NMI interrupt is asserted by writing a 1 to the CHIPSIG4 bit in CHIPSIG. The NMI interrupt is cleared by writing a 1 to the CHIPSIG4 bit in CHIPSIG_CLR. For more information on CHIPSIG and CHIPSIG_CLR, see the *System Configuration (SYSCFG) Module* chapter.

Copyright © 2011–2013, Texas Instruments Incorporated

1.3.2.2.2 Power-Down Controller (PDC)

The C674x megamodule includes a power-down controller (PDC). The PDC can power-down all of the following components of the C674x megamodule and internal memories of the DSP subsystem:

- C674x CPU
- Level 1 program memory controller (PMC)
- Level 1 data memory controller (DMC)
- Level 2 unified memory controller (UMC)
- Extended memory controller (EMC)
- Internal direct memory access (IDMA) controller
- L1P memory
- L1D memory
- L2 memory

This device supports the static power-down feature from the C674x megamodule. The *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5) describes the power-down control in more detail.

- Static power-down: The PDC initiates power-down (clock gating) of the entire C674x megamodule and all internal memories immediately upon command from software.

Static power-down (clock gating) affects all components of the C674x megamodule and all internal memories. Software can initiate static power-down by way of a register bit in the power-down controller command register (PDCCMD) of the PDC. For more information on the PDC, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.2.2.3 Bandwidth Manager (BWM)

The bandwidth manager (BWM) provides a programmable interface for optimizing bandwidth among the requesters for resources, which include the following:

- EDMA3-initiated DMA transfers (and resulting coherency operations)
- DSP subsystem IDMA-initiated transfers (and resulting coherency operations)
- Programmable cache coherency operations
  - Block based coherency operations
  - Global coherency operations
- CPU direct-initiated transfers
  - Data access (load/store)
  - Program access

The resources include the following:

- L1P memory
- L1D memory
- L2 memory
- Resources outside of the C674x megamodule: external memory, on-chip peripherals, registers

Since any given requestor could potentially block a resource for extended periods of time, the bandwidth manager is implemented to assure fairness for all requesters.

The bandwidth manager implements a weighted-priority-driven bandwidth allocation. Each requestor (EDMA3, DSP subsystem IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system. There are a total of nine priority levels, where priority zero is the highest priority and priority eight is the lowest priority. When requests for a single resource contend, access is granted to the highest-priority requestor. When the contention occurs for multiple successive cycles, a contention counter assures that the lower-priority requestor gets access to the resource every 1 out of *n* arbitration cycles, where *n* is programmable. A priority level of -1 represents a transfer whose priority has been increased due to expiration of the contention counter or a transfer that is fixed as the highest-priority transfer to a given resource.

Copyright © 2011–2013, Texas Instruments Incorporated

1.3.2.2.4 Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the C674x megamodule. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port. The IDMA cannot transfer data to or from the internal DSP memory-mapped register space. The IDMA is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

1.3.3 Memory Map

Refer to your device-specific data manual for the addresses of the memory-map registers.

1.3.3.1 DSP Internal Memory

See the *System Memory* chapter for a description of the DSP internal memory.

1.3.3.2 External Memory

See the *System Interconnect* chapter and the *System Memory* chapter for a description of the additional memory and peripherals that the DSP has access to.

1.3.4 Advanced Event Triggering (AET)

The C674x megamodule supports advanced event triggering (AET). This capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

1.4 HD Video Coprocessor Subsystem

1.4.1 HDVICP2 Overview

The HDVICP2 is the image and video imaging hardware accelerator subsystem.

The HDVICP2 supports resolutions up to 1080 p/i with full performance of 60 fps (or 120 fields). The HDVICP2 subsystem supports the following codec standards natively; that is, all functions of standards are accelerated (without any intervention of the digital signal processor [Media Controller]):

- H.264: BP/MP/HP Encode and Decode
- H.264: Fast Profile/RCDO Encode and Decode
- MPEG-4: SP/ASP Encode/Decode (No support for GMC)
- DivX 5.x & higher Encode/Decode (No lower version; for example, 3.11 and 4.x)
- H.263: Profile 0 and 3 for Decode, Profile 0 for Encode
- Sorenson Spark: V0 and V1 Decode (No encode support)
- MPEG-2 SP/MP Encode/Decode
- MPEG-1 Encode/Decode
- VC1/WMV9/RTV : SP/MP/AP Encode and Decode
- ON2 VP6/VP7 Decode
- RV 8/9/10 Decode
- AVS 1.0 Encode and Decode

Copyright © 2011–2013, Texas Instruments Incorporated

- JPEG (also MJPEG) Baseline Encode/Decode
- H264 Annex H (MVC)

The HDVICP2 subsystem is composed of:

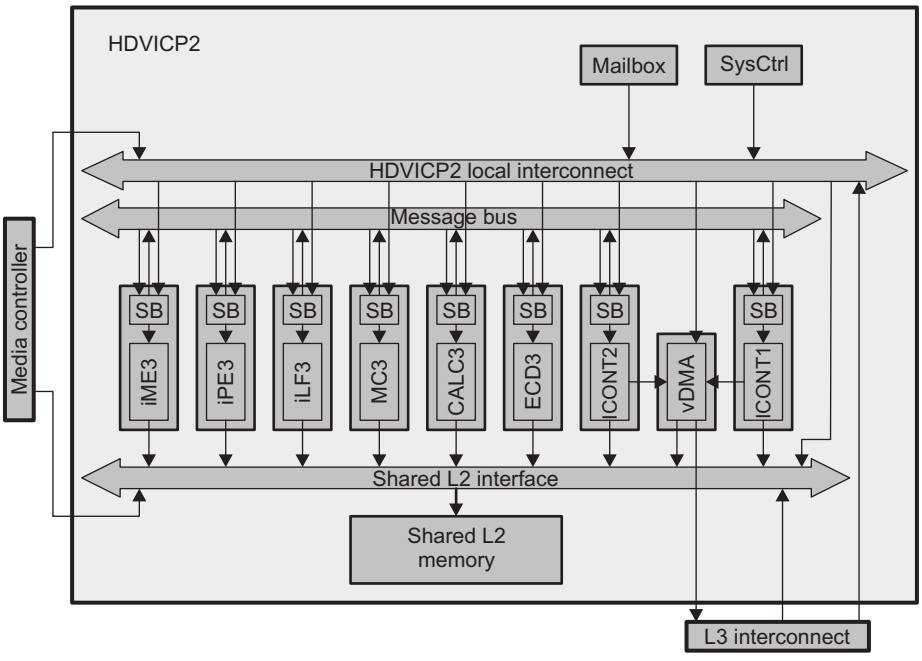
- A primary and a secondary sequencer: ICONT1 & ICONT2, which include its memories and an interrupt controller. Both these sequencers, ICONT1 and ICONT2, are identical.
- A video DMA engine: vDMA
- An entropy coder/decoder: ECD3
- A motion compensation engine: MC3
- A transform and quantization calculation engine: CALC3
- A loop filter acceleration engine: iLF3
- A motion estimation acceleration engine: iME3
- An intraprediction estimation engine: iPE3
- Shared level 2 (L2) interface and memory (of size 256 Kbytes)
- Local interconnect
- A message interface for communication between SyncBoxes
- Mailbox
- A debug module for trace event and software instrumentation: SMSET

TI has chosen eXpress DSP Digital Media (xDM) standard as the principle software interface to HDVICP2. The xDM standard defines application programming interfaces (APIs) through which an application invokes a particular class of codec, such as video, imaging, speech, and audio (aka VISA). The video and imaging classes for encode and decode apply to HDVICP2.

1.4.1.1 HDVICP2 Functional Description

Figure 1-8 shows the block diagram of the HDVICP2 subsystem.

Figure 1-8. HDVICP2 Block Diagram



Copyright © 2011–2013, Texas Instruments Incorporated

1.4.1.2 SyncBox

The SyncBox is a configurable module that is in charge of scheduling all embedded hardware modules within the HDVICP2 subsystem. It handles all aspects of synchronization, data sharing, and parameters passing between accelerators. It also offers the possibilities to use asynchronous messages.

1.4.2 ICONTs

The ICONT module is an ARM968E-S based microcontroller with 32KB of instruction tightly coupled memory (TCM) and 16KB of data tightly coupled memory. It includes an interrupt controller (INTC), a local data mover, its own SyncBox module for synchronizing tasks with other modules and its associated SyncBox handler.

Two identical instances of the ICONT, ICONT1 and ICONT2, are present in the HDVICP2 subsystem. They can typically be used to perform high-level processing (at frame and slice level), control at macroblock-level bounding box computation and other vDMA processing tasks.

Software can map processing equally on either ICONT.

1.4.3 vDMA

The vDMA is a DMA engine to perform data transfer between external memories and shared L2 memory. The VDMA can also perform memory copies inside SL2 and inside external memory.

1.4.4 iME3

The iME3 accelerator is used to perform motion estimation for Video encoding. iME3 has its own embedded SyncBox module for synchronizing tasks with other modules.

The iME3 compares a current macroblock to a reference area and provides an area in the reference region (in terms of offsets) which is least different to the current macroblock. It can also interpolate a block with half or quarter pixel precision, thus producing 4 (half pixel) or 16 (quarter pixel) interpolated blocks from the original block. Additionally, the IME3 supports searching of the best matching block within the interpolated planes.

1.4.5 iPE3

The iPE3 accelerator is used to perform the intraprediction estimation for video encoding. The iPE3 has its own embedded SyncBox module for synchronizing tasks with other modules and an LSE to transfer data from internal memories to shared L2 memory.

The iPE3 supports two modes, depending on the video standard:

- Spatial intraprediction estimation for H264 and AVS. It creates intraprediction macroblocks with given intramodes from the original macroblock and provides a cost estimation between the original macroblock and each pseudo intraprediction macroblock, and then chooses a mode with the smallest cost to recommend it as an optimal intraprediction mode.
- Spatial activity for MPEG-1/2/4 and VC-1. It calculates the spatial activity of the original luminance samples with the specified block size. This mode is designed to provide information about the original Luma pixels. The values can be used to decide the coding parameters of the macroblock such as the coding mode and the quantization parameter.

1.4.6 MC3

The MC3 accelerator is used to perform the motion compensation. The MC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It creates an interprediction macroblock with given motion vectors and modes from the reference data.

Copyright © 2011–2013, Texas Instruments Incorporated

1.4.7 CALC3

The CALC3 accelerator is used to perform forward and inverse transform and quantization calculation. CALC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It can perform transform/inverse transform, Q/iQ and DC/AC prediction.

1.4.8 iLF3

The iLF3 accelerator is used to perform deblocking filtering and boundary strength computation. The iLF3 has its own embedded SyncBox module for synchronizing tasks with other HWAs.

1.4.9 ECD3

The ECD3 accelerator is designed to encode and decode the stream. ECD3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It supports Huffman codes and arithmetic codes.

For encode, the ECD3 encodes the macroblock information and residual data into a bitstream. For decode, the ECD3 decodes the bitstream and recovers the macroblock information and residual data.

1.4.10 SL2 Interface

The shared L2 interface, SL2IF, is an arbitrator that allows 18 initiators to access to an interleaved set of eight memory banks.

The SL2IF has two sets of interfaces:

- Eighteen 128-bit interfaces for accesses from module's to shared L2 memories.
- Eight 128-bit memory interfaces for direct accesses to the memory banks.

1.4.11 Message Bus

The message bus is an arbitrator that allows eight initiators to access eight targets. It is used to dispatch messages generated by the SyncBox of the different IPs.

1.4.12 HDVICP2 Local Interconnect

The HDVICP2 local interconnect provides connectivity between two external host interconnects (Media Controller and L3), two local sequencers (ICONT1 and ICONT2) and video hardware accelerators (iME3, iLF3, ECD3, CALC3, MC3, iPE3), video DMA engine (vDMA), and local modules (mailbox and sysctrl).

1.4.13 MailBox

The function of the mailbox is to support a 2-way communication between two hosts through interrupts. It allows the software to establish a communication channel between processors through a set of registers and associated interrupt signals by sending and receiving messages.

The mailbox embedded inside the HDVICP2 subsystem implements a 2-way communication between three external users and one internal user. This communication is ensured through three pairs of mailboxes and four-message FIFO depth for each message queue.

NOTE: The internal user is one of the two ICONTs. ICONT1 and ICONT2 are connected on a shared interrupt line. The choice between ICONT1 and ICONT2 is done by masking mailbox interrupt on ICONT1 or ICONT2. ICONT1 and ICONT2 can access the mailbox through the HDVICP2 local interconnect.

1.4.14 HDVICP2 System Control

The SYSCTRL module of HDVICP2 is in charge of:

Copyright © 2011–2013, Texas Instruments Incorporated

- Controlling clocks to the modules via software control and the hardware power handshaking state.
- Controlling power, reset, and clock management (PRCM) module power handshaking.
- Providing status of the above operation.
- Supporting synchronization through external event.

1.5 System MMU

1.5.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management).

The device contains the following MMUs:

- System MMU for: C674x™ (via its MDMA Port), EDMA Transfer Controller 0 (TPTC0), and EDMA Transfer Controller 1 (TPTC1).
- L1 Shared cache MMU and L2 MMU in Media Controller Subsystem
- ARM® Cortex™-A8 MMU
- SGX530™ MMU

This user guide provides a detailed description of System MMU and L2 MMU present in the Media Controller Subsystem. For more details on Cortex A8 MMU, see the ARM® Cortex™-A8 Core Technical Reference Manual (contact your TI representative). For more details on the L1 Shared cache MMU present in the Media Controller subsystem, please refer to the *Media Controller Subsystem* section.

1.5.2 MMU Integration

The MMU communicates accesses from the requestor (e.g., C674x MDMA bus requests) to the L3 main interconnect, performing virtual to physical address translation. The MMU will assert an interrupt when a translation fault occurs; or for other error conditions. For MMU interrupt details, refer to the device datasheet.

Figure 1-9 shows the System MMU integration. Requests initiated by the EDMA Transfer Controllers 0 and 1 (TPTC0, and TPTC1) can optionally be routed through the System MMU. These requestors' use (or not) of the MMU is independently controllable via the Control Module MMU_CFG register bitfields (TC0MMU and TC1MMU, respectively). The C674x DSP MDMA port accesses will always be routed through the MMU so no configuration bit is instantiated in the MMU_CFG register for C674x DSP. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3 interconnect to the MMU and will again go through the L3 interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3 interconnect to the requested physical address, thus minimizing bus request latency as illustrated in Figure 1-9.

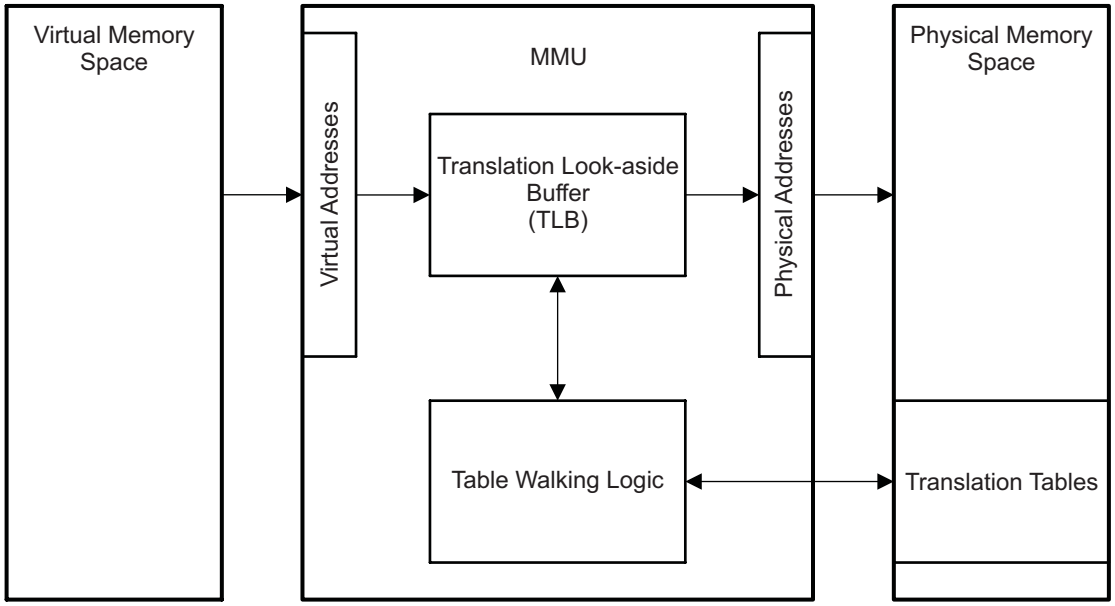
1.5.3 MMU Functional Description

1.5.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. The MMU can be programmed through the L4 interconnect.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-10. MMU Block Diagram



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Translation Tables.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

1.5.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 1-11 summarizes the process.

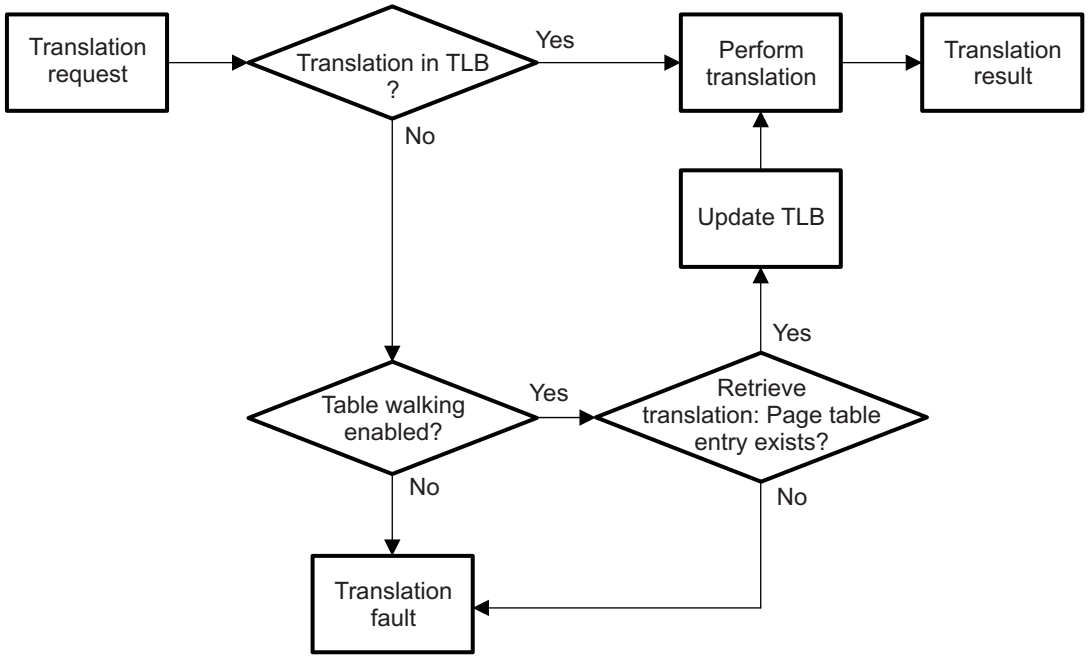
Figure 1-11. MMU Address Translation Process



1.5.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

1.5.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages reduces the flexibility of the typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

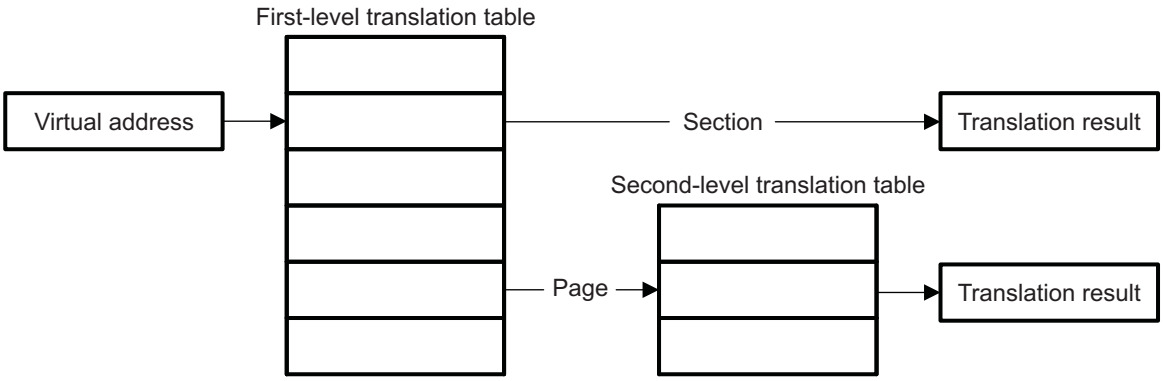
- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on

Copyright © 2011–2013, Texas Instruments Incorporated

smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used.

Figure 1-12. Translation Hierarchy



The structure of the first and second-level translation tables and their entries are described in more detail in First-Level Translation Table and Two-Level Translation.

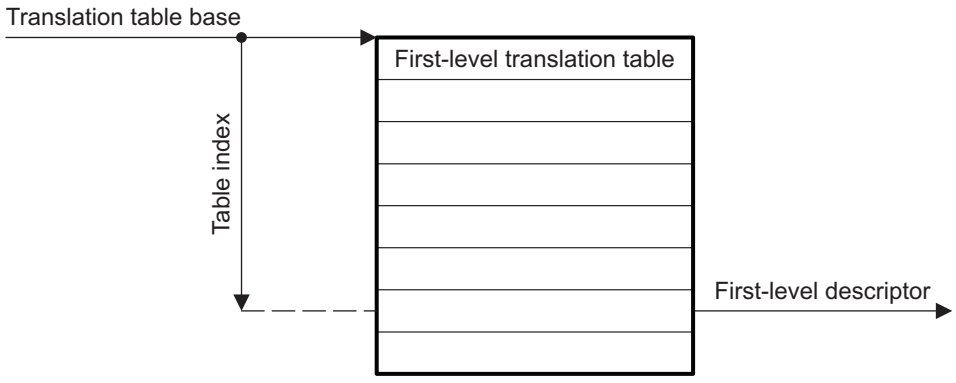
1.5.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address.

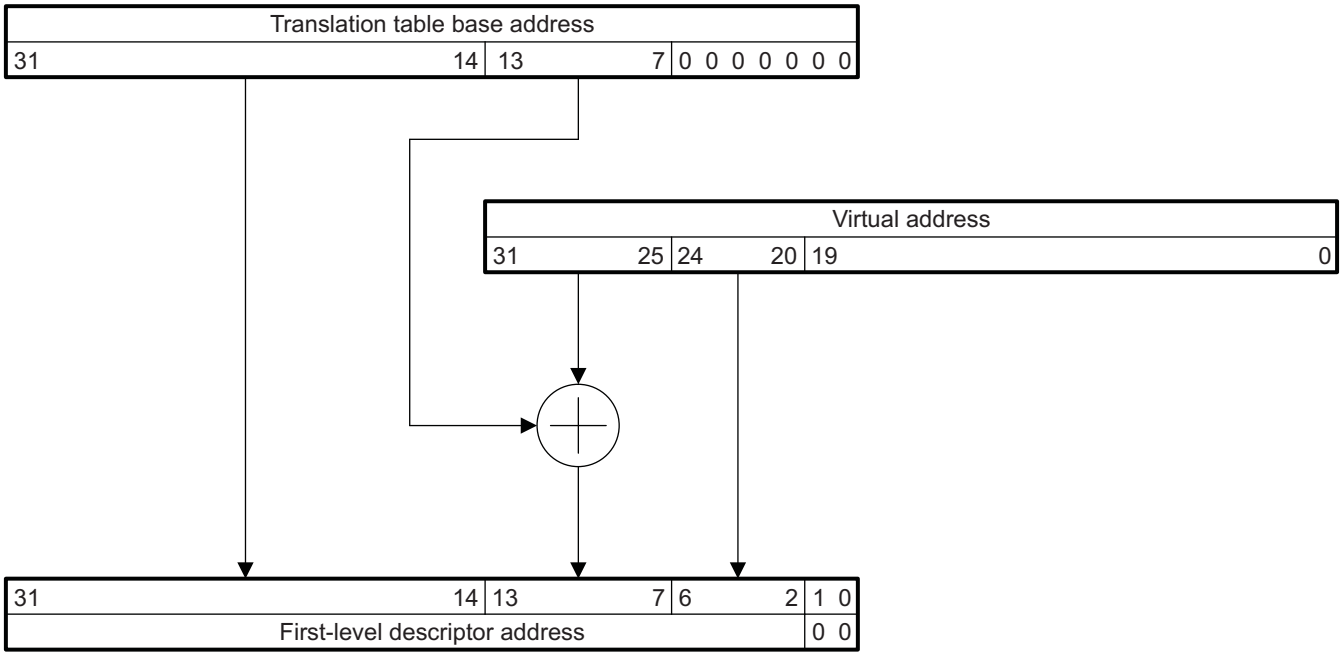
Figure 1-13. First-Level Descriptor Address Calculation



To summarize, the translation table base and the translation table index together define the first-level descriptor address. The precise mechanism used to calculate this address is shown below.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-14. Detailed First-Level Descriptor Address Calculation



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is:

0x8000:0000 + (0x123 <<2) = 0x8000:048C.

1.5.3.1.2.3 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages.

Table 1-44. First-Level Descriptor Format

31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-level Translation Table Base Address									X	0	1	Page
Section Base Address		X	0	M	X	E	X	ES	X	1	0	Section
Super Section base Address		X	1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

M = Mixed region: Don't care when E=0. Set to 0 to ensure future compatibility.

E = Endianness: Set to 0 for little-endian. Big-endian mode is not supported.

ES = Element Size: Don't care when E=0. Set to 00 to ensure future compatibility.

X = Don't care. Set to 0 to ensure future compatibility.

1.5.3.1.2.4 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

Copyright © 2011–2013, Texas Instruments Incorporated

1.5.3.1.2.5 First-Level Section Descriptor Format

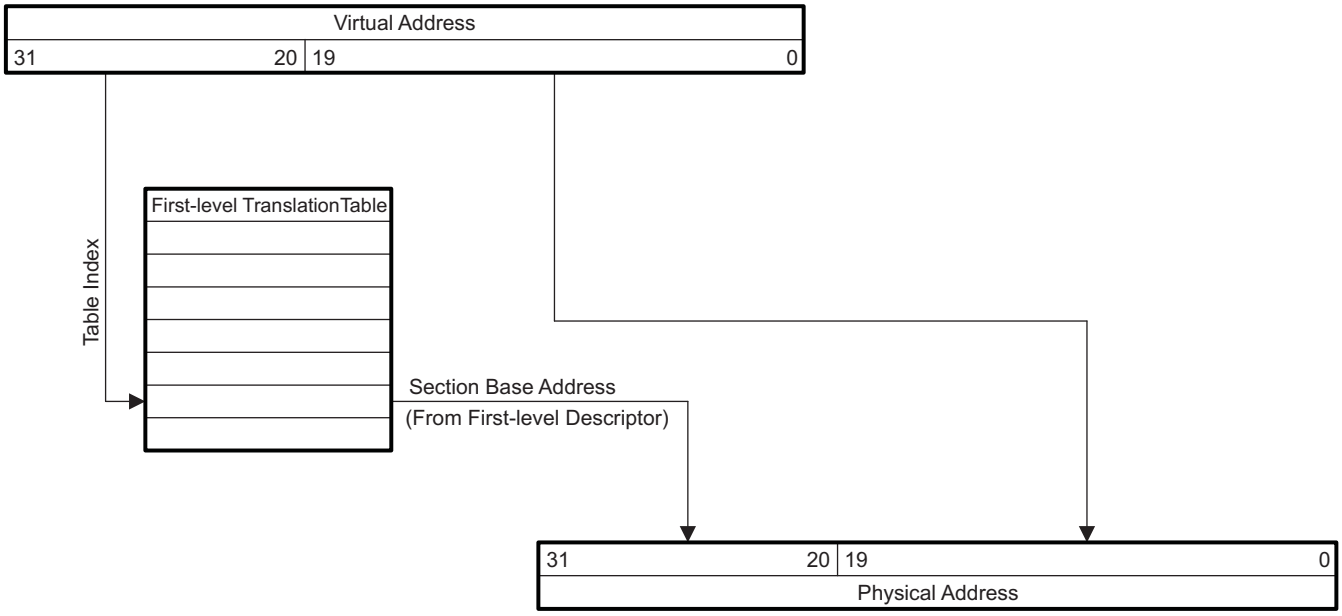
Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

1.5.3.1.2.6 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table.

Figure 1-15. Section Translation Summary



Copyright © 2011–2013, Texas Instruments Incorporated

1.5.3.1.2.7 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

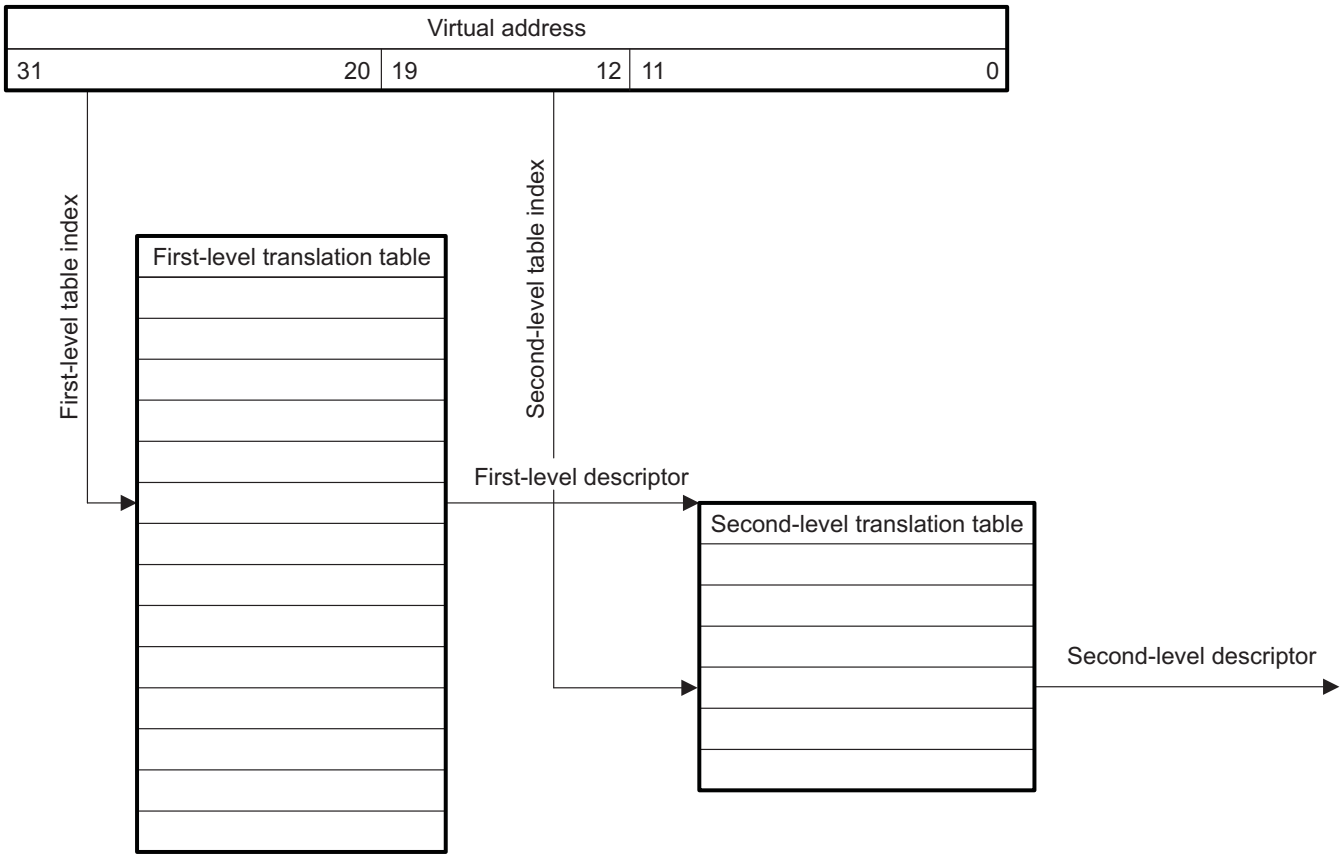
Figure 1-16. Supersection Translation Summary

Copyright © 2011–2013, Texas Instruments Incorporated

1.5.3.1.2.8 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address.

Figure 1-17. Two-Level Translation



Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way."

Copyright © 2011–2013, Texas Instruments Incorporated

1.5.3.1.2.9 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 1-45. Second-Level Descriptor Format

31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X								0	0	Fault
Large Page Base Address	X	M	X	E	X	ES	X	0	1	Large Page
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page

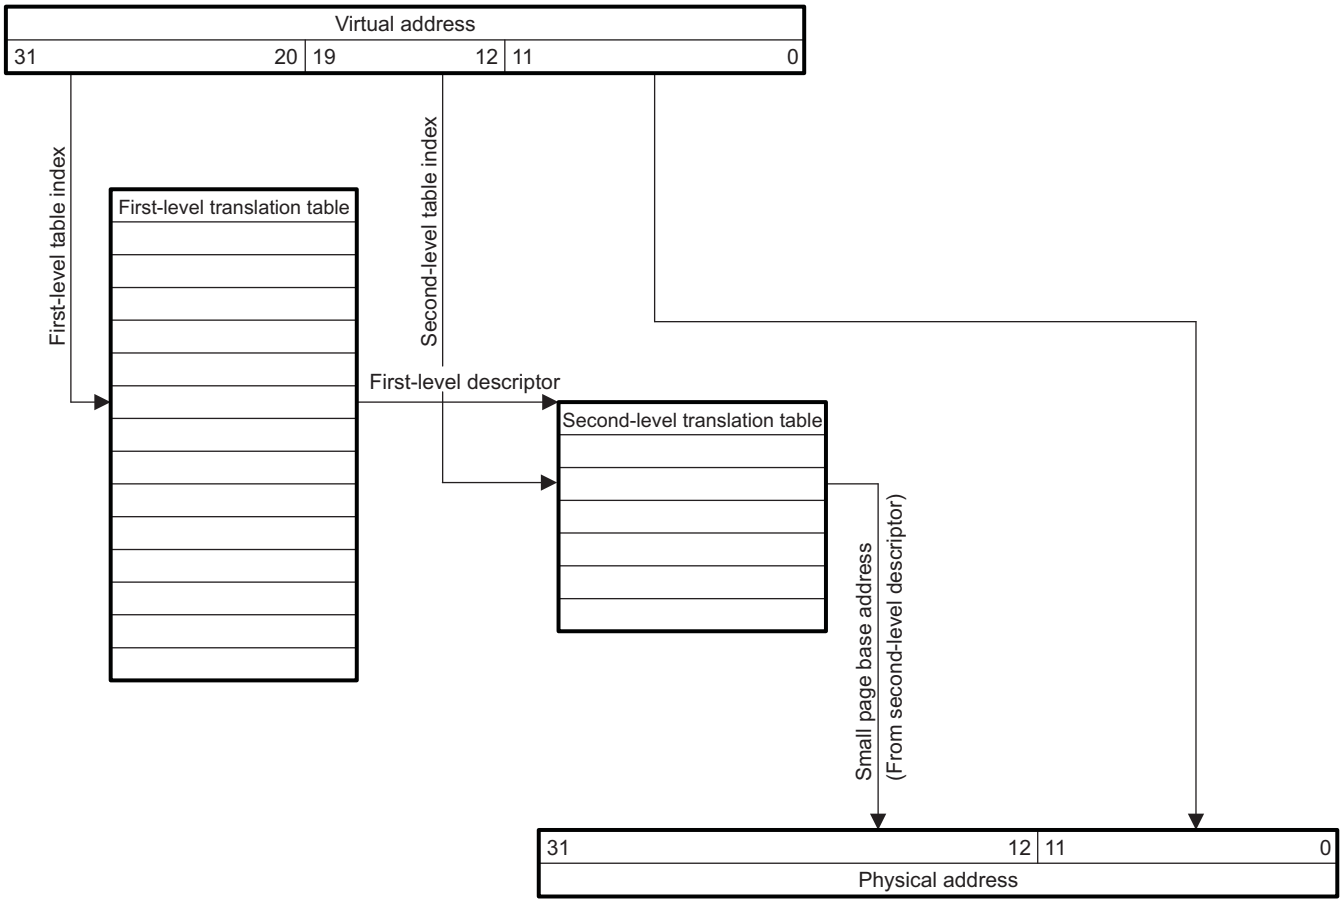
M = Mixed region: Don't care when E=0. Set to 0 to ensure future compatibility.

E = Endianness: Set to 0 for little-endian. Big-endian mode is not supported.

ES = Element Size: Don't care when E=0. Set to 00 to ensure future compatibility.

X = Don't care. Set to 0 to ensure future compatibility.

Figure 1-18. Small Page Translation Summary



Copyright © 2011–2013, Texas Instruments Incorporated

1.5.3.1.2.10 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page.

Figure 1-19. Large Page Translation Summary

1.5.3.1.3 Translation Lookaside Buffer

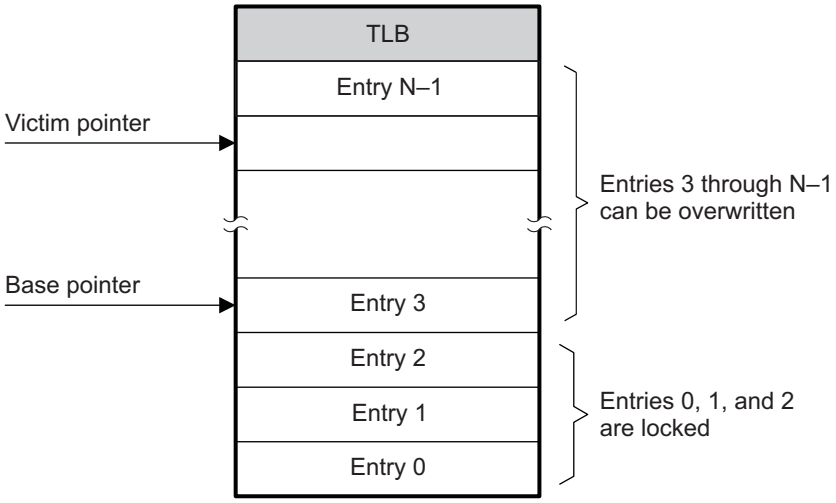
Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where n < Total Number N of TLB Entries , can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 1-20 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry N-1) always remains unprotected.

Figure 1-20. TLB-Entry Lock Mechanism



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

1.5.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in First-Level Translation Table. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually.

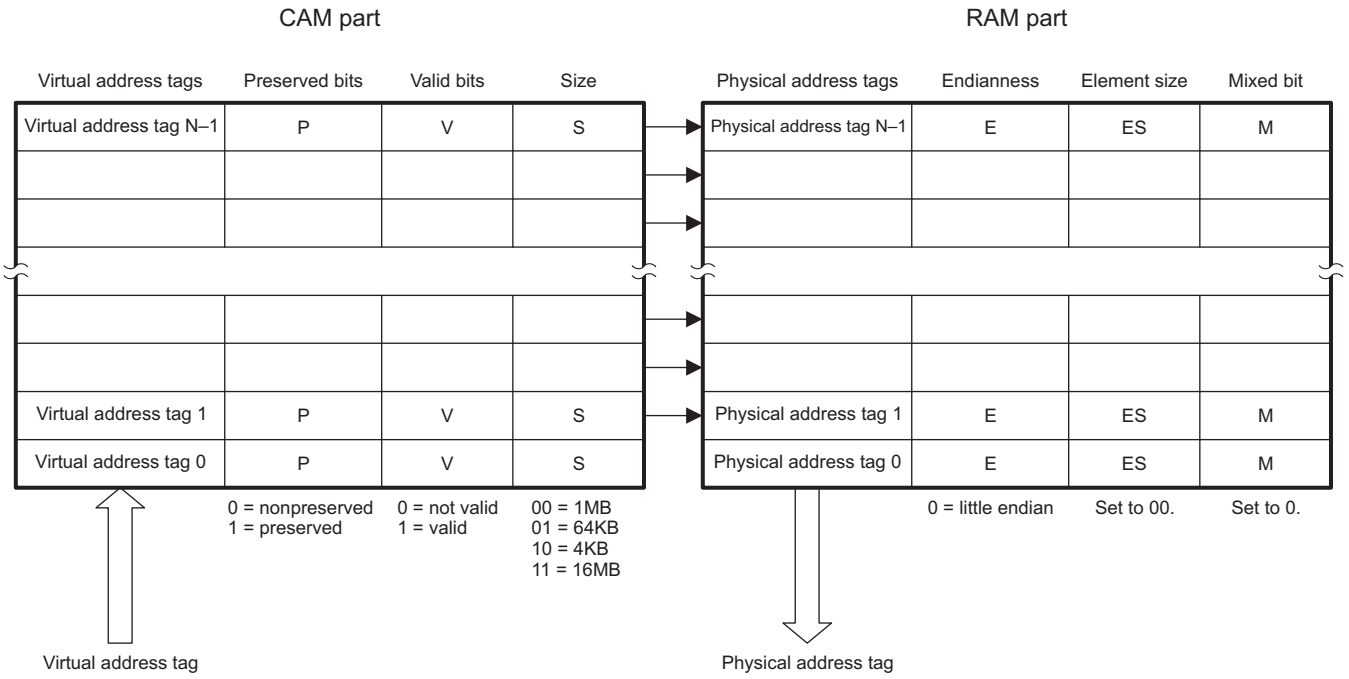
Figure 1-21. TLB-Entry Structure



1.5.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the MMU_SYSCONFIG register. This is a system configuration register that controls the various parameters of the L3 interface.

1.5.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See the Clocks and Resets tables for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

1.5.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

1.5.3.5 MMU Local Power Management Features

Table 1-46. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

1.5.3.6 MMU Interrupt Requests

Table 1-47. Events

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

1.5.3.7 MMU Error Handling

Table 1-48. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending.
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

1.5.4 MMU Low-level Programming Models

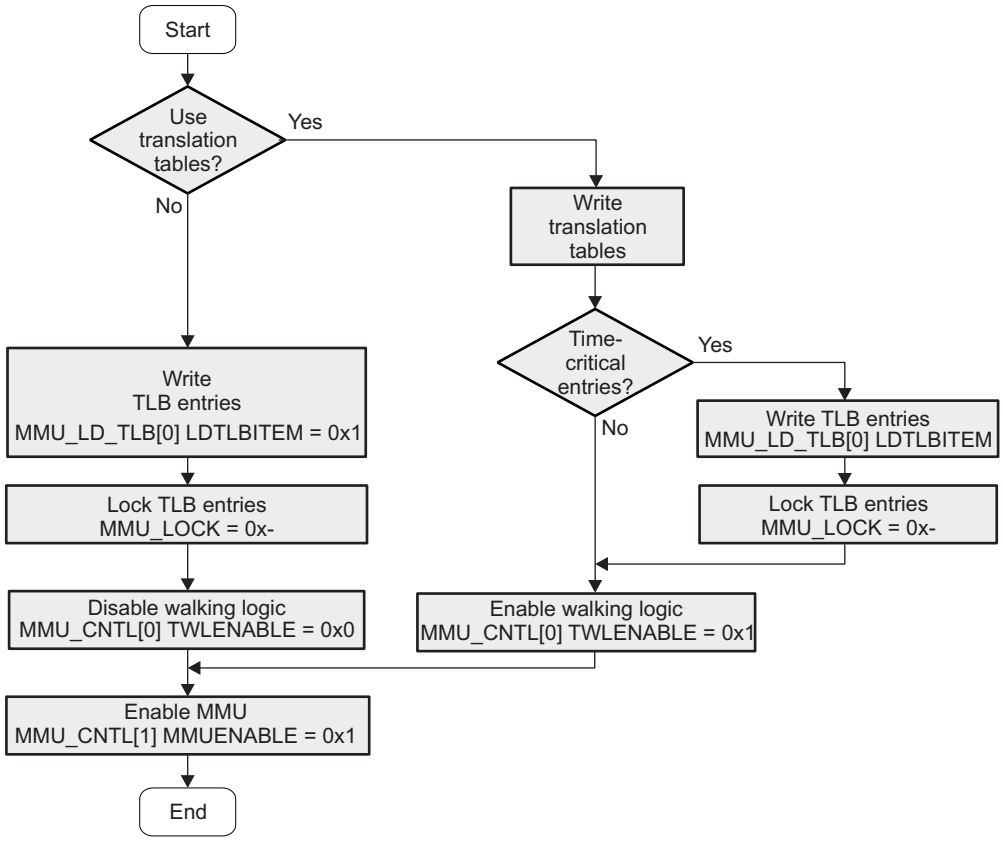
This section covers the low-level hardware programming sequences for configuration and usage of the module.

1.5.4.1 MMU Global Initialization

1.5.4.1.1 Main Sequence - MMU Global Initialization

The System MMU can be enabled or disabled in MMU_CFG register (refer to the *Control Module* chapter). Figure 1-22 shows the procedure to initialize the MMU after a power-on or software reset.

Figure 1-22. MMU Global Initialization



1.5.4.1.2 Subsequence - Configure a TLB entry

Table 1-49. Configure a TLB Entry

Step	Registe/Bitfield/Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

Copyright © 2011–2013, Texas Instruments Incorporated

1.5.4.2 Operational Modes Configuration

1.5.4.2.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 1-50. MMU Writing TLB Entries Statically

Step	Register/ Bitfield / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	Refer to table Configure a TLB Entry	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNESS	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

1.5.4.2.2 Main Sequence - Protecting TLB Entries

The first n TLB entries (with n < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 1-51. Protecting TLB Entries

Step	Register/Bitfield/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

Copyright © 2011–2013, Texas Instruments Incorporated

1.5.4.2.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 1-52. Deleting TLB Entries

Step	Registe/Bitfield/Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

1.5.4.2.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 1-53. Read TLB Entries

Step	Register/Bitfield/Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM

1.6 SGX530 Graphics Subsystem

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

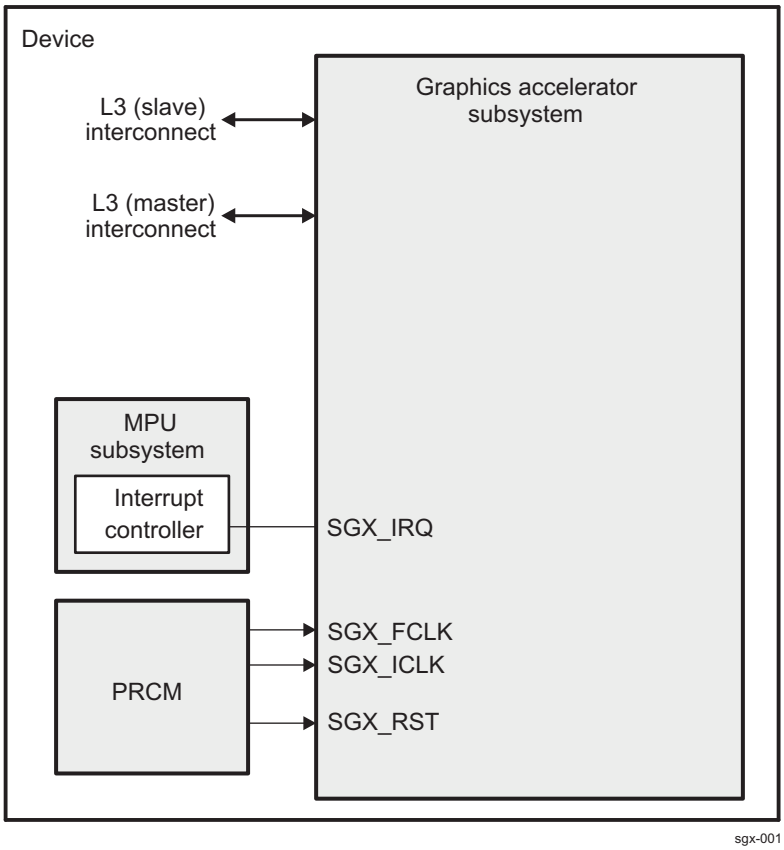
POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

1.6.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 1-42 shows the SGX subsystem in the device.

Figure 1-42. Graphics Accelerator Highlight



The SGX graphics accelerator can simultaneously process various multimedia data types:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

Copyright © 2011–2013, Texas Instruments Incorporated

This is achieved through a multithreaded architecture using two levels of scheduling and data partitioning enabling zero-overhead task switching.

The SGX subsystem is connected to the L3 interconnect by a 128-bit master and a 32-bit slave interface.

1.6.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

1.6.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear, anisotropic
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing

Copyright © 2011–2013, Texas Instruments Incorporated

  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).
  Note: Performance is limited when the on-chip memory is not available.

1.6.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

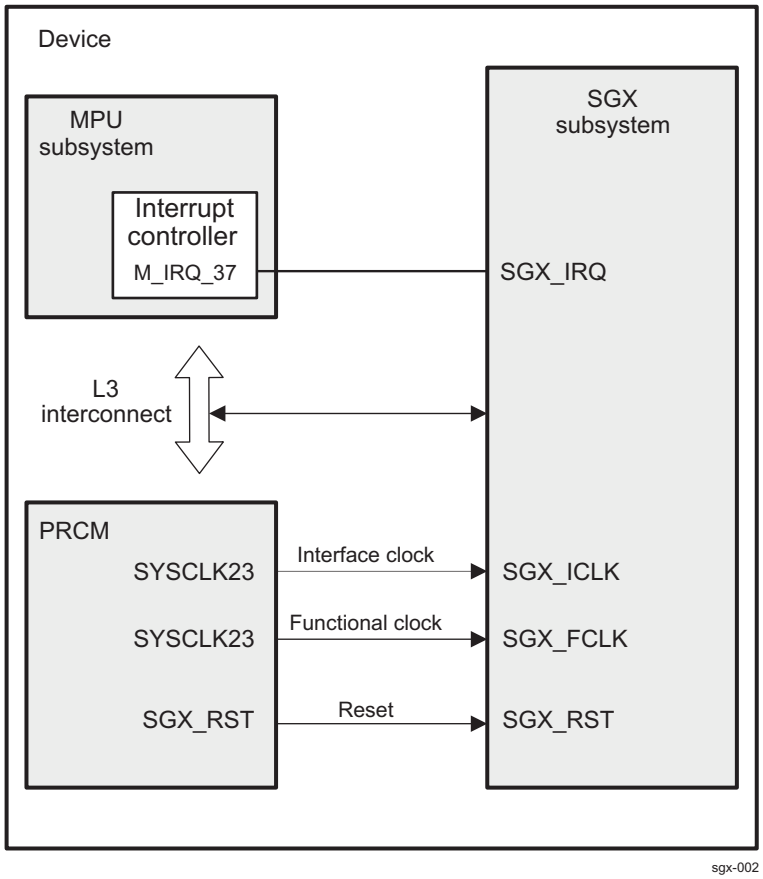
- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

Copyright © 2011–2013, Texas Instruments Incorporated

1.6.2 SGX Integration

Figure 1-43 highlights the SGX subsystem integration in the device.

Figure 1-43. SGX Subsystem Integration



1.6.2.1 Clocking, Reset, and Power-Management Scheme

1.6.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SYSCLK23). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device.

Table 1-75. Clock Descriptions

Functional Name	Signal Name	I/O (1)	Description
SGX_FCLK	SYSCLK23	I	Functional clock → Functional clock domain
SGX_ICLK	SYSCLK23	I	Interface clock → Interface clock domain

(1) I =Input; O=Output

- SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports.
- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

To Enable the SGX Functional and Interface Clock

Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x2
Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x2
Poll for the PRCM.CM_SGX_SGX_CLKCTRL IDLEST to be 0x0

Copyright © 2011–2013, Texas Instruments Incorporated

To Disable the SGX Functional and Interface Clock

Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x0
Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x0

The SGX_ICLK and SGX_FLCK are sourced from SYSCLK23 Depending on the DPLL_SGX and the PRCM.CM_SYSCLK23_CLKSEL[CLKSEL] settings, SGX can support a frequency up to 200 MHz. SGX530 Clocks can be divided from the original DPLL_SGX frequency. The divider can be programmed from /1../8 using the PRCM.CM_SYSCLK23_CLKSEL[CLKSEL] bits

1.6.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_SGX_RSTCTRL[0] SGX_RST bit.

1.6.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See the *Power, Reset, and Clock Management* chapter for additional information about the SGX power domain.

As described in the *SGX Integration* chapter, the SGX subsystem receives two clock signals from the PRCM module. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see the *Power, Reset, and Clock Management* chapter.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains. SGX is in the same voltage domain as that of the Core logic. For more information refer to the Power, Reset, Clock Management chapter.

1.6.2.2 Hardware Requests

1.6.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_37.

Copyright © 2011–2013, Texas Instruments Incorporated

1.6.3 SGX Functional Description

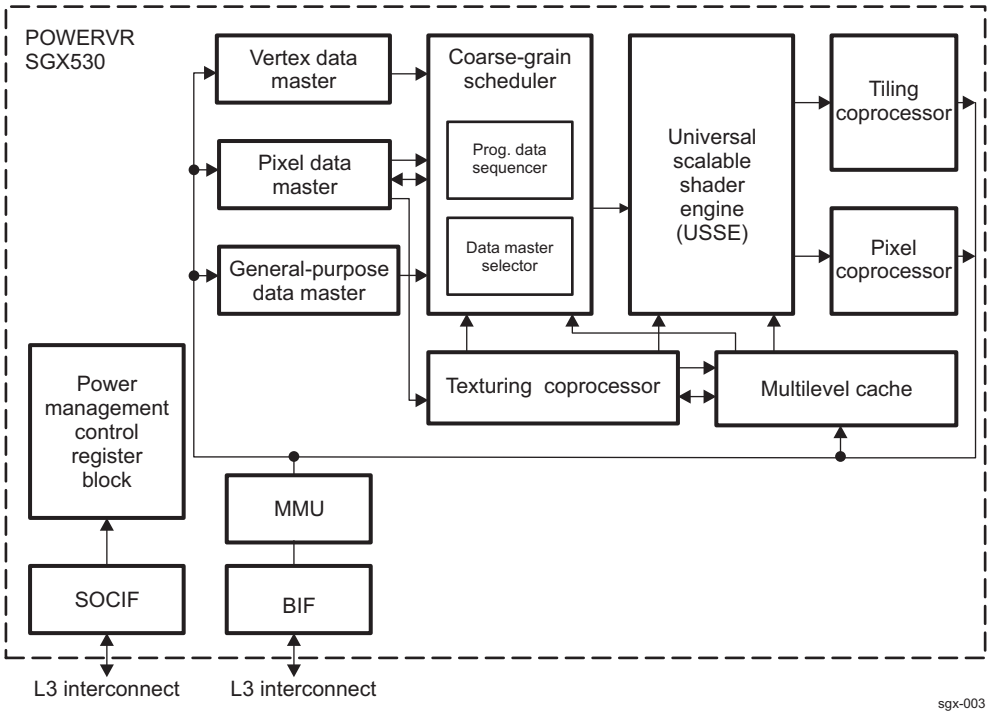
1.6.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable data sequencer (PDS)
  - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 1-44 shows a block diagram of the SGX cores.

Figure 1-44. SGX Block Diagram



1.6.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an

Copyright © 2011–2013, Texas Instruments Incorporated

input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

1.7 Device Interrupts and EDMA Events

1.7.1 Interrupt Controllers

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The ARM Cortex-A8, C674x DSP, and Media Controller are capable of servicing these interrupts via their integrated interrupt controllers. In addition, the C674x DSP and Media Controller interrupt controllers are preceded by an Interrupt Controller Crossbar that provides flexibility in mapping the device interrupts to processor interrupts. For more information about crossbars, see the *Control Module* chapter.

Cortex™-A8 MPU Subsystem Interrupt Controller

The ARM Cortex-A8 Interrupt Controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either IRQs or FIQs to the Cortex-A8. The AINTC has the capability to handle up to 128 requests, and the priority of the interrupt inputs is programmable. Table 1-96 lists the interrupt sources for the AINTC.

For detailed information about this module, see the *ARM Interrupt Controller (AINTC)* chapter.

DSP subsystem (DSPSS) Interrupt Controller

The C674x DSPx interrupt controller combines up to 128 interrupts into 12 prioritized interrupts presented to the CPU. The default sources of the 128 interrupts are shown in Table 1-97. In addition, device interrupts 15 through 95 can alternatively be sourced through the DSP's Interrupt Crossbar from one of the 31 multiplexed device interrupts shown in Table 1-98. The DSP_INTMUX_x registers in the Control Module are used to select between the default interrupt and the multiplexed interrupt. The interrupt controller also controls the generation of the CPU exceptions, NMI, and emulation interrupts.

For detailed information about this module, refer to Chapter 7 of the TMS320C674x DSP Megamodule.

Media Controller Interrupt Controllers

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M3. The interrupt mapping is the same for the two cores to facilitate parallel processing. The default sources of the 79 interrupts are shown in Table 1-99. In addition, device interrupts 23 through 79 can alternatively be sourced through the Media Controller's Interrupt Crossbar from one of the 63 multiplexed device interrupts shown in Table 1-100. The Media_Controller_INTMUX_x registers in the Control Module are used to select between the default interrupt and the multiplexed interrupt. The NVIC supports:

- 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to ARM *Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Figure 1-64 shows the top-level block diagram of the interrupt controllers in this device.

1.7.5 EDMA Channel Synchronization Events

The EDMA channel controller supports up to 64 channels which service peripherals and memory. Each EDMA channel is mapped to a default EDMA synchronization event as shown in Table 1-101. In addition, each EDMA channel can alternatively be mapped through a crossbar to one of the 31 multiplexed EDMA synchronization events shown in Table 1-102. The EDMA3CC_EVTMUX_x registers in the Control Module are used to select between the default event and the multiplexed events for each channel.

For more detailed information on the EDMA module and how EDMA events are enabled, captured, processed, linked, chained, cleared, and more, see the *Enhanced Direct Memory Access Controller* chapter.

Figure 1-65 shows the top-level block diagram of the EDMA channel synchronization events.

1.8 Inter-Processor Communication

This SoC is a heterogeneous multi-core device, which requires software to efficiently manage and communicate between the cores. The following are the main features that need to be implemented by any such software:

1. Device management of the slave processors from the host processor.
2. Inter-processor communication between the cores for transfer and exchange of information between them.

In this SoC, the host processor is usually the Cortex A8. This processor is responsible for boot-loading the slave processors (Video-M3, VPSS-M3).

Boot-loading includes power management of the slaves (power-up/down and other power management), reset control (reset/release of the slave processor) and setting the entry point of the slave executable into the appropriate register.

For implementing efficient Inter-Processor Communication between the multiple cores on the device, certain hardware features are provided:

- Mailbox interrupts
- Hardware Spinlocks

1.8.1 Reset Requirements

This SoC has a power on reset (POR) and warm reset. For the POR reset, the A8 is taken out of reset and it boots from its boot ROM. Once booted, the A8 will boot load the VPSS M3 and Video M3.

1.8.2 Features

Different methods of IPC are used between the various processing elements in the SoC:

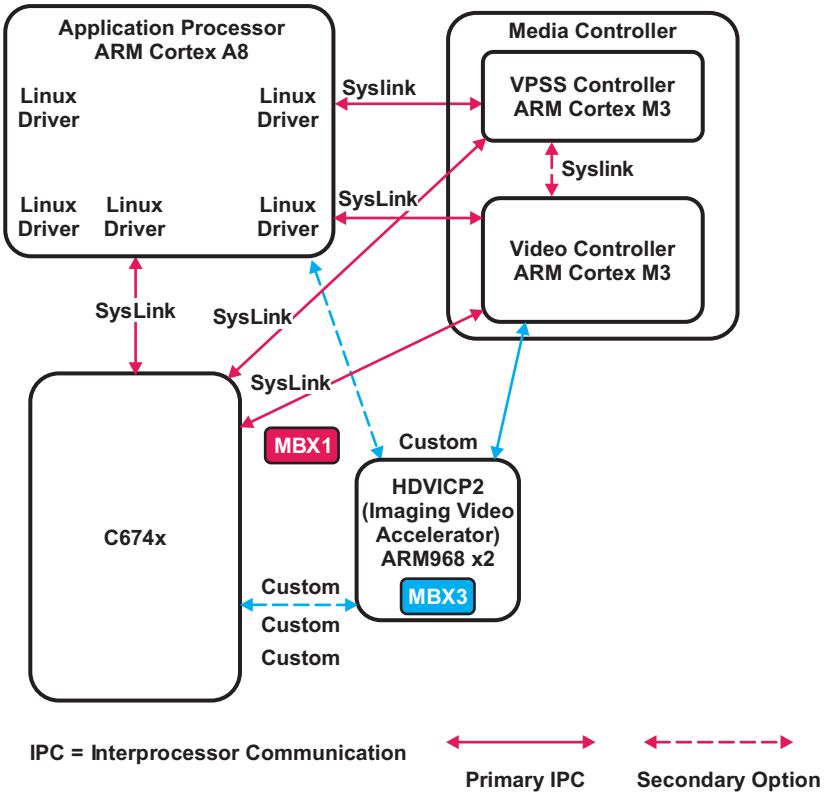
- Custom IPC – This is an IPC that doesn't use any standard IPC software.
- SysLink – This is a new implementation of the BIOS Link that allows communication between the processors in the SoC. SysLink includes ProcMgr module for device management of the slave cores (Video-M3, VPSS-M3, C674x™). The Notify method is the API for responding to interrupts. SysLink also incorporates full IPC features including MessageQ, RingIO, and FrameQ.

Copyright © 2011–2013, Texas Instruments Incorporated

1.8.3 Overview and Strategy

Figure 1-66 depicts the processing elements that are part of the SoC.

Figure 1-66. IPC Overview Diagram



The SoC contains Mailbox and Spinlock hardware to facilitate the IPC mechanism.

Mailboxes provide a mechanism for one processor to write a value to a register and send an interrupt to another processor. One system level mailbox is provided for the IPCs between the A8, the C674x™, and the Media M3s. The HDVICP2 has its own mailbox within its IP module. The SoC shall provide Spinlocks to facilitate Mutexes for access to shared resources in the system.

Mailboxes and Spinlocks will be discussed in more detail later in this document.

It is intended that the following IPC mechanisms shall be used between various processors:

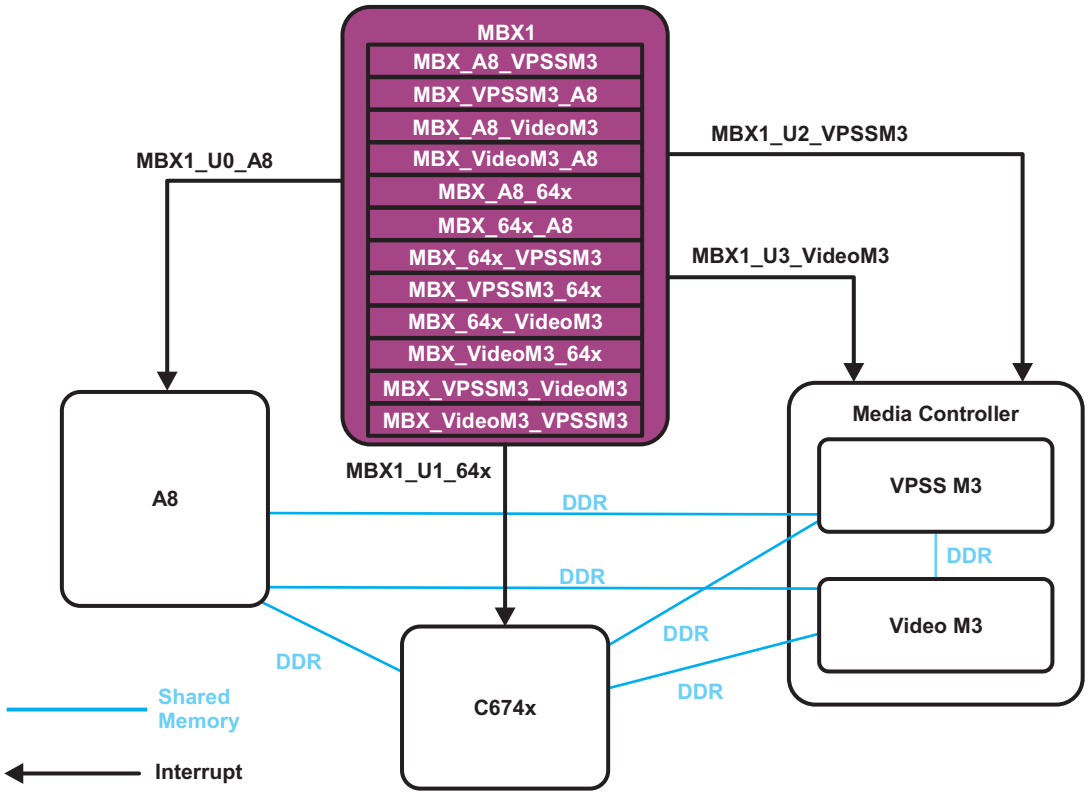
- SysLink / IPC
  - A8 to C674x™
  - A8 to Video M3
  - A8 to VPSS M3
  - Video M3 to VPSS M3
  - C674x™ to VideoM3
  - C674x™ to VPSS M3
- Custom
  - Video M3 to HDVICP2

Copyright © 2011–2013, Texas Instruments Incorporated

1.8.3.1 System IPCs

Figure 1-67 depicts how Mailbox 1 (MBX1) will be used for system IPCs. Four interrupts are generated from the mailbox that allows the A8, C674x™, VPSS M3, and Video M3 to communicate. DDR is used as the shared memory interface. An IPC can be created between any of the processors listed. The A8 will communicate to the C674x™, Video M3 and VPSS M3 using SysLink.

Figure 1-67. System IPCs

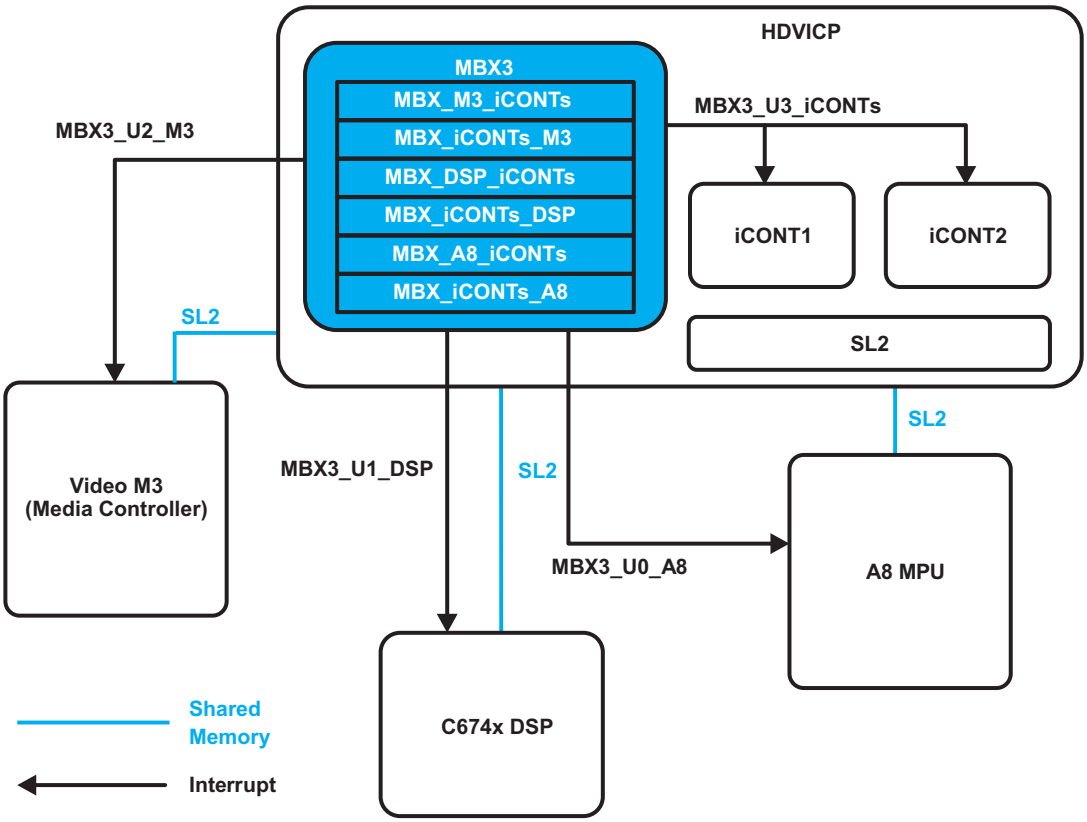


Copyright © 2011–2013, Texas Instruments Incorporated

1.8.3.2 HDVICP2 IPC

Figure 1-68 depicts how Mailbox 3 (MBX3) will be used for the IPC between the HDVICP2 and the other processors that may control it. The plan of record is that only one processor will be chosen to control the HDVICP2 at a time. The Video M3 is the primary processor that will control the HDVICP2. Interrupts from the mailbox are provided as shown in Figure 1-68. IPCs will use the Shared Level 2 memory that is part of the HDVICP2 module. This is necessary since the HDVICP2 processors cannot access DDR or the L3/L4 switch fabric. The HDVICP2 software will reside beneath the xDM API.

Figure 1-68. HDVICP2 IPC



Copyright © 2011–2013, Texas Instruments Incorporated

1.8.4 IPC Component Configuration

1.8.4.1 Shared Memory

Shared memory will be used as necessary for the IPCs of the system and it is important that cache coherency is maintained.

1.8.4.2 IPC Interrupt Module - Mailboxes

Interrupts used by IPCs are generated from mailbox modules.

All mailboxes use interrupts with both an active high level and active low level. The appropriate type of interrupt is connected to each processor based on the characteristics of that processor.

Each mailbox provides two messages per mailbox submodule.

1.8.4.3 Hardware Spinlocks

Spinlocks are pared down semaphores designed to provide direct access mutex support without the need for interrupt generator or queues. Spinlocks can be used very effectively as a mechanism to protect data structures in shared memory space that might be accessed by multiple processing cores simultaneously. They can be utilized if the following conditions apply:

1. The time to hold the lock is predictable and small. (How small is a hardware/software system design consideration. For example a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted or suspended or interrupted while holding the lock. (This would make the hold time large and unpredictable).
3. The lock is lightly contended, i.e., the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions hold, then the locking code can retry a failed attempt to acquire the lock until success.

The spin lock unit is responsible for providing hardware assistance for synchronizing the processes running on multiple processors in the device:

- The application processor (ARM Cortex-A8)
- C674x™

Note that the HDVICP2 can’t access the L3/L4 switch fabric, so IPCs to the HDVICP2 can’t use spinlocks.

Hardware spinlocks are used by SysLink and IPC products to provide multi-core mutual-exclusion between the processors on this SoC. This is used to protect access to control structures in shared memory. In addition spinlocks can provide a mutual exclusion mechanism that could be used in a system level resource manager.

This SoC has 128 spinlocks for the system.

Table 1-103. Hardware Spinlock Configuration

Hardware Spinlocks	Name	Configuration
0.127	SPINLOCK_0 .. SPINLOCK_127	No configurable options

1.9 Mailbox

1.9.1 Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A8 microprocessor unit (Cortex-A8 MPU) and digital signal processor (DSP) communications.
- HDVICP2 mailbox - used for communication between one internal to the HDVICP2 subsystem user (imaging controller 1 - iCont1, or imaging controller 2 - iCont2) and three external to the HDVICP2 subsystem users (Cortex-A8 MPU, DSP and Video M3). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Four users for the system mailbox instance (Cortex-A8 MPU, DSP and Media Controller Subsystem) or four users for the HDVICP2 mailbox instance (iCont1/iCont2, Cortex-A8 MPU, DSP and Video-M3 MPU)
- Four mailbox message queues for the system mailbox instance/six mailbox message queues for the HDVICP2 mailbox instance
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Four interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the HDVICP2 mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

1.9.2 System Mailbox Integration

This section describes the system mailbox integration in the device, including information about clocks, resets, and hardware requests. Figure 1-69 shows the system mailbox integration.

Table 1-104 through Table 1-106 summarize the system mailbox integration in the device.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-69. System Mailbox Integration

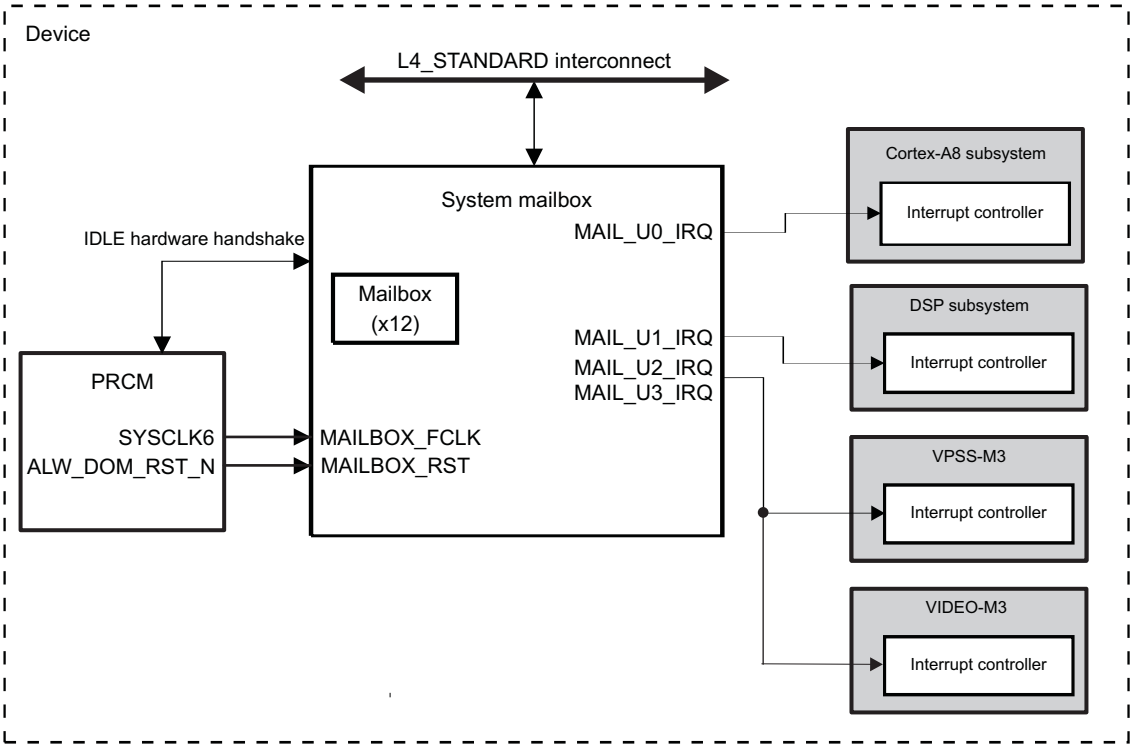

Table 1-104. Integration Attributes

Module Instance	Attributes

Table 1-106. Hardware Requests (continued)

Module Instance	Source Signal Name	Destination Signal	Destination	Description
	MAIL_U1_IRQ	D_IRQ_56	DSP	System Mailbox user 1 interrupt

1.9.3 Functional Description

This device has the following mailbox instances:

- System mailbox
- HDVICP2 mailbox

Table 1-107 shows Mailbox Implementation in this device, where u is the user number and m is the mailbox number.

Table 1-107. Mailbox Implementation

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System mailbox	0 to 3	0 to 11	4
HDVICP2 mailbox	0 to 3	0 to 5	4

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (12 for the system mailbox instance, six for the HDVICP2 mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

The system mailbox module includes the following user subsystems:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)

The HDVICP2 mailbox module includes the following user subsystems, where x=0,1,2.:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)
- User 2: HDVICP2 subsystem - only available to the HDVICP2 mailbox instance (u = 3)

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers. Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_STANDARD interconnect.

For the HDVICP2 mailbox instance, a user can query its interrupt status register as follows:

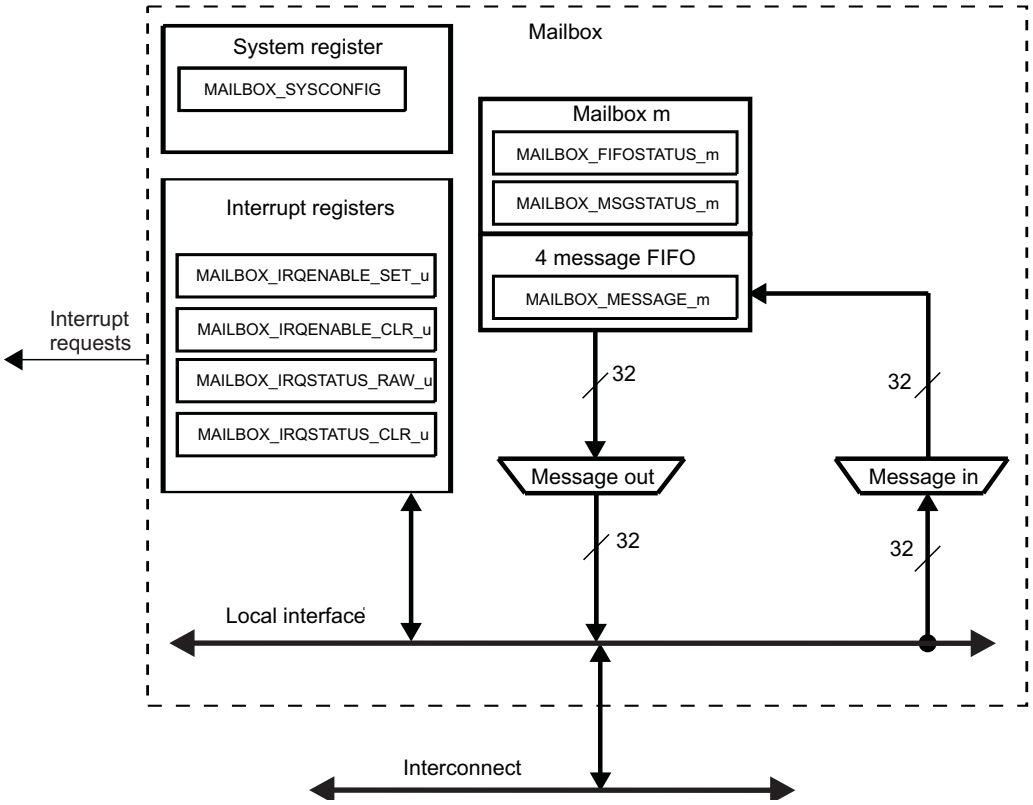
- Cortex-A8 MPU and DSP - through the L3 interconnect
- iCont1/iCont2 and DSP - private access (directly through the HDVICP2 and DSP local interconnect respectively)

1.9.3.1 Mailbox Block Diagram

Figure 1-70 shows the mailbox block diagram.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-70. Mailbox Block Diagram



1.9.3.2 Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0].SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going
- Read 0: the software reset is complete

The software must ensure that the software reset completes before doing mailbox operations.

1.9.3.3 Power Management

Table 1-108 describes power-management features available for the mailbox module.

Table 1-108. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

Copyright © 2011–2013, Texas Instruments Incorporated

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

1.9.3.4 Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user. Table 1-109 lists the event flags, and their mask, that can cause module interrupts.

Table 1-109. Interrupt Events

Non-Maskable Event Flag (1)	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].		
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2]. NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2]. NEWMSGSTATUSUUMBm	Mailbox m receives a new message
MAILBOX_IRQSTATUS_RAW_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2]. NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2]. NOTFULLSTATUSUMBm	Mailbox m message queue is not full

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register. Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

Copyright © 2011–2013, Texas Instruments Incorporated

1.9.3.5 Assignment

1.9.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where u is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

1.9.3.6 Sending and Receiving Messages

1.9.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded. Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it. Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned. The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

Copyright © 2011–2013, Texas Instruments Incorporated

1.9.3.7 16-Bit Register Access

1.9.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02). All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

1.9.4 Programming Guide

1.9.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

1.9.4.1.1 Global Initialization

1.9.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 1.9.2 for further information.

Table 1-110. Global Initialization of Surrounding Modules for System Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem.

Table 1-111. Global Initialization of Surrounding Modules for HDVICP2 Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPUor DSP subsystem or HDVICP2 Subsystem

1.9.4.1.1.2 Mailbox Global Initialization

1.9.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 1-114. Mailbox Global Initialization

	Register/Bitfield/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0].SOFTRESET	1
Wait until reset is complete	MAILBOX_SYSCONFIG[0].SOFTRESET	0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	0x-

1.9.4.1.2 Operational Modes Configuration

1.9.4.1.2.1 Main Sequence - Sending a Message (Polling Method)

Table 1-115. Sending a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=0h
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

1.9.4.1.2.2 Main Sequence - Sending a Message (Interrupt Method)

Table 1-116. Sending a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	1h
User(processor) can perform anothr task until interrupt occurs		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

Copyright © 2011–2013, Texas Instruments Incorporated

1.9.4.1.2.3 Main Sequence - Receiving a Message (Polling Method)

Table 1-117. Receiving a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

1.9.4.1.2.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 1-118. Receiving a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	1h
User(processor) can perform anothr task until interrupt occurs		

1.9.4.1.3 Events Servicing

1.9.4.1.3.1 Sending Mode

Table 1-119 describes the events servicing in sending mode.

Table 1-119. Events Servicing in Sending Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1

1.9.4.1.3.2 Receiving Mode

Table 1-120 describes the events servicing in receiving mode.

Table 1-120. Events Servicing in Receiving Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
ENDIF

1.9.5 Mailbox Registers

Table 1-121 lists the Mailboxes available on the device. The previous register set is applicable to these mailboxes. See the device-specific data manual for the memory address of these mailboxes.

Table 1-121. Mailboxes

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System Mailbox	0 to 3	0 to 11	4
HDVICP2-1Mailbox	0 to 3	0 to 5	4
HDVICP2-2 Mailbox	0 to 3	0 to 5	4

Table 1-122 lists the memory-mapped registers for the Mailbox Registers. See the device-specific data manual for the memory address of these registers.

Table 1-122. Mailbox Registers Mapping Summary

Offset	Acronym	Register Description	Section
0000h	MAILBOX_REVISION	Mailbox Revision Register	Section 1.9.5.1
0010h	MAILBOX_SYSCONFIG	Mailbox System Configuration Register	Section 1.9.5.2
0040h + (4h * m)	MAILBOX_MESSAGE_m (1)	Mailbox Message Register	Section 1.9.5.3
0080h + (4h * m)	MAILBOX_FIFOSTATUS_m (1)	Mailbox FIFO Status Register	Section 1.9.5.4
00C0h + (4h * m)	MAILBOX_MSGSTATUS_m (1)	Mailbox Message Status Register	Section 1.9.5.5

1.9.5.3 Message Register (MAILBOX_MESSAGE_m)

The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue. The Mailbox Message Register (MAILBOX_MESSAGE_m) is shown in Figure 1-73 and described in Table 1-125.

Figure 1-73. Message Register (MAILBOX_MESSAGE_m)

31	0
MESSAGEVALUEMBM	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-125. Message Register (MAILBOX_MESSAGE_m) Field Descriptions

Bit	Field	Value	Description
31-0	MESSAGEVALUEMBM	0-FFFF FFFFh	Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue.

1.9.5.4 FIFO Status Register (MAILBOX_FIFOSTATUS_m)

The FIFO status register has the status related to the mailbox internal FIFO. The Mailbox FIFO Status Register (MAILBOX_FIFOSTATUS_m) is shown in Figure 1-74 and described in Table 1-126.

Figure 1-74. FIFO Status Register (MAILBOX_FIFOSTATUS_m)

31	1	0
MESSAGEVALUEMBM		FIFOFULLMBM
R/W-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-126. FIFO Status Register (MAILBOX_FIFOSTATUS_m) Field Descriptions

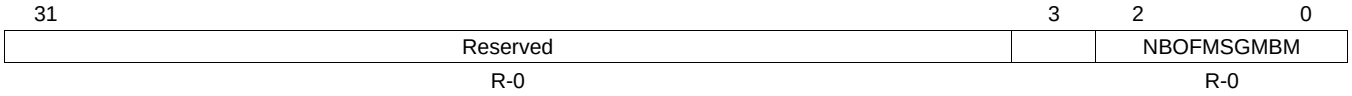
Bit	Field	Value	Description
31-1	MESSAGEVALUEMBM	0-7FFF FFFFh	Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue.
0	FIFOFULLMBM		Full flag for Mailbox
		0	Mailbox FIFO is not full
		1	Mailbox FIFO is full

Copyright © 2011–2013, Texas Instruments Incorporated

1.9.5.5 Message Status Register (MAILBOX_MSGSTATUS_m)

The message status register has the status of the messages in the mailbox. The Mailbox Message Status Register (MAILBOX_FIFOSTATUS_m) is shown in Figure 1-75 and described in Table 1-127.

Figure 1-75. Message Status Register (MAILBOX_MSGSTATUS_m)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-127. Message Status Register (MAILBOX_MSGSTATUS_m) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved.
2-0	NBOFMSGMBM	0-7h	Number of unread messages in Mailbox. Limited to four messages per mailbox.

Copyright © 2011–2013, Texas Instruments Incorporated

1.9.5.6 IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)

The interrupt status register has the raw status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit sets this bit. This register is mainly used for debug purpose. The Mailbox IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u) is shown in Figure 1-76 and described in Table 1-128.

Figure 1-76. IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)

1.9.5.7 IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u)

The interrupt status register has the status combined with irq-enable for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. The Mailbox IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u) is shown in Figure 1-77 and described in Table 1-129.

1.10 Spinlock

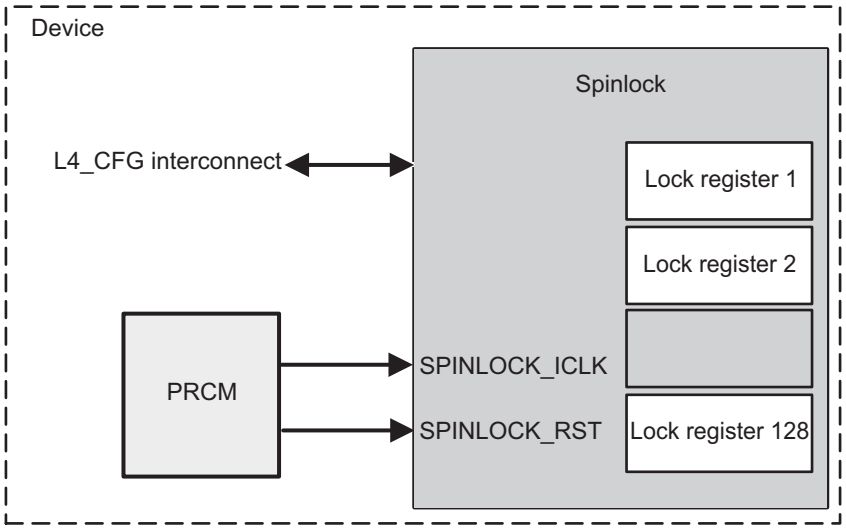
1.10.1 Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A8 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Media Controller subsystem

The Spinlock module implements 128 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 1-80. Spinlock Module



Copyright © 2011–2013, Texas Instruments Incorporated

1.10.2 Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 1-81 shows the Spinlock integration.

Figure 1-81. Spinlock Integration

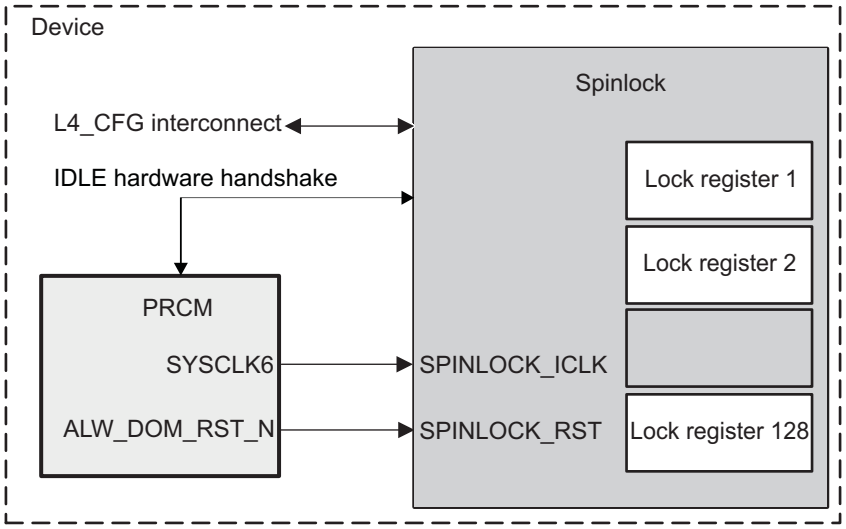


Table 1-132 and Table 1-133 summarize the integration of the module in the device.

Table 1-132. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_ALWAYS_ON	L4_STANDARD

Table 1-133. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	SYSCLK6	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	ALW_DOM_RST_N	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock registers.

The Spinlock module does not support any interrupt and DMA requests.

Copyright © 2011–2013, Texas Instruments Incorporated

1.10.3 Functional Description

1.10.3.1 Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. This bit also indicates that the software reset is complete when its value is reset to 0. The software must ensure that the software reset completes before doing Spinlock operations.

1.10.3.2 Power Management

Table 1-134 describes power-management features available to the Spinlock module.

Table 1-134. Local Power Management Features

Feature	Registers	Description
Clock auto gating	[0] AUTOGATING bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	[4:3] SIDLEMODE bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	[8] CLOCKACTIVITY bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
  - Already powered off
  - Notified that Spinlock is not available and the notification is acknowledged
- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 128 locks can be read from the register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

1.10.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

- The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
- The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
- The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

1.10.3.4 Functional Operation

The Spinlock module supports 128 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock i (where i = 0 to 127) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock i is Taken, a read returns 1 and does not change the state of the lock. A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

1.10.4 Programming Guide

1.10.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

1.10.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

1.10.4.1.2 Global Initialization of Surrounding Modules

Table 1-135. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, Refer PRCM User Guide.
Interconnect	For more information about the L4-Standard interconnect configuration, Refer Bus Topology.

1.10.4.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

1.10.4.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

Table 1-136. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 128 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 127)	0
END		

1.10.4.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be re-attempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before re-attempting to acquire the lock. Figure 1-83 shows the described above procedure.

1.11 Error Location Module

1.11.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

1.11.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Copyright © 2011–2013, Texas Instruments Incorporated

1.11.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 1-88 shows the integration of the ELM subsystem in the device.

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A8	BCH error-location module interrupt

1.11.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

1.11.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

1.11.3.2 ELM Power Management

Table 1-145 describes the power-management features available to the ELM module.

Table 1-145. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

Copyright © 2011–2013, Texas Instruments Incorporated

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

1.11.3.3 ELM Interrupt Requests

Table 1-146 lists the event flags, and their masks, that can cause module interrupts.

Table 1-146. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

1.11.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Copyright © 2011–2013, Texas Instruments Incorporated

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

1.11.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 1-147. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

1.11.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Copyright © 2011–2013, Texas Instruments Incorporated

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

1.11.4 ELM Basic Programming Model

1.11.4.1 ELM Low Level Programming Model

1.11.4.1.1 Processing Initialization

Table 1-148. ELM Processing Initialization

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
endif		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value

Table 1-148. ELM Processing Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

1.11.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 1-149 and Table 1-150 describe the processing completion for continuous and page modes, respectively.

Table 1-149. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 1-150. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-150. ELM Processing Completion for Page Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

1.11.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 1-151. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-151. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 1-152 are given in decimal format.

...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

1.11.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 1-153. Use Case: Page Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1

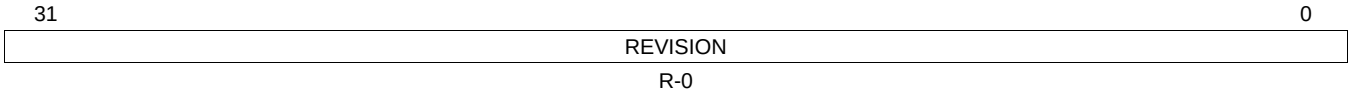
1.11.5.1 ELM Revision Register (ELM_REVISION)

This register contains the IP revision code. The ELM Revision Register (ELM_REVISION) is shown in Figure 1-89 and described in Table 1-155.

Figure 1-89. ELM Revision Register (ELM_REVISION)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

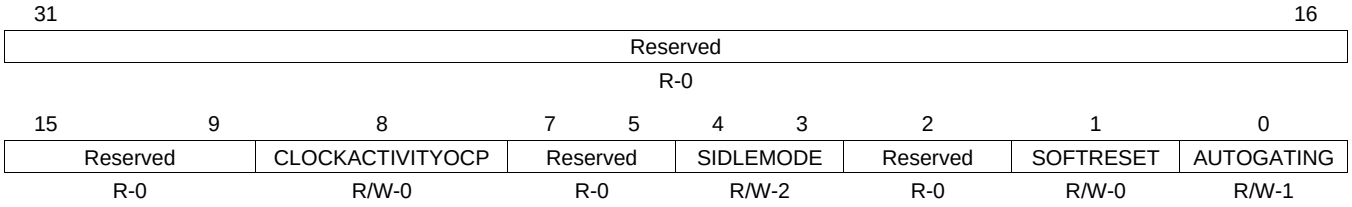
Table 1-155. ELM Revision Register (ELM_REVISION) Field Descriptions

Bit	Field	Value	Description
31-0	REVISION	0-FFFF FFFFh	IP Revision

1.11.5.2 ELM System Configuration Register (ELM_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The ELM System Configuration Register (ELM_SYSCONFIG) is shown in Figure 1-90 and described in Table 1-156.

Figure 1-90. ELM System Configuration Register (ELM_SYSCONFIG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 1-156. ELM System Configuration Register (ELM_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	CLOCKACTIVITY OCP		OCP Clock activity when module is in IDLE mode (during wake up mode period).
		0	OCP Clock can be switch-off
		1	OCP Clock is maintained during wake up period
7-5	Reserved	0	Reserved
4-3	SIDLEMODE		Slave interface power management (IDLE req/ack control).
		0	FORCE Idle. IDLE request is acknowledged unconditionally and immediately. (Default *Dumb* mode for safety)
		1h	NO idle. IDLE request is never acknowledged.
		2h	SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity.
		3h	Reserved - do not use
2	Reserved	0	Reserved
1	SOFTRESET		Module software reset. This bit is automatically reset by hardware (During reads, it always returns 0.). It has same effect as the OCP hardware reset.
		0	Normal mode.
		1	Start soft reset sequence.
0	AUTOGATING		Internal OCP clock gating strategy. (No module visible impact other than saving power.)
		0	OCP clock is free-running.
		1	Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.

1.12 Bus Interconnect

1.12.1 Interconnect Overview

1.12.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behavior is defined by the protocol semantics.
- Sideband signal: Any signal whose behavior is not associated to a precise transaction or data flow.
- Out-of-band error: Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the

Copyright © 2011–2013, Texas Instruments Incorporated

request and is used for firewall and error-logging mechanism.

- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 1-171 lists the commands encoded.

Table 1-171. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Read link
1 0 1	Write nonposted
1 1 0	Write conditional
1 1 1	Write broadcast

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 1-172.

Table 1-172. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 1-173.

Table 1-173. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

1.12.1.2 Architecture Overview

The device memory hierarchy includes four levels:

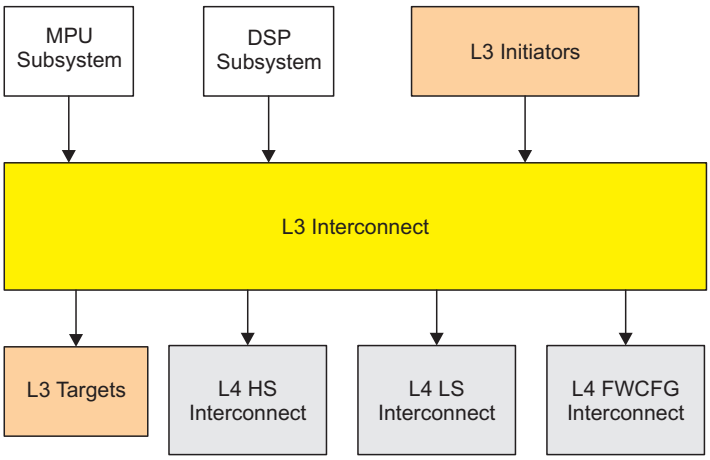
- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core.
- L2 is included in the DSP subsystem and the MPU subsystem.

Copyright © 2011–2013, Texas Instruments Incorporated

- The chip-level interconnect consists of one L3 interconnect and three L4 interconnects. It enables communication among the modules and subsystems in the device.

Figure 1-105 shows an overview of the L3 and L4 interconnect architecture.

Figure 1-105. Interconnect Overview



Copyright © 2011–2013, Texas Instruments Incorporated

- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- The L4 is composed of the following:
  - L4 HS: Includes the majority of the configuration interface for level 3 (L3) system modules and peripheral interconnect
  - L4 LS : Includes the main peripherals that require enhanced direct memory access (EDMA) access
  - L4 FWCFG: Includes peripherals attached to the WKUP power domain.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default settings are fully functional; they enable all possible functional data paths and a minimal default protection setting. However, the interconnect parameters can be modified to fit user expectations.

1.12.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

1.12.2.1 L3 Interconnect Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3 interconnects are:

- Network interface units (NIUs): Master NIUs for the initiator agents (IAs) and slave NIUs for the target agents (TAs)
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting satistical events on the L3 interconnect

Figure 1-106 is an overview of the L3 interconnect and the peripherals attached to it.

1.12.2.3 L3 Interconnect Functional Description

1.12.2.3.1 Module Use in L3 Interconnect

The L3 interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUX to mask interrupts: Three, one for each clock domain
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration.
- Some rate adapters for control of throughput ratio

1.12.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 1-176 and Table 1-177 list all the modules and subsystems with their associated agents. The agents are listed for each L3 interconnect domain.

1.12.2.3.2.1 L3 Interconnect Agents

Any initiator or target core is connected to the L3 interconnect through an NIU. NIUs act as entry points to the L3 interconnect, and also include various programming registers. Table 1-176 lists the supported master NIU ports.

Table 1-176. Master NIUs

Master NIU	Description
L3_MN_MPU	Cortex A8 microprocessor subsystem unit 128-bit port
L3_MN_HDVICP	HDVICP subsystem port 1 128-bit initiator port

1.12.2.3.2.2 L3 Connectivity Matrix

The L3 interconnect is divided into two main clock domains plus one small domain dedicated to DRAM performance monitorring:

- L3F clock domain (220 MHz)
- L3S clock domain (110 MHz)
- L3M cock domain (200MHz clock domain for performance monitoring)

The two main clock domains (L3F and L3S) are sychronous and balanced to each other. The third clock domain L3M, dedicated to performance monitoring is asynchronous to all other domains.

Copyright © 2011–2013, Texas Instruments Incorporated

1.12.2.3.2.2.1 Clock Domain Mapping of the L3 Interconnect Modules

Each clock domain (L3F, L3S, and L3M) has its own host, flag mux, slave NIUs, and bandwidth regulators.

1.12.2.3.2.3 Master NIU Identification

An master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 1-179). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3 interconnect error logging

Table 1-179. ConnID Values

4 Bit ConnID Value (security) (hex)	6 Bit ConnID Value (debug) (hex)	Master NIU
F	3F	STATCOLL3

1.12.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. It is used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 1.12.2.5.1.4, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following masters: HDVICP, TPTC_RD2/4, TPTC_WR2/4, MMU, ISS and SGX.

1.12.2.3.4 Flag Muxing

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU interrupt controller without interfering with the interconnect traffic. Flag mux unit contains software registers that are able to eventually mask some interrupts in order to prevent the unit from seeing them and to help with debug.

There are four registers in this group:

- One register to mask application error sources
- One status register to check which application error sources are active
- One register to mask debug error sources
- One status register to check which debug error source are active

By default none of the flags are masked.

There are four flag muxes in Centaurus L3 Interconnect, one per each clock domain plus additional flag mux collecting flags from the three previous ones. In concequnce L3 will generate two flags: APPLICATION error and DEBUG error.

The unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) are used to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number. Flag mux inputs for the different sources can be see in Table 1-232.

1.12.2.3.5 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Copyright © 2011–2013, Texas Instruments Incorporated

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Table 1-270).

Filters are programmed through the Table 1-270 configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 1-252). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 1-252).

There are five statistic collectors embedded in Centaurus L3, one dedicated to DRAM load monitoring and four statistic collectors dedicated to master latency monitoring.

1.12.2.3.6 L3 Interconnect Error Handling

Error logging is enabled in the L3 interconnect. The three major types of errors are:

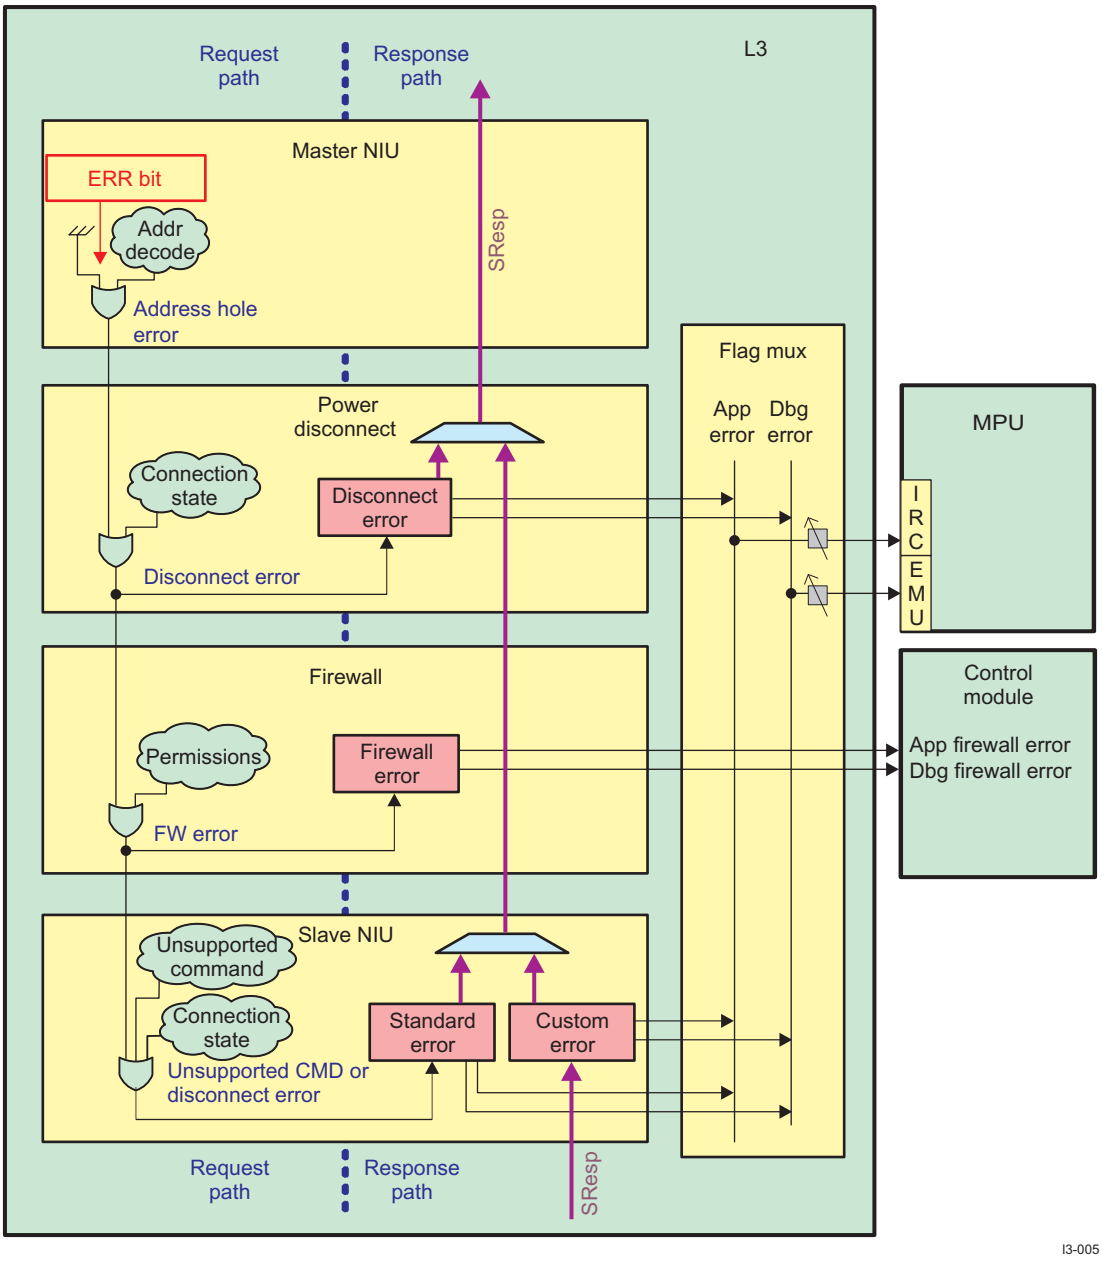
- Slave NIU errors
- Firewall errors (see , *L3Firewall Error Logging*)
- Flag mux errors

1.12.2.3.6.1 Global Error-Routing Scheme

Figure 1-108 shows the L3 global error-routing scheme.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-108. L3 Global Error-Routing Scheme



1.12.2.3.6.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 1-180).

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-180. L3 Connectivity and Holes Error Routing

Master	Connectivity and Holes Errors Logged Into Slave NIUs
DAP	GPMC
Dual Cortex M3 (Media Controller)	
Expansion slot	
JTag interface (IEEE1500)	
MMU	
MPU (Modena)

HDVPSS1/2	
HDVICP	
FACEDETECT	
PATA	
DSP (GEM_CFG)	USB Targ
DSP (GEM_MDMA)	MMU Targ
USB1	DSP (GEM_SDMA)

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module.
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
  - None: Error logging for this type of error is disabled.
  - Error: Error is logged for this type of error.
  - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
  - Application error - Fault[0]
  - Debug error - Fault[1]

  By default, all slave NIUs are configured with standard and custom error levels set to FAULT, active high. The errors are reported on the two flag muxes (see Figure 1-108), depending on the access type, application or debug. For more information, see Section 1.12.2.3.6.3, *Flag Mux Error Logging*.

  The slave NIU power-disconnect component also has error logging enabled. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the slave is awake. This is inefficient but it simplifies NIU implementation and should not be a problem,

Copyright © 2011–2013, Texas Instruments Incorporated

because errors are supposed to occur only during software debug.

1.12.2.3.6.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- L3_FLAGMUX_MASK0: Masks application error sources
- L3_FLAGMUX_MASK1: Masks debug error sources
- L3_FLAGMUX_REGERR0: Checks which application error sources are active
- L3_FLAGMUX_REGERR1: Checks which debug error sources are active

The two L3_FLAGMUXMASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

Table 1-181 describes the mapping of the flags to the corresponding sources.

Table 1-181. Interconnect Flag Mapping

	Flag Mux Input	Source
L3F Flag Mux	0	MMU
	1	DMM port1

1.12.2.3.6.4 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors (see Table 1-193).
- The L3_TARG_STDERRLOG_MAIN register is the main register for error-logging management. It shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

1.12.2.4 L3 Interconnect Programming Guide

1.12.2.4.1 L3 Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3 interconnect module.

1.12.2.4.1.1 Global Initialization

1.12.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3 interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3interconnect. For more information, see Section 1.12.2.2, *L3 Interconnect Integration* .

Table 1-182. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see the *PRCM* chapter.
Control module	For information about the configuration of the control module, see the *Control Module* chapter.
MPU INTC	The MPU INTC must be configured to enable interrupts from the L3 interconnect module. See the *ARM Interrupt Controller (AINTC)* chapter.
EDMA	For information about the configuration of the EDMA, see the *EDMA* chapter.
L3 interconnect	For information about the configuration of the interconnect, see the *L3 Interconnect* section.

1.12.2.4.2 Operational Modes Configuration

1.12.2.4.2.1 L3 Interconnect Error Analysis Mode

1.12.2.4.2.1.1 Main Sequence: L3 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 1-109 shows the software sequence required in most cases.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-109. Typical Error Analysis Sequence

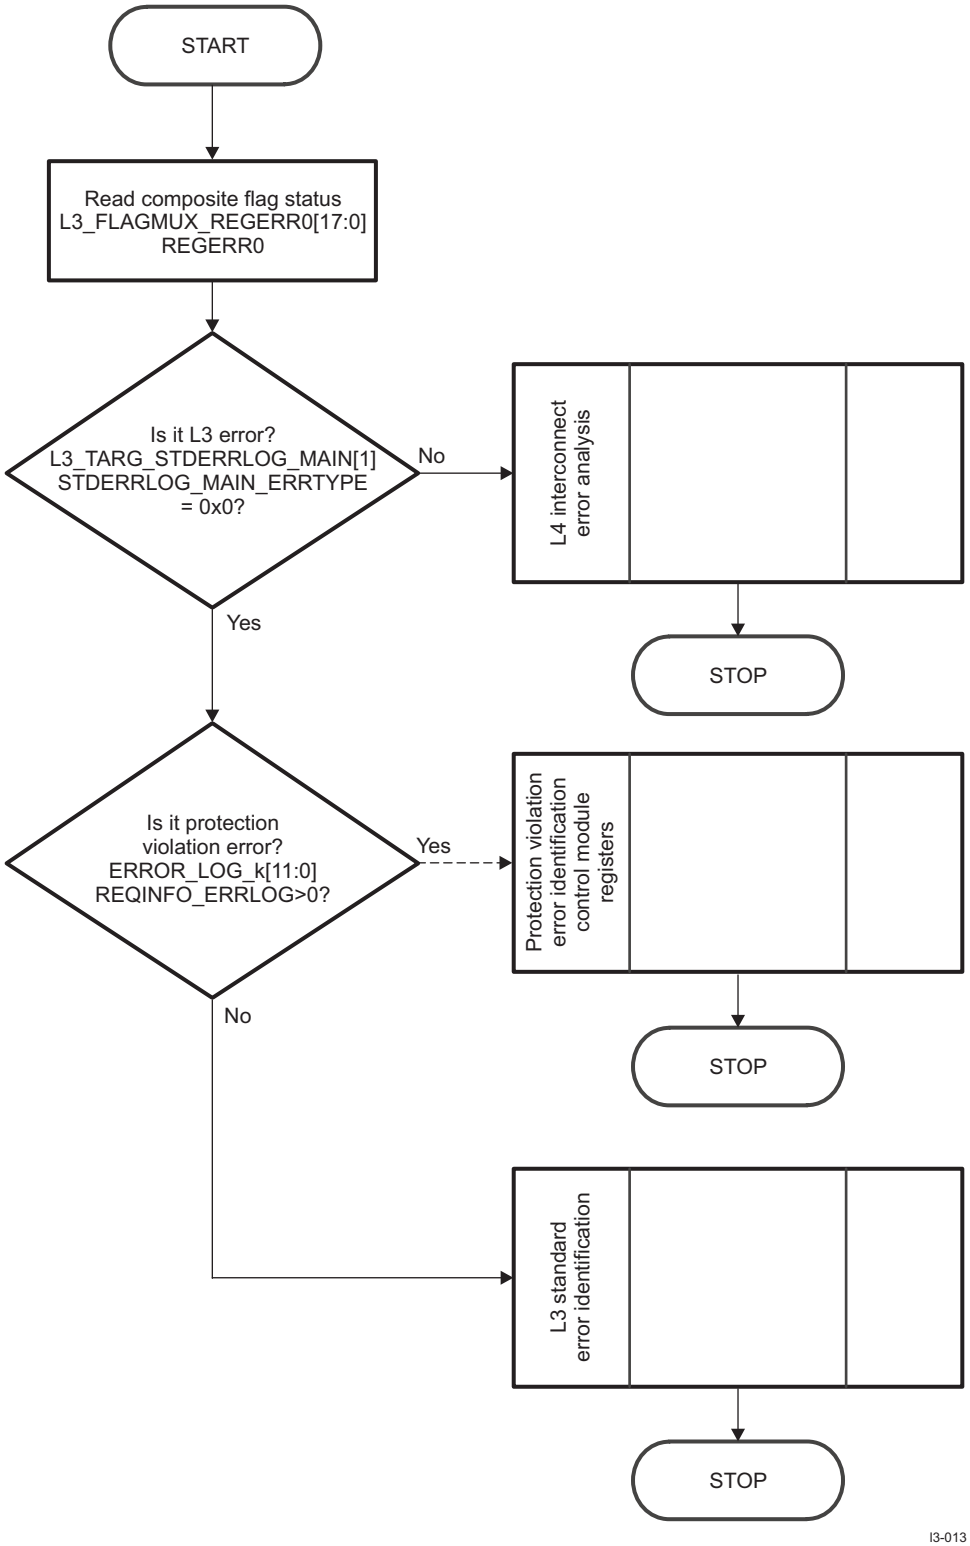

Table 1-183 lists the subprocess call summary for error analysis mode in the main sequence.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-183. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L4 interconnect error analysis	See Section 1.12.2.4.2.1, *L4 Interconnect Error Analysis Mode.*
L3 interconnect protection violation error identification	See Section 1.12.2.4.2.1.1.2, *Subsequence: L3 Interconnect Protection Violation Error Identification.*
L3 interconnect unsupported command/address hole error identification	See Section 1.12.2.4.2.1.1.3, *Subsequence: L3Interconnect Unsupported Command/Address Hole Error Identification.*
L3 interconnect reset FLAGMUX and module	See Section 1.12.2.4.2.1.1.4, *Subsequence: L3 Interconnect Reset FLAGMUX and Module.*

1.12.2.4.2.1.1.1 Subsequence: L3 Custom Error Identification

The procedure listed in Table 1-184 describes custom error identification.

Table 1-184. Custom Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is custom error detected?	L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE	=0x1
Read info field of the response packet.	L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO	xxx
Read the address of the initiator that caused error.	L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[5:0] STDERRLOG_CUSTOMINFO_MSTADDR	xxx
Read the type of operation (read/write).	L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE	xxx
ENDIF		

1.12.2.4.2.1.1.2 Subsequence: L3 Interconnect Protection Violation Error Identification

The procedure listed in Table 1-185 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 1-185. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	xxx
Read the initiator ID.	ERROR_LOG_k[3:0] ConnID	xxx
Read the command that caused the error.	ERROR_LOG_k[7] MCMD	xxx
Read the address of the request that caused the error.	ERROR_LOG_k[31:12] SLVOFS_LOGICAL	xxx
IF: Is it an application error?	L3_FLAGMUX_REGERR0 [10:0] REGERROR0	0x0
Clear the status bit.	L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG	0x0
ELSE IF	L3_FLAGMUX_REGERR1[10:0] REGERROR1	= 0x1
Clear the status bit.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
ENDIF		
Clear the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	0x0
Clear the error status.	ERROR_LOG_k[21:17] REGION_START_ERRLOG	0x00

1.12.2.4.2.1.1.3 Subsequence: L3 Interconnect Standard Error Identification

The procedure listed in Table 1-186 describes the identification of standard errors inside the L3 interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-186. L3 Standard Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is an error detected?	L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT	= 0x1
Read the corresponding flag.	L3_FLAGMUX_REGERR0[10:0] REGERROR0	xxx
Read the corresponding flag.	L3_FLAGMUX_REGERR1[10:0] REGERROR1	xxx
Localize the slave NIU that generated the error.	See Table 1-181, *Interconnect Flag Mapping*.	
ELSE		
Clear the error log.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
Clear the severity error status.	L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0	0x2
ENDIF		

1.12.2.4.2.1.1.4 Subsequence: L3 Interconnect FLAGMUX Configuration

The procedure listed in Table 1-187 gives information about the configuration of FLAGMUX masks.

Table 1-187. FLAGMUX Configuration

Step	Register/Bit Field/Programming Model	Value
Set the FLAGMUX masks to mask an event.	L3_FLAGMUX_MASK0[10:0] MASK0 L3_FLAGMUX_MASK1[10:0] MASK1	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_REGERR0[10:0] REGERR0 L3_FLAGMUX_REGERR1[10:0] REGERR1	xxx
Clear the slave NIU error log and the FLAGMUX error.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0	0x1

1.12.2.5 L3 Interconnect Register Manual

1.12.2.5.1 L3 Register Group Summary

The registers in the L3 interconnect are divided into eight groups:

- HOST registers (See Table 1-189)
- TARG registers (See Table 1-208)
- FLAGMUX registers (See Table 1-233)
- BW registers (See Table 1-243)
- STATCOLL registers (See Table 1-252)

1.12.2.5.1.1 L3 Host Register Summary and Description

Table 1-188. HOST Instance Summary

Module Name	Base Address	Size
L3F	0x4400 0000	8MB

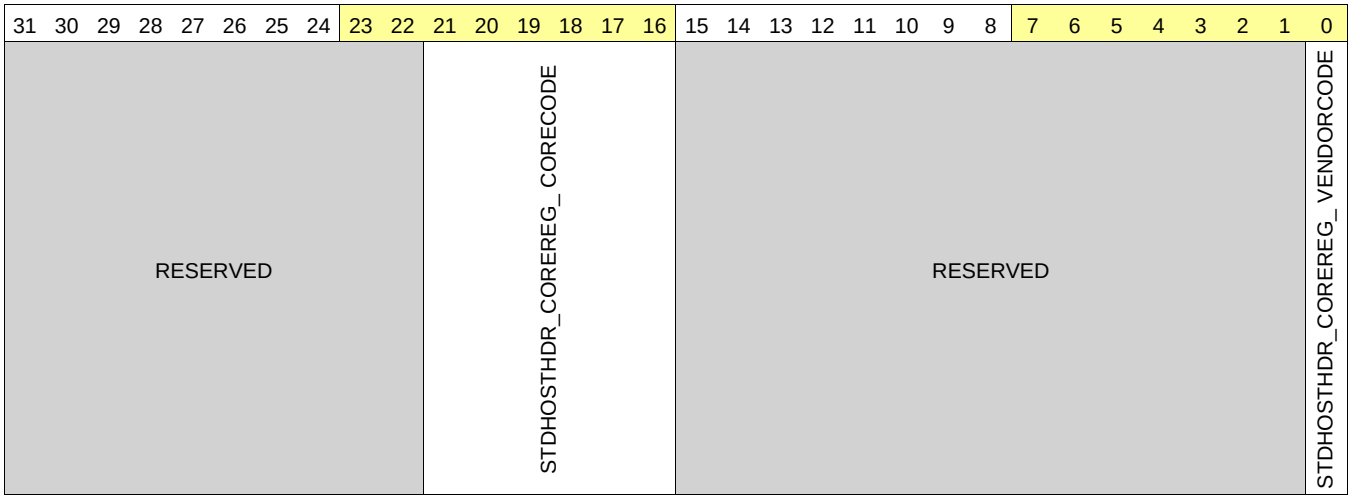
1.12.2.5.1.2.2 L3 TARG Registers Description

Table 1-215. L3_TARG_STDHOSTHDR_COREREG

Address Offset	0x0000 0000		
Physical Address	See Table 1-208 through Table 1-214	**Instance**	See Table 1-208 through Table 1-214
Description			
Type	R		



Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21:16	STDHOSTHDR_COREREG_ CORECODE	The Core Code field is a constant reporting a vendor-specific core generator code. Type: Constant. Reset value: 0x13.	R	0x13
15:1	RESERVED		R	0x0000
0	STDHOSTHDR_COREREG_ VENDORCODE	The Vendor Code field is a constant reporting the core generator vendor code. Type: Constant. Reset value: 0x1. Read 0x0: Third-party vendor. Read 0x1:	R	1

Table 1-216. L3_TARG_STDHOSTHDR_VERSIONREG

Address Offset	0x0000 0004		
Physical Address	See Table 1-208 through Table 1-214	**Instance**	See Table 1-208 through Table 1-214
Description			
Type	R

STDHOSTHDR_VERSIONREG_REVISIONID								STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM																							

Bits	Field Name	Description	Type	Reset
31:24	STDHOSTHDR_VERSIONREG_REVISIONID	The Revision Identifier field is a constant reporting the core generator revision number. Type: Constant. Reset value: 0x0.	R	0x00
23:0	STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM	Reserved. Type: Reserved. Reset value: Reserved.	R	0x000000

Table 1-217. L3_TARG_STDHOSTHDR_MAINCTLREG

Address Offset	0x0000 0008		
Physical Address	See Table 1-208 through Table 1-214	**Instance**	See Table 1-208 through Table 1-214
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											RESERVED	STDHOSTHDR_MAINCTLREG_CM	STDHOSTHDR_MAINCTLREG_FLT	RESERVED	STDHOSTHDR_MAINCTLREG_EN

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x0000000
4	RESERVED	Reserved	R	0
3	STDHOSTHDR_MAINCTLREG_CM	Reserved for internal testing. Must be set to 0. Type: Control. Reset value: 0x0.	R	0
2	STDHOSTHDR_MAINCTLREG_FLT	Asserted when a Fault condition is detected: if the unit includes Error Logging, Flt is asserted when the FltCnt register field indicates a Fault, and deasserted when FltCnt is reset. If no Error Logging is implemented, this bit becomes unit-dependent. In all cases, Flt bit and Flt pin (service network) have the same logical level. Type: Status. Reset value: X.	R	0

Table 1-247. L3_BW_R_BANDWIDTH

Address Offset	See Table 1-243.		
Physical Address	See Table 1-243 andTable 1-244.	**Instance**	See Table 1-243 andTable 1-244.
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																BANDWIDTH															

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved	R	0x0000
16:0	BANDWIDTH	Bandwidth, in bytes per second. Type: Control. Reset value: 0x0.	RW	0x0000

Table 1-248. L3_BW_R_WATERMARK

Address Offset	See Table 1-243.		
Physical Address	See Table 1-243 andTable 1-244.	**Instance**	See Table 1-243 andTable 1-244.
Description			
Type	RW		

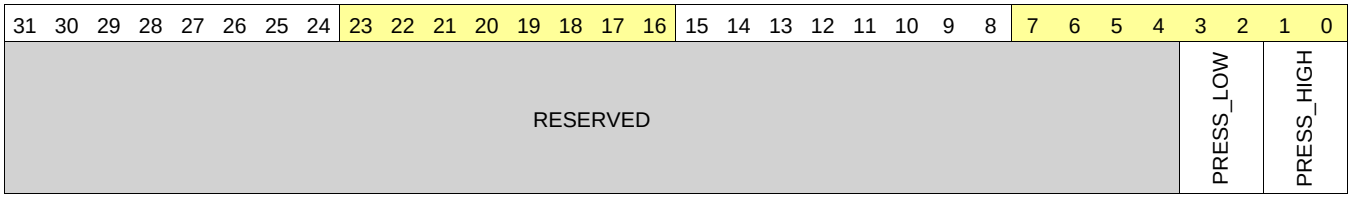
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				WATERMARK											

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reserved	R	0x00000
11:0	WATERMARK	Peak permissible bandwidth, in bytes. Type: Control. Reset value: 0x1.	RW	0x001

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-249. L3_BW_R_PRESS

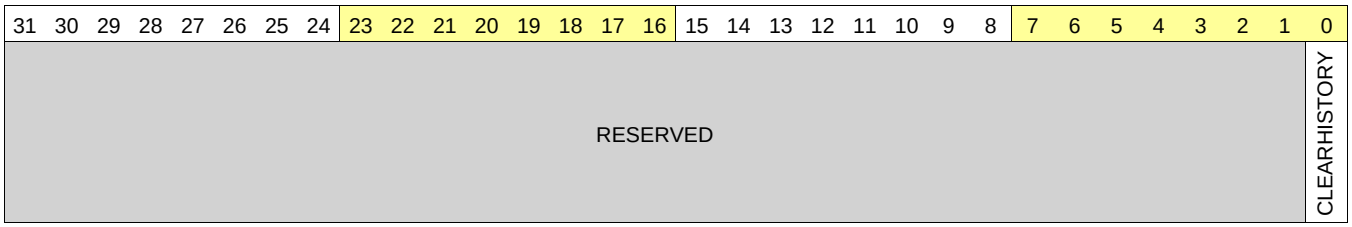
Address Offset	See Table 1-243.		
Physical Address	See Table 1-243 andTable 1-244.	**Instance**	See Table 1-243 andTable 1-244.
Description			
Type	R		



Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000 0000
3:2	PRESS_LOW	Pressure value inserted if the measured bandwidth is over the watermark. The pressure is bar graph encoded. Type: Control. Reset value: 0x0.	R	0
1:0	PRESS_HIGH	Pressure value inserted if the measured bandwidth is under the watermark. The pressure is bar graph encoded. Type: Control. Reset value: 0x1.	R	0x3

Table 1-250. L3_BW_R_CLEARHISTORY

Address Offset	See Table 1-243.		
Physical Address	See Table 1-243 andTable 1-244.	**Instance**	See Table 1-243 andTable 1-244.
Description			
Type	RW		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x0000 0000
0	CLEARHISTORY	Write a 1 clear the traffic counter Type: Give_AutoCleared. Reset value: 0x0.	RW	0

1.12.3 L4 Interconnects

This section details the device L4 interconnects.

1.12.3.1 L4 Interconnect Overview

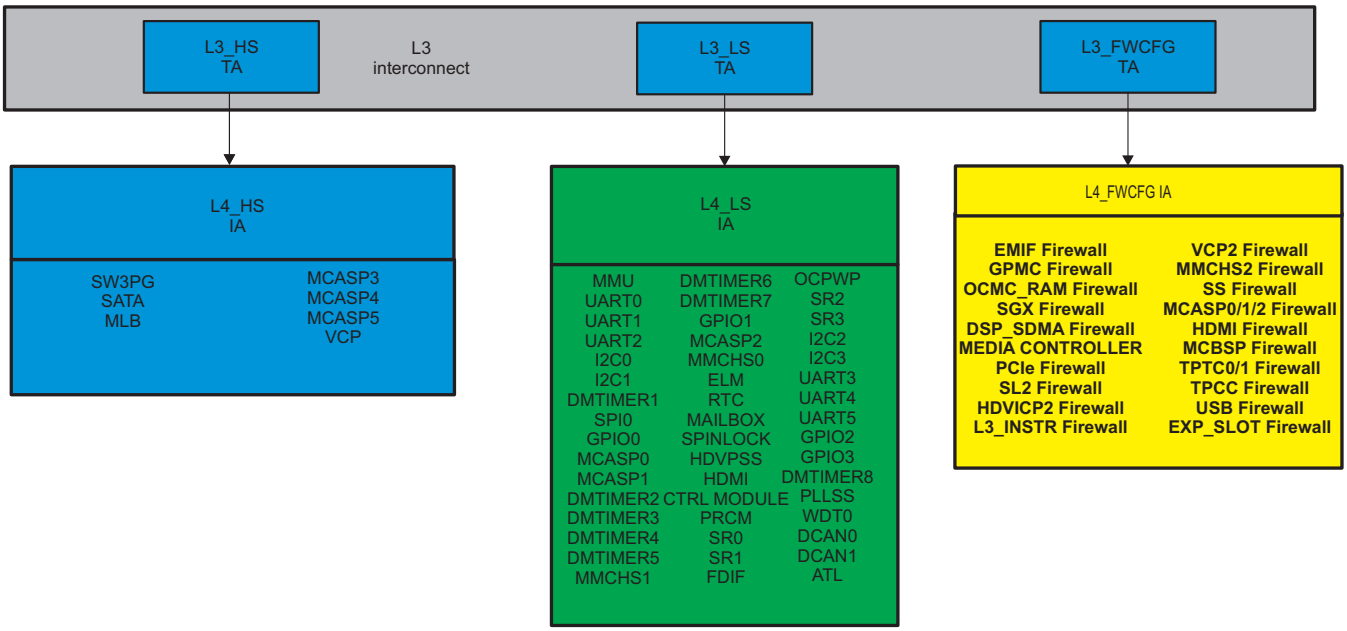
The device uses two separate L4 interconnect structures to connect peripheral modules, and one additional L4 interconnect for the firewalls. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 1-110 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_HS: Configuration peripheral interconnect, for configuration of high speed masters. Located in the 220MHz clock domain.
- L4_LS: Main peripheral interconnect for peripherals that requre DMA accesses. This is a configuration interconnect for the low speed masters, located in the 110 MHz clock domain.
- L4_FWCFG: Firewall configuration interconnect located in the 110 MHz clock domain.

Figure 1-110. L4 Interconnect Overview



The main features of the L4 interconnects are:

- From one to two 32-bit initiator ports for each L4 interconnect instance.
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little endian
- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- Protection logic that provides user-configurable access control to targets by each initiator
- L4LS and L4HS are each with its own PRCM interface
- All peripherals are protected by firewall

1.12.3.2 L4 Interconnect Integration

Table 1-292 and Table 1-293 summarize the integration of the module in the device.

1.12.3.3 L4 Interconnect Functional Description

1.12.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 1-294 through Table 1-299 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

1.12.3.3.1.1 L4_HS Interconnect Agents

Table 1-294 lists the L4 HS TAs.

Table 1-294. L4 HS TAs

Module Target Name	Description
L4HS_TA_SW3PG	SW3PG L4 HS target port
L4HS_TA_SATA	SATA L4 HS target port
L4HS_TA_MLB	MLB L4 HS target port
L4HS_TA_MCASP3	MCASP3 L4 HS target port
L4HS_TA_MCASP4	MCASP4 L4 HS target port
L4HS_TA_MCASP5	MCASP5 L4 HS target port
L4HS_TA_VCP	VCP L4 HS target port

Two ports communicate beteween L3 and the L4 HS interconnect to allow L3 Initiators to access L4HS targets. Table 1-295 lists the L4HS initiator TAs.

For the list of initiators authorized to access the L4 peripheral peripherals, see *Connectivity Matrix*.

Table 1-295. L4 HS IAs

Module Iniator Name	Description
L4HS_IA_0	L3 enhanced direct memory access (EDMA) RD interconnect port
L4HS_IA_1	L3 EDMA WR interconnect port

1.12.3.3.1.2 L4_LS Interconnect Agents

The L4_LS interconnect handles only transfers to peripherals in the core power domain. Table 1-296 lists the TAs.

Table 1-296. L4_LS TAs

Module Target Name	Description
L4LS_TA_MMU	System MMU L4LS target port
L4LS_TA_UART0	UART0 L4LS target port

1.12.3.3.1.3 L4_FWCFG Interconnect Agents

The L4 FWCFG interconnect handles transfers only to peripherals in the FWCFG. Table 1-298 lists the TAs. Table 1-299 lists the L4FWCFG initiator agents.

Table 1-298. L4 FWCFG TAs

Module Target Name	Description
L4FWCFG_TA_EMIF	EMIF firewall
L4FWCFG_TA_GPMC	GPMC firewall
L4FWCFG_TA_OCMC_RAM	OCMC RAM firewall
L4FWCFG_TA_SGX	SGX firewall
L4FWCFG_TA_DSP_SDMA	DSP SDMA firewall
L4FWCFG_TA_MEDIA_CONTROLLER	Media Controller firewall
L4FWCFG_TA_PCIE	PCIe firewall
L4FWCFG_TA_SL2	HDVICP2-0 SL2 firewall
L4FWCFG_TA_HDVICP2	HDVICP2-0 CFG firewall
L4FWCFG_TA_VCP2	VCP2 firewall
L4FWCFG_TA_MMCHS2	MMCHS2 firewall
L4FWCFG_TA_ISS	ISS firewall
L4FWCFG_TA_MCASP0/1/2	MCASP0/1/2 firewall
L4FWCFG_TA_HDMI	HDMI firewall
L4FWCFG_TA_MCBSP	MCBSP firewall
L4FWCFG_TA_TPTC0/1	TPTC0/1 firewall
L4FWCFG_TA_TPCC	TPCC firewall
L4FWCFG_TA_USB	USB firewall
L4FWCFG_TA_EXP_SLOT	Expansion slot firewall
L4FWCFG_TA_L3_INSTR	L3 Instrumentation firewall

Table 1-299. L4_FWCFG IAs

Module Iniator Name	Description
L4FWCFG_IA_0	L3 interconnect port

1.12.3.3.2 Power Management

Each L4 has a single power management interface connected to a power control bridge. Power control bridge is managing the different internal power interfaces. It has na external slave interface to the PRCM, an internal master interface to L4 power interface and one interface to each power bridge. The power disconnect bridge is responsible for returning OCP responses or asking for target wake up. The bridge is under the control of the PRCM.

As part of the Always On power domain L4 interconnects do not support idle state or retention.

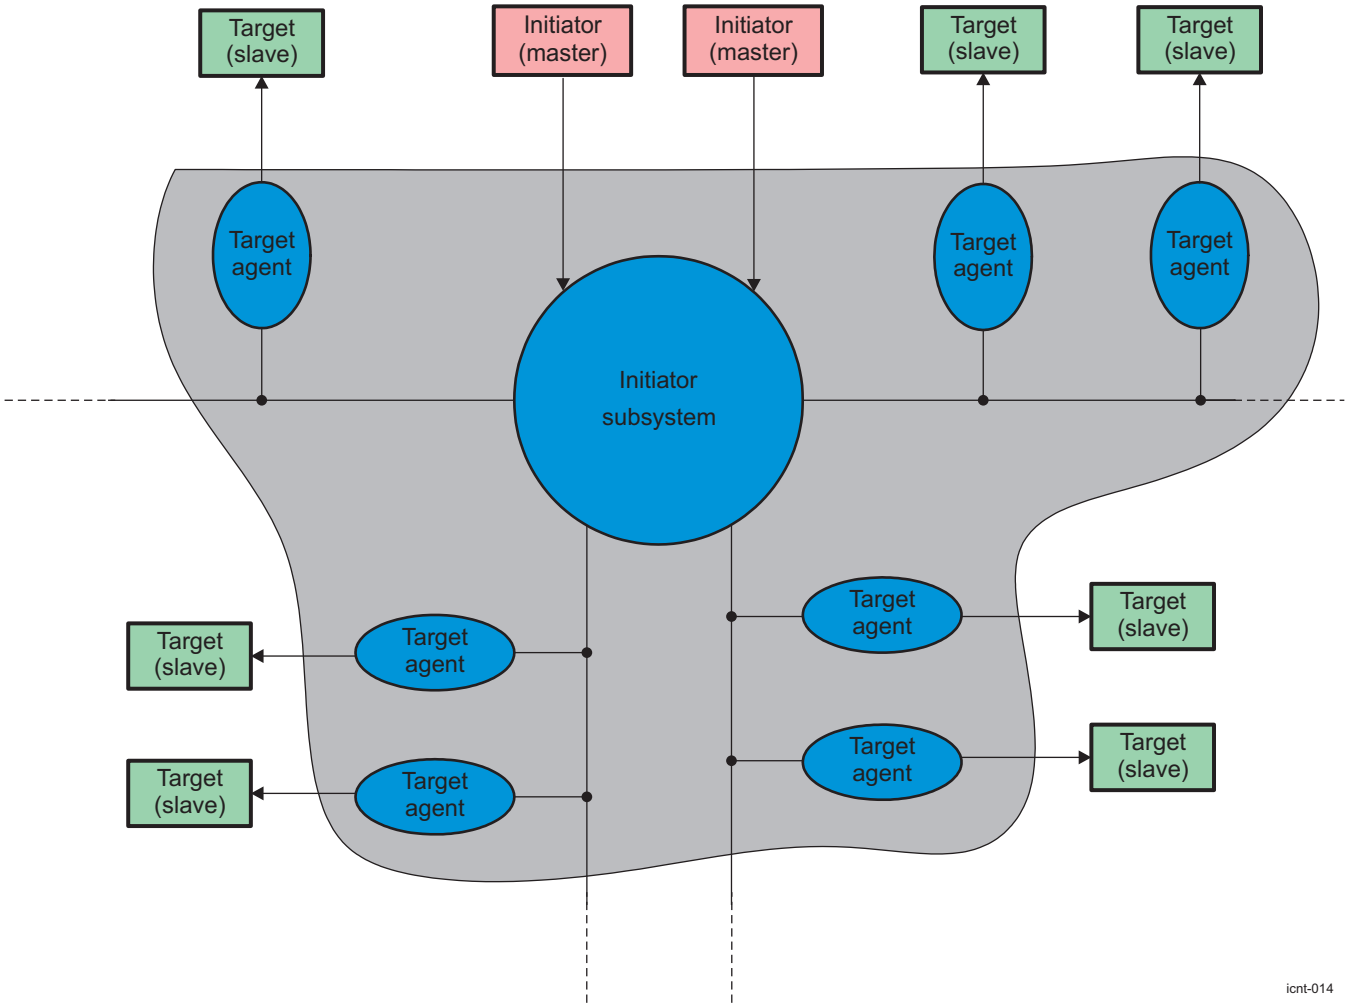
For more information about L4 interconnects power managemnet, clocking and resets see *Chapter: Power Reset and Clock management*.

1.12.3.3.3 L4 Firewalls

Figure 1-111 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-111. L4 Initiator-Target Connectivity



NOTE: As Figure 1-111 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators
  - Eight protection groups for L4_HS and L4_LS interconnect
- Segments divided into regions of 4KB
  - 29 regions for the L4_HS interconnect
  - 128 regions for the L4_LS interconnect
  - 47 regions for the L4_FWCFG interconnect.

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

All L4 interconnect information, such as numbers of protection groups, regions, and segments, is available in the L4_LA_INITIATOR_INFO_L register.

Copyright © 2011–2013, Texas Instruments Incorporated

1.12.3.3.3.1 Protection Group

A protection group is defined by its initiators and REQ_INFO is allowed. Two registers define these two settings:

- The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k_L is a 1-bit vector that defines which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 1-300 lists all the ConnID available at the L4 levels.
- The ENABLE field L4_AP_PROT_GROUP_ROLES_k_L lists all possible REQ_INFO combinations associated with the L4_AP_PROT_GROUP_MEMBERS_k_L register. Setting a Req bit in this register determines the initiators type of access. Two REQ_INFOs are used in L4 interconnects: MReqDebug and MReqSupervisor.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

L indicates the region number.

Table 1-300. L4 ConnID Definition

ConnID	Initiator
0	Modena MPU Cortex A8
1	DAP/ IEEE1500
2	DSP (GEM_MDMA, GEM_CFG), MMU

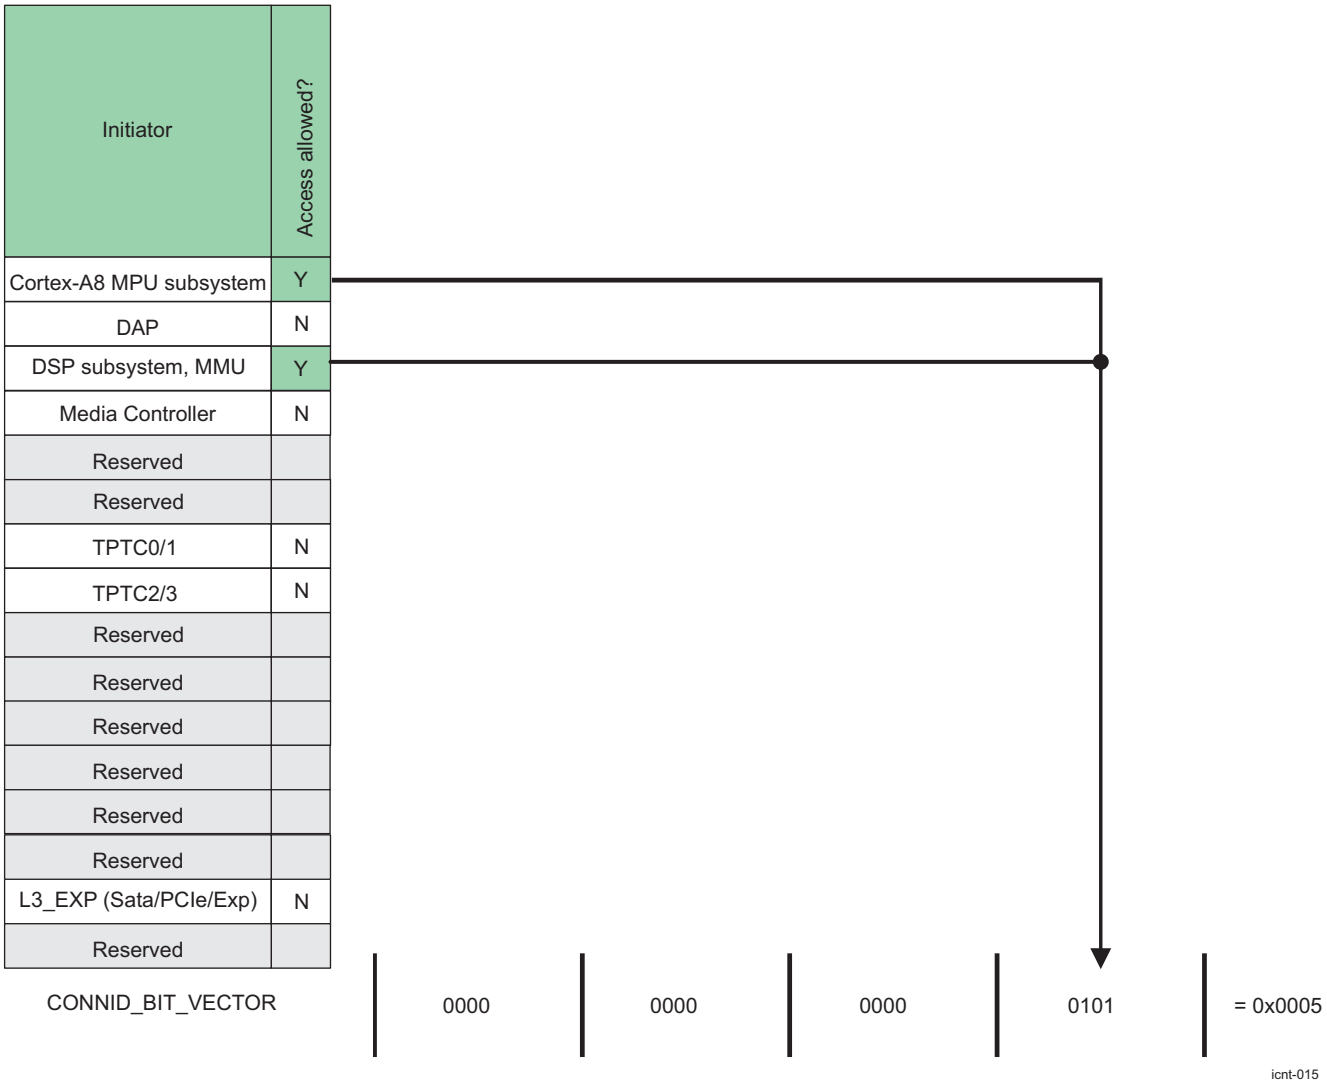
Figure 1-112 is an example of CONNID_BIT_VECTOR.

Figure 1-112. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k



Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A8 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_l_H.PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of CONNID_BIT_VECTOR and ENABLE fields are exported by the control module at reset or are user writable (see Figure 1-112 for more information).

Table 1-301 and Table 1-303 list the default configuration of the various groups for each L4 interconnect. For each group, some modules/regions are associated with it with default initiator members.

Copyright © 2011–2013, Texas Instruments Incorporated

		L4_AP_PROT_GROUP_MEMBERS_k_L	No	0xFFFF (all)

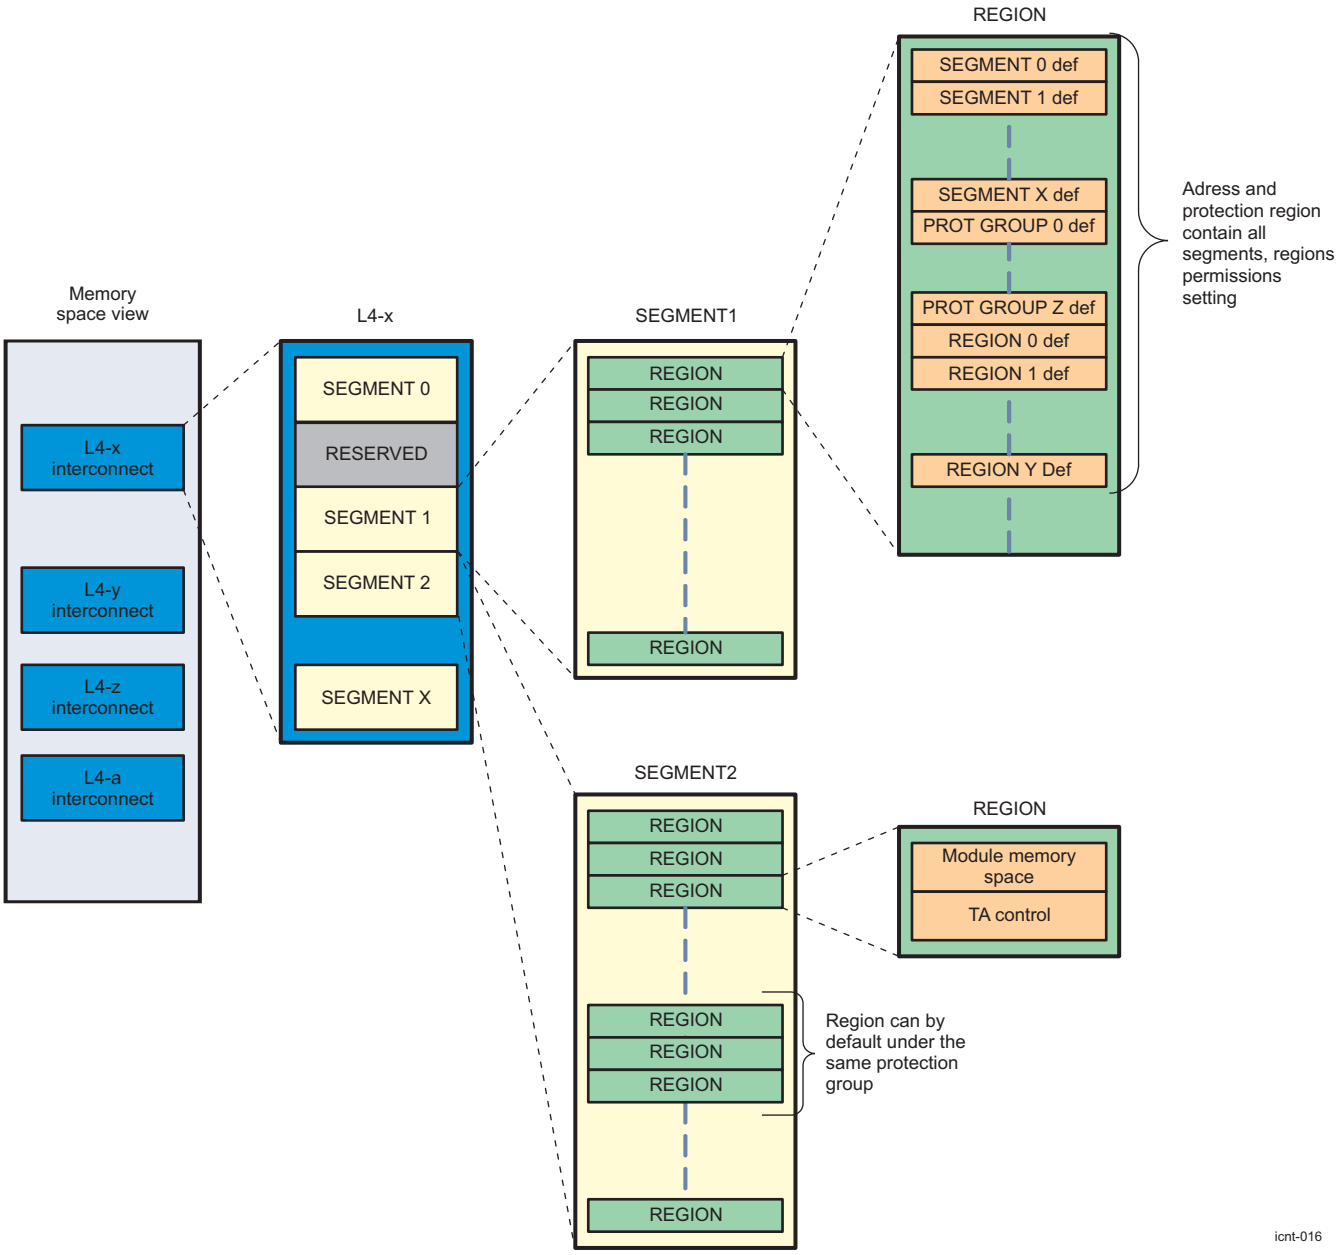
1.12.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 1-113. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-113. L4 Segmentation



All interconnect address spaces are covered by regions. Table 1-304 through Table 1-306 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

NOTE: Module refers to the configuration registers of the module.

TA refers to the interconnect configuration registers of the TA associated with the module.

1.12.3.3.3 L4 Address and Protection Register Settings

Table 1-307 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 1-307. L4 Address and Protection Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L (1)	23:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H (1)	4:0	SIZE	Segment size equals to 2^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L (2)	15:0	CONNID_BIT_VECTOR	For L4ConnID, see Table 1-300.
	L4_AP_PROT_GROUP_ROLES_k_L (2)	31:0	ENABLE	See for REQ_INFO description(3)
	L4_AP_PROT_GROUP_ROLES_k_H	31:0	ENABLE	See for REQ_INFO description(3)
Region setting	L4_AP_REGION_l_L (4)	23:0	BASE	Defines the base address of region with respect to its segment base address
	L4_AP_REGION_l_H (4)	31:28	MADDRSPACE	Target OCP MAddrSpace value
		26:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		18:17	BYTE_DATA_WIDTH_EXP	Determines the number of byte in an access
		14:8	PHY_TARGET_ID	Physical target ID
		6:1	SIZE	Size of the region equals to 2^{SIZE}
		0	ENABLE	Enables the region protection

(1) i = 0 to 1 forHS_AP
i = 0 to 2 for LS_AP
(2) k = 0 to 7 for HS_AP
k = 0 to 7 for LS_AP
(3) For L4 interconnects, only MReqDebug and MReqSupervisor are available.
(4) l = 0 to 28 for HS_AP
l = 0 to 127 for LS_AP

The value of L4_AP_PROT_GROUP_ROLES_k is exported at the chip boundary. Those values are latched in the register at reset or by using the load firewall mechanism, which allows to latch exported values simply by writing into a register of the control module, this avoids resetting the interconnect in this case. The values of the other protection registers can be modified on the fly.

1.12.3.3.4 L4 Error Detection and Reporting

1.12.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_LS, L4_HS and FWCFG.

L4_TA denotes the TA for all L4 interconnects: L4_LS, L4_HS and FWCFG.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 1.12.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 1.12.3.3.4.2, *Time-Out*).

Table 1-308 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 1-308. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type access (REQ_INFO qualifier) that caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ID of the initiator that caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] register logs the address for error conditions.

  A L4_IA_ERROR_LOG_L[31] MULTI bit is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

1.12.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the L4_TA_AGENT_STATUS_L[10:8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, the TA must be reset by the system software. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

Copyright © 2011–2013, Texas Instruments Incorporated

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. Selection is done by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 1-309 lists all values in number of L4 clock cycles.

Table 1-309. L4 Time-Out Link and TA Programming

	L4_TA_AGENT_CONTROL_L REQ_TIMEOUT[2:0]				
L4_LA_NETWORK_CONTROL_L TIMEOUT_BASE[2:0]	**0**	**1**	**2**	**3**	**4**
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16,384
3		1024	4096	16,384	65,536
4		4096	16,384	65,536	262,144

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of one to three time-base periods.

On detection of a time-out condition, the TA logs the error in L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the corresponding IA, which forward it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

1.12.3.3.4.3 Error Reporting

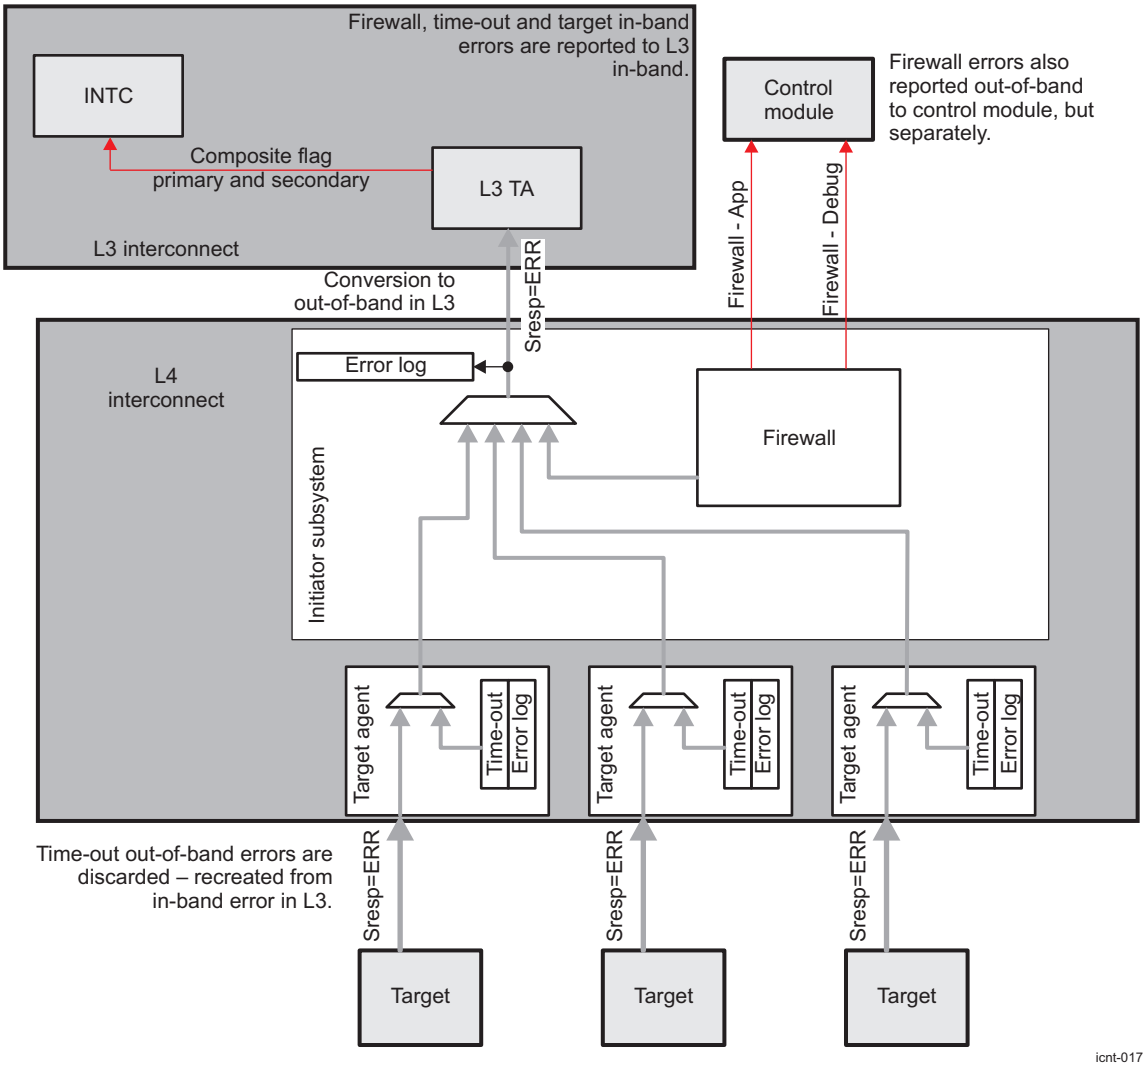
Figure 1-114 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to L3 Interconnect with SRESP = ERR, as well as being stored in the appropriate registers. Any target error response is send back to the initiator via L3 interconnect.

Protection errors are always reported out-of-band to the Control Module. This asynchronous reporting uses separate flags for debug requests and for non-debug reuqests. Out-of-band firewall error reporting can be disabled by software from the L4_IA_AGENT_CONTROL register.

By setting the register L4_LA_FLAG_MASK_i_L registers errors comming form different initiator ports can be masked independently. The default settings of these registers are 0x3 so that all errors can be reported. In case of error, the L4_LA_FLAG_STATUS_i_L registers can be read to determine the error source.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 1-114. L4 Error Reporting



1.12.3.3.4.4 Error Recovery

Writing 1 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Writing 0 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit terminates the software reset period.

The attached module must then be reset to complete the recovery.

1.12.3.4 L4 Interconnect Programming Guide

1.12.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

1.12.3.4.1.1 Global Initialization

1.12.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see Section 1.12.3.2, *L4 Interconnect Integration* .

Table 1-310. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see the *PRCM* chapter.
Control module	For more information about the configuration of the module, see the *Control Module* chapter.
MPU INTC	The MPU INTC must be configured to enable the interrupts from L4 interconnect module. See the *ARM Interrupt Controller (AINTC)* chapter.
EDMA	For more information about the configuration of the EDMA, see the *EDMA* chapter.
L3 interconnect	For more information about the interconnect configuration, see the *L3 Interconnect* section.

1.12.3.4.1.2 Operational Modes Configuration

1.12.3.4.1.2.1 L4 Interconnect Error Analysis Mode

1.12.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers.The number of registers to access depends on the error source.

Figure 1-115 and Figure 1-116 show the software sequence required in most cases.

Table 1-311 and Table 1-312 show the main sequence for error analysis mode and its subprocess call summary, respectively.

1.12.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 1-313).

Table 1-313. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[13:8] CONNID	
Read command that cause the error.	L4_IA_ERROR_LOG_L[3:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	=0x1
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Write 1 to clear IA status bit	L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY	0x1
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear in-band error status.	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR	0x1

1.12.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see Table 1-314).

Table 1-314. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[13:8] CONNID	
Read command that caused the error.	L4_IA_ERROR_LOG_L[3:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
Read secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	
Write 1 to clear secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x1
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[27 INBAND_ERROR	0x1

1.12.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see Table 1-315).

Table 1-315. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time - out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module.(1)		

(1) For more information, see the respective module chapter.

1.12.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

1.12.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see Table 1-316).

Table 1-316. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status.(1)	L4_TA_AGENT_STATUS_L[10:8] REQ_TIMEOUT	0x1
Set time-out at TA level.(1)	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

(1) Must be done for each TA.

1.12.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

1.12.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see Table 1-317).

Table 1-317. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k.(1)	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k.(1)	L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE	xx
Set region affiliation to protection group.(2)	L4_AP_REGION_I_L[22:20] PROT_GROUP_ID	xxx

(1) Must be done for each protection group.
(2) Must be done for each region.

1.12.3.5.2.2 L4 Initiator Agent (L4 IA) Register Description

through describe the L4 IA registers.

Table 1-321. L4_IA_COMPONENT_L

Address Offset	0x0000 0000
Physical Address	0x4800 1000 0x4A00 1000
Description	COMPONENT register identifies the component to which this register block belongs. The register contains a component code and revision, which are used to identify the hardware of the component. The COMPONENT register is read-only.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CODE																REV															

Bits	Field Name	Description	Type	Reset
31:16	CODE	Interconnect code	R	See (1).
15:0	REV	Component revision code	R	See(1).

Table 1-322. L4_IA_COMPONENT_H

Address Offset	0x0000 0004
Physical Address	0x4800 1004 0x4A00 1004
Description	COMPONENT register identifies the component to which this register block belongs. The register contains a component code and revision, which are used to identify the hardware of the component. The COMPONENT register is read-only.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															

Bits	Field Name	Description	Type	Reset
31:0	RESERVED	Read returns 0.	R	0x0000

Table 1-323. L4_IA_CORE_L

Address Offset	0x0000 0018
Physical Address	0x4800 1018 0x4A00 1018
Description	Provide information about the core initiator
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CORE_CODE																CORE_REV															

Bits	Field Name	Description	Type	Reset
31:16	CORE_CODE	Interconnect core code	R	See (1).
15:0	CORE_REV	Component revision code code	R	See(1).

(1) TI Internal Data

Table 1-324. L4_IA_CORE_H

Address Offset	0x0000 001C
Physical Address	0x4800 101C 0x4A00 101C
Description	Provide information about the core initiator
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																VENDOR_CODE															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15:0	VENDOR_CODE	Vendor revision core code	R	See (1).

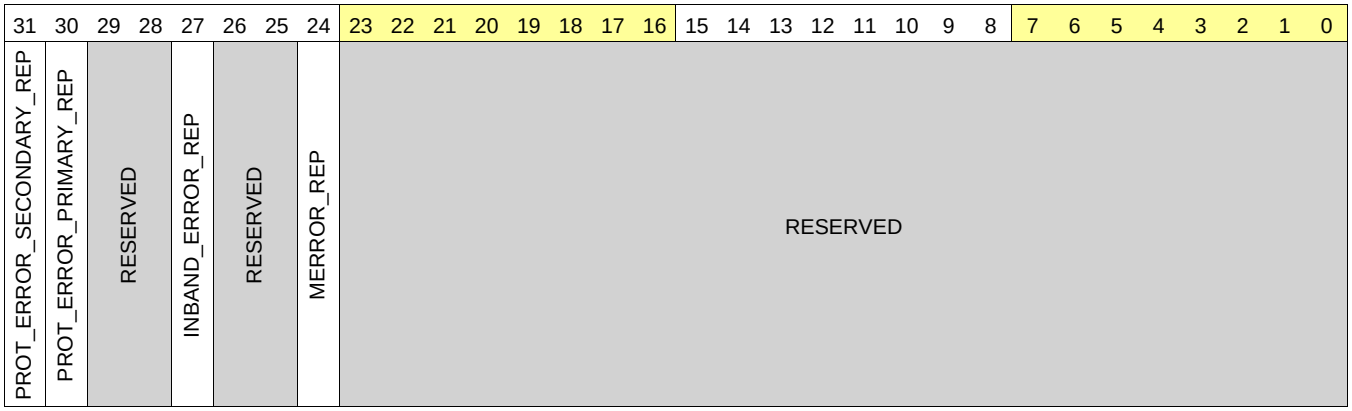
Table 1-325. L4_IA_AGENT_CONTROL_L

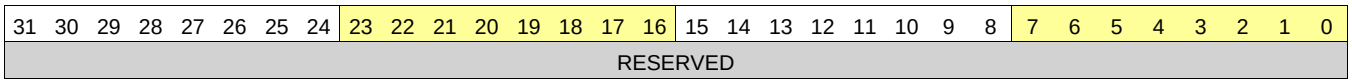
Address Offset	0x0000 0020
Physical Address	0x4800 1020 0x4A00 1020
Description	Enable error reporting on an initiator interface.The error reporting mechanism is enabled when the INBAND_ERROR_REP bit field is set to 1. The out-of-band OCP MError reporting mechanism is enabled when the MERROR_REP bit field is set to 1.
Type	RW



Bits	Field Name	Description	Type	Reset
31	PROT_ERROR_SECONDARY_REP	Out-of-band reporting of protection mechanism secondary errors	RW	1
30	PROT_ERROR_PRIMARY_REP	Out-of-band reporting of protection mechanism primary errors	RW	1
29:28	RESERVED	Read returns 0.	R	0x0
27	INBAND_ERROR_REP	Setting this field to 1 reports on in-band errors using the INBAND_ERROR log bit of IA.AGENT_STATUS register.	RW	1
26:25	RESERVED	Read returns 0.	R	0x0
24	MERROR_REP	OCP MError reporting control	R	0
23:0	RESERVED	Read returns 0.	R	0x0

Table 1-326. L4_IA_AGENT_CONTROL_H

Address Offset	0x0000 0024
Physical Address	0x4800 1024 0x4A00 1020
Description	Enable error reporting on an initiator interface.
Type	R

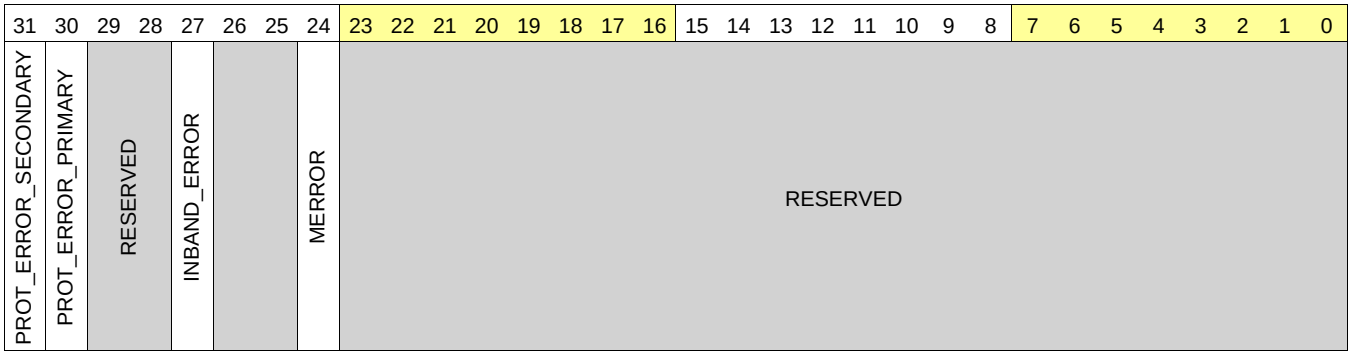


Bits	Field Name	Description	Type	Reset
31:0	RESERVED	Read returns 0.	R	0x0000 0000

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-327. L4_IA_AGENT_STATUS_L

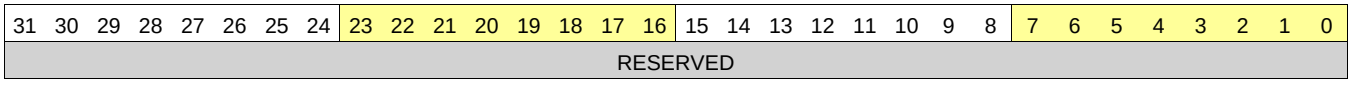
Address Offset	0x0000 0028
Physical Address	0x4800 1028 0x4A00 1028
Description	Stores status information for an initiator. The INBAND_ERROR and MERROR fields are read/write and are implemented as log bits.
Type	RW



Bits	Field Name	Description	Type	Reset
63:32	RESERVED	Read returns 0s	R	0x0000 0000
31	PROT_ERROR_SECONDARY	Protection error status. MErrorSteer indicates a secondary error.	RW W1toClr	0
30	PROT_ERROR_PRIMARY	Protection error status. MErrorSteer indicates a primary error (or is not enabled).	RW W1toClr	0
29:28	RESERVED	Read returns 0s	R	0x0
27	INBAND_ERROR	Error status	RW W1toClr	0
26:25	RESERVED	Read returns 0s	R	0x0
24	MERROR	Value of the OCP MError signal	R	0
23:0	RESERVED	Read returns 0s	R	0x00 0000

Table 1-328. L4_IA_AGENT_STATUS_H

Address Offset	0x0000 002C
Physical Address	0x4800 102C 0x4A00 102C
Description	Stores status information for an initiator.
Type	R



Bits	Field Name	Description	Type	Reset
31:0	RESERVED	Read returns 0.	R	0x0000 0000

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-329. L4_IA_ERROR_LOG_L

Address Offset	0x0000 0058
Physical Address	0x4800 1058 0x4A00 1058
Description	Log information about error conditions. The CODE field logs any protection violation or address hole errors detected by the initiator subsystem while decoding a request.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MULTI	SECONDARY	RESERVED				CODE		RESERVED								CONNID								RESERVED						CMD	

Bits	Field Name	Description	Type	Reset
31	MULTI	Multiple errors detected	RW W1toClr	0
30	SECONDARY	Indicates whether protection violation was a primary or secondary error	RW W1toClr	0
29:26	RESERVED	Read returns 0.	R	0x0
25:24	CODE	The error code of an initiator request. 0x00: No errors 0x01: Reserved 0x10: Address hole 0x11: Protection violation	RW W1toClr	0x0
23:14	RESERVED	Read returns 0.	R	0x000
13:8	CONNID	ConnID of request causing the error, refer to Table 1-300	R	0x00
7:3	RESERVED	Read returns 0.	R	0x00
2:0	CMD	Command that caused error	R	0x0

Table 1-330. L4_IA_ERROR_LOG_H

Address Offset	0x0000 005C
Physical Address	0x4800 105C 0x4800 105C
Description	Log information about error conditions.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REQ_INFO															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0.	R	0x0000
15:0	REQ_INFO	MReqInfo bits of request that caused the error REQ_INFO[0] = supervisor, REQ_INFO[1] = Debug	R	0x0000

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-331. L4_IA_ERROR_LOG_ADDR_L

Address Offset	0x0000 0060
Physical Address	0x4800 1060 0x4A00 1060
Description	Extended error log (address information)
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																															

Bits	Field Name	Description	Type	Reset
31:0	ADDR	Address of request that caused the error. N is the number MAddr bits.	R	0x0000 0000

Table 1-332. L4_IA_ERROR_LOG_ADDR_H

Address Offset	0x0000 0064
Physical Address	0x4800 1064 0x4A00 1064
Description	Extended error log (address information)
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															

Bits	Field Name	Description	Type	Reset
31:0	RESERVED	Read returns 0.	R	0x0000 0000

1.12.3.5.3 L4 Target Agent (L4 TA)

1.12.3.5.3.1 L4 Target Agent (L4 TA) Register Summary

Table 1-333 through Table 1-349 summarizes the L4 TA mapping of the CFG_TA, PER_TA, and WKUP_TA registers.

Table 1-354. L4_TA_AGENT_CONTROL_L

Address Offset	0x0000 0020
Physical Address	See Table 1-333 to Table 1-349.
Description	Enable error reporting
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							SERROR_REP	RESERVED													REQ_TIMEOUT			RESERVED							OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	RESERVED	Read returns 0.	UNDEFINED_TYPE_STRING	
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x2
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

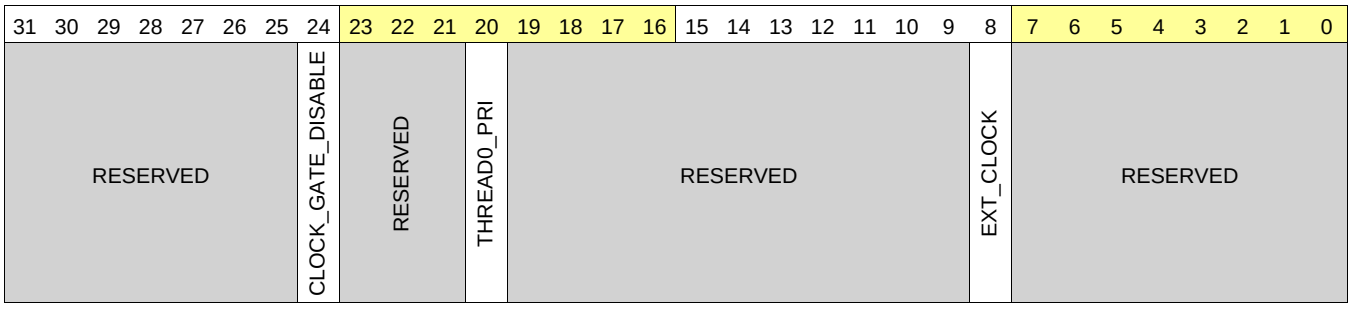
Description	Control interconnect global power control
Type	RW



Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0

Copyright © 2011–2013, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	0
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	RESERVED	Read returns 0.	R	0x00

Table 1-368. L4_LA_FLAG_MASK_i_L

31:16	Reserved	Reserved	R	0x000000000000
15:0	CONNID_BIT_VECTOR	Specifies protection group members N is 2**W, where W is the connID width	RW	0xFFFF

Copyright © 2011–2013, Texas Instruments Incorporated

Table 1-379. L4_AP_PROT_GROUP_MEMBERS_k_H

Address Offset	0x204 + (0x08*k)
Physical address	0x4800 0204 + (0x08*k) 0x4A00 0204 + (0x08*k)
Description	Define ConnID bit vectors for a protection group.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															

Bits	Field Name	Description	Type	Reset
31:0	Reserved	Read returns 0's	R	0x0000 0000

Table 1-380. L4_AP_PROT_GROUP_ROLES_k_L

Address Offset	0x200 + (0x08*k)	**Index**	k = 0 to 7 for L4LS_AP k = 0 to 7 for L4HS_AP
Physical address	0x4800 0280 + (0x08*k) 0x4A00 0280 + (0x08*k)		
Description	Define MReqInfo bit vectors for a protection group.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENABLE																															

Bits	Field Name	Description	Type	Reset
31:0	ENABLE	Enabled bits N is 2**W, where W (W is less than or equal to 6) is the number of MReqInfo bits configured for role checking	R	0xFFFF FFFF

Table 1-381. L4_AP_PROT_GROUP_ROLES_k_H

Address Offset	0x204 + (0x08*k)	**Index**	k = 0 to 7 for L4LS_AP k = 0 to 7 for L4HS_AP
Physical address	0x4800 0284 + (0x08*k) 0x4A00 0284 + (0x08*k)		
Description	Define ConnID bit vectors for a protection group.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENABLE																															

Bits	Field Name	Description	Type	Reset
31:0	ENABLE	Enabled bits N is 2**W, where W (W is less than or equal to 6) is the number of MReqInfo bits configured for role checking	R	0xFFFF FFFF

Table 1-382. L4_AP_REGION_I_L

Address Offset	0x300 + (0x08*I)
Physical address	0x4800 0300 + (0x08*I) 0x4A00 0300 + (0x08*I)
Description	Define the base address of the region in respect to the segment it belongs to.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BASE																							

Bits	Field Name	Description	Type	Reset
31:20	Reserved	Read returns 0.	R	0x00
19:0	BASE	Sets the base address of the region relative to its segment base.	R	See Table 1-384 to Table 1-385

Table 1-383. L4_AP_REGION_I_H

Address Offset	0x304 + (0x08*I)
Physical address	0x4800 0304 + (0x08*I) 0x4A00 0304 + (0x08*I)
Description	Define the size, protection group and segment ID of the region
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MADDRSPACE				RESERVED	SEGMENT_ID			RESERVED	PROT_GROUP_ID			RESERVED	BYTE_DATA_WIDTH_EXP		RESERVED	PHY_TARGET_ID								RESERVED	SIZE						ENABLE

Bits	Field Name	Description	Type	Reset
31:28	MADDRSPACE	Target OCP MAddrSpace value	R	See Table 1-384 and Table 1-385.
27	RESERVED	Read returns 0.	R	0x0
26:24	SEGMENT_ID	The segment associated to the region.	R	See Table 1-384 and Table 1-385.
23	RESERVED	Read returns 0.	R	0
22:20	PROT_GROUP_ID	The protection group associated to the region.	RW	See Table 1-384 and Table 1-385.
19	RESERVED	Read returns 0.	R	0
18:17	BYTE_DATA_WIDTH_EXP	The target data byte width is $2^{(BYTE_DATA_WIDTH_EXP)}$ bytes.	R	See Table 1-384 and Table 1-385.
16:15	Reserved	Read returns 0.	R	0x0
14:8	PHY_TARGET_ID	Physical target ID	R	See Table 1-384 and Table 1-385.
7	RESERVED	Read returns 0.	R	0
6:1	SIZE	Define the size of the region in bytes. 2^{SIZE} equals the region.	R	See Table 1-384 and Table 1-385.
0	ENABLE	0x0: Disable the region, no access allows 0x1: Enable the region, with access as define in registers	R	0x1

2.1 Introduction

The device power-management architecture ensures maximum performance and operation time for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements. This section contains the following information:

- Power-management architecture building blocks for the device.
- State-of-the-art power-management techniques supported by the power-management architecture of the device.

2.1.1 Device Power-Management Architecture Building Blocks

To provide a versatile architecture supporting multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage management.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

2.1.1.1 Clock Management

The PRCM module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management.

Each module within the device has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks.

The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.
- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is identified by an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity.
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

Figure 2-1 provides a representation of the functional and interface clocks.

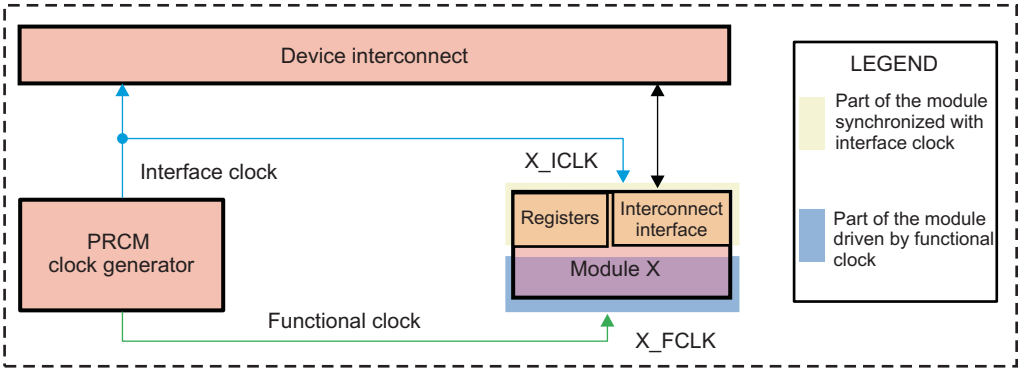
Figure 2-1. Functional and Interface Clocks



2.1.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or may be gated otherwise. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks. The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module or initiators) or cannot initiate transactions and only responds to the transactions initiated by the master (called slave module or targets). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules

2.1.2.1 Master Standby Protocol

This protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for the purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes. Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the module register bit field <Module>_SYSCONFIG. IDLEMODE or <Module>_SYSCONFIG. STANDBYMODE (see Table 2-1). The behavior, identified by standby mode values, must be configured.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-1. Master Module Standby-Mode Settings

Standby Mode Value	Selected Mode	Description
0	Force-standby	The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent the loss of data at the time the clocks are gated.
1h	No-standby	The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it never allows the output clocks of the PRCM module to be gated.
2h	Smart-standby	The module asserts the standby request based on its internal activity status.The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module.
3h	Smart-standby wakeup-capable mode	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in STANDBY state. The mode is relevant only if the appropriate module mwakeup output is implemented.

The standby status of a master module is indicated by the CM_<Power_domain>_<Module>_CLKCTRL[x].STBYST bit in the PRCM module. Table 2-2 describes the master module standby status.

Table 2-2. Master Module Standby Status

STBYST Bit Value	Description
0	The module is functional.
1	The module is in standby mode.

2.1.2.2 Slave Idle Protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an idle request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module. Similarly, an idled slave module may need to be wakened because of a service request from a master module or as a result of an event (called a wake-up event; for example, interrupt or DMA request) received by the slave module. In this situation the PRCM module enables the clocks to the module and then deasserts the idle request to signal the module to wake up. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the module register bit field <Module>_SYSCONFIG. SIDLEMODE or <Module>_SYSCONFIG. IDLEMODE (see Table 2-3). The behavior, listed in the Idle Mode Value column, must be configured by software.

Table 2-3. Module Idle Mode Settings

Idle Mode Value	Selected Mode	Description
0h	Force-idle	The module unconditionally acknowledges the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent the loss of data at the time the clock is switched off.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-3. Module Idle Mode Settings (continued)

Idle Mode Value	Selected Mode	Description
1h	No-idle	The module never acknowledges any idle request from the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state.
2h	Smart-idle	The module acknowledges the idle request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or direct memory access (DMA) requests are processed. This is the best approach to efficient system power management.
3h	Smart-idle wakeup-capable mode	The module acknowledges the idle request basing its decision on its internal wakeup-capable mode activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module's wakeup output(s) is implemented.

The idle status of a slave module is indicated by the CM_<Powerdomain>_<Module>_CLKCTRL[x] IDLEST bit field in the PRCM module. Table 2-4 lists the possible idle status for a slave module.

Table 2-4. Slave Module Idle Status

IDLEST Bit	Idle Status	Description
0h	Functional	The module is fully functional. The interface and functional clocks are active.
1h	In transition	The module is performing a wake-up or a sleep transition.
2h	Interface idle	The module interface clock is idled. The module may remain functional if using a separate functional clock.
3h	Full idle	The module is fully idle. The interface and functional clocks are gated.

For the idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM_<Powerdomain>_<Module>_CLKCTRL[x] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the idle request to the module unconditionally (that is, immediately when the software requests). Table 2-5 describes the configurable behavior of MODULEMODE.

Table 2-5. Slave Module Mode Settings in PRCM

MODULE MODE Bit Value	Selected Mode	Description
0h	Disabled	The PRCM module unconditionally asserts the module idle request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled).
1h	Reserved	Reserved
2h	Enabled	This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module idle request based on the clock-domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module.
3h	Reserved	Reserved

Copyright © 2011–2013, Texas Instruments Incorporated

In addition to the IDLE and STANDBY protocol, PRCM offers also the possibility to manage optional clocks, through a direct software control: “OPTFCLKEN” bit from programming register.

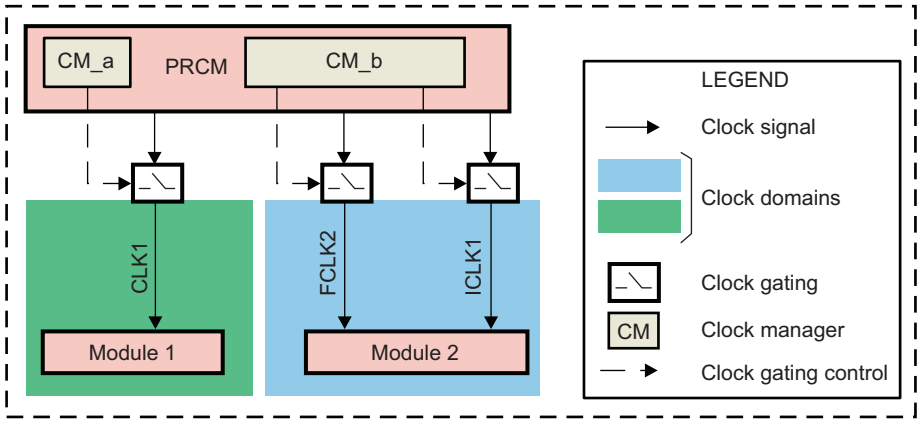
Table 2-6. Module Clock Enabling Condition

Clock Enabling Condition	Condition: AND	Condition: OR
Clock associated with STANDBY protocol	Clock domain is ready	MStandby is de-asserted Mwakeup is asserted
Clock associated with IDLE protocol, as interface clock	Clock domain is ready	Idle status = FUNCT Idle status = TRANS SWakeup is asserted
Clock associated with IDLE protocol, as functional clock	Clock domain is ready	Idle status = FUNCT Idle status = TRANS Idle status = IDLE SWakeup is asserted
Optional clock	Clock domain is ready	OPTFCLKEN = Enabled (0x1)

2.1.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module (see Figure 2-2). By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE (GATED) states). Thus, a clock domain allows control of the dynamic power consumption of the device. The device is partitioned into multiple clock domains, and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to individually activate and gate each clock domain of the device.

Figure 2-2. Generic Clock Domain



Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-2 is an example of two clock managers: CM_a and CM_b. Each clock manager manages a clock domain. The clock domain of CM_b is composed of two clocks: a functional clock (FCLK2) and an interface clock (ICLK1), while the clock domain of CM_a consists of a clock (CLK1) that is used by the module as a functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use. The PRCM module lets software check the status of the clock domain functional clocks. The CM_<Clock_domain>_CLKSTCTRL[x] CLKACTIVITY_<FCLK/Clock name_FCLK> bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table 2-7 shows the possible states of the functional clock.

Table 2-7. Clock Domain Functional Clock States

CLKACTIVITY Bit	Status	Description
0	Gated	The functional clock of the clock domain is inactive
1	Active	The functional clock of the clock domain is running

2.1.3.1 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings. A clock domain can switch between three possible states: ACTIVE, IDLE_TRANSITION, and INACTIVE. Figure 2-3 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

Figure 2-3. Clock Domain State Transitions

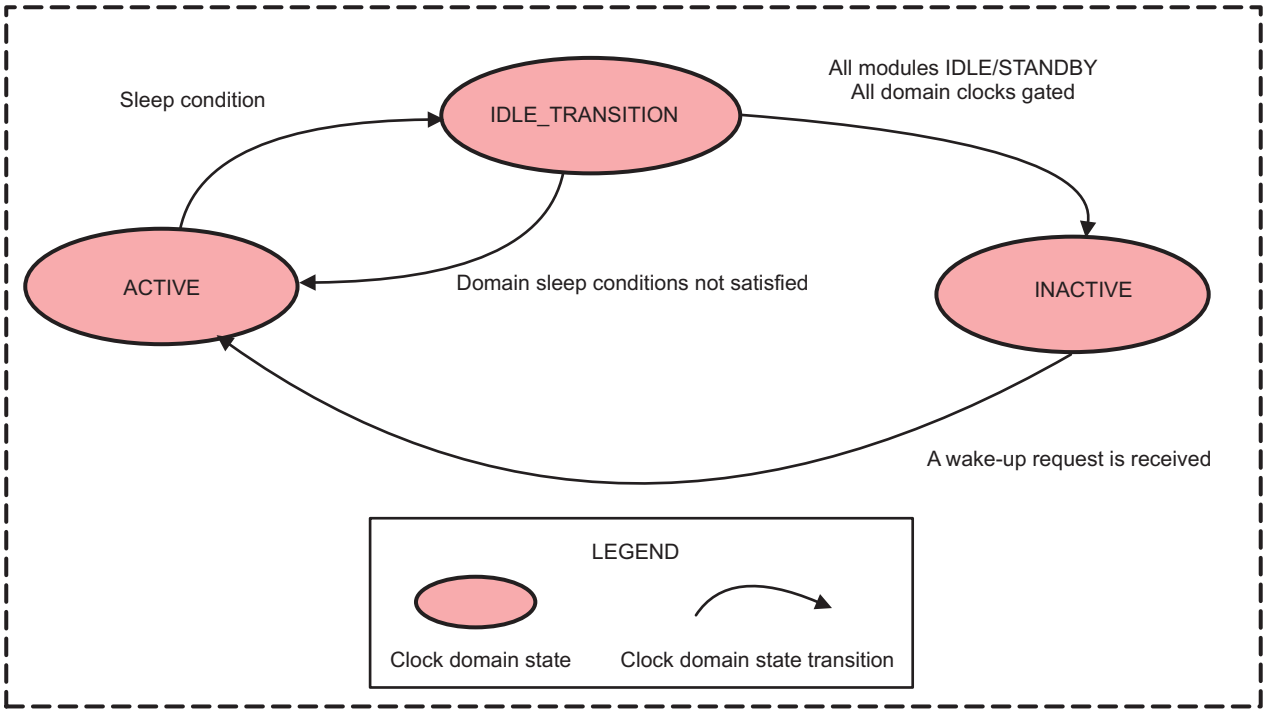


Table 2-8. Clock Domain States

State	Description
ACTIVE	Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state. · All interface clocks to the nondisabled slave modules in the clock domain are provided. All functional and interface clocks to the active master modules (that is, not in STANDBY) in the clock domain are provided.· All enabled optional clocks to the modules in the clock domain are provided.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-8. Clock Domain States (continued)

State	Description
IDLE_TRANSITION	This is a transitory state.· Every master module in the clock domain is in STANDBY state · Every idle request to all the slave modules in the clock domain is asserted.· The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active.· All enabled optional clocks to the modules in the clock domain are provided.
INACTIVE	All clocks within the clock domain are gated.· Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled or auto) is in IDLE state and set to disabled or auto mode.· Every optional functional clock in the clock domain is gated.

Each clock domain transition behavior is managed by an associated register bit field in the CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL PRCM module. Table 2-9 describes the clock transition mode settings in the clock domain.

Table 2-9. Clock Transition Mode Settings

CLKTRCTRL Bit	Selected Mode	Description
0	Reserved	Reserved
1h	SW_SLEEP	A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied
2h	SW_WKUP	A software-forced clock domain wake-up transition is initiated
3h	Reserved	Reserved

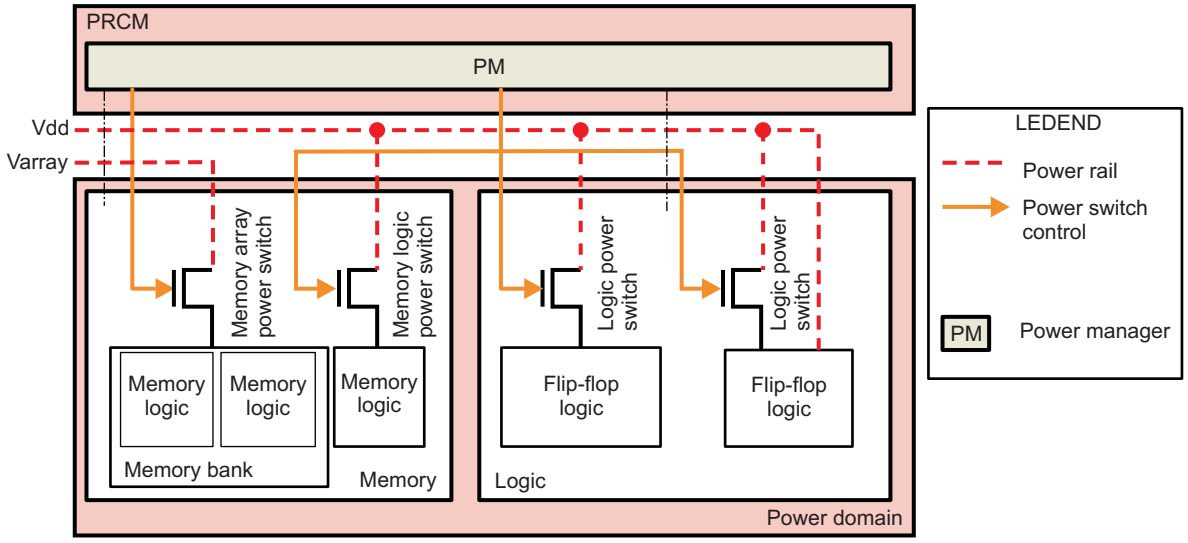
2.1.4 Power Management

The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allows the PRCM module to turn on and off specific sections of the device without affecting the others.

2.1.4.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see Figure 2-4). A power domain can be turned on and off without affecting the other parts of the device.

Figure 2-4. Power Domain Block Diagram



Copyright © 2011–2013, Texas Instruments Incorporated

To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into a logic area (Table 2-11) and a memory area (Table 2-10).

Table 2-10. States of a Memory Area in a Power Domain

State	Description
On	The memory array is powered and fully functional.
Off	The memory array is powered down.

Table 2-11. States of a Logic Area in a Power Domain

State	Description
On	Logic is fully powered
Off	Logic power switches are off. All the logic (DFF) is lost.

2.1.4.2 Power Domain Management

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state.

Table 2-12. Power Domain Control and Status Registers

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE	Control	Selects the target power state of the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[1:0] POWERSTATEST	Status	Identifies the current state of the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[2] LOGICSTATEST	Status	Identifies the current state of the logic area in the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[5:4] MEMSTATEST	Status	Identifies the current state of the memory area in the power domain. It is OFF or ON.

2.1.4.3 Power-Management Techniques

The following section describes the state-of-the-art power-management techniques supported by the device.

2.1.4.3.1 Dynamic Voltage and Frequency Scaling

Dynamic voltage and frequency scaling (DVFS) consists of opportunistically reducing the operating frequency of a logic block so that the operating voltage may be reduced accordingly. Dynamic power is related to the supply voltage so it is generally advantageous to reduce frequency and voltage instead of completing task faster and then going idle. The DVFS technique uses dynamic selection of the optimal operating frequency and voltage to allow a task to be performed in the required length of time. This reduces the active power consumption (power consumed while executing a task) of the device while still meeting task requirements.

NOTE: The values in Figure 2-5 are hypothetical. They are ment to clarify the concept only and do not represent valid test results on the device.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-5. Comparison of Energy Consumed With/Without DVFS

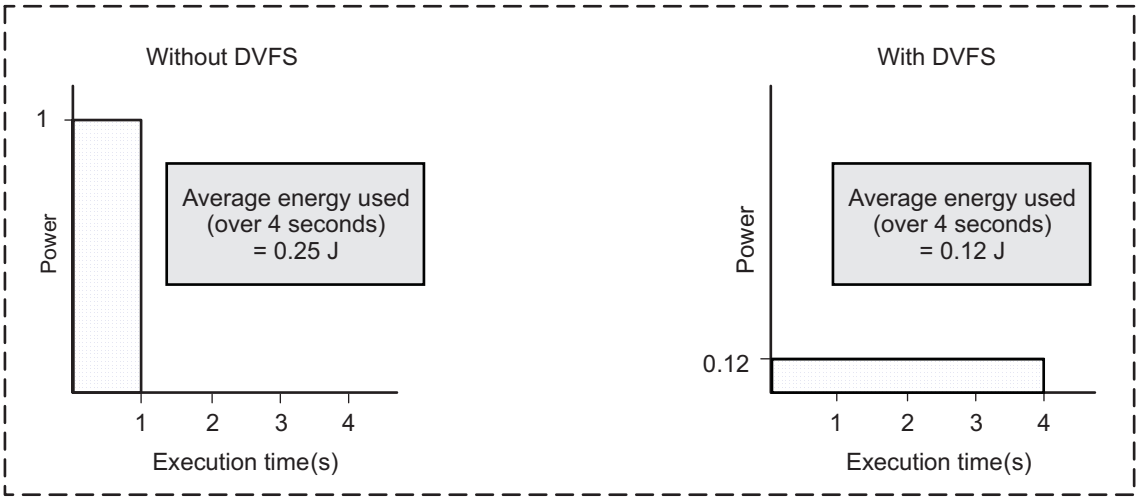


Figure 2-5 shows the DVFS technique by comparing a process executed at maximum frequency and operating voltage without applying DVFS to the same process executed at optimal frequency and voltage using DVFS, based on the task requirements. If a task that must terminate in 4 seconds is performed at maximum operating frequency (left side of the figure), it terminates in 1 second, and the remaining 3 seconds are spent in idle mode. With DVFS (right side of the figure), the operating frequency is reduced to an optimal level; the task takes the full 4 seconds to complete, but power consumption is reduced. In addition, the voltage can be reduced further to save power so the dynamic and leakage power consumption are reduced.

DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching the individual elements of the device to their OPPs, the power consumption of the device for a given task can be minimized.

For practical reasons related to device making (flow, tools), DVFS can be used only for a few discrete steps, not over a continuum of voltage and frequency values. Each step, or OPP, is composed of a voltage (V) and frequency (F) pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally; the voltage corresponds to the minimum voltage allowed for a frequency.

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. The user determines the optimal OPP for a given task and then switches to that OPP to save power.

2.2 Power Reset Clock Management Structure

2.2.1 Introduction

The PRCM is structured using the architectural concepts presented in the 5000x Power Management Framework. This framework provides:

- A set of modular, reusable FSM blocks to be assembled into the full clock and power management mechanism.
- A register set and associated programming model.
- Functional sub-block definitions for clock management, power management, system clock source generation, and master clock generation.

The device supports an enhanced power management scheme based on:

- Six functional power domains:

Generic power domains:

- Active (DSP)
- AlwaysOn
- ISP (ISS)
- HDVICP
- SGX
- DSS

The PRCM provides the following functional features:

- Software configurable for direct, automatic, or a combination thereof, functional power domain state transition control
- Device power-up sequence control
- Device sleep / wake-up sequence control
- Centralized reset generation and management
- Centralized clock generation and management

The PRCM modules implement these general functional interfaces, further described in Table 2-13:

- OCP configuration ports
- Direct interface to device boundary
- Power switch control signals
- Device control signals
- Clocks control signals
- Resets signals
- A set of power management protocol signals for each module to control and monitor standby, idle and wake-up modes (CM and PRM)
- Emulation signals

Table 2-13. PRCM Functional Interfaces

Interface	Description
OCP configuration ports	The OCP port for the PRCM module is used to control power, reset and wake-up Management.
OCP slave	PRCM implements a 32-bit OCP target interface.
Power switch control signals	The device has power domain switches over the device. This interface provides PRCM control over power domain switches and receives responses from the power domains which indicate the switch status. It also controls the isolation signals. The control for power domain switches is latched in the PRCM Status Registers.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-13. PRCM Functional Interfaces (continued)

Interface	Description
Device control signals	This interface provides PRM management of several device-level features which are not specific to any single power domain. This PRCM interface controls signals to/from the device for global control: • Device type coding • I/Os isolation control
Clocks control signals	This interface gathers all clock inputs and outputs managed by PRCM modules.
Resets signals	This interface gathers all resets inputs and outputs managed by PRCM module.
Modules Power Management Control	Modules or subsystems in the device are split over two categories: • **Initiator:** an initiator is a module able to generate traffic on the device interconnects (typically: processors, MMU, eDMA...). The PRCM module handles all initiator modules' power management interfaces: MStandby signal MWait signal. • **Target:** a target is a module that cannot generate traffic on the device interconnects, but that can generate interrupts or DMA request to the system (typically, peripherals). PRCM handles a power management handshake protocol with each module or subsystem. This protocol allows performing proper clock and power transition, taking into account each module activity or state. PRCM module handles all target modules' power management interfaces: SIdleReq signal, SIdleAck signal, FCLKEN signal. It also handles all target modules' wake-up: SWakeup signal (1).

(1) Only USB and PCIe support SWakeUp.

Copyright © 2011–2013, Texas Instruments Incorporated

2.3 Clock Generation and Management

PRCM provides a centralized control for the generation, distribution and gating of most clocks in the device. PRCM gathers externally generated clocks and device internally generated clocks (DPLL clocks) for distribution to the other modules in the device. The PRCM module manages system clock generation.

2.3.1 Types of Clocks

The PRCM produces two types of clocks: interface and functional.

Interface clocks: these clocks primarily provide clocking for the system interconnect modules and the portions of device's functional modules which interface to the system interconnect modules. In most cases, the interface clock supplies the functional module's system interconnect interface and registers. For some modules, the interface clock is also used as functional clock. In this specification, interface clocks are represented by blue lines.

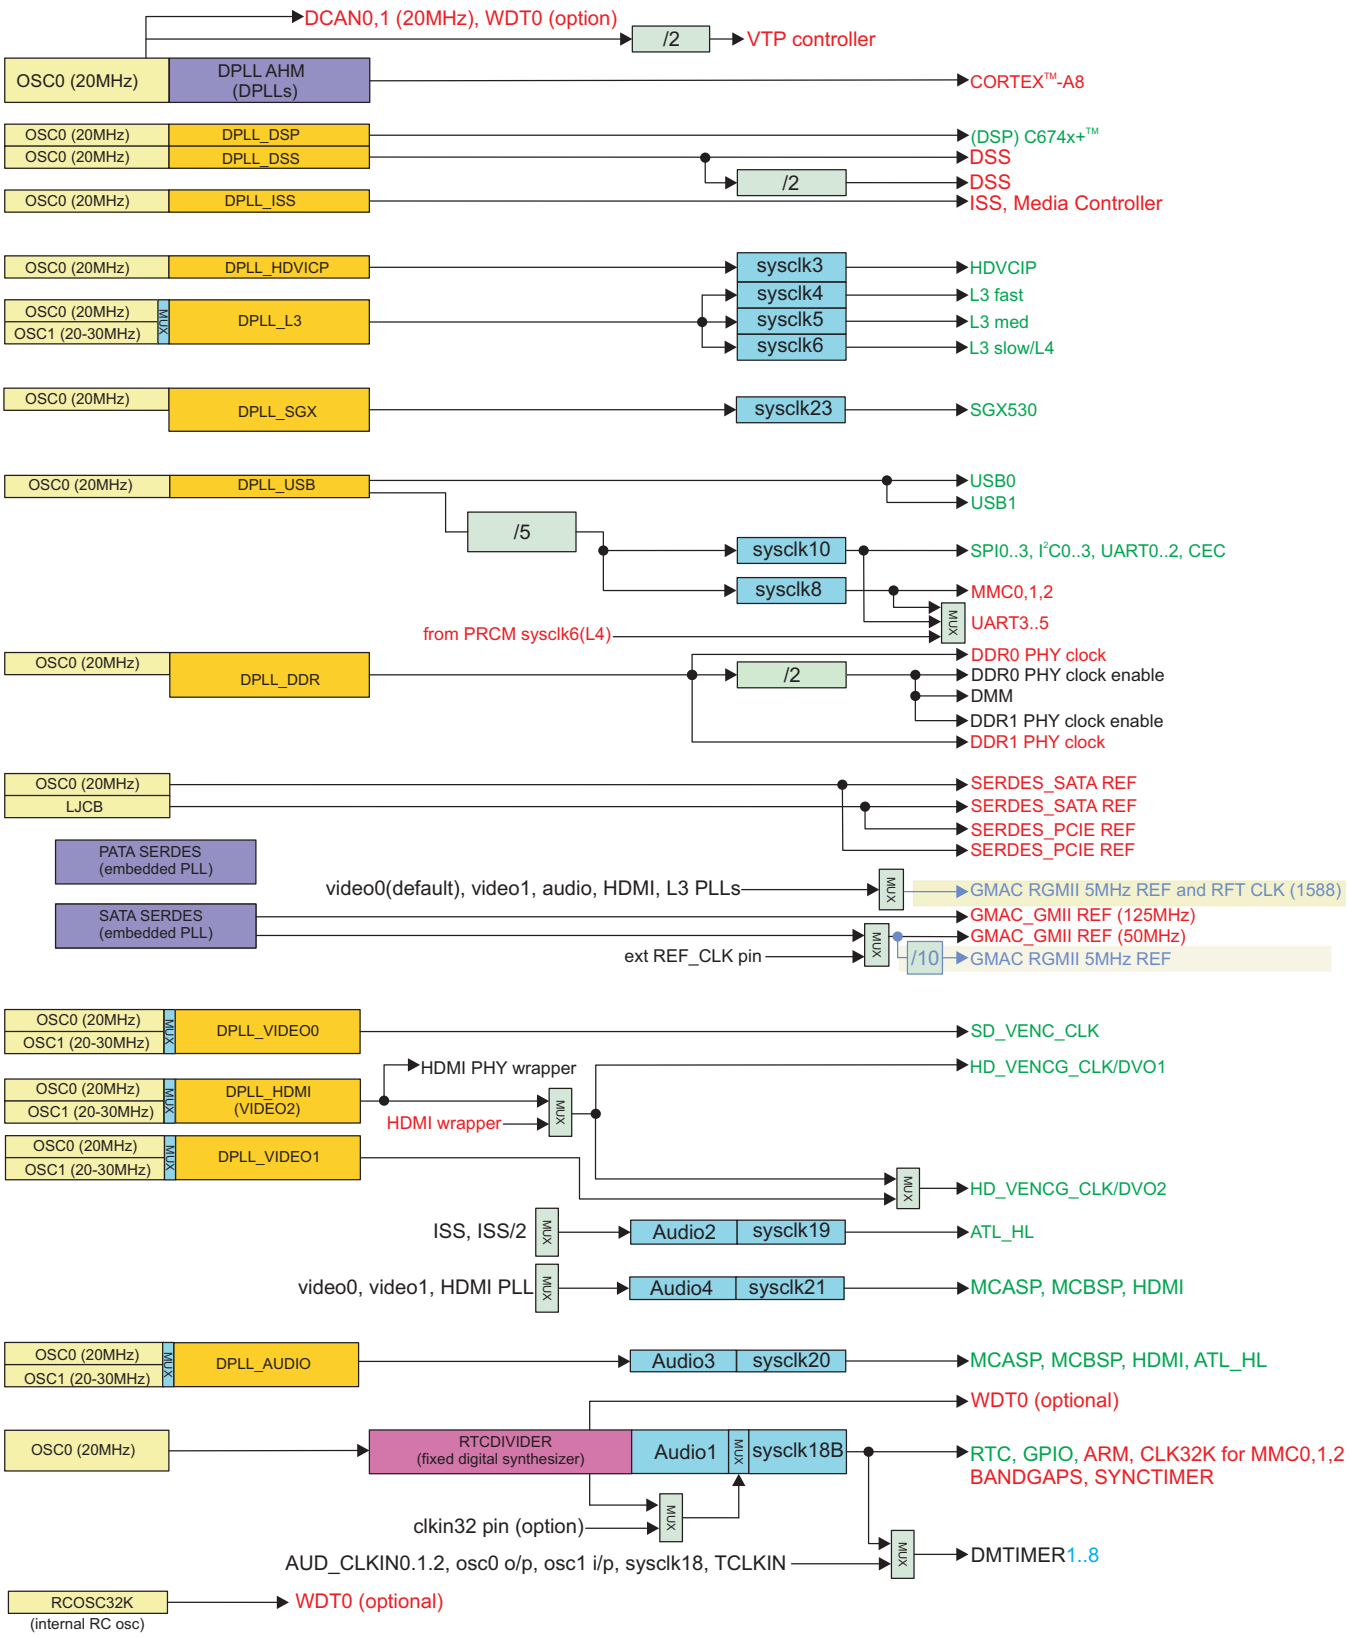
Functional clock: this clock supplies the functional part of a module or a sub-system. In some cases, a module or a subsystem may require several functional clocks: 1 or several main functional clock(s), 1 or several optional clock(s). A module needs its main clock(s) to be operational. Optional clocks are used for specific features and can be shutdown without stopping the module.

2.3.2 Clock Structure

The device has 12 on-chip PLLs at top level, and three additional inside hard macros (two of them in SERDES, one of them in Cortex™-A8 Subsystem). All of the twelve top level DPLLs are DPLLLJ instances which includes bypass feature inside. The Cortex™-A8 Subsystem is a DPLLS instance. Figure 2-6 shows the detailed clock structure of the device.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-6. Clock Structure



Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-14. PLL Names and Types

PLL Name	PLL Type
DPLL_MPU(For Cortex™-A8)	DPLLS
DPLL_DSP	DPLLLJ
DPLL_ISS (DPLL_ISP)	DPLLLJ
DPLL_HDVICP	DPLLLJ
DPLL_L3	DPLLLJ
DPLL_DDR	DPLLLJ
DPLL_USB	DPLLLJ
DPLL_SGX530	DPLLLJ
DPLL_AUDIO	DPLLLJ
DPLL_HDMI	DPLLLJ
DPLL_VIDEO0	DPLLLJ
DPLL_VIDEO1	DPLLLJ
DPLL_DSS	DPLLLJ
DPLL_SATA_SERDES	DPLLLJ
DPLL_PATA_SERDES	DPLLLJ

The device has two reference clocks which are generated by on-chip oscillators or externally. The main oscillator on the device is 20 MHz (DEVOSC). Optionally, if DEVOSC is 20 MHz and a precise audio or video frequency is desired, a second oscillator (AUXOSC) may be utilized for video and/or audio PLLs (e.g., 27, 22.5792 MHz or other frequency between 20-30 MHz). For instance, if a precise audio reference clock is needed, AUXOSC would provide this (e.g., 22.5792 for 44.1k audio) and then the video clock must be derived from Video PLL based on a multiply/divide of 20 MHz (pre-divide in PLL allows precise 27 MHz multiples from 20 MHz reference).

It is also possible to have one off-chip VCXO to supply the AUXOSC reference clock and in this case, the on-chip oscillator is bypassed.

In addition to the DEVOSC (20 MHz) and AUXOSC (20-30 MHz) reference clocks, there are an optional external 100 MHz differential clock input for the PCIe SERDES. The SATA SERDES also provides references for EMAC switch IP (125 MHz for GMII, 50 MHz RMII, 5 MHz RGMII).

A separate 250 MHz reference is used for EMAC RGMII mode, this comes from a mux which also feeds the 1588 reference clock. This clock has multiple options (see SERDES and Ethernet clocking diagram), but defaults to VIDEO0 PLL. Therefore to use reset isolation, the user must use VIDEO0 PLL at 250 MHz, which is also a suitable for 1588 reference clock rate.

There is third clock input for the RTC and GPIO0,1,2,3 and MMC0,1,2 debounce. This is an optional 32768 Hz clock input (no on-chip oscillator). Alternatively a fixed divider of the on-chip 20 MHz oscillator (DEVOSC) may be used to generate the 32768 Hz clock (provided by RTCDIVIDER). The 32k clock (regardless of source: pin or RTCDIVIDER source) is also used as optional reference for the eight timers, a reference clock for memory LDOs and bandgaps, and SYNCTIMER. The direct RTCDIVIDER output is also used as optional clock for WDT0 (Cortex™-A8 watchdog and as an optional clock source for ARM functional clock for very low power mode). By the Control Module MMR bits is provided a glitchless clock gating (enable/disable). This allows the clocks to be turn off when the modules are inactive state with a goal to minimize power consumption. During reset however, free running clock should be allowed such that reset can fully propagate.

NOTE: The ADPLLS in Cortex™-A8 Subsystem and the two ADPLLJ in SERDES could be controlled by Control Module MMR bits through a wrapper which utilizes the direct mode control ports on the DPLLs.

There are four individual clock mux instances that select between the DEVOSC and AUXOSC in the Main/Video/Audio PLL structures. In addition, the Cortex™-A8 subsystem clock has a mux to select between DEVOSC clock and RTCDIVIDER clock. The mux is controlled by the register MPU_CLKSRC.MPU_SOURCE.

Copyright © 2011–2013, Texas Instruments Incorporated

CAUTION

"Glitch-free" muxes have an output which is free from any glitches. It requires the previously selected clock and the newly selected clock to both be free-running for switch-over to occur. Switchover could take 1-2 clock cycles of previously selected and newly selected clock to complete. If newly selected clock is idle, a switchover never occurs (previously selected clock continues to pass through the mux). Do not switch to a non-existent clock.

2.3.3 Main PLL Clock Structure

The PLL clock structure includes the DSP, SGX530, HDVICP, L3, ISS, and DSS PLLs. Figure 2-7 shows the clock structure.

Figure 2-7. Main PLL Clock Structure

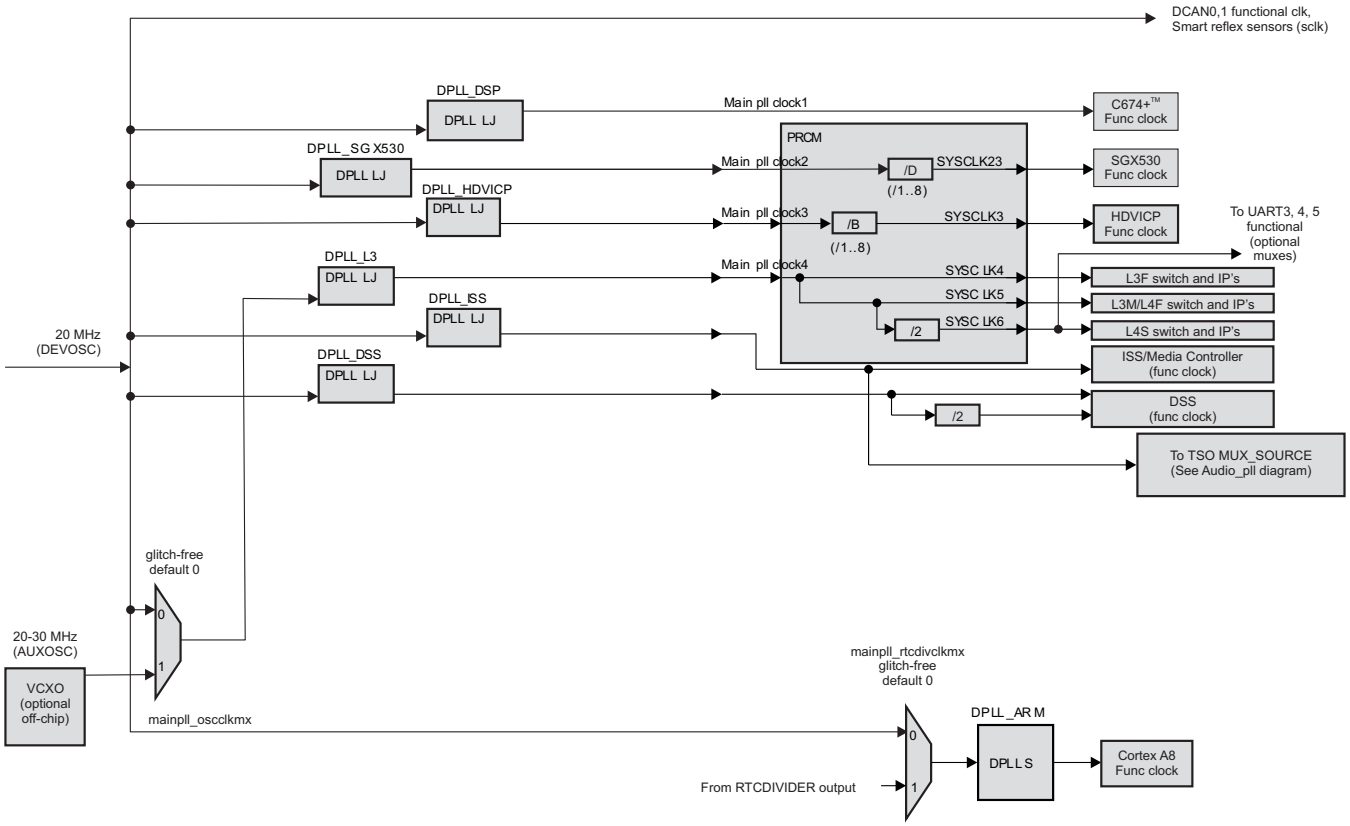


Table 2-15. Main PLL Clock Source

SYSCLK	Source	Destination
-	DPLL_DSP	To C674x+™SubSystem
SYSCLK23	DPLL_SGX530	SGX530 functional clock (CORECLK)
SYSCLK3	DPLL_HDVICP	To HDVICP

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-15. Main PLL Clock Source (continued)

SYSCLK	Source	Destination
SYSCLK4	DPLL_L3	L3_FAST, OCP clock for Cortex™-A8, HDVICP, expansion slot(master), MMU,C674x+ Subsystem, ISS, TPTCs, C674x+Subsystem, HDVICP SL2, TPCC
		L3_MID, L4_FAST, OCP clock for SGX530 (SYSCLK and MEMCLK), ISS Media Controller, 3PGSW, SATA, PCI ex, VCP2, MLB, FDIF, DAP, OCMC RAM, MMCHS2.
SYSCLK6		L3_SLOW, L4_SLOW, OCP clock for UART0..2,3..5, I2C, SPI, SDIO, TIMER, GPIO, PRCM, McASP, McBSP, GPMC, HDMI, MLB, WDT0, PATA, Mailbox, Spinlock, , USB SS.
		Func clock for UART3,4,5 (optional), Efuse control, MMU config, P1500, ELM, MMCHS0..1, ATL, FDIF config.
	DPLL_ISS (DPLL_ISP)	ISS/Media Controller
	DPLL_DSS	DSS (proc, l3) also div2 of this clock (top level divider) goes to DSS proc_d2 and l4 clocks.

As shown in Table 2-15, each of the DPLLLJs can be configured as appropriate for the desired functional clock of each major core (C674x+ subsystem, HDVICP, ISS, SGX530, DSS, L3/4, A8). They are entirely independent from one another other than the shared reference clock (DEVOSC) except for the DPLL_L3, can optionally choose to use AUXOSC. This is useful as some IPs may use their L4 clock to derive other key frequencies so a slight change to L3/L4 speed could help achieve this while still being in reasonable range for L3/L4 functionality.

The DCAN0..1 functional clocks come from the 20 MHz oscillator to allow fixed rate for baud rate generation and minimal jitter (DEVOSC clock versus PLL clock). Also, the Smart Reflex sensor clock comes from fixed DEVOSC oscillator (20MHz) and the VTP controller clock comes from DEVOSC/2 (fixed /2 divider at top level) such that the frequency of these is the same across all operating points (OPPs).

Table 2-16 lists the divide ratios supported for each of the divider in Main PLL.

Table 2-16. : Main PLL Supported Configurable Dividers

PLL Source	Destination	Control Bit Filed	Divider	Supported Divide Ratios	Default Value
DPLL_HDVICP	HDVICP Clocks	CM_SYSCLK3_CLKSEL.[CLKSEL]	B	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
DPLL_SGX530	SGX530 Clocks	CM_SYSCLK23_CLKSEL.[CLKSEL]	D	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/3

Table 2-17. Clock Multiplexing Used With Main PLLs

Mux	Mux Source 0	Mux Source 1	Control Bit Field

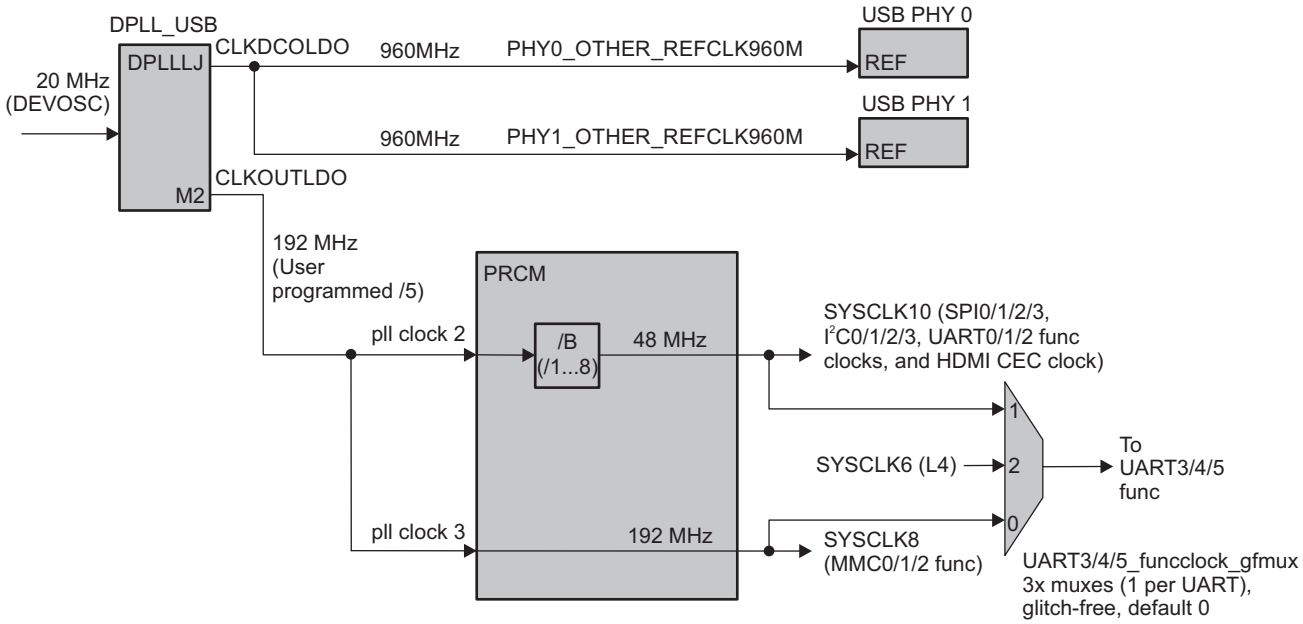
2.3.4 USB PLL Clock Structure

Figure 2-8 shows the clock structure of the USB PHY. The PRCM gets the inputs from the divide by 5 output of the DPLL for clocking the UART, McBSP. These are driven by the DPLL_USB (DPLLLJ), SYSCLK10 which is 48 MHz and goes to SPI0,1,2,3, I2C0,1,2,3, UART0,1,2, UART3,4,5 (optional via glitchless muxes), and the CEC clock of HDMI wrapper. SYSCLK8 is used to generate 192 MHz to UART3,4,5 (optional via glitchless muxes) and MMC0,1,2. Optionally, the PRCM SYSCLK6 (L4 clock) clock output could optionally source each of UART3,4 or 5 functional clocks (this provides additional baud rate options for UART3,4,5, without affecting MMC0,1,2). This mux is controlled by McBSP_UART_CLKSRC register in the PRCM.

Figure 2-8. USB PLL Clock Structure



NOTE: The /5 divider (M2 post divider) is embedded inside the DPLL_USB module (see Figure 2-19 for details). The /5 divider can be configured in the USBPLL_M2NDIV[22:16] M2 bit field. It is stated as a /5 divider, as the reset (default) value of the M2 bit field is 0x5.

Table 2-18 shows supported divide ratios for dividers in PRCM.

Table 2-18. USB PLL Supported Dividers

PLL Source	Destination	Control Bit Filed	Divider	Supported Divide Ratios	Default Value
PLL_USB	SPI0..3,I2C0..3, UART0..2, HDMI CEC	CM_SYSCLK10_CLKSEL.[CLKSEL]	B	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1

Table 2-19. Clock Multiplexing used with USB PLL

Mux	Mux Source 0	Mux Source 1	Mux Source 2	Control Bit Field
UART3 clock source	SYSCLK8	SYSCLK10	SYSCLK6	MCBSP_UART_CLKSRC.UART3_CLK_SOURCE
UART4 clock source	SYSCLK8	SYSCLK10	SYSCLK6	MCBSP_UART_CLKSRC.UART4_CLK_SOURCE
UART5 clock source	SYSCLK8	SYSCLK10	SYSCLK6	MCBSP_UART_CLKSRC.UART5_CLK_SOURCE

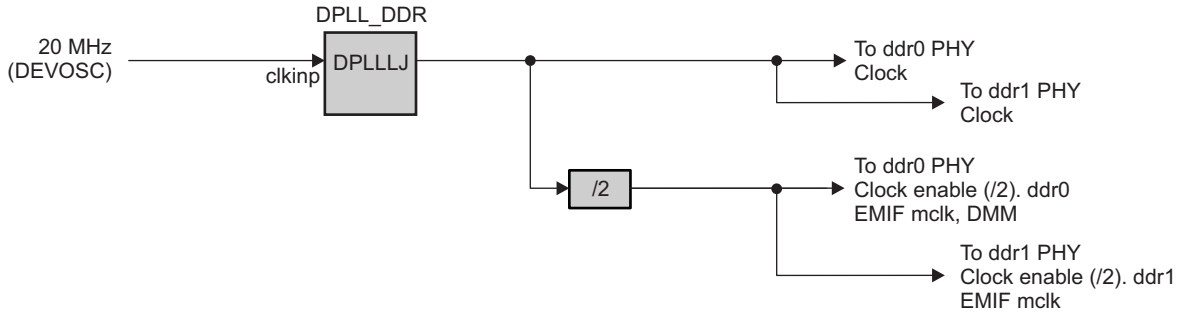
2.3.5 DDR PLL Clock Structure

Figure 2-9 shows the DDR PLL. The two DDR PHY interfaces (DDR0 or DDR1) share a single PLL. DMM is synchronous to the DDR EMIF controller.

Figure 2-9. : DDR PLL Clock Structure



NOTE: Each EMIF must be configured to the same rate due to the shared PLL (If different memory configurations are used even with same rates, there could be some performance impact through DMM for asymmetrical configurations when interleaving).

PRCM does not provide a clock signal to DDR_PHY.

2.3.6 SERDES and Ethernet Clock Structure

Figure 2-10 shows the SERDES and Ethernet clocking. The SATA SERDES reference input is driven from the 20 MHz on-chip oscillator. The SATA SERDES also provides reference clocks to the Ethernet GMII (125 MHz) and RMII (50 MHz) and RGMII 5 MHz clock. Ethernet clocking provides several options to receive or output the RMII reference clock from a pin. This mux is controlled by the bit RMII_REFCLK_SRC. REFCLK_SOURCE in the PRCM. Also, several clock sources are required for the 1588 reference clock (cpts_rft_clk), also shown in Figure 2-10.

This 1588 reference clock also feeds the RGMII 250 MHz reference clock in case of RGMII. To use reset isolation, the VIDEO0 PLL option must be used for this clock since the clock mux control is not reset-isolated and VIDEO0 is the default clock. Note that 250 MHz is also a suitable frequency for 1588 reference. Also note that the use of this clock also means that VIDEO0 cannot be set to 54 MHz to support AVDAC use, which is a use case limitation. To use AVDAC, lose the reset isolation feature and select another clock.

The PCIe SERDES always requires its reference clock to be sourced from an external 100 MHz reference from the LJCB input pads.

The SATA SERDES could optionally use the external 100 MHz reference as well (same LJCB inputs as used for PCIe). This may be practical if spread spectrum clocking (SSC) is desired to reduce EMI on the SATA interface and especially if such clock is already present due to PCIe usage. If the clock is not present, then using the DEVOSC 20 MHz as reference for SATA SERDES is another solution.

NOTE: The PLL inside of SATA SERDES is isolated from the rest of the SERDES naturally by design. The PLL may remain active while the rest of the SERDES is put in low power mode (feature of SERDES). The control to the PLL within SERDES is located at top level in the control module to allow the ability to keep PLL in its active/configured state for reset-isolation of Ethernet.

RMII Ref Clk Mux	50 MHz SATA SerDes	REFCLK_PIN				RMII_REFCLK_ SRC.REFCLK_ SOURCE

2.3.7 Video PLL Clock Structure

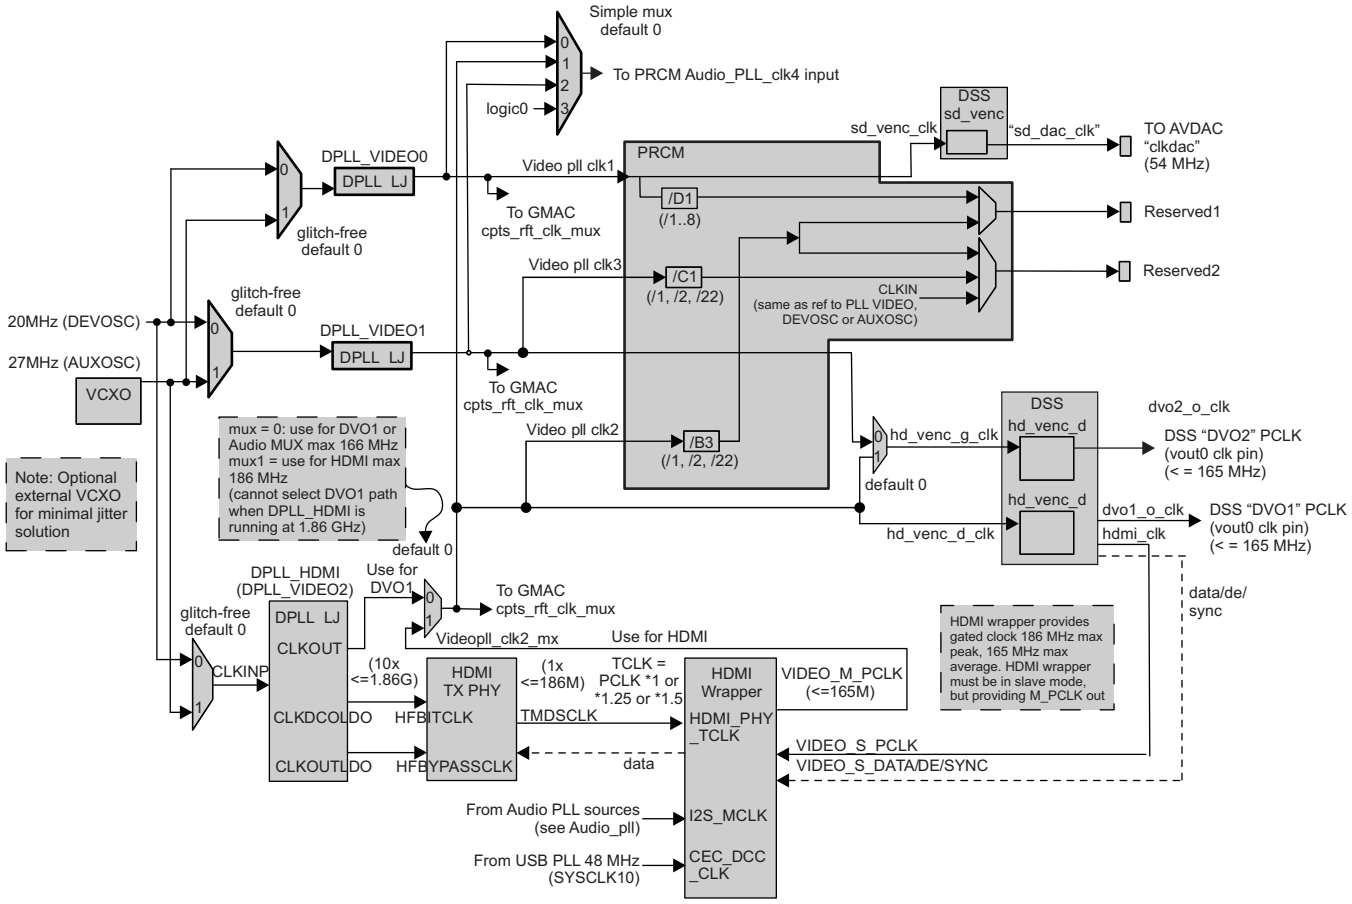
As shown in Figure 2-11, there are three DPLLLJs for video. Each of the video DPLLs (DPLL_VIDEO0, DPLL_VIDEO1, DPLL_HDMI), can be optionally supply from DEVOSC (20 MHz) or AUXOSC (20-30 MHz osc). Deriving 54/27 MHz clocks from 20 MHz DPLL reference is useful in case it is desired to use AUXOSC instead for an precise audio frequency crystal (e.g., 22.5792). Because the device uses DPLLLJ, this is easy to achieve, as the user may pre-divide (e.g,. to 1 or 2 MHz) and then multiply up to 27 or 54MHz.

PLL_VIDEO0 supplies the SD VENC clock to display subsystem directly. This clock is always 54 MHz. DPLL_HDMI provides clock to HD_VENC_D_CLK either directly or via HDMI wrapper logic. This clock is used by the display subsystem to derive DVO1 clock (vout1). HD_VENC_D_CLK needs to support 13.5 MHz, 27 MHz, 54 MHz, 74.25 MHz, 148.5 MHz, 162 MHz and 165 MHz frequencies. It supports 1000/1001 times all of these frequencies (e.g., via fractional multiply adjustment). DPLL_VIDEO1 supplies clock to HD_VENC_G_CLK of display subsystem which is used to derive the DVO2 clock (vout0). This clock has similar frequency requirements as HD_VENC_D_CLK.

Optionally the HD_VENC_G_CLK could also be supplied from DPLL_HDMI. HD_VENC_G (DVO2) has similar frequency requirements, and supports independent frequency from HDMI/DVO1. This addresses the requirements for two digital displays on DVO2 and DVO1 with different resolutions and or timings.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-11. Video Clock Structure



The device has options for DCXO/VCXO type feature to adjust video frequency on the fly: Use an off-chip VCXO on AUXOSC (can feed clock to AUXOSC_XI pad and run AUXOSC in bypass). This provides the most smooth, low jitter solution.

In each case, software controls the frequency adjustment (via manipulation of off-chip VCXO or other means). There is a 27 or 54 MHz clock generated from each of these PLLs (via PRCM) which is routed back to the STC to generate the error with respect to the clock embedded in the in-coming transport stream.

The HDMI PHY requires a high speed clock (up to 1.85 GHz) from a dedicated DPLLLJ. From this clock a TMDS clock is derived which is 1/10 the high speed clock and which is driven to the HDMI wrapper. The clock to DSS used to generate PCLK is equal to TMDS clock /1, /1.25 or /1.5 depending on deep color mode. The HDMI wrapper provides a shaped clock for this purpose. This clock is muxed into the DSS clock inputs.

NOTE: If any of the three video DPLLs are not needed for video, any of these can be optionally used to generate a second audio master frequency, as the sources are muxed and routed to the Audio pll clk4 input of the PRCM and to ATL and McASP 3,4,5 references (see Figure 2-12).

2.3.8 Audio PLL Clock Structure

Audio clocking is based on a single dedicated Audio PLL which is a DPLLLJ. It provides several options for other sources of audio clocks including directly using AUXOSC input pad (drive clock onto AUXOSC XI pad and use AUXOSC in bypass), external pins (AUD_CLKIN0,1,2) and optionally using any of the video PLLs (PLL_VIDEO0, PLLVIDEO1, PLL_HDMI, and more, if any of these resources are not used for video).

Refer back to Figure 2-12 to see the connection of audio clocks to McASP0,1,2, McBSP and HDMI modules. In addition to the mux options provided inside PRCM, top-level muxes provide for McASP3,4,5 and ATL to share any of the audio clock sources as well as to add path from any of the sources to McASP0,1,2, McBSP or HDMI. Notice also that the McASP peripherals also have a setup of clock muxes to feed various clocks to their AHCLKX and AHCLKR inputs. Since there are six McASPs, rather than pin mux all 12 possible AHCLKX and AHXLKR pins, there are three loosely dedicated pins referred to as AUD_CLKIN0,1,2 which are used as optional sources for all of the McASP AHCLK ports as well as for

Copyright © 2011–2013, Texas Instruments Incorporated

various other timing functions (e.g., dmtimer, STC, etc). Any function which optionally uses an AUD_CLKIN0,1,2 pin as an input timing reference should use the signal coming off the input pad itself (and not through pin muxing logic). This is because some timing sources are also optionally routed as an output to these pins (e.g., ATL clock out and McASP AHCLKX outputs), in which case another peripheral could use that same pin as an input timing reference.

NOTE: Similar to the video case, there are several options for implementing adjustments to audio clocks. The smoothest is external VCXO (e.g., on AUXOSC For McASPs one can also use the ATL clock outputs as reference which is adjusted via ATL register writes.

Table 2-24. Audio PLL Supported Dividers

Control Bit Filed	Divider	Supported Divide Ratios	Default Value
CM_APA_CLKSEL[CLKSEL]	A	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
CM_SYSCLK19_CLKSEL[CLKSEL]	B	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1

CM_SYSCLK21_CLKSEL[CLKSEL]	D	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1
CM_SYSCLK22_CLKSEL[CLKSEL]	E	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1

A fixed 32,768 Hz clock frequency is provided on PRCM SYSCLK18. This clock has two sources. The Audio PLL Clock1 which is fed from a fixed divider (RTCDIVIDER) on the 20 MHz clock, and the “clkin32” input pin. SYSCLK18 provides clock for: RTC, DMTIMER1..8 (optional via mux), BANDGAPS, synctimer and debounce circuit for MMC0,1,2 and GPIO0,1,2,3.

2.3.9 Timer Clock Structure

The output of RTCDIVIDER is also taken directly to optionally feed the WDT0 watchdog (Cortex™-A8 watchdog). The external 32KHz clock is not an option for WDT0. The other option for WDT0 is internal RCOSC32 oscillator. RTCDIVIDER output may also be optionally used as Cortex™-A8 Subsystem functional clock (via mux) for very low power operation (e.g., waiting in loop to bring clocks/system back up to full rate).

The following figures show the optional functional/reference clocks for DMTIMER1..8 and the functional/reference clocks for the watchdog timer (WDT0) and the Synctimer (which is available for generic use).

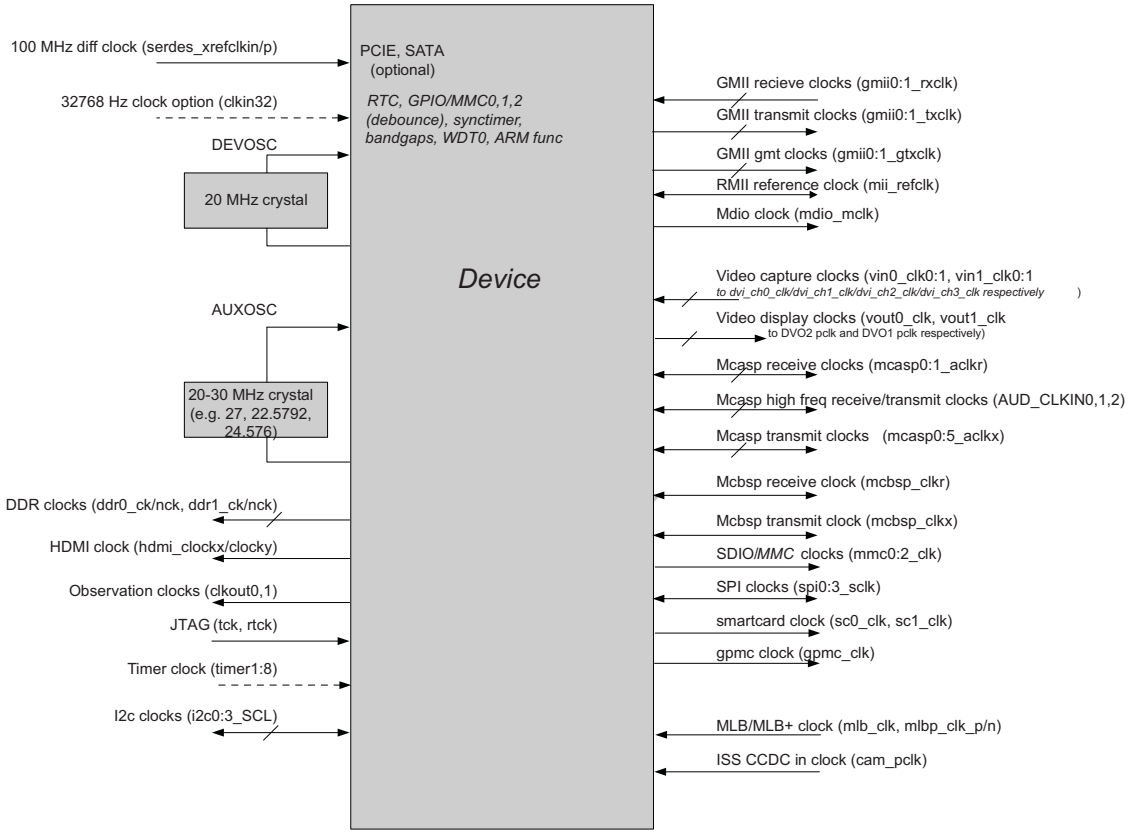
2.3.10 Device Clocking from External Sources

As shown in Figure 2-15, AUXOSC (20-30MHz) and DEVOSC (20 MHz) crystals are connected to generate the reference clocks. It is also possible to supply AUXOSC using an off-chip VCXO. A 100 MHz external differential clock must be used for PCIe. SATA uses 20 MHz oscillator as a reference.

Output clock SYSCLK_OUT can deliver clock outputs of each DPLL. The CM_CLKOUT_CTRL register controls the clock selection and division ratios.

Copyright © 2011–2013, Texas Instruments Incorporated

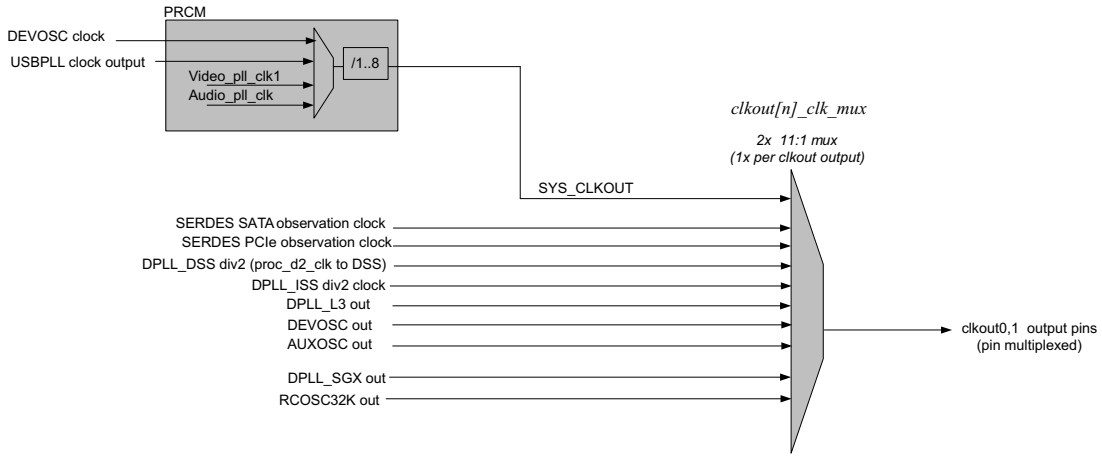
Figure 2-15. Device Clocking External Clock Sources



2.3.11 Clock Output Pin

The device has two clock output options. When chosen from the mux, the PLL clocks can be divided further before being exported out. The clock out is controlled by the register CM_CLKOUT_CTRL. The CLKOUT also has an enable option CM_CLKOUT_CTRL.CLKOUTEN.

Figure 2-16. Clock Output Pin Options



Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-27. Clkout Divider Options

Control Bit Filed	Divider	Supported Divide Ratios	Default Value
CM_CLKOUT_CTRL [CLKOUTDIV]	A	1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8	1/1

The clock outputs are controlled by two mux options respectively CLKOUT0 and CLKOUT1. Refer to the CLKOUT_MUX register for more details on the options of CLKOUT multiplexing.

2.4 Oscillator

As discussed in previous sections, the device has two conventional on-chip oscillators: DEVOSC and AUXOSC.

Figure 2-17 shows the conventional oscillator connections. DEVOSC is always needed, while AUXOSC is optional for video/audio reference and can run at any desired frequency in range of 20-30 MHz (e.g., typically could be 27 MHz or 22.5792 MHz). Table 2-28 and Table 2-29 show the settings for the two on-chip oscillators.

Figure 2-17. Oscillator Connection

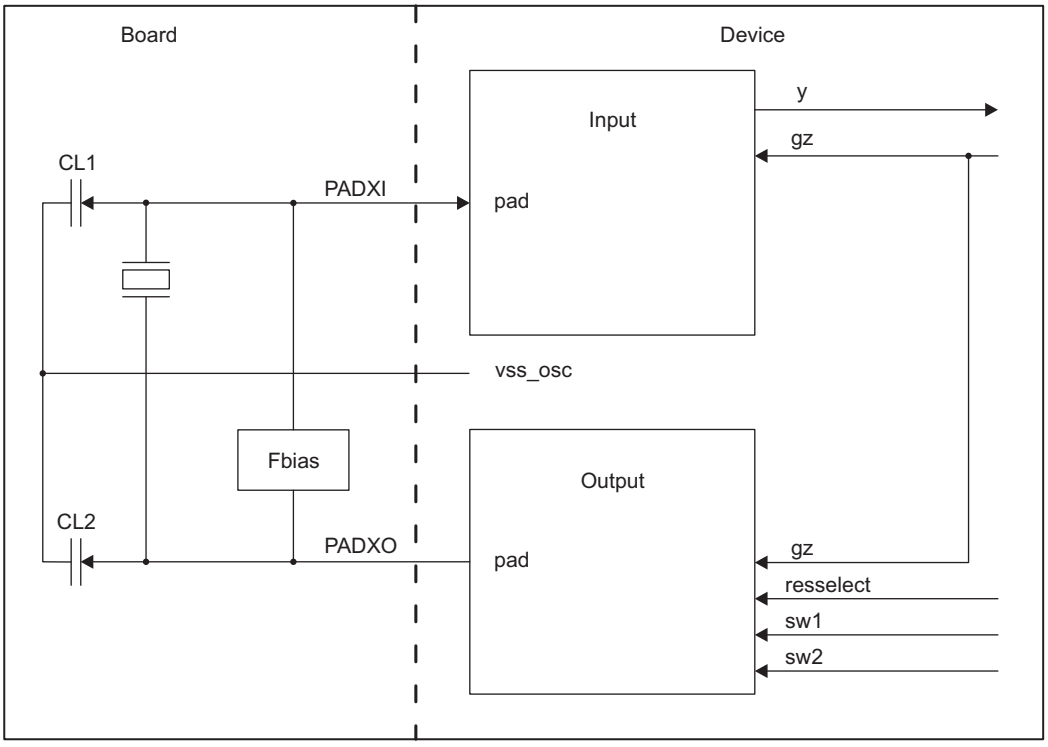


Table 2-28. AUXOSC Oscillator Settings

Pin	Value
sw1	1 (select 15-35 MHz range)
sw2	0 (select 15-35 MHz range)
gz	MMR (Default 0 - Setting this to “1” disable the oscillator)
reselect	MMR (Default 0 - Use internal feedback resistor)

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-29. DEVOSC Oscillator Settings

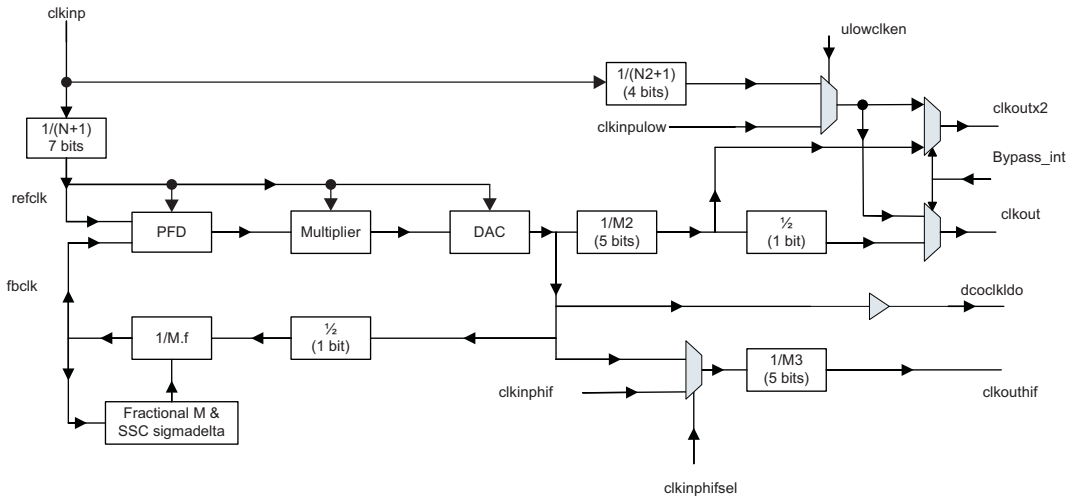
Pin	Value
sw1	1 (select 15- 20 MHz range)
sw2	0 (select 15-20 MHz range)
gz	Controlled solely by Sleep control logic (Default 0 - sleep control logic sets to “1” to disable the oscillator while in sleep)
resselect	MMR (Default 0 - Use internal feedback resistor)

NOTE: To enter sleep, the software must configure the desired sense of the wakeup (OSC_WAKE pin) and write to AUXOSC.GZ in the control module to force a hardware mechanism to turn off DEVOSC. The DEVOSC is cleanly re-started upon a wakeup event (rising or falling edge on the OSC_WAKE pin depending on configured sense before going into sleep). In case that an external oscillator/vcxo, a clock can directly be connected to XI pin and oscillator is put in bypass mode.

2.5 DPLLS

The DPLLS is a high resolution frequency synthesizer PLL with built in level shifters which allows the generation of frequencies upto 1GHz. DPLLLS has a pre-divide feature which allows the user to divide, for instance, a 20 MHz or 27 MHz reference clock to 1 MHz and then multiply up to 1 GHz maximum frequency. All PLLs come up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked. Once it is locked, then PLLs can be taken out of bypass mode. The Cortex™-A8 PLL is of this type.

Figure 2-18. DPLLS Clocks Structure



The DPLLS has three input clocks:

- CLKINP : Reference input clock
- CLKINPULOW : Low frequency input clock for bypass mode only
- CLKINPHIF : High Frequency Input Clock for post-divider M3
- The DPLLS has four output clocks:
- CLKOUTHIF: High Frequency Output Clock from Post divider M3
- CLKOUTX2: Secondary 2x Output
- CLKOUT: Primary output clock
- DCOCLKLDO: Oscillator(DCO) output clock with no bypass

Copyright © 2011–2013, Texas Instruments Incorporated

The DPLL has internal clocks: REFCLK (Internal reference clock) and BCLK.

2.5.1 DPLLS Frequency Range

The internal reference clock, REFCLK, is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK. Here, REFCLK = CLKINP/(N+1).

2.5.2 DPLLS Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm.

M is the software-configured Integer Feedback Multiplier Value.

N is the software-configured Input Divider Value.

M2 is the software-configured post-divider value

N2 is the software-configured Bypass divider value.

Frac M is software-configured Fractional Feedback Multiplier.

M3 is the software-configured additional divider

For more information for DPLLS programing and detailed descriptions of DPLLS registers see section *PLLSS Registers* in the device TRM.

2.5.3 DPLLS Clock Functions

The DPLL clock functions are shown in the tables Table 2-30:

Table 2-30. Clock Functions

Output Clocks in Locked Condition		
REGM4XEN = '0'		
Pin Name	**Frequency**	**Comments**
CLKOUT	[M /(N+1)] * CLKINP * [1/M2]	
CLKOUTX2	2 * [M /(N+1)] * CLKINP * [1/M2]	
DCOCLKLDO	2 * [M /(N+1)] * CLKINP	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL = '1'
	2 * [M /(N+1)] * CLKINP * [1/M3]	CLKINPHIFSEL = '0'
REGM4XEN = '1'		
Pin Name	**Frequency**	**Comments**
CLKOUT	[4M /(N+1)] * CLKINP * [1/M2]	
CLKOUTX2	2 * [4M /(N+1)] * CLKINP * [1/M2]	
DCOCLKLDO	2 * [4M /(N+1)] * CLKINP	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL = '1'
	2 * [4M /(N+1)] * CLKINP * [1/M3]	CLKINPHIFSEL = '0'
Output Clocks before Lock & during Relock modes		
Pin Name	**Frequency**	**Comments**
CLKOUT	CLKINP/(N2+1)	ULOWCLKEN = '0'
	CLKINPULOW	ULOWCLKEN = '1'
CLKOUTX2	CLKINP/(N2+1)	ULOWCLKEN = '0'
	CLKINPULOW	ULOWCLKEN = '1'
DCOCLKLDO	Low	
CLKOUTHIF	CLKINPHIF/M3	CLKINPHIFSEL = '1'
	Low	CLKINPHIFSEL = '0'

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: Since M3 divider is running on the internal LDO domain, in the case when CLKINPHIFSEL='1,' CLKOUTHIF could be active only when internal LDO is ON. Hence, whenever LDOPWDN goes low to high to powerdown LDO (happens when TINITZ activated / when entering slow relock bypass mode), output CLKOUTHIF glitch and stop. To avoid this glitch, it is recommended to gate CLKOUTHIF using control CLKOUTHIFEN before asserting TINITZ entering any slow relock bypass mode.

The Min and Max Values of the Clock generation supported by PLLs across different OPPs.

NOTE: For detailed information about PLL frequency limits at all OPPs see section *PLL Frequency Limits* in the device *Datasheet*.

2.5.4 DPLLS Frequency Factors

The divide values have to be selected with the ranges in the Table 2-31 so as to generate the required CLOCKOUT in the Frequency Ranges mentioned in the previous sections are satisfied.

Table 2-31. Frequency factors

Feedback Multiplier	M [1]	2 - 2047	00000000010 - 11111111111
Input Divider	**N + 1**	1 - 128	(0000000 - 1111111) + 1
Bypass Divider	**N2 + 1**	1 - 16	(0000 - 1111) + 1
Post Divider	**M2**[2]	1 - 31	00001 - 11111
Additional Divider	**M3**[2]	1 - 31	00001 - 11111

(1) M = 0 & 1 correspond to MN Bypass mode setting.
(2) M2 = 0 and M3 = 0 are invalid setting.

2.6 DPLLLJ

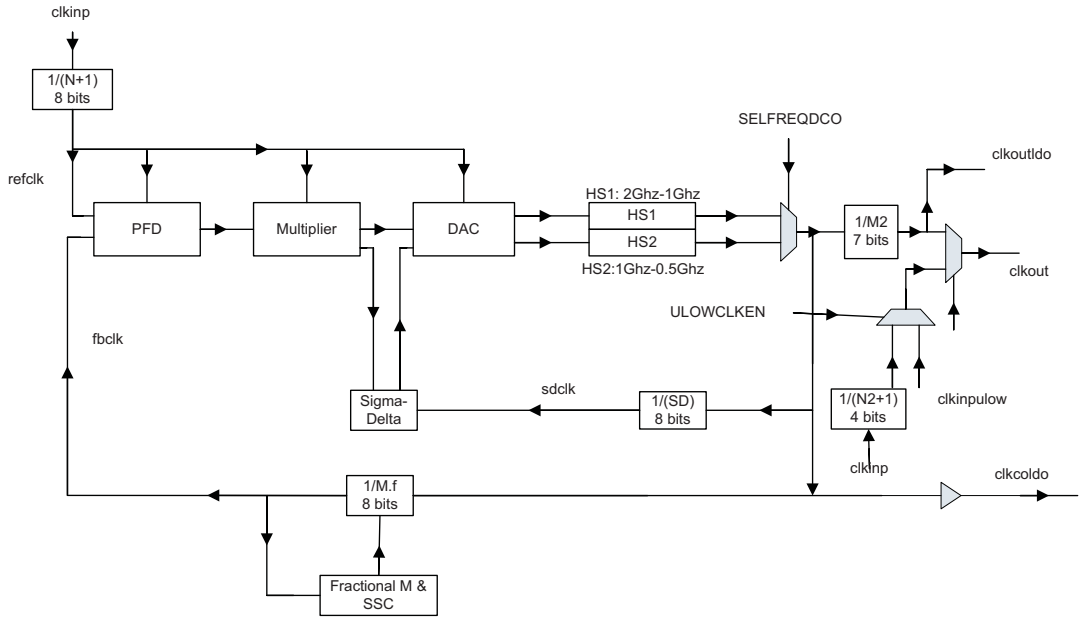
The DPLLLJ is a low-jitter PLL with a 2GHz maximum output. The DPLLLJ has a pre-divide feature which allows users to divide, for instance, a 20 MHz or 27 MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum.

The DPLLLJ also has an 18b fractional multiplier which is useful for configuring very specific frequencies as desired (for example, audio and video).

All PLLs come up in bypass mode at reset. The software needs to program all the DPLL settings appropriately and then wait for theDPLL to be locked. Once the DPLL is locked, then DPLLs can be taken out of bypass mode.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-19. DPLLJ Basic Structure



The following PLLs belong to type DPLLJ:

- DSPPLL
- SGXPLL
- HDVICPPLL
- L3PLL
- ISSPLL
- DSSPLL
- VIDEO0PLL
- VIDEO1PLL
- HDMIPLL
- AUDIOPLL
- USBPLL
- DDRPLL

The DPLL has two input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Bypass input clock

The DPLL has two internal clocks: REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK. Here, REFCLK = CLKINP/(N+1)

DCOCLK (Internal Oscillator clock.): This is the raw clock directly out of the digitally controlled oscillator (DCO) before the post-divider. The PLL output clock is synthesized by an internal oscillator which is phase locked to the REFCLK. There are two oscillators built within DPLLLJ. The oscillators are user selectable based on the synthesized output clock frequency requirement. In locked condition, DCOCLK= CLKINP *[M/(N+1)].

The DPLL has three external output clocks:

- CLKOUTLDO
  Primary output clock in VDDLDOOUT domain. Bypass option not available on this output
  CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)

Copyright © 2011–2013, Texas Instruments Incorporated

- CLKOUT
  Primary output clock on digital core domain
  CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- CLKDCOLDO
  Oscillator (DCO) output clock before post-division in VDDLDOOUT domain. Bypass option is not available on this output.
  CLKDCOLDO = (M / (N+1))*CLKINP

All clock outputs of the DPLL can be gated. The Control module provides the DPLL with a clock gating control signal to enable or disable the clock, and the DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. Output clock gating control for various clockouts: CLKOUTEN/CLKOUTLDOEN/CLKDCOLDOEN.

2.6.1 DPLLLJ Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm.

M is the software-configured Integer feedback multiplier value.

N is the software-configured input divider value.

M2 is the software-configured post-divider value

N2 is the software-configured bypass divider value.

SD is the software-configured Sigma2Delta divider.

Frac M is software-configured fractional feedback multiplier.

For more information for DPLLs programing and detailed descriptions of DPLLSJ registers see section *PLLSS Registers* in the device TRM.

2.6.2 DPLLLJ Clock Functions

The clock functions are shown in Table 2-32 and Table 2-33 the tables below.

Table 2-32. Output Clocks in Locked Condition

PINNAME	FREQUENCY
CLKOUT	[M /(N+1)] * CLKINP * [1/M2]
CLKOUTLDO	[M /(N+1)] * CLKINP * [1/M2]
CLKDCOLDO	[M /(N+1)] * CLKINP

Table 2-33. Output Clocks Before Lock and During Relock Modes

PINNAME	FREQUENCY	Conditions
CLKOUT	CLKINP/N2+1	ULOWCLKEN = ’0’
	CLKINPLOW	ULOWCLKEN = ’1’
CLKOUTLDO	LOW	
CLKDCOLDO	LOW

2.6.3 DPLLLJ Frequency Range (MHz)

The Min and Max Values of the Clock generation supported by PLLs across different OPPs.

NOTE: For detailed information about PLL frequency limits at all OPPs see section *PLL Frequency Limits* in the device *Datasheet*.

2.6.4 DPLLLJ Frequency Factors

The divide values have to be selected with the ranges in the Table 2-34 so as to generate the required CLOCKOUT in the Frequency Ranges mentioned in the previous sections are satisfied.

Table 2-34. DPLLLJ Frequency Factors

Multiplier/Divider		Range	
Feedback Multiplier (Integer)	M	2 - 4095	00000000010 – 11111111111
Feedback Multiplier (Fractional)	Frac M		000000000000000000 - 111111111111111111
Input Divider	N+1	1-256	(00000000 – 11111111) + 1
Post Divider	M2	1-127	0000001 - 1111111
Sigma2Delta Divider	SD	2-255	000000010-11111111
Bypass Divider	N2+1	16-1	(0000 – 1111) + 1

2.6.5 Mode of Operations

Table 2-35. Modes of Operations

Mode	Control Signal	CLKINP	REFCLK	Digital	Analog Bias	DCO OSC	CLKOUT	CLKDCOLDO(CLKOUTLDO)	FreqLock time (Phaselock time) from specific mode to “Active & Locked mode”
OFF	SYSRESET = 1 or TINITZ = 0	ON or OFF	OFF	ON	OFF	OFF	Bypass clk	LOW	350REFCLKs (500REFCLKs)
Active & Locked	SYSRESET = 0 TINITZ = 1 IDLE = 0	ON	CLKINP /(N+1)	ON	ON	ON	M/(N+1) * CLKINP * (1/M2)	DCOCLK (DCOCLK/M2)	Locked
Idle Bypass low power	SYSRESET = 0 TINITZ = 1 IDLE = 1	ON	OFF	ON	OFF	OFF	Bypass clk	LOW	20REFCLKs (150REFCLKs)
Lossclk – Bypass low power	SYSRESET = 0 TINITZ = 1	OFF	OFF	ON	OFF	OFF	Bypass clk	LOW	20REFCLKs (150REFCLKs)
Standby Retention-Bypass low power	STBYRET= 1 ULOWCLK EN=0/1	ON	OFF	ON	OFF	OFF	Bypass clk	LOW	7.5us+30REFCLKs (7.5us+125 REFCLKs)
MN Bypass	M = 0 or 1	ON	OFF	ON	OFF	OFF	Bypass clk	LOW	350REFCLKs (500REFCLKs)
Retention	Enter into RETENTION from Idle Bypass Mode			OFF	OFF	OFF	Low	LOW	7.5us + 30REFCLKs (7.5us+125 REFCLKs)

Copyright © 2011–2013, Texas Instruments Incorporated

TINITZ: TINITZ activation (Low) gives softreset to DPLLJ. TINITZ does not reset the entire digital control logic. It forces the FSM into RESET State so that DPLLJ could restart. DPLLJ starts calibration and lock sequence when TINITZ is disabled (Low to High).

TENABLEDIV: TENABLEDIV rising edge loads the values of M2REG and N2REG into PLL register (PLL_M2NDIV). It is not necessary to recalibrate PLL with the updated values. The change in values of M2REG reflects appropriately in the output clocks CLKOUT and CLKOUTLDO.

OFF MODE: SYSRESET= 1 or TINITZ = 0 PLL is in off mode when SYSRESET/TINITZ is configured to the values SYSRESET= 1 or TINITZ = 0. CLKOUT is bypass clk and CLKOUTLDO, and CLKDCOLDO are low irrespective of the presence of the inputclock.

ACTIVE and Locked Mode: SYSRESET = 0 & TINITZ = 1 , IDLE = ‘0’ PLL is in Active and locked mode when SYSRESET = 0 & TINITZ = 1, IDLE = ‘0’

- TENABLE rising edge loads the values of MREG and NREG into the ADPLLJ registers.
- TENABLEDIV rising edge loads the values of M2REG and N2REG into the ADPLLJ register.
- ADPLLJ starts calibration and lock sequence begins from the first CLKINP edge when TINITZ is disabled (low to high).
- TINITZ rising edge should follow the TENABLE rising edge, so that ADPLLJ performs the calibration and lock sequence after the loop control values are loaded.
- The change in values of M2REG reflects appropriately in the output clocks CLKOUT and CLKOUTLDO.
- Following this internal calibration sequence is performed followed by locking sequence. ADPLLJ has two lock outputs viz. FREQLOCK and PHASELOCK.
- The FREQLOCK output indicates frequency lock. FREQLOCK is asserted when internally the normal clk frequency is within + 1 / 2% of the final output frequency. The PHASELOCK output indicates phase tracking between output clocks (CLKOUT, CLKOUTLDO and CLKDCOLDO) and input clock (CLKINP). The FREQLOCK, PHASELOCK gets asserted in the ADPLLJ status register. The ouptut clocks CLKOUT, CLKOUTLDO and CLKDCOLDO are generated as per the register values (M, N, M2, N2) values.

IDLE Bypass: TINITZ =1 IDLE =1 The IDLE input signal can force ADPLLJ into bypass mode. Also the internal reference clock REFCLK is gated inside the ADPLLJ digital control logic to save power. In the IDLE mode, the PHASELOCK and FREQLOCK output signals are asserted low.CLKOUT is bypass clk and CLKOUTLDO, CLKDCOLDO are low

2.6.6 BYPASS Mode

After digital power-up and before SYSRESET is active (high), DPLL is in an undefined state. Hence, power-up with SYSRESET active (high). On SYSRESET = ‘1’, VDD should be active, PONIN = ‘1’, PGOODIN = ‘1’ as shown in <MODULE>PLL_PWRCTRL register in PRCM and also the acknowledge signals PONOUT = ‘1’ and PGOODOUT = ‘1’ shown in <MODULE>PLL_STATUS register of PRCM.

CLKOUT is in the bypass mode and would give out bypass clk during and after sysreset.

<MODULE>PLL_CLKCTRL.ULOWCLKEN = ‘1’ – BYPASS CLK = CLKINPULOW

<MODULE>PLL_CLKCTRL.ULOWCLKEN = ‘0’ – BYPASS CLK = CLKINP/(N2+1); N2 =0

The bypass mode CLKOUT could be kept active or inactive during sysreset by controlling the status of <MODULE>PLL_CLKCTRL. CLKOUTEN during SYSRESET = ‘1’.

<MODULE>PLL_CLKCTRL.CLKOUTEN = ‘1’ during SYSRESET = ‘1’ asynchronously enables CLKOUT. And the acknowledge bit in the register is <MODULE>PLL_STATUS.CLKOUTENACK = ‘1’

<MODULE>PLL_CLKCTRL.CLKOUTEN = ‘0’ during SYSRESET = ‘1’ asynchronously disables CLKOUT. And the acknowledge bit in the register <MODULE>PLL_STATUS.CLKOUTENACK = ‘0’

CLKOUTLDO and CLKDCOLDO are low during and after SYSRESET.

Check the status bits CLKOUTENACK, BYPASS, BYPASSACK in the status register <MODULE>PLL_STATUS in the PRCM.

Copyright © 2011–2013, Texas Instruments Incorporated

2.6.7 M2 & N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly. The output clock CLKOUT/ CLKOUTLDO perform a clean switch from OLD period to NEW period without any clock period being different from OLD or NEW period.

2.6.8 Gating and Power Down of Output Clocks

The high to low transition of the input signal CLKOUTEN/ CLKOUTLDOEN/ CLKDCOLDOEN performs synchronous gating of the output clock CLKOUT/ CLKOUTLDO/ CLKDCOLDO respectively.The gating acknowledge output CLKOUTENACK/ CLKOUTLDOENACK/CLKDCOLDOENACK is asserted Low once the gating is complete.

The low to high transition of the input signal CLKOUTEN/ CLKOUTLDOEN/ CLKDCOLDOEN performs synchronous enabling of the output clock CLKOUT/ CLKOUTLDO/ CLKDCOLDO.The gating acknowledge output CLKOUTACK/ CLKOUTLDOACK/CLKDCOLDOACK is asserted High once the enabling is complete.

2.6.9 M2PWDNZ / CLKDCOLDOPWDNZ bits

<MODULE>PLL_CLKCTRL. M2PWDNZ active (low) will powerdown the M2 divider. Hence, the output clock CLKOUT is in bypass mode. Also, even after DPLL has locked and <MODULE>PLL_STATUS. FREQLOCK has gone high, and <MODULE>PLL_STATUS. BYPASSACK output continues to remain high. Changing this bit in active locked condition is not supported.

INITIALIZATION should follow the change of these bits <MODULE>PLL_CLKCTRL.CLKDCOLDOPWDNZ / CLKOUTLDOPWDNZ active (low) will powerdown the CLKDCOLDO/CLKOUTLDO output. CLKDCOLDO/CLKOUTLDO is Low in this condition. Changing these bits in active locked condition is not supported. INITIALIZATION should follow change of these bits.

2.7 Reset Management

2.7.1 Overview

The PRCM manages the reset signals to all power domains. And, it manages generation of a single reset output signal through device pin, SYS_RESWARM_RST, for external use. The PRCM has no control over resets generated locally within a module, e.g., via the OCP configuration register bit <IPName>_SYSCONFIG.SOFTRESET.

All PRM reset outputs are asynchronously asserted. These outputs are active-low except for the DPLL resets. Deassertion is synchronous to the clock which runs a counter used to stall, or delay, reset de-assertion upon source deactivation. This clock is SYS_CLK used by all the reset managers. All modules receiving a PRCM generated reset are expected to treat the reset as asynchronous and implement local re-synchronization upon de-activation as needed.

One or more reset managers are required per power domain. Independent management of multiple reset domains is required to meet the reset sequencing requirements of all modules in the power domain.

2.7.2 Reset Concepts and Definitions

The PRCM manages many sources of reset signals with different characteristics. Reset signals are categorized as:

- Scope: Global or Local reset.
  - Global reset: Affects the entire logic of the device; all modules are reset. Generally, occurs when the device powers up or an abnormal operation is detected (the eFuse bad device is detected, etc.).
  - Local reset: Affects one power domain, reset domain, or module. Generally, when a power domain transitions from off mode to active mode, or when a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

Copyright © 2011–2013, Texas Instruments Incorporated

- Occurrence: Cold or Warm reset.
  - Cold reset: global reset that affects every module in the device. It usually corresponds to the initial power-on reset.
  - Warm reset: A module may use a warm reset to reset a subset of its logic.
- Source type: Software or Hardware triggered reset
  - Software reset: Triggered by setting a bit in a configuration register of the PRCM module.
  - Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

Each reset source is specified as being a cold or warm type. Cold types sources are applied globally within each receiving entity (i.e., subsystem, module, macro-cell) upon assertion. Cold reset events include: device power-up, power-domain power-up, and E-Fuse programming failures.

Warm reset types are not necessarily applied globally within each receiving entity. This is often done to speed-up reset recovery time, i.e., the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include: software initiated per power-domain, watch-dog time-out, externally triggered, and emulation initiated.

Reset sources, warm or cold types, intended for device-wide effect are classified as global sources. Reset sources intended for regional effect are classified as local sources.

Each reset manager provides two reset outputs. One is a cold reset generated from the group of global and local cold reset sources it receives. The other is a warm+cold reset generated from the combined groups of, global and local, cold and warm reset sources it receives.

The reset manager asserts one, or both, of its reset outputs asynchronously upon reset source assertion. Reset deassertion is extended beyond the time the source gets de-asserted. The reset manager will then extend the active period of the reset outputs beyond the release of the reset source, according to the PRCM's internal constraints and device's constraints. Some reset durations can be software-configured. Most (but not all) reset sources are logged by PRCM's reset status registers. The same reset output can generally be activated by several reset sources and the same reset source can generally activate several reset outputs. All the reset signals output of the PRCM are active low. Several conventions are used in this document for signal and port names. They include:

- "_RST" in a signal or port name is used to denote reset signal.
- "_PWRN_RST" in a signal or port name is used to denote a cold reset source

Copyright © 2011–2013, Texas Instruments Incorporated

2.7.3 Power On Reset (PORz)

The source of power on reset is the PORz pin on the device. Everything on device is reset with assertion of power on reset. This reset is non-blockable. Power on Reset is also referred to as a cold reset since it is required to be asserted when the device goes through a power-up cycle. However, a device power-up cycle is not required to initiate a Power-on Reset.

2.7.4 External Warm Reset (RESETz)

The source for this reset is the RESETz pin on the device. This signal resets everything except test and emulation logic, and efuse to provide a clean starting stage. This reset is also optionally blocked to the GMAC switch and it's reference clock source PLL (controlled in protected control module MMR). This reset DOES reset PLL, PRCM and EMIF. This reset is different from POR as during Warm reset, reset controller can assume that clocks and power to the chip are stable from assertion through deassertion, whereas for POR they can become stable during assertion. This reset source is fully blockable only via emulation.

2.7.5 Emulation Cold Reset (ICEPICK POR)

The source for this reset is on-chip emulation logic. This reset is same as POR reset. Only difference is that ICEPICK POR reset does not affect emulation logic and efuse.

2.7.6 Emulation Warm Reset

The source for this reset is on-chip emulation logic. This reset is same as external Warm reset (RESETz).

2.7.7 Reset Requestor

There is a watchdog timer on the device that can act as a reset requestor. This reset is not blockable. The watchdog is optionally combined with other device-level resets based on bootstrap latch and goes as chip output as board reset on the $\overline{\text{RSTOUT_WD_OUT}}$ pin. If BTMODE[11] (from gpmc_ad11 pin) is 0, then $\overline{\text{RSTOUT}}$ is asserted when a Watchdog Timer reset, $\overline{\text{POR}}$, $\overline{\text{RESET}}$, or Emulation/Software-Global Cold/Warm reset occurs. If BTMODE[11] is 1, then the $\overline{\text{RSTOUT_WD_OUT}}$ is asserted only when a Watchdog Timer reset occurs. The register PRM_RSTST in the PRCM logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software.

2.7.8 Software Controlled Reset

The device also has software controlled reset. There is three types of software resets:

- SW Global cold reset (SWGCR)
- SW Global warm reset (SWGWR)
- Local reset (for IPs with CPUs)

2.7.9 Test Reset (TRSTz)

This reset is triggered from TRSTz pin on JTAG interface. This is a non-blockable reset and it resets test and emulation logic.

NOTE: A PORz reset assertion should cause entire device to reset including all test and emulation logic regardless of the state of TRSTz. Therefore, PORz assertion achieves full reset of the device even if TRSTz pin is pulled permanently high and no special toggling of TRSTz pin is required during power ramp to achieve full POR reset to the device. Further, it should also be perfectly acceptable for TRSTz input to be pulled permanently low during normal functional usage of the device in the end-system to ensure that all test and emulation logic is kept in reset.

Copyright © 2011–2013, Texas Instruments Incorporated

2.7.10 Reset Priority

If more than one of these reset sources are asserted simultaneously then following priority order should be used:

1. POR
2. TRSTz
3. External Warm reset
4. Emulation
5. Reset requestors
6. Software resets

2.7.11 Reset Characteristics

Table 2-36 shows the characteristics of each reset source.

Table 2-36. Reset Sources

Characteristics	Pin POR (PORz)	SW Global Cold Reset	Emu Cold Reset (Icepick POR)	Bad Device (eFUSE)	Pin Warm Reset (RESETz)	Emu Warm Reset	Watchdog Timer	SW Global Warm Reset	TRSTz
Resets PLLs and enable bypass mode	Y	Y	Y	Y	Y	Y	Y	Y	N
Resets Dividers	Y	Y	Y	Y	Y	Y	Y	Y	N
Resets Fusefarm	Y	N	N	N	N	N	N	N	N
Resets chip functional logic	Y	Y	Y	Y	Y	Y	Y	Y	N
Resets GMAC switch and related chip logic	Y	N(1)	Y	Y	N(1)	N(1)	N(1)	N(1)	N
Resets test and emulation logic	Y	Y	N	N	N	N	N	N	Y
Resets Memory (DDR controller/PHY)	Y	Y	Y	Y	Y	Y	Y	Y	N
Resets power state for each IP	Y	Y	Y	Y	Y	Y	Y	Y	N
Reset source blockable	N	Y	N	N	Y	Y	Y (only emulation)	Y	N
Config pins latched4	Y	N	N	N	Y	N	N	N	N
Puts Ios in tristate	Y	Y	Y(2)	Y(2)	Y(2)	Y(2)	Y(2)	Y(2)	N
Pin mux registers	Y	Y	Y(3)	Y(3)	Y(3)	Y(3)	Y(3)	Y(3)	N
RSTOUTn pin asserted	Y(4)	Y(4)	Y(4)	Y(4)	Y(4)	Y(4)	Y	Y(4)	N

(1) Only true if GMAC switch reset isolation is enabled in control registers, otherwise is in reset.
(2) Some special IOs like test and emulation related is not in reset.
(3) Some special IOs like test and emulation related muxing is not in reset.
(4) RSTOUT_WD_OUT pin asserted only in case BTMODE[11] = 0 (latched from gpmc_ad11 pin). For pin reset conditions (PORz and RESETz), the pin is asserted only after the bootstrap value is latched (therefore asserts during internal stretched version of the reset, but not during assertion of the external pin).

NOTE: The Bandgap macros for the LDO's is in reset on PORz only.

2.7.12 Trace Functionality Across Reset

Other than POR, TRSTz and SW cold reset, none of the other resets affect trace functionality. This requires that Debug_SS has required reset isolation for the trace logic. Also the IOs and muxing control (if any) for trace IOs should not get affected by any other reset. Since none of the PLLs getting reset with other resets, clocks are any way stable.

Copyright © 2011–2013, Texas Instruments Incorporated

2.7.13 Reset Isolation

2.7.13.1 PCIe Reset Isolation

The device supports reset isolation for the PCI Express IP in the limited fashion as described below. It means that the user should be able to control the chip warm reset and PCI express in-band reset independently.

1. **RC (Root Complex), PCIE_SS reset and chip not reset**
   Local reset is asserted to the PCIE_SS from the PRCM. SW needs to make sure that there were no ongoing transactions at this point of time. This can be ensured by first taking the PCIE_SS to IDLE state. After coming out reset the bus enumeration needs to be performed again. Driver SW should behave as if all downstream devices are just connected again
2. **RC (Root Complex), PCIESS not reset and chip reset**
   In Root Complex mode, the chip is master of the PCI Express network. There is no utility of keeping PCIE_SS running if the chip is rebooting. All state information is lost and it is simpler to restart. When resuming, the Root Complex can issue Hot Reset to all downstream devices and start with the bus enumeration stage.
3. **EP (Endpoint), PCIE_SS reset and chip not reset**
   This can happen due to an in-band reset or because of PCIERST getting asserted. PCIE_SS indicates this by interrupting the Cortex™-A8 core. SW should then take the PCIE_SS to IDLE state and then local reset can be asserted to the PCIE_SS.
4. **EP (Endpoint), PCIE_SS not reset and chip reset**
   This is not supported as PCIE is a point to point connection and resetting one endpoint does not impact the complete system. So whenever chip gets reset even PCIE_SS gets reset.

2.7.13.2 EMAC Switch Reset Isolation

The device supports reset isolation for the Ethernet Switch IP by register RESET_ISO[0] ISO_CONTROL in the control module. This allows the device to undergo a warm reset without disrupting the switch or traffic being routed through the switch during the reset condition.

If configured by registers in control module that EMAC reset isolation ISO_CONTROL is active, then behavior is as follows:

Any “Warm” reset source (except the software warm reset) is blocked to the EMAC switch logic in the IP (the IP has two reset inputs to support such isolation) and to PLL (and it’s control bits) which is sourcing the EMAC switch clocks as required by the IP (50 or 125MHz reference clocks). Also, the EMAC switch related IO pins must retain their pin muxing and not glitch (continuously controlled by the EMAC switch IP) by blocking reset to the controlling register bits.

If configured by registers in control module that EMAC reset isolation ISO_CONTROL is NOT active (default state), then the warm reset sources are allowed to propagate as normal including to the EMAC Switch IP (both reset inputs to the IP).

All cold or POR resets are always propagate to the EMAC switch IP as normal (as otherwise defined in this document).

2.7.14 Reset Output ($\overline{\text{RSTOUT_WD_OUT}}$)

The device has one pin $\overline{\text{RSTOUT_WD_OUT}}$ which reflects chip reset status. This output is always assert asynchronously when any chip watchdog timer reset occurs (any of the 3 chip watchdogs) and if BTMODE[11] bootstrap is 0, then additionally the pin asserts if any of the following reset events occurs:

1. POR (only internal stretched portion of reset event after bootstrap is latched)
2. External Warm reset ($\overline{\text{RSTOUT_WD_OUT}}$ pin, only internal stretched portion of reset event after bootstrap is latched)
3. Emulation reset (Cold or warm from ICEPICK)
4. Reset requestor
5. SW Cold/Warm reset
   This output remains asserted as long as PRCM keeps reset to the host processor asserted.

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE:

- The RSTOUT_WD_OUT pin is output only and not bidirectional.
- TRST does not cause RSTOUT_WD_OUT assertion

2.7.15 Power-on-Reset (PORz) Sequence

The following is the sequence of actions for PORz:

1. PORz pin at chip boundary gets asserted (goes low).

NOTE: The state of the Reset Output during PORz assertion should be a don't care, it should not affect PORz (only implication is if they are both asserted and RSTOUT_WD_OUT is deasserted after PORz gets re-latching of boot config pins and may see warm RESET flag set in PRCM versus POR).

2. All IOs go to tri-state immediately.
3. When power comes-up, PORz value propagates to the PRCM.
4. PRCM fans out reset to the complete chip and all logic which uses async reset gets reset. RSTOUT_WD_OUT goes low to indicate reset-in-progress.
5. External clocks start toggling and PRCM propagates these clocks to the chip keeping PLLs in bypass mode.
6. All logic using sync reset gets reset.
7. When power and clocks to the chip are stable, PORz is de-asserted.
8. Boot Config pins are latched upon de-assertion of PORz pin
9. FuseFarm reset is de-asserted to start eFuse scanning.
10. Once eFuse scanning is complete, reset to the host processor and to all other peripherals (peripherals without local processor) is de-asserted.
11. RSTOUT_WD_OUT is de-asserted.
12. Once host processors finish booting then all remaining peripherals see reset de-assertion.

NOTE: All IPs with local CPUs have local reset asserted by default at PORz and reset de-assertion requires host processor to write to corresponding registers in PRCM.

2.7.16 RESETz Sequence

The following is the sequence of actions for RESETz:

1. RSTOUT_WD_OUT pin at chip boundary gets asserted (goes low).

NOTE: For RESETz sequence to work as described, it is expected that PORz pin is always inactive, otherwise refer to PORz functionality as described in previous section.

2. All IOs (except test and emulation) go to tri-state immediately.
3. PRCM propagates reset to the complete chip and all logic. RSTOUT_WD_OUT goes low to indicate reset-in-progress.
4. Chip clocks are not affected as both PLL and dividers are intact.
5. RESETz gets de-asserted after 30 cycles
6. Boot Config pins are latched upon de-assertion of PORz pin
7. PRCM de-asserts reset to the host processor and all other peripherals without local CPUs.
8. Once host processors finish booting then all remaining peripherals see reset de-assertion.

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: All IPs with local CPUs have local reset asserted by default at RESETz and reset de-assertion requires host processor to write to corresponding registers in PRCM.

2.7.17 Power-Up/Down Sequence

The power-up/down sequence is as follows:

1. Each power domain has dedicated warm and cold reset.
2. Warm reset gets asserted each time there is any warm reset source requesting reset. Warm reset is also asserted when power domain moves from ON to OFF state.
3. Cold reset for the domain is asserted in response to cold reset sources. When domain moves from OFF to ON state then also cold reset gets asserted as this is similar to power-up condition for that domain.

2.7.18 IO State

All IOs except for JTAG and Reset output (and any special cases mentioned in pinlist) should have their output drivers tri-state, and internal pulls enabled during assertion of all reset sources. JTAG IO is affected only by TRSTz.

NOTE: The DSP, HDVICP, and Media Controller are held under reset after global warm reset by assertion of software source of reset. Other domains such are held under reset after global warm reset until the MPU software enables their respective interface clock.

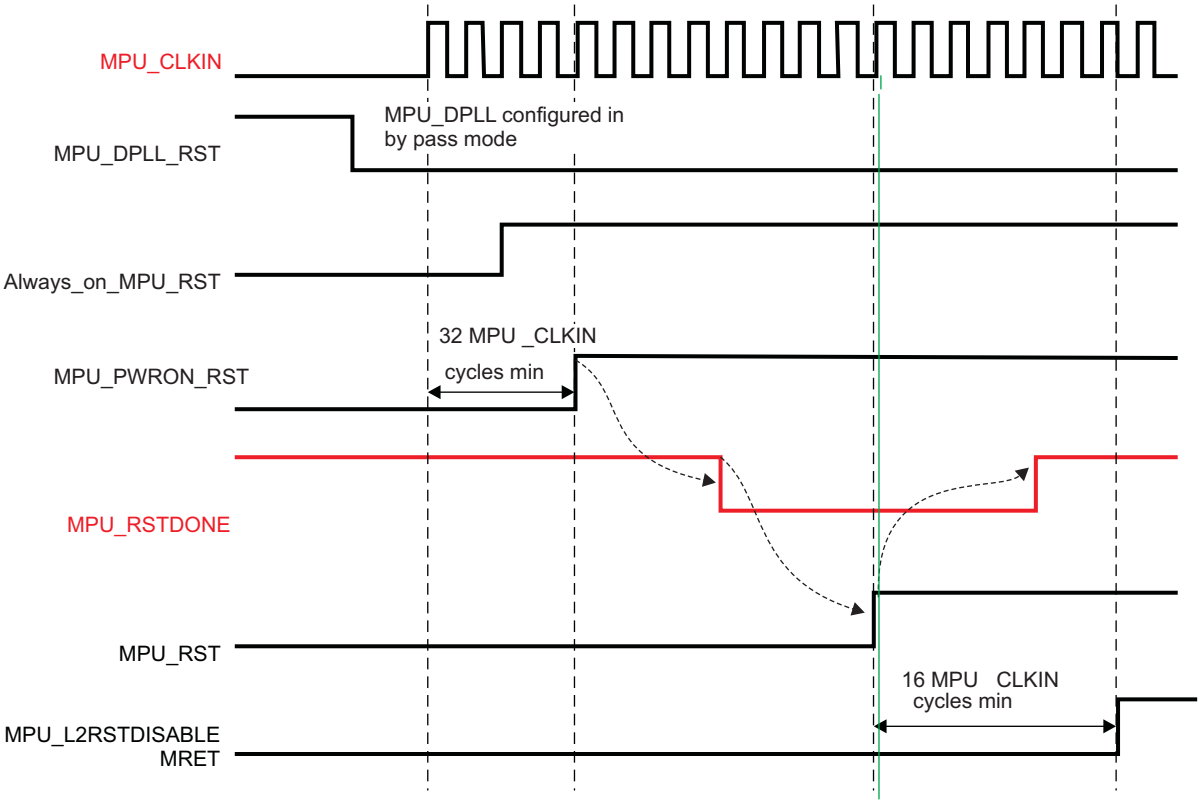
2.7.19 MPU Subsystem POR Sequence

The power on reset must be applied when MPU SS is first powered up. Following is the detailed description of MPU power on reset sequence.

1. During the initial power up sequence, the PRCM it asynchronously releases the DPLL_MAIN_RST signal for the main PLL. Once the main PLL reset is released, it starts the PLL initialization. The PLL is configured in bypass mode and it provides the bypass output CLK to all the modules inside MPU SS.
2. The PRCM releases the reset to INTC module inside MPUSS i.e. it asynchronously releases the MPU_AO_RST signal to MPUSS.
   Before the MPU power on reset is de-asserted, the PRCM must ensure that the MPU CLK is running so that MPU can be reset properly.
3. The PRCM releases MPU_PWRON_RST and it waits until MPUSS power-on Reset is complete. That is, the MPU_PWRON_RSTDONE signal is asserted HIGH by the MPUSS.
4. Following the de-assertion of MPU_PWRON_RST signal, the MPU SS de-asserts the nPORESET signal to the Cortex™-A8 CPU and after sufficient number of MPU CLK cycles MPU SS asserts the MPU_PWRON_RSTDONE signal high to indicate to the PRCM that synchronous power on reset sequence is completed inside MPU SS.
5. Once the PRCM sees that this MPU_PWRON_RSTDONE signal is asserted HIGH, PRCM de-asserts the MPU_RST signal and then the MPU starts booting.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-20. MPU SS POR Sequence



2.7.20 MPU Subsystem Warm Sequence

During the warm reset of MPU, the PRCM asserts the MPU_RST signal only and power on reset signal is not asserted.

The MPU_RST is kept asserted for minimum 32 MPU clock cycles, that is, SYS_CLK in this case since during warm the reset of MPU.

Figure 2-21 illustrates the timing diagram for MPU warm reset sequence.

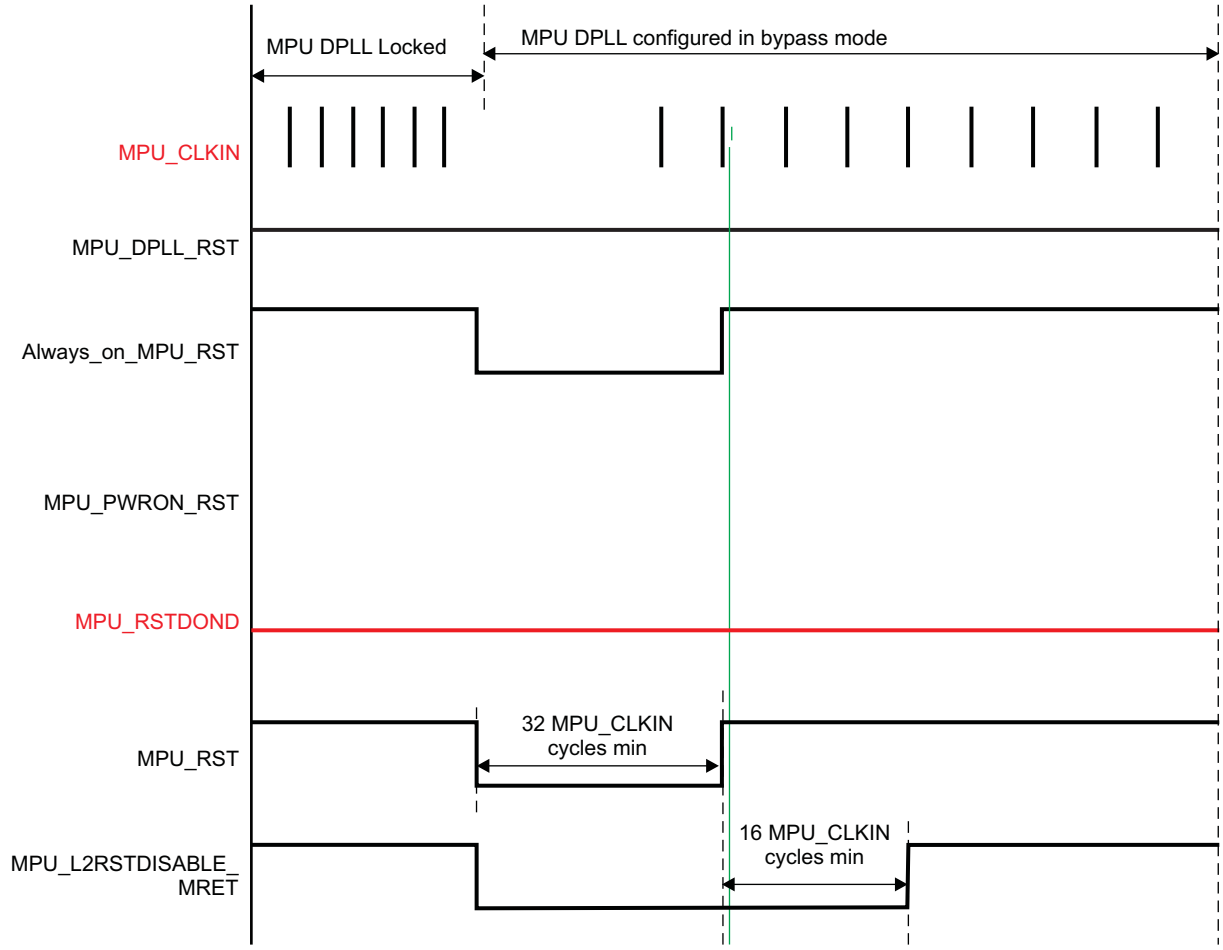
Figure 2-21. MPU Warm Reset Sequence

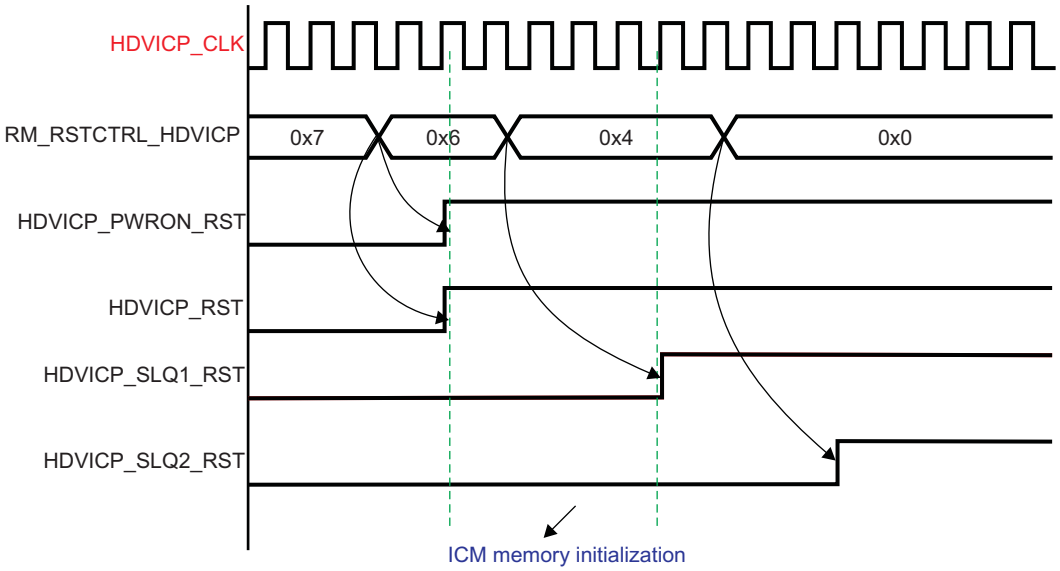


2.7.21 HDVICP Power-On Reset Sequence

Figure 2-22 illustrates the POR sequence of the HDVICP subsystem.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 2-22. POR Sequence of the HDVICP2



POR to HDVICP is applied when PD_HDVICP is powered up.

Whenever the HDVICP is enabled by software control, the following sequence happens:

- The PRCM module provides the functional clock HDVICP_CLK to the HDVICP SUBSYSTEM
- The POR to HDVICP is de-asserted

After POR de-assertion, the sequence is:

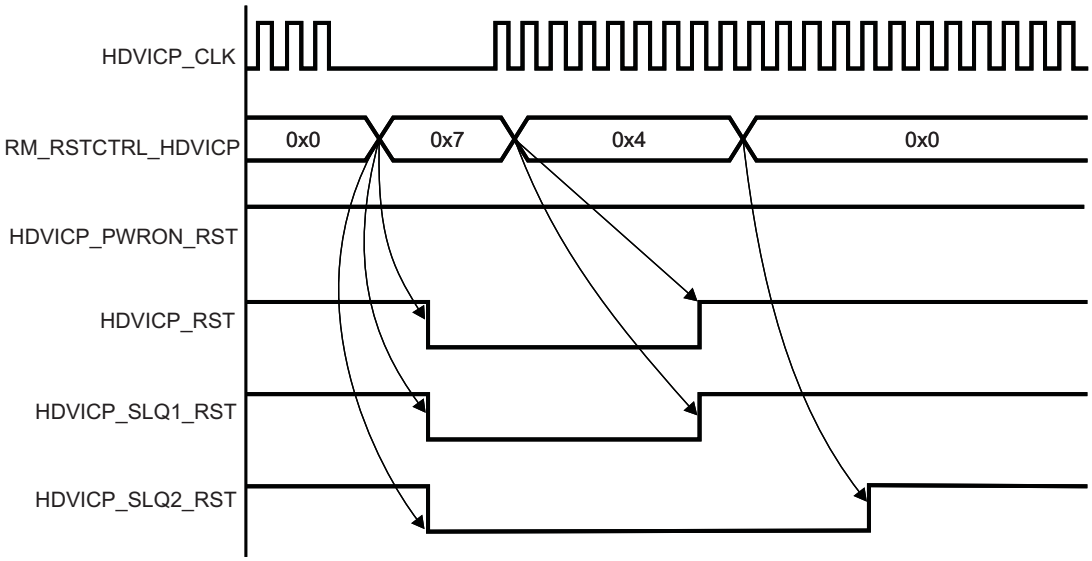
- Software clears the RM_HDVICP_RSTCTRL[2] RST3 bit. This causes the PRCM module to release the HDVICP_PWRN_RST reset, which is used inside HDVICP primarily to reset the emulation logic and the HDVICP_RST reset, which is used to reset all logic inside HDVICP. Then, software can download data into the TCM memory while keeping the sequencer CPUs under reset.
- Software clears the RM_HDVICP_RSTCTRL[0] RST1 bit. This releases the HDVICP_SEQ1_RST reset to the Sequencer1 CPU.
- Software can clear the RM_HDVICP_RSTCTRL[1] RST2 bit. This releases the HDVICP_SEQ2_RST reset to the Sequencer2 CPU.

Copyright © 2011–2013, Texas Instruments Incorporated

2.7.22 HDVICP Software Warm Reset Sequence

Figure 2-23 illustrates the software warm reset sequence of the HDVICP.

Figure 2-23. Software Warm Reset Sequence of the HDVICP



Before asserting the software reset to the HDVICP, the MPU software must ensure that:

- The HDVICP sequencer CPUs are in IDLE state (CM_HDVICP_CLKCTRL[17:16] IDLEST).
- The HDVICP2 is in STANDBY state CM_HDVICP_CLKCTRL[[18] STBYST).
- The functional clock to the HDVICP has been gated by the PRCM module (CM_HDVICP_CLKSTCTRL[8] CLKACTIVITY_HDVICP_CLK).

The software reset sequence occurs when the MPU software:

1. Sets the RM_HDVICP_RSTCTRL[2] RST3, RM_HDVICP_RSTCTRL[1] RST2, and RM_HDVICP_RSTCTRL[0] RST1 bits. This causes the PRCM module to assert the HDVICP_RST, HDVICP_SEQ1_RST, and HDVICP_SEQ2_RST resets to the HDVICP2. HDVICP_PWRN_RST remains deasserted.
2. Enables the functional clock to the HDVICP.
3. clears the RM_HDVICP_RSTCTRL[2] RST3 and RM_HDVICP_RSTCTRL[0] RST1 bits. This causes the PRCM module to release the HDVICP_RST and HDVICP_SEQ1_RST resets to the HDVICP.
4. clears the RM_HDVICP_RSTCTRL[1] RST2 bit. This releases the HDVICP_SEQ2_RST reset to the Sequencer2 CPU.

2.7.23 C674x DSP Power-On Reset Sequence

The assumptions about POR de-assertion are:

- The MPU software sets the CM_ACTIVE_GEM_CLKCTRL [1:0] MODULEMODE bit field to enabled.
- The MPU software sets the CM_ACTIVE_GEM_CLKSTCTRL [1:0] CLKTRCTRL bit field to SW_WKUP.
- The PRCM is providing the clocks to C674x DSP.

The POR sequence is:

- The PRCM module releases GEM_POR when the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) reaches its limit.
- The MPU software clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to release the DSP, MMU, and CACHE interface from reset.

Copyright © 2011–2013, Texas Instruments Incorporated

- Once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the GEM_GRST signal.
- On deassertion of the GEM_GRST signal, the C674x subsystem starts the initialization sequence. During the initialization sequence all the internal registers inside the C674x subsystem are properly reset and the reset for the DSP, MMU, and CACHE interface completes.
- The MPU software must configure the MMU once the MMU is out of reset. After the MMU is configured, the MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.

The PRCM module releases GEM_LRST, which causes the DSP to start booting.

2.7.24 C674x DSP Warm Reset Sequence

The assumptions about WARM reset de-assertion are:

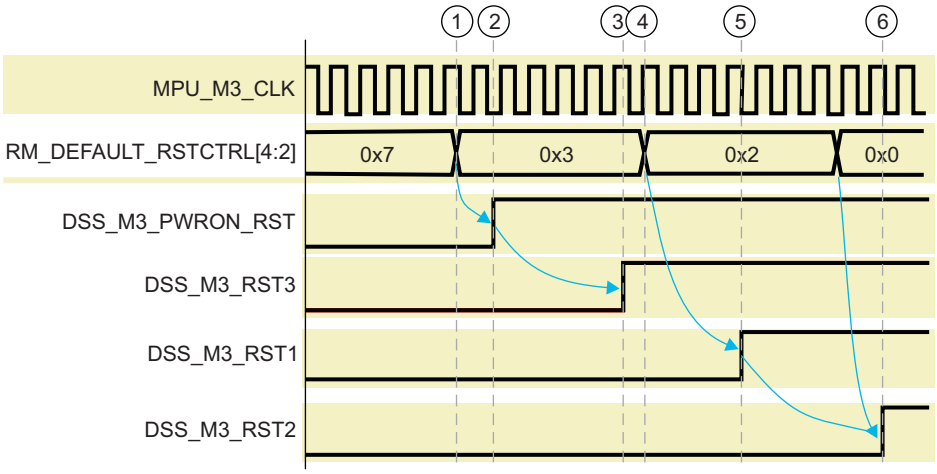
- The DSP is in IDLE state

The sequence is:

1. The MPU software sets the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST and RM_ACTIVE_RSTCTRL[0] GEM_LRST bits.
2. The PRCM module asserts the GEM_GRST and GEM_LRST reset signals.GEM_POR remains deasserted in this case.
3. The MPU software re-enables the C674x DSP Clocks and clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to reset the DSP, MMU, and CACHE interface. The DSP subsystem starts the partial initialization sequence for the warm reset.
4. The MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.
5. The PRCM module releases GEM_LRST, which causes the DSP to start booting.

2.7.25 Media Controller Power-On Reset Sequence

Figure 2-24. Media Controller Power-On Reset Sequence



The assumptions about POR de-assertion are:

- The Media Controller MPU subsystem is held in reset by the PRCM module and the following are asserted:
  - DSS_PWRN_RST
  - DSS_RST1
  - DSS_RST2
  - DSS_RST3

Copyright © 2011–2013, Texas Instruments Incorporated

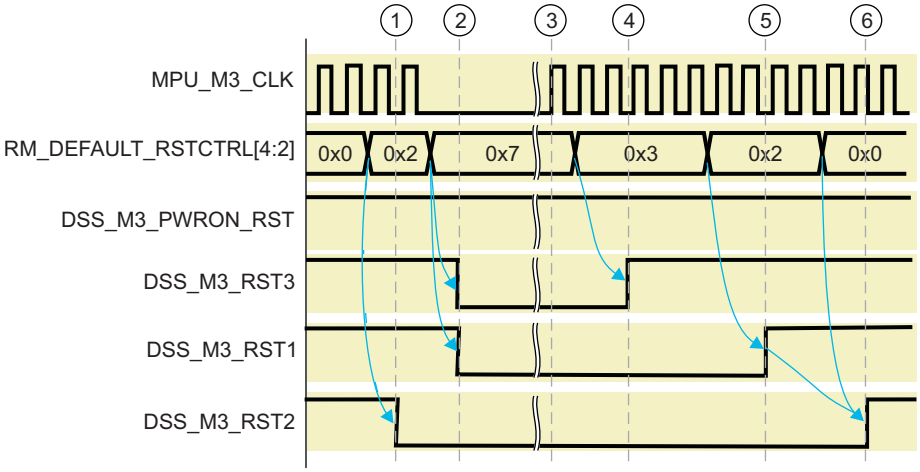
The POR sequence is:

1. Software enables Media Controller MPU subsystem.
2. Software clears the RM_DEFAULT_RSTCTRL[4] RST3 bit in the PRCM module register to release the Media Controller MPU Cache and MMU from reset.
3. Once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the DSS_RST3 signal.
4. Upon the deassertion of the DSS_M3_RST3 signal, the Media Controller MPU subsystem starts the CPU and MMU initialization sequence
5. The MPU software must configure the MMU once the MMU is out of reset. After MMU configuration and cache initialization is done, the MPU software clears the RM_DEFAULT_RSTCTRL[3] RST1 bit in the PRCM module register.
6. The PRCM module releases DSS_RST1, which causes the Media Controller MPU Core 1 to start booting.
7. The MPU software can clear the RM_DEFAULT_RSTCTRL[2] RST2 bit in the PRCM module register so that the PRCM module releases DSS_RST2 to the Media Controller MPU Core 2.

Copyright © 2011–2013, Texas Instruments Incorporated

2.7.26 Media Controller Warm Reset Sequence

Figure 2-25. Media Controller MPU Subsystem Software Warm Reset Sequence



The assumption about Warm reset assertion is:

- The Media Controller MPU Core2 is in IDLE state.

The sequence is:

1. Media Controller MPU Core 1 software or Cortex™-A8 MPU software sets the RM_DEFAULT_RSTCTRL[3] RST2 bit. The PRCM module asserts the DSS_RST2 reset signal to the Media Controller Core 2.
2. The Cortex™-A8 MPU cuts the MPU_M3_CLK and software sets the RM_DEFAULT_RSTCTRL[4] RST3 and RM_DEFAULT_RSTCTRL[2] RST1 bits.
3. The PRCM module asserts the DSS_RST3, DSS_RET_RST, and the DSS_RST1 reset signals. The DSS_PWRN_RST remains deasserted in this case.
4. The MPU software re-enables the MPU_M3_CLK and the initialization sequence starts inside the Media Controller subsystem. Software clears the RM_DEFAULT_RSTCTRL[4] RST3 bit in the PRCM module register.
5. When the reset sequence in Step 4 completes and the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the DSS_RST3, and DSS_RST1 reset signals. Media Controller Core 1 starts rebooting.
6. Software clears the RM_DEFAULT_RSTCTRL[3] RST2 bit in the PRCM module register. The PRCM module releases the DSS_RST2 reset signal to the Media Controller Core 2. Core 2 starts to boot.

2.8 Voltage and Power Domains

Table 2-37 shows how the device core logic is partitioned into 4 core logic voltage domains, 4 memory voltage domains and 6 power domains. The table lists which voltage and power domain a functional module belongs. All voltage domains must be supplied during any mode of operation while 5 of the 6 power domains can turned off by internal switch.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-37. Volage and Power Domains

Logic Voltage Domain Name	Module
ARM	Cortex™-A8,
CORE	DCAN0, DCAN1, DDR_PHY_LOGIC0, DDR_PHY_LOGIC1, DMM EDMA, ELM, EMIF0, EMIF1, 2 Channel GMAC Switch, GPIO_CNTL0, GPIO_CNTL1, GPIO_CNTL2, GPIO_CNTL3,GPMC, I2C0, I2C1, I2C2, I2C3, Interconnect, IPC, MCASP0, MCASP1, MCASP2, MCASP3, MCASP4, MCASP5, ATL, MCBSP, MLB, OCMC SRAM, PATA, PBIST, PCI, PRCM, RTC, SATA, SCR, SD/MMC0, SD/MMC1, SD/MMC2, SPI0, SPI1, SPI2, SPI3, Switch fabric, Timer1, Timer2, Timer3, Timer4, Timer5, Timer6, Timer7, Timer8, UART0, UART1, UART2, UART3, UART4, UART5, USB0, USB1, WDT0, VCP, XBAR, Debug_SS
	FACEDETECT
	SGX530 Subsystem
	HDD_SS, HDMI, SD-DAC LOGIC
ACTIVE (DSP)	C674x+™ Subsystem. , C674x+™ L2 SRAM,
HDVICP	HDVICP,

2.8.1 Voltage Domains

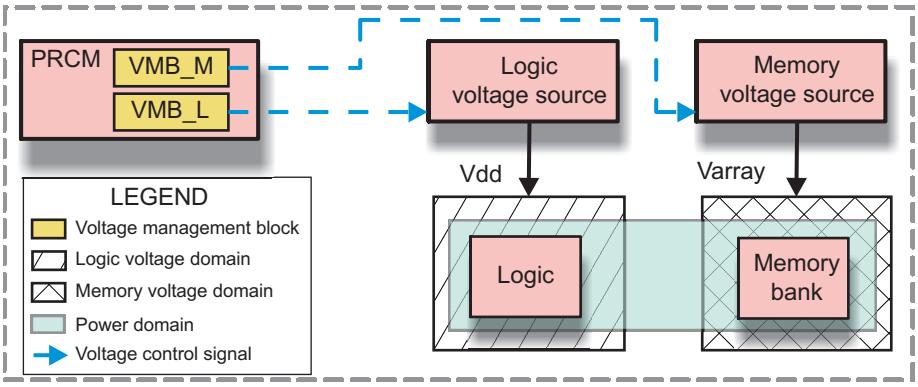
The PRCM module controls the voltage scaling (that is, switching the voltage in discrete steps or in a continuum within a range of possible values) of the power sources of the device. This allows control of the device power consumption according to the performance criteria defined. Higher performance is ensured with higher voltage and clock frequencies (and hence higher power consumption), while lower performance can be supported with lowered power consumption by reducing or completely gating the power supply to specific areas of the device and gating the associated clocks.
A voltage domain is a section of the device supplied by a dedicated voltage source (that is, an internal LDO or external switched mode power supply [SMPS]). A voltage domain may or may not be controlled by the PRCM module. When a voltage domain is controlled by the PRCM module, a dedicated voltage manager is associated. The voltage manager allows regulation of the voltage level of the source for the voltage domain, independently of other voltage domains of the device.
The core logic is divided into four voltage domains. This division permits the system to scale down voltage to some functional blocks while maintaining highest performance on other blocks.

The voltage managers in the PRCM module can be of two types:

- Hardware controlled to automatically switch the domain voltage levels according to the associated hardware conditions.

Figure 2-26 shows a voltage domain.

Figure 2-26. Generic Voltage Domain



Copyright © 2011–2013, Texas Instruments Incorporated

2.8.2 Power Domains

In order to reduce power due to leakage, the core logic supply voltage to six of the device power domains can be turned OFF with internal power switches. The internal power switches are controlled through memory mapped registers in the PRCM. In an use case whereby all the modules within a power domain are not used that power domain can be place in the OFF state.

Table 2-38 shows the allowable combination power domain ON/OFF states and which power domains are switched via internal power switches. At power-on-reset, all domains except always-on are in the power domain OFF state.

Table 2-38. Power Domain State Table

	POWER DOMAIN					
MODE	ALWAYS_ON	ISP (ISS)	GFX	DSS	ACTIVE (DSP)	HDVICP
No Voltage Supply	N/A	N/A	N/A	N/A	N/A	N/A
Power On Reset	ON	OFF	OFF	OFF	OFF	OFF
ALL OTHER FUNCTIONAL MODES	ON	DON'T CARE	DON'T CARE	DON'T CARE	DON'T CARE	DON'T CARE
Internal Power Switch	NO	YES	YES	YES	YES	YES

2.8.3 Device Modules and Power Management Attribute List

The device modules and power management list are described below:

Table 2-39. Device Modules

Power Domain Name	Module
ALWAYS_ON	Cortex™-A8, , DCAN0, DCAN1, DDR_PHY_LOGIC0, DDR_PHY_LOGIC1, DMM EDMA, ELM, EMIF0, EMIF1, 2 Channel GMAC Switch, GPIO_CNTL0, GPIO_CNTL1, GPIO_CNTL2, GPIO_CNTL3,GPMC, I2C0, I2C1, I2C2, I2C3, Interconnect, IPC, MCASP0, MCASP1, MCASP2, MCASP3, MCASP4, MCASP5, ATL,MCBSP, MLB, OCMC SRAM, PATA, PBIST, PCI, PRCM, RTC, SATA, SCR, SD/MMC0, SD/MMC1, SD/MMC2, SPI0, SPI1, SPI2, SPI3, Switch fabric, Timer1, Timer2, Timer3, Timer4, Timer5, Timer6, Timer7, Timer8, UART0, UART1, UART2, UART3, UART4, UART5, USB0, USB1, WDT0, VCP, XBAR, Debug_SS
ISS (ISP)	FACEDETECT, ISS
SGX530	SGX530 Subsystem
DSS	HDD_SS, HDMI, SD-DAC LOGC
ACTIVE (DSP)	C674x+™ Subsystem. , C674x+™ L2 SRAM,
HDVICP	HDVICP, SRSense2

2.8.4 Power Domain Power-Down Sequence

Below is the sequence of steps which happen during power down of a power domain.

All IPs (belonging to a power domain) with STANDBY interface asserts STANDBY. The STANDBY assertion should get triggered by the IP based on its activity on OCP initiator port. The IP should assert STANDBY whenever initiator port is IDLE. Some of the DSPS IPs may not have this feature and they require SW write to standby-mode register to get STANDBY assertion from IP.

1. SW requests all modules in given power domain to go to disable state by programming module control register inside PRCM.
2. PRCM starts and waits for completion of power management handshake with IPs (IdleReq/IdleAck).
3. PRCM gates-off all the clocks to the power domain.
4. SW requests all clock domains in given power domain to go to “force sleep” mode by programming functional clock domain register in PRCM. PRCM has already gated-off clocks and this register programming may look redundant.
5. SW requests PRCM to take this power domain to OFF state by programming PWRSTCTRL register. This step can be skipped if PWRSTCTRL is permanently programmed to OFF state. When this is done, functional clock domain register decides when power domain is taken to OFF state. Only reason not to have OFF state in PWRSTCTRL is to take power domain to just clock gate state without power gating.
6. PSCON specific to this power domain asserts isolation enable for the domain.
7. PRCM asserts warm and cold reset to the power domain.
8. PSCON asserts control signals to switch-off power using on-die switches.
9. On-die switches sends acknowledge back to PSCON.

2.8.5 Power Domain Power-Up Sequence

Below is the sequence of steps during power-up of a power domain. This sequence is not relevant to ALWAYS_ON power domain as this domain never goes to OFF state as long as the device is powered. This sequence is repeated each time a domain is taken to ON state from OFF (including first time power-up).

There can be multiple reasons to start power-up sequence for a domain. For example it can be due to an interrupt from one of the IPs which is powered-up.

1. SW requests required clock domains inside this power domain to go to force wake-up state by

Copyright © 2011–2013, Texas Instruments Incorporated

programming the functional clock domain register.

2. PRCM enables clocks to the required clock domains.
3. PSCON specific to this power domain asserts control signal to ungate the power.
4. Once power is ungated, on-die switches sends acknowledge back to PSCON.
5. PRCM deasserts cold and warm reset to the power domain.
6. PRCM turns off isolation cells.
7. SW requests PRCM to enable the required module in the power domain by programming the module control register.
8. PRCM initiates and waits for completion of PM protocol to enable the modules (IdleReq/IdleAck).

2.9 Voltage Management Functional Description

This section describes the voltage domains and voltage control architecture. It also explains the interactions between the device and the external power IC.

2.9.1 Overview

The voltage-management architecture of the device is based on voltage sources managed by the PRCM module. They define the voltage domains within the device (see Section 2.8.1, *Voltage Domains*). This partition of the voltage domains ensures independent voltage control of each voltage domain through dedicated SMPS or LDO. The following voltage domains are managed by the PRCM module:

- VDD_ARM_L
- VDD_CORE_L
- VDD_DSP_L
- VDD_HDVICP_L
- LDO_ARM_M
- LDO_CORE_M
- LDO_DSP_M
- LDO_HDVICP_M
- LDO_ARM_ABB
- LDO_DSP_ABB
- LDO_HDVICP_ABB

NOTE: See the device *Datasheet* document for device power supply pin association to the power domain.

Table 2-40 lists the supported DVFS OPPs for each voltage domain. The exact values depend on the silicon; for more information, see the device *Datasheet*.

Table 2-40. Supported DVFS OPPs Summary

Voltage Domain	Operating Point	Control
VDD_ARM_L (cvdd_arm)	OPP100	Hardware and software
	OPP120	
	OPP166	
VDD_HDVICP_L (cvdd_hdvicp)	OPP100	Hardware and software
	OPP120	
	OPP166	
VDD_CORE_L (cvdd)	OPP100	Hardware and software
	OPP120	
	OPP166	
VDD_DSP_L (cvdd_dsp)	OPP100	Hardware and software
	OPP120	
	OPP166	

NOTE: For the supported OPPs for each device in the *Davinci* family, see in the device *Datasheet*.

DVFS OPPs Dependencies

For detailed information about DVFS OPP dependencies, see the device *Datasheet*.

2.9.2 Internal LDOs Control

2.9.2.1 Memory LDOs

Embedded SRAM LDOs (that is, LDO_CORE_M, LDO_HDVICP_M, LDO_ARM_M and LDO_DSP_M) are used to supply power to the split-rail memory arrays. The PRM generates the controls used to select LDO operating mode: on-active, or off.

Split-rail type SRAMs are used in the device to implement the larger memories. These SRAMs feature memory array and periphery logic which are on separate supplies to allow independent power management. Proper memory operation, however, requires the SRAM array voltage to never be operated at a level lower than the SRAM periphery logic.

Memory LDO can switch to on, and off mode:

- On mode: 1.2 V is the normal voltage reference used through all functional OPPs, whenever memories must be functional. When logic voltage level VDD_x_L (where x can be ARM, CORE, HDVICP and DSP) becomes higher than the associated memory voltage level VDD_x_M, the LDO operates in the tracking mode and follows its respective the VDD_x_L voltage level.
- Off mode: 0 V is set when the device switches to off mode.

NOTE: The voltage levels associated with the different modes may depend on the device characteristics.

2.9.2.2 ABB LDOs Control

The ABB LDO supports three voltage modes:

- Bypass mode: In this mode the <x>_ABB LDO is bypassed and outputs the VDD_<x>_L voltages (x refers to ARM, DSP, HDVICP). This mode is activated when ABB is not required, or when voltage domain enters low-power mode.
- ABB Set1: This mode is enabled at OPP_166.
- ABB Set2: This mode is enabled at OPP_120.

The Control module provides the SGX_VBBLDO_CTRL, HDVICP_VBBLDO_CTRL, C674x_DSP_VBBLDO_CTRL, ARM_CORTEX_A8_VBBLDO_CTRL registers for configuration with the following controls:

- LDOBYPASSZ – Bypass the ABB power management
- BBSEL – high selects FBB

The register RAMLDO_CTRL in Control module controls RAM LDOs. It provides following controls:

- AIPOFF - Disable LDO and enables IDDQ mode.
- SRAMALLRET - puts VDDAR in retention mode.
- ABBOFF - shorts VDDAR to VNWA.

2.10 PRCM Registers

The following are memory-mapped registers for the PRCM.

Table 2-41. PRCM Memory Mapped Registers

Module Name	Base Address Offset	Size
PRM_DEVICE	0x0000	256 Bytes
CM_DEVICE	0x0100	256 Bytes
OCP_SOCKET_PRM	0x0200	256 Bytes
CM_DPLL	0x0300	256 Bytes
CM_ACTIVE (DSP)	0x0400	256 Bytes
CM_DEFAULT	0x0500	256 Bytes

Copyright © 2011–2013, Texas Instruments Incorporated

Table 2-41. PRCM Memory Mapped Registers (continued)

Module Name	Base Address Offset	Size
CM_HDVICP	0x0600	256 Bytes
CM_ISS	0x0700	256 Bytes
CM_DSS	0x0800	256 Bytes
CM_SGX530	0x0900	256 Bytes
PRM_ACTIVE (DSP)	0x0A00	256 Bytes
PRM_DEFAULT	0x0B00	256 Bytes
PRM_HDVICP	0x0C00	256 Bytes
PRM_ISP (ISS)	0x0D00	256 Bytes
PRM_DSS	0x0E00	256 Bytes
PRM_SGX530	0x0F00	256 Bytes
CM_ALWON	0x1400	1 KBytes
PRM_ALWON	0x1800	1 KBytes

2.10.1 PLLSS Registers

Table 2-42 lists the memory-mapped registers for the PLLSS. All register offset addresses not listed in Table 2-42 should be considered as reserved locations and the register contents should not be modified.

Table 2-42. PLLSS REGISTERS

Offset	Acronym	Register Name	Section
0h	CONTROL_REVISION	The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.	Section 3.2.1
4h	CONTROL_HWINFO	The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any).	Section 3.2.2
10h	CONTROL_SYSCONFIG	The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the OCP Design Guidelines.	Section 3.2.3
40h	PLLSS_MMR_LOCK	The PLLSS_MMR_LOCK Register is used allow/block writes to the registers in address region Start_Addess_x -End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x -End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of PLLSS_MMR_LOCK registers but they should follow the underlying security specified in each section, e.g. Firewall setting, Non Secure Supervisior etc.	Section 2.10.1.4
48h	MPUPLL_PWRCTRL	The MPU PLL Power Control register is used to control the power state of the MPU _PLL.	Section 2.10.1.5
4Ch	MPUPLL_CLKCTRL	The MPU PLL Clock Control register is used to control the different clock control state of the MPU_PLL	Section 2.10.1.6
50h	MPUPLL_TENABLE	The MPU PLL TENABLE register is used to load the M, N dividers of MPU_PLL	Section 2.10.1.7
54h	MPUPLL_TENABLEDIV	The MPU PLL TENABLEDIV register is used to load the M2,N2 dividers of MPU_PLL	Section 2.10.1.8
58h	MPUPLL_M2NDIV	MPU PLL M2NDIV register is for programming M2 and N values of MPU _PLL	Section 2.10.1.9
5Ch	MPUPLL_MN2DIV	MPU PLL MN2DIV register is for programming M and N2 values of MPU _PLL	Section 2.10.1.10
60h	MPUPLL_FRACDIV	The MPU PLL FRACDIV register is for controlling the fractional values of MPU _PLL	Section 2.10.1.11
64h	MPUPLL_BWCTRL	The MPU PLL_BWCTRL register is for controlling the loop bandwidth of MPU _PLL	Section 2.10.1.12
68h	MPUPLL_FRACCTRL	Controlls the fractional portion of Modena PLL	Section 2.10.1.13
6Ch	MPUPLL_STATUS	The MPU PLL Status register is for viewing the status of the MPU PLL.	Section 2.10.1.14
70h	MPUPLL_M3DIV	The MPU PLL_M3DIV register is for controlling the M3 divider of MPU _PLL	Section 2.10.1.15
74h	MPUPLL_RAMPCTRL	The MPUPLL_RAMPCTRL register is for controlling the ramping of MPU _PLL	Section 2.10.1.16
80h	DSPPLL_PWRCTRL	The PLL Power Control register is used to control the power state of therespective PLL.	Section 2.10.1.17
84h	DSPPLL_CLKCTRL	The PLL Clock Control register is used to control the different clock control state of the respective PLL	Section 2.10.1.18
88h	DSPPLL_TENABLE	Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ.	Section 2.10.1.19
8Ch	DSPPLL_TENABLEDIV	The PLL TENABLEDIV register is used to load the M2,N2 dividers of respective PLL	Section 2.10.1.20

Table 2-42. PLLSS REGISTERS (continued)

Offset	Acronym	Register Name	Section
90h	DSPPLL_M2NDIV	PLL M2NDIV register is for programming M2 and N values of respective PLL	Section 2.10.1.21
94h	DSPPLL_MN2DIV	PLL MN2DIV register is for programming M and N2 values of respective PLL	Section 2.10.1.22
98h	DSPPLL_FRACDIV	The PLL FRACDIV register is for controlling the fractional values of respective PLL	Section 2.10.1.23
9Ch	DSPPLL_BWCTRL	The PLL_BWCTRL register is for controlling the loop bandwidth of respective PLL	Section 2.10.1.24
A0h	DSPPLL_FRACCTRL	Controlls the fractional portion of respective ADPLLLJ.	Section 2.10.1.25
A4h	DSPPLL_STATUS	The PLL Status register is for viewing the status of the respective PLL.	Section 2.10.1.26
B0h	SGXPLLL_PWRCTRL	The PLL Power Control register is used to control the power state of therespective PLL.	Section 2.10.1.27
B4h	SGXPLL_CLKCTRL	The PLL Clock Control register is used to control the different clock control state of the respective PLL	Section 2.10.1.28
B8h	SGXPLLL_TENABLE	Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ.	Section 2.10.1.29
BCh	SGXPLL_TENABLEDIV	The PLL TENABLEDIV register is used to load the M2,N2 dividers of respective PLL	Section 2.10.1.30
C0h	SGXPLL_M2NDIV	PLL M2NDIV register is for programming M2 and N values of respective PLL	Section 2.10.1.31
C4h	SGXPLL_MN2DIV	PLL MN2DIV register is for programming M and N2 values of respective PLL	Section 2.10.1.32
C8h	SGXPLL_FRACDIV	The PLL FRACDIV register is for controlling the fractional values of respective PLL	Section 2.10.1.33
CCh	SGXPLL_BWCTRL	The PLL_BWCTRL register is for controlling the loop bandwidth of respective PLL	Section 2.10.1.34
D0h	SGXPLL_FRACCTRL	Controlls the fractional portion of respective ADPLLLJ.	Section 2.10.1.35
D4h	SGXPLL_STATUS	The PLL Status register is for viewing the status of the respective PLL.	Section 2.10.1.36
E0h	HDVICPPLL_PWRCTRL	The PLL Power Control register is used to control the power state of therespective PLL.	Section 2.10.1.37
E4h	HDVICPPLL_CLKCTRL	The PLL Clock Control register is used to control the different clock control state of the respective PLL	Section 2.10.1.38
E8h	HDVICPPLL_TENABLE	Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ.	Section 2.10.1.39
ECh	HDVICPPLL_TENABLEDIV	The PLL TENABLEDIV register is used to load the M2,N2 dividers of respective PLL	Section 2.10.1.40
F0h	HDVICPPLL_M2NDIV	PLL M2NDIV register is for programming M2 and N values of respective PLL	Section 2.10.1.41
F4h	HDVICPPLL_MN2DIV	PLL MN2DIV register is for programming M and N2 values of respective PLL	Section 2.10.1.42
F8h	HDVICPPLL_FRACDIV	The PLL FRACDIV register is for controlling the fractional values of respective PLL	Section 2.10.1.43
FCh	HDVICPPLL_BWCTRL	The PLL_BWCTRL register is for controlling the loop bandwidth of respective PLL	Section 2.10.1.44
100h	HDVICPPLL_FRACCTRL	Controlls the fractional portion of respective ADPLLLJ.	Section 2.10.1.45
104h	HDVICPPLL_STATUS	The PLL Status register is for viewing the status of the respective PLL.	Section 2.10.1.46
110h	L3PLL_PWRCTRL	The PLL Power Control register is used to control the power state of therespective PLL.	Section 2.10.1.47
114h	L3PLL_CLKCTRL	The PLL Clock Control register is used to control the different clock control state of the respective PLL	Section 2.10.1.48
118h	L3PLL_TENABLE	Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ.	Section 2.10.1.49

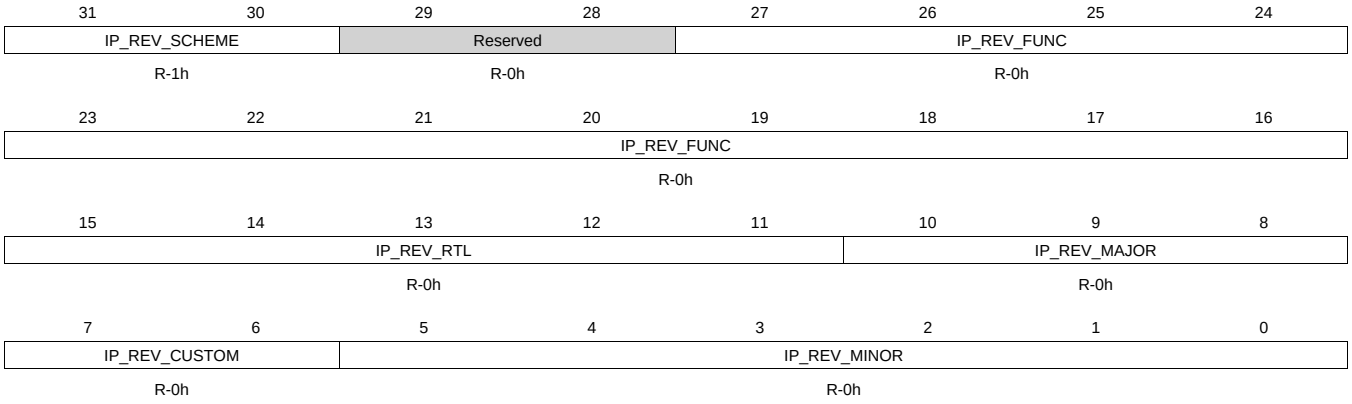
2.10.1.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h]

CONTROL_REVISION is shown in Figure 3-2 and described in Table 3-4.

The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.

Figure 2-27. CONTROL_REVISION Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 2-43. CONTROL_REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	IP_REV_SCHEME	R	1h	Used to distinguish register scheme 0x0: Legacy (ASP or WTBU) scheme 0x1: Highlander 0.8 scheme
29-28	Reserved	R	0h	
27-16	IP_REV_FUNC	R	0h	Function indicates a software compatible module family. If there is no level of software compatibility a new Func number (and hence REVISION) should be assigned.
15-11	IP_REV_RTL	R	0h	RTL Version (R), maintained by IP design owner.
10-8	IP_REV_MAJOR	R	0h	Major Revision (X), maintained by IP specification owner.
7-6	IP_REV_CUSTOM	R	0h	Indicates a special version for a particular device. Consequence of use may avoid use of standard Chip Support Library (CSL) / Drivers
5-0	IP_REV_MINOR	R	0h	Minor Revision (Y), maintained by IP specification owner.

2.10.1.4 PLLSS_MMR_LOCK Register (offset = 40h) [reset = 1F125B64h]

PLLSS_MMR_LOCK is shown in Figure 2-30 and described in Table 2-46.

The PLLSS_MMR_LOCK Register is used allow/block writes to the registers in address region Start_Addess_x -End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x -End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of PLLSS_MMR_LOCK registers but they should follow the underlying security specified in each section, e.g. Firewall setting, Non Secure Supervisior etc.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 2-178. DDRPLL_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	PONOUT	R	1h	status of the weak power-switch 0x0 : indicates the/OFF status of the weak power-switch in digital to SOC. 0x1 : ndicates the ON status of the weak power-switch in digital to SOC.
30	PGOODOUT	R	1h	status of the strong power-switch 0x0 : indicates the/OFF status of the strong power-switch in digital to SOC. 0x1 : ndicates the ON status of the strong power-switch in digital to SOC.
29	LDOPWDN	R	0h	1 indicates ADPLLLJ internal LDO is power down. VDDLDOOUT will be un-defined in this condition.
28	RECAL_BSTATUS3	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration)
27	RECAL_OPPIN	R	0h	Recalibration status flag. 1 ADPLLLJ requires recalibration)
26-11	Reserved	R	0h	
10	PHASELOCK	R	0h	Status on PHASELOCK output pin
9	FREQLOCK	R	0h	Status on FREQLOCK output pin
8	BYPASSACK	R	1h	Status of BYPASSACK output pin
7	STBYRETACK	R	0h	Standby and retention status 0x0 : indicates to SOC that all internal clocks in ADPLLLJ are active and it is starting the relock process. 0x1 : indicates to SOC that all internal clocks in ADPLLLJ are gated and it is ready for retention.
6	LOSSREF	R	0h	Reference input loss
5	CLKOUTENACK	R	1h	1 /0indicates enable/disable condition of CLKOUTEN
4	LOCK2	R	0h	ADPLL internal loop lock status
3	M2CHANGEACK	R	0h	acknowledge for M2 change

Table 2-200. CM_CLKOUT_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7	CLKOUTEN	R/W	0h	This bit controls the external clock activity 0x0: DIS : SYS_CLKOUT is disabled 0x1: EN : SYS_CLKOUT is enabled
6	Reserved	R	0h	
5-3	CLKOUTDIV	R/W	0h	This field controls the external clock divison factor of the CLKOUT Second Pin CLKOUT2 0x0 = SYS_CLKOUT2/1 0x1 = SYS_CLKOUT2/2 0x2 = SYS_CLKOUT2/3 0x3 = SYS_CLKOUT2/4 0x4 = SYS_CLKOUT2/5 0x5 = SYS_CLKOUT2/6 0x6 = SYS_CLKOUT2/7 0x7 = SYS_CLKOUT2/8
2	Reserved	R	0h	
1-0	CLKOUTSOURCE	R/W	0h	This field selects the external output clock source 0x0: MAIN_PLL_CLK : DEVOSC clock 0x1: DPLL_DSP_CLK : USB PLL clock output 0x2: VIDEO_PLL_CLK : VIDEO0 PLL clock output 0x3: AUDIO_PLL_CLK : RTCDIVIDER output

2.10.4 OCP_SOCKET_PRM Registers

Table 2-201 lists the memory-mapped registers for the OCP_SOCKET_PRM. All register offset addresses not listed in Table 2-201 should be considered as reserved locations and the register contents should not be modified.

2.10.11.1 CM_SGX_CLKSTCTRL Register (offset = 0h) [reset = 1h]

CM_SGX_CLKSTCTRL is shown in Figure 2-221 and described in Table 2-247.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

2.10.17.3 PM_SGX_PWRSTST Register (offset = 10h) [reset = 17h]

PM_SGX_PWRSTST is shown in Figure 2-244 and described in Table 2-276.

This register provides a status on the current HDVICP power domain state. [warm reset insensitive]

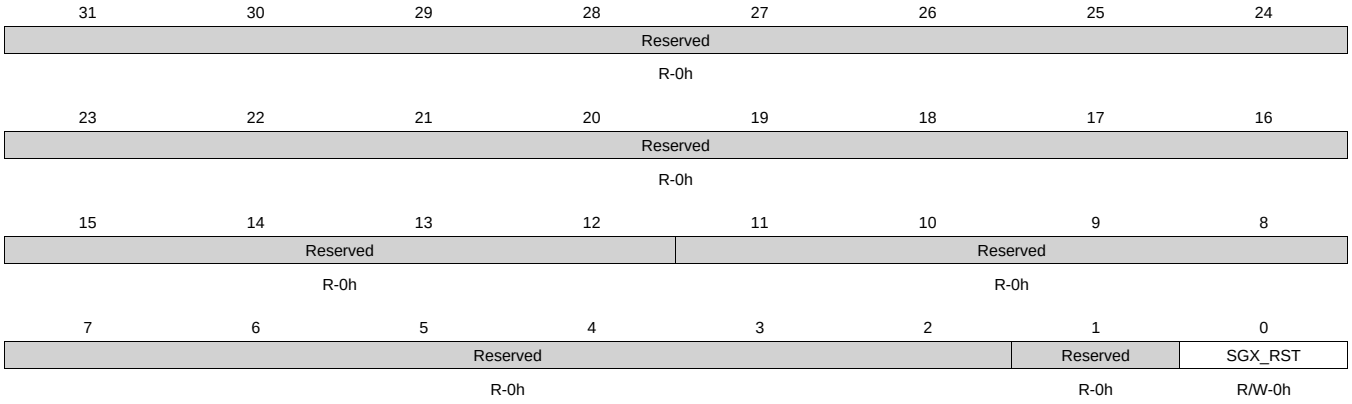
2.10.17.4 RM_SGX_RSTST Register (offset = 14h) [reset = 0h]

RM_SGX_RSTST is shown in Figure 2-245 and described in Table 2-277.

This register logs the different reset sources of the SGX domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

Figure 2-245. RM_SGX_RSTST Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

2.10.18.1 CM_ALWON_L3_SLOW_CLKSTCTRL Register (offset = 0h) [reset = C002h]

CM_ALWON_L3_SLOW_CLKSTCTRL is shown in Figure 2-246 and described in Table 2-279.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

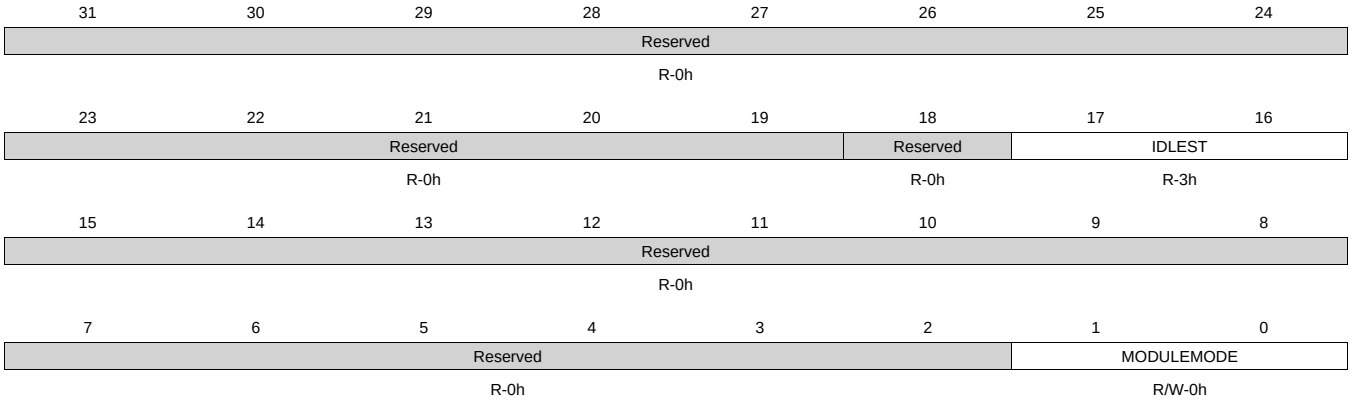
2.10.18.18 CM_ALWON_UART_0_CLKCTRL Register (offset = 150h) [reset = 30000h]

CM_ALWON_UART_0_CLKCTRL is shown in Figure 2-263 and described in Table 2-296.

This register manages the UART_0 clocks.

Figure 2-263. CM_ALWON_UART_0_CLKCTRL Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 2-296. CM_ALWON_UART_0_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	Reserved	R	0h	
18	Reserved	R	0h	
17-16	IDLEST	R	3h	Module idle status. 0x0: Func: Module is fully functional, including INTERCONN 0x1: Trans: Module is performing transition: wakeup, or sleep, or sleep abortion 0x2: Idle: Module is in Idle mode (only INTERCONN part). It is functional if using separate functional clock 0x3: Disable: Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. 0x0: DISABLED: Module is disable by SW. Any INTERCONN access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: RESERVED 0x2: ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 0x3: RESERVED

Table 2-322. CM_ALWON_DEBUGSS_CLKCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	STBYST	R	0h	Module standby status. 0x0: Func: Module is functional (not in standby) 0x1: Standby: Module is in standby
17-16	IDLEST	R	0h	Module idle status. 0x0: Func: Module is fully functional, including INTERCONN 0x1: Trans: Module is performing transition: wakeup, or sleep, or sleep abortion 0x2: Idle: Module is in Idle mode (only INTERCONN part). It is functional if using separate functional clock 0x3: Disable: Module is disabled and cannot be accessed
15-10	Reserved	R	0h	
9	OPTCLK_DEBUG_CLKA	R/W	1h	Optional functional clock control. 0x0 FCLK_DIS: Optional functional clock is disabled 0x1: FCLK_EN: Optional functional clock is enabled
8	OPTCLK_DEBUG_SYSCLK	R/W	1h	Optional functional clock control. 0x0: FCLK_DIS: Optional functional clock is disabled 0x1: FCLK_EN: Optional functional clock is enabled
7-2	Reserved	R	0h	
1-0	MODULEMODE	R	2h	Control the way mandatory clocks are managed. 0x0: Reserved 0x1: Reserved 0x2: ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 0x3: Reserved

Control Module

This chapter provides information about the control module.

Topic **Page**

3.1 Control Module 832
3.2 CONTROL_MODULE Registers 836

Copyright © 2011–2013, Texas Instruments Incorporated

3.1 Control Module

This device contains a system-level control logic block. The control module includes status and control logic not addressed within the peripherals or the rest of the device infrastructure.

This module is the primary point of control for the following areas of the device:

- Functional I/O multiplexing
- Device status
- Static device configuration
- Reset isolation logic inside the chip control module
- Lock/unlock mechanism for section of MMR inside the chip control module

The device control module primarily implements a bank of registers accessible (read/write) by the software along with some read-only registers carrying status information.

Note: The following operating systems and devices are used interchangeably throughout this chapter:

- DSP and C674x
- MPU and CORTEX-A8

The Control Module registers are documented in the section *CONTROL_MODULE Registers*. The following sections give an overview of the most important functionality provided by the Control Module.

NOTE: A processor (or other bus master) must be operating in the Supervisor privilege state in order to write to the control module registers. Registers are readable in either User or Supervisor privilege state.

3.1.1 MMR_LOCK Register (Locked/Unlocked States)

The control module is segmented into 5 regions that are protected by a corresponding MMR_LOCKx register. The intent of the LOCK/UNLOCK mechanism is to prevent critical registers from being corrupted by undesired or malicious writes to the memory mapped addresses.

These regions default to LOCKED state, at which time the corresponding MMRs cannot be written. In order to write to the MMRs of the corresponding region, software must first UNLOCK the region by writing a specified 32-b value to the MMR_LOCKx register. At that point, the MMRs can be successfully written. Software should, in general, relock the registers after the necessary accesses have been done.

Table 3-1 summarizes the MMR_LOCKx registers including offset address range that is protected by each register.

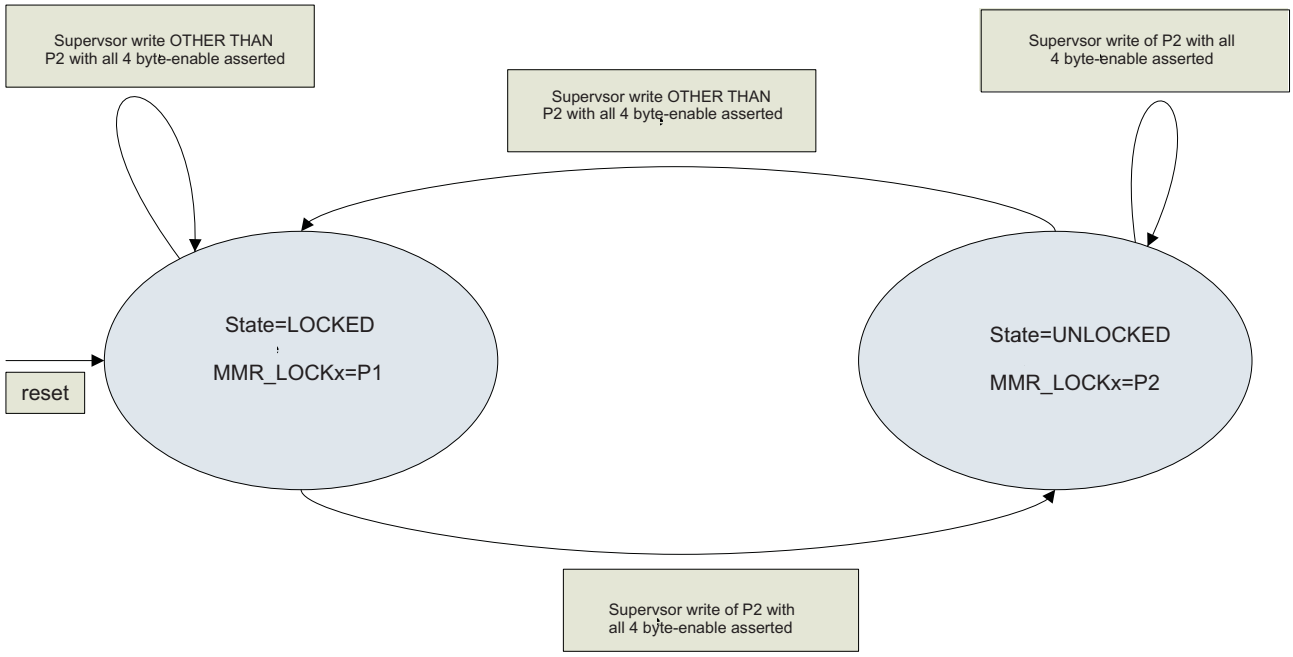
Table 3-1. MMR_LOCKx Registers

Register Name	LOCKED State (register value=P1)	UNLOCKED State (register value=P2)	Start_Addess_x	End_Address_x
MMR_LOCK0	0x1A1C 8144	0x2FF1 AC2B	0x0400	0x05FF
MMR_LOCK1	0xFDF4 5530	0xF757 FDC0	0x0600	0x07FF
MMR_LOCK2	0x1AE6 E320	0xE2BC 3A6D	0x0800	0x0FFF
MMR_LOCK3	0x2FFA 927C	0x1EBF 131D	0x1000	0x12FF
MMR_LOCK4	0x143F 832C	0x6F36 1E05	0x1300	0x17FF

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 3-1 shows the transition from locked to unlocked state for the MMR_LOCK register.

Figure 3-1. MMR_LOCKx Transition from LOCKED/UNLOCKED State



Note: Non-supervisor writes should not reach this register.
Reads should always return the value P1 or P2, depending on the state.

3.1.2 Pin Multiplexing (Pin Mux)

Many I/O pin can be internally routed to/from one of several peripheral modules within the device. This routing is referred to as Pin Multiplexing. Pin Multiplexing allows software to choose the subset of internal signals which will be mapped to balls of the device for a given application.

Device-level pin multiplexing is controlled on a pin-by-pin basis by the MUXMODE bits of the PINCNTL1 – PINCNTL270 registers in this control module. The PINCNTLx registers' descriptions and functions can be found in the device data manual, *Pin Multiplexing Control* section.

A second level of pin selection is provided via specific control module registers. The secondary control is described in the following sections.

3.1.2.1 Other Pin Muxing Control

The GPIO_MUX register is used to select whether specific GPIO pins are sourced from device inputs or from internal interrupt sources. Refer to the register description for details.

The GMII_SEL register is used to select between GMII/MII, RMII, and RGMII modes of operation.

3.1.2.2 Special Muxing of GPIO1[7:10] Signals

The GPIO1[7:10] signals can be mapped on the following device balls:

- GPIO1[7] - on device ball W1
- GPIO1[8] - on device ball W2
- GPIO1[9] - on device ball V1
- GPIO1[10] - on device ball V2

To ensure this mapping, the user must not only configure the PINCTNL[62:65] registers properly, but also make the following settings in the MLBP_SIG_IO_CTRL and MLBP_DAT_IO_CTRL registers:

- MLBP_SIG_IO_CTRL register:

Copyright © 2011–2013, Texas Instruments Incorporated

  - Set bit [2] ENLVCMOS to '1' to map GPIO1[7] on device ball W1 and GPIO1[8] on device ball W2.
  - Set bit [1] ENN to '0' to enable GPIO1[8] as output; or set this bit to '1' to enable GPIO1[8] as input.
  - Set bit [0] ENP to '0' to enable GPIO1[7] as output; or set this bit to '1' to enable GPIO1[7] as input.
- MLBP_DAT_IO_CTRL register:
  - Set bit [2] ENLVCMOS to '1' to map GPIO1[9] on device ball V1 and GPIO1[10] on device ball V2.
  - Set bit [1] ENN to '0' to enable GPIO1[10] as output; or set this bit to '1' to enable GPIO1[10] as input.
  - Set bit [0] ENP to '0' to enable GPIO1[9] as output; or set this bit to '1' to enable GPIO1[9] as input.

NOTE: The GPIO[7:10] signals can also be mapped on other device balls. The MLBP_SIG_IO_CTRL and MLBP_DAT_IO_CTRL settings are only necessary for mapping GPIO1[7:10] to the [W1, W2, V1, V2] device balls. For more information about device balls mapping, see device data manual.

3.1.3 BOOT Status

The Control Module CONTROL_STATUS and BOOTSTAT register allows the software to poll the status of the device boot to determine which boot sequence was detected and if any boot errors persist.

This register can be used by software for verification of a (un)successful boot and if necessary display error messages to the user.

3.1.4 DSP / EDMA Memory Management Unit Configuration

The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU, accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance. MMU_CFG Additional details are provided in the *System MMU* chapter.

3.1.5 Interrupt and DMA Controller Crossbars

The device contains a large number of system interrupts that are triggered by on chip events. Each CPU has an interrupt controller which allows a limited number of system events to trigger a CPU interrupt.

For the device DSP and Media Controller, to accommodate CPU interrupt generation by all system events, an Interrupt Event Crossbar precedes their corresponding interrupt controllers. To allow a multiple DMA request sources mapping versus each line of the device EDMA subsystem, a DMA Event Crossbar precedes the EDMA3CC controller. This allows a flexible mapping where any input to the Interrupt / DMA event Crossbar can be mapped to any of the interrupt/event outputs of the crossbar (which maps to inputs to the processor interrupt controller or device DMA controller).

This functionality is controlled by the DSP_INTMUX, Media_Controller_INTMUX and EDMA3CC_EVTMUX registers, which format is briefly described in below sections.

3.1.5.1 DSP Interrupt Mux

Each DSP Interrupt mux is controlled by a MMR field which is 6 bit in length (of which only the 5 LSBs are used) .This field value descriptions are available in table *DSP INTC Interrupt Crossbar Mapping* of the section, *Interrupt Requests to DSP INTC*.

This MMR field DSP_INT_MUX_[#int_number], where #int_number is the interrupt number at GEM boundary.There is not interrupt mux for GEM interrupt number a) 0 to 14 and b) 96 to 127 so the range of #int_number is 15 to 95.

Copyright © 2011–2013, Texas Instruments Incorporated

After reset DSP_INT_MUX_[#int_number] defaults to 0b000000, which maps the interrupt from default mapping to interrupt_[#int_number], e.g. interrupt_15's default mapping is MMCHS0's SDINT, interrupt_16's default mapping is McSPI0's SPIINT etc. The mapping for other values of DSP_INT_MUX_[#int_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

3.1.5.2 Media Controller Interrupt Mux

Each Media Controller interrupt mux is controlled by a MMR field which is 6 bit in length. This field value descriptions are available in table *Media Controller INTC Interrupt Crossbar Mapping* of the section, *Interrupt Requests to Media Controller*.

This MMR field Media_Controller_INT_MUX_[#int_number], where #int_number is the interrupt number at Media Controller boundary. The range of #int_number is 0 to 56.

After reset Media_Controller_INT_MUX_[#int_number] defaults to 0b000000, which maps the interrupt from default mapping to Media_Controller_interrupt_[#int_number], e.g. interrupt_0's default mapping is HDMI's HDMIINT, interrupt_2's default mapping is Timer1's TINT1, etc. The mapping for other values of Media_Controller_INT_MUX_[#int_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

3.1.5.3 EDMA3CC Event Mux

Each EDMA3CC (TPCC) Event mux is controlled by a MMR field which is 6 bit in length (of which only the 5 LSBs are used). This field value descriptions are available in table *EDMA Multiplexed Synchronization Events* of the section, *EDMA Channel Synchronization Events*.

This MMR field EDMA3CC_MUX_[evt_number], where #evt_number is the event number at EDMA3CC boundary. The range of #evt_number is 0 to 63.

After reset EDMA3CC_MUX_[#evt_number] defaults to 0b000000, which maps the event from default mapping to event_[#evt_number], e.g. EDMA3CC event_0's default mapping is VCP's VCPREVT0, EDMA3CC event_1's default mapping is VCP's VCPXEVT0etc. The mapping for other values of EDMA3CC_MUX_[#evt_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

3.1.6 Device Level Peripheral Configuration

Various peripherals within the device contain various device level configuration that are not contained within the peripheral configuration registers. Device level configuration includes Power Management, MAC Address, USB Configuration / Status Registers, USB Product ID, Vendor ID Registers and PCIe Vendor ID, Product ID Registers.

3.1.7 Reset Isolation

The device supports reset isolation for the Ethernet Subsystem. For more information refer to the section *Reset Isolation* of the chapter, *Power, Reset, and Clock Management (PRCM) Module*.

Table 3-2 describes the subset of device pins and the corresponding PINCNTLx registers that can be reset-isolated. The specific combination of pins that are enabled for isolation is controlled by the RESET_ISO register and is detailed in the Register section of this chapter. In summary, the ISO_CONTROL field can enable/disable reset isolation. The GMII_ISO, RMII_ISO0, and RMII_ISO1 fields control which subset of the Pin Groups (and PINCNTL registers) are selected for reset isolation.

Table 3-2. List of PINCNTLx Registers, reset affected by RESET_ISO.

RESET_ISO Pin Group	Associated PINCNTL Registers
MDIO/MDCLK	PINCNTL233 to PINCNTL234
EMAC[1]_Mx/Other(1)	PINCNTL204 to PINCNTL227
EMAC[0]_Mx/EMAC[1:0]_RGx	PINCNTL235 to PINCNTL258
EMAC_RMREFCLK	PINCNTL232

(1) Several pins not related to the Ethernet Subsystem are included in this Pin Group for device compatibility.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 3-2. List of PINCNTLx Registers, reset affected by RESET_ISO. (continued)

RESET_ISO Pin Group	Associated PINCNTL Registers
EMAC[1]_RMx_MUX0	PINCNTL252 to PINCNTL258
EMAC[1]_RMx_MUX1	PINCNTL157 to PINCNTL163
EMAC[0]_RMx	PINCNTL236 to PINCNTL242

3.2 CONTROL_MODULE Registers

Table 3-3 lists the memory-mapped registers for the CONTROL_MODULE. All register offset addresses not listed in Table 3-3 should be considered as reserved locations and the register contents should not be modified.

All these registers can only be modified by SUPERVISR mode access.

Table 3-3. CONTROL_MODULE REGISTERS

Offset	Acronym	Register Name	Section
0h	CONTROL_REVISION	The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.	Section 3.2.1
4h	CONTROL_HWINFO	The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any).	Section 3.2.2
10h	CONTROL_SYSCONFIG	The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the register implements various standby and emulation control bits.	Section 3.2.3
40h	CONTROL_STATUS	The CONTROL_STATUS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) or warm reset (RESETz) signal goes high.	Section 3.2.4
44h	BOOTSTAT	The Boot Status (BOOTSTAT) register indicates the status of the device boot process	Section 3.2.5
48h	DSPBOOTADDR	The DSP boot address defaults to 0x00800000 (C674x_DSP L2 space). The Host ARM must place DSP boot code into C674x_DSP L2 prior to releasing C674x_DSP reset or change the DSPBOOTADDR to point to the code location. The DSPBOOTADDR register is reset to its default value by a hard reset only and retains its current value over a soft reset.	Section 3.2.6
60h	MMR_LOCK0	The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.	Section 3.2.7
64h	MMR_LOCK1	The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.	Section 3.2.8

Copyright © 2011–2013, Texas Instruments Incorporated

Table 3-3. CONTROL_MODULE REGISTERS (continued)

Offset	Acronym	Register Name	Section
68h	MMR_LOCK2	The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.	Section 3.2.9
6Ch	MMR_LOCK3	The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.	Section 3.2.10
70h	MMR_LOCK4	The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.	Section 3.2.11
100h	CONTROL_SEC_CTRL	Security Control Register	Section 3.2.12
468h	DEVOSC	Oscillator 0 Control. Note for deepsleep: - 1st program bit16 (DSPOLARITY) of register DEEPSLEEP_CTRL to the desired polarity - To enter deepsleep mode, set bit 17 (DSENABLE) of DEEPSLEEP_CTRL to 1. - To exit, toggle the external pin DEEPSLEEPZ.	Section 3.2.13
46Ch	AUXOSC	Oscillator 1 Control	Section 3.2.14
480h	PCIE_CFG	5.6.20. PCIE Configuration Register	Section 3.2.15
600h	DEVICE_ID	The DEVICE_ID register contains a software readable version of the device JTAG ID. Software can use this register to determine the version of the device on which it is executing.	Section 3.2.16
604h	DEV_FEATURE	The DEV_FEATURE register reflects the eFuse settings enabling or disabling certain device functions and capabilities. Note that DEV_FEATURE bits are all implemented as feature enabled bits. This may require inverting the value of those eFuses which are implemented as disable signals.	Section 3.2.17
608h	INIT_PRIORITY_0	The INIT_PRIORITY_0 register configures the infrastructure pressure input for L3 initiators to provide dynamic priority escalation.	Section 3.2.18
60Ch	INIT_PRIORITY_1	The INIT_PRIORITY_1 register configures the infrastructure pressure input for L3 initiators to provide dynamic priority escalation.	Section 3.2.19
610h	MMU_CFG	The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance.	Section 3.2.20
614h	TPTC_CFG	The TPTC_CFG register configures the default burst size for TPTC0, 1, 2, and 3.	Section 3.2.21

62Ch	USB_STS1	USB Status Register 1 reflects the status of the USB0.	Section 3.2.26
630h	MAC_ID0_LO	The MAC_ID0_LO register contains the lower 2 bytes of the 48-bit ID for MAC0.	Section 3.2.27
634h	MAC_ID0_HI	The MAC_ID0_HI register contains the upper 4 bytes of the 48-bit ID for MAC0.	Section 3.2.28
638h	MAC_ID1_LO	The MAC_ID1_LO register contains the lower 2 bytes of the 48-bit ID for MAC1.	Section 3.2.29
63Ch	MAC_ID1_HI	The MAC_ID1_HI register contains the upper 4 bytes of the 48-bit ID for MAC1.	Section 3.2.30
640h	SW_REVISION	The SW_REVISION register reads the Paper Spin Variant 32bit efuse. The SW can read this bit and decide what to do with a specific SW package.	Section 3.2.31
644h	DCAN_RAMINIT	The DCAN_RAMINIT register is used to start/check status of the autoinitialization process of DCAN RAM.	Section 3.2.32
64Ch	AUD_CTRL	The register controls loopback of McBSP data for testing purposes.	Section 3.2.33
650h	GMII_SEL	Ethernet GMII Select	Section 3.2.34
654h	OCMEM_PWRDN	The OCMEM_PWRDN Register determines the powerdown behavior of the OCMC RAM memories.	Section 3.2.35
65Ch	MEDIA_CONTROLLER_MEM_PWRDN	The MEDIA_CONTROLLER_MEM_PWRDN Register determines the powerdown behavior of the Media Controller memories.	Section 3.2.36
670h	SD_DAC_CTRL	The SD_DAC_CTRL Register controls operation of the Standard Definition video DACs.	Section 3.2.37
674h	SD_DAC0_CAL	The SD_DAC0_CAL Register is used to calibrate the output level of SD DAC 0 (SD Y). Users can use this register to drive a known value to the DAC input for performing system video level calibration.	Section 3.2.38
678h	SD_DAC1_CAL	The SD_DAC1_CAL Register is used to calibrate the output level of SD DAC 1 (SD C). Users can use this register to drive a known value to the DAC input for performing system video level calibration.	Section 3.2.39
67Ch	SD_DAC0_REGCTRL	The SD_DAC0_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked).	Section 3.2.40
680h	SD_DAC0_REGSTATUS	The SD_DAC0_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked).	Section 3.2.41
684h	SD_DAC1_REGCTRL	The SD_DAC1_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked).	Section 3.2.42
688h	SD_DAC1_REGSTATUS	The SD_DAC1_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked).	Section 3.2.43
694h	EMIF_CLK_GATE	This register provides a mechanism to control clock gating of DDR PHYs and see status of Self Refresh.	Section 3.2.44

3.2.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h]

CONTROL_REVISION is shown in Figure 3-2 and described in Table 3-4.

The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.

Figure 3-2. CONTROL_REVISION Register

31	30	29	28	27	26	25	24

3.2.2 CONTROL_HWINFO Register (offset = 4h) [reset = 0h]

CONTROL_HWINFO is shown in Figure 3-3 and described in Table 3-5.

The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any).

Figure 3-3. CONTROL_HWINFO Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3.2.3 CONTROL_SYSCONFIG Register (offset = 10h) [reset = 0h]

CONTROL_SYSCONFIG is shown in Figure 3-4 and described in Table 3-6.

The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the register implements various standby and emulation control bits.

3.2.4 CONTROL_STATUS Register (offset = 40h) [reset = 0h]

CONTROL_STATUS is shown in Figure 3-5 and described in Table 3-7.

The CONTROL_STATUS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) or warm reset (RESETz) signal goes high.

Figure 3-5. CONTROL_STATUS Register

31	30	29	28	27	26	25	24

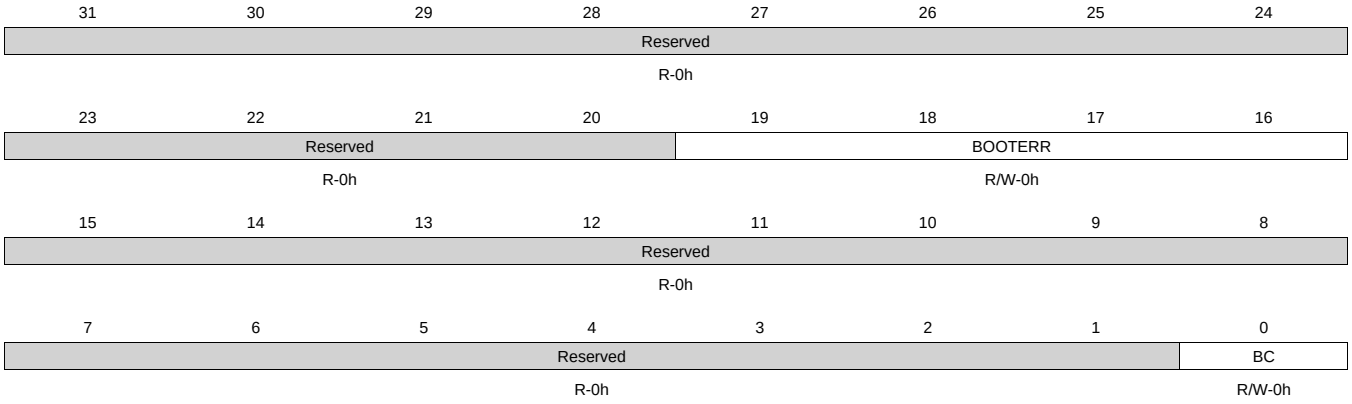
3.2.5 BOOTSTAT Register (offset = 44h) [reset = 0h]

BOOTSTAT is shown in Figure 3-6 and described in Table 3-8.

The Boot Status (BOOTSTAT) register indicates the status of the device boot process

Figure 3-6. BOOTSTAT Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 3-8. BOOTSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	Reserved	R	0h	
19-16	BOOTERR	R/W	0h	Boot Error The exact meaning of the various error codes will be determined by the bootloader software. 0x0: No Boot Error 0x1: Others. Bootloader detected boot error
15-1	Reserved	R	0h	
0	BC	R/W	0h	Boot Complete.This bit may be optionally set by a host boot device to indicate that it has finished loading code. The Host ARM can poll this bit to determine whether to continue the boot process 0x0 : Host hasn't complete boot seq. 0x1 : Host boot sequence is complete

Copyright © 2011–2013, Texas Instruments Incorporated

3.2.6 DSPBOOTADDR Register (offset = 48h) [reset = 800000h]

DSPBOOTADDR is shown in Figure 3-7 and described in Table 3-9.

The DSP boot address defaults to 0x00800000 (C674x_DSP L2 space). The Host ARM must place DSP boot code into C674x_DSP L2 prior to releasing C674x_DSP reset or change the DSPBOOTADDR to point to the code location. The DSPBOOTADDR register is reset to its default value by a hard reset only and retains its current value over a soft reset.

3.2.7 MMR_LOCK0 Register (offset = 60h) [reset = 1A1C8144h]

MMR_LOCK0 is shown in Figure 3-8 and described in Table 3-10.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

3.2.8 MMR_LOCK1 Register (offset = 64h) [reset = FDF45530h]

MMR_LOCK1 is shown in Figure 3-9 and described in Table 3-11.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

3.2.20 MMU_CFG Register (offset = 610h) [reset = 80h]

MMU_CFG is shown in Figure 3-21 and described in Table 3-23.

The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance.

Figure 3-21. MMU_CFG Register

3.2.30 MAC_ID1_HI Register (offset = 63Ch) [reset = 0h]

MAC_ID1_HI is shown in Figure 3-31 and described in Table 3-33.

The MAC_ID1_HI register contains the upper 4 bytes of the 48-bit ID for MAC1.

Figure 3-31. MAC_ID1_HI Register

3.2.31 SW_REVISION Register (offset = 640h) [reset = 0h]

SW_REVISION is shown in Figure 3-32 and described in Table 3-34.

The SW_REVISION register reads the Paper Spin Variant 32bit efuse. The SW can read this bit and decide what to do with a specific SW package.

Figure 3-32. SW_REVISION Register

Table 3-40. SD_DAC_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	DAC0_cm2	R/W	0h	Optional control used only for dual-channel configuration. It should be low by default (single-channel configuration). 0x0 : Module configured as Luma video channel (dual-channel configuration) or Composite video channel (single-channel configuration) 0x1 : Module configured as Chroma video channel (dual-channel configuration, see section 7.5.1)
17	DAC0_cm1	R/W	0h	Optional control for lower output swing. It should be low by default (high output swing). 0x0 : High full-scale output swing 0x1 : Low full-scale output swing.
16	DAC0_cm0	R/W	0h	Optional control for internal current reference. It should be low by default (external current reference). 0x0 : External current reference (external resistor connected to rset) 0x1 : DO NOT USE. The switched-capacitor resistor has been removed.
15-9	Reserved	R	0h	
8	TVOUTBYPASS	R/W	0h	TVOUT Bypass Signal. signal. Active high. Video Buffer is bypassed when tvoutbypass is high. Static Signal
7	ACEN	R/W	1h	AC coupling enable. Active high. Must be set low for DC coupling, high for AC coupling. Static signal.
6	INPUTINV	R/W	1h	Inversion of din[9:0]. Active high. It allows polarity alignment with Video Encoder data. It should be LOW for inverted video input data and HIGH for non-inverted video input data. Static signal.
5	DEMEN	R/W	0h	Dynamic Element Matching (DEM) enable. signal. Active high. When high DEM logic is enabled. Static Signal
4	PBNDACz	R/W	0h	DAC Power-Down Control Input. Active low. When low puts the entire DAC channel in power down mode, except the Bandgap and the internal LDO. 0x0 : DAC is powered down 0x1 : DAC is functional
3	PBNBGz	R/W	0h	Bandgap (BG) Power-Down Control. internal LDO in power down mode. Active low. When low puts Bandgap and internal LDO in power down mode. 0x0 : DAC BG is powereddown 0x1 : DAC BG is functional
2	OFFMODE	R/W	1h	Master power-down pin from a permanent (always-on) supply. Active high. When high it powers down all analog blocks regardless of the state of other power control pins. This pin must be used to power down if VDD is turned off. 0x0 : DAC normal operation 0x1 : DAC powered down
1	SD_CALSEL	R/W	1h	SD DAC Calibration Select Controls the video path mux between the Display Subsystem SD output and calibration register values. 0x0 : Output calibration value 0x1 : Normal operation (DSS output)
0	RESETz	R/W	0h	Reset signal. Asynchronous. Active low. When low, it resets data registers to mid-code (10000000) which is the default value. This signal can only be toggled when VDDA is ON.

3.2.38 SD_DAC0_CAL Register (offset = 674h) [reset = 0h]

SD_DAC0_CAL is shown in Figure 3-39 and described in Table 3-41.

The SD_DAC0_CAL Register is used to calibrate the output level of SD DAC 0 (SD Y). Users can use this register to drive a known value to the DAC input for performing system video level calibration.

3.2.45 SMRT_CTRL Register (offset = 6A0h) [reset = 0h]

SMRT_CTRL is shown in Figure 3-46 and described in Table 3-48.

The SMRT_CTRL Register reflects the control for the srsleep signal for the SRs .

3.2.46 ARM_CORTEX_A8_HW_DBG_SEL Register (offset = 6A4h) [reset = 0h]

ARM_CORTEX_A8_HW_DBG_SEL is shown in Figure 3-47 and described in Table 3-49.

This register controls what kind of debug info is returned by ARM Cortex-A8.

30	DIGCLRZ	R/W	1h	CLRZ for APLL DIG and DLL DIG. Used to reset flops and state machines
29-28	Reserved	R/W	0h	Reserved
27	AMUXSEL	R/W	0h	AMUX select : 0b0 = KVCO 0b1 = VRTRIM
26	TESTCLKMUXSEL	R/W	0h	Selects test clock mux : 0b0=REF Clock 0b1=Divided clock
25-20	APLL_MISC_CTRL	R/W	0h	Used by APLL DIG **Bitfield [21:20]** encoding is : 0b00 = No step 0b01 = 75% to 100% 0b10 = 75% to 87.5% to 100% in 60, 20 , 20 cycle steps 0b11 = same as 0b10 but in 40, 40, 40 cycle steps **Bit 22** specifies power saving : 0b0 = Default mode 0b1 = Used for debug **Bit 23** function is: 0b0 = fixed divider 0b1 = programmable divider **Bit 24** is for 50 MHz rtrim disable **Bit 25** controls the lock speed : 0 = 128 clock 1 = 256 clock

Copyright © 2011–2013, Texas Instruments Incorporated

Table 3-53. PCIE_PLLCFG0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	DIS_REFCLK	R/W	0h	Disable CML that control FREF output clock buffer. 0=Enable, 1= Disable
18	EN_3P	R/W	0h	Post_Cent_PG1.0. When high, enables the SC circuit in the APLL LF Pre_Cent_PG1.0. Logic '1' generates single phase output and puts other phases at '0' using 3-phase ring oscillator 0 = 4-phase output 1 = single phase output
17	PFD_CLR	R/W	0h	To open PLL loop; 0 = Closed loop, 1 = Open loop
16	CLK_FLIP	R/W	0h	Logic '1' flips the output clock phase
15	EN_RTRIM	R/W	0h	Enable resistor calibration 0=OFF, 1=ON
14	EN_MEAS	R/W	1h	To enable measurement circuit inside APLL ANA to control AMUX output. 0 = OFF, 1 = ON
13-12	EN_LATCH	R/W	3h	Enables output latch in differential ring to control power. Designer should be contacted while changing this value: 0b00 = All latch on 0b01 = Remove 33% 0b10 = Remove 16% 0b11 = Remove 50 %
11-8	CP_CTRL	R/W	0h	Charge pump control bit +- 50 % : 0b0000 = Nom 0b0001 = +13% 0b0010 = +27% 0b0011 = +50% 0b0100 = -20% 0b1000 = -27% 0b1010 = -50% All others are not valid.
7-6	RESVALUE	R/W	0h	Sets loop filter resistor value: 0b00 = 1 Kohm for PCIe 0b01 = 1.67 kohm for eSata 0b10 = 2.5 kohm for SSC 0b11 is not valid
5	C1_2X	R/W	0h	Increase filter capacitance by 2x in low reference (20 MHz) clock: 0b0 = 120 pF for PCIe 0b1 = 240 pF for eSATA and SSC
4	ENDIGLDO	R/W	0h	Enable DIG LDO. Required to wake pll up for plll dig
3	APLL_CP_CURR	R/W	0h	Post_Cent_PG1.0. When high, this bit increases the APLL CP current. Pre_Cent_PG1.0. Unused.
2	ENBGSC_REF	R/W	0h	Enable switched cap bias current module/REFGEN
1	ENPLLLDO	R/W	0h	Enable PLL LDO
0	ENPLL	R/W	0h	Enable PLL

Table 3-54. PCIE_PLLCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENSATAMODE	R/W	0h	Mode select 0 = PCIe (2.5 GHz) / 1 = SATA (1.5 GHz). Used by APLLDIG and TRX_DIG for different purpose. Needs to configure this bit to get ethernet clocks
30	PLLREFSEL	R/W	0h	Chose reference clock value 0 = 100 MHz / 1 = 20 MHz (Note: only needs to be set if using fixed FB divider) For fixed divider mode [31:30] defines division ratio as: 0b00 = 25 0b01 = 125 0b10 = 15 0b11 = 75
29-26	NP1_DIV_INT	R/W	0h	Integer value of N+1 divider 0 value maps to 1 4 value maps to 5
25-18	MDIVINT	R/W	0h	8-bit integer value for M divider (Osc/ref). Valid range is 4 to 255
17-6	MDIVFRAC	R/W	0h	12-bit fractional value for M divider (Osc/ref)
5	EN_CLKAUX	R/W	0h	Old -- Enable for auxilary clock (testclk) clock 0 = Enable / 1 = Disable Corrected on 11/30/2010 Updated -- Enable for auxilary clock (testclk) clock 0 = Disable / 1 = Enable
4	EN_CLK125m	R/W	0h	Enable for 125MHz clock 0 = Disable / 1 = Enable. This is one of the Ethernet clocks
3	EN_CLK100m	R/W	0h	Enable for 100MHz clock 0 = Disable / 1 = Enable
2	EN_CLK50m	R/W	0h	Enable for 50MHz clock 0 = Disable / 1 = Enable. This is one of the Ethernet clocks
1	ENSSC	R/W	0h	Enable spread specturm support 0 = Disable / 1 = Enable
0	MDIVPULSE	R/W	0h	Update M div when pulse is high

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 3-56. PCIE_PLLCFG3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R/W	0h	Reserved for future use
27	DIGLDO_BYPASS	R/W	0h	Digital signal when high puts the DIG LDO in bypass mode. Need to be careful while exercising this mode, the 1.8V external supply must be lowered before asserting this bit.
26	DIGLDO_PULLDOWNZ	R/W	1h	Digital signal when high disables all the pull down paths for LDO output
25	DIGLDO_DIS_SC_PROT	R/W	0h	Digital signal when high disables short circuit protection
24	DIGLDO_EN_SUB_REGULATION	R/W	0h	Digital signal when high disables sub regulation
23	DIGLDO_EN_HP_CAPLESSMODE	R/W	0h	Digital signal when high enables high performance Capless mode. In this mode, quiescent LDO current increases by 240uA
22	DIGLDO_EN_CAPLESSMODE	R/W	0h	Digital signal when high enables Capless Mode. In particular: (1) The 800fF capacitor between VDDAR and the gate of the power FET is bypassed (2) The output of the error amplifier connects to a 30pF capacitor and the other terminal of the capacitor connects to a 40k resistor whose other terminal goes to VSSA. This resistor is also bypassed.
21	DIGLDO_EN_LP_CAPLESSMODE	R/W	0h	Digital signal when high enables Low Power Capless Mode. Quiescent LDO current increases by 240uA typical when this bit is set to low.
20-16	DIGLDO_VSET	R/W	0h	Changed on Jan 12th 2011 Post PG1.0 Inversion in VSET bits, 1 and 0 swap Based upon Sami's measured data and DIGLDO spice sims VSET(4:0) VDDAR (V) 11111 1.20 11110 1.19 11101 1.18 11100 1.17 11011 1.16 11010 1.15 11001 1.14 11000 1.13 10111 1.12 10110 1.11 10101 1.10 10100 1.09 10011 1.08 10010 1.07 10001 1.06 10000 1.05 01111 1.36 01110 1.35 01101 1.34 01100 1.33 01011 1.32 01010 1.31 01001 1.30 01000 1.29 00111 1.28 00110 1.27 00101 1.26 00100 1.25 00011 1.24 00010 1.23 00001 1.22 00000 1.21

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 3-64. SATA_PLLCFG3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R/W	0h	Reserved
27	DIGLDO_BYPASS	R/W	0h	Digital signal when high puts the DIG LDO in bypass mode. Caution Need to be careful while exercising this mode, the 1.8V external supply must be lowered before asserting this bit.
26	DIGLDO_PULLDOWNZ	R/W	1h	Digital signal when high disables all the pull down paths for LDO output
25	DIGLDO_DIS_SC_PROT	R/W	0h	Digital signal when high disables short circuit protection
24	DIGLDO_EN_SUB_REGULATION	R/W	0h	Digital signal when high disables sub regulation
23	DIGLDO_EN_HP_CAPLESSMODE	R/W	0h	Digital signal when high enables high performance Capless mode. In this mode, quiescent LDO current increases by 240uA
22	DIGLDO_EN_CAPLESSMODE	R/W	0h	Digital signal when high enables Capless Mode. In particular: (1) The 800fF capacitor between VDDAR and the gate of the power FET is bypassed (2) The output of the error amplifier connects to a 30pF capacitor and the other terminal of the capacitor connects to a 40k resistor whose other terminal goes to VSSA. This resistor is also bypassed.
21	DIGLDO_EN_LP_CAPLESSMODE	R/W	0h	Digital signal when high enables Low Power Capless Mode. Quiescent LDO current increases by 240uA typical when this bit is set to low.

ROM Code Memory and Peripheral Booting

This chapter describes the booting functionality of the public ROM code, referred hereafter as ROM Code. The booting functionality covers the following features:

- *Memory Booting* – booting the device by starting code stored on permanent memories like flash-memory or memory cards. This process is usually performed after either device cold or warm reset.
- *Peripheral Booting* – booting the device by downloading the executable code over a communication interface like UART or Ethernet. This process is intended for flashing a device.

The device always starts up in secure mode. The ROM Code takes care of early initialization. The ROM code switches the device into public mode; hence, the Public ROM Code provides run-time services for cache maintenance.

This chapter is intended for all who design systems based on this device, develop bootloader images and flashing tools.

4.1 Introduction

This chapter describes the booting functionality of the Public ROM Code.

4.1.1 Acronyms and Naming Conventions

The following tables provides acronyms and abbreviations, as well as the naming conventions used in this document.

Table 4-1. Acronyms and Abbreviations

Acronym/Abbreviation	Definition
ASIC	Application Specific Integrated Circuit
B	Byte (8 bits)
CS	Chip Select
CH	Configuration Header
DPLL	Digital PLL
EMIF	External Memory InterFace (SDRAM Controller)
FIQ	Fast Interrupt Request
FS USB	Full Speed USB
GPMC	General Purpose Memory Controller
HLOS	High Level Operating System
HS USB	High Speed USB
HW	Hardware
HWA	Hardware Accelerator
I2C	Inter-Integrated Circuit
IRQ	Interrupt
ISR	Interrupt Service Routine
JTAG	Joint Test Action Group. This term is used to refer to the Debugging and Testing interface.
Kbps	Kilobits per second
KB	Kilobyte, 1024 B
LPDDR2	Low Power Double Data Rate rev. 2
LPDDR2-NVM	Non volatile type of memory connected to EMIF interface
MB	Megabyte, 1024 KB
MMC	Multimedia Card.
MPU	Micro Processor Unit
OCM	On-Chip Memory
OneNAND™	A type of Flash memory
PA	Protected Application (also see Table 4-2)
PLL	Phase Locked Loop
PK	Public Key
PPA	Primary Protected Application (also see Table 4-2)
POR	Power On Reset
PMU	Power Management Unit
PRCM	Power, Reset and Clock Management module
RAM	Random Access Memory. Refers to the OMAP internal static RAM
ROM	Read Only Memory
RSA	Rivest, Shamir, Adleman encryption algorithm
SAR	Save & Restore
SDRAM	Synchronous Dynamic Random Access Memory
SWI	Software Interrupt
TOC	Table Of Contents – a structure within an executable image
UART	Universal Asynchronous Receiver/Transmitter

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-1. Acronyms and Abbreviations (continued)

Acronym/Abbreviation	Definition
USB	Universal Serial Bus
XIP	Execute In Place
WDT	Watchdog timer

Table 4-2. Naming Conventions

Name	Definition
Bootstrap	Initial SW that is launched by the ROM Code during the Memory Booting phase
Downloaded SW	Initial SW that is downloaded into internal RAM by the ROM Code during peripheral booting phase.
E-Fuse	A one-time programmable memory location usually set at the factory
Flash Loader	Downloaded software launched by the ROM Code in Pre-Flashing and which programs an image into external memories.
Initial SW	Software which is executed by any of the ROM Code mechanisms (Memory Booting or Peripheral Booting). Initial software is a generic term for Bootstrap and Downloaded software.
Memory Booting	ROM Code mechanism that consists of executing an Initial SW from external memory.
Monitor Mode Manager	ROM Code software component in charge of handling all entry/exit to/from MPU Secure State.
Peripheral Booting	ROM Code mechanism that consists of polling selected interfaces, downloading and executing an Initial SW (in this case called Downloaded SW) in internal RAM.
Pre-Flashing	Specific case of peripheral booting, where the ROM Code mechanism is used to program external Flash memories.

4.2 Overview

4.2.1 Architecture

The architecture of the ROM code is shown in Figure 4-1. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower level layer through a unified interface.

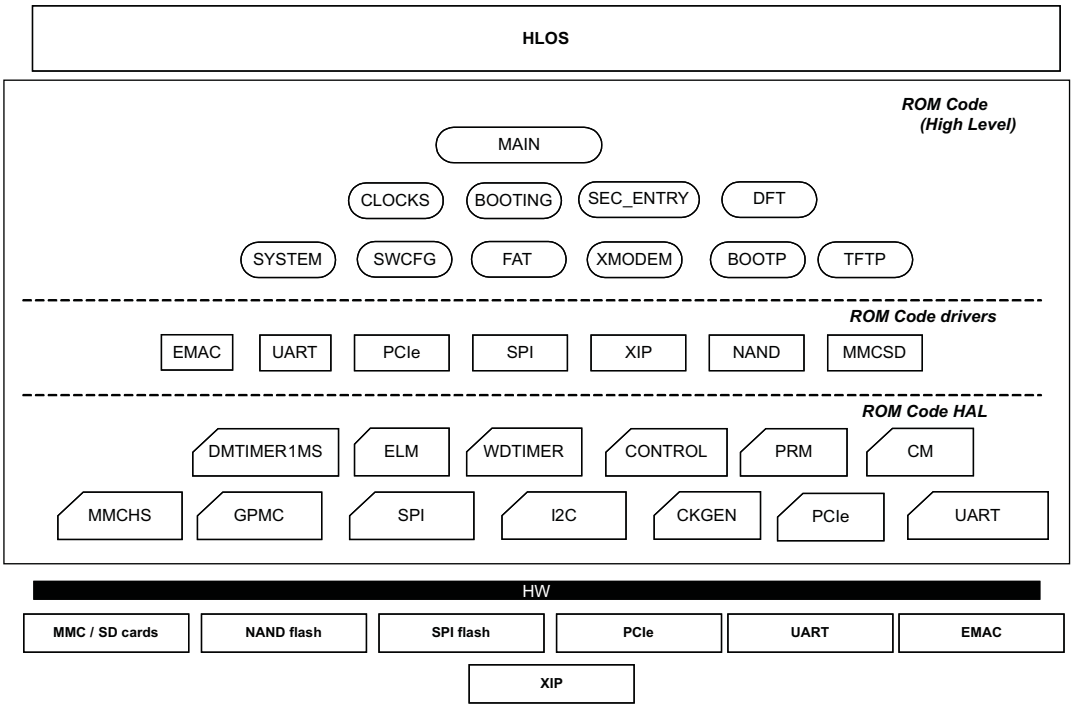
The high level layer is in charge of the main tasks of the ROM Code: watchdog and clocks configuration and main booting routine.

The drivers layer implements the logical and communication protocols for any booting device in accordance with the interface specification.

Finally the HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to device IO pads.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-1. ROM Code Architecture



4.2.2 Functionality

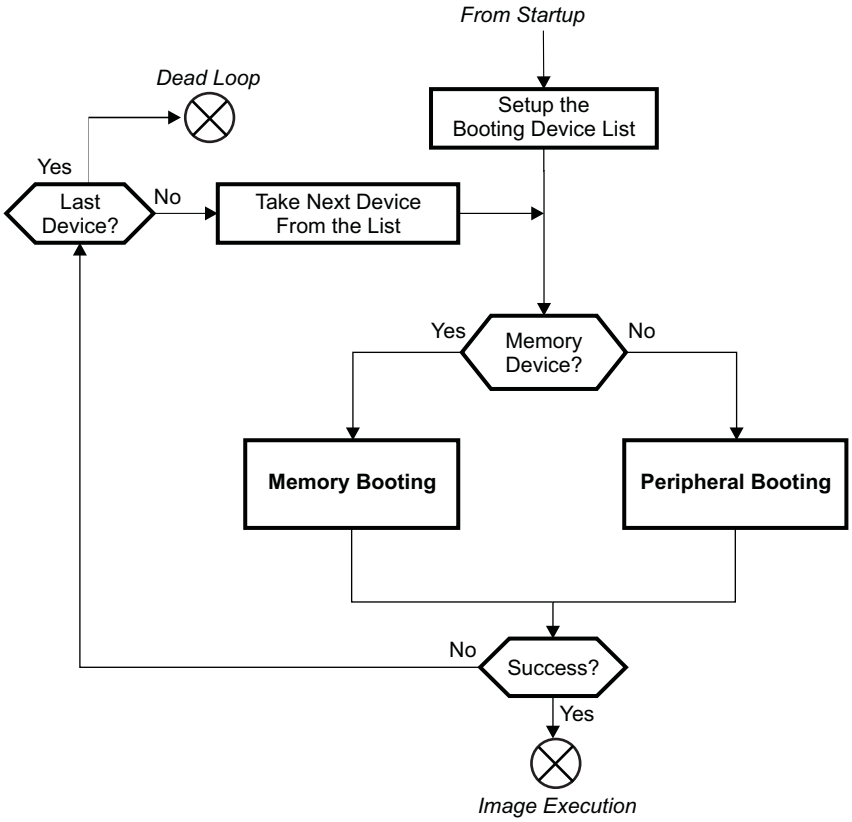
Figure 4-2 illustrates the high level flow for the Public ROM Code booting procedure. On the device, the Public ROM Code starts upon completion of the secure startup (performed by the Secure ROM Code). The ROM Code then performs platform configuration and initialization as part of the public start-up procedure.

The booting device list is created based on the MBOOT. A booting device can be a memory booting device (soldered flash memory or temporarily booting device like memory card) or a peripheral interface connected to a host.

The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-2. ROM Code Boot Procedure



4.3 Memory Map

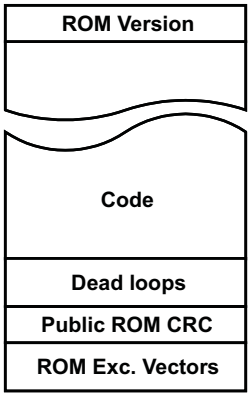
4.3.1 ROM Memory Map

The on-chip ROM memory map is shown in Figure 4-3. The ROM Code mapping consists in the following:

- Exception vectors
- CRC
- Dead loops collection
- Code and const data sections
- API Table
- ROM Version

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-3. ROM Memory Map



4.3.1.1 ROM Exception Vectors

Table 4-3 lists the ROM exception vectors. The reset exception is redirected to the ROM Code startup. Other exceptions are redirected to their RAM handlers by loading appropriate addresses into the PC register.

Table 4-3. ROM Exception Vectors

Address	Exception	Content
20000h	Reset	Branch to the ROM Code startup
20004h	Undefined	PC = 4030 D004h
20008h	SWI	PC = 4030 D008h
2000Ch	Pre-fetch abort	PC = 4030 D00Ch
20010h	Data abort	PC = 4030 D010h
20014h	Unused	PC = 4030 D014h
20018h	IRQ	PC = 4030 D018h
2001Ch	FIQ	PC = 4030 D01Ch

4.3.1.2 ROM Code CRC

The ROM Code CRC is calculated as 32 bit CRC code (CRC-32-IEEE 802.3) for the address range 20000h–2BFFFh. The four bytes CRC code is stored at location 20020h.

4.3.1.3 Dead Loops

Built-in dead loops are used for different purposes as shown in Table 4-4. All dead loops are branch instructions coded in ARM mode. The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors. The dead loops might be called directly from the user code. However there exists a special function which can be called from ROM code in order to execute a dead loop. The function is an assembly code in ARM mode which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global SW reset before going to a dead loop. The function is located at address 200C0h. In addition the function clears global cold reset status upon issuing the global SW reset.

Table 4-4. Dead Loops

Address	Purpose
20080h	Undefined exception default handler
20084h	SWI exception default handler
20088h	Pre-fetch abort exception default handler
2008Ch	Data abort exception default handler

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-4. Dead Loops (continued)

Address	Purpose
20090h	Unused exception default handler
20094h	IRQ exception default handler
20098h	FIQ exception default handler
2009Ch	Validation tests PASS
200A0h	Validation tests FAIL
200A4h	Reserved
200A8h	Image not executed or returned.
200ACh	Reserved
200B0h	Reserved
200B4h	Reserved
200B8h	Reserved
200BCh	Reserved

4.3.1.4 Code

This space is used to hold code and constant data.

4.3.1.5 Public ROM Code Version

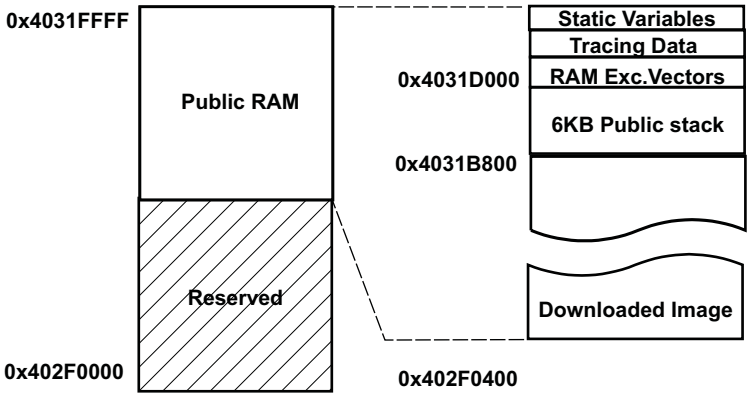
The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM Code release version burnt in a given IC (e.g., useful to identify an IC version). The ROM code version is a 32 bits hexadecimal value located at address 2BFFCh.

Copyright © 2011–2013, Texas Instruments Incorporated

4.3.2 RAM Memory Map

The ROM code makes use of the on chip RAM module connected to the L3 interconnect (further referred as L3 RAM in this document). Its usage is shown in Figure 4-4. The RAM memory map ranges from address 4020F000h to 4031FFFFh.

Figure 4-4. Public RAM Memory Map



4.3.2.1 Downloaded Image

This area is used by the ROM code to store the downloaded boot image. It can be up to 173 KB.

4.3.2.2 Public Stack

Space reserved for stack.

4.3.2.3 RAM Exception Vectors

The RAM exception vectors enable a simple means for redirecting exceptions to custom handlers. Table 4-5 shows content of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load the value located in the subsequent seven addresses into the PC register. Theses instructions are executed when an exception occurs since they are called from the ROM exception vectors. Undefined, SWI, Unused and FIQ exceptions are redirected to a hardcoded dead loop. Pre-fetch abort, data abort, and IRQ exception are redirected to pre-defined ROM handlers. User code can redirect any exception to a custom handler either by writing its address to the appropriate location from 4031 D024h to 4031 D03Ch or by overriding the branch (load into PC) instruction between addresses from 4031 D004h to 4031 D01Ch.

Table 4-5. RAM Exception Vectors

Address	Exception	Content
4031 D000h	Reserved	Reserved
4031 D004h	Undefined	PC = [4031 D024h]
4031 D008h	SWI	PC = [4031 D028h]
4031 D00Ch	Pre-fetch abort	PC = [4031 D02Ch]
4031 D010h	Data abort	PC = [4031 D030h]
4031 D014h	Unused	PC = [4031 D034h]
4031 D018h	IRQ	PC = [4031 D038h]
4031 D01Ch	FIQ	PC = [4031 D03Ch]
4031 D020h	Reserved	20090h
4031 D024h	Undefined	20080h
4031 D028h	SWI	20084h
4031 D02Ch	Pre-fetch abort	Address of default pre-fetch abort handler (*)

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-5. RAM Exception Vectors (continued)

Address	Exception	Content
4031 D030h	Data abort	Address of default data abort handler (*)
4031 D034h	Unused	20090h
4031 D038h	IRQ	Address of default IRQ handler
4031 D03Ch	FIQ	20098h

(*) the default handlers for pre-fetch and data abort are performing reads from CP15 debug registers to retrieve the reason of the abort:

- In case of pre-fetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM Code jumps to the pre-fetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM Code jumps to the data abort dead loop (2008Ch).

4.3.2.4 Tracing Data

This section contains trace vectors reflecting the execution path of the public boot. Section 4.12 describes the usage of the different trace vectors and lists all the possible trace codes.

Table 4-6. Tracing Data

Address	Size [bytes]	Description
4031 D040h	4	Current tracing vector, word 1
4031 D044h	4	Current tracing vector, word 2
4031 D048h	4	Current tracing vector, word 3
4031 D04Ch	4	Current copy of the PRM_RSTST register (reset reasons)
4031 D050h	4	Cold reset run tracing vector, word 1
4031 D054h	4	Cold reset run tracing vector, word 2
4031 D058h	4	Cold reset run tracing vector, word 3
4031 D05Ch	4	Reserved
4031 D060h	4	Reserved
4031 D064h	4	Reserved

4.3.2.5 Static Variables

This area contains the ROM code static variables used during boot time (and possibly during run-time, if calling the Public ROM API functions).

Copyright © 2011–2013, Texas Instruments Incorporated

4.4 Startup and Configuration

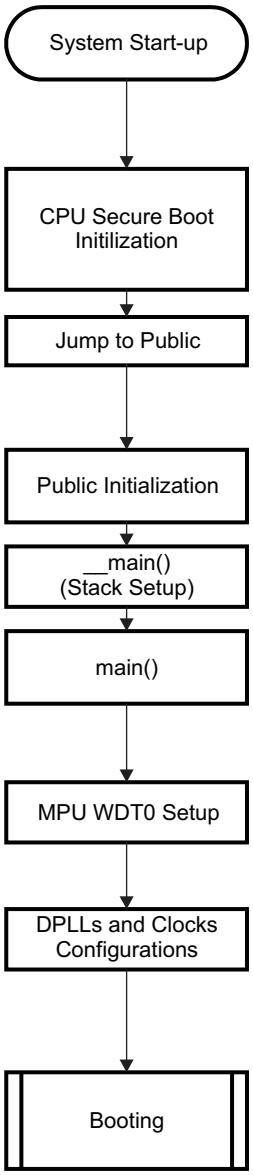
4.4.1 ROM Code Start-up

The main MPU subsystem always starts its execution in secure mode after reset due to the TrustZone architecture (the Secure ROM code implements the reset handler). The Public ROM code is physically located at the address 20000h that is immediately next to the Secure ROM code.

As shown at top of Figure 4-5, the CPU jumps to the Public ROM Code reset vector once it has completed the secure boot initialization.

Once in public mode the CPU performs the public-side initialization and stack setup (compiler auto generated C- initialization or “scatter loading”) as shown in left hand side of Figure 4-5. Then it configures the watchdog timer 2 (set to three minutes), and performs system clocks configuration. Finally it jumps to the booting routine.

Figure 4-5. ROM Code Start-up Sequence



Copyright © 2011–2013, Texas Instruments Incorporated

4.4.2 CPU State at Public Startup

The CPU L1 instruction cache and branch prediction mechanisms are not activated as part of the public boot process. The public vector base address is configured to the reset vector of Public ROM Code (20000h). MMU is left switched off during the public boot (hence L1 data cache off).

No specific configuration is performed for the slave CPU which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public vectors base address).

4.4.3 Clocking Configuration

The supported system clock frequencies are OSC0 = 20 MHz.

The ROM Code configures the clocks and DPLLs that are necessary for ROM Code execution:

- L3 DPLL locked to provide 220MHz clocks for peripheral blocks
- DDR DPLL locked to provide 400MHz
- ARM DPLL is locked to provide 600MHz for the A8
- USB DPLL is locked to provide 960MHz and 192MHz for peripheral blocks

Table 4-7 summarizes the ROM Code default settings for clocks. This default configuration enables all the ROM Code functionalities with minimized needs on power during boot.

The DPLLs and PRCM clock dividers are configured with the ROM Code default values after cold or warm reset in order to give the same working conditions to the Public ROM Code sequence

Table 4-7. ROM Code Default Clock Settings

Clock	Frequency (MHz)	Source
PLL_ARM	600	OSC0
PLL_L3	220	OSC0
PLL_USB	960	OSC0
PLL_DDR	400	OSC0
SYSCLK4	220	PLL_L3/1
SYSCLK8	192	(PLL_USB/5)/1
SYSCLK10	48	(PLL_USB/5)/4
SYSCLK18B	32KHz	RTCDIVIDER

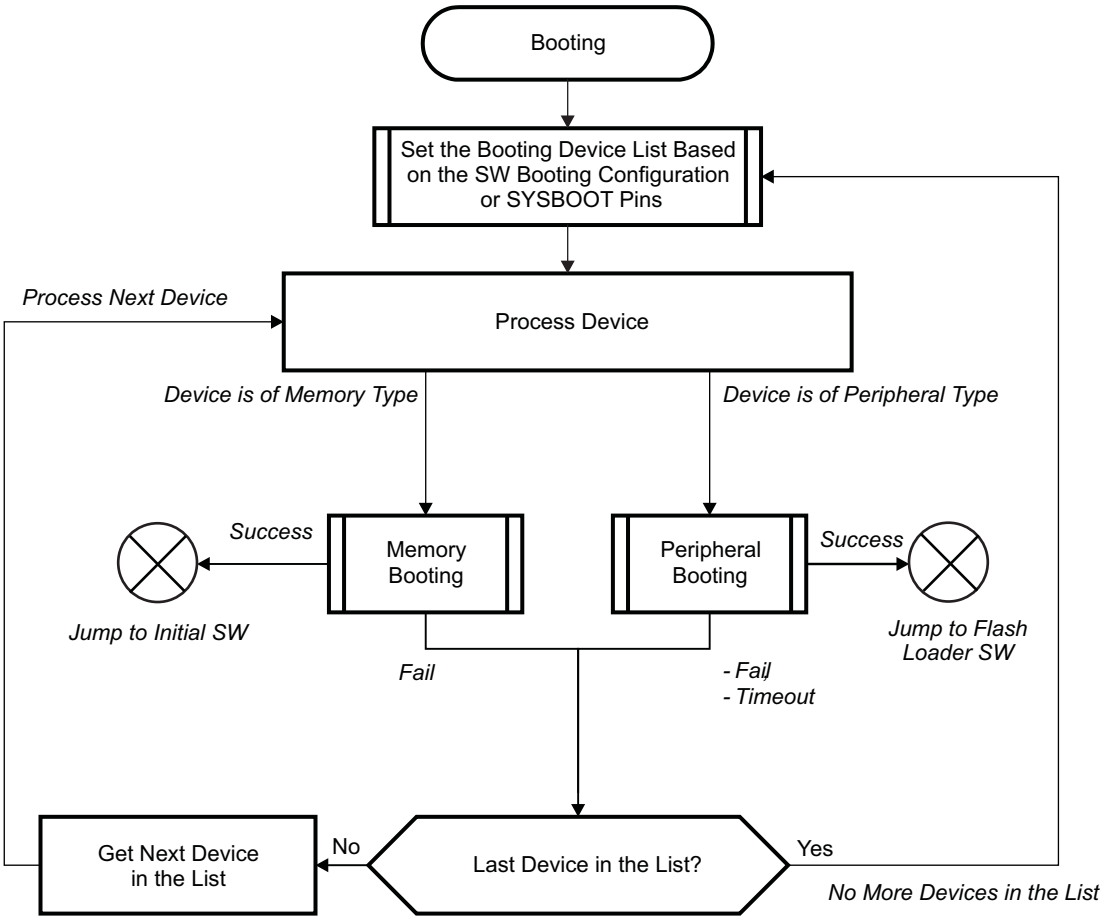
4.5 Booting

4.5.1 Overview

Figure 4-6 shows the booting procedure. First, a booting device list is created. The list consists of all devices which will be searched for a booting image. The list is filled in based on the SYSBOOT.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-6. ROM Code Booting Procedure



Once the booting device list is set up, the booting routine examines the devices enumerated in the list sequentially and either executes the memory booting or peripheral booting procedure depending on the booting device type. The memory booting procedure is executed when the booting device type is one of NOR, NAND, MMC, or SPI-EEPROM. The peripheral booting is executed when the booting device type is Ethernet, PCIe or UART.

The memory booting procedure reads data from a memory type device. If a valid booting image is found and successfully read from the external memory device, the initial SW is simply started.

The peripheral booting procedure downloads data from a host (commonly a PC) to the device by means of Ethernet, PCIe or UART links. The ROM Code uses a host-slave logical protocol for synchronization. Upon successful PCIe enumeration (or UART or Ethernet connection) the host sends the image binary contents. The peripheral booting procedure is described in detail in Section 4.8.

If the memory or peripheral booting fails for all devices enumerated in the device list, then the ROM Code gets back to the first device in the list. The device list is then processed again in a loop. This loop shall be further interrupted by the MPU or secure watchdog.

4.5.2 Device List

The ROM Code creates the device list based on information gathered from the SYSBOOT configuration pins sensed in the control module. The pins are used to index the device table from which the list of devices is extracted.

4.5.2.1 BTMode[4-0] Configuration Pins

The following table describes the BTMode[4-0] configuration pins.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-8. BTMode[4-0] Configuration Pins

Boot Modes				BTMODE[4:0]
1st	2nd	3rd	4th	
Reserved	Reserved	Reserved	Reserved	00000
UART	XIP w/ WAIT (MUX0)	MMC	SPI	00001
UART	SPI	NAND	NANDI2C	00010

Fast external Boot	EMAC	UART	PCIE_32	11111

The ROM Code uses the row pointed by the MBOOT configuration value .The device list is filled in with the 1st to 4th devices. is the decoding table for MBOOT configuration pins. The following shortcuts are used in the table:

MMC	MMC or SD card (MMC port 1)
NAND / NANDI2C	NAND flash memory / read flash geometry from I2C EEPROM
XIP / XIP w/ WAIT	NOR or other XIP device with or without wait monitoring
UART	UART interface (UART port 0)
EMAC	Ethernet GMII0m RGMII and RMII interface (EMAC port 0)
SPI	SPI EEPROM (SPI 0, CS0)
PCIE_32 / PCIE_64	PCI Express interface with 32 bit / 64 bit addressing

Copyright © 2011–2013, Texas Instruments Incorporated

4.6 Fast External Booting

4.6.1 Overview

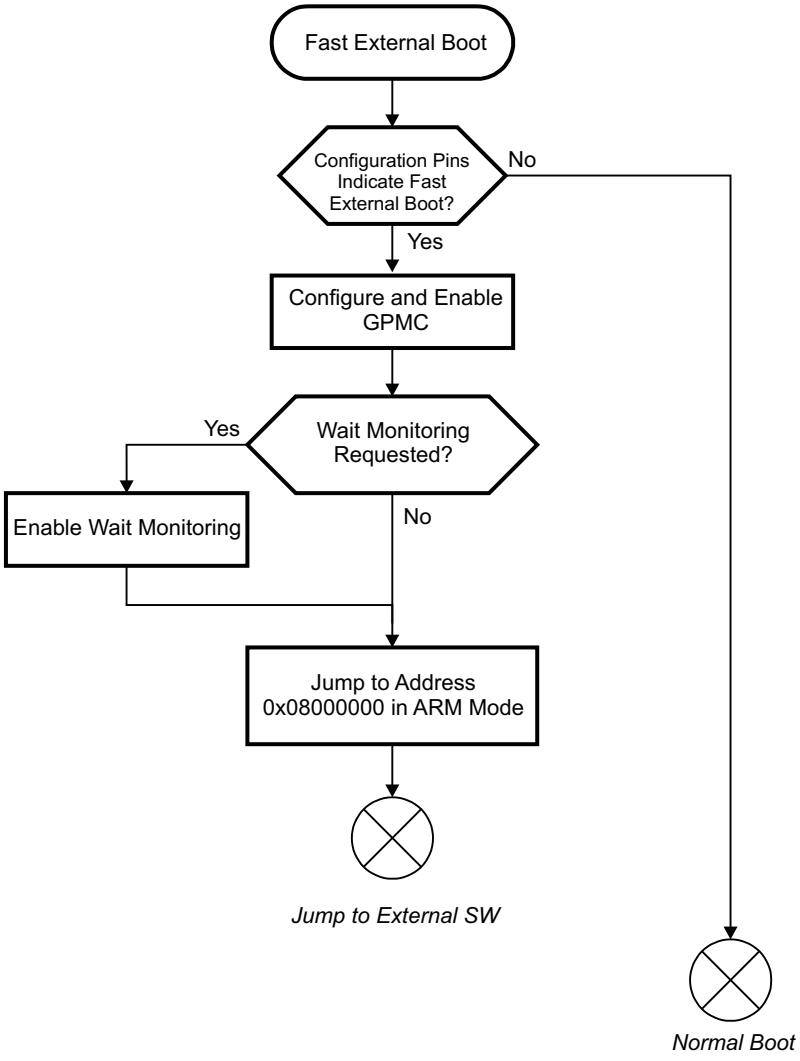
The fast external boot feature:

- Consists of a blind jump in ARM mode to a code located in an external XIP device connected to CS0
- The jump is performed with minimum on-chip ROM Code execution, without configuring any PLL
- Allows the customer to create its own booting code
- Is set up by means of the configuration pins, see Table 4-8

4.6.2 External Booting

Figure 4-7 shows the fast external boot procedure. The code does not make use of RAM and is designed for fast execution.

Figure 4-7. Fast External Boot



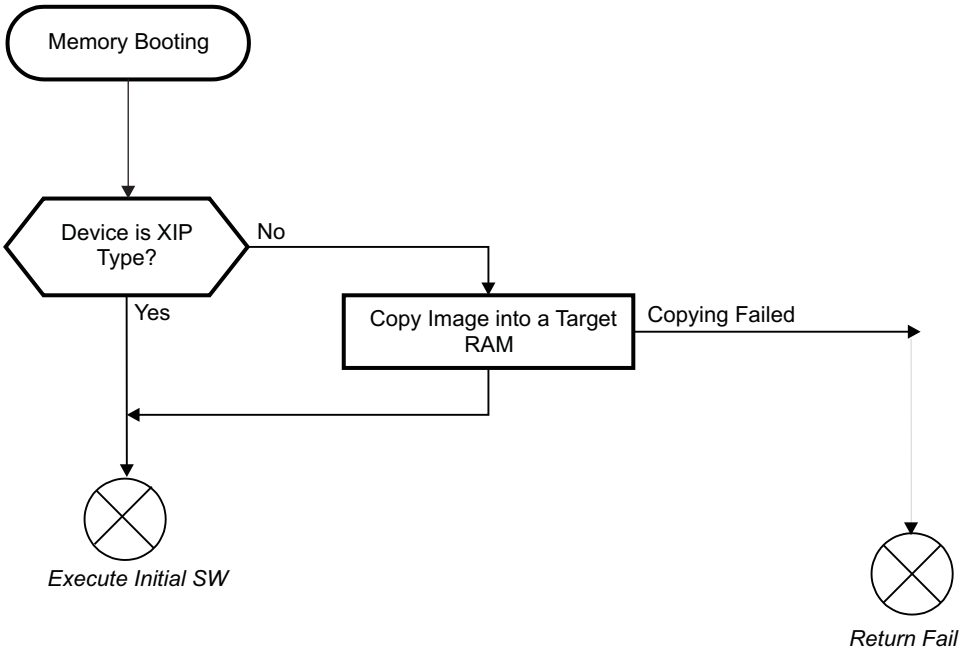
Copyright © 2011–2013, Texas Instruments Incorporated

4.7 Memory Booting

4.7.1 Overview

The memory booting procedure takes care of starting an external code located in memory device types. These devices are also called permanent booting devices since they are used in that manner.

Figure 4-8. Memory Booting



The permanent booting devices supported are:

- MMC/SD cards
- NOR flash
- NAND flash
- SPI EEPROMs

There are two groups of permanent booting devices distinguished by the need of code shadowing. The code shadowing means copying a code from a non-directly addressable device into a location (typically a RAM area) from where the code can be executed. Devices which are directly addressable are called eXecute In Place (XIP) devices.

Copyright © 2011–2013, Texas Instruments Incorporated

The memory booting flowchart is shown in Figure 4-8. The second step is about performing the shadowing of the image that is copying the image from external mass storage (non-XIP) into internal RAM. Failure in image copy results in memory booting returning to the main booting procedure which will select the next device for booting. The next sections detail procedures for device initialization & detection in addition to the description of the sector read routine for each supported device type. A sector is a logical unit of 512 bytes.

A valid image is considered to be present when the first 4 bytes word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector call, sectors are copied to a temporary RAM buffer. Once the image is found and a destination address is known, the content of the temporary buffer is moved to the target RAM location so it is needed to re-read the first image sector. The header is discarded; therefore, only executable code is located in RAM with the first executable instruction located at the destination address.

For more information about image formats and contents refer to Section 4.9.

MMC/SD cards and NAND devices can hold up to four copies of the booting image. Therefore the ROM Code searches for one valid image out of the four if present by walking over the first four blocks of the mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

4.7.2 XIP Memory

The ROM Code can boot directly from XIP devices. A typical XIP device is a NOR flash memory. Support for XIP devices is performed under the following assumptions:

- Uses GPMC as the communication interface
- Can connect up to 1 Gbit (128 Mbytes) memories
- Uses both ×8 and ×16 data bus width
- Follows asynchronous protocol
- Supports address / data multiplexed mode and non-multiplexed mode
- GPMC clock is 55 MHz
- Device is connected to CS0 mapped to address 800 0000h
- Wait pin signal WAIT0 is monitored depending on the MBOOT configuration pins (XIP/XIPWAIT).

Depending on the MBOOT option the GPMC is configured to use the WAIT signal connected on the WAIT0 pin or not. Wait pin polarity is set to stall accessing memory when the WAIT0 pin is low. The wait monitoring is intended to be used with memories which require long time for initialization after reset or need to pause while reading data. The boot procedure from XIP device can be described as such:

1. Configure GPMC for XIP device access
2. Set the image location to 800 0000h
3. Verify if bootable image is present at the image location.
4. If the image has been found, start it.
5. If the image has not been found, return from XIP booting to the main booting loop.

4.7.2.1 XIP Initialization and Detection

GPMC Initialization

Figure 4-9 and Table 4-9 describes the GPMC timing settings set for XIP boot and other address-data accessible devices (e.g., OneNAND).

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-9. GPMC XIP Timings

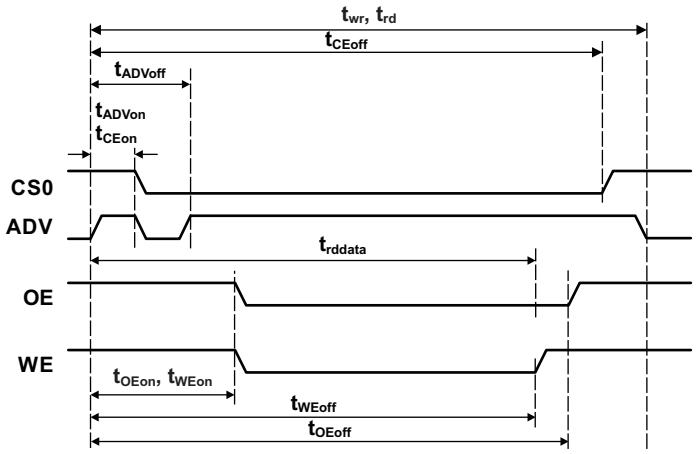


Table 4-9. XIP Timings Parameters

Parameter	Description	Value [clock cycles]
twr	write cycle period	17
trd	read cycle period	17
tCEon	CE low time	1
tCEoff	CE high time	16
tADVon	ADV low time	1
tADVoff	ADV high time	2
tOEon	OE low time	3
tWEon	WE low time	3
trddata	data latch time	15
tOEoff	OE high time	16
tWEoff	WE high time	15

The one clock cycle is 18.182 ns which corresponds to 55MHz frequency.

Device Detection

There is no specific identification routine executed prior to booting from an XIP device.

4.7.2.2 Pins Used for NOR Boot

The list of pins that are configured by the ROM in the case of NOR boot mode are listed in Table 4-10. Note that all the pins might not be driven at boot time. The decision as to which pins need to be driven is based on the type of NOR flash selected.

Table 4-10. Pins Used for NOR Boot

Signal name	Pin used in XIP_MUX0 mode	Pin used in XIP_MUX1 mode
cs0	gpmc_cs0	gpmc_cs0
advn_ale	gpmc_advn_ale	gpmc_advn_ale
oen_ren	gpmc_oen_ren	gpmc_oen_ren
be0n_cle	gpmc_be0n_cle	gpmc_be0n_cle
wen	gpmc_wen	gpmc_wen
wait	gpmc_wait	gpmc_wait

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-10. Pins Used for NOR Boot (continued)

Signal name	Pin used in XIP_MUX0 mode	Pin used in XIP_MUX1 mode
clk	gpmc_clk	gpmc_clk
ad0 - ad15	gpmc_ad0 - gpmc_ad15	gpmc_ad0 - gpmc_ad15
a0	gmii0_rxd[3]	vout1_b_cb_c[2]
a1	gmii0_rxd[4]	mmc2_dat[3]
a2	gmii0_rxd[5]	mmc2_dat[2]
a3	gmii0_rxd[6]	mmc2_dat[1]
a4	gmii0_rxd[7]	mmc2_dat[0]
a5	gmii0_rxdv	vout1_g_y_yc[1]
a6	gmii0_gtxclk	vout1_g_y_yc[0]
a7	gmii0_txd[0]	vout1_r_cr[1]
a8	gmii0_txd[1]	vout1_r_cr[0]
a9	gmii0_txd[2]	vout1_b_cb_c[1]
a10	gmii0_txd[3]	vout1_b_cb_c[0]
a11	gmii0_txd[4]	vout1_fid
a12	gmii0_txd[5]	vout0_fid

Note: The ROM code does not multiplex high order address lines gpmc_a[27:13] to their address functions, although the external memory device generally needs to see logic "0" on its higher order address bits to correctly address memory. Many of the high order address pads default to internal pull-down active; however, some pins will default to internal pull-up active and therefore will need to be driven or pulled low by external hardware for the duration of XIP boot operation. See the device data manual for specific details.

In PG2.0, if MBOOT[10] = 1b, the following changes come into effect. These override the pin configuration mentioned above.

- GPMC_CLK is not configured
- GPMC_BE0N_CLE is not configured
- GPMC_ADVN_ALE is configured only for multiplexed NOR boot
- GPMC_A0 configured pinmux in case of 8-bit wide data NOR boot ONLY.
- GPMC_WAIT0 is configured for NOR (muxed and Non-muxed) with default settings in case we use as WAIT , else do a PULL DOWN
- For the following Pins a PULL DOWN is done for both Muxed NOR and Non-Muxed NOR devices
  - GPMC_A[20]
  - GPMC_A[22]
  - SD2_DAT[7]
  - SD2_DAT[6]
  - SD2_DAT[5]
  - GPMC_WAIT[0] (UNLESS configured as WAIT per BOOTMODE)
- For the following Pins a PULL DOWN is done for Non-Muxed NOR devices only
  - VOUT[1]_G_Y_YC[2]
  - VOUT[1]_R_CR[3]

4.7.2.3 Sysboot Pins

Some of the SYSBOOT pins have special meanings when NOR boot is selected.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-11. Special SYSBOOT Pins for NOR Boot

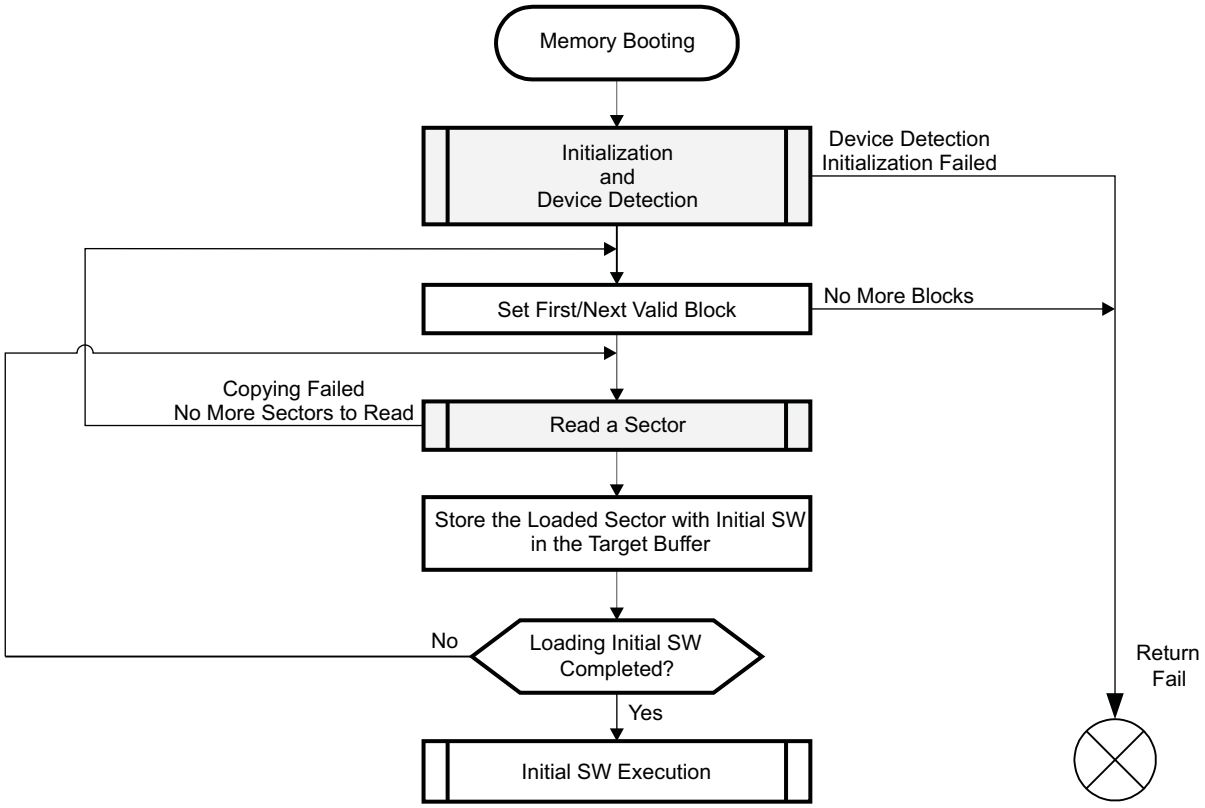
SYSBOOT[n]	Description
[12] (CS0BW)	Must be 0 if 8-bit device is used Must be 1 if 16-bit device is used
[15] (CS0WAIT)	Must be 0 if XIP WIAT if not used Must be 1 if XIP WAIT is used
[14:13] (CS0MUX[1:0])	00b – Non-muxed device 01b – A/D muxed device 10b – AAD muxed device 11b – reserved.

4.7.2.4 Image Shadowing for non-XIP memories

Shadowing on the device

Shadowing uses the following approach.

Figure 4-10. Image Shadowing on the Device



Copyright © 2011–2013, Texas Instruments Incorporated

4.7.3 NAND

The NAND flash memory is not XIP and requires shadowing before the code can be executed.

4.7.3.1 NAND Features

The NAND features include:

- GPMC as the communication interface
- Device from 512Mbit (64 MByte)
- ×8 and ×16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128 / 218 spare bytes)
- CE don't care devices only
- Single Level Cell (SLC) and Multiple Level Cell (MLC) devices
- Device Identification based on ONFI or ROM table
- ECC correction : 8 bits/sector for most devices (16b/sector for devices with large spare area)
- GPMC timings adjusted for NAND access
- 55MHz GPMC clock
- Device connected to CS0
- Wait pin signal WAITPIN0 connected to NAND BUSY output
- Four physical blocks are searched for an image. The block size depends on device.

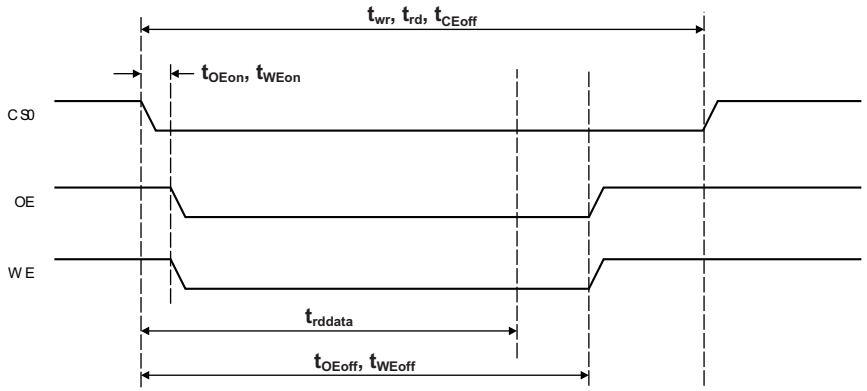
4.7.3.2 Initialization and Detection

The initialization routine for NAND devices consists in three parts: GPMC initialization, device detection with parameters determination and finally bad block detection.

- **ONFI support.** The NAND identification starts with ONFI detection.
- **GPMC initialization.** The GPMC interface is configured such that it can be used for accessing NAND devices. The address bus is released since a NAND device does not use it. The data bus width is initially set to 8 bits; and changed to 16 bits if needed after device parameters determination. The following scheme is applied since NAND devices require different timings when compared to regular NOR devices:

Figure 4-11 and Table 4-12 describes the timings configured for NAND device access. The one clock cycle is 18.181 ns which correspond to 55 MHz frequency.

Figure 4-11. GPMC NAND Timings



Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-12. NAND Timings Parameters

Parameter	Description	Value [clock cycles]
twr	write cycle period	30
trd	read cycle period	30
tCEon	CE low (not marked on the figure)	0
tOEon	CE low to OE low time	7
tWEon	CE low to WE low time	5
trddata	CE low to data latch time	21
tOEoff	CE low to OE high time	24
tWEoff	CE low to WE high time	22

- **Device detection and parameters.** The ROM code first performs an initial wait for device auto initialization (with 250ms timeout) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100ms timeout). The ONFI Read ID (command 90h / address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent.
- If the parameters page does not have the ONFI signature, then the ONFI identification fails and the device falls back to using the look up table. If the parameter page contains the ONFI signature, the information shown in Table 4-13 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameters page stream are simply ignored.

Table 4-13. ONFI Parameters Page Description

Offset	Description	Size (bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 100ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM Code table. The list of supported devices is shown in Table 4-14.

Table 4-14. Supported NAND Devices

Capacity	Device ID	Bus Width	Page size
512 Mb	F0	x8	2048

64 Gb	BE	x16	2048/4096

When the parameters are retrieved from the ROM table: page size and block size is updated based on 4th byte of NAND ID data. Due to inconsistency amongst different manufacturers, only devices which has been recognized to be at least 2Gb (included) have these parameters updated. Therefore, the ROM Code supports 4kB page devices but only if their size, according to the table, is at least 2Gb. Devices which are smaller than 2Gb have the block size parameter set to 128kB (when page size is 2KB). Table 4-15 shows the 4th ID Data byte encoding used in ROM Code.

Table 4-15. 4th NAND ID Data Byte

Item	Description	I/O #							
		7	6	5	4	3	2	1	0
Page Size	1kB							0	0
	2kB							0	1
	4kB							1	0
	8kB							1	1
Cell type	2 levels					0	0		
	4 levels					0	1		
	8 levels					1	0		
	16 levels					1	1		
Block Size	64kB			0	0				
	128kB			0	1				
	256kB			1	0				
	512kB			1	1				

- **Reading NAND geometry from I2C EEPROM.** ROM supports a special boot mode called NANDI2C to support NAND devices whose geometry cannot be detected by the ROM automatically using methods described in the previous section (Figure 4-12). If this boot mode is selected, the ROM code tries to read NAND geometry from an I2C EEPROM. If the read is successful, ROM code then proceeds to the next steps of NAND boot, beginning with reading bad blocks of information.

  The list of pins that are configured by the ROM in case of NANDI2C boot mode (this is in addition to the NAND boot pins) is described in Table 4-18).

Table 4-16. Pins used for NANDI2C boot for I2C EEPROM access

Signal name	Pin used
I2C SCL	i2c0_scl
I2C SDA	i2c0_sda

ROM accesses the I2C EEPROM at I2C slave address 50h and reads 7 bytes starting from address offset 80h. The format of this (NAND geometry information) is as follows:

Table 4-17. NAND Geometry Information on I2C EEPROM

Byte address	Information	
	Upper nibble	Lower nibble
80h	Magic Number – 10h	
81h	Magic Number – B3h	
82h	Magic Number – 57h	
83h	Magic Number – A6h	
84h	NAND column address (word/byte offset within a page) size in bytes, Example: 2	NAND row address (page offset) size in bytes. Example: 3
85h	Page size (2N) exponent “N”. Example (for page size of 2048): 11	Pages per block (2N) exponent “N” Example (for number of blocks 64): 6
86h	NAND bus width 0 → 8-bit, 1 → 16-bit	ECC Type 0→ No ECC, 1 → BCH8, 2 → BCH16

Copyright © 2011–2013, Texas Instruments Incorporated

- **ECC correction.** The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

  For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when manufacturer code (first ID byte) is 98h the cell type information is checked in the 4th byte of ID data. If it is equal to 10b then the ECC correction applied is BCH 16b/sector.

The detection procedure is described in Figure 4-12. Once the device has been successfully detected, the ROM code changes GPMC to 16-bit bus width if necessary.

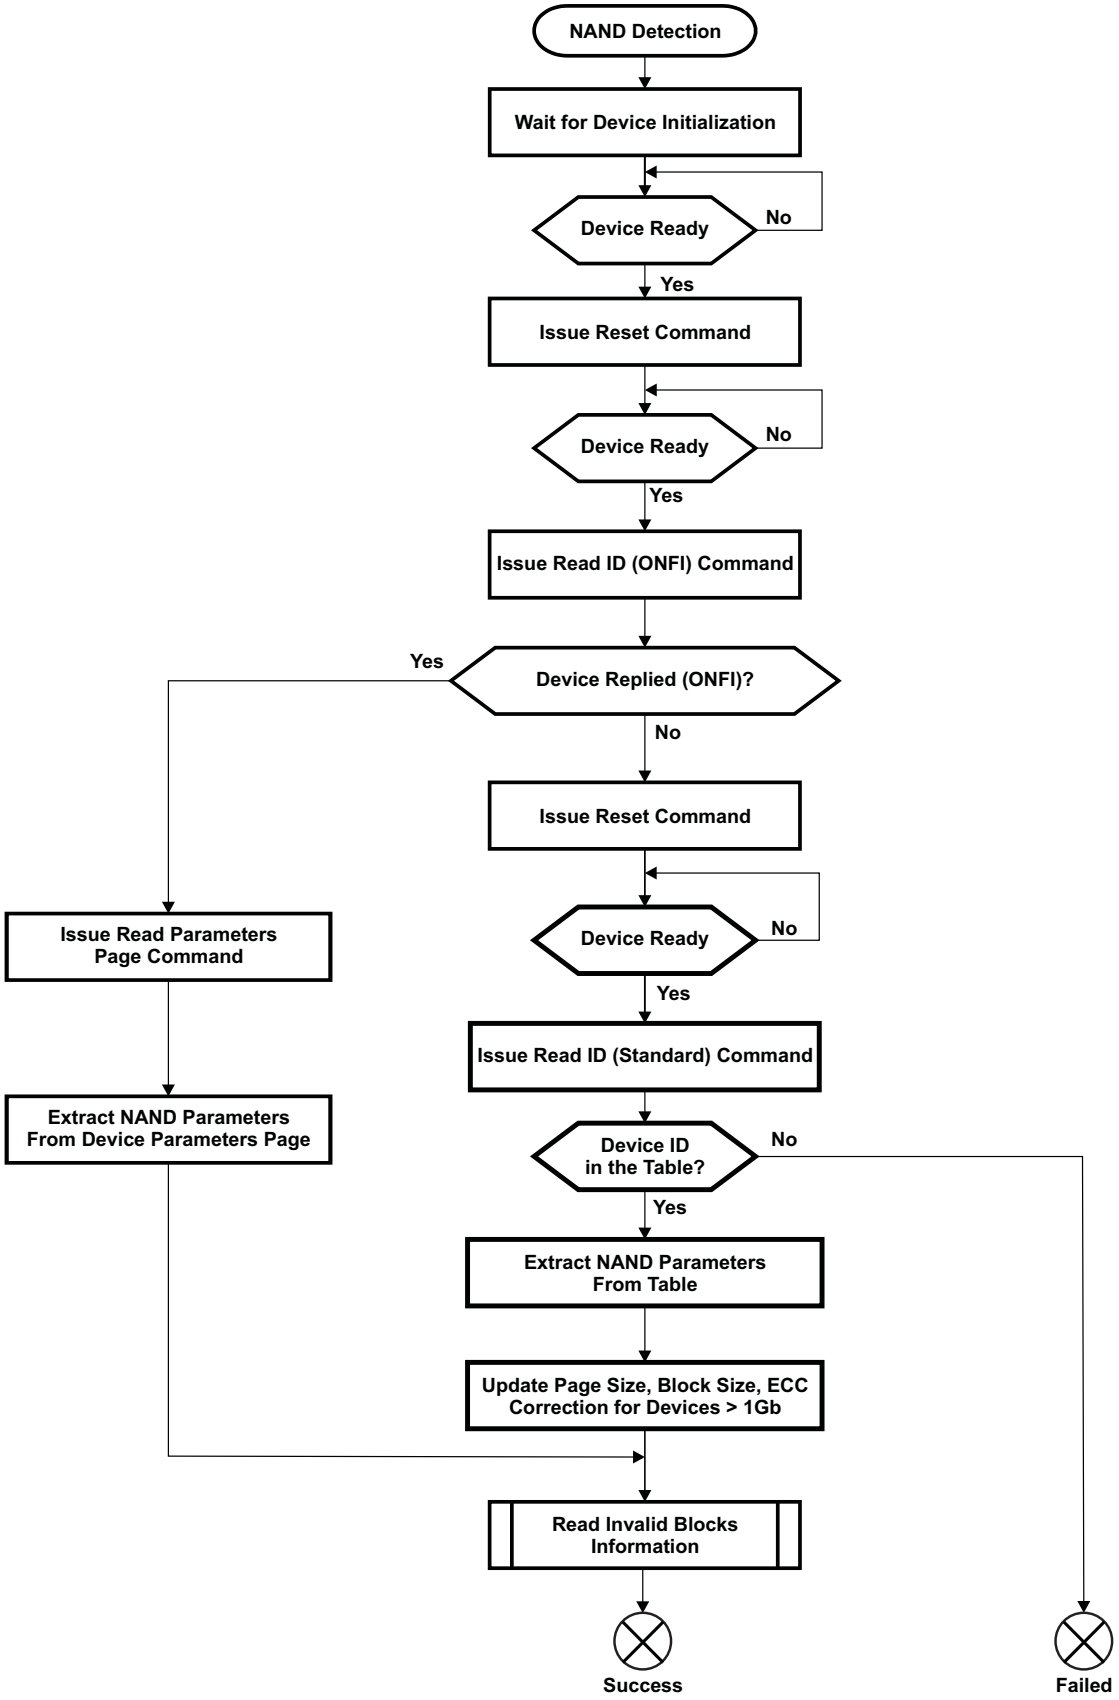
Figure 4-12. NAND Device Detection

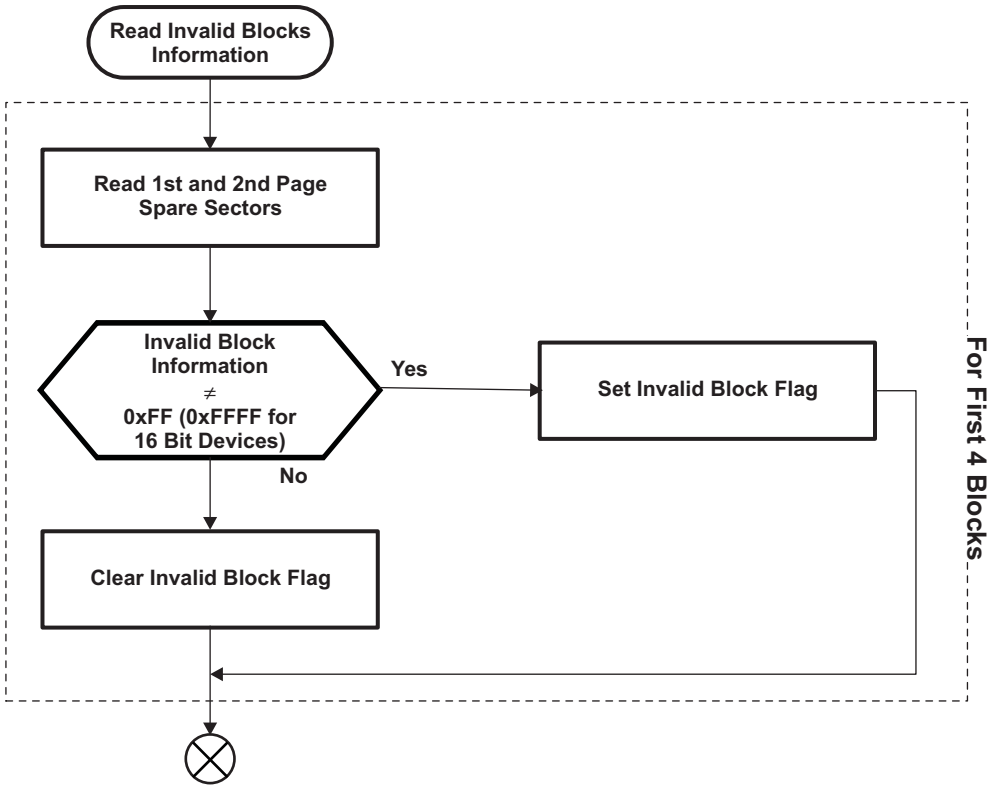


Copyright © 2011–2013, Texas Instruments Incorporated

- **Bad block verification.** Invalid blocks are blocks which contain invalid bits whose reliability cannot be guaranteed by the manufacturer. Those bits are identified in the factory or during the programming and reported in the initial invalid block information located in the spare area on the 1st and 2nd page of each block. Since the ROM Code is looking for an image in the first four blocks, it must detect block validity status of these blocks. Blocks which are detected as invalid are not accessed later on. Blocks validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in 1st and 2nd pages for an 8 bits device / first word equal to FFFFh in 1st and 2nd page for a 16-bit device).

  Figure 4-13 depicts the invalid block detection routine. The routine consists in reading spare areas and checking validity data pattern.

Figure 4-13. NAND Invalid Blocks Detection



Copyright © 2011–2013, Texas Instruments Incorporated

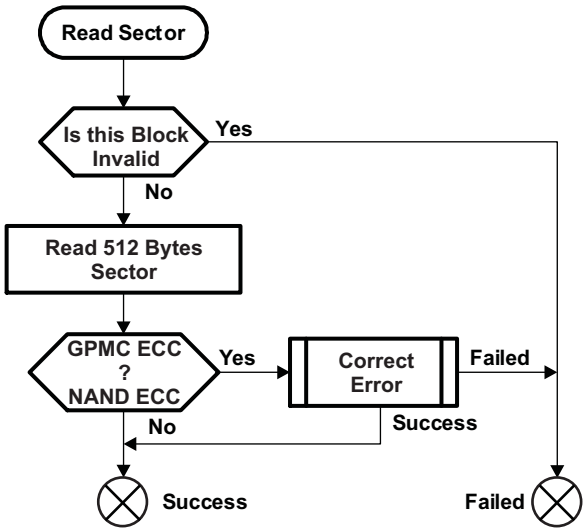
4.7.3.3 NAND Read Sector Procedure

The ROM Code reads data from NAND devices in 512 bytes sectors. The read function fails in two cases:

- The accessed sector is within a block marked as invalid
- The accessed sector contains an error which cannot be corrected with ECC

Figure 4-14 shows the read sector routine for NAND devices. The ROM Code uses normal read (command 00h 30h) for reading NAND page data.

Figure 4-14. NAND Read Sector Procedure



Page data can contain errors due to memory alteration. The ROM Code uses an ECC correction algorithm to detect and possibly correct those errors. The ECC algorithm used is BCH with capability for correcting 8b or 16b errors per sector. The BCH data is automatically calculated by the GPMC on reading each 512 bytes sector. The computed ECC is compared against ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 4-15 and Figure 4-16 show the mapping of ECC data inside the spare area for respectively 2KB-page and 4KB- page devices. If both ECC data are equal then the Read Sector function returns the read 512 bytes sector without error. Otherwise, the ROM Code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

4.7.3.4 Pins Used for NAND Boot

The list of pins that are configured by the ROM in case of NAND boot mode are in Table 4-18. Note that all the pins might not be driven at boot time.

Table 4-18. Pins Used for NAND Boot

Signal name	Pin used
cs0	gpmc_cs0
advn_ale	gpmc_advn_ale

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-18. Pins Used for NAND Boot (continued)

Signal name	Pin used
oen_ren	gpmc_oen_ren
be0n_cle	gpmc_be0n_cle
wen	gpmc_wen
wait	gpmc_wait
clk	gpmc_clk(1)
ad0 - ad15	gpmc_ad0 - gpmc_ad15

(1) gpmc_clk is not configured in MBOOT[10] = 1b

4.7.3.5 Sysboot Pins for NAND Boot

Some of the SYSBOOT pins have special meanings when NAND boot is selected.

Table 4-19. Special SYSBOOT pins for NAND boot

SYSBOOT[n]	Description
[12] (CS0BW)	Must be 0 if 8-bit NAND is used
	Must be 1 if 16-bit NAND is used
[15] (CS0WAIT)	Must be 0
[14:13] (CS0MUX[1:0])	Must be 0

4.7.4 MMC/SD Cards

4.7.4.1 Overview

The ROM code supports booting from MMC/SD cards in the following conditions:

- MMC/SD Cards compliant to low and high capacities
- MMC/SD cards connected to MMC interface #1
- 3V VCC power supply, support for 3V or 1.8V I/O voltages
- Initial 1-bit MMC Mode, optional 4-bits or 8-bits mode
- Clock Frequency: identification mode: 400 KHz; data transfer mode up to 10 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from sectors in the user area
- File system mode (FAT12/16/32 supported with or without Master Boot Record), image data is read from a booting file

4.7.4.2 System Interconnection

An MMC/SD card can be connected to the MMC1 interface typically through a card cage.

Notes:

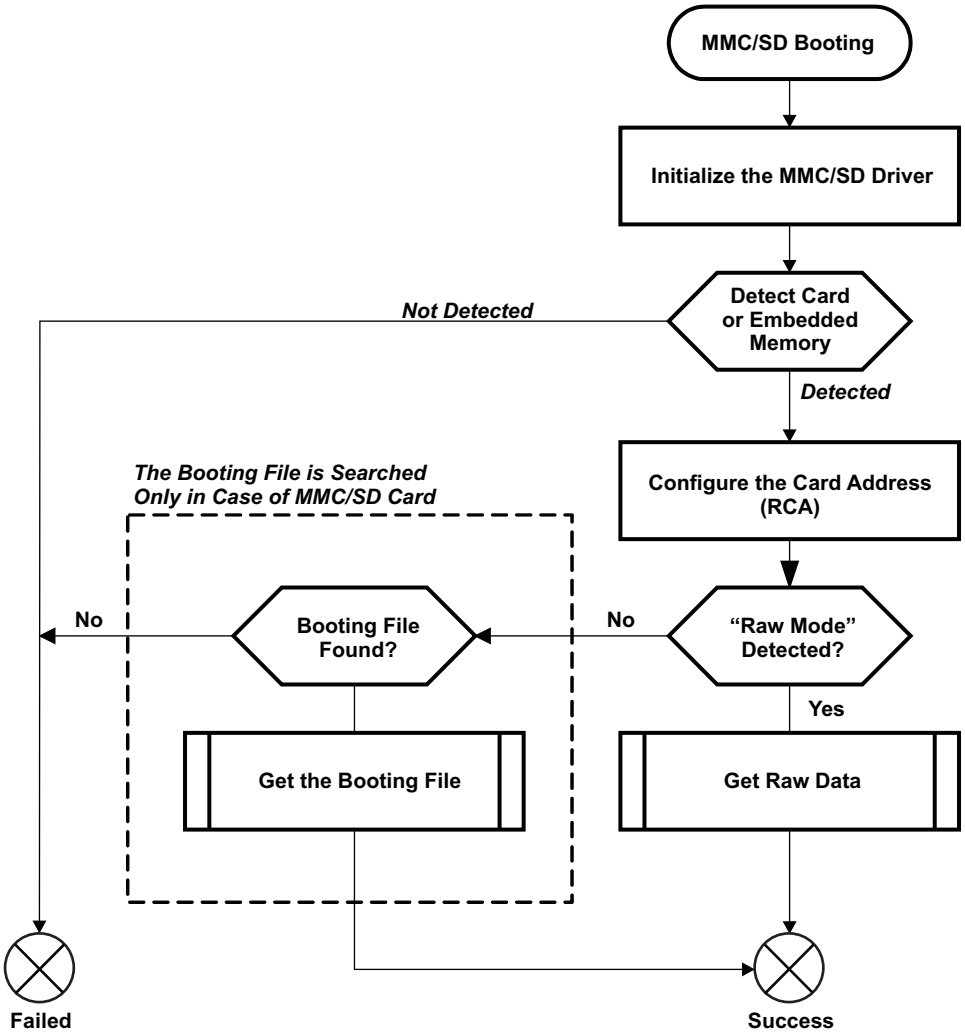
- It may be possible to design the system so that an eMMC/eSD memory type is connected to the MMC1 interface. However, the dual voltage IOs feature of MMC1 dedicates it preferably to cards.
- The ROM Code does not handle the card detection feature on card cage.

4.7.4.3 Booting Procedure

The high level flowchart of the eMMC/eSD and MMC/SD booting procedure is depicted in Figure 4-17. The booting file is searched only in case of booting from a card. eMMC/eSD embedded memories only support raw mode.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-17. MMC/SD Booting



4.7.4.4 Initialization and Detection

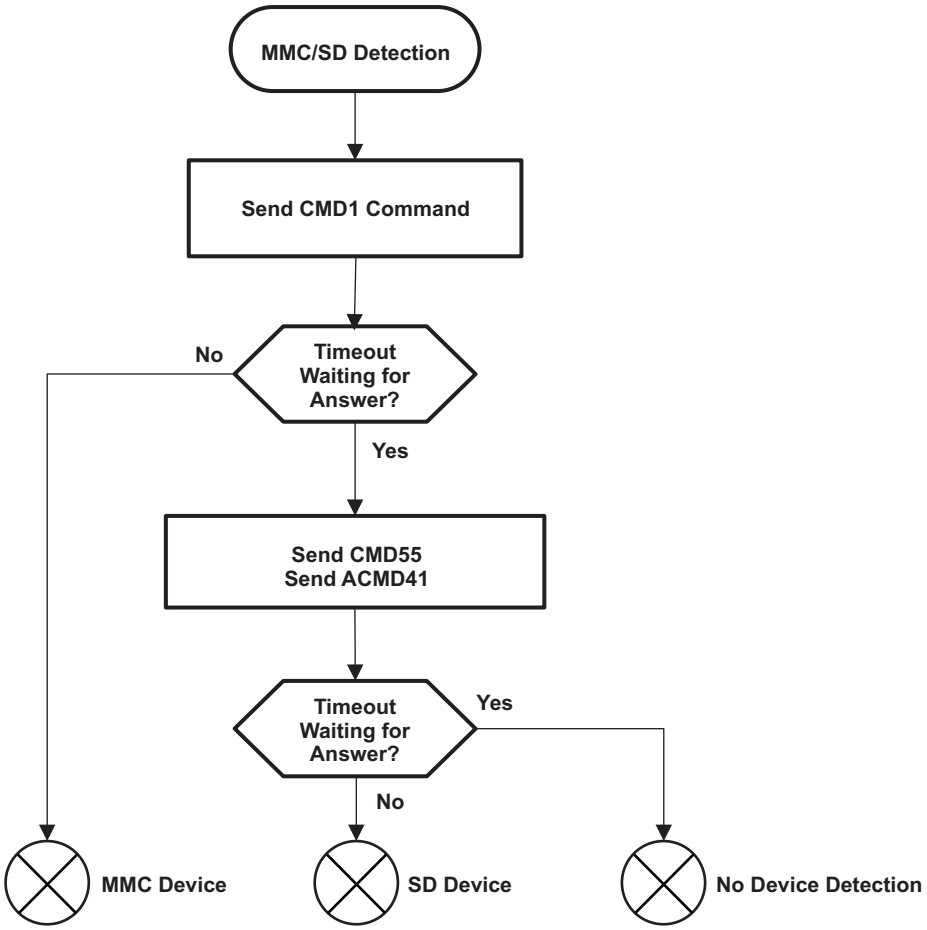
The ROM Code initializes the memory device or card connected on MMC interface using the standard High-Voltage range (3.0V). If neither memory device nor card is detected then the ROM code carries on to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM Code assumes that only one memory or card is present on the bus. This first sequence is done using the CMD signal that is common to SD and MMC devices.

MMC and SD standards detail this phase as initialization phase. Both standards differ in the first commands involved: CMD1 and ACMD41. The ROM code uses this difference in command set to discriminate between MMC and SD devices: CMD1 is supported only by the MMC standard whereas ACMD41 is only supported by SD standard. The ROM code first sends a CMD1 to the device and gets a response only if an MMC device is connected. If no response is received then ACMD41 (ACMD41 is made out of CMD55 and ACMD41) is sent and a response is expected from an SD device. If no response is received then it is assumed that no device is connected and the ROM Code exits the MMC/SD Booting procedure with FAIL. This is detection procedure is shown in Figure 4-18.

As previously mentioned, the contents of an MMC/D card may be formatted as raw binary or within a FAT filesystem. eMMC/SD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 4-18. MMC/SD Detection Procedure



As previously mentioned, the contents of an MMC/D card may be formatted as raw binary or within a FAT filesystem. eMMC/SD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

4.7.4.5 MMC/SD Read Sector Procedure in Raw Mode

In raw mode the booting image can be located at one of the four consecutive locations in the main area: offset 0/20000h (128KB)/40000h (256KB)/60000h (384KB). For this reason a booting image shall not exceed 128KB in size. However it is possible to flash a device with an image greater than 128KB starting at one of the aforementioned locations. Therefore the ROM code does not check the image size. The only drawback is that the image will cross the subsequent image boundary.

The raw mode is detected by reading sectors #0, #256, #512, #768. The content of these sectors is then verified for presence of a TOC structure as described in Figure 4-26. A configuration header (CH) must be located in the first sector followed by a header. The CH might be void (only containing a CHSETTINGS item for which the Valid field is zero).

4.7.4.6 MMC/SD Read Sector Procedure in FAT Mode

MMC/SD cards may hold a FAT file system which ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named “MLO.” This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any master boot record (MBR) holding a partition table

Copyright © 2011–2013, Texas Instruments Incorporated

- When acting as hard-drive-like, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary and active.

The card should always hold an MBR except for MMC cards using floppy-like file system (refer to the CSD internal Register fields FILE_FORMAT_GRP and FILE_FORMAT). However, depending on the operating system, the MMC/SD card will be formatted either with partition(s) (using an MBR) or without. The ROM code supports both types; this is described in the following section.

The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512 byte sector within the booting file without involving ROM code FAT module.

The sector read procedure utilizes standard MMC/SD raw data read function. The sector address is generated based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

4.7.4.7 FAT File System

This paragraph describes functionalities which are used by the ROM Code. It is not intended to fully describe the Master Boot Record and the FAT file system, but does include:

- How to recognize if a sector is the 1st sector of an MBR
- How to recognize if a sector is the 1st sector of a FAT12/16/32
- How to find the 1st cluster of the booting file
- How to buffer the booting file FAT entries

Some memory devices which support file systems can be formatted with or without MBR, therefore the first task of the ROM Code is to detect whether or not the device is holding an MBR in the first sector. If this is the case, an active FAT12/16/32 partition is searched in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no useable partition is found then the ROM Code returns to the Booting procedure with FAIL. The Extended partitions are not checked, the booting file must reside in a primary partition.

If a partition is found then its first sector is read and used further on. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used further on. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, in case another partition type is used (i.e., Linux FS or any other) or if the partition is not valid, the ROM Code returns with FAIL.

Otherwise, the Root Directory entries are searched for a file named depending on the booting device. The Long File Names (LFN) format is not used and only File Names in 8.3 Format are searched for. If no valid file is found, the ROM Code returns with FAIL.

Once the file has been found, the ROM Code reads the File Allocation Table (FAT) and buffers the singly-linked chain of clusters in a FAT Buffer which will be used by the Booting Procedure to access the file directly sector by sector. For FAT12/16 and for FAT32 (valid if a specific flag has been set in the FAT32 Boot Sector), there exist multiples copies of the FAT (ROM Code supports only two copies). When buffering FAT entries, the two FATs are compared. If they are not the same, only entries from the last FAT are used. The FAT Buffer holds sector numbers and not cluster numbers. The ROM Code converts each cluster entry to one or several sector entries if applicable.

The whole process is described in Figure 4-19. Every part related to MBR or FAT12/16/32 is described in the next paragraph.

4.7.4.7.1 Master Boot Record: MBR

The Master boot record is the 1st sector of a memory device. It is made out of some executable code and four partition entries. The aim of such a structure is to be able to divide the hard disk in partitions mostly used to boot different systems (Microsoft Windows™, Linux, …). Its structure is described in Table 4-20 and Table 4-21. The valid partition types searched by the ROM Code are described in Table 4-22.

Table 4-20. Master Boot Record Structure

Offset	Length [bytes]	Entry Description	Value
0000h	446	Optional Code	
01BEh	16	Partition Table Entry	(see)
01CEh	16	Partition Table Entry	(see)
01DEh	16	Partition Table Entry	(see)
01EEh	16	Partition Table Entry	(see)
01FEh	2	Signature	AA55h

Table 4-21. Partition Entry

Offset	Length [bytes]	Entry Description	Value
0000h	1	Partition State	00h: Inactive 80h: Active
0001h	1	Partition Start Head	H_s
0002h	2	Partition Start Cylinder and Sector	C_s[7:0]-C_s[9:8]-S_s[5:0]
0004h	1	Partition Type	Refer to for partial partition types
0005h	16	Partition End Head	H_e
0006h	2	Partition End Cylinder and Sector	C_e[7:0] - C_e[9:8] - S_e[5:0]
0008h	4	First sector position relative to the beginning of media	$LBA_s = C_s.H.S + H_s.S + S_s - 1$
000Ch	4	Number of sectors in partition	$LBA_e = C_e.H.S + H_e.S + S_e - 1$ $Nb_s = LBA_e - LBA_s + 1$

Table 4-22. Partition Types

Partition Type	Description
01h	FAT12
04h, 06h, 0Eh	FAT16
0Bh, 0Ch, 0Fh	FAT32

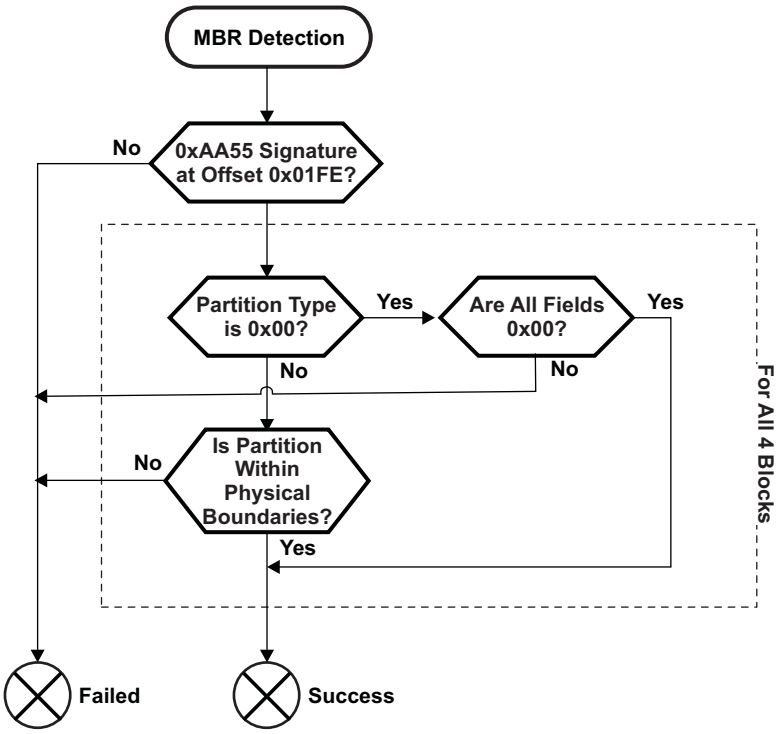
Copyright © 2011–2013, Texas Instruments Incorporated

The way the ROM Code detects whether a sector is the 1st sector of an MBR or not is described in Figure 4-20.

The ROM Code first checks if the signature is present. Each partition entry is checked:

- If its type is set to 00h then all fields in the entry must be 00h
- The partition is checked to be within physical boundaries, i.e. the partition is located inside and its size fits the total physical sectors.

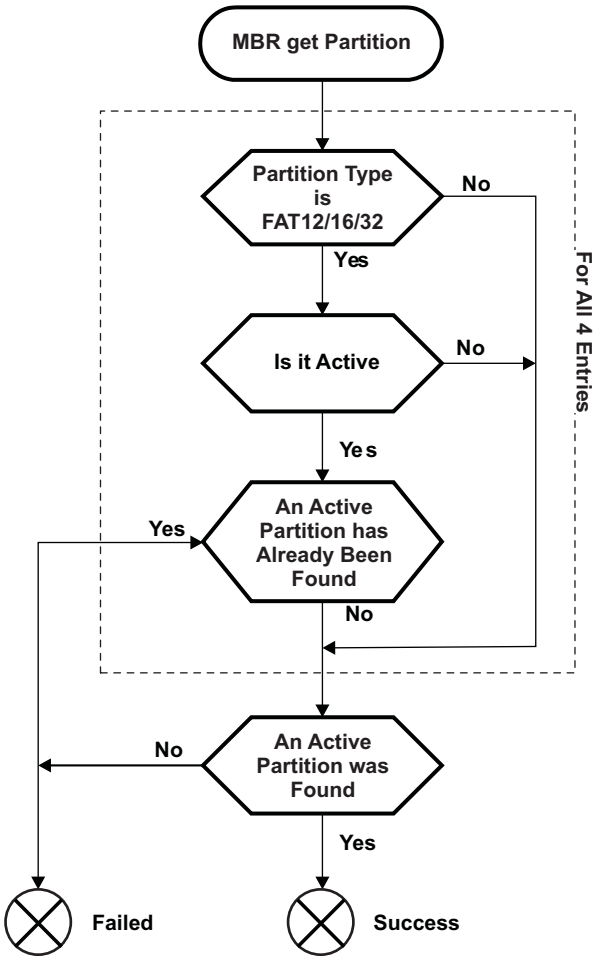
Figure 4-20. MBR Detection Procedure



Copyright © 2011–2013, Texas Instruments Incorporated

Once identified, the ROM Code gets the partition using the procedure described in Figure 4-21. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h or 80h (if there is more than one active partition the test fails). The ROM Code returns with FAIL if no active primary FAT12/16/32 could be found.

Figure 4-21. MBR, Get Partition



4.7.4.7.2 FAT12/16/32 Boot Sector

The FAT file system is made out of several parts:

- Boot Sector which holds the BIOS Parameter Block (BPB)
- File Allocation Table (FAT) which describes the use of each cluster of the partition
- Data Area which holds the Files, Directories and Root Directory (for FAT12/16, the Root Directory has a specific fixed location)

The boot sector is described in Table 4-23. In the following description, all the fields whose names start with BPB_ are part of the BPB. All the fields whose names start with BS_ are part of the Boot Sector and not really part of the BPB (not mandatory); they are not used at all by the ROM Code.

Table 4-23. FAT Boot Sector

	Offset	Length [bytes]	Name	Description
	0000h	3	BS_jmpBoot	Jump Instruction to Boot Code (not used)
	0003h	8	BS_OEMName	Name of the System which created the partition

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-23. FAT Boot Sector (continued)

	Offset	Length [bytes]	Name	Description
	000Bh	2	BPB_BytsPerSec	Counts of Bytes per sector (usually 512)
	000Dh	1	BPB_SecPerClus	Number of sectors per allocation unit
	000Eh	2	BPB_RsvdSecCnt	Number of reserved sectors for the Boot Sector For FAT12/16 is 1, for FAT32, usually 32
	0010h	1	BPB_NumFATs	Number of copies of FAT, usually 2
	0011h	2	BPB_RootEntCnt	For FAT12/16, number of 32 bytes entries in the Root Directory (multiple of BPB_BytsPerSec/32) For FAT32 this value is 0
	0013h	2	BPB_TotSec16	Total Count of sectors on the volume. If the size is bigger than 10000h or for FAT32, this field is 0 and BPB_TotSec32 holds the value
	0015h	1	BPB_Media	Media Type, usually F8h: fixed, non-removable
	0016h	2	BPB_FATSz16	For FAT12/16, size in sectors of one FAT For FAT32, holds 0
	0018h	2	BPB_SecPerTrk	Number of sectors per track, 63 for MMC/SD
	001Ah	2	BPB_NumHeads	Number of heads, 255 for MMC/SD
	001Ch	4	BPB_HiddSec	Number of sectors preceding the partition
	0020h	4	BPB_TotSec32	Total Count of sectors on the volume. If the size is smaller than 10000h (for FAT12/16), this field is 0 and BPB_TotSec16 is valid
FAT12/16	0024h	1	BS_DrvNum	Drive Number
	0025h	1	BS_Reserved1	00h
	0026h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0027h	4	BS_VolID	Volume Serial Number
	002Bh	11	BS_VolLab	Volume Label
	0036h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”. Note: This field is not mandatory (i.e., BS_) therefore it cannot be used to indentify the partition type.
FAT32	0024h	4	BPB_FATSz32	Size in sectors of one FAT. Field BPB_FATSz16 must be 0
	0028h	2	BPB_ExtFlags	FAT Flags: [7]: 0 = FAT is mirrored; 1 = Only one FAT is used [3:0]: Number of used FAT if no mirroring used
	002Ah	2	BPB_FSVer	File system Version Number
	002Ch	4	BPB_RootClus	First Cluster number of the Root Directory
	0030h	2	BPB_FSInfo	Sector number of FSINFO Structure in the reserved-area, usually 1
	0032h	2	BPB_BkBootSec	If non-zero, indicates the sector number in the reserved-area of a copy of the Boot Sector
	0034h	12	BPB_Reserved	Reserved, set to 00h
	0040h	1	BS_DrvNum	Drive Number
	0041h	1	BS_Reserved1	00h
	0042h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0043h	4	BS_VolID	Volume Serial Number
	0047h	11	BS_VolLab	Volume Label
	0052h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”. Note: This field is not mandatory (i.e., BS_) therefore it cannot be used to indentify the partition type.
	01FEh	2	BPB_Signature	AA55h

Copyright © 2011–2013, Texas Instruments Incorporated

To check whether or not a sector holds a valid FAT12/16/32 partition, only fields starting with BPB can be checked as they are mandatory. The fields starting from offset 0024h to 01FDh cannot be used for the check as they will differ if using FAT12/16 or FAT32. The procedure is described in Figure 22. First the ROM Code checks if the BPB_Signature is equal to AA55h. Then it checks some fields which must have some specific values (BPB_BytsPerSec, BPB_SecPerClus, BPB_RsvdSecCnt, BPB_NumFATs, BPB_RootEntCnt). If the geometry of the device is known then it is compared against BPB_SecPerTrk and BPB_NumHeads fields. If an MBR was found before, the partition size is also checked.

$$BPB_TotSec16 = MBR_Partition_Size$$

or

$$BPB_TotSec32 = MBR_Partition_Size$$

The field BPB_ToSec16 is used if the total number of sectors is below 65518 (in this case BPB_TotSec32=0), otherwise, BPB_TotSec32 is used (BPB_TotSec16=0). The partition sector offset is also checked: BPB_HiddSec = MBR_Partition_Offset (if this value is not 0 as some operating systems do not update this field correctly). The last step is to decide which type of FAT file system it is. The ROM Code computes the number of clusters in the Data Area part of the partition:

$$Nb_{clusters} < 4085 \Rightarrow \text{FAT12}$$

$$4085 \le Nb_{clusters} < 65525 \Rightarrow \text{FAT16}$$

$$65525 \le Nb_{clusters} \Rightarrow \text{FAT32}$$

Where Nbclusters is given by the size of the Data Area:

$$RootDirSectors = \frac{BPB_RootEntCnt * 32}{BPB_BytesPerSec}$$

$$DataSec = BPB_TotSec - (BPB_\text{Re}svdSecCnt + (BPB_NumFATs.BPB_FATSz) + RootDirSectors)$$

$$Nb_{clusters} = \frac{DataSec}{BPB_SecPerClus}$$

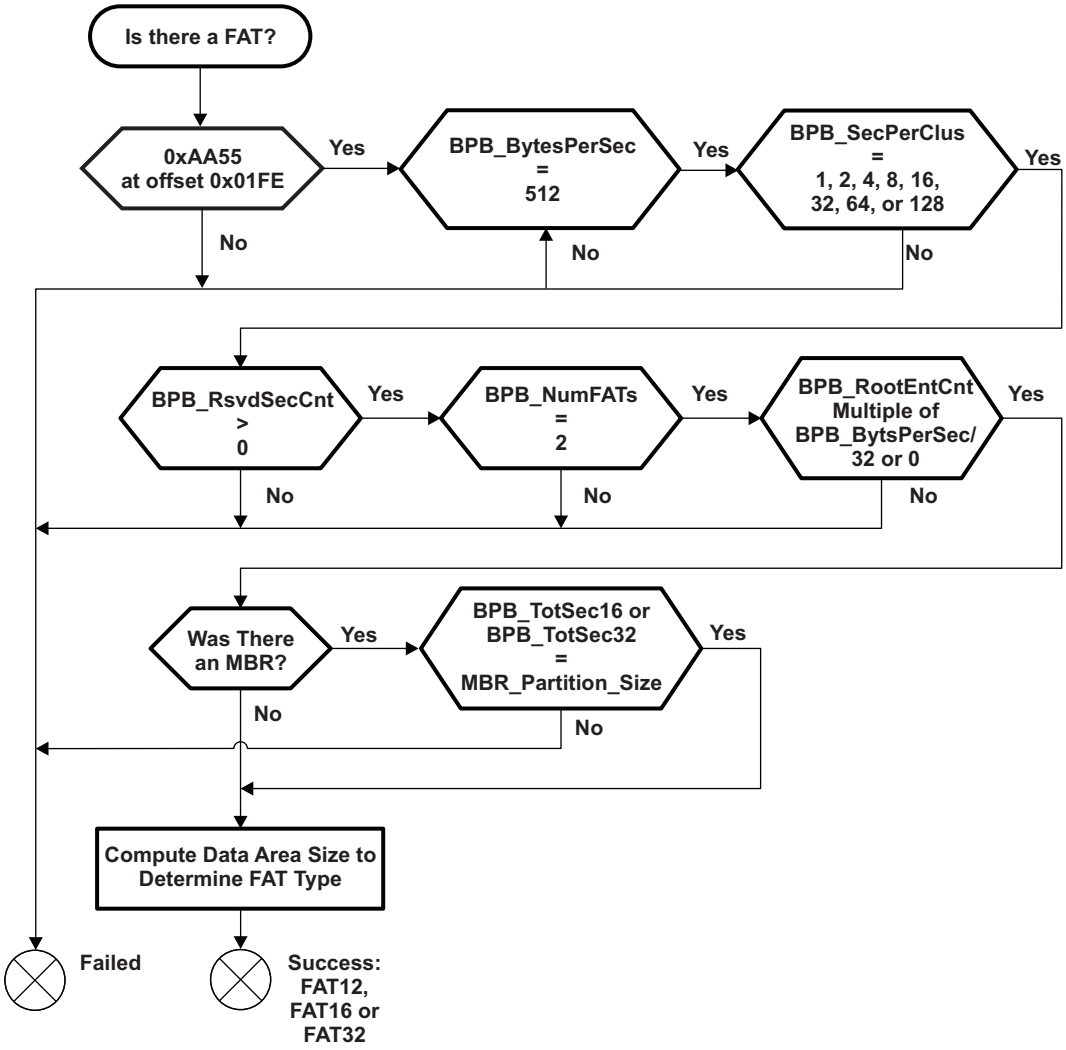
Figure 4-22. FAT Detection Procedure



4.7.4.8 FAT12/16/32 Root Directory

The next task for the ROM Code is to find the booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The general formulae to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerClus$$

Note: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

Note: The BPB_HiddSec field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used.

Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e., filename, date of creation, rights, cluster location etc. This is described in Table 4-24.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-24. FAT Directory Entry

Offset	Length	Name	Description	
	[bytes]			
0000h	11	DIR_Name	Short Name (8+3)	
000Bh	1	DIR_Attr	File Attributes:	
			ATTR_READ_ONLY	01h
			ATTR_HIDDEN	02h
			ATTR_SYSTEM	04h
			ATTR_VOLUME_ID	08h
			ATTR_DIRECTORY	10h
			ATTR_ARCHIVE	20h
			ATTR_LONG_NAME	ATTR_READ_ONLY | ATTR_HIDDEN | ATTR_SYSTEM | ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved, set to 00h	
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation	
000Eh	2	DIR_CrtTime	Time file was created	
0010h	2	DIR_CrtDate	Date file was created	
0012h	2	DIR_LstAccDate	Last Access date	
0014h	2	DIR_FstClusHi	High word of this entry's first cluster number	
0016h	2	DIR_WrtTime	Time of last write	
0018h	2	DIR_WrtDate	Date of last write	
001Ah	2	DIR_FstClusLo	Low word of this entry's first cluster number	
001Ch	4	DIR_FileSize	File size in bytes	

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the next paragraph.

4.7.4.9 FAT12/16/32 File Allocation Table

The ROM Code needs to read the FAT in order to retrieve sectors either for the booting file or for the Root Directory (in case the file system is FAT32).

There can be multiple copies of the FAT inside the file system (ROM Code supports only 2) located after the Boot Sector:

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_FatSz \cdot n$$

Its size is given by BPB_FATSz16 or BPB_FATSz32. The ROM Code checks each copy of the FAT if identical. In case the values are different, the ROM Code uses the value from the last FAT copy. With FAT32 file system, the copy system can be disabled according to a flag located in BPB_ExtFlags[7]. If this flag is set then FAT BPB_ExtFlags[3:0] is used. In this case no verification is made by the ROM Code with other copies of FAT.

Copyright © 2011–2013, Texas Instruments Incorporated

The FAT is a simple array of values each refering to a cluster located in the Data Area. One entry of the array is 12, 16 or 32 bits depending on the file system in use. The value inside an entry defines whether the cluster is being used or not and if another cluster has to be taken into account. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in Table 4-25.

Note: : For compatibility reasons, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); FFFFFF8h and FFFFFFFh (for FAT32).

Table 4-25. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	?0000000h	Free Cluster
001h	0001h	?0000001h	Reserved Cluster
002h-FEFh	0002h-FFEFh	00000002h-?FFFFFEFh	Used Cluster; value points to next cluster
FF0h-FF6h	FFF0h-FFF6h	?FFFFFF0h-?FFFFFF6h	Reserved values
FF7h	FFF7h	?FFFFFF7h	Bad Cluster
FF8h-FFFh	FFF8h-FFFFh	?FFFFFF8h-?FFFFFFFh	Last Cluster in File

Note: FAT32 uses only bits [27:0], the upper 4 bits are usually 0 and should be left untouched. When accessing the Root Directory for FAT32, the ROM Code just starts from the Root Directory Cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM Code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later on by the booting procedure to access the file.

4.7.4.10 Pins Used for MMC Boot

The list of pins that are configured by the ROM in case of MMC boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 4-26. Pins Used for MMC Boot

Signal name	Pin used
clk	mmc1_clk
cmd	mmc1_cmd_mux0
dat0	mmc1_dat0
dat1	mmc1_dat1
dat2	mmc1_dat2
dat3	mmc1_dat3

4.7.5 SPI

SPI EEPROMs or SPI flashes have an EEPROM or NOR flash backend and they connect to the device using the serial SPI protocol. These typically devices operate in three stages – the command stage, the address stage and the data transfer stage. The command is usually an 8 bit value followed by the address (depending on the size of the device) followed by the data to be read or written. Because of the need for fewer pins, these devices are comparatively inexpensive, easy for board layout, and are the devices of choice when cost, complexity and form factor are critical considerations.

4.7.5.1 SPI Features

The following features are included in SPI:

- Supports 12 MHz clock (50% duty cycle)
- Supports only SPI Mode 3 (clock polarity = 1, clock phase = 1)
- Supports only 24 bit addressable EEPROMs

Copyright © 2011–2013, Texas Instruments Incorporated

- Supports only 4-pin SPI mode (CS, CLK, Serial Input, Serial Output)
- The boot devices must be connected to channel 0 and must support the read command (03h)
- The boot image is copied into internal memory and then executed

4.7.5.2 Initialization and Detection

The ROM Code initializes the SPI controller, pin muxing and clocks for communicating with the SPI device. The controller is initialized in Mode 3 and the clock is setup to operate at 12 MHz. There is no specific device identification routine that is executed by the ROM code to identify whether a boot device is preset or not. If no SPI device is present, the sector read will return only 0xFFFFFFFF and the SPI boot will be treated as failed.

4.7.5.3 SPI Read Sector Procedure

The ROM Code reads SPI data from the boot device in 512 byte sectors. For each call to the SPI Read Sector routine, the SPI Read Command (0x03) is sent along with the 24 bit start address of the data to be read.

From the next iteration onwards, a dummy value is transmitted on the master out line and the data is received on the master in line. This needs to be done because SPI protocol always operated in full duplex mode. The dummy data transmitted by the ROM is the Read Command appended to the start address. The data from the boot device is received MSB first.

As the A8 is a little-endian processor, and SPI operates in a big-endian format, this means that while writing to the flash, care needs to be taken to write the image in a big-endian format. This way we can avoid doing the endian conversion at boot time, thus improving boot performance

4.7.5.4 Pins Used for SPI Boot

The list of device pins that are configured by the ROM in the case of SPI boot mode are shown in the table below. Please note that all the pins might not be driven at boot time.

The default state of the other SPI chip select pins could be low at POR, so care must be taken if any other devices are connected to CS[1], CS[2] or CS[3]. External logic must be used to ensure that the chip select to these devices are not enabled by default. .

Table 4-27. Pins Used for SPI Boot

Signal name	Pin used
cs	spi0_cs0
miso	spi0_d0
mosi	spi0_d1
clk	spi0_sclk

4.7.6 Blocks and Sectors Search Summary

Table 4-28 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NAND is organized with blocks, which are erasable units.

Table 4-28. Blocks and Sectors Searched on non-XIP Memories

Memory	Maximum number of blocks checked	Number of sectors searched
NAND	first 4	Number of sectors in one block (1)
SPI, eMMC/eSD and MMC/SD cards (raw mode)	first 4	1

(1) Depends on NAND geometry.

Copyright © 2011–2013, Texas Instruments Incorporated

Regarding MMC/SD card booting in FAT mode, the file system area is searched for one file.

4.8 Peripheral Booting

4.8.1 Overview

The ROM Code can boot from three different peripheral interfaces:

EMAC	1000/100/10 Mbps Ethernet, using standard TCP/IP network boot protocols BOOTP and TFTP
PCIe	One lane @250 MB/s
UART	115.2Kbps, 8 bits, even parity, 1 stop bit, no flow control

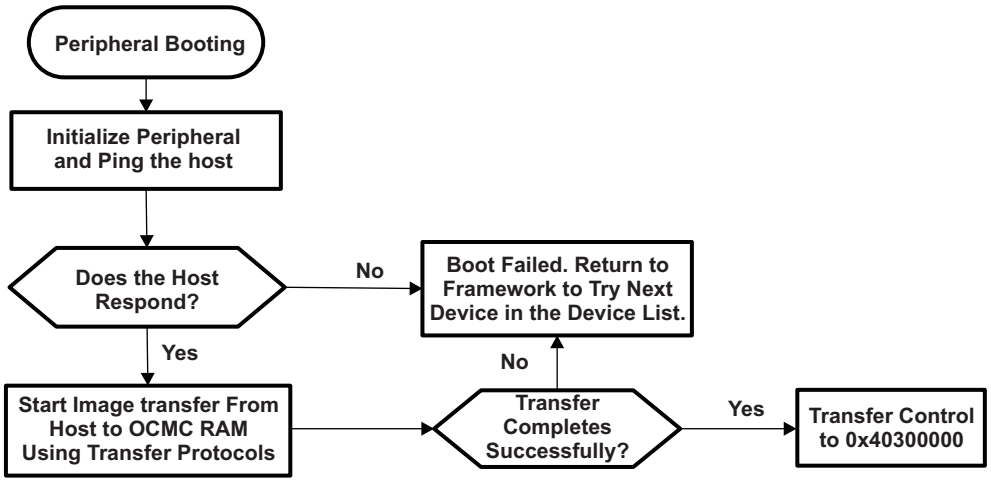
The purpose of booting from a peripheral interface is to download a boot image from an external host (typically a PC). This booting method is mostly used for programming flash memories connected to the device (e.g., in the case of initial flashing, firmware update or servicing).

4.8.2 Boot Image Location and Size

The boot image is downloaded directly into internal RAM at the location 40300000h. The maximum size of downloaded image is 110KB.

4.8.3 Peripheral Boot Procedure Overview

Figure 4-23. Peripheral Booting Procedure



4.8.4 EMAC Boot Procedure

4.8.4.1 Device Initialization

- EMAC boot uses the CPGMAC0 subsystem of the device. It can be connected to external Ethernet PHY using the GMII0, RMII or RGMII interfaces and MDIO pins
- Device uses EFUSE register MAC_ID0 for Ethernet MAC address of the device.
- Device detects if the PHY is alive on the MDIO interface and
  - Reads the STATUS register to check if Ethernet link is active
  - Reads the CONTROL register to detect the auto-negotiated mode of operation
    - Is the mode full-duplex or half duplex
    - Speed of operation, 1000/100/10 Mbps

Copyright © 2011–2013, Texas Instruments Incorporated

4.8.4.2 BOOTP (RFC 951)

The device then proceeds to obtain the IP and Boot information using BOOTP protocol. The device prepares and broadcasts the BOOTP message that has the following information:

- Device MAC address in “chaddr” field – to uniquely identify the device to the server.
- “Vender-class-identifier” option number 60 (RFC 1497, RFC 1533). Servers could use this information to identify the device type. The value present is "DM816x ROM v1.0"
- ”Client-identifier” option number 61 (RFC 1497, RFC 1533). This has the ASIC-ID structure which contains additional info for the device.

The device then expects a BOOTP response that provides the following information for the booting to proceed:

- Device IP address from “yiaddr” field
- Subnetmask from extended option 1 (RFC 1497, RFC 1533)
- Gateway IP from extended option number 3 (RFC 1497, RFC 1533) or from “giaddr” field of BOOTP response.
- Boot image filename from “file” field
- TFTP server IP address from the “siaddr” field

  Timeouts and retries
- Exponentially increasing timeouts starting from 4s
- Five retries

4.8.4.3 FTP (RFC 1350)

After a successful BOOTP completion, the device initiates the TFTP download of the boot image into SRAM. The device has the capability to reach TFTP server within the local subnet or outside, though the gateway.

Timeouts and retries

- Timeout of 1s to receive a response for the READ request
- 5 retries for the READ request
- Retries are managed by server once data transfer starts (server re-sends a data packet if the ACK was not received within a timeout value)
- Device has a 60s timeout to complete the data transfer, to handle the scenario if the server dies in the middle of a data transfer

4.8.4.4 Pins Used for EMAC Boot

The list of pins that are configured by the ROM in case of EMAC boot mode are in . Note that all the pins might not be driven at boot time.

4.8.5 PCIe Boot Procedure

4.8.5.1 Device Initialization

- ROM code configures the PCIe vendor ID as 104Ch

Copyright © 2011–2013, Texas Instruments Incorporated

- ROM code configures the PCIe device ID as B801h.
- The BAR window sizes for inbound translation are configurable as per the tables below
- Only legacy interrupt A is enabled. MSI is disabled
- The device is configured in the D0 power state
- The link and device capability is configured for maximum flexibility
- The PCIe settings used by the ROM can be overridden after boot by the Root Complex

Figure 4-24. PCIe Peripheral Booting Procedure

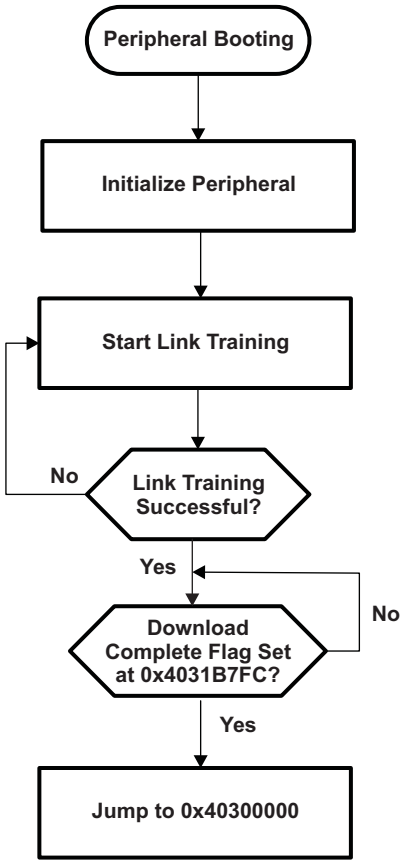

Table 4-33. PCIe 32 BAR Window Size Configuration

	11	1GB	11	4GB

Table 4-35. PCIe BAR Window Base Address and Offset Configuration

BAR	Base Address	Offset	Comments
0	0000 0000h	0000 0000h	
1 (64bit BAR0)	4000 0000h	4030 0000h	OCMC RAM
2	6000 0000h	5000 0000h	GPMC
3 (64 Bit BAR2)	8000 0000h	8000 0000h	DDR 0
4	A000 0000h	C000 0000h	DDR 1

Note that the base address and offset configurations can be changed from the host after the enumeration is complete.

4.8.6 UART Boot Procedure

4.8.6.1 Device Initialization

- UART boot uses UART0
- UART0 is configured to run at 115200 baud, 8-bits, even parity, 1 stop bit and no flow control.

4.8.6.2 Boot Image Download

- UART boot uses x-modem client protocol to receive the boot image.
- Utilities like hyperterm, teraterm, minicom can be used on the PC side to download the boot image to the board
- With x-modem packet size of 1K throughout is roughly about 4KBytes/Sec.
- The ROM code will ping the host 10 times in 3s to start x-modem transfer. If host does not respond, UART boot will timeout.
- Once the transfer has started, if the host does not send any packet for 3s, UART boot will time out.
- If the delay between two consecutive bytes of the same packet is more than 2ms, the host is requested to re-transmit the entire packet again.
- Error checking using the CRC-16 support in x-modem. If an error is detected, the host is requested to re-transmit the packet again.

Copyright © 2011–2013, Texas Instruments Incorporated

4.8.6.3 Pins Used for UART Boot Mode

The list of pins that are configured by the ROM incase of UART boot mode are in Table 4-36. Note that all the pins might not be driven at boot time.

Table 4-36. Pins Used for UART Boot

Signal name	Pin used
rx	uart0_rxd
tx	uart0_txd

4.8.6.4 ASIC ID Structure

The ASIC ID size is 58 Bytes for UART and 81 Bytes for others.

4.9 Image Format

4.9.1 Overview

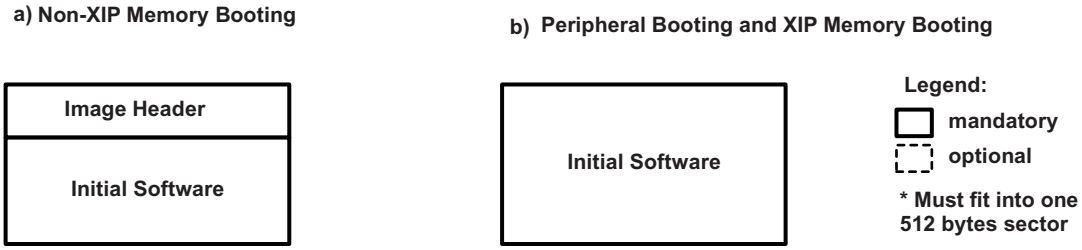
All preceding sections describe how the ROM Code searches and detects a boot image from a memory or a peripheral device type. This section describes the format of the boot image itself.

A boot image is basically made out of two major parts:

- The software to execute
- A header containing the destination address and size of the image for non-XIP memory devices

The mandatory section of a boot image contains the software which will be loaded into the memory and executed. An overview of the image formats is shown in Figure 4-25.

Figure 4-25. Image Formats



(a) Non - XIP Memory Booting
It is used for memories which require shadowing (for example, an MMC). The image must begin with a header which contains information on image size and destination address

(b) Peripheral Booting and XIP Memory Booting
When the memory device is of XIP type (e.g., NOR) the header is not needed and the image can contain code for direct execution. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

Copyright © 2011–2013, Texas Instruments Incorporated

4.9.1.1 Image Formats

When the booting memory device is non-XIP (for example, an MMC), the image must contain a small header with the size of the software to load, and the destination address which tells where to store it.

The header is not needed when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 4-37. Image Formats

Field	non-XIP device (offset)	XIP device (offset)	Size (bytes)	Description
Size	0000h	-	4	Size of the image
Destination	0004h	-	4	Address where to store the image / code entry point
Image	0008h	0000h	x	Executable code

Note: the “Destination” address field stands for both:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

In other words, the user must take care to locate the code entry point to the target address for image copy.

4.9.2 Table of Contents

The TOC is 512 bytes long and consists of a maximum of 16 TOC items (32 bytes long each), located one after the other. If the number of TOC items is less than 16, the TOC item after the last used TOC item must be filled by FFh. Each TOC item contains information required by the ROM Code such as item location, size and name, as illustrated in Figure 4-26 and Table 4-38

Figure 4-26. TOC Structure

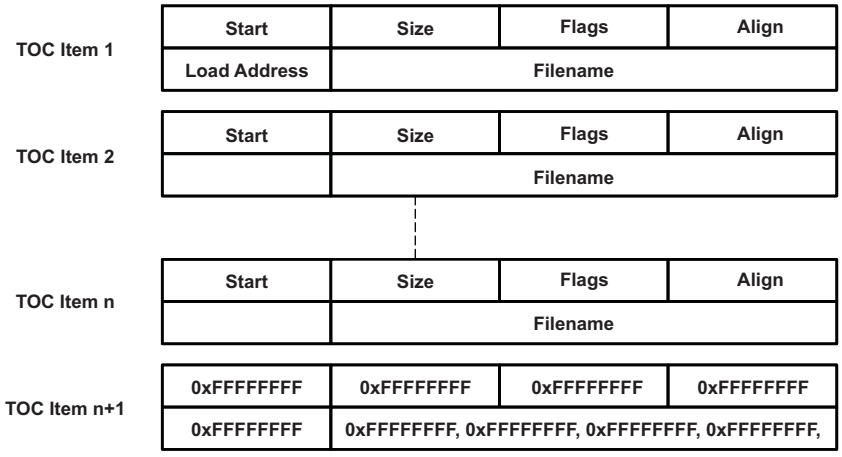


Table 4-38. TOC Item Fields

Offset	Field	Size [bytes]	Description
0h	Start	4	Offset from the start address of TOC to the actual address of sub image.
4h	Size	4	Size of sub image.
8h	Flags	4	Reserved
Ch	Align	4	Reserved

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-38. TOC Item Fields (continued)

Offset	Field	Size [bytes]	Description
10h	Load Address	4	For an Initial SW TOC item during Memory Booting this field is the target address for item copy. It is ignored in other cases.
14h	Filename	12	12 character long name of sub image, including the zero ('\0') terminator.

The ROM Code recognizes sections pointed to by the TOC based on the filename as described in Table 4-39.

- The 'X-LOADER', '2ND', 'MLO', or 'ULO' section contains the Initial Software
- Optionally, the TOC may contain CH sections. CHSETTINGS is a mandatory section of CH and is used to recognize CH presence.

Table 4-39. Filenames in TOC

Filename	Description
X-LOADER	Bootstrap
2ND	Secondary loader (peripheral booting)
MLO	MMC/SD Loader (Memory booting)
ULO	Alternative filename used for Secondary Loader via USB (Peripheral booting)
CHSETTINGS	Configuration Header general setting item. this item is mandatory for CH
CHRAM	Configuration Header EMIF item
CHFLASH	Configuration Header GPMC item
CHMMCSD	Configuration Header MMD/SD item

4.10 Execution

4.10.1 Overview

One of the early steps of the public ROM code execution is to search for a boot image from the requested medium (configured by the MBOOT pins) and copy it to RAM if needed. If the boot interface is non-XIP then the image is simply copied to the provided destination address (internal or external RAM) and then executed. If the boot interface is of XIP type then the image copy is not needed and execution is directly given to the XIP memory.

4.10.2 Execution

The image is executed at the time the ROM Code performs the branch to the first executable instruction inside the Initial SW. For a non-XIP device, the execution address is the first word after the header. The branch is performed in ARM supervisor mode. The R0 register points to the booting parameters structure (see Table 4-40) which contains details about the booting execution.

Table 4-40. Booting Parameters Structure

Offset	Field	Size [bytes]	Description
0h	Reserved	4	Reserved
4h	Memory booting device descriptor address	4	Pointer to the memory device descriptor that has been used during the memory booting process
5h	Current Booting Device	1	Code of device used for booting 0h – void, no device 1h – XIP MUX1 memory 2h – XIPWAIT MUX1 memory (wait monitoring on)

Copyright © 2011–2013, Texas Instruments Incorporated

Table 4-40. Booting Parameters Structure (continued)

Offset	Field	Size [bytes]	Description
			3h –XIP MUX2 memory 4h – XIPWAIT MUX 2 (wait monitoring on) 5h – NAND 6h – NAND with I2C 8h – MMC/SD port 0 9h – MMC/SD port 1 15h – SPI 41h – UART0 44h - USB 46h – CPGMAC0
6h	Reset Reason	1	Current reset reason bit mask (bit=1-event present) [0] – power-on reset [1] – global software reset [3] – security violation reset [4] – MPU watchdog reset [5] – secure watchdog reset [6] – external warm reset Other bits – reserved
7h	Reserved	1	Reserved

4.11 Services for HLOS Support

The TrustZone® architecture of the Cortex™-A8 core restricts accesses to secure mode only coprocessor registers. The Cortex-A8 core of the device is forbidden from entering the secure mode and hence cannot directly access any secure resources. However, a high-level OS needs to access secure registers for L2 cache maintenance and other operations.

For these purposes, the ROM Code provides different primitives that can be called. These services are implemented in monitor mode (service must be called by writing function ID into R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the MPU. The caller must take care of saving R0, R1, and R12 before using these APIs, as these get overwritten by the ROM code.

The services provided are:

- Write Auxiliary Control Register (WRITE_ACR).
- Write Nonsecure Access Control Register (WRITE_NACR).
- Write L2 Cache Auxiliary Control Register (WRITE_CACR).

Table 4-41. Write Auxiliary Control Register (WRITE_ACR)

Function ID	Description	
R12 = 0x100	This function writes the ARM CP15 Auxiliary Control Register with the input value in R0.	
Parameters

Function ID	Description	
R12 = 0x102	This function writes the ARM CP15 L2 Cache Auxiliary Control Register with the input value in R0.	
Parameters		
Type	**Field**	**Description**
Input	32 bit unsigned integer – R0 32 bit unsigned integer – R1	Value to set in the register Don't care
Output	-	-
Return	-	-

For more information about ARM registers, see the *Cortex™-A8 Technical Reference Manual*.

4.12 Tracing

Tracing in the Public ROM Code consist in three 32 bit vectors for which each bit corresponds to a particular “way point” in the ROM Code execution sequence (refer to Section 4.3.2.4). Tracing vectors are initialized at the very beginning of the startup phase and updated all along the boot process.

There are two sets of tracing vectors. The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM Code run after cold reset. As a consequence after a warm reset, it is possible to have visibility on the boot scenario that occurred during cold reset.

Table 4-44. Tracing Vectors

Trace vector	Bit #	Group	Meaning
1	0	General	Passed the public reset vector

5.1 Overview

This chapter contains a general description of the DCAN Controller Area Network module, a high-integrity serial communications protocol for distributed real-time applications.

The DCAN module supports bit rates up to 1 Mbit/s and is compliant to the CAN 2.0B protocol specification. This device has two DCAN modules, referred to as DCAN0 and DCAN1 in this document.

5.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 MBit/s
- Dual clock source
- 64 message objects (see Section 5.1.2.3)
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- CAN Rx/Tx pins configurable as general purpose input/output (I/O) pins
- Support for two interrupt lines: Level 0 and Level 1
- Local power down and wakeup support
- Automatic RAM initialization
- Support for DMA access

5.1.2 Functional Description

The DCAN module consists of the components CAN Core, Message RAM, Message RAM Interface, Message Handler, Registers and Message Object access and Module Interface (see Figure 5-1). The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 MBit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

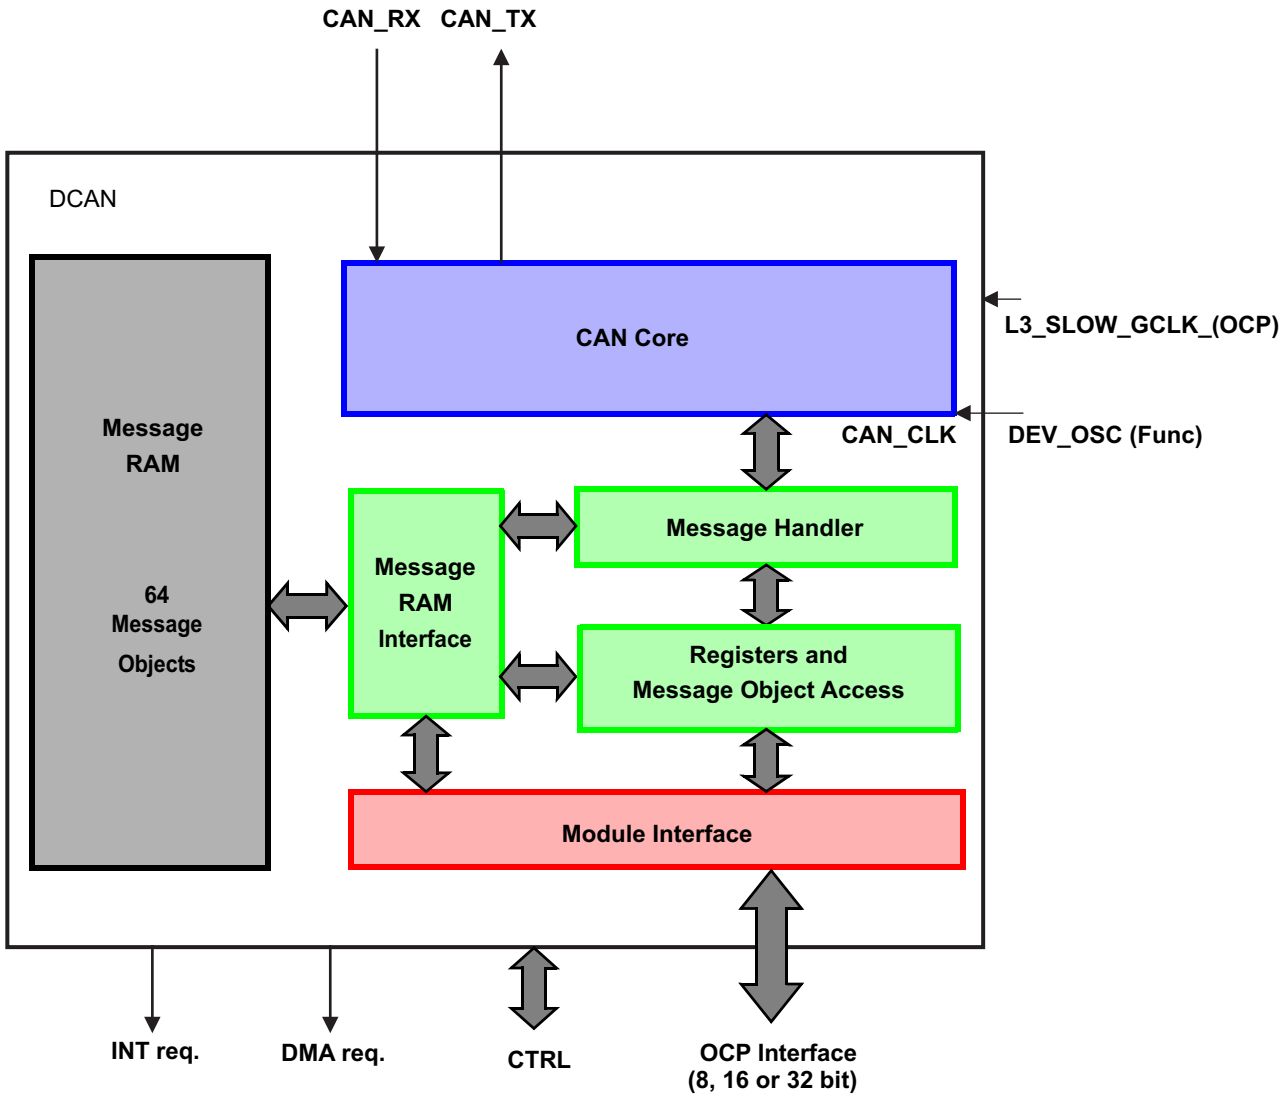
All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly by the CPU via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 5-1 shows the DCAN block diagram and its features are described below.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 5-1. DCAN Block Diagram



5.1.2.1 CAN Core

The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

5.1.2.2 Message Handler

The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

5.1.2.3 Message RAM

DCAN0 and DCAN1 enables the storage of 64 CAN messages.

5.1.2.4 Message RAM Interface

Three interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 5.9.12.

Copyright © 2011–2013, Texas Instruments Incorporated

The interface registers have the same word-length as the message RAM.

5.1.2.5 Registers and Message Object Access

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either CPU or DMA.

5.1.2.6 Module Interface

The DCAN module registers are accessed by the CPU or user software through a 32-bit peripheral bus interface.

5.1.2.7 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) and the peripheral asynchronous clock source domain (DEV_OSC) for CAN_CLK.

5.2 CAN Operation

After hardware reset, the Init bit in the CAN control register (DCAN CTL) is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 5-2 illustrates the basic initialization flow for the CAN module.

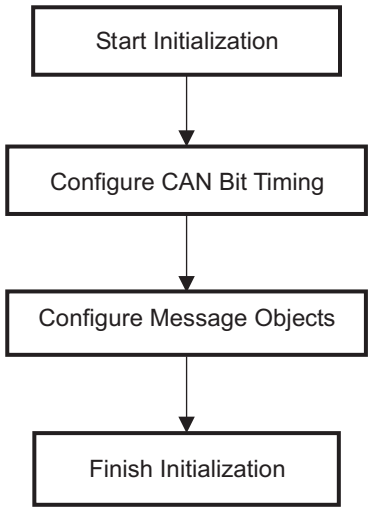
5.2.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the CPU has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 5-2. CAN Module General Initialization Flow



5.2.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 5-3.

Step 1: Enter *initialization mode* by setting the Init (Initialization) bit in the CAN control register.

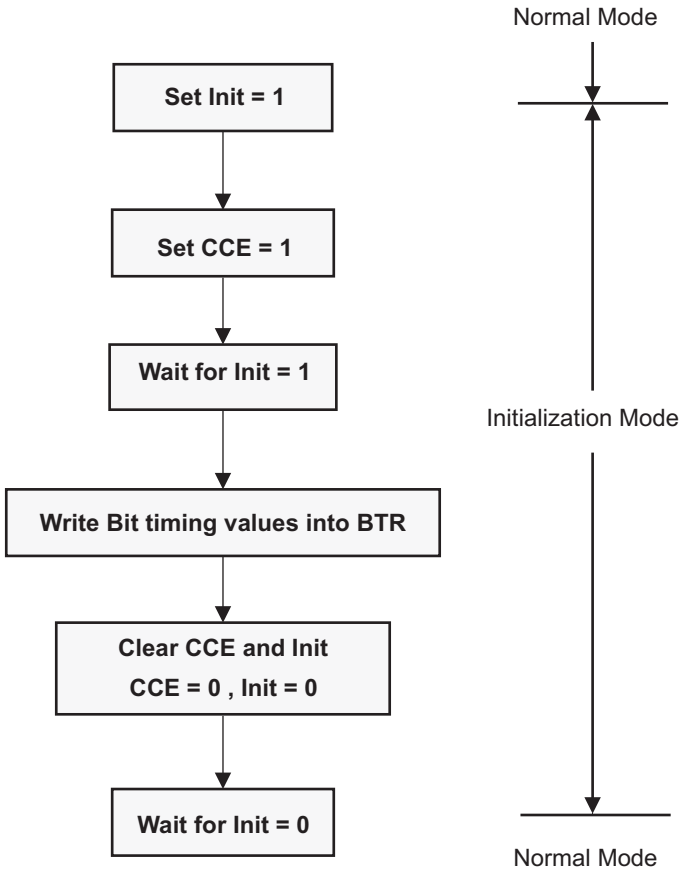
Copyright © 2011–2013, Texas Instruments Incorporated

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on hardware reset and during Bus-Off.

Figure 5-3. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable (CCE) bit in the CAN control register.

The access to the Bit Timing register (BTR) for the configuration of the bit timing is enabled when both Init and CCE bits in the CAN Control register are set.

Step 3: Wait for the Init bit to get set. This would make sure that the module has entered *Initialization mode*.

Step 4: Write the bit timing values into the bit timing register. See Section 5.10.2 for the BTR value calculation for a given bit timing.

Step 5: Clear the CCE and Init bit.

Step 6: Wait for the Init bit to clear. This would ensure that the module has come out of *initialization mode*.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the *initialization mode* if any incorrect BTR values are written in step 4.

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 5.2.1.

5.2.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the CPU does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 5.11) and the message object structure (see Section 5.12) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 5.8. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

5.2.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control register, DCAN_RAMINIT, which initializes the RAM with zeros and sets parity bits accordingly. Wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on RAM hardware initialization, see the system module reference guide.

5.2.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and Init bit is reset to zero, the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to ‘1’) at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The interrupt register points to those message objects with IntPnd = ‘1’. It is updated even if the interrupt lines to the CPU are disabled (IE0/IE1 are zero).

The CPU may poll all MessageObject’s NewDat and TxRqst bits in parallel from the NewData X registers and the Transmission Request X Registers (DCAN TXRQ X). Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to “don’t care” may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Copyright © 2011–2013, Texas Instruments Incorporated

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

5.2.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DAR) in the CAN Control register. Further details to this mode are provided in Section 5.9.3.

5.2.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting the Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit ABO in the CAN control register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of L3_SLOW_GCLK cycles which can be defined in the Auto-Bus-On Time register (DCAN ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

5.2.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the Test bit in the CAN control register needs to be set to 1. This enables write access to the test register (DCAN TEST).

NOTE: When using any of the Loop Back modes, it must be ensured by software that all message transfers are finished before setting the Init bit to 1.

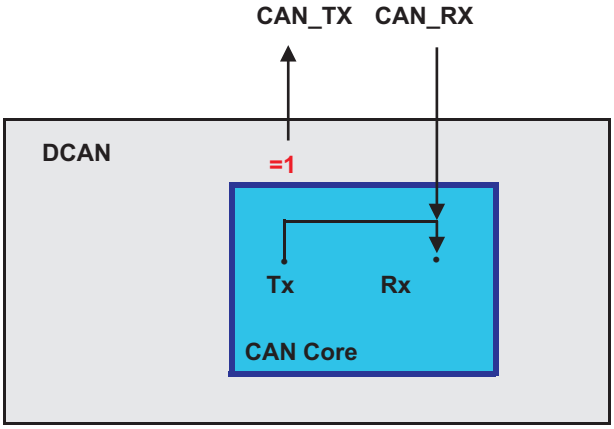
5.2.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 5-4 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in the Test register to one. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 5-4. CAN Core in Silent Mode



5.2.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

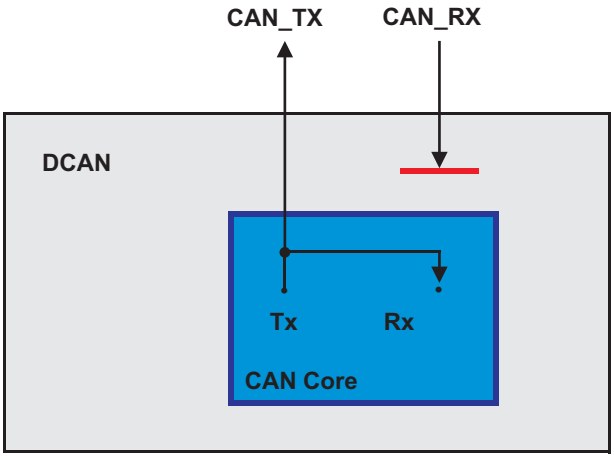
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 5-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit LBack in the test register to one.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 5.2.3.3.

Figure 5-5. CAN Core in Loopback Mode



Copyright © 2011–2013, Texas Instruments Incorporated

5.2.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

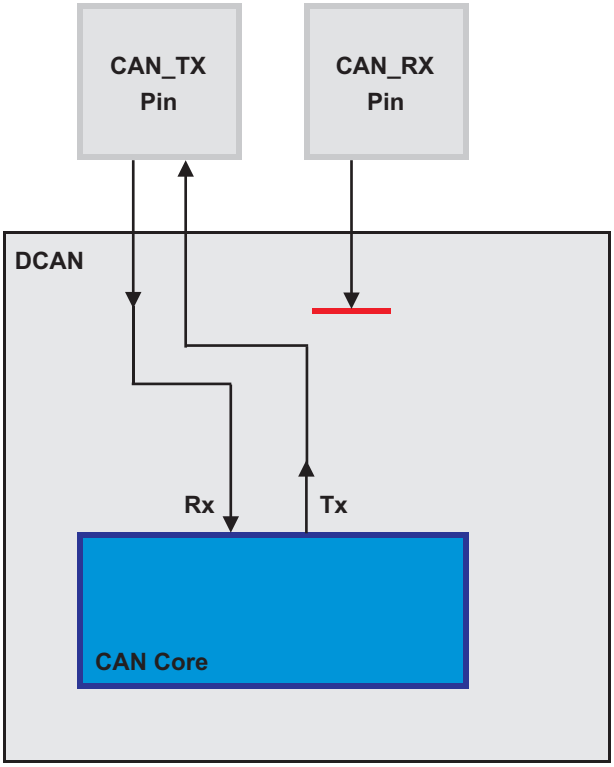
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit **ExL** in test register to one.

Figure 5-6 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBack bit set), the ExL bit will be ignored.

Figure 5-6. CAN Core in External Loopback Mode



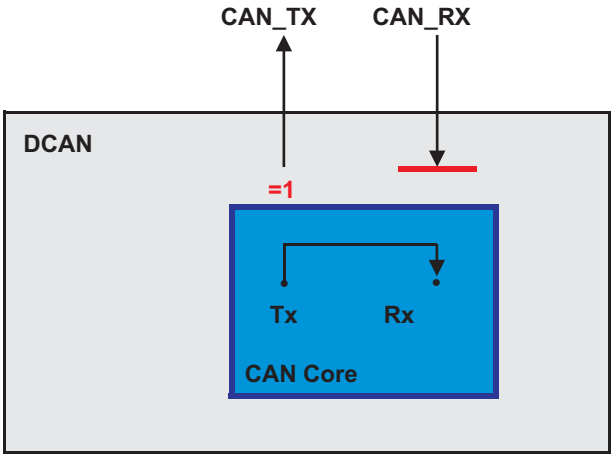
5.2.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest,” i.e., the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 5-7 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 5-7. CAN Core in Loop Back Combined With Silent Mode



5.2.3.5 Software Control of CAN_TX pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the test register bits Tx[1:0] as described in section Section 5.14.1.6.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

5.3 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) as the general module clock source, and the peripheral asynchronous clock source domain (DEV_OSC) provided to the CAN core (as clock source CAN_CLK) for generating the CAN bit timing.

Both clock domains can be derived from the same clock source (so that L3_SLOW_GCLK = DEV_OSC).

For more information on how to configure the relevant clock source registers in the system module, see the system module reference guide and the device-specific data sheet.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

NOTE: If the dual clock functionality is used, then L3_SLOW_GCLK must always be higher or equal to CAN_CLK (DEV_OSC) (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated L3_SLOW_GCLK has to be considered:

$f_{0,\ L3_SLOW_GCLK}(OCP) \pm \Delta f_{FM,\ L3_SLOW_GCLK}(OCP) \geq f_{CANCLK}$

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK (DEV_OSC), an oscillator frequency of 8MHz or higher has to be used.

5.4 Interrupt Functionality

Interrupts can be generated on two interrupt lines: DCANINT0 and DCANINT1. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN control register. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 5-8 and Figure 5-9).

The source of an interrupt can be determined by the interrupt identifiers Int0ID/Int1ID in the interrupt register (see Section 5.14.1.5). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN ES and PARITYERR_EOI). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the error and status register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 command register). When IntPnd is cleared, the interrupt register will point to the next message object with a pending interrupt.

5.4.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE that are described in Section 5.12.1.

Message object interrupts can be routed to either DCANINT0 or DCANINT1 line, controlled by the interrupt multiplexer register (DCAN INTMUX12 to DCAN INTMUX78), see Section 5.14.1.17.

5.4.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in error and status register (DCAN ES) belong to the status change interrupts. The status change interrupt group can be enabled by SIEbit in the CAN control register.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN control register.

NOTE: Reading the error and status register will clear the WakeUpPnd flag. If in global power-down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur.

Copyright © 2011–2013, Texas Instruments Incorporated

5.4.3 Error Interrupts

The events PER, BOff and EWarn, monitored in the Error and Status register, DCAN ES, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE in the CAN Control register.

Error interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN Control register.

Figure 5-8. CAN Interrupt Topology 1

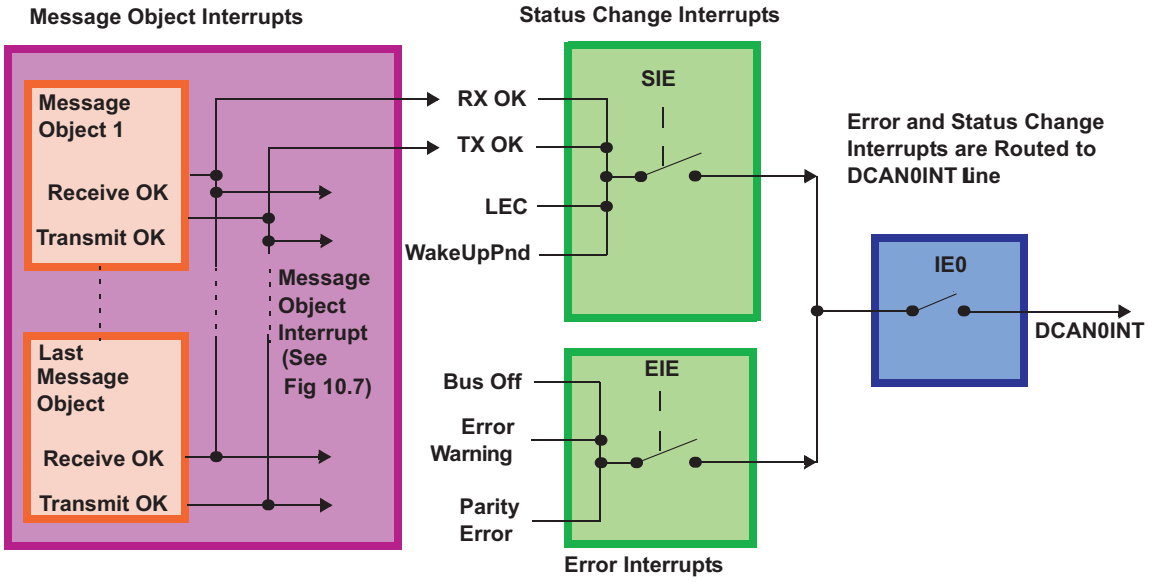


Figure 5-9. CAN Interrupt Topology 2

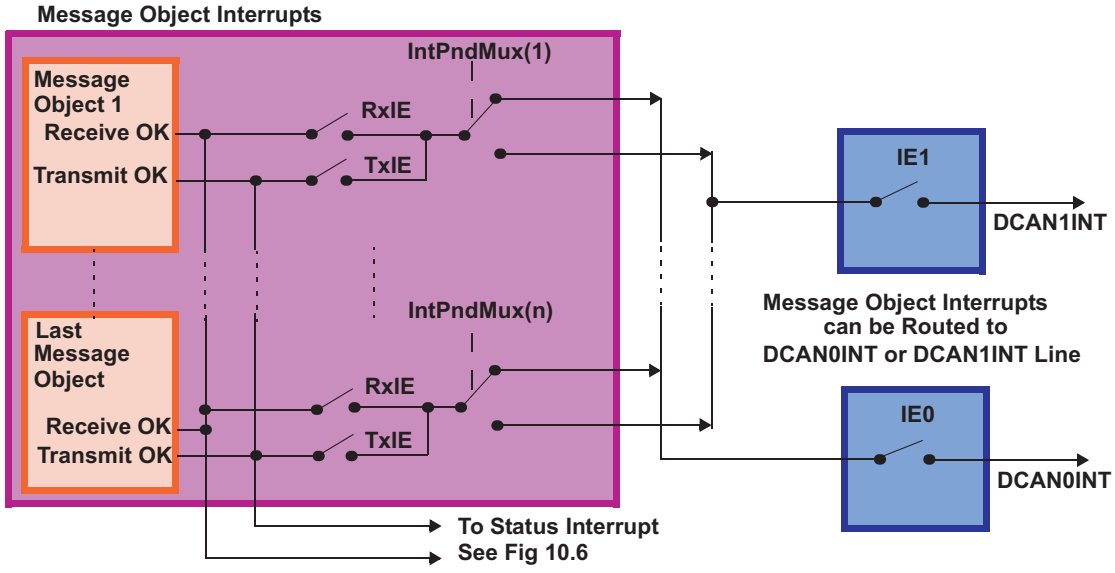


Copyright © 2011–2013, Texas Instruments Incorporated

5.5 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN control registers.

5.5.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the PDR bit in CAN Control register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Init bit in CAN control register to prevent any further CAN transfers, and it will also set the PDA bit in CAN error and status register. With setting the PDA bits, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 5.5.2) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the init bit, these messages may get sent.

5.5.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control register.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (WUBA) in the CAN control register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the PDR bit in the CAN Control register and also clear the PDA bit in the error and status register. The WakeUpPnd bit in CAN error and status register will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

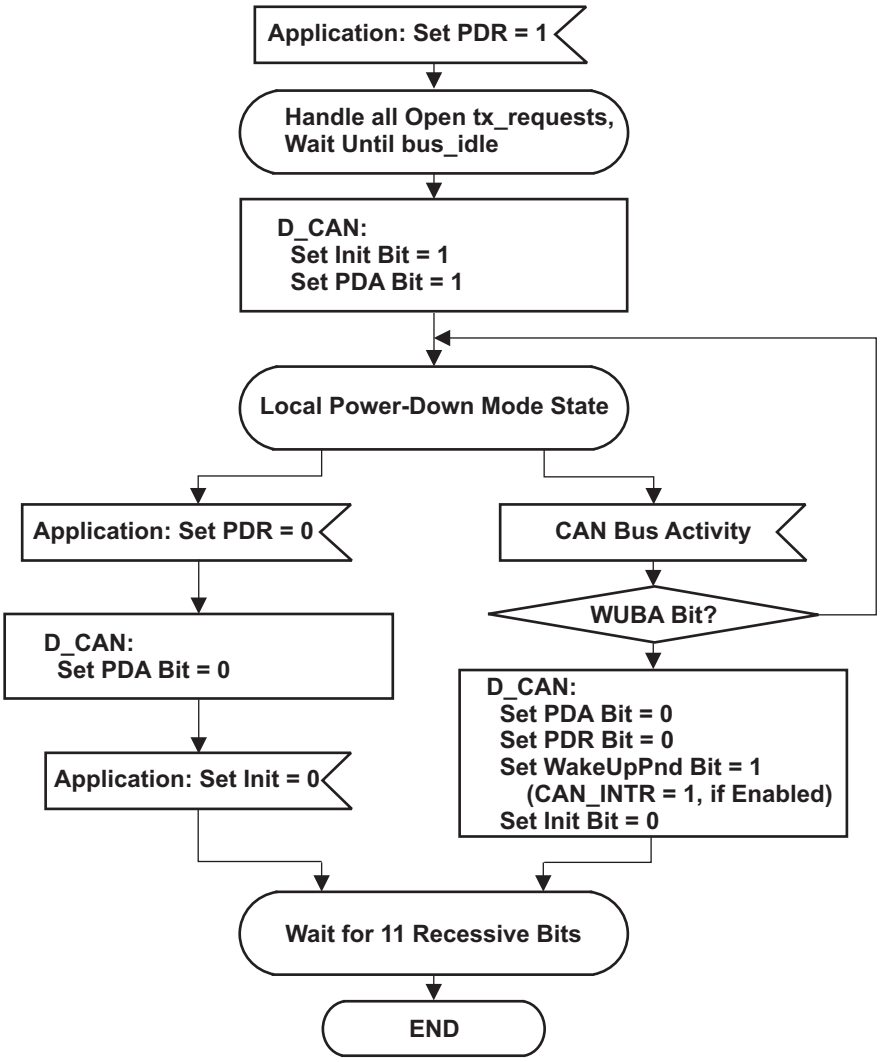
After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 5-10 shows a flow diagram about entering and leaving local power-down mode.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 5-10. Local Power-Down Mode Flow Diagram



Copyright © 2011–2013, Texas Instruments Incorporated

5.6 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 5.12.4.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by PMD bit field in the CAN control register.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 5.12.3) or in RDA mode (see Section 5.12.4). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

NOTE: The parity scheme is tied to even parity at the device level.

5.6.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the PER bit in the error and status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the host CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, e.g., by immediately checking the parity error code register (DCAN PERR) on parity error interrupt.

NOTE: During RAM initialization, no parity check will be done, but if the PMD bit is set, the parity bits will be generated.

5.6.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

NOTE: If parity check was disabled, the application has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

Copyright © 2011–2013, Texas Instruments Incorporated

5.7 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via OCP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in the CAN control register.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 5.12.3).

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- Error and status register (clear of status flags by read)
- IF1/IF2 command registers (clear of DMAActive flag by read/write)

5.8 Configuration of Message Objects

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver library should offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

5.8.1 Configuration of a Transmit Object for Data Frames

Table 5-1 shows how a transmit object can be initialized.

Table 5-1. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 5.9.8. Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

5.8.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

5.8.3 Configuration of a Single Receive Object for Data Frames

Table 5-2 shows how a receive object for data frames can be initialized.

Table 5-2. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

Copyright © 2011–2013, Texas Instruments Incorporated

5.8.4 Configuration of a Single Receive Object for Remote Frames

Table 5-3 shows how a receive object for remote frames can be initialized.

Table 5-3. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 5.8.5).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 5.9.8.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

5.8.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

Copyright © 2011–2013, Texas Instruments Incorporated

5.9 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

5.9.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

5.9.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

5.9.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MsgVal bits in the Message Valid register (DCAN MSGVAL12 to DCAN MSGVAL78) and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

Copyright © 2011–2013, Texas Instruments Incorporated

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

5.9.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither d nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN IF1DATA/DCAN IF2DATA) or IF1/IF2 Data B register (DCAN IF1DATB/DCAN IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN IF1CMD/DCAN IF2CMD) and then the number of the message object is written to bits [7:0] of the command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 5.9.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

5.9.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Before changing the configuration of a message object, MsgVal has to be reset.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

Copyright © 2011–2013, Texas Instruments Incorporated

5.9.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

5.9.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the interrupt register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

5.9.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

5.9.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the command register. That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

Copyright © 2011–2013, Texas Instruments Incorporated

5.9.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register.

5.9.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

5.9.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N –1 plus A FIFO buffer of length N will store –1 plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 5-11.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

5.10 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

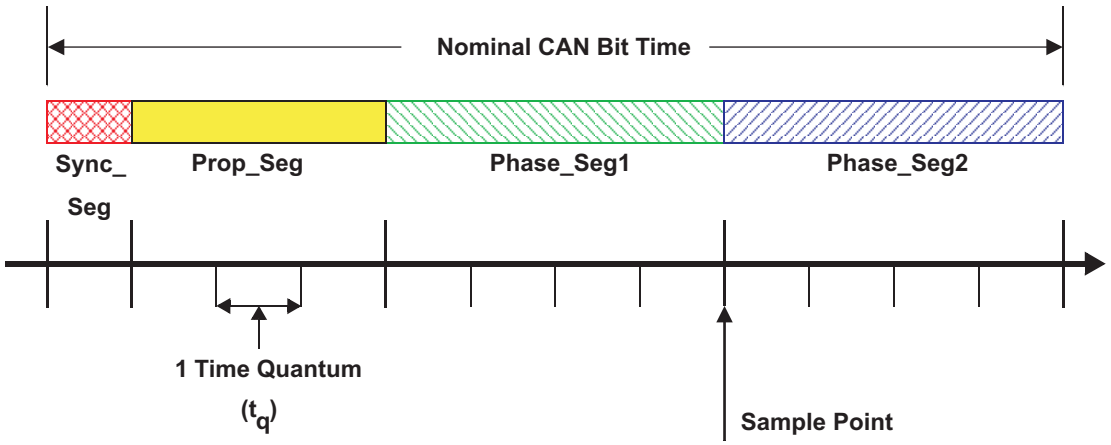
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

5.10.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 5-12):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 5-12. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 5-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-4. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

5.10.1.1 Synchronization Segment

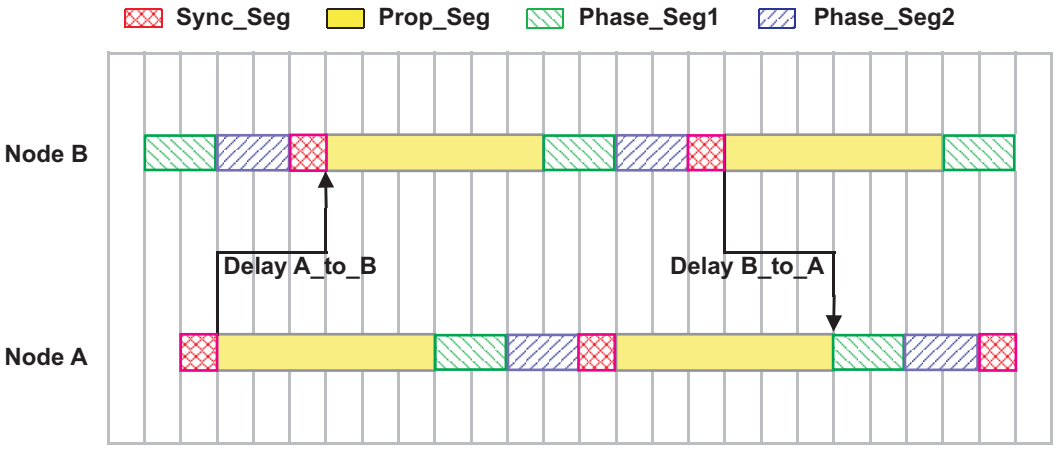
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

5.10.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's non-destructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 5-13 shows the phase shift and propagation times between two CAN nodes.

Figure 5-13. The Propagation Time Segment



Delay A_to_B >= node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg >= Delay A_to_B + Delay B_to_A

Prop_Seg >= 2 • [max(node output delay+bus line delay + node input delay)]

Copyright © 2011–2013, Texas Instruments Incorporated

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3 Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

5.10.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

Copyright © 2011–2013, Texas Instruments Incorporated

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

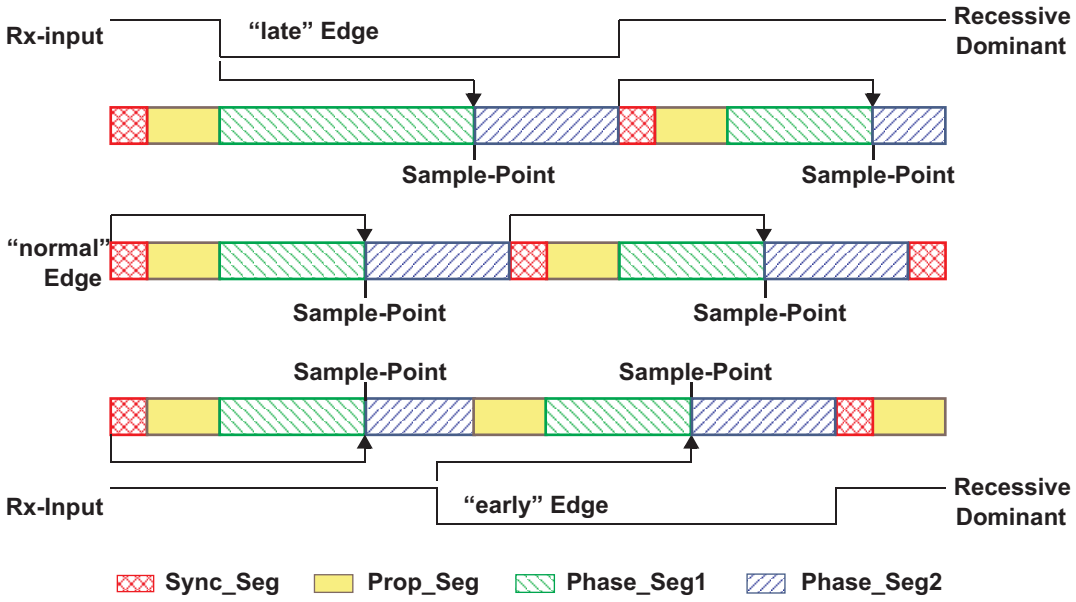
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 5-14 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 5-14. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

Copyright © 2011–2013, Texas Instruments Incorporated

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

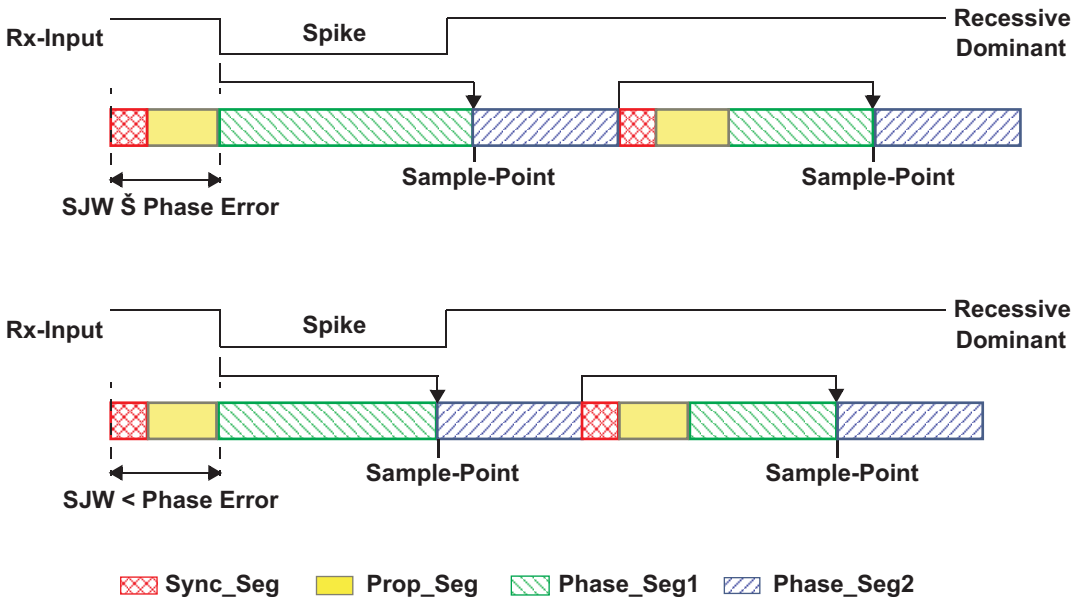
In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 5-15 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 5-15. Filtering of Short Dominant Spikes



5.10.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit_time}$$

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

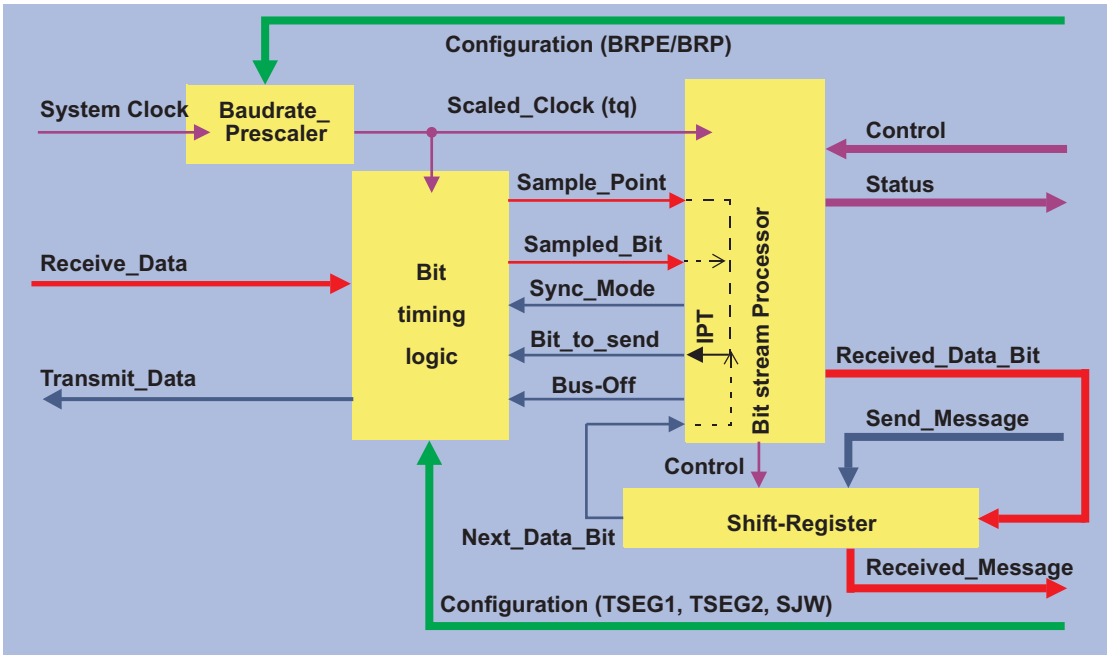
Copyright © 2011–2013, Texas Instruments Incorporated

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

5.10.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of four bits (BRPE) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 5-16).

Figure 5-16. Structure of the CAN Core's CAN Protocol Controller



In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, for example, SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Copyright © 2011–2013, Texas Instruments Incorporated

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

5.10.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 5.10.2.3.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register:

Tseg2 = Phase_Seg2-1

Tseg1 = Phase_Seg1+ Prop_Seg-1

SJW = SynchronizationJumpWidth-1

BRP = Prescaler-1

Copyright © 2011–2013, Texas Instruments Incorporated

5.10.2.2 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

t_q	100 ns	=	t_{CAN_CLK}
delay of bus driver	90 ns	=	
delay of receiver circuit	40 ns	=	
delay of bus line (40 m)	220 ns	=	
t_{Prop}	700 ns	=	INT (2*delays + 1) = 7 • t_q
t_{SJW}	100 ns	=	1 • t_q
t_{TSeg1}	800 ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100 ns	=	Information Processing Time + 1 • t_q
$t_{Sync\text{-}Seg}$	100 ns	=	1 • t_q
bit time	1000 ns	=	$t_{Sync\text{-}Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	0.43 %	=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$&$(8\text{-}1)_4$&$(1\text{-}1)_2$&$(1\text{-}1)_6$, so the bit timing register is programmed to = 0x00000700.

5.10.2.3 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	1 µs	=	t_{CAN_CLK}
Delay of bus driver	200 ns	=	
Delay of receiver circuit	80 ns	=	
Delay of bus line (40 m)	220 ns	=	
t_{Prop}	1 µs	=	1 • t_q
t_{SJW}	4 µs	=	4 • t_q
t_{TSeg1}	5 µs	=	t_{Prop} + t_{SJW}
t_{TSeg2}	3 µs	=	Information Processing Time + 3 • t_q
$t_{Sync\text{-}Seg}$	1 µs	=	1 • t_q
Bit time	9 µs	=	$t_{Sync\text{-}Seg}$ + t_{TSeg1} + t_{TSeg2}
Tolerance for CAN_CLK		=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(3\text{-}1)_3$&$(5\text{-}1)_4$&$(4\text{-}1)_2$&$(2\text{-}1)_6$, so the bit timing register is programmed to = 0x000024C1.

5.11 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in the command register, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in the command register, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent CPU accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 5.12.1) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 5.14.1.19) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

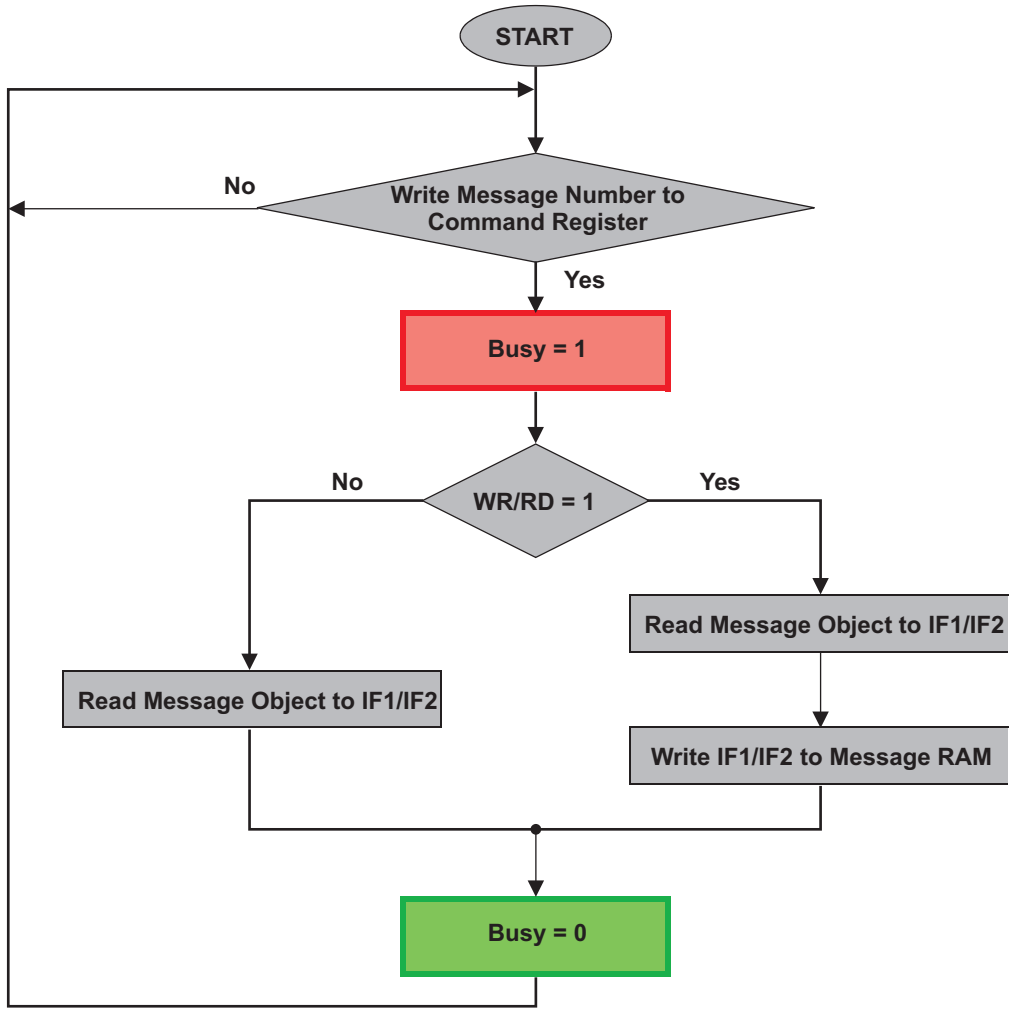
5.11.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. The command register addresses the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the command register.

When the CPU initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the busy bit in the respective command register to ‘1’. After the transfer has completed, the busy bit is set back to ‘0’ (see Figure 5-17).

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 5-17. Data Transfer Between IF1/IF2 Registers and Message RAM



5.11.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (Section 5.14.1.28).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN control register. Please refer to the device datasheet to find out if this DMA source is available.

NOTE: The IF3 register set can not be used for transferring data into message objects.

5.12 Message RAM

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the CPU cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the CPU to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the CPU:

- Debug/Suspend mode (see Section 5.12.3)
- RAM Direct Access (RDA) mode (see Section 5.12.4)

For the message RAM base address, see the device-specific data sheet.

5.12.1 Structure of Message Objects

Table 5-5 shows the structure of a message object. Table 5-6 provides a description of the fields.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 5-5. Structure of a Message Object

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 5-6. Field Descriptions

Name	Value	Description
MsgVal		Message valid. The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the Init bit in the CAN control register.
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required.
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Extended identifier
	0	The 11-bit ("standard") identifier will be used for this message object.
	1	The 29-bit ("extended") identifier will be used for this message object.
MXtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-6. Field Descriptions (continued)

Name	Value	Description
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0-8	Data frame has 0-8 data bits.
	9-15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

Copyright © 2011–2013, Texas Instruments Incorporated

5.12.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) * 0x20

This means that message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

‘0’ is not a valid message object number.

The base address for DCAN0 RAM is 0x481C_D000 and DCAN1 RAM is 0x481D_1000.

Message object number 1 has the highest priority.

Table 5-7. Message RAM addressing in Debug/Suspend and RDA Mode

Message Object Number	Offset From Base Address	Word Number	Debug/Suspend Mode, see Section 5.12.3	RDA mode, see Section 5.12.4
1	0x0020	1	Parity	Data Bytes 4-7
	0x0024	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0028	3	Xtd,Dir,ID	ID[27:0],DLC

5.12.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Table 5-8. Message RAM Representation in Debug/Suspend Mode

Bit #	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0
MsgAddr + 0x00	Reserved															
	Reserved											Parity[4:0]

5.12.4 Message RAM Representation in Direct Access Mode

When the RDA bit in the test register is set while the DCAN module is in test mode (test bit in the CAN control register is set), the CPU has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit not set) will be ignored.

Table 5-9. Message RAM Representation in RAM Direct Access Mode

Bit #	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0
MsgAddr + 0x00	Data 4								Data 5							
	Data 6								Data 7							
MsgAddr + 0x04	Data 0								Data 1							
	Data 2								Data 3							
MsgAddr + 0x08	ID[27:12]															
	ID[11:0]												DLC[3:0]			
MsgAddr + 0x0C	Msk[28:13]															
	Msk[12:0]													Xtd	Dir	ID[28]
MsgAddr + 0x10	Reserved															Parity [4]
	Parity[3:0]				Unused				Msg Lst	UMask	TxIE	RxTE	Rmt En	EOB	MXtd	MDir

NOTE: Writes to unused bits has no effect.

5.13 GIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN TIOC) (see Section 5.14.1.29) and the CAN RX IO control register (DCAN RIOC) (see Section 5.14.1.30).

5.14 Registers

The base address for the:

- DCAN0 registers is 0x481C_C000
- DCAN1 registers is 0x481D_0000

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1 DCAN Control Registers

After hardware reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The Init bit in the CAN control register is set to enable the software initialization. The DCAN will not influence the CAN bus until the CPU resets Init to '0'.

LEGEND: R/W = Read/Write; R = Read only; WP = Write protected by init bit; *-n* = value after reset

Table 5-11. CAN Control Register (DCAN CTL) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	These bits are always read as 0. Writes have no effect.
26	WUBA		Automatic wake up on bus activity when in local power-down mode
		0	No detection of a dominant CAN bus level while in local power-down mode.
		1	Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).
			Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost.
24	PDR		Request for local low power-down mode
		0	No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the Init bit has to be cleared.
		1	Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the error and status register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).
23-21	Reserved	0	These bits are always read as 0. Writes have no effect.
20	DE3		Enable DMA request line for IF3
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers.
19	DE2		Enable DMA request line for IF2
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers.
18	DE1		Enable DMA request line for IF1
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers.
17	IE1		Interrupt line 1 enable
		0	Disabled - Module interrupt DCAN1INT is always low.
		1	Enabled - interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-11. CAN Control Register (DCAN CTL) Field Descriptions (continued)

Bit	Field	Value	Description
16	InitDbg		Internal init state while debug access
		0	Not in debug mode, or debug mode requested but not entered.
		1	Debug mode requested and internally entered; the DCAN is ready for debug accesses.
15	SWR		SW reset enable
		0	Normal Operation
		1	Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one OCP clock cycle. Note: To execute software reset, the following procedure is necessary: 1. Set Init bit to shut down CAN communication. 2. Set SWR bit additionally to Init bit.
14	Reserved	0	This bit is always read as 0. Writes have no effect.
13-10	PMD		Parity on/off
		0x5	Parity function disabled
		Others	Parity function enabled
9	ABO		Auto-Bus-On enable
		0	The Auto-Bus-On feature is disabled
		1	The Auto-Bus-On feature is enabled
8	IDS		Interruption debug support enable
		0	When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode
		1	When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	Test		Test mode enable
		0	Normal Operation
		1	Test Mode
6	CCE		Configuration change enable
		0	The CPU has no write access to the configuration registers.
		1	The CPU has write access to the configuration registers (when Init bit is set).
5	DAR		Disable automatic retransmission
		0	Automatic retransmission of not successful messages enabled.
		1	Automatic retransmission disabled.
4	Reserved	0	This bit is always read as 0. Writes have no effect.
3	EIE		Error interrupt enable
		0	Disabled - PER, BOff and EWarn bits can not generate an interrupt.
		1	Enabled - PER, BOff and EWarn bits can generate an interrupt at DCAN0INT line and affect the interrupt register.
2	SIE		Status change interrupt enable
		0	Disabled - WakeUpPnd, RxOk, TxOk and LEC bits can not generate an interrupt.
		1	Enabled - WakeUpPnd, RxOk, TxOk and LEC can generate an interrupt at DCAN0INT line and affect the interrupt register.
1	IE0		Interrupt line 0 enable
		0	Disabled - Module interrupt DCAN0INT is always low.
		1	Enabled - interrupts will assert line DCAN0INT to one; line remains active until pending interrupts are processed.
0	Init		Initialization
		0	Normal operation
		1	Initialization mode is entered

Copyright © 2011–2013, Texas Instruments Incorporated

NOTE: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities.

When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset.

After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the error and status register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

5.14.1.2 Error and Status Register (DCAN ES) and DCAN Parity Error EOI Register (PARITYERR_EOI)

The error and status register (DCAN ES) is shown in Figure 5-19 and described in Table 5-12. The DCAN Parity Error EOI register is shown in Figure 5-20 and described in Table 5-13.

Figure 5-19. Error and Status Register (DCAN ES)

Table 5-12. Error and Status Register (DCAN ES) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	These bits are always read as 0. Writes have no effect.
10	PDA		Local power-down mode acknowledge
		0	DCAN is not in local power-down mode.
		1	Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.
9	WakeUp Pnd		Wake up pending. This bit can be used by the CPU to identify the DCAN as the source to wake up the system.
		0	No Wake Up is requested by DCAN.
		1	DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.
			This bit will be reset if error and status register is read.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-12. Error and Status Register (DCAN ES) Field Descriptions (continued)

Bit	Field	Value	Description
8	PER		Parity error detected
		0	No parity error has been detected since last read access.
		1	The parity check mechanism has detected a parity error in the Message RAM.
			This bit will be reset if error and status register is read.
7	BOff		Bus-Off state
		0	The CAN module is not bus-off state.
		1	The CAN module is in bus-off state.
6	EWarn		Warning state
		0	Both error counters are below the error warning limit of 96.
		1	At least one of the error counters has reached the error warning limit of 96.
5	EPass		Error passive state
		0	On CAN Bus error, the DCAN could send active error frames.
		1	The CAN core is in the error passive state as defined in the CAN Specification.
4	RxOk		Received a message successfully
		0	No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering).
			This bit will be reset if error and status register is read.
3	TxOk		Transmitted a message successfully
		0	No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU.
			This bit will be reset if error and status register is read.
2-0	LEC		Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.
		0	No error
		1	Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.
		2	Form error: A fixed format part of a received frame has the wrong format.
		3	Ack error: The message this CAN core transmitted was not acknowledged by another node.
		4	Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.
		5	Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
		6	CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).
		7	No CAN bus event was detected since the last time the CPU read the error and status register. Any read access to the error and status register re-initializes the LEC to value '7.'

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-13. Parity Error End of Interrupt Register (PARITYERR_EOI) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	These bits are always read as 0. Writes have no effect.
8	PARITYERR_ EOI		End of interrupt indication for parity error
		0	Has no effect writing
		1	Indicated end of interrupt for parity error
7-0	Reserved		These bits are always read as 0. Writes have no effect.

Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN control register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN control register is set).

A change of bit EPass will not generate an interrupt.

PARITYERR_EOI is used to signal an end of interrupt of the parity error interrupt (dcan_parity) to the IP. PARITYERR_EOI register is a *Write only* register.

A read from this offset address will result in a read from the DCAN ES register, where as a write will result in a write to the PARITYERR_EOI register.

NOTE: Reading the error and status register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the interrupt register will be replaced by the next lower priority interrupt value. The EOI for all other interrupts (DCANINT0 and DCANINT1) are automatically handled by hardware.

NOTE: For debug support, the auto clear functionality of error and status register (clear of status flags by read) is disabled when in debug/suspend mode.

5.14.1.3 Error Counter Register (DCAN ERRC)

The error counter register (DCAN ERRC) is shown in Figure 5-21 and described in Table 5-14.

Figure 5-21. Error Counter Register (DCAN ERRC)

31			16
Reserved			
R-0			
15	14	8	7 0

R-0	R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 5-14. Error Counter Register (DCAN ERRC) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are always read as 0. Writes have no effect.
15	RP		Receive error passive
		0	The receive error counter is below the error passive level.
		1	The receive error counter has reached the error passive level as defined in the CAN specification.
14-8	REC[6:0]		Receive error counter. Actual state of the receive error counter (values from 0 to 255).
7-0	TEC[7:0]		Transmit error counter. Actual state of the transmit error counter (values from 0 to 255).

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.4 Bit Timing Register (DCAN BTR)

The bit timing register (DCAN BTR) is shown in Figure 5-22 and described in Table 5-15.

Figure 5-22. Bit Timing Register (DCAN BTR)

31	20	19	16
Reserved		BRPE	
R-0		R-0	

15	14 12	11 8	7 6	5 0
Reserved	TSeg2	TSeg1	SJW	BRP
R-0	R/WP-0x2	R/WP-0x3	R/WP-0	R/WP-0x1

LEGEND: R = Read only; WP = Write protected by CCE bit; *-n* = value after reset

Table 5-15. Bit Timing Register (DCAN BTR) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	These bits are always read as 0. Writes have no effect.
19-16	BRPE	0x00-0x0F	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.
15	Reserved	0	These bits are always read as 0. Writes have no effect.
14-12	TSeg2	0x0-0x7	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.
11-8	TSeg1	0x01-0x0F	Time segment before the sample point Valid programmed values are 1 to15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.
7-6	SJW	0x0-0x3	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.
5-0	BRP	0x00-0x3F	Baud rate prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.

NOTE: This register is only writable if CCE and Init bits in the CAN control register are set.

NOTE: The CAN bit time may be programmed in the range of 8 to 25 time quanta.

NOTE: The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

With a CAN_CLK of 8 MHz and BRPE = 0x00, the reset value of 0x00002301 configures the DCAN for a bit rate of 500kBit/s.

5.14.1.5 Interrupt Register (DCAN INT)

The interrupt register (DCAN INT) is shown in Figure 5-23 and described in Table 5-16.

Figure 5-23. Interrupt Register (DCAN INT)

31	24	23	16
Reserved		Int1ID[7:0]	
R-0		R-0	

15	0
Int0ID[15:0]	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 5-16. Interrupt Register (DCAN INT) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23-16	Int1ID[23:16]		Interrupt 1 Identifier (indicates the message object with the highest pending interrupt)
		0x00	No interrupt is pending
		0x01-0x80	Number of message object which caused the interrupt.
		0x81-0xFF	Unused
			If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared.
			A message interrupt is cleared by clearing the message object's IntPnd bit.
			Among the message interrupts, the message object's interrupt priority decreases with increasing message number.
15-0	Int0ID[15:0]		Interrupt Identifier (the number here indicates the source of the interrupt)
		0x0000	No interrupt is pending
		0x0001-0x0080	Number of message object which caused the interrupt.
		0x0081-0x7FFF	Unused
		0x8000	Error and status register value is not 0x07.
		0x8001-0xFFFF	Unused
			If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared.
			The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.6 Test Register (DCAN TEST)

The test register (DCAN TEST) is shown in Figure 5-24 and described in Table 5-17.

Figure 5-24. Test Register (DCAN TEST)

31	16
Reserved	
R-0	

15	10	9	8	7	6	5	4	3	2	1	0
Reserved		RDA	EXL	Rx	Tx[1:0]		LBack	Silent	Reserved		
R-0		R/WP-0	R/WP-0	R-U	R/WP-0		R/WP-0	R/WP-0	R-0		

LEGEND: R = Read only; WP = Write protected by test bit; -*n* = value after reset; U = Undefined

Table 5-17. Test Register (DCAN TEST) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	These bits are always read as 0. Writes have no effect.
9	RDA		RAM direct access enable
		0	Normal pperation
		1	Direct access to the RAM is enabled while in test mode
8	EXL		External loopback mode
		0	Disabled
		1	Enabled
7	Rx		Receive pin. Monitors the actual value of the CAN_RX pin
		0	The CAN bus is dominant
		1	The CAN bus is recessive
6-5	Tx[1:0]		Control of CAN_TX pin
		00	Normal operation, CAN_TX is controlled by the CAN core.
		01	Sample point can be monitored at CAN_TX pin.
		10	CAN_TX pin drives a dominant value.
		11	CAN_TX pin drives a recessive value.
4	LBack		Loopback mode
		0	Disabled
		1	Enabled
3	Silent		Silent mode
		0	Disabled
		1	Enabled
2-0	Reserved	0	These bits are always read as 0. Writes have no effect.

For all test modes, the test bit in CAN control register needs to be set to one. If test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when test bit is cleared.

NOTE: The test register is only writable if test bit in CAN control register is set.

NOTE: Setting Tx[1:0] other than '00' will disturb message transfer.

NOTE: When the internal loop-back mode is active (bit LBack is set), bit EXL will be ignored.

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.7 Parity Error Code Register (DCAN PERR)

The parity error code register (DCAN PERR) is shown in Figure 5-25 and described in Table 5-18.

Figure 5-25. Parity Error Code Register (DCAN PERR)

31	16
Reserved	
R-0	

15	11	10	8	7	0
Reserved		Word Number		Message Number	
R-0		R-U		R-U	

LEGEND: R = Read only; -*n* = value after reset; U = Undefined

Table 5-18. Parity Error Code Register (DCAN PERR) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	These bits are always read as 0. Writes have no effect.
10-8	Word Number	0x01-0x05	Word number where parity error has been detected RDA word number (1 to 5) of the message object (according to the message RAM representation in RDA mode).
7-0	Message Number	0x01-0x80	Message object number where parity error has been detected

If a parity error is detected, the PER flag will be set in the error and status register. This bit is not reset by the parity check mechanism; it must be reset by reading the error and status register.

In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number).

If more than one word with a parity error was detected, the highest word number with a parity error will be displayed.

After a parity error has been detected, the register will hold the last error code until power is removed.

5.14.1.8 Auto-Bus-On Time Register (DCAN ABOTR)

The Auto-Bus-On time register (DCAN ABOTR) is shown in Figure 5-26 and described in Table 5-19.

Figure 5-26. Auto-Bus-On Time Register (DCAN ABOTR)

31	16	15	0
ABO Time[31:16]		ABO Time[15:0]	
R/W-0		R/W-0	

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 5-19. Auto-Bus-On Time Register (DCAN ABOTR) Field Descriptions

Bit	Field	Value	Description
31-0	ABO Time		Number of OCP clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. This function has to be enabled by setting bit ABO in CAN control register. The Auto-Bus-On timer is realized by a 32-bit counter that starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO time register after this phase.

NOTE: On write access to the CAN control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.

NOTE: During Debug/Suspend mode, running Auto-Bus-On timer will be paused.

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.9 Transmission Request X Register (DCAN TXRQ X)

With the transmission request X register (DCAN TXRQ X), the CPU can detect if one or more bits in the different transmission request registers are set. Each register bit represents a group of eight message objects. If at least one of the TxRqst bits of these message objects are set, the corresponding bit in the transmission request X register will be set. The transmission request X register is shown in Figure 5-27.

Figure 5-27. Transmission Request X Register (DCAN TXRQ X)

5.14.1.10 Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

These registers hold the TxRqst bits of the implemented message objects. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific message object can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

The transmission request registers are shown in Table 5-20 and described in Table 5-21.

Table 5-20. Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

5.14.1.11 New Data X Register (DCAN NWDAT X)

With the new data X register, the CPU can detect if one or more bits in the different new data registers are set. Each register bit represents a group of eight message objects. If at least on of the NewDat bits of these message objects are set, the corresponding bit in the new data X register will be set.

The new data X register (DCAN NWDAT X) is shown in Figure 5-28.

Figure 5-28. Transmission Request X Register (DCAN TXRQ X)

5.14.1.12 New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

These registers hold the NewDat bits of the implemented message objects. By reading out these bits, the CPU can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

The new data registers (DCAN NWDAT12 to DCAN NWDAT78) are shown in Table 5-22 and described in Table 5-23.

5.14.1.13 Interrupt Pending X Register (DCAN INTPND X)

With the interrupt pending X register, the CPU can detect if one or more bits in the different interrupt pending registers are set. Each bit of this register represents a group of eight message objects. If at least one of the IntPnd bits of these message objects are set, the corresponding bit in the interrupt pending X register will be set.

The interrupt pending X register (DCAN INTPND X) is shown in Figure 5-29.

Figure 5-29. Interrupt Pending X Register (DCAN INTPND X)

5.14.1.14 Interrupt Pending Registers (DCAN INTPND12 to DCAN INTPND78)

These registers hold the IntPnd bits of the implemented message objects. By reading out these bits, the CPU can check for pending interrupts in the message objects. The IntPnd bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The interrupt pending registers (DCAN INTPND12 to DCAN INTPND78) are shown in Table 5-24 and described in Table 5-25.

Table 5-24. New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

5.14.1.15 Message Valid X Register (DCAN MSGVAL X)

With the message valid X register, the CPU can detect if one or more bits in the different message valid registers are set. Each bit of this register represents a group of eight message objects. If at least one of the MsgVal bits of these message objects are set, the corresponding bit in the message valid X register will be set.

The message valid X register (DCAN MSGVAL X) is shown in Figure 5-30.

Figure 5-30. Message Valid X Register (DCAN MSGVAL X)

5.14.1.16 Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the CPU can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The message valid registers (DCAN MSGVAL12 to MSGVAL78) is shown in Table 5-26 and described in Table 5-27.

Table 5-26. Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

5.14.1.17 Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register.

The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

The interrupt multiplexer registers are shown in Table 5-28 and described in Table 5-29.

Table 5-28. Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

Offset/Register	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0

5.14.1.18 IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD)

The IF1/IF2 Command Register (DCAN IF1CMD, DCAN IF2CMD) configure and initiate the transfer between the IF1/IF2 register sets and the message RAM. It is configurable which portions of the message object should be transferred.

A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress.

After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

The IF1/IF2 command registers are shown in Figure 5-31 and Figure 5-32 and described in Table 5-30.

NOTE: While Busy bit is one, IF1/IF2 register sets are write protected.

NOTE: For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode.

NOTE: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 command register, the message handler may access an implemented (valid) message object instead.

Table 5-30. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23	WR/RD		Write/Read
		0	Direction = Read: Transfer direction is from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set.
		1	Direction = Write: Transfer direction is from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
22	Mask		Access mask bits
		0	Mask bits will not be changed
		1	Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set.
			Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
21	Arb		Access arbitration bits
		0	Arbitration bits will not be changed
		1	Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 register set.
			Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
20	Control		Access control bits
		0	Control bits will not be changed
		1	Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF1/IF2 registerset.
			Direction = Write: The message control bits will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]).
			If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF1/IF2 message control register will be ignored.
19	ClrIntPnd		Clear interrupt pending bit
		0	IntPnd bit will not be changed
		1	Direction = Read: Clears IntPnd bit in the message object.
			Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1/IF2 Registers to message RAM can only be controlled by the control flag (Bit [20]).
18	TxRqst/NewDat		Access transmission request bit
		0	Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit.
		1	Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in message object.
			Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF1/IF2 message control Register.
			Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1/IF2 message control registeralways reflect the status before resetting them.
17	Data A		Access Data Bytes 0-3
		0	Data Bytes 0-3 will not be changed.
		1	Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset.
			Direction = Write: The data bytes 0-3 will be transferred from the IF1/IF2 registerset to the message object addressed by the Message Number (Bits [7:0]).
			Note: The duration of the message transfer is independent of the number of bytes to be transferred.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-30. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions (continued)

Bit	Field	Value	Description
16	Data B		Access Data Bytes 4-7
		0	Data Bytes 4-7 will not be changed.
		1	Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset.
			Direction = Write: The data bytes 4-7 will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]).
			Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	Busy		Busy flag
		0	No transfer between IF1/IF2 register set and message RAM is in progress.
		1	Transfer between IF1/IF2 register set and message RAM is in progress.
			This bit is set to one after the message number has been written to bits [7:0]. IF1/IF2 register set will be write protected. The bit is cleared after read/write action has been finished.
14	DMAactive		Activation of DMA feature for subsequent internal IF1/IF2 update
		0	DMA request line is independent of IF1/IF2 activities.
		1	DMA is requested after completed transfer between IF1/IF2 register set and message RAM.
			The DMA request remains active until the first read or write to one of the IF1/IF2 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
			Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately.
13-8	Reserved	0	These bits are always read as 0. Writes have no effect.
7-0	Message Number		Number of message object in message RAM which is used for data transfer
		0x00	Invalid message number
		0x01-0x80	Valid message numbers
		0x81-0xFF	Invalid message numbers

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.19 IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK)

The bits of the IF1/IF2 mask registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 mask registers (DCAN IF1MSK, DCAN IF2MSK) are shown in Figure 5-33 and Figure 5-34 and described in Table 5-31.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

Figure 5-33. IF1 Mask Register (DCAN IF1MSK)

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

Table 5-31. IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK) Field Descriptions

Bit	Field	Value	Description
31	MXtd		Mask Extended Identifier
		0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
		1	The extended identifier bit (IDE) is used for acceptance filtering.
			When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
30	MDir		Mask Message Direction
		0	The message direction bit (Dir) has no effect on the acceptance filtering.
		1	The message direction bit (Dir) is used for acceptance filtering.
29	Reserved	0	These bits are always read as 0. Writes have no effect.
28-0	Msk[28:0]		Identifier Mask
		0	The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care).
		1	The corresponding bit in the identifier of the message object is used for acceptance filtering.

5.14.1.20 IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB)

The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 arbitration registers (DCAN IF1ARB, DCAN IF2ARB) are shown in Figure 5-35 and Figure 5-36 and described in Table 5-32.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

Figure 5-35. IF1 Arbitration Register (DCAN IF1ARB)

R/WP-0

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

Table 5-32. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions

Bit	Field	Value	Description
31	MsgVal		Message valid
		0	The message object is ignored by the message handler.
		1	The message object is to be used by the message handler.
			The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN control register. This bit must also be reset before the identifier ID[28:0], the control bits Xtd, Dir or DLC[3:0] are modified, or if the messages object is no longer required.
30	Xtd		Extended identifier
		0	The 11-bit (“standard”) Identifier is used for this message object.
		1	The 29-bit (“extended”) Identifier is used for this message object.
29	Dir		Message direction
		0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object.
		1	Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).

Copyright © 2011–2013, Texas Instruments Incorporated

Table 5-32. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions (continued)

Bit	Field	Value	Description
28-0	ID[28:0]		Message identifier
		ID[28:0]	29-bit identifier (extended frame)
		ID[28:18]	11-bit identifier (standard frame)

The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Copyright © 2011–2013, Texas Instruments Incorporated

5.14.1.21 IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL)

The bits of the IF1/IF2 message control registers mirror the message control bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 message control registers (DCAN IF1MCTL, DCAN IF2MCTL) are shown in Figure 5-37 and Figure 5-38 and described in Table 5-33.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

Table 5-33. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are always read as 0. Writes have no effect.
15	NewDat		New data
		0	No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the CPU.
		1	The message handler or the CPU has written new data into the data portion of this message object.
14	MsgLst		Message lost (only valid for message objects with direction = receive)
		0	No message lost since the last time when this bit was reset by the CPU.
		1	The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	IntPnd		Interrupt pending
		0	This message object is not the source of an interrupt.
		1	This message object is the source of an interrupt. The Interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
12	UMask		Use acceptance mask
		0	Mask ignored
		1	Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering
			If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.

Table 5-33. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions (continued)

Bit	Field	Value	Description
11	TxIE		Transmit interrupt enable
		0	IntPnd will not be triggered after the successful transmission of a frame.
		1	IntPnd will be triggered after the successful transmission of a frame.
10	RxIE		Receive interrupt enable
		0	IntPnd will not be triggered after the successful reception of a frame.
		1	IntPnd will be triggered after the successful reception of a frame.
9	RmtEn		Remote enable
		0	At the reception of a remote frame, TxRqst is not changed.
		1	At the reception of a remote frame, TxRqst is set.
8	TxRqst		Transmit request
		0	This message object is not waiting for a transmission.
		1	The transmission of this message object is requested and is not yet done.
7	EoB		End of Block
		0	The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block.
		1	The message object is a single message object or the last message object in a FIFO Buffer Block.
			Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
6-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3-0	DLC[3:0]		Data length code
		0-8	Data frame has 0-8 data bits.
		9-15	Data frame has 8 data bytes.
			Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.

5.14.1.22 IF1/IF2 Data A and Data B Registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB)

The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order:

1. In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received.
2. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

The IF1/IF2 data A and data B registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB) registers are shown in Figure 5-39, Figure 5-40, Figure 5-41 and Figure 5-42.

5.14.1.23 IF3 Observation Register (DCAN IF3OBS)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU (Additional information can be found in *Structure of Message Objects*).

The observation flags (Bits [4:0]) in the IF3 observation register are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register.

The status of the current read-cycle can be observed via status flags (Bits [12:8]).

If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device-specific data sheet for the availability of this interrupt source.

With this interrupt, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

The IF3 observation register (DCAN IF3OBS) is shown in Figure 5-43 and described in Table 5-34.

Figure 5-43. IF3 Observation Register (DCAN IF3OBS)

5.14.1.27 IF3 Data A and Data B Registers (DCAN IF3DATA/DATB)

The data bytes of CAN messages are stored in the IF3 registers in the following order.

In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

The IF3 data A and data B registers (DCAN IF3DATA/DATB) are shown in Figure 5-47 and Figure 5-48.

5.14.1.28 Update Enable Registers (DCAN IF3UPD12 to IF3UPD78)

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set.

The update enable registers (DCAN IF3UPD12 to IF3UPD78) are shown in Table 5-38 and described in Table 5-39.

NOTE: IF3 Update enable should not be set for transmit objects.

Table 5-38. Update Enable Registers (DCAN IF3UPD12 to IF3UPD78))

5.14.1.29 CAN TX I/O Control Register (DCAN TIOC)

The CAN_TX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN TX I/O control register (DCAN TIOC) is shown in Figure 5-49 and described in Table 5-40.

NOTE: The values of the IO control registers are only writable if Init bit of the CAN control register is set.

NOTE: The OD, Func, Dir and Out bits of the CAN TX IO control register are forced to certain values when Init bit of CAN control register is reset (see bit descriptions).

5.14.1.30 CAN RX IO Control Register (DCAN RIOC)

The CAN_RX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN RX I/O control register (DCAN RIOC) is shown in Figure 5-50 and described in Table 5-41.

NOTE: The values of the IO control registers are writable only if Init bit of CAN control register is set.

NOTE: The OD, Func and Dir bits of the CAN RX IO control register are forced to certain values when the Init bit of CAN control register is reset (see bit descriptions).

6.1 Introduction

6.1.1 Overview

This section describes the Dynamic Memory Manager (DMM) and its Tiling and Isometric Lightweight Engine for Rotation (TILER) submodule.

As shown in Figure 6-1, the DMM is located in front to the SDRAM controllers and thus interfaces to the memory accesses generated by all the initiators.

The dynamic memory manager (DMM), is a module aimed at managing – in a broad sense – various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM memory interleaving configuration
- Block object transfer optimization – tiling and sub-tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability – and hence the run-time nature – of the four aspects of memory management handled by the DMM.

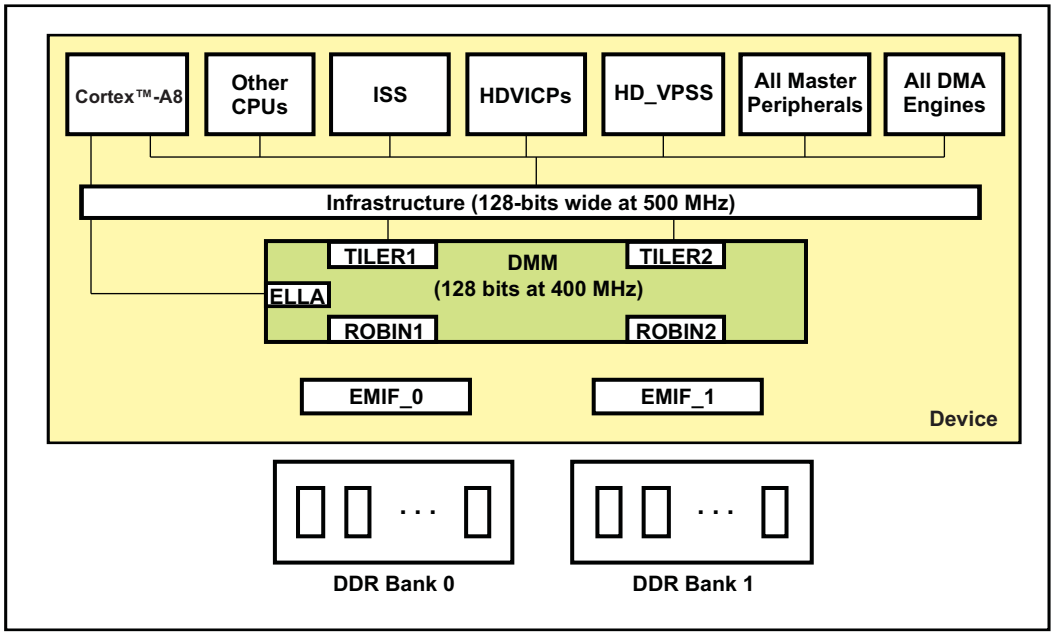
On a functional perspective, the role of the DMM is to:

- add initiator-based priority to any incoming requests
- perform to-and-fro tiling conversions of "tiled" requests
- provide an optional low-latency page-based translation to handle memory fragmentation - MMU
- distribute the traffic on both the attached memory controllers according to the interleaving configuration

The TILER is a submodule within the DMM aimed at efficient handling of two dimensional data, such as video/graphics accesses for HDVICP2, by the use of tiled format.

- optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- making on-the-fly, zero overhead transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection

Figure 6-1. DMM Integration



Copyright © 2011–2013, Texas Instruments Incorporated

6.1.2 Features

- Special low latency interconnect port. ELLA, only for Cortex™-A8 accesses.
- Ability to interleave the DDR data between two EMIF banks, using the programmable multi-zone DRAM memory mapping . This increases the memory throughput by a factor of 2. Up-to four unique memory sections supported.
- Programmable Initiator based request priority extension, for up to 16 Initiator groups.
- Support for address translations of tiled data, on a 4KB page granularity using the PAT. This helps manage memory fragmentation.
- One internal address lookup table (LUT) with 256x128 entries. Four refill engines to program the LUT, with automatic synchronized reload.
- Supports up to 4 unique PAT views.

6.1.3 Functional Block Diagram

Figure 6-2 shows the DMM macro architecture. The DMM consists of six blocks:

- A Priority Extension Generator (PEG) to generate priorities required by the SDRAM controller, note that these priorities are not used in the DMM
- One Extra Low Latency Access (ELLA), having its own interconnect slave port, for providing lower latency accesses to the memory
- A Local Interconnect and Synchronization Agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers
- A Physical Address Translator (PAT) for managing the memory fragmentation
- Two Re-Ordering Buffer and Initiator Nodes (ROBIN), having each their own interconnect master port, to initiate requests to the SDRAM controller and allow tiled data, tiled response and split response reconstruction. The ROBIN block is only managing the re-ordering buffer and performing the data re-ordering due to the orientation.
- Two Tiling and Isometric Lightweight Engine for Rotation (TILER), having each their own interconnect slave port, for converting requests to-and-fro between the input virtual addressing mode and the output physical tiled addressing mode. Note that, the tiling conversions of requests, write data and responses is fully performed in the TILER blocks.

6.1.4 Terminologies and Acronyms Used in this Document

The following is a brief explanation of some terms used in this document:

bpp— Bits per pixel

DMM— Dynamic Memory Manager

ELLA— Extra Low Latency Access

GB, GiB— Both imply Giga Byte

Initiator— A node inside the Device and is either a CPU, peripheral or DMA engine, which can be internal bus Master. Each initiator is identified by a ConnID (Connection ID). With a limit of only 16 ConnIDs, some of the Initiators are grouped together with same ConnID.

Interlaced— Qualifier for accesses skipping one line every line

IVA— Image Video Accelerator. Also called HDVICP2, IVA_HD.

LISA— Local Interconnect and Synchronisation Agent

KB, KiB— Both imply Kilo Byte

LUT— Look Up Table

MMU— Memory Management Unit

MPU— Main Processing Unit. For this device, it is Cortex™-A8

PAT— Physical Address Translator

PEG— Priority Extension Generator

Progressive— Qualifier for line-by-line accesses

ROBIN— Re-Ordering Buffer and Initiator Node

Tiled access— 1D or 2D Access to the tiled area, where the image data is read and written in two dimensional format, to improve the efficiency of accesses of 2D accesses, example image macro block. TILER Tiling and Isometric Lightweight Engine for Rotation 1D access A simple linear read or write access request. The DMM responds with read/write from/to the contiguous memory starting with address specified in the request.

2D access— HDVICP2 and HD_VPSS, can generate a special access to 2D image buffers, with read/write request, with Height and Width information. The DMM-TILER decodes the access type based on the Height, width and address, and responds with read/write from/to data in the physical memory, which has been co-located, with sub-tile granularity.

6.2 Architecture

6.2.1 DMM Functional Description

6.2.1.1 Priority Extension Generator (PEG)

The priority extension generator (PEG) is a dynamic software-programmable initiator-indexed table of priorities. Its unique role is to generates priorities for each access forwarded by the DMM to the SDRAM controller. For initiators that do not generate their own per-transaction priority, the priority value that is programmed in the table, will be assigned to all SDRAM accesses generated by that initiator. These priorities are not used by the DMM, for internal arbitrations.

The 16 priority entries are software-programmable with DMM_PEG_PRIO0 (for the first eight entries of the ConnID table) and DMM_PEG_PRIO1 (for the last eight entries) registers and set on a 3-bit scale, ranging from values 0-7, with Priority=0, being the highest priority.

When a request is passed to the SDRAM controller, the priority from the corresponding DMM_PEG_PRIOx field for an initiator is passed to SDRAM. For example, an access from the C674x DSP is sent to SDRAM with the priority captured in DMM_PEG_PRIOn. Note that the priority does not impact the behavior in DMM itself. It is passed to the SDRAM controller and the controller may use it in the prioritization of requests. However, for HD_VPSS, the peripheral itself generates a priority. The DMM_PEG_PRIOx field for HD_VPSS is bypassed and the priority indicated by HD_VPSS access is sent to SDRAM controller.

6.2.1.2 ELLA

The Extra Low Latency Access (ELLA) of the DMM is a simple interface port for all accesses made by Cortex™-A8. As the name suggests, this interface is simplified to reduce latency to the request from Cortex™-A8. In this respect, the ELLA block:

- Is limited to 1D bursts only
- Is not capable of performing tiling conversions
- Does not interact with the PAT block

The ELLA block main role is to split incoming requests at DMM atomic unit boundaries to ensure that requests sent to the SDRAM controller fit in a single SDRAM page. More precisely, the ELLA block is responsible for:

- Allocating an internal response context to timely generate the appropriate responses
- Splitting the incoming requests at DMM atomic section boundaries
- Requesting internal buffer allocation in the appropriate ROBIN
- In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer

NOTE: In the Device, Cortex™-A8 accesses in the system address space of 8000 0000h-FFFF FFFFh, are only routed through ELLA port. Accesses made by Cortex™-A8, in the all four tiled modes, including Paged mode, will be routed through the TILER ports, thus not getting benefit of lower latency of the ELLA port.

ELLA sub-module is not software configurable.

6.2.1.3 LISA

The Local Interconnect and Synchronisation Agent (LISA) is a hardware interconnect module, aimed at setting priorities, managing tags and memory mapping. LISA maps the system addresses on the incoming DMM requests to the SDRAM addresses, as per the LISA sections programming.

LISA interconnect routes:

1. ELLA and TILER requests on the ROBIN initiator nodes.
2. ELLA and TILER write data on the ROBIN write buffers.

Copyright © 2011–2013, Texas Instruments Incorporated

3. ROBIN read data to the relevant TILER initiators or to ELLA initiator.

The LISA block registers are DMM_LISA_MAP_i (i = 0 to 3) and DMM_LISA_LOCK.

LISA block manages all the incoming requests to ELLA, TILER and PAT and translates then to requests to Registers and ROBIN ports. Highest priority is given to accesses coming to the low-latency port (ELLA). When both DMM-ROBIN ports are in use, LISA module interleaves the two ports at a programmable boundary from 128 Bytes or more, as programmed in the DMM_LISA_MAPn registers. See sub-section on Section Mapping for details about LISA sections programming.

6.2.1.3.1 LISA LOCK

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to one, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK itself cannot be written back to 0. A reset is required to re-program the sections.

It is expected that LISA MAP is set up once during system configuration and not changed subsequently. The LOCK feature helps accomplish this and is expected to be set once the configuration is done.

6.2.1.4 PAT, Physical Address Translator Engine

The physical address translation engine (PAT) of the DMM is composed of two 32-k entry physical address translation vector table and a set of four refill engines. The refill engine is a specialized DMA aimed at refilling the content of the physical address translation table.

The address translation mechanism is only available when the incoming request is hitting a page mode or tiled mode container, that is, when the incoming address is targeting the TILER or its aliased view in the system addressing space. Otherwise the physical address translation logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT is supporting multiple address translation schemes, called views, which can be bound to one or more initiator through a view mapping mechanism.

The usage of the Refill Engines is described in detail in the later section.

6.2.1.4.1 PAT Views

A PAT view defines the kind of physical address translation to perform for each tiled mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to either use PAT Direct Access Translation or PAT In-Direct Access Translation.

The PAT supports up to four unique Views, using the DMM_PAT_VIEW_MAP[0..3] Registers.

6.2.1.4.2 PAT View Mappings

The 16 groups of initiators of the Device, each identified by their ConnID, share a set of 4 PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. The register DMM_PAT_VIEW0 is used for the first eight initiator groups and DMM_PAT_VIEW1 for the second eight. Thus each initiator can choose one of the four configurable PAT views in the system.

6.2.1.4.3 PAT View Map Base Address

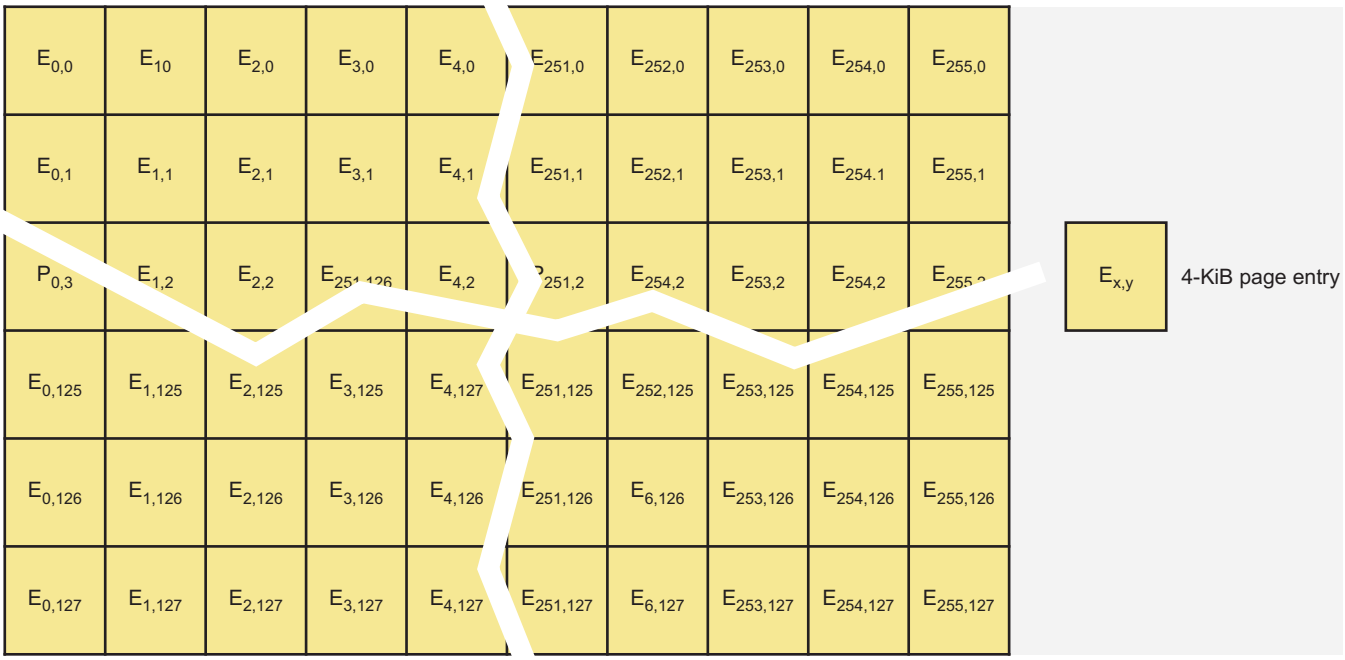
The PAT view map base address is defining the base address of all PAT translated addresses. The bit 31 of all PAT translated address is set to BASE_ADDR. In the Device, the bit 31 should be set to 1, which corresponds top 2GB assigned for external SDRAM in the system memory map. Hence the addresses translated by PAT range in addresses 8000 0000h-FFFF FFFFh.

6.2.1.4.4 PAT - Look Up Tables (LUTs)

The PAT contains one LUT, having 32K (256 × 128) entries. This geometry corresponds to that of the Virtual TILER container. So incoming address maps the actual entry in the LUT. The PAT shall then translate to a physical memory mapped to any 4K page the DDR. Each entry of the PAT address corresponds to the page in the DMM container that has the same location. For example - The entry (74, 42) in the table corresponds to the page (74, 42) in any DMM container.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 6-3. DMM Look-Up Table



Each of this entry points to a 4K page in the memory. Hence a total of 128 MB of tiled memory can be mapped using one LUT. With upto 2G of DDR space, supported in the Device, each LUT entry is 19 bits wide.

The PAT uses the LUTs only in case of PAT In-Direct Access Translation.

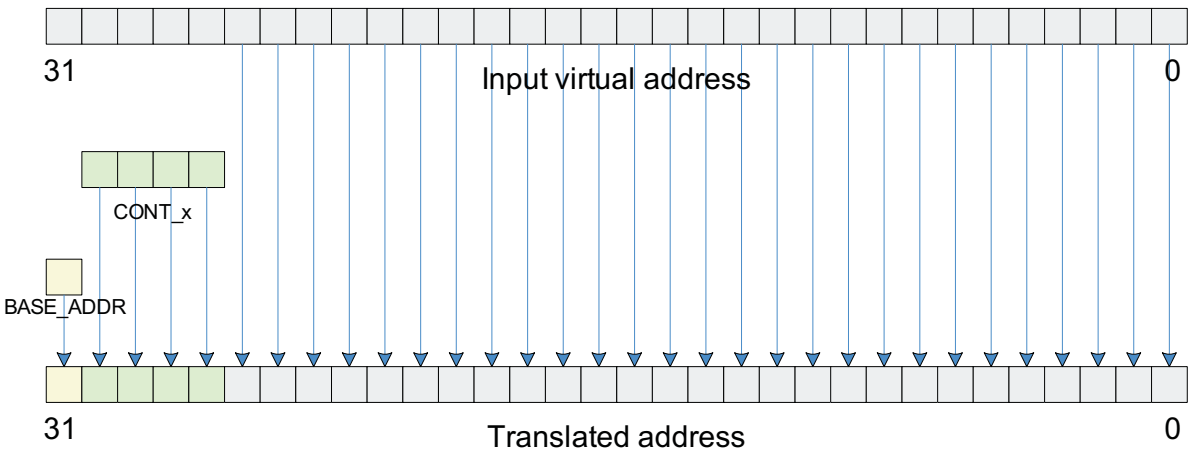
6.2.1.4.5 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is directly given by the CONT_x field, in DMM_PAT_VIEW_MAP register, corresponding to the accessed mode(8-bit/16-bit/32-bit/paged mode).

With PAT Direct Access translation, the 128 MB virtual containers for all the four modes, 8-bit, 16-bit, 32-bit, and paged modes can be mapped to their unique System Address, by defining their base addresses.

Figure 6-4 describes the actual translation that happens.

Figure 6-4. DMM PAT Direct Access Translation



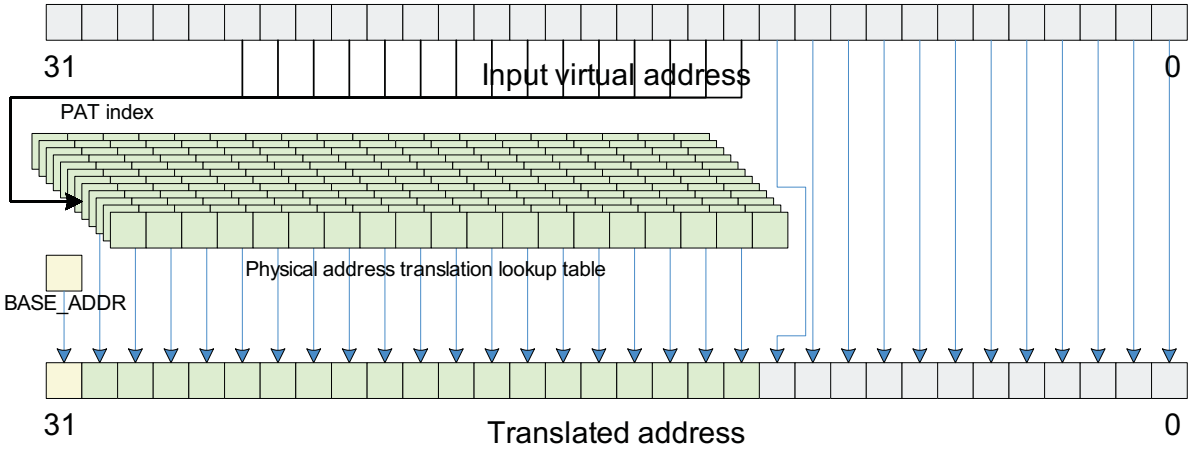
Copyright © 2011–2013, Texas Instruments Incorporated

6.2.1.4.6 PAT In-Direct Access Translation - Paged Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. In case of In-direct access translation, the single LUT in the system is used for address lookup. Then bits [19:12] of input address specify the X co-ordinate and bits [26:20] of input address specify the Y co-ordinate LUT entry. The PAT replaces bits[30:12] of input address, with 19-bit value specified in LUT entry.

This translation happens on the 4K page boundary and hence the lower 12 bits are not translated. Figure 6-5 describes the actual translation that happens.

Figure 6-5. DMM PAT In-Direct Access Translation



6.2.1.4.7 PAT In-Direct Access Translation - 8-bit, 16-bit, 32-bit Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. Per each of the 8-bit,16-bit ,32-bit and paged container mode, user specifies which LUT to use for address lookup, by using CONT_x field, in DMM_PAT_VIEW_MAP registers.

How the 26 LSBs of this incoming virtual address is interpreted by the PAT is different for 8-bit,16-bit ,32-bit mode accesses, as compared to the paged mode access described in the preceding section. Please refer the TILER section describes the rationale behind decoding the address this way.

Virtual address decoding in 8-bit mode access mode is:

- Bits 0:5 - 6 bits offset into the horizontal line of the page
- Bits 6:13 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 14:19 - 6 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 8 bit mode, their value is binary (01100), that is address in range 6000 0000h-67FF FFFFh

Virtual address decoding in 16-bit mode access mode is:

- Bit 0 - is always 0, as accesses are at-least 16-bit aligned
- Bits 1:6 - 6 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 16 bit mode, their value is binary (01101), that is address in range 6800 0000h-

Copyright © 2011–2013, Texas Instruments Incorporated

6FFF FFFFh

Virtual address decoding in 32-bit mode access mode is:

- Bit 0,1 - are always 0, as accesses are at-least 32-bit aligned
- Bits 2:6 - 5 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 32 bit mode, their value is binary (01110), that is address in range 7000 0000h-77FF FFFFh

6.2.1.5 ROBIN

The re-ordering buffer and initiator node (ROBIN) is a block aimed at providing some working buffering for converting data and responses to-and-fro between raster and tiled organizations and a master port to connect to the SDRAM controller.

The ROBIN block does:

- Request Forwarding
- Buffering of Write access data and buffering of Read access Response data
- Keeps write data ordering
- Intra-word tiling and orientation transforms
- Tag handling

NOTE: Both ROBIN sub-modules are not software configurable.

6.2.1.6 Section Mapping

In the device, DMM supports two unique SDRAM controllers, with a software configurable option to interleave data between both banks, at granularity of 128 Bytes, 256 Bytes and 512 Bytes. When accessing tiled data in 8-bit, 16-bit and 32-bit modes, which in the interleaved section of the memory, the interleaving will happen at the tile boundary of 1KB, over-riding the interleaving definition of the section.

For optimal system performance, it is recommended to enable interleaving between the 2 EMIF banks and thus have same sized memory on both the EMIF banks. Example : 512MB of DDR3 on EMIF bank 0 and 512MB of DDR3 on EMIF bank 1, for a total system DDR3 memory of 1GB.

NOTE: This interleaving is supported only if DDRs system connected to both the SDRAM controllers have same electrical characteristics.

If for cost reduction, one chooses to build a system with asymmetrical memory on both EMIF banks, then a few limited configurations can be supported by using the LISA section programming feature of DMM.

The address mapping inside the DMM is configurable through up to four sections. Each section is defined based on:

- Its system address: the base address of the decoding range for the section. This is the address of the incoming access to the DMM, also referred to as System Address.
- Its size: the encoding is the number of bits actually used in the upper 8-bits of the incoming system address. Hence the size of the section can be a value 16MB-2GB and power of 2. With interleaving enabled, the minimum size of the section is 32 MB.
- Its physical address: the base address of the memory range access in the external memory controller. It is also referred to as SDRC address.
- The target memory controller: A section may hit either of EMIF banks or both.

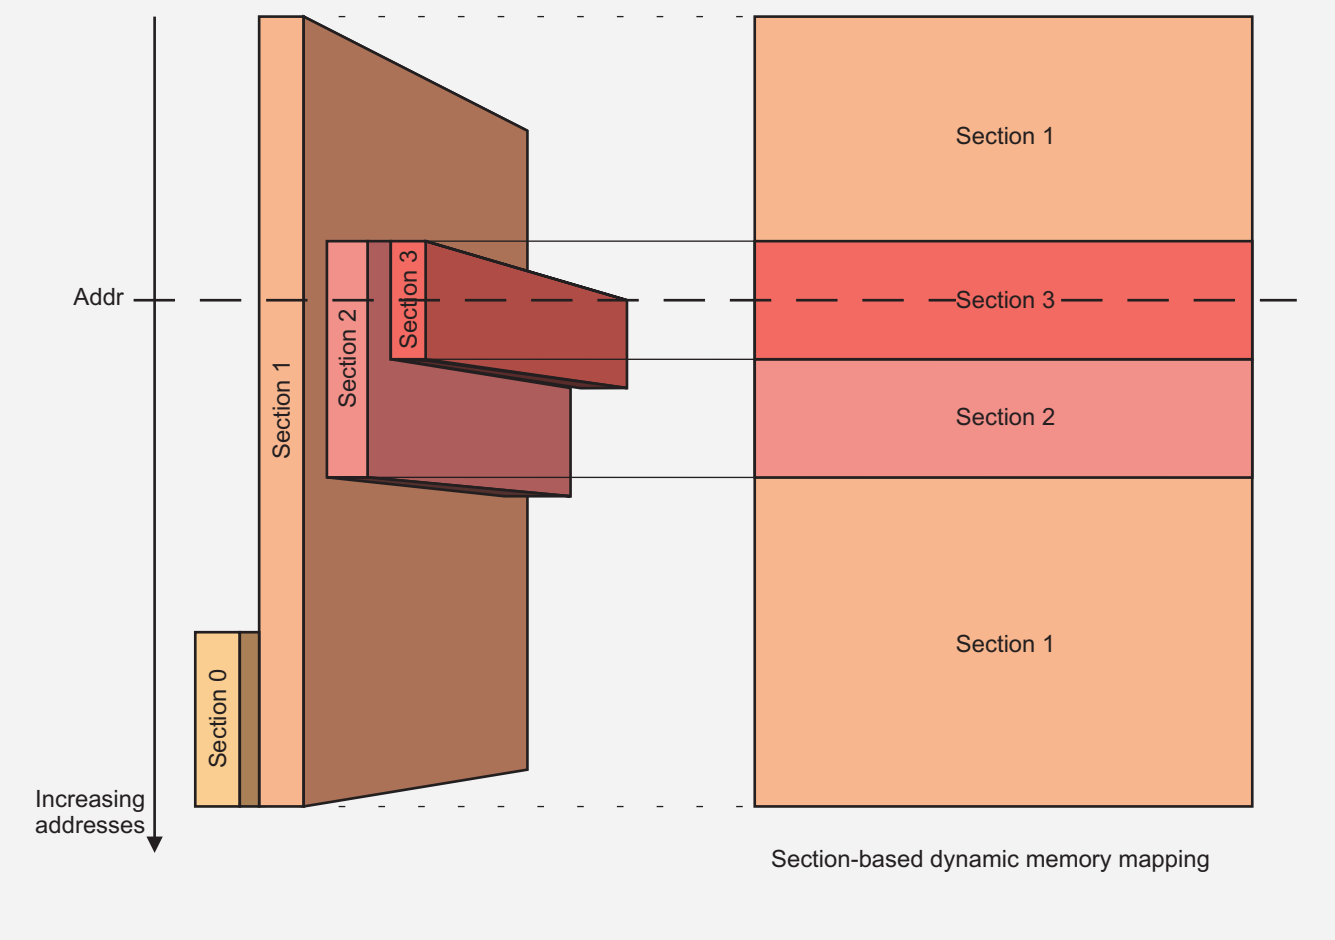
Copyright © 2011–2013, Texas Instruments Incorporated

- Its interleaving definition : Interleave at 128Bytes, 256 Bytes, 512 Bytes or no interleaving.

A LISA section is:

- a memory segment of size 16MB – 2GB, which is a power of two and aligned to that size in the system map. If the section is configured to interleave data between 2 EMIF, then the minimum section size is 32 MB.
- An area with constant interleaving scheme, with fixed interleaving granularity. Interleaving between 2 EMIF banks can be also disabled, for this section.
- If two sections overlap, then the property of higher section number will be applied, as shown in Figure 6-6. There can be a total of 4 unique section definition in DMM.

Figure 6-6. DMM Section and Memory Mapping



In Figure 6-6, a request at the system address Addr will follow the interleaving scheme of section 3, although hitting sections 1, 2 and 3. Similarly, this DMM configuration also prevents any request to use the interleaving scheme of section 0, since section 0 is fully masked by section 1 – which has a higher priority.

The DMM section specifies the range of incoming (to DMM) System address (granularity of 16 MB) and how it maps to the physical SDRC address of EMIF0 and/or EMIF 1, with similarly aligned granularity.

The interleaving of data between two EMIF banks is transparent to all the initiators of the system and will not require special address conversions. Figure 6-7 and Figure 6-8 give examples of all the interleaving schemes.

6.2.1.7 TILER

As can be seen in Figure 6-2, the two TILER ports interface to the incoming accesses to DMM. Its primary function is increase efficiency of a 2D Tiled Block access. Mentioned below are the main functions of the TILER module:

1. primary handling efficiently 2 dimensional data mapped in tiles, such as video or graphics macro blocks.
2. optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation, on 4KB page granularity.
3. making isometric – distance preserving – transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection, with no overhead.

Written differently, the functionality of this TILER module is to map a 2D virtually-addressed incoming request into one or more physically-addressed SDRAM requests by:

1. Decoding the incoming access address to qualify whether the request targets the TILER or the memory directly.
2. If the incoming access is a TILER-specific requests, then transforming to the virtual address, data and byte enable to match the requested 0°, 90°, 180°, or 270° orientation in a tiled 2D addressing space.
3. optionally translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing, as shown in Figure 6-9.
4. Splitting tiled requests at tile boundaries and non-tiled requests at DMM atomic section boundaries
5. Requesting the page-based address translation
6. Requesting buffer allocation in the appropriate ROBIN.
7. In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer.

Figure 6-9. Overview of Request Conversion

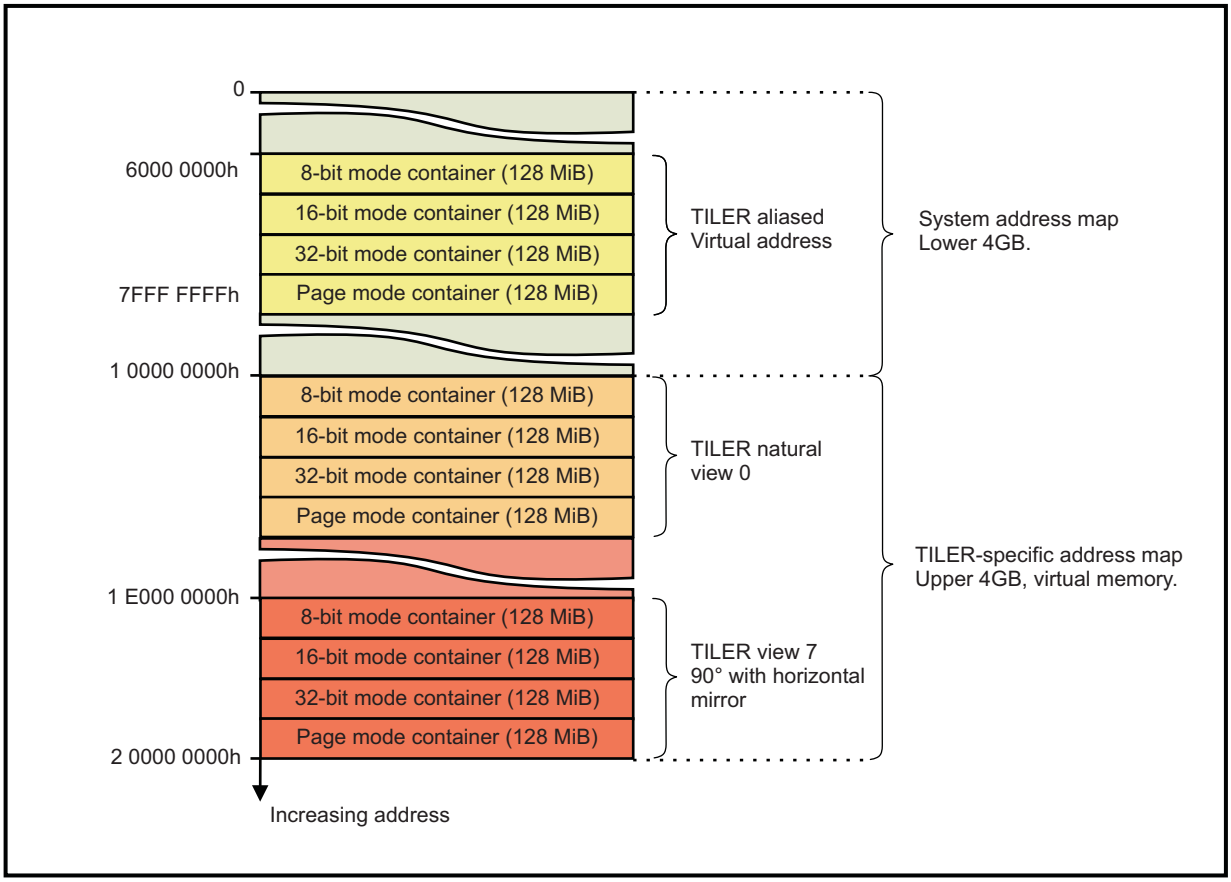
6.2.1.7.1 Device Memory Map - For Tiled Data

In the Device, the initiators read and write tiled data by generating accesses to the tiled space by the one of the two methods:

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh), and allows any of the eight 512-MB oriented sub-spaces – or views – to be remapped in the system virtual addressing space.

Figure 6-10. Memory Map



NOTE: Despite the larger virtual address windows, 512 MB in the system memory map and 4GB in the TILER memory map, the maximum size of physical tiled data is only 128MB. This 128MB is co-located in a 128MB aligned space, if using PAT direct access translation. In case of using the optional PAT Indirect access translation, then this 128MB is mapped to any location in the SDRAM, using the LUT tables, at the granularity of 4KB page.

6.2.1.8 Clock

The DMM is a synchronous design and operates from the same clock as the internal L3 interconnect. All timings use this clock as a reference.

6.2.1.9 Interrupts

DMM module generates interrupt to Cortex™-A8, for status and error conditions related to PAT refills engines. There 8 different conditions which can be individually enabled or disabled. With 4 Refill engines, there are total 32 unique sources of interrupts.

Refer to Section 6.3.3 for detailed description on using the PAT refill engines.

Per Refill engine, status and error conditions are mentioned below:

1. FILL_DSCn: Refill of any descriptor, for engine n, complete.
2. FILL_LSTn: Refill of the last descriptor, for engine n, complete.
3. ERR_INV_DSCn: Invalid descriptor pointer, for engine n.
4. ERR_INV_DATAn: Invalid data table pointer, for engine n.
5. ERR_UPD_AREAn: Error caused by area register update while refilling, for engine n.
6. ERR_UPD_CTRLn: Error caused by control register update while refilling, for engine n.
7. ERR_UPD_DATAn: Error caused by data register update while refilling, for engine n.
8. ERR_LUT_MISSn: Access to a yet-to-be-filled entry, that is part of the area being refilled, for engine n.

The six error conditions mentioned above are also reported in the respective DMM_PAT_STATUSn register.

6.2.1.10 Address Translations Within DMM, For Tiled Accesses

This section describes address translations that happen at various interfaces within DMM, for tiled accesses.

From a user perspective, the PAT can be seen as an additional step in the process applied to the tiled addresses by the TILER:

- the TILER first transforms a tiled address into a 27 bit physical address which fits within a 128MB address range.
- the PAT then processes the high order bits of the physical address output by the TILER, and outputs a 32-bit physical address which covers a 4GB address range. Section 6.2.1.4 describes the exact details for this address translation.

The purpose of the PAT is to map the tiled data anywhere in the 4GB physical address range, with a PAGE granularity (The TILER page is the granularity of physical memory allocation in TILER container. Each page is 4KB). This can be summed-up in Figure 6-11 where the PAT process appears in red.

Only the high order bits of the physical address are modified by the PAT: the 12 low-order bits remain unchanged. This means that the data ordering within each 4kB PAGE remains as calculated by the TILER.

A PAT view is defining the kind of physical address translation to perform for each of the page, 8-bit, 16-bit and 32-bit mode accesses. Each mode in each PAT view can be programmed in 2 different modes (direct translation and indirect translation) which will be described in PAT section. Note that indirect mode is the most commonly used. Direct mode is used only for debug or in case of a DMM without PAT module.

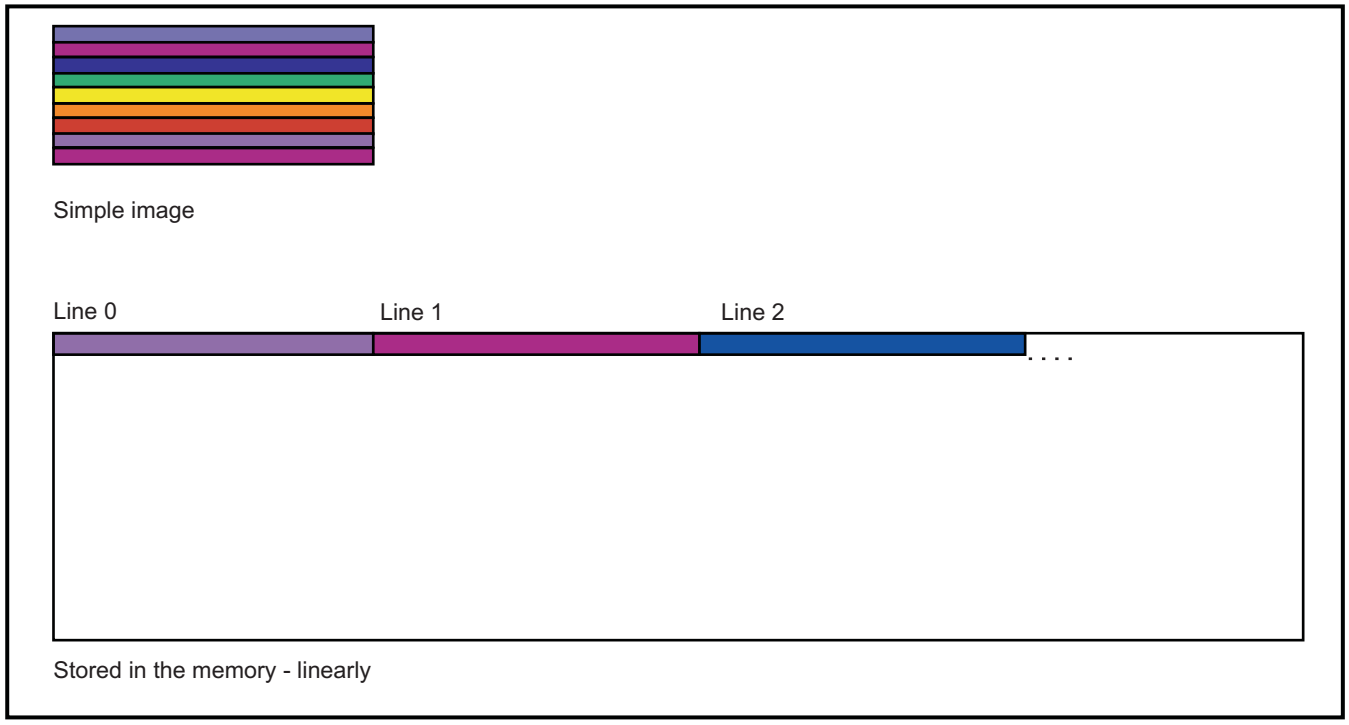
6.2.2 TILER Functional Description

6.2.2.1 Introduction to TILER

6.2.2.1.1 Need for a TILER

Image processing algorithms like H.264 encode and decode, which works on the principle of spatial locality, access the image data in two-dimensional format, for example, 16 pixels wide by 16 pixels high. If the image is stored in the memory in linear format then it would appear as in Figure 6-12. Thus, to access the macroblock, multiple memory accesses would need to be made. In the device, each memory access can be up to 128 bytes large. However, because macroblock is not stored contiguously in the memory, only partial pixels is useful in each memory access and the rest is discarded and a new access is generated to fetch rest of the data.

Figure 6-12. Image Stored in the Memory Linearly



Instead, if the image is stored in bi-dimensional format, much fewer accesses are needed to read the entire macroblock of data, which directly transforms into several advantages:

1. Faster processing of algorithms.
2. Fewer SDRAM page opens.
3. Lesser wastage of memory bandwidth in the system.

This concept is the primary motive for storing the image data in the tiled format.

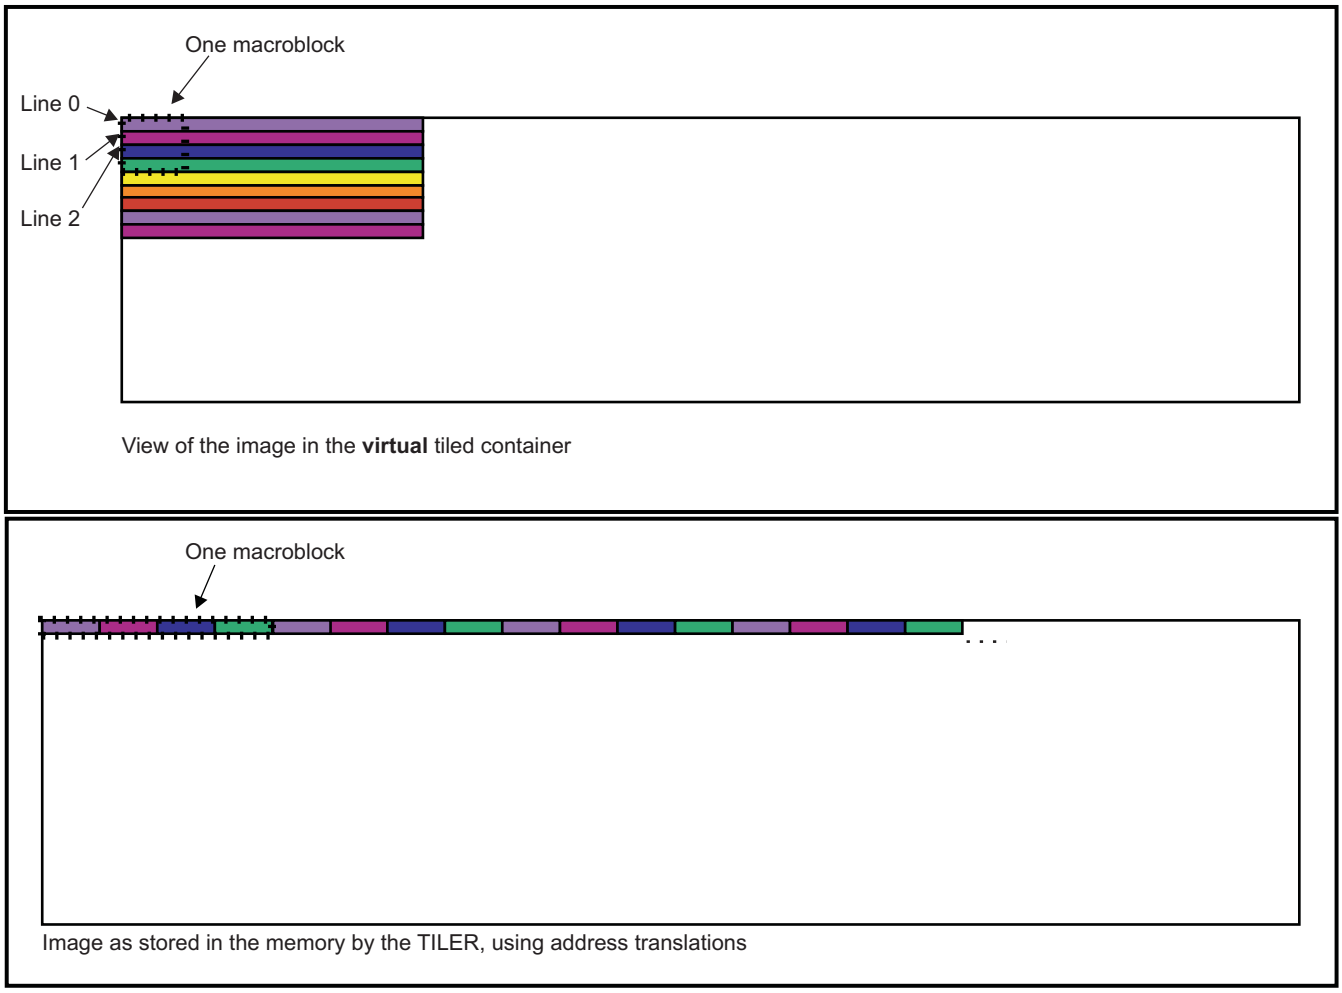
Figure 6-13. Image Stored in the Memory by TILER



NOTE : This is only a pictorial representation and actual arrangement of the data in the 128-bit subtile may be different.

6.2.2.1.2 Consuming Tiled Data

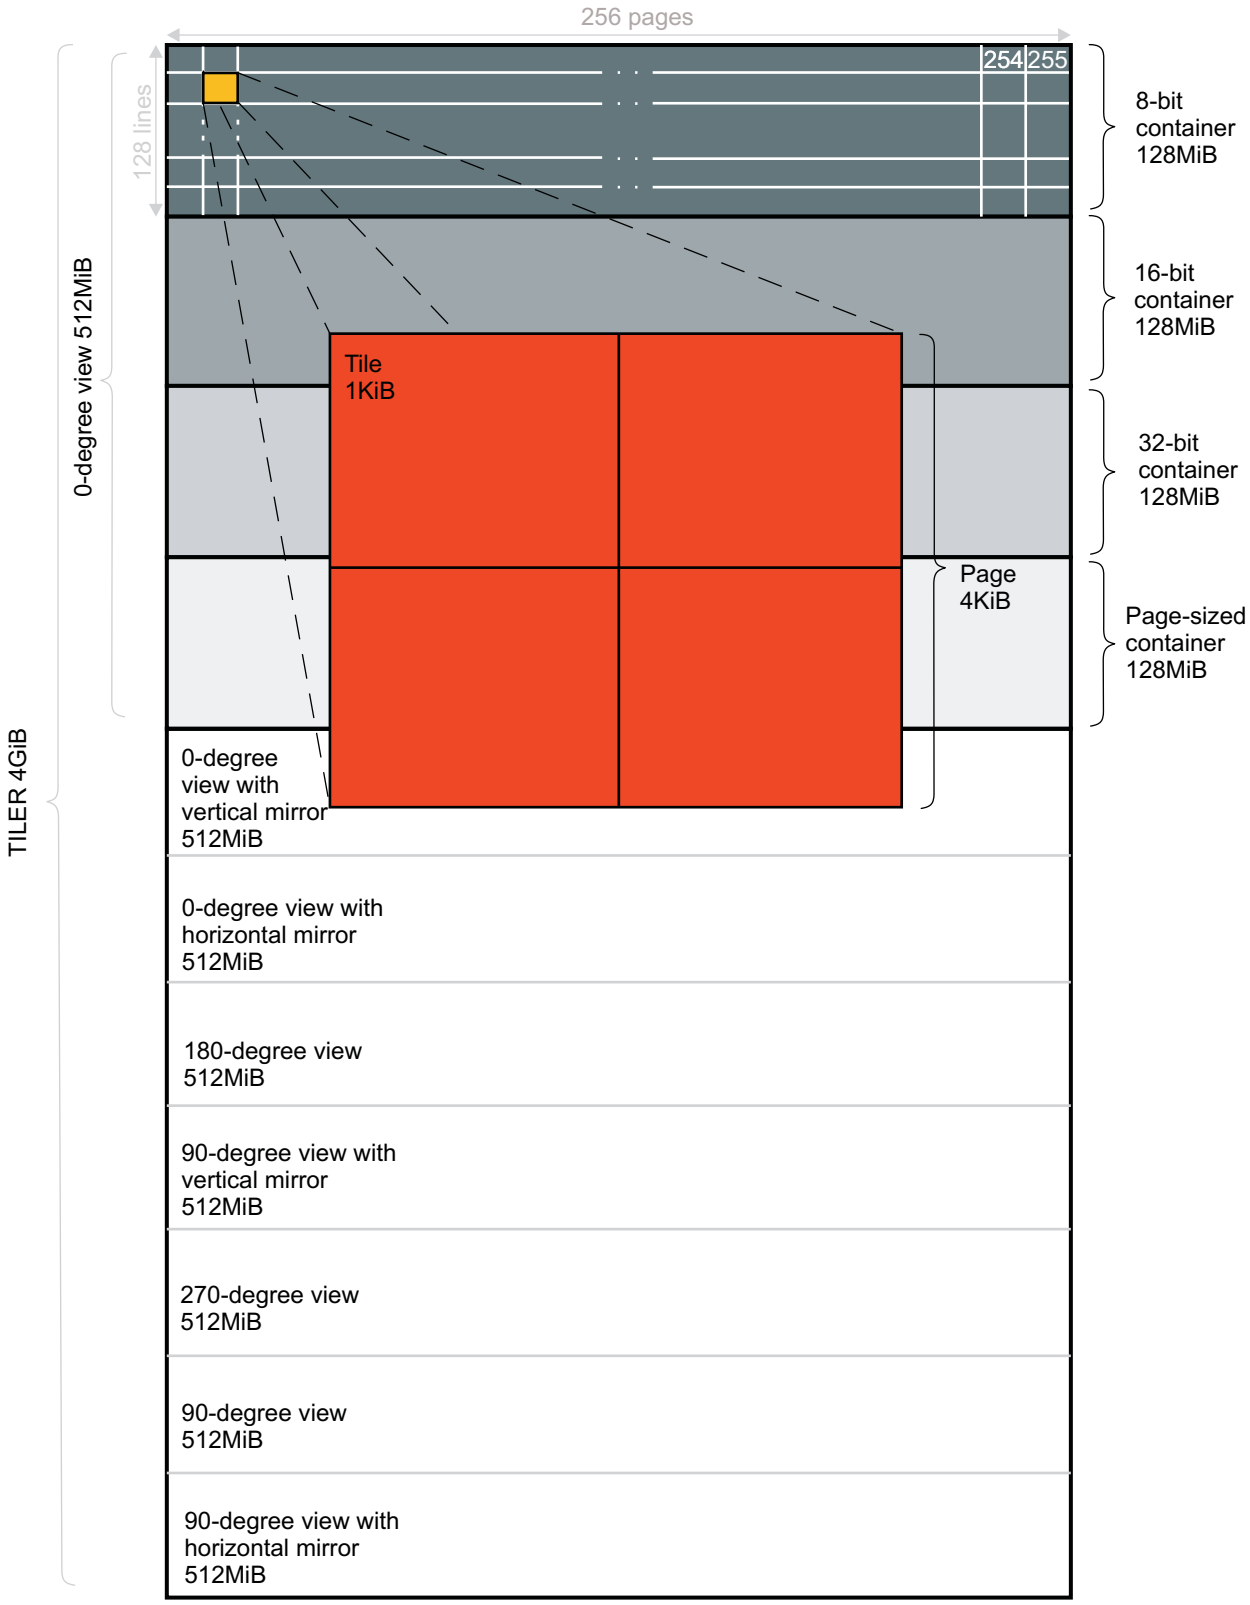
In the device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its capture and display paths (called clients). For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or 2^{2n} number of lines.

6.2.2.2 TILER Rationale - A Top-down Approach

This section is a synthesis of all TILER concepts, through a top-down approach starting from the main object container, giving one rule per TILER structure level. Figure 6-14 shows the TILER address space structure for tiled modes.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 6-14. Address Space Structure for Tiled Modes



Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.2.1 The TILER is a 4-GB Virtual Address Space Composed of Eight Views

A TILER is addressed using a virtual 4 GB address space, containing 8 unique orientation views of 512 MB each. There is one view for each of the eight possible way of scanning a frame-buffer.

1. From left to right then from top to bottom (0 natural orientation)
2. From right to left then from top to bottom
3. From left to right then from bottom to top
4. From right to left then from bottom to top
5. From top to bottom then from left to right
6. From top to bottom then from right to left
7. From bottom to top then from left to right
8. From bottom to top then from right to left

Section 6.2.2.7 summarizes how the view can be visualized on a 128MB TILER container.

6.2.2.2.2 A View is a 512-MB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated. The element is the entity of maximum size - 8 bits, 16 bits, 32 bits or page-sized - which is invariant in any orientation.

6.2.2.2.3 A Container is a 128-MB Virtual Address Space

A 128 MB container can be visualized as an array of 128 x 256 pages of 4 KB each. The page defines the granularity of physical memory allocation through a physical address translation unit - MMU.

6.2.2.2.4 A Page is a 4-KB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles. Figure 6-15, Figure 6-16, and Figure 6-17 illustrate the Page geometry for 8-,16-, and 32-bit views, respectively.

Figure 6-15. 4KB Page, 8-bit Mode

Figure 6-16. 4KB Page, 16-bit Mode

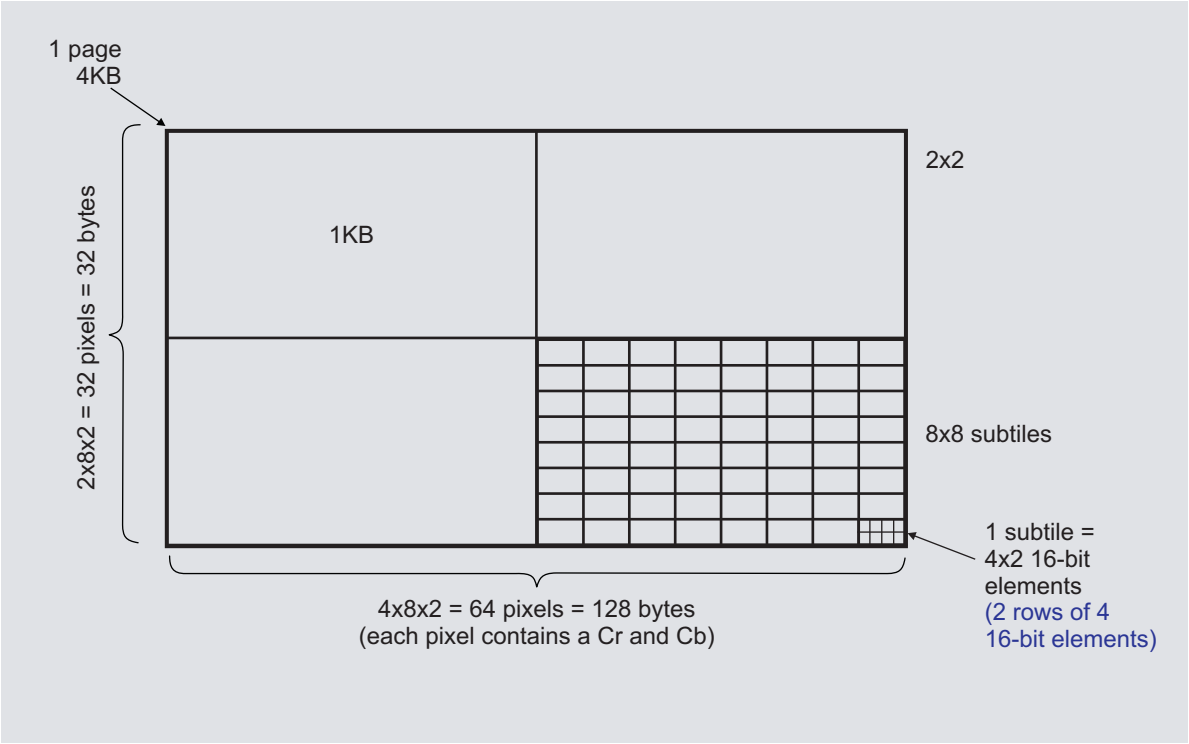

Figure 6-17. 4KB Page, 32-bit Mode

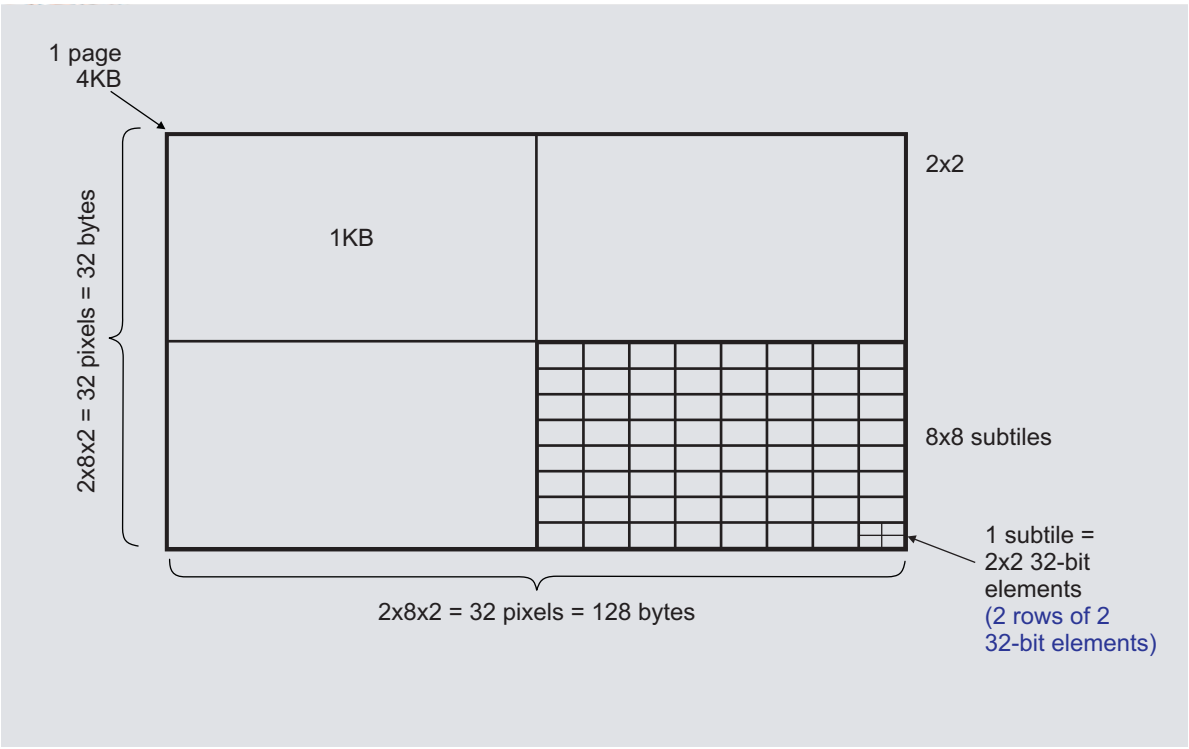


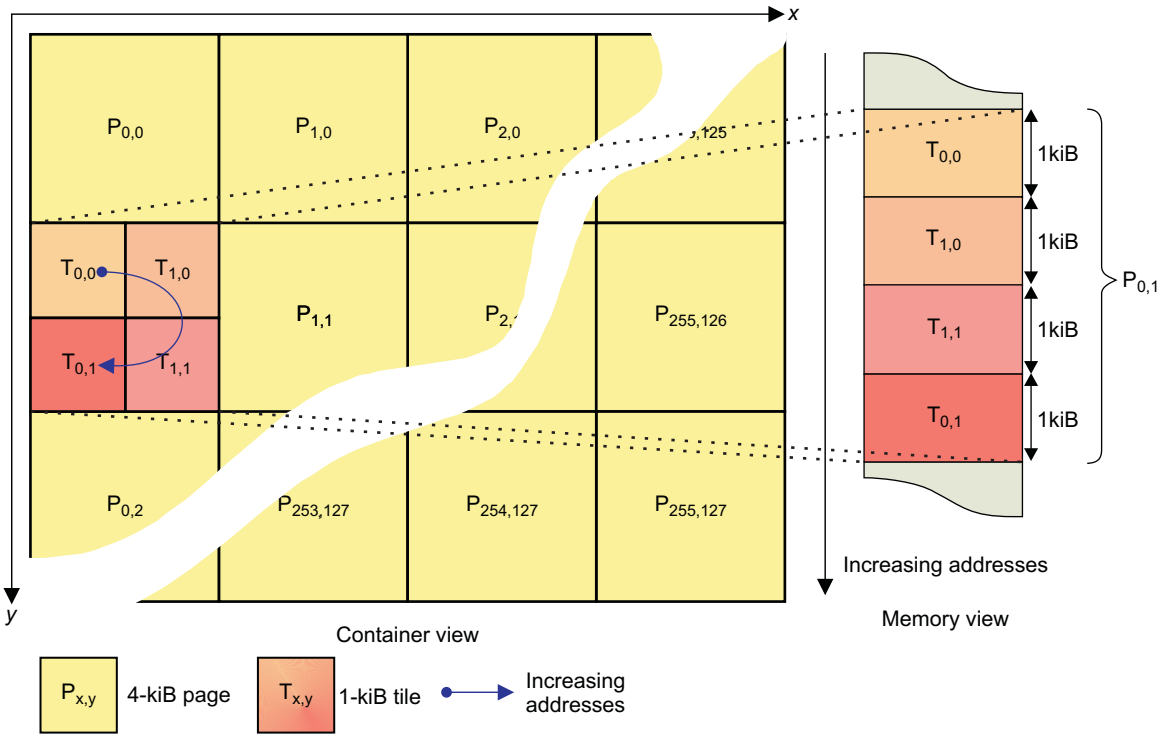
Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.2.5 A Tile is a 1-KB Address Space

The tile is designed to offer bi-dimensional data locality in a single SDRAM page. In this respect, it has been sized to 1 KB (the size of the smallest SDRAM page).

Figure 6-18 shows how 4 tiles are arranged in a page. This arrangement ensures that any two adjacent tiles in a page are not stored on the same EMIF(when interleaving is enabled). Thus a large tiled access will be efficient as it will be evenly spread across both SDRAM controllers.

Figure 6-18. Four 1KB Tiles in One 4KB Page



Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.2.6 A Sub-tile is a 128-bit Address Space

A 1KB tile is further decomposed into 64 sub-tiles, each sized 128 bits. The sub-tile structure is such that it balances accesses in two-dimensional modes, thus improving SDRAM access efficiency.

Furthermore, using Sub-tile pairing, the interlaced accesses to the tiled data can be improved. A Sub-tile is defined as follows:

1. An 8-bit sub-tile (Figure 6-19) is defined as an array of four horizontal lines of four 8-bit data. Thus, in 8-bit tiled mode, the TILER container is a 16384 × 8192 2D array of 8-bit elements.
2. A 16-bit sub-tile (Figure 6-20) is defined as an array of two horizontal lines of four 16-bit data. Thus, in 16-bit tiled mode, the TILER container is a 16384 × 4096 2D array of 16-bit elements.
3. A 32-bit tiled (Figure 6-21) mode as an array of two horizontal lines of two 32-bit data. Thus, in 32-bit tiled mode, the TILER container is an 8192 × 4096 2D array of 32-bit elements.

Figure 6-19. 8-bit Sub-tile

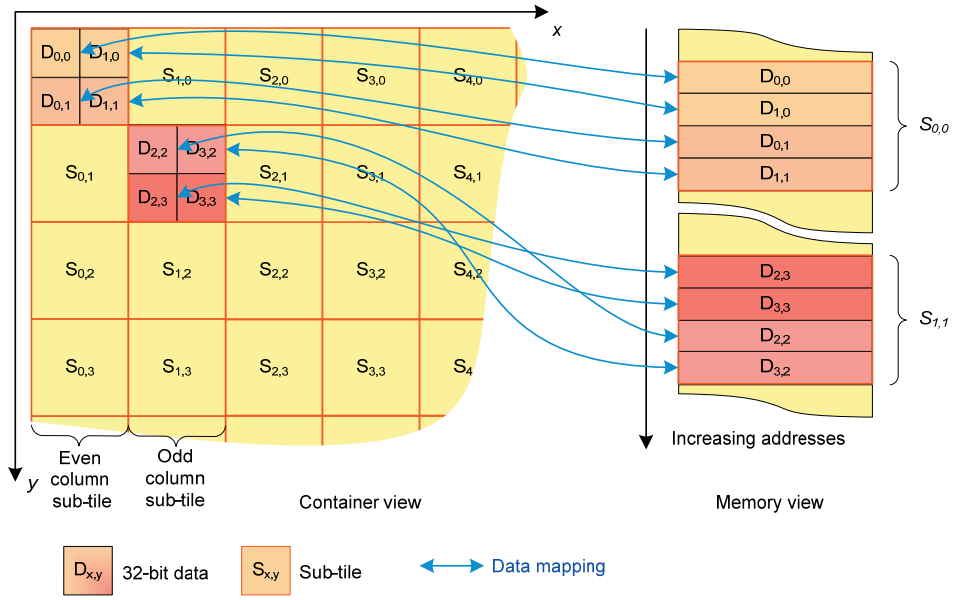
Figure 6-21. 32-bit Sub-tile



6.2.2.3 TILER Container - Summary

TILER is a 128-MB virtual container arranged in 2 dimensions as 256 × 128 pages, each of 4KB.

Each 4-KB page is has 4 tiles.

Each 1-KB tile has 64 subtiles, each of size 128 bits.

Based on the mode of access, 8/16/32 bit, the data stored can be aligned differently, as explained in the previous section.

6.2.2.3.1 Where Will the Tiled Data Be Stored in Physical Memory?

Using PAT Direct Access Translation:

By bypassing the LUT, the entire 128MB space has to be contiguous in the physical memory. Then each of the 8-bit 128 MB virtual container, 16-bit 128 MB virtual container, 32-bit 128 MB virtual container and paged container, can be mapped to either the same physical 128 MB space or at different locations. Refer to the PAT_VIEW_MAP register, which defines the base address of this 128 MB space. As can be seen, this base address is 256 MB aligned.

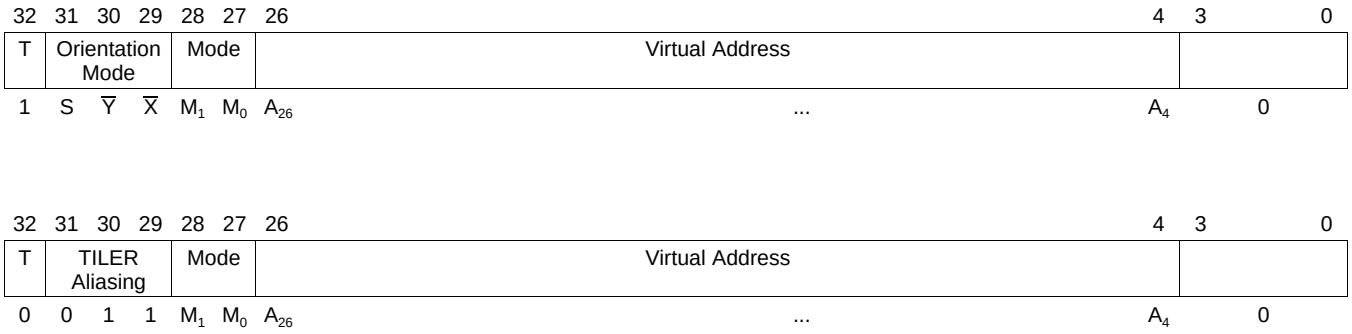
Using PAT In-Direct Access Translation:

A more common use case would be to use the single LUT in the DMM, to map the virtual data to physical address, at 4KB granularity. Then the physical 128MB need not be contiguous. However, with one LUT in the system, only 128 MB of data is possible; therefore the 8, 16, 32-bit and paged containers may need to be aliased to same pages. Thus use the LUT to map 8-bit, 16-bit, 32-bit containers, and paged mode containers, whereby they would all correspond to same physical memory pages, as shown in Figure 6-24.

Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.3.2 Addressing Formats

Figure 6-22. Address Format



1. The 33rd bit, noted T, is aimed at distinguishing the standard 4-GB system address map from the 4-GB TILER-specific address map In the Device, only HD_VPSS can generate accesses in the latter space.
2. The orientation bits, noted S, Y, and X, define the request orientation as specified in Section 6.2.2.7.
3. The mode bits, noted M1 and M0, encoded as in Section 6.2.2.8.1.
4. The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address.

6.2.2.4 TILER Modes

The TILER is supporting three major access modes - bypass, page and tiled - each having a specific output request generation.

6.2.2.4.1 Bypass Mode

This mode is transparent at the TILER perspective. Bypass mode is for accesses generated by initiators with System addresses outside the virtual tiled address range, since TILER will bypass PAT. Still, at the DMM perspective:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at the DMM atomic unit of the section hit by the burst at:
  - at the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - at 1-KB boundary in non-interleaved sections

6.2.2.4.2 Paged Mode

The purpose of this mode is to use the DMM PAT address translation mechanism for non-tiled accesses. In this respect it is similar to the bypass mode:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at:
  - the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - 1-KB boundary in non-interleaved sections

Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.4.3 Tiled Mode

When the being accessed in tiled mode, it can be either of the following:

- A well formed 2D block requests - conforming to the orientation, mode and stride
- A 1D incremental requests and ill-formed 2D block requests

Table 6-1. Stride for Well-formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride (bytes)	Description
S	Y	X	M1	M0		
0	x	x	0	0	16384	Plain access to an 8-bit progressive frame in 0° or 180°
					32768	Field access to an 8-bit interlaced frame in 0° or 180°
			0	1	32768	Plain access to a 16-bit progressive frame in 0° or 180°
					65536	Field access to a 16-bit interlaced frame in 0° or 180°
			1	0	32768	Plain access to a 32-bit progressive frame in 0° or 180°
					65536	Field access to a 32-bit interlaced frame in 0° or 180°
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90° or 270°
					16384	Field access to an 8-bit interlaced frame in 90° or 270°
			0	1	8192	Plain access to a 16-bit progressive frame in 90° or 270°
					16384	Field access to a 16-bit interlaced frame in 90° or 270°
			1	0	16384	Plain access to a 32-bit progressive frame in 90° or 270°
					32768	Field access to a 32-bit interlaced frame in 90° or 270°

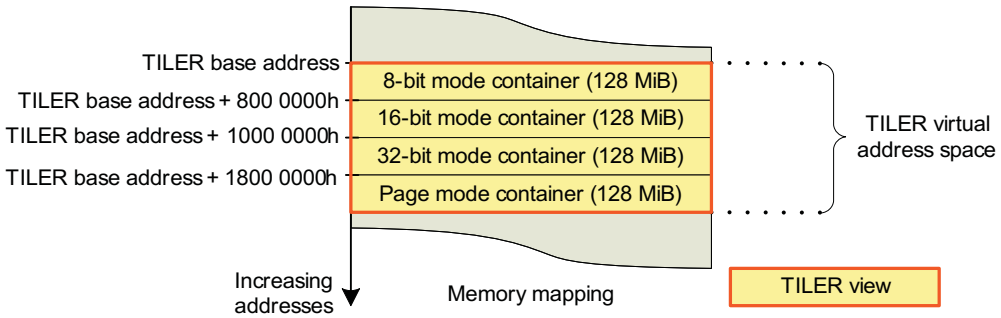
6.2.2.5 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MB virtual address space, where all objects of a same kind - and orientation - are allocated. Four main types of containers are present in the TILER, each one being referred by a mode:

- A 8-bit element mode, for efficiently accessing bi-dimensional arrays of 8-bit data, example 8-bits per pixel Luma buffers of image.
- A 16-bit element mode, for efficiently accessing bi-dimensional arrays of 16-bit data, example 16-bits per pixel interleaved-Chroma(CbCr) buffers of image.
- A 32-bit element mode, for efficiently accessing bi-dimensional arrays of 32-bit data, example 32-bits per pixel, ARGB graphics buffers.
- A page mode, for efficient 1D accesses

Figure 6-23 shows the TILER object containers and views.

Figure 6-23. TILER Object Containers and Views

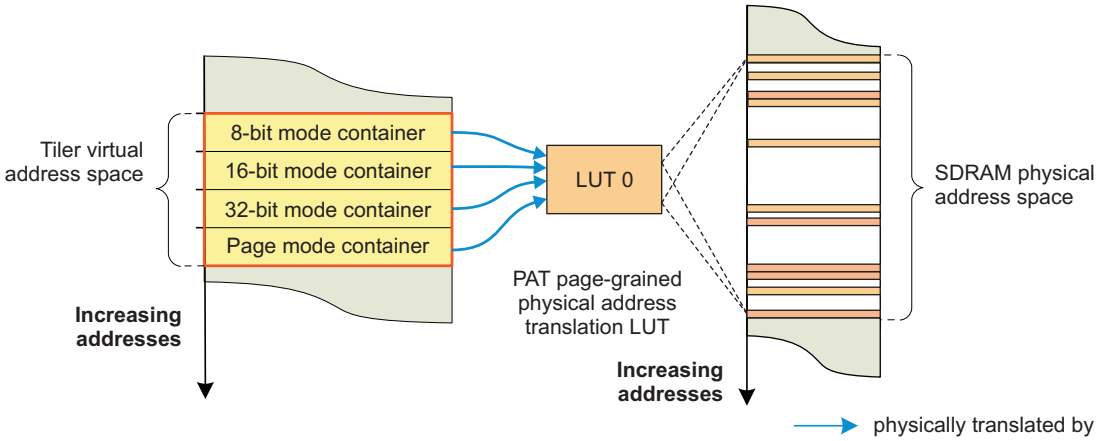


Copyright © 2011–2013, Texas Instruments Incorporated

In the device, there is a single LUT in the PAT. Each LUT can map up to 128MB of objects at a 4KB page granularity. The four modes share the single LUT.

As shown in Figure 6-24, 128MB of objects are available simultaneously in 8, 16, 32-bit modes and paged mode accesses.

Figure 6-24. Using LUT to Translate Tiled Virtual Address to Physical SDRC Address



NOTE: You need to ensure that an object allocated in a particular container mode does not physically overlap with any other object either in the same mode or other container modes.

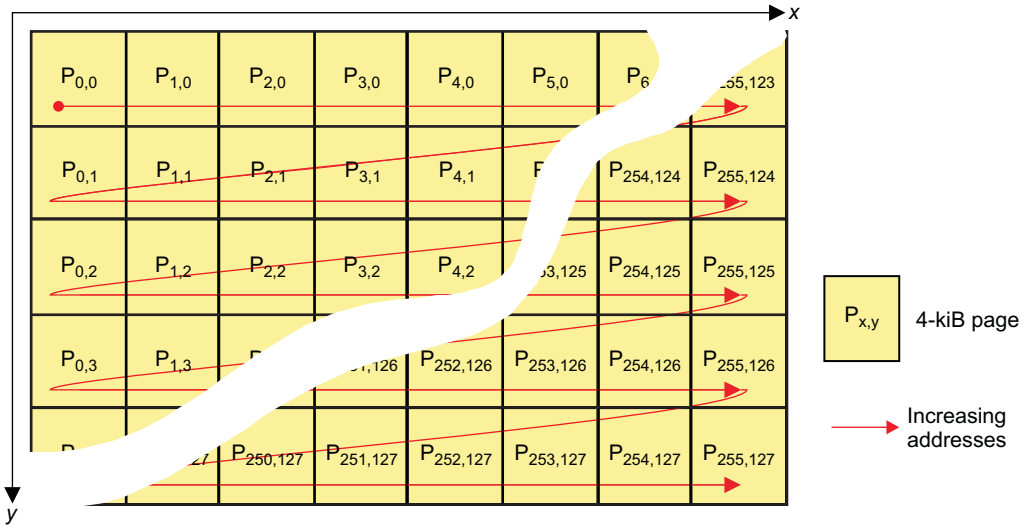
6.2.2.6 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers. Given that the sub-page structure is mode specific, the 4KB page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

6.2.2.6.1 Container Geometry with 4-kiB Pages

As pages size is 4KB, any 128MB object container is a set of 256 × 128 = 32768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 6-25.

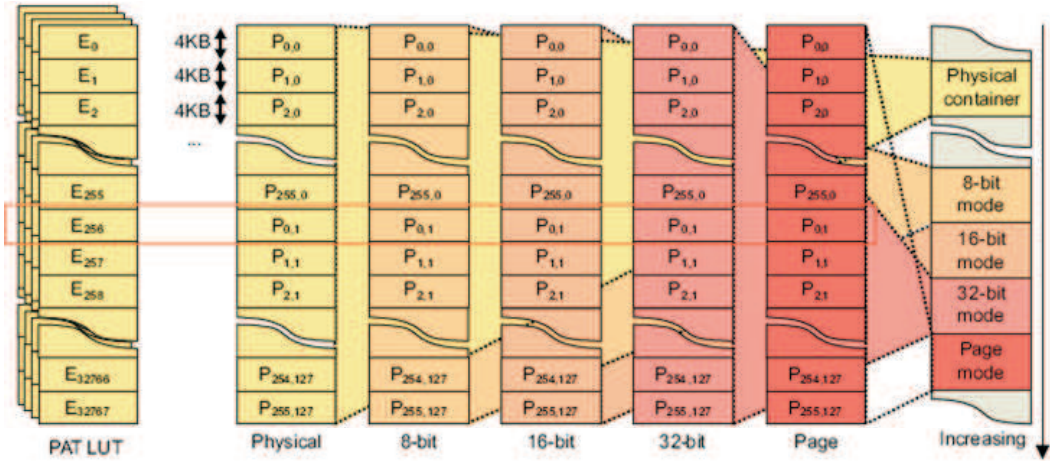
Figure 6-25. Object Container Geometry with 4KB Pages



Copyright © 2011–2013, Texas Instruments Incorporated

This array of pages is mapped to the system address space as shown in Figure 6-26.

Figure 6-26. TILER Page Mapping When Using 4KB Pages



In any 128-MB object container, the 4KB page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is found at an offset of 4096. (x + 256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is translated by the LUT entry Ex + 256.y found at the index x + 256.y.

6.2.2.6.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page Px,y:

- has maxx = 256 and maxy = 128
- is found at an offset of: 4096.(x + maxx.y) bytes from the base address of the related object container
- is translated by the entry found at the index (x + maxx.y) of the LUT table

6.2.2.7 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, corresponding to all available changes of orthonormal basis in the TILER container bi-dimensional space.

Figure 6-27 shows isometric transforms in the TILER container.

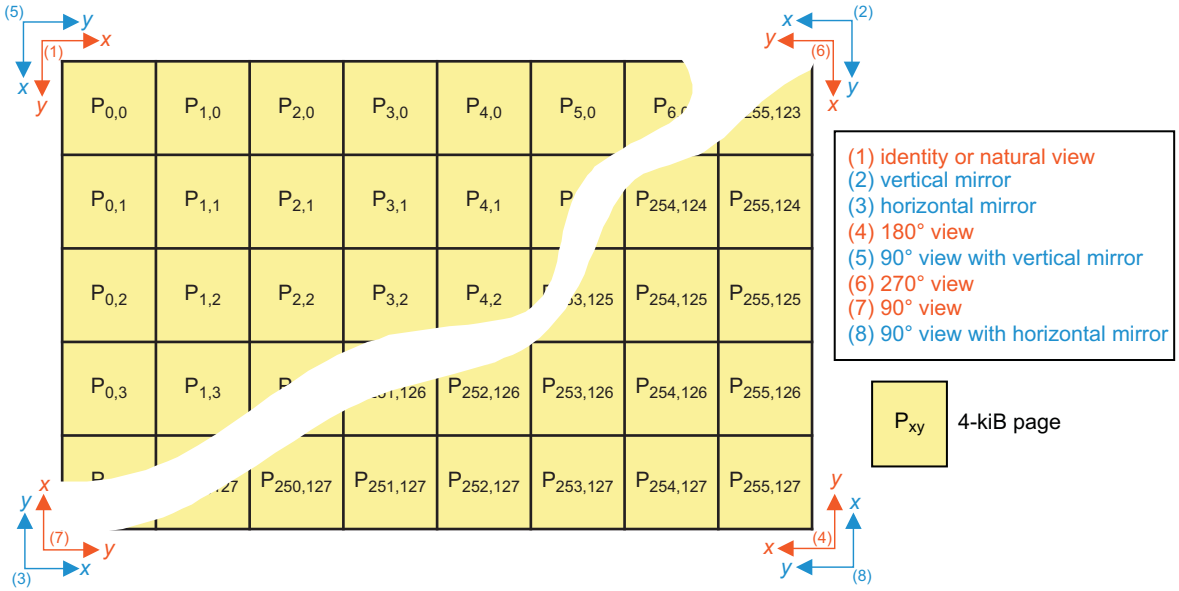
Mathematically speaking, all these transforms correspond to the composition of a 0º, 90º, 180º, or 270º rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- X to change the direction of the x axis of the TILER container
- Y to change the direction of the y axis of the TILER container
- S to swap the modified x and y axis

From now on, and in the rest of this document, the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal - flip-flop - or vertical mirroring.

Copyright © 2011–2013, Texas Instruments Incorporated

Figure 6-27. Isometric Transforms in the TILER Container



Selection of orientation:

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of the 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh). These eight 512MB spaces correspond to the 8 availables views. With multiple display, capture and transcode path, using the unique 512 MB address space, these ports of HD_VPSS can simultaneously generate access in any of the 8 views.

6.2.2.8 Tile Definition

A tile is a subdivision of a page, aimed at:

- Representing a 2D block to better balance the accesses in both directions
- Ensuring that any "tiled" access that fits within a tile is made atomic in the SDRAM controller, and fits in a single SDRAM memory page
- Minimising the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1KB 2D block, and a 4KB page as an array of 2 lines of 2 tiles each, as described in section detailing a 4KB page.

When the considered page is in an interleaved DMM section, it is necessary that:

- the DMM memory interleaving size of tiled accesses is set to 1 KB - a tile size - so that any tiled request that fits within a tile, fits in a single SDRAM memory page
- any request that spans over 2 or 4 tiles, is distributed on a maximum number of SDRAM memory controllers

6.2.2.8.1 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes, namely 8-bit, 16-bit, 32-bit and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 6-2.

Copyright © 2011–2013, Texas Instruments Incorporated

Table 6-2. TILER Modes

Mode	Name	Granularity (element size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirroring of a 16-byte horizontal line containing the word 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh, leads to:

- 0F0E 0D0C 0B0A 0908 0706 0504 0302 0100h in 8-bit tiled mode
- 0E0F 0C0D 0A0B 0809 0607 0405 0203 0001h in 16-bit tiled mode
- 0C0D 0E0F 0809 0A0B 0405 0607 0001 0203h in 32-bit tiled mode
- 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh in page mode - unchanged as the element granularity is 4KB

Besides, as each of the eight orientations is available for any of the four modes, this gives 32 TILER addressing possibilities.

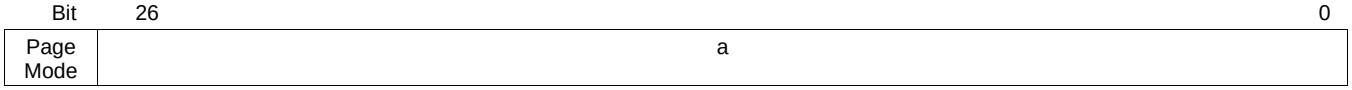
NOTE: The format that the TILER manages the tiled data is dictated by which 4 modes (8-,16-, 32-bit or paged) and which orientation (8 views) is used while accessing (read and write) the data.

As long as the data accessed is written and read in the same mode, it is assured that the response to the access will be correct. While accessing in the same mode, if written in one view and read back in the other view, then the read back data will be rotated and/or mirrored as per the view used.

6.2.2.8.2 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32768 pages of 4 kiB each. The access sequence inside a page is left unchanged. Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

Figure 6-28. Paged Mode Addressing



6.2.2.8.3 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer - the container. The addressing and characteristics of this giant frame-buffer depends on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis - and hence the container geometry

Table 6-3 summarizes tiled mode container characteristics.

Table 6-3. Tiled Mode Container Characteristics

Orientation			Element Size (bits)	Width (elements)	Height (elements)	Stride (bytes)	
S	Y	X				Progressive	Interlaced
			8	16384	8192	16384	32768

Copyright © 2011–2013, Texas Instruments Incorporated

Table 6-3. Tiled Mode Container Characteristics (continued)

Orientation			Element Size (bits)	Width (elements)	Height (elements)	Stride (bytes)	
S	Y	X				Progressive	Interlaced
0	x	x	16	16384	4096	32768	65536
			32	8192	4096	32768	65536
1	x	x	8	8192	16384	8192	16384
			16	4096	16384	8192	16384
			32	4096	8192	16384	32768

As a result, the coordinate (x0, y0) of a pixel in an oriented view is translated in a virtual address as shown in Figure 6-29 and Figure 6-30, for all the four orientations.

Figure 6-29. Tiled Mode Addressing in 0° or 180° Orientations, (S = 0)

Bit	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit tiled mode	y_0													x_0													
16-bit tiled mode	y_0													x_0													
32-bit tiled mode	y_0													x_0													

Figure 6-30. Tiled Mode Addressing in 90° or 270° Orientations, (S = 1)

Bit	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit tiled mode	y_0														x_0												
16-bit tiled mode	y_0 x_0														x_0												
32-bit tiled mode	y_0													x_0													

Having understood the characteristic of the tiled container and the how the data is stored in bi-dimensional manner, it is easy to understand how stride is calculated. Stride is calculated as the number bytes between pixel (m,n) and pixel (m,(n+1)), where m = x co-ordinate of the image buffer, n = y co-ordinate of the image buffer.

For S = 0, that is, all views with 0º and 180º:

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 1 × 8 × 2 × 256 = 16KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB

For S = 1, that is, all views with 90º and 270º:

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 8KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 16KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 2 × 8 × 2 × 128 = 16KB

Copyright © 2011–2013, Texas Instruments Incorporated

6.2.2.8.4 Element Ordering in the TILER Container

This section highlights how elements - 8-bit data, 16-bit data, 32-bit data or 4-kiB page - are ordered in the container. In other words, this section highlights how the path of incrementing virtual addresses is mapped in the container.

It is interesting to note that whatever the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and only depends on the related orientation. In other words:

- Mode is about element granularity
- Orientation is about change of orthornormal basis for ordering the elements in the mode-specific container

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged whatever the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the next sections, the natural container orthonormal basis is referenced as: (Xn , Yn) and the oriented orthonormal basis as: (Xo , Yo).

6.2.2.8.4.1 Natural View or 0º View (Orientation 0)

This orientation defined by S = 0, Y = 0, and X = 0 and means that the operated change of basis is:

X0 = Xn

Y0 = Yn

In any TILER mode, the elements are then ordered from left-to-right and then from top-to-bottom in their container, as shown in Figure 6-31 and Figure 6-32.

6.2.2.8.5 Tiled and Rotational Efficiency

Because of the distribution of the image data in both direction and co-locating them, using sub-tiling, the Image processing algorithms running on the HDVICPs are more efficient by making fewer accesses to the SDRAM, to fetch Macro-blocks of data.

In the Device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its clients. For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or 2^{2n} number of lines.

6.3 Use Case

6.3.1 DMM Basic Register Setup

This section describes basic steps to initialize the DMM, in the device.

1. Set base address, DMM_PAT_VIEW_MAP_BASE to value 8000 0000h, which corresponds to base SDRAM address in the device memory map.
2. Program the four PAT views, by writing DMM_PAT_VIEW_MAP__0..3 registers. By default, all the four PAT views are having value of 0, which implies Direct access translation for all the four tiled modes of (8,16,32-bit and paged mode) and all the four containers will overlap with their base address mapped to 8000 0000h.
3. Program PAT views for all initiators, indexed by ConnID, by programming the DMM_PAT_VIEW__0..1 registers. There are 4 possible views available in device. Default is for all initiators to use PAT view 0.
4. Program PEG priority for all the initiators. By default - all are having priority = 0.
5. Program the TILER orientation for all the initiators, by writing to DMM_TILER_OR__0..1 registers. By default - all will access tiled data in Orientation = 0, which is the normal view.
6. Program Section mapping, based on the SDRAM configuration of the system, which depends on the size of the SDRAM on one or both the banks.
   - Example 1: Symmetrical DDRs on both EMIF banks. Each size = 512MB to add up to 1GB of total SDRAM memory. In all DMM_LISA_MAP__0..3 registers, program value 8064 0300h, which implies 1GB section starting from System address : 8000 0000h, mapped to 0000 0000h of both EMIF0 and EMIF1, with interleaving of 128 bytes enabled. Note that the above example uses only one DMM section and the three other are identical. There are other ways to define up-to 4 sections and configure each differently

6.3.1.1 PAT Direct Access Translation with Distinct 128 MB Containers for Each of the 4 Modes

Following is a simplistic use case, bypassing the LUTs for address translation and setting aside a chunk of 128MB contiguous memory, with base address 128MB aligned, for each of the 4 modes (8, 16,32-bit and paged mode). The same addresses will be used by all initiators in the system.

Configure PAT view 0:

Program DMM_PAT_VIEW_MAP__0 to a value of 0302 0100h. Here : 8-bit mode container will be mapped to 8000 0000h. 16-bit mode container will be mapped to 8800 0000h. 32-bit mode container will be mapped to 9000 0000h. Paged mode container will be mapped to 9800 0000h.

Configure all initiators to use PAT view 0:

Program DMM_PAT_VIEW__0..1 to a value of 0.

Copyright © 2011–2013, Texas Instruments Incorporated

6.3.2 Simple LUT Bypass Use Case: Arrangement of Video Buffers

This section describes one possible arrangement of H.264 video buffers which are in YUV 420 format. Setup is as follows:

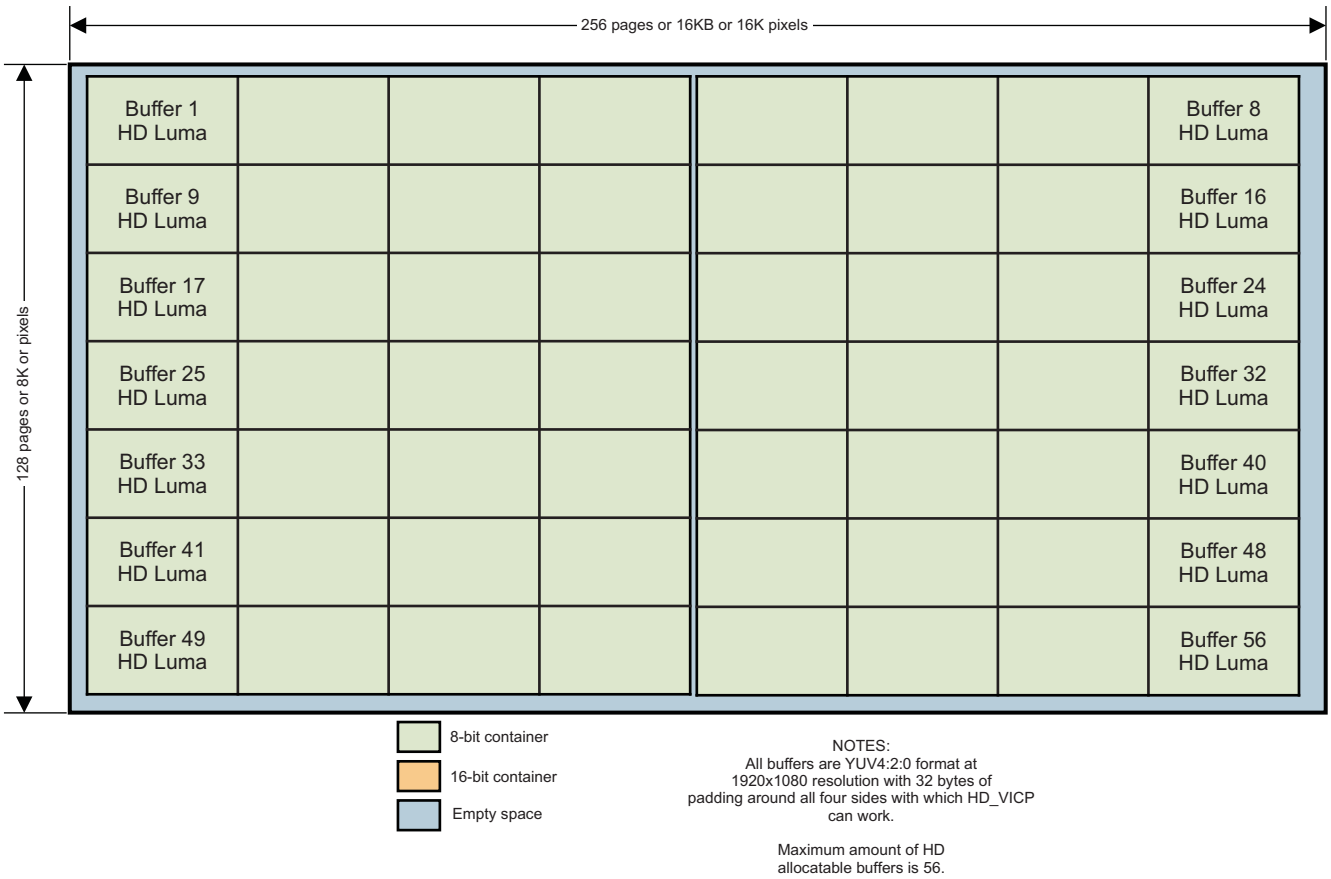
1. The buffers size if 1920 × 1080
2. The Luma buffers are allocated in the 8-bit mode container
3. The Chroma buffers are allocated in the 16-bit mode container
4. The H.264 algorithm needs 32 bytes of padding on each side for Luma buffer and 16 bytes padding in each side for a chroma buffer
5. All buffers are allocated on a 4K aligned address

6.3.2.1 Luma Buffers

In 8-bit tiled mode (Figure 6-47), each 4K page is arranged as 64-pixels wide and 64-pixels high, where each pixel is of size 8-bits. In YUV 420 format, the Luma buffer of the image is 1920 × 1080 and each pixel is 8-bits. Thus, each buffer is 1920 bytes wide. With a pad of 32 bytes on each side, the buffer is (1920 + 64 =) 1984-bytes wide. So one video buffer needs (1984/64 =) 31 pages, along the width of the tiler container. So the tiler container can fit (256/31 ~) 8 buffers, along its width.

Similarly, with a pad of 32 bytes on top and bottom, the buffer is (1080 + 64 =) 1144. Rounding it to (1144 + 8 =) 1152, so that buffer is allocated on page boundary. So one video buffer needs (1152/64 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

Figure 6-47. Buffer Arrangement for HD Luma Buffers in 128MB 8-bit Mode Container



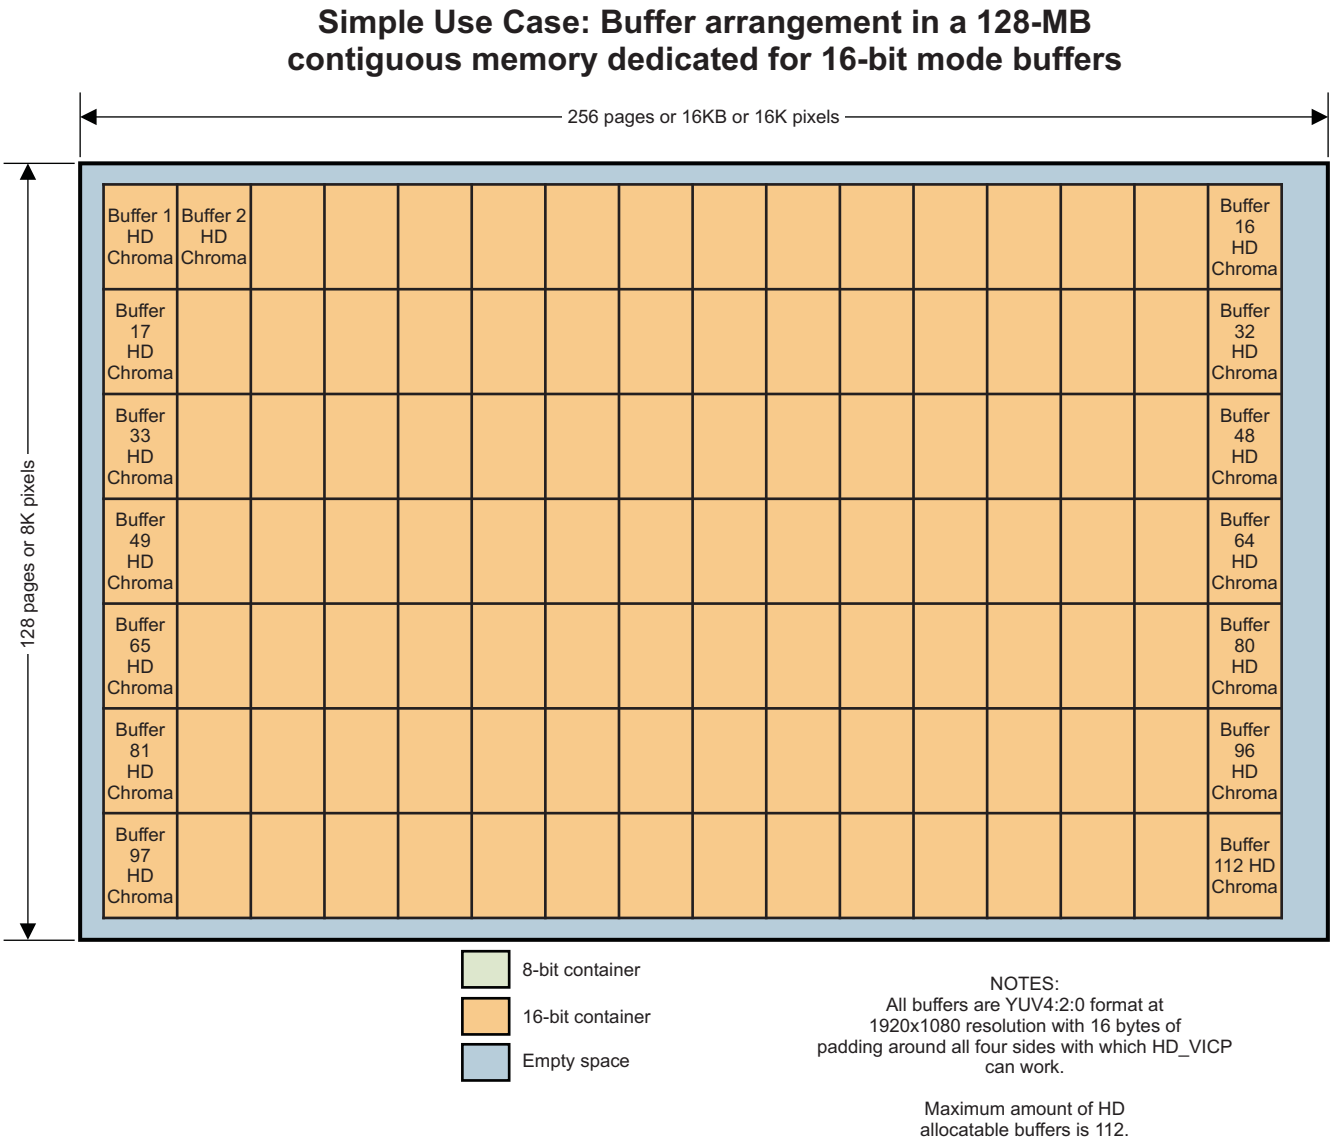
Copyright © 2011–2013, Texas Instruments Incorporated

6.3.2.2 Chroma Buffers

In 16-bit tiled mode (Figure 6-48), each 4K page is arranged as 64-pixels wide and only 32-pixels high, where each pixel is of size 16-bits. In YUV 420 format, the Chroma buffer of the image is 960 × 540 and each pixel is 16-bits. Thus, each buffer is 960-bytes wide. With a pad of 16 bytes on each side, the buffer is (960 + 32 =) 992-bytes wide. Rounding it to (992 + 32 =) 1024, so that buffer is allocated on page boundary. So one video buffer needs (1024/64 =) 16 pages, along the width of the tiler container. So the tiler container can fit (256/16 =) 16 buffers, along its width.

Similarly, with a pad of 16 bytes on top and bottom, the buffer is (540 + 32 =) 572. Rounding it to (572 + 4 =) 576, so that buffer is allocated on page boundary. So one video buffer needs (576/32 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

Figure 6-48. Buffer Arrangement for HD Chroma Buffers in 128MB 16-bit Mode Container



NOTE: The above scheme of Luma and Chroma buffer arrangement can be optimized further, by allocating buffers on sub-tile boundary, instead of page boundary (which is required when using LUT for address translation).

6.3.3 LUT Refill Using the PAT Refill Engines

There is a single LUT of size 256 × 128 elements, in the device.

There four refill engines, along with their own set of registers, to program the LUTs.

Also in this section are described in five different ways to program the LUT.

1. Simple manual area refill
2. Single auto-configured area refill
3. Chained auto-configured area refill
4. Synchronised auto-configured area refill
5. Cyclic synchronised auto-configured area refill

Some of the guidelines, in programming the LUTs are mentioned below:

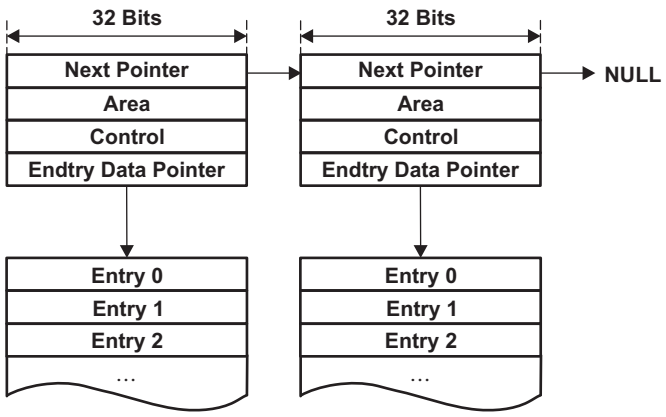
1. Entry table must be in DDR and cannot be split between 2 EMIF banks, when data interleaving enabled.
2. The data table should start from address 16-byte aligned.
3. With one set of descriptor, up to 64 LUT entries can be programmed, in any 2D area dimension.

6.3.3.1 PAT Memory Mapped Refill Descriptors

A PAT descriptor is a singly-linked list node as shown in Figure 6-49, containing:

- a description of the LUT area to reload
- a description of how to reload the defined LUT area
- a pointer to the location where the corresponding LUT entries are stored

Figure 6-49. PAT Descriptor Node



The PAT descriptor node and the entry data pointer must both be 16-byte aligned. A typical 'C' language description of this node is as follows:

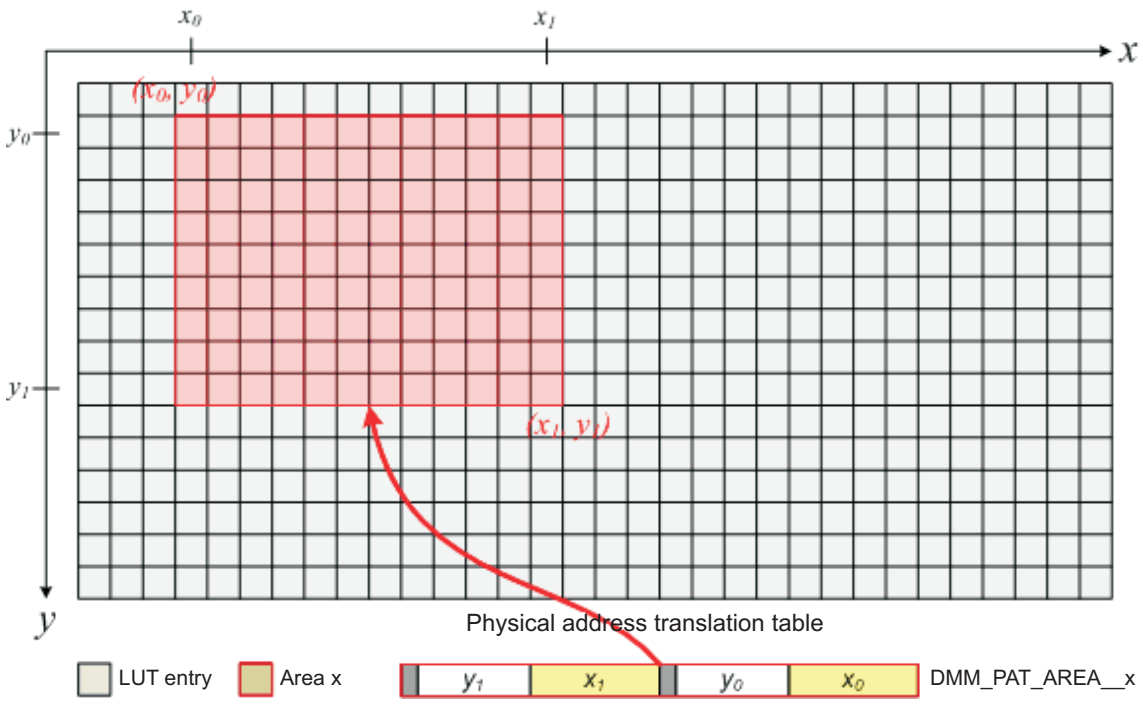
```
struct PAT_desc {
         struct PAT_desc *next;
   u32_t            area;
   u32_t            ctrl;
   PAT_data        *data;
} __attribute__ ((aligned(16)));
```

Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.1.1 PAT Area Refill Description

The area refill description is actually describing the top-left and bottom right corner of the PAT vector table as shown in Figure 6-50.

Figure 6-50. PAT Area Description



6.3.3.1.2 PAT Data Description

The pointer to the address in SDRAM, containing the memory based Data table, should be 16 byte aligned. Each field in this table is a 32 bit value, corresponding to the value to be programmed in one LUT entry. Though it is a 32 bit value, only 19 bits [30:12] are relevant. Bit 31 and bits [0:11] are ignored by the PAT refill engine.

6.3.3.1.3 PAT Memory Dump

This section presents how to dump the PAT LUT. This has to be done using the direct access mode of PAT, following the below steps:

1. Set at least one of the refill engine to direct LUT access mode. This has to be done using DMM_PAT_CONFIG register. Only bit 0 to 3 are used for mode of refill engine 0 to 3. (Value 0 is normal mode, value 1 is direct LUT access mode).
2. Set system coordinates we would like to read/write in the LUT. This has to be done using DMM_PAT_AREA__x. x is the refill engine index that has to be coherent with the refill engine used in direct mode (DMM_PAT_CONFIG). Only (x0,y0) is used in direct mode.
3. Select the LUT_ID = 0 using DMM_PAT_CTRL__x register.
4. Read (or write) the data in DMM_PAT_DATA__x register. x is the refill engine index.

Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.1.4 PAT Refill Direction

The DMM_PAT_CTRL__x.DIRECTION field gives the “order” of the area refill with the same “SYX” encoding as in the TILER orientations:

- 0: from left to right then from top to bottom
- 1: from right to left then from top to bottom
- 2: from left to right then from bottom to top
- 3: from right to left then from bottom to top
- 4: from top to bottom then from left to right
- 5: from top to bottom then from right to left
- 6: from bottom to top then from left to right
- 7: from bottom to top then from right to left

This feature allows the initiators HD_VPSS and HDVICPs to start an access to an on going refill area. In this case, the direction field is set in accordance with the orientation accesses made by the initiators. The DMM_PAT_STATUS__x.ERROR is asserted to 1 if an access is done to a not yet refilled page.

6.3.3.2 Simple Manual Area Refill

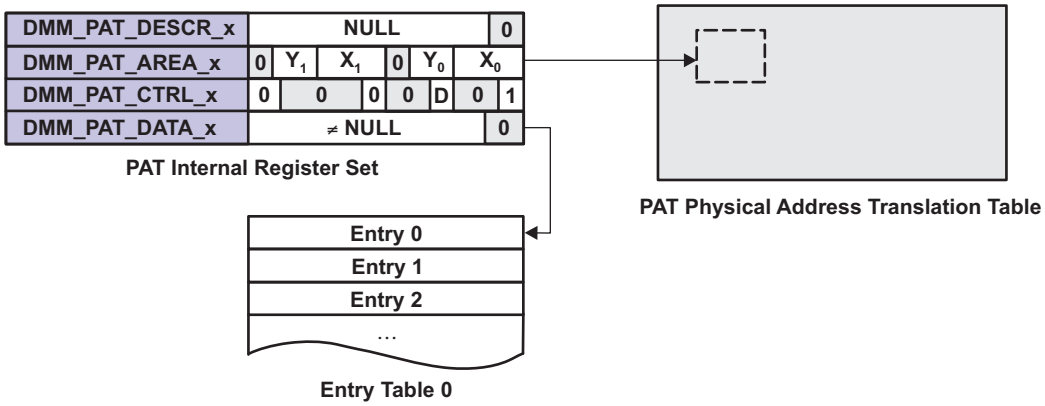
These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 6-51.

- Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition
- Write the DMM_PAT_DATA_i register with the physical address of the created entry table
- Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the

DMM_PAT_CTRL_i[0] START bit:

- The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
- A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 6-51. DMM Simple Manual Area Refill



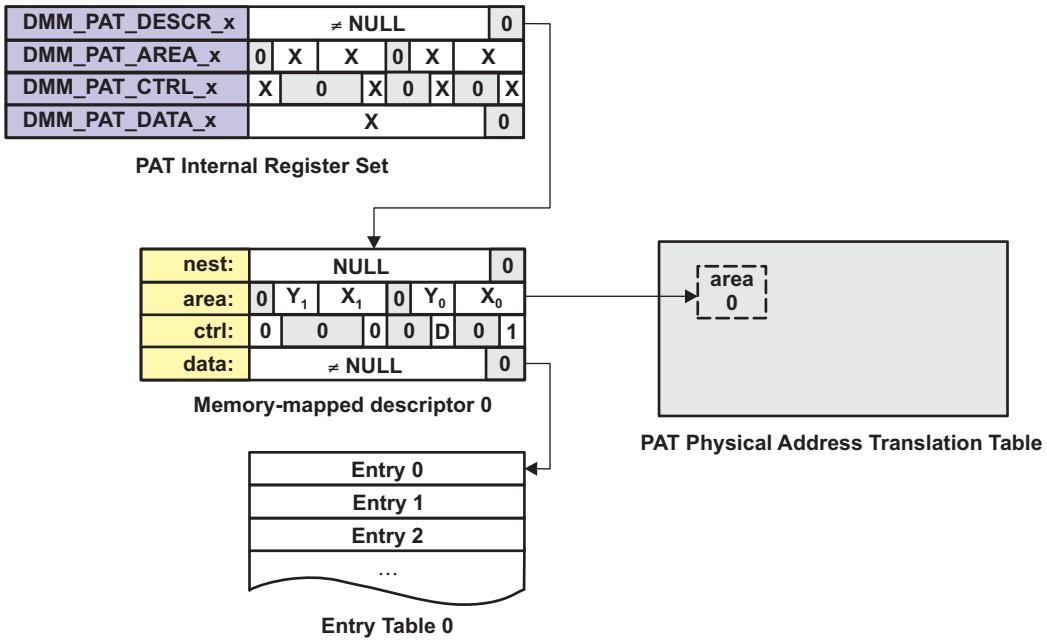
Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.3 Single Auto-Configured Area Refill

These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 6-52.

1. Create a 16-byte aligned memory-mapped descriptor structure where:
   (a) the next field is set to NULL
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the start bit asserted to start refilling as soon as this descriptor enters the PAT refill engine
   (d) the data field is set to the physical address of the created entry table
2. The DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 6-52. DMM Single Auto-configured Area Refill



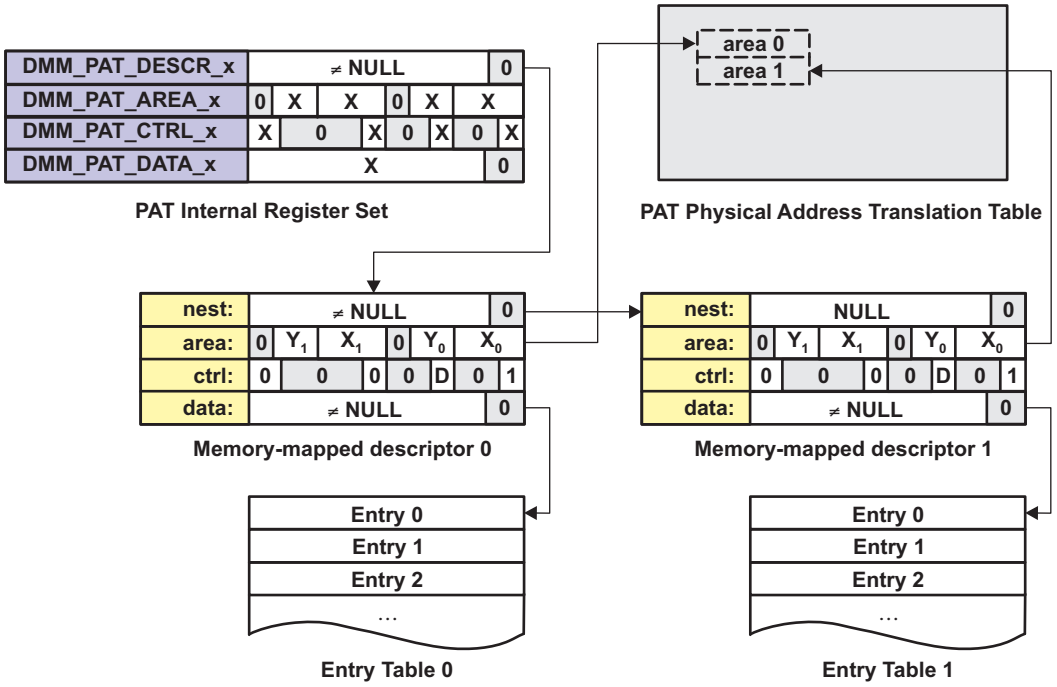
Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.4 Chained Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-53.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the START bit asserted to start refilling as soon as the previous area refill is done
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 6-53. DMM Chained Auto-configured Area Refill



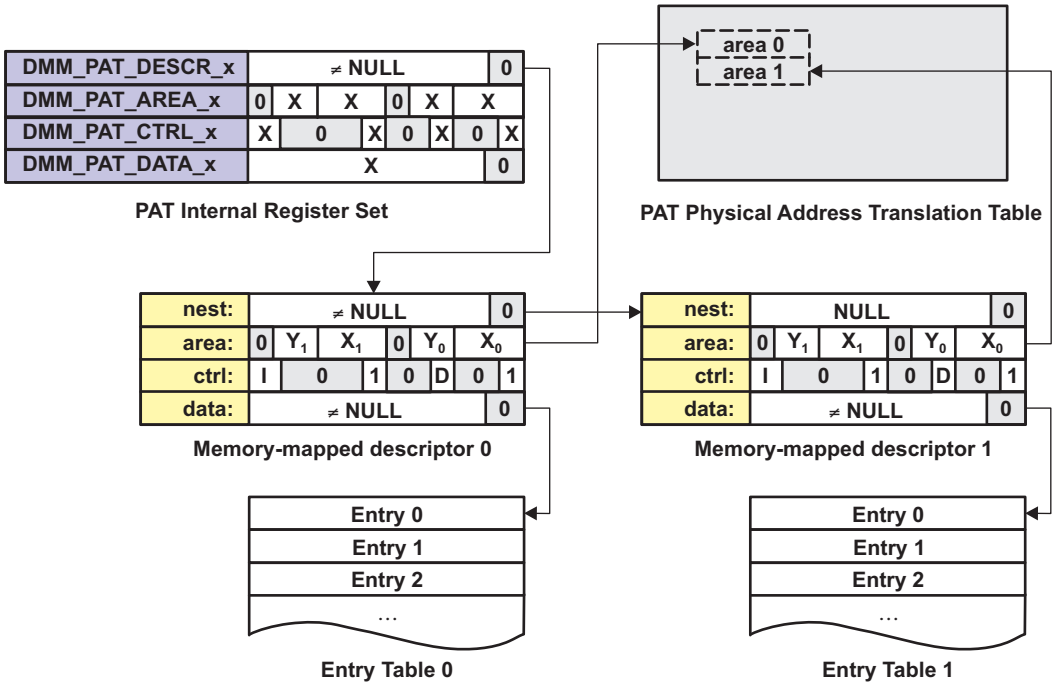
Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.5 Synchronised Auto-configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-54.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 6-54. DMM Synchronised Auto-configured Area Refill



Copyright © 2011–2013, Texas Instruments Incorporated

6.3.3.6 Cyclic Snchronised Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-55.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor in the circular list
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i to abort the current one.

Figure 6-55. DMM Cyclic Synchronised Auto-configured Area Refill

6.3.4 Address Management Using LISA Sections

In the device, there are either one ot two memory controllers (EMIFs).

6.3.4.1 DMM Sections

The DMM section definition is certainly the very first step in the DMM software configuration, as it is about defining the system address map to be used when accessing the SDRAM controllers.

A DMM section description fits in a single 32-bit register (DMM_LISA_MAP_x), where:

- SYS_ADDR defines the base address of the decoding range for the section
- SYS_SIZE defines the size of the section. Note that the encoding of this parameter is the number of bits actually used in the upper 8-bits of the incoming system address.
- SDRC_ADDR defines the physical base address of the section in the external memory controller
- SDRC_ADDRSPC defines the address space used on the SDRAM controller when hitting this section. The address space feature is not supported.
- SDRC_MAP defines the target memory controllers for this section. A section may hit a one or two controllers. The section is not used if this parameter is set to zero.
- SDRC_INTL defines the granularity of the interleaving if the section is mapped on more than one memory controllers

A couple of examples are given in the next subsections.

Copyright © 2011–2013, Texas Instruments Incorporated

6.3.4.1.1 Case 1: Two Memory Controllers, 2GB DDR Symmetrical Distribution

Use Case: In this example we assume 2GB of external memory, spread evenly between 2 SDRAM controllers.

Table 6-4. Case 1 Memory Controllers

System Address Range	Memory Controller	EMIF Address Range
8000 0000-FFFF FFFFh	1 and 2, interleaved at 256 Bytes	0000 0000h-7FFF FFFFh

Configuration:

Table 6-5. Controller Configuration

Bit	Field	Section 0
31-24	SYS_ADDR	80h (incoming System Address MSB)
22-20	SYS_SIZE	7h (2 GB)
19-18	SDRC_INTL	2h (256 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1
7-0	SDRC_ADDR	0 (SDRC address MSB)

NOTE: Section 1, Section 2 and Section 3 - identical to Section 0.

How DMM decodes and translates:

1. To check if an address hits a section, use the eight upper address bits of the address and mask them with the hit mask (2 8 - 2SYS_SIZE). If the result is equal to SYS_ADDR, the section is hit.
2. To define the physical address to be issued to the memory controller, use the eight upper address of the system address, mask them with the address mask ($2^{SYS_SIZE} – 1$), and then OR them with SDRC_ADDR. This will give the resulting eight upper physical address bits. All lower address bits are forwarded unchanged.
3. If interleaving enabled, the physical address generation is modified. In case of a 256 bytes interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the SDRAM controller ID, 0 for the first controller and 1 for the second one (system address bit 7 would be used for interleaving at 128 bytes boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits 9 to 31 are shifted to bits 8 to 30 when generating the physical address.

Example with above configuration:

1. Incoming access's System address 99AE 37F0h:
2. Hit mask: $2^8 - 2^7 = 80h$
3. Masked upper address bits: 80h AND 80h = 80h (the SYS_ADDR) , thus hits section 0
4. Address mask: $2^7 - 1 = 7Fh$
5. Masked upper address bits: 99h AND 7Fh = 19h
6. Full masked address: 19AE 37F0h
7. Bit 8 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 8): 0CD7 1BF0h
9. OR upper physical address bits with SDRC_ADDR: 0CD7 1BF0h
10. Physical address: 0CD7 1BF0h

Copyright © 2011–2013, Texas Instruments Incorporated

This request will be forwarded to address 0CD7 1BF0h, of the second memory controller, that is, EMIF1.

6.3.4.1.2 Case 2: Two Memory Controllers, 1152 MB (1 GB + 128 MB) DDR Symmetrical Distribution

In this example we assume 2GB of external memory, spread evenly between two EMIF controllers.

Table 6-6. Case 2 Memory Controllers

System Address Range	SDRAM Controller	EMIF Address Range
8000 0000h-C7FF FFFFh	1 and 2, interleaved at 256 Bytes	0000 0000h-47FF FFFFh

Configuration:

Table 6-7. Controller Configuration

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	C0h (incoming System Address MSB)
22-20	SYS_SIZE	6h (1 GB)	3h (128 MB)
19-18	SDRC_INTL	2h (256 bytes interleaving)	1 (128 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1)	3h (Map to both EMIF0 and EMIF1)
7-0	SDRC_ADDR	0 (SDRC address MSB)	20h (SDRC address MSB)

NOTE: Section 2 and Section 3 are identical to Section 1.

How DMM decodes and translates:

Identical to Section 6.3.4.1.1.

See Figure 6-56 for System Address Memory Range and its mapping to EMIFs.

Example with above configuration:

Incoming accesses System address C022 34C0h:

1. Upper address bits: C0h
2. Hit mask: $2^8 - 2^3$ = F8h
3. Masked upper address bits: C0h AND F8h = C0h (the SYS_ADDR) , thus hits section 1
4. Address mask: $2^3 - 1$ = 7h
5. Masked upper address bits: C0h AND 7h = 0
6. Full masked address: 0022 34C0h
7. Bit 7 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 7): 0011 1A60h
9. OR upper physical address bits with SDRC_ADDR: 0011 1A60h
10. Physical address: 0011 1A60h

This request will be forwarded to address 0011 1A60h, of the second memory controller; that is, EMIF1.

6.3.4.1.3 Case 3: Two SDRAM Controllers, 1152 MB (1 GB + 128 MB) DDR Asymmetrical Distribution

NOTE: For optimal system performance, symmetric configuration is HIGHLY recommended. Unless dictated by system cost and other constraints, Asymmetrical distribution of memory should not be considered.

There are many ways to configure the section mapping in this use case.

Option 1: Asymmetrical section of EMIF0 is mapped to system address C000 0000h-C7FF FFFFh, higher portion of the SDRAM in system memory map.

Table 6-8. Section Mapping Option 1

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	88h (incoming System Address MSB)
22-20	SYS_SIZE	3h (128 MB)	6h (1 GB)
19-18	SDRC_INTL	0 (No interleaving)	2h (256 bytes interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	1 (Map to EMIF0)	3h (Map to both EMIF0 and EMIF1)
7-0	SDRC_ADDR	20h (SDRC address MSB)	0 (SDRC address MSB)

Option 2: Asymmetrical section of EMIF0 is mapped to system address 8000 0000h-87FF FFFFh, Lower portion of the SDRAM in system memory map.

Table 6-9. Section Mapping Option 2

Bit	Field	Section 0	Section 1
31-24	SYS_ADDR	80h (incoming System Address MSB)	C0h (incoming System Address MSB)
22-20	SYS_SIZE	6h (1 GB)	3h (128 MB)
19-18	SDRC_INTL	2h (256 bytes interleaving)	0 (No interleaving)
17-16	SDRC_ADDRSPC	0 (Unused Reserved field)	0 (Unused Reserved field)
8	SDRC_MAP	3h (Map to both EMIF0 and EMIF1)	1 (Map to EMIF0)
7-0	SDRC_ADDR	0 (SDRC address MSB)	20h (SDRC address MSB)

6.4.9 DMM PAT View Mapping Base Address Register: DMM_PAT_VIEW_MAP_BASE

The DMM PAT View Mapping Base Address register is shown in Figure 6-65 and described in Table 6-19.

Figure 6-65. DMM_PAT_VIEW_MAP_BASE Register

31	30	0
BASEADDR	Reserved	
R/W-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 6-19. DMM_PAT_VIEW_MAP_BASE Register Field Descriptions

Bit	Field	Value	Description	Type
31	BASEADDR	0	MSB of the PAT view mapping base address	R/W
30-0	Reserved	0	Reserved	R

6.4.10 DMM PAT End of Interrupt Register: DMM_PAT_IRQ_EOI

The DMM PAT End of Interrupt register is shown in Figure 6-66 and described in Table 6-20. This register is per-event raw interrupt status vector. The purpose is mostly for debug. Raw status is set even if the related event is not enabled. Write 1 to set the (raw) status.

6.4.11 DMM PAT Raw Interrupt Status Register: DMM_PAT_IRQSTATUS_RAW

The DMM PAT Raw Interrupt Status Register is shown in Figure 6-67 and described in Table 6-21. Per-event raw interrupt status vector. Raw status is set even if the related event is not enabled. Write 1 to set the (raw) status, mostly for debug.
