Logic Block Diagram

Functional Description

The CY7C199D is a high performance CMOS static RAM organized as 32,768 words by 8-bits. Easy memory expansion is provided by an active LOW chip enable ($\overline{\text{CE}}$), an active LOW output enable ($\overline{\text{OE}}$) and tri-state drivers. This device has an automatic power-down feature, reducing the power consumption when deselected. The input and output pins (I/O_0 through I/O_7) are placed in a high impedance state when the device is deselected ($\overline{\text{CE}}$ HIGH), the outputs are disabled ($\overline{\text{OE}}$ HIGH), or during a write operation ($\overline{\text{CE}}$ LOW and $\overline{\text{WE}}$ LOW).

Write to the device by taking chip enable ($\overline{\text{CE}}$) and write enable ($\overline{\text{WE}}$) inputs LOW. Data on the eight I/O pins (I/O_0 through I/O_7) is then written into the location specified on the address pins (A_0 through A_{14}).

Read from the device by taking chip enable ($\overline{\text{CE}}$) and output enable ($\overline{\text{OE}}$) LOW while forcing write enable ($\overline{\text{WE}}$) HIGH. Under these conditions, the contents of the memory location specified by the address pins appears on the I/O pins.

Notes

- Test conditions assume signal transition time of 3 ns or less for all speeds, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V, and output loading of the specified $I_{\text{OL}}/I_{\text{OH}}$ and 30-pF load capacitance.
- t_{POWER} gives the minimum amount of time that the power supply should be at typical V_{CC} values until the first memory access can be performed.
- At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any given device.
- t_{HZOE} , t_{HZCE} , and t_{HZWE} are specified with $C_L = 5$ pF as in part (b) of [Figure 3 on page 5](#). Transition is measured ± 200 mV from steady-state voltage.
- This parameter is guaranteed by design and is not tested.
- The internal write time of the memory is defined by the overlap of $\overline{\text{CE}}$ LOW and $\overline{\text{WE}}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing should be referenced to the rising edge of the signal that terminates the write.
- The minimum write cycle time for Write Cycle No. 3 ($\overline{\text{WE}}$ controlled, $\overline{\text{OE}}$ LOW) is the sum of t_{HZWE} and t_{SD} .

Data Retention Characteristics

Switching Waveforms

Figure 5. Read Cycle No. 2 $\overline{OE}$ Controlled [14, 15]

Notes

11. Tested initially and after any design or process changes that may affect these parameters.
12. Full device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)} \geq 50\text{ }\mu\text{s}$ or stable at $V_{CC(min)} \geq 50\text{ }\mu\text{s}$.
13. Device is continuously selected. $\overline{OE}$, $\overline{CE} = V_{IL}$.
14. $\overline{WE}$ is HIGH for read cycle.
15. Address valid prior to or coincident with $\overline{CE}$ transition LOW.

Figure 7. Write Cycle No. 3 $\overline{\text{WE}}$ Controlled, $\overline{\text{OE}}$ LOW [18, 19]

Notes

16. The internal write time of the memory is defined by the overlap of $\overline{\text{CE}}$ LOW and $\overline{\text{WE}}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing should be referenced to the rising edge of the signal that terminates the write.
17. Data I/O is high impedance if $\overline{\text{OE}} = V_{IH}$.
18. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ HIGH, the output remains in a high-impedance state.
19. The minimum write cycle time for Write Cycle No. 3 ($\overline{\text{WE}}$ controlled, $\overline{\text{OE}}$ LOW) is the sum of t_{HZWE} and t_{SD} .
20. During this period the I/Os are in the output state and input signals should not be applied.
