

# EFM32PG1 Reference Manual

The EFM32 Gecko MCUs are the world's most energy-friendly microcontrollers.

EFM32PG1 features a powerful 32-bit ARM® Cortex-M4 and a wide selection of peripherals, including a unique cryptographic hardware engine supporting AES, ECC, and SHA. These features, combined with ultra-low current active mode and short wake-up time from energy-saving modes, make EFM32PG1 microcontrollers well suited for any battery-powered application, as well as other systems requiring high performance and low-energy consumption.

Example applications:

- IoT devices and sensors
- Health and fitness
- Smart accessories
- Home automation and security
- Industrial and factory automation

## ENERGY FRIENDLY FEATURES

- ARM Cortex-M4 at 40 MHz
- Ultra low energy operation:
  - 2.1  $\mu$ A EM3 Stop current (CRYOTIMER running with state/RAM retention)
  - 2.5  $\mu$ A EM2 DeepSleep current (RTCC running with state and RAM retention)
  - 63  $\mu$ A/MHz in Energy Mode 0 (EM0)
- Hardware cryptographic engine supports AES, ECC, and SHA
- Integrated dc-dc converter
- CRYOTIMER operates down to EM4
- 5 V tolerant I/O

Lowest power mode with peripheral operational:

# 1. About This Document

## 1.1 Introduction

This document contains reference material for the EFM32 Gecko devices. All modules and peripherals in the EFM32 Gecko devices are described in general terms. Not all modules are present in all devices and the feature set for each device might vary. Such differences, including pinout, are covered in the device data sheets and applicable errata documents.

## 1.2 Conventions

### Register Names

Register names are given with a module name prefix followed by the short register name:

TIMERn\_CTRL - Control Register

The "n" denotes the module number for modules which can exist in more than one instance.

Some registers are grouped which leads to a group name following the module prefix:

GPIO\_Px\_DOUT - Port Data Out Register

The "x" denotes the different ports.

### Bit Fields

Registers contain one or more bit fields which can be 1 to 32 bits wide. Bit fields wider than 1 bit are given with start (x) and stop (y) bit [y:x].

Bit fields containing more than one bit are unsigned integers unless otherwise is specified.

Unspecified bit field settings must not be used, as this may lead to unpredictable behaviour.

### Address

The address for each register can be found by adding the base address of the module found in the Memory Map (see [Figure 4.2 System Address Space With Core and Code Space Listing on page 35](#)), and the offset address for the register (found in module Register Map).

### Access Type

The register access types used in the register descriptions are explained in [Table 1.1 Register Access Types on page 22](#).

**Table 1.1. Register Access Types**

| Access Type           | Description                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| R                     | Read only. Writes are ignored                                                                                                                           |
| RW                    | Readable and writable                                                                                                                                   |
| RW1                   | Readable and writable. Only writes to 1 have effect                                                                                                     |
| (R)W1                 | Sometimes readable. Only writes to 1 have effect. Currently only used for IFC registers (see <a href="#">3.3.1.2 IFC Read-clear Operation</a> )         |
| W1                    | Read value undefined. Only writes to 1 have effect                                                                                                      |
| W                     | Write only. Read value undefined.                                                                                                                       |
| RWH                   | Readable, writable, and updated by hardware                                                                                                             |
| RW(nB), RWH(nB), etc. | "(nB)" suffix indicates that register explicitly does not support peripheral bit set or clear (see <a href="#">4.2.3 Peripheral Bit Set and Clear</a> ) |

| Access Type       | Description                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| RW(a), R(a), etc. | "(a)" suffix indicates that register has actionable reads (see <a href="#">5.3.6 Debugger Reads of Actionable Registers</a> ) |

### Number format

**0x** prefix is used for hexadecimal numbers

**0b** prefix is used for binary numbers

Numbers without prefix are in decimal representation.

### Reserved

Registers and bit fields marked with **reserved** are reserved for future use. These should be written to 0 unless otherwise stated in the Register Description. Reserved bits might be read as 1 in future devices.

### Reset Value

The reset value denotes the value after reset.

Registers denoted with X have unknown value out of reset and need to be initialized before use. Note that read-modify-write operations on these registers before they are initialized results in undefined register values.

### Pin Connections

Pin connections are given with a module prefix followed by a short pin name:

CMU\_CLKOUT1 (Clock management unit, clock output pin number 1)

The location for the pin names given in the module documentation can be found in the device-specific data sheet.

## 1.3 Related Documentation

Further documentation on the EFM32 Gecko devices and the ARM Cortex-M4 can be found at the Silicon Labs and ARM web pages:

[www.silabs.com](http://www.silabs.com)

[www.arm.com](http://www.arm.com)

## 2. System Overview

### Quick Facts

#### What?

The EFM32 Gecko is a highly integrated, configurable and low power MCU with a complete set of peripherals.

#### Why?

EFM32 Gecko features an Cortex-M4 core, a unique cryptographic hardware engine supporting AES, ECC, and SHA, ultra-low current active mode, and short wake-up time from energy-saving modes.

#### How?

EFM32 Gecko microcontrollers are well suited for any battery-powered application, as well as other systems requiring high performance and low-energy consumption

### 2.1 Introduction

The EFM32 MCUs are the world's most energy friendly microcontrollers. With a unique combination of the powerful 32-bit ARM Cortex-M4, innovative low energy techniques, short wake-up time from energy saving modes, and a wide selection of peripherals, the EFM32 Gecko microcontroller is well suited for any battery operated application as well as other systems requiring high performance and low-energy consumption.

## 2.2 Block Diagrams

The block diagram for the EFM32 Gecko MCU series is shown in (Figure 2.1 EFM32 Gecko System-On-Chip Block Diagram on page 25).

Figure 2.1. EFM32 Gecko System-On-Chip Block Diagram

## 2.3 MCU Features Overview

- **ARM Cortex-M4 CPU platform**
  - High Performance 32-bit processor @ up to 40 MHz
  - Memory Protection Unit
  - Wake-up Interrupt Controller
- **Flexible Energy Management System**
  - Power routing configurations including DCDC control
  - Voltage Monitoring and Brown Out Detection
  - State Retention
- **256 KB Flash**
- **32 KB RAM**
- **Up to 32 General Purpose I/O pins**
  - Configurable push-pull, open-drain, pull-up/down, input filter, drive strength
  - Configurable peripheral I/O locations
  - 16 asynchronous external interrupts
  - Output state retention and wake-up from Shutoff Mode
- **8 Channel DMA Controller**
  - Alternate/primary descriptors with scatter-gather/ping-pong operation
- **12 Channel Peripheral Reflex System**
  - Autonomous inter-peripheral signaling enables smart operation in low energy modes
- **CRYPTO Advanced Encryption Standard Accelerator**
  - AES encryption / decryption, with 128 or 256 bit keys
  - Multiple AES modes of operation, including Counter (CTR), Galois/Counter Mode (GCM), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB).
  - Accelerated SHA-1 and SHA-2
  - Accelerated Elliptic Curve Cryptography (ECC), with binary or prime fields
  - Flexible 256-bit ALU and sequencer
- **General Purpose Cyclic Redundancy Check**
  - Programmable 16-bit polynomial, fixed 32-bit polynomial
- **Communication interfaces**
  - 2× Universal Synchronous/Asynchronous Receiver/Transmitter
    - UART/SPI/SmartCard (ISO 7816)/IrDA/I2S
    - Triple buffered full/half-duplex operation
    - Hardware flow control
    - 4-16 data bits
  - 1× Low Energy UART
    - Autonomous operation with DMA in Deep Sleep Mode
  - 1× I<sup>2</sup>C Interface with SMBus support
    - Address recognition in Stop Mode
- **Timers/Counters**
  - 2× 16-bit Timer/Counter
    - 3 or 4 Compare/Capture/PWM channels
    - Dead-Time Insertion on TIMER0
  - 16-bit Low Energy Timer
  - 32-bit Ultra Low Energy Timer/Counter (CRYOTIMER) for periodic wake-up from any Energy Mode
  - 32-bit Real-Time Counter and Calendar
  - 16+16+32 bit Protocol Timer
  - 16-bit Pulse Counter
    - Asynchronous pulse counting/quadrature decoding
  - Watchdog Timer with dedicated RC oscillator @ 50 nA

- **Ultra low power precision analog peripherals**
  - 12-bit 1 Msamples/s Analog to Digital Converter
    - 8 input channels and on-chip temperature sensor
    - Single ended or differential operation
    - Conversion tailgating for predictable latency
  - Current Digital to Analog Converter
    - Source or sink a configurable constant current
  - 2× Analog Comparator
    - Programmable speed/current
    - Capacitive sensing with up to 8 inputs
  - Analog Port
- **Ultra efficient Power-on Reset and Brown-Out Detector**
- **Debug Interface**
  - 4-pin Joint Test Action Group (JTAG) interface
  - 2-pin serial-wire debug (SWD) interface

## 2.4 Oscillators and Clocks

EFM32 Gecko has six different oscillators integrated, as shown in [Table 2.1 EFM32 Gecko Oscillators on page 27](#)

**Table 2.1. EFM32 Gecko Oscillators**

| Oscillator | Frequency       | Optional? | External components | Description                                                                                                                              |
|------------|-----------------|-----------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| HFXO       | 38 MHz - 40 MHz | Yes       | Crystal             | High accuracy, low jitter high frequency crystal oscillator. Tunable crystal loading capacitors are fully integrated.                    |
| HFRCO      | 1 MHz - 38 MHz  | No        | -                   | Medium accuracy RC oscillator, typically used for timing during startup of the HFXO or if a precise oscillator is not required.          |
| AUXHFRCO   | 1 MHz - 38 MHz  | No        | -                   | Medium accuracy RC oscillator, typically used as alternative clock source for Analog to Digital Converter or Debug Trace.                |
| LFRCO      | 32768 Hz        | No        | -                   | Medium accuracy frequency reference typically used for medium accuracy RTCC timing.                                                      |
| LFXO       | 32768 Hz        | Yes       | Crystal             | High accuracy frequency reference typically used for high accuracy RTCC timing. Tunable crystal loading capacitors are fully integrated. |
| ULFRCO     | 1000 Hz         | No        | -                   | Ultra low frequency oscillator typically used for the watchdog timer.                                                                    |

The RC oscillators can be calibrated against either of the crystal oscillators in order to compensate for temperature and voltage supply variations. Hardware support is included to measure the frequency of various oscillators against each other.

Oscillator and clock management is available through the Clock Management Unit (CMU), see section [10. CMU - Clock Management Unit](#) for details.

## 2.5 Hardware CRC Support

EFM32 Gecko supports a configurable CRC generation:

- 8, 16, 24 or 32 bit CRC value
- Configurable polynomial and initialization value
- Optional inversion of CRC value over air
- Configurable CRC byte ordering
- Support for multiple CRC values calculated and verified per transmitted or received frame

## 2.6 Data Encryption and Authentication

EFM32 Gecko has hardware support for AES encryption, decryption and authentication modes. These security operations can be performed on data in RAM or any data buffer, without further CPU intervention. The key size is 128 bits.

AES modes of operations directly supported by the EFM32 Gecko hardware are listed in [Table 2.2 AES Modes of Operation With Hardware Support on page 28](#). In addition to these modes, other modes can also be implemented by using combinations of modes. For example, the CCM mode can be implemented using the CTR and CBC-MAC modes in combination.

**Table 2.2. AES Modes of Operation With Hardware Support**

| AES Mode | Encryption / Decryption | Authentication | Comment                                                  |
|----------|-------------------------|----------------|----------------------------------------------------------|
| ECB      | Yes                     | -              | Electronic Code Book                                     |
| CTR      | Yes                     | -              | Counter mode                                             |
| CCM      | Yes                     | Yes            | Counter with CBC-MAC                                     |
| CCM*     | Yes                     | Yes            | CCM with encryption-only and integrity-only capabilities |
| GCM      | Yes                     | Yes            | Galois Counter Mode                                      |
| CBC      | Yes                     | -              | Cipher Block Chaining                                    |
| CBC-MAC  | -                       | Yes            | Cipher Block Chaining, Message Authentication Code       |
| CMAC     | -                       | Yes            | Cipher-basec MAC                                         |
| CFB      | Yes                     | -              | Cipher Feedback                                          |
| OFB      | Yes                     | -              | Output Feedback                                          |

The CRYPTO module can provide data directly from the embedded Cortex-M4 or via DMA.

## 2.7 Timers

EFM32 Gecko includes multiple timers, as can be seen from [Table 2.3 EFM32 Gecko Timers Overview](#) on page 29.

**Table 2.3. EFM32 Gecko Timers Overview**

| Timer         | Number of instances | Typical clock source                  | Overview                                                                                                                                                                   |
|---------------|---------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTCC          | 1                   | Low frequency (LFXO or LFRCO)         | 32 bit Real Time Counter and Calendar, typically used to accurately time inactive periods and enable wakeup on compare match.                                              |
| TIMER         | 2                   | High frequency (HFXO or HFRCO)        | 16 bit general purpose timer.                                                                                                                                              |
| Systick timer | 1                   | High frequency (HFXO or HFRCO)        | 32 bit systick timer integrated in the Cortex-M4. Typically used as an Operating System timer.                                                                             |
| WDOG          | 1                   | Low frequency (LFXO, LFRCO or ULFRCO) | Watch dog timer. Once enabled, this module must be periodically accessed. If not, this is considered an error and the EFM32 Gecko is reset in order to recover the system. |
| LETIMER       | 1                   | Low frequency (LFXO, LFRCO or ULFRCO) | Low energy general purpose timer.                                                                                                                                          |

Advanced interconnect features allows synchronization between timers. This includes:

- Start / stop any high frequency timer synchronized with the RTCC
- Trigger RSM state transitions based on compare timer compare match, for instance to provide clock cycle accuracy on frame transmit timing

### 3. System Processor

#### Quick Facts

##### What?

The industry leading Cortex-M4 processor from ARM is the CPU in the EFM32 Gecko devices.

##### Why?

The ARM Cortex-M4 is designed for exceptionally short response time, high code density, and high 32-bit throughput while maintaining a strict cost and power consumption budget.

##### How?

Combined with the ultra low energy peripherals available in EFM32 Gecko devices, the Cortex-M4 processor's Harvard architecture, 3 stage pipeline, single cycle instructions, Thumb-2 instruction set support, and fast interrupt handling make it perfect for 8-bit, 16-bit, and 32-bit applications.

#### 3.1 Introduction

The ARM Cortex-M4 32-bit RISC processor provides outstanding computational performance and exceptional system response to interrupts while meeting low cost requirements and low power consumption.

The ARM Cortex-M4 implemented is revision r0p1.

### 3.2 Features

- Harvard architecture
  - Separate data and program memory buses (No memory bottleneck as in a single bus system)
- 3-stage pipeline
- Thumb-2 instruction set
  - Enhanced levels of performance, energy efficiency, and code density
- Single cycle multiply and hardware divide instructions
  - 32-bit multiplication in a single cycle
  - Signed and unsigned divide operations between 2 and 12 cycles
- Atomic bit manipulation with bit banding
  - Direct access to single bits of data
  - Two 1MB bit banding regions for memory and peripherals mapping to 32MB alias regions
  - Atomic operation, cannot be interrupted by other bus activities
- 1.25 DMIPS/MHz
- Memory Protection Unit
  - Up to 8 protected memory regions
- 24 bits System Tick Timer for Real Time OS
- Excellent 32-bit migration choice for 8/16 bit architecture based designs
  - Simplified stack-based programmer's model is compatible with traditional ARM architecture and retains the programming simplicity of legacy 8-bit and 16-bit architectures
- Aligned or unaligned data storage and access
  - Contiguous storage of data requiring different byte lengths
  - Data access in a single core access cycle
- Integrated power modes
  - Sleep Now mode for immediate transfer to low power state
  - Sleep on Exit mode for entry into low power state after the servicing of an interrupt
  - Ability to extend power savings to other system components
- Optimized for low latency, nested interrupts

### 3.3 Functional Description

For a full functional description of the ARM Cortex-M4 implementation in the EFM32 Gecko family, the reader is referred to the ARM Cortex-M4 documentation provided by ARM.

### 3.3.1 Interrupt Operation

Figure 3.1. Interrupt Operation

The interrupt request (IRQ) lines are connected to the Cortex-M4. Each of these lines (shown in [Table 3.1 Interrupt Request Lines \(IRQ\) on page 33](#)) is connected to one or more interrupt flags in one or more modules. The interrupt flags are set by hardware on an interrupt condition. It is also possible to set/clear the interrupt flags through the IFS/IFC registers. Each interrupt flag is then qualified with its own interrupt enable bit (IEN register), before being OR'ed with the other interrupt flags to generate the IRQ. A high IRQ line will set the corresponding pending bit (can also be set/cleared with the SETPEND/CLRPEND bits in ISPR0/ICPR0) in the Cortex-M4 NVIC. The pending bit is then qualified with an enable bit (set/cleared with SETENA/CLRENA bits in ISER0/ICER0) before generating an interrupt request to the core. [Figure 3.1 Interrupt Operation on page 32](#) illustrates the interrupt system. For more information on how the interrupts are handled inside the Cortex-M4, the reader is referred to the **ARM Cortex-M4 Technical Reference Manual**.

#### 3.3.1.1 Avoiding Extraneous Interrupts

There can be latencies in the system such that clearing an interrupt flag could take longer than leaving an Interrupt Service Routine (ISR). This can lead to the ISR being re-entered as the interrupt flag has yet to clear immediately after leaving the ISR. To avoid this, when clearing an interrupt flag at the end of an ISR, the user should execute ARM's Data Synchronization Barrier (DSB) instruction. Another approach is to clear the interrupt flag immediately after identifying the interrupt source and then service the interrupt as shown in the pseudo-code below. The ISR typically is sufficiently long to more than cover the few cycles it may take to clear the interrupt status, and also allows the status to be checked for further interrupts before exiting the ISR.

```
irqXServiceRoutine() {
    do {
        clearIrqXStatus();
        serviceIrqX();
    } while(irqXStatusIsActive());
}
```

#### 3.3.1.2 IFC Read-clear Operation

In addition to the normal interrupt setting and clearing operations via the IFS/IFC registers, there is an additional atomic Read-clear operation that can be enabled by setting IFCREADCLEAR=1 in the MSC\_CTRL register. When enabled, reads of peripheral IFC registers will return the interrupt vector (mirroring the IF register), while at the same time clearing whichever interrupt flags are set. This operation is functionally equivalent to reading the IF register and then writing the result immediately back to the IFC register.

### 3.3.2 Interrupt Request Lines (IRQ)

**Table 3.1. Interrupt Request Lines (IRQ)**

| IRQ # | Source(s)      |
|-------|----------------|
| 0     | EMU            |
| 2     | WDOG0          |
| 8     | LDMA           |
| 9     | GPIO_EVEN      |
| 10    | TIMER0         |
| 11    | USART0_RX      |
| 12    | USART0_TX      |
| 13    | ACMP0<br>ACMP1 |
| 14    | ADC0           |
| 15    | IDAC0          |
| 16    | I2C0           |
| 17    | GPIO_ODD       |
| 18    | TIMER1         |
| 19    | USART1_RX      |
| 20    | USART1_TX      |
| 21    | LEUART0        |
| 22    | PCNT0          |
| 23    | CMU            |
| 24    | MSC            |
| 25    | CRYPTO         |
| 26    | LETIMER0       |
| 29    | RTCC           |
| 31    | CRYOTIMER      |
| 33    | FPUEH          |

## 4. Memory and Bus System

### Quick Facts

#### What?

A low latency memory system including low energy Flash and RAM with data retention which makes the energy modes attractive.

#### Why?

RAM retention reduces the need for storing data in Flash and enables frequent use of the ultra low energy modes EM2 DeepSleep and EM3 Stop.

#### How?

Low energy and non-volatile Flash memory stores program and application data in all energy modes and can easily be reprogrammed in system. Low leakage RAM with data retention in EM0 Active to EM3 Stop removes the data restore time penalty, and the DMA ensures fast autonomous transfers with predictable response time.

### 4.1 Introduction

The EFM32 Gecko contains an AMBA AHB Bus system to allow bus masters to access the memory mapped address space. A multi-layer AHB bus matrix connects the 4 master bus interfaces to the AHB slaves (Figure 4.1 EFM32 Gecko Bus System on page 34). The bus matrix allows several AHB slaves to be accessed simultaneously. An AMBA APB interface is used for the peripherals, which are accessed through an AHB-to-APB bridge connected to the AHB bus matrix. The 4 AHB bus masters are:

- **Cortex-M4 ICode:** Used for instruction fetches from Code memory (valid address range: 0x00000000 - 0x1FFFFFFF)
- **Cortex-M4 DCode:** Used for debug and data access to Code memory (valid address range: 0x00000000 - 0x1FFFFFFF)
- **Cortex-M4 System:** Used for data and debug access to system space. It can access entire memory space except Code memory (valid address range: 0x20000000 - 0xFFFFFFFF)
- **DMA:** Can access the entire memory space except the internal core memory region and the DMEM code region

Figure 4.1. EFM32 Gecko Bus System

## 4.2 Functional Description

The memory segments are mapped together with the internal segments of the Cortex-M4 into the system memory map shown by [Figure 4.2 System Address Space With Core and Code Space Listing on page 35](#).

**Figure 4.2. System Address Space With Core and Code Space Listing**

Additionally, the peripheral address map is detailed by [Figure 4.3 System Address Space With Peripheral Listing on page 36](#).

Figure 4.3. System Address Space With Peripheral Listing

The embedded SRAM is located at address 0x20000000 in the memory map of the EFM32 Gecko. When running code located in SRAM starting at this address, the Cortex-M4 uses the System bus interface to fetch instructions. This results in reduced performance as the Cortex-M4 accesses stack, other data in SRAM and peripherals using the System bus interface. To be able to run code from SRAM efficiently, the SRAM is also mapped in the code space at address 0x10000000.

When running code from this space, the Cortex-M4 fetches instructions through the I/D-Code bus interface, leaving the System bus interface for data access.

The SRAM mapped into the code space can however only be accessed by the CPU and not any other bus masters, e.g. DMA. See [4.5 SRAM](#) for more detailed info on the system SRAM.

#### 4.2.1 Peripheral Non-Word Access Behavior

When writing to peripheral registers, all accesses are treated as 32-bit accesses. This means that writes to a register need to be large enough to cover all bits of register, otherwise, any uncovered bits may become corrupted from the partial-word transfer. Thus, the safest practice is to always do 32-bit writes to peripheral registers.

When reading, there is generally no issue with partial word accesses, however, note that any read action (e.g. FIFO popping) will be triggered regardless of whether the actual FIFO bit-field was included in the transfer size.

**Note:** The implementation of bit-banding in the core is such that bit-band accesses forward the transfer size info into the actual bus transfer size, so the same restrictions apply to bit-band accesses as apply to normal read/write accesses.

### 4.2.2 Bit-banding

The SRAM bit-band alias and peripheral bit-band alias regions are located at 0x22000000 and 0x42000000 respectively. Read and write operations to these regions are converted into masked single-bit reads and atomic single-bit writes to the embedded SRAM and peripherals of the EFM32 Gecko.

**Note:** Bit-banding is only available through the CPU. No other AHB masters (e.g. DMA) can perform Bit-banding operations.

Using a standard approach to modify a single register or SRAM bit in the aliased regions, would require software to read the value of the byte, half-word or word containing the bit, modify the bit, and then write the byte, half-word or word back to the register or SRAM address. Using bit-banding, this can be done in a single operation, consuming only two bus cycles. As read-writeback, bit-masking and bit-shift operations are not necessary in software, code size is reduced and execution speed improved.

The bit-band regions allow each bit in the SRAM and Peripheral areas of the memory map to be addressed. To set or clear a bit in the embedded SRAM, write a 1 or a 0 to the following address:

$$\text{bit\_address} = 0x22000000 + (\text{address} - 0x20000000) \times 32 + \text{bit} \times 4$$

where address is the address of the 32-bit word containing the bit to modify, and bit is the index of the bit in the 32-bit word.

To modify a bit in the Peripheral area, use the following address:

$$\text{bit\_address} = 0x42000000 + (\text{address} - 0x40000000) \times 32 + \text{bit} \times 4$$

4.2.3 Peripheral Bit Set and Clear

The EFM32 Gecko supports bit set and bit clear access to all peripherals except those listed in [Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 38](#). The bit set and bit clear functionality (also called Bit Access) enables modification of bit fields (single bit or multiple bit wide) without the need to perform a read-modify-write (though it is functionally equivalent). Also, the operation is contained within a single bus access (for HF peripherals), unlike the Bit-banding operation described in section [4.2.2 Bit-banding](#) which consumes two bus accesses per operation. All AHB masters can utilize this feature.

The bit clear aliasing region starts at 0x44000000 and the bit set aliasing region starts at 0x46000000. Thus, to apply a bit set or clear operation, write the bit set or clear mask to the following addresses:

```
bit_clear_address = address + 0x04000000
bit_set_address = address + 0x06000000
```

For bit set operations, bit locations that are 1 in the bit mask will be set in the destination register:

```
register = (register OR mask)
```

For bit clear operations, bit locations that are 1 in the bit mask will be cleared in the destination register:

```
register = (register AND (NOT mask))
```

**Note:** It is possible to combine bit clear and bit set operations in order to arbitrarily modify multi-bit register fields, without affecting other fields in the same register. In this case, care should be taken to ensure that the field does not have intermediate values that can lead to erroneous behavior. For example, if bit clear and bit set operations are used to change an analog tuning register field from 25 to 26, the field would initially take on a value of zero. If the analog module is active at the time, this could lead to undesired behavior.

The peripherals listed in [Table 4.1 Peripherals that Do Not Support Bit Set and Bit Clear on page 38](#) do not support Bit Access for any registers. All other peripherals do support Bit Access, however, there may be cases of certain registers that do not support it. Such registers have a note regarding this lack of support.

Table 4.1. Peripherals that Do Not Support Bit Set and Bit Clear

| Module    |
|-----------|
| EMU       |
| RMU       |
| CRYOTIMER |

## 4.2.4 Peripherals

The peripherals are mapped into the peripheral memory segment, each with a fixed size address range according to [Table 4.2 Peripherals on page 39](#), [Table 4.3 Low Energy Peripherals on page 39](#), and [Table 4.4 Core Peripherals on page 39](#).

**Table 4.2. Peripherals**

| Address Range           | Module Name |
|-------------------------|-------------|
| 0x400E6000 - 0x400E6400 | PRS         |
| 0x4001E000 - 0x4001E400 | CRYOTIMER   |
| 0x4001C000 - 0x4001C400 | GPCRC       |
| 0x40018400 - 0x40018800 | TIMER1      |
| 0x40018000 - 0x40018400 | TIMER0      |
| 0x40010400 - 0x40010800 | USART1      |
| 0x40010000 - 0x40010400 | USART0      |
| 0x4000C000 - 0x4000C400 | I2C0        |
| 0x4000A000 - 0x4000B000 | GPIO        |
| 0x40006000 - 0x40006400 | IDAC0       |
| 0x40002000 - 0x40002400 | ADC0        |
| 0x40000400 - 0x40000800 | ACMP1       |
| 0x40000000 - 0x40000400 | ACMP0       |

**Table 4.3. Low Energy Peripherals**

| Address Range           | Module Name |
|-------------------------|-------------|
| 0x40052000 - 0x40052400 | WDOG0       |
| 0x4004E000 - 0x4004E400 | PCNT0       |
| 0x4004A000 - 0x4004A400 | LEUART0     |
| 0x40046000 - 0x40046400 | LETIMER0    |
| 0x40042000 - 0x40042400 | RTCC        |

**Table 4.4. Core Peripherals**

| Address Range           | Module Name |
|-------------------------|-------------|
| 0xE0000000 - 0xE0040000 | CM4         |
| 0x400F0000 - 0x400F0400 | CRYPTO      |
| 0x400E2000 - 0x400E3000 | LDMA        |
| 0x400E1000 - 0x400E1400 | FPUEH       |
| 0x400E0000 - 0x400E0800 | MSC         |

## 4.2.5 Bus Matrix

The Bus Matrix connects the memory segments to the bus masters as detailed in [4.1 Introduction](#).

#### 4.2.5.1 Arbitration

The Bus Matrix uses a round-robin arbitration algorithm which enables high throughput and low latency, while starvation of simultaneous accesses to the same bus slave are eliminated. Round-robin does not assign a fixed priority to each bus master. The arbiter does not insert any bus wait-states during peak interaction. However, one wait state is inserted for master accesses occurring after a prolonged inactive time. This wait state allows for increased power efficiency during master idle time.

#### 4.2.5.2 Peripheral Access Performance

The Bus Matrix is a multi-layer energy optimized AMBA AHB compliant bus with an internal bandwidth of 4x a single AHB interface.

The Cortex-M4, DMA Controller, and peripherals (not peripherals in the low frequency clock domain) run on clocks which can be pre-scaled separately. Clocks and prescaling are described in more detail in [10. CMU - Clock Management Unit](#). This section describes the expected bus wait states for a peripheral based on its frequency relative to the HFCLK frequency. For this discussion, PERCLK refers to a selected peripheral's clock frequency, which is some integer division of the HFCLK frequency.

##### 4.2.5.2.1 WS0 Mode

In general, when accessing a peripheral, the latency in number of HFCLK cycles, not including master arbitration, is given by:

$$N_{\text{bus cycles}} = N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ best-case write accesses}$$

$$N_{\text{bus cycles}} = N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}} + 1, \text{ best-case read accesses}$$

$$N_{\text{bus cycles}} = (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}} - 1, \text{ worst-case write accesses}$$

$$N_{\text{bus cycles}} = (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ worst-case read accesses}$$

where  $N_{\text{slave cycles}}$  is the throughput of the slave's bus interface in number of PERCLK cycles per transfer, including any wait cycles introduced by the slave.

**Figure 4.4. Bus Access Latency (General Case)**

Note that a latency of 1 cycle corresponds to 0 wait states.

Additionally, for back-to-back accesses to the same peripheral, the throughput in number of cycles per transfer is given by:

$$N_{\text{bus cycles}} = N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ write accesses}$$

$$N_{\text{bus cycles}} = (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ read accesses}$$

**Figure 4.5. Bus Access Throughput (Back-to-Back Transfers)**

Lastly, in the highest performing case, where PERCLK equals HFCLK and the slave does not introduce any additional wait states, the access latency in number of cycles is given by:

$$N_{\text{bus cycles}} = 1, \text{ write accesses}$$

$$N_{\text{bus cycles}} = 2, \text{ read accesses}$$

**Figure 4.6. Bus Access Latency (Max Performance)**

#### 4.2.5.2.2 WS1 Mode

In general, when accessing a peripheral, the latency in number of HFCLK cycles, not including master arbitration, is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}} + 2, \text{ best-case write accesses} \\ N_{\text{bus cycles}} &= N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}} + 1, \text{ best-case read accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}} + 1, \text{ worst-case write accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ worst-case read accesses} \end{aligned}$$

where  $N_{\text{slave cycles}}$  is the throughput of the slave's bus interface in number of PERCLK cycles per transfer, including any wait cycles introduced by the slave.

**Figure 4.7. Bus Access Latency (General Case)**

Note that a latency of 1 cycle corresponds to 0 wait states.

Additionally, for back-to-back accesses to the same peripheral, the throughput in number of cycles per transfer is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= \max\{f_{\text{HFCLK}}/f_{\text{PERCLK}}, 2\} + N_{\text{slave cycles}} \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ write accesses} \\ N_{\text{bus cycles}} &= (N_{\text{slave cycles}} + 1) \times f_{\text{HFCLK}}/f_{\text{PERCLK}}, \text{ read accesses} \end{aligned}$$

**Figure 4.8. Bus Access Throughput (Back-to-Back Transfers)**

Lastly, in the highest performing case, where PERCLK equals HFCLK and the slave does not introduce any additional wait states, the access latency in number of cycles is given by:

$$\begin{aligned} N_{\text{bus cycles}} &= 3, \text{ write accesses} \\ N_{\text{bus cycles}} &= 2, \text{ read accesses} \end{aligned}$$

**Figure 4.9. Bus Access Latency (Max Performance)**

#### 4.2.5.2.3 Core Access Latency

Note that the cycle counts in the equations above is in terms of the HFCLK. When the core is prescaled from the bus clock, the core will see a reduced number of latency cycles given by:

$$\begin{aligned} N_{\text{core cycles}} &= \text{ceiling}(N_{\text{bus cycles}} \times f_{\text{HFCORECLK}}/f_{\text{HFCLK}}) \\ &\text{where master arbitration is not included.} \end{aligned}$$

**Figure 4.10. Core Access Latency**

#### 4.2.5.3 Bus Faults

System accesses from the core can receive a bus fault in the following condition(s):

- The core attempts to access an address that is not assigned to any peripheral or other system device. These faults can be enabled or disabled by setting the ADDRFAULTEN bit appropriately in MSC\_CTRL.
- The core attempts to access a peripheral or system device that has its clock disabled. These faults can be enabled or disabled by setting the CLKDISFAULTEN bit appropriately in MSC\_CTRL.

In addition to any condition-specific bus fault control bits, the bus fault interrupt itself can be enabled or disabled in the same way as all other internal core interrupts.

**Note:** The icache flush is not triggered at the event of a bus fault. As a result, when an instruction fetch results in a bus fault, invalid data may be cached. This means that the next time the instruction that caused the bus fault is fetched, the processor core will get the invalid cached data without any bus fault. In order to avoid invalid cached data propagation to the processor core, software should manually invalidate cache by writing 1 to MSC\_CMD\_INVCACHE bitfield at the event of a bus fault.

### 4.3 Access to Low Energy Peripherals (Asynchronous Registers)

The Low Energy Peripherals are capable of running when the high frequency oscillator and core system is powered off, i.e. in energy mode EM2 DeepSleep and in some cases also EM3 Stop. This enables the peripherals to perform tasks while the system energy consumption is minimal.

The Low Energy Peripherals are listed in [Table 4.3 Low Energy Peripherals on page 39](#).

All Low Energy Peripherals are memory mapped, with automatic data synchronization. Because the Low Energy Peripherals are running on clocks asynchronous to the high frequency system clock, there are some constraints on how register accesses are performed, as described in the following sections.

#### 4.3.1 Writing

Every Low Energy Peripheral has one or more registers with data that needs to be synchronized into the Low Energy clock domain to maintain data consistency and predictable operation. There are two different synchronization mechanisms on the EFM32PG1, immediate synchronization, and delayed synchronization. Immediate synchronization is available for the RTCC and LETIMER, and results in an immediate update of the target registers. Delayed synchronization is used for the remaining Low Energy Peripherals, and for these peripherals, a write operation requires 3 positive edges of the clock on the Low Energy Peripheral being accessed. Registers requiring synchronization are marked "Async Reg" in their description header.

**Note:** On the Gecko series of devices, all LE peripherals are subject to delayed synchronization.

Figure 4.11. Write Operation to Low Energy Peripherals

#### 4.3.1.1 Delayed Synchronization

After writing data to a register which value is to be synchronized into the Low Energy Peripheral using delayed synchronization, a corresponding busy flag in the <module\_name>\_SYNCBUSY register (e.g. LETIMER\_SYNCBUSY) is set. This flag is set as long as synchronization is in progress and is cleared upon completion.

**Note:** Subsequent writes to the same register before the corresponding busy flag is cleared is not supported. Write before the busy flag is cleared may result in undefined behavior. In general the SYNCBUSY register only needs to be observed if there is a risk of multiple write access to a register (which must be prevented). It is not required to wait until the relevant flag in the SYNCBUSY register is cleared after writing a register. E.g., EM2 DeepSleep can be entered directly after writing a register.

See [Figure 4.12 Write Operation to Low Energy Peripherals on page 43](#) for an overview of the writing mechanism operation.

**Figure 4.12. Write Operation to Low Energy Peripherals**

#### 4.3.1.2 Immediate Synchronization

In contrast to the peripherals with delayed synchronization, peripherals with immediate synchronization do not experience a register write delay for most registers. Registers are updated immediately on the peripheral write access. If such a write is done close to an edge on the clock of the peripheral, the write can be delayed until after that clock edge. This will introduce wait-states on the peripheral access.

One exception is made for commands (writing to the CMD register) in peripherals with immediate synchronization. Peripherals with immediate synchronization each have a SYNCBUSY register with a bit for the CMD register status. Commands written to a peripheral with immediate synchronization are not executed before the first peripheral clock after the write. In this period, the SYNCBUSY flag for the command register is set, indicating that the command has not yet been performed.

To maintain compatibility with earlier Gecko series, the SYNCBUSY register reserves placeholders where other register synchronization bits resided. These bits always read 0, indicating that register writes are always safe.

**Note:** If compatibility with earlier Gecko series is a requirement for a given application, the rules that apply to delayed synchronization with respect to SYNCBUSY should also be followed for the peripherals that support immediate synchronization.

### 4.3.2 Reading

When reading from a Low Energy Peripheral, the data read is synchronized regardless if it originates in the Low Energy clock domain or High Frequency clock domain. See [Figure 4.13 Read Operation From Low Energy Peripherals on page 44](#) for an overview of the reading operation.

**Note:** Writing a register and then immediately reading the new value of the register may give the impression that the write operation is complete. This may not be the case. Refer to the SYNCBUSY register for correct status of the write operation to the Low Energy Peripheral.

**Figure 4.13. Read Operation From Low Energy Peripherals**

### 4.3.3 FREEZE Register

In all Low Energy Peripheral with delayed synchronization there is a `<module_name>_FREEZE` register (e.g. `RTCC_FREEZE`). The register contains a bit named `REGFREEZE`. If precise control of the synchronization process is required, this bit may be utilized. When `REGFREEZE` is set, the synchronization process is halted allowing the software to write multiple Low Energy registers before starting the synchronization process, thus providing precise control of the module update process. The synchronization process is started by clearing the `REGFREEZE` bit.

**Note:** The FREEZE register is also present on peripherals with immediate synchronization, but there it has no effect

## 4.4 Flash

The Flash retains data in any state and typically stores the application code, special user data and security information. The Flash memory is typically programmed through the debug interface, but can also be erased and written to from software.

- Up to 256 KB of memory
- Page size of 2 KB (minimum erase unit)
- Minimum 10K erase cycles endurance
- Greater than 10 years data retention at 85 °C
- Lock-bits for memory protection
- Data retention in any state

## 4.5 SRAM

The primary task of the SRAM memory is to store application data. Additionally, it is possible to execute instructions from SRAM, and the DMA may be set up to transfer data between the SRAM, flash and peripherals.

- Up to 32 KB of memory
- Bit-band access support
- Set of RAM blocks may be powered down when not in use
- Data retention of the entire memory in EM0 Active to EM3 Stop

The SRAM memory may be split among two or more different AHB slaves (e.g., RAM0, RAM1, ...) in order to allow simultaneous access to different sections of the memory from two different AHB masters. For example, the Cortex-M4 can access RAM0 while the DMA controller accesses RAM1 in parallel. See [4.1 Introduction](#) for AHB slave connectivity details.

## 4.6 DI Page Entry Map

The DI page contains production calibration data as well as device identification information. See the peripheral chapters for how each calibration value is to be used with the associated peripheral.

The offset address is relative to the start address of the DI page (see [6.3 Functional Description](#)).

| Offset | Name          | Type | Description                                |

## 5. DBG - Debug Interface

### Quick Facts

#### What?

The Debug Interface is used to program and debug EFM32 Gecko devices.

#### Why?

The Debug Interface makes it easy to re-program and update the system in the field, and allows debugging with minimal I/O pin usage.

#### How?

The Cortex-M4 supports advanced debugging features. EFM32 Gecko devices can use a minimum of two port pins for debugging or programming. The internal and external state of the system can be examined with debug extensions supporting instruction or data access break and watch points.

### 5.1 Introduction

The EFM32 Gecko devices include hardware debug support through a 2-pin serial-wire debug (SWD) interface or a 4-pin Joint Test Action Group (JTAG) interface.

For more technical information about the debug interface the reader is referred to:

- ARM Cortex-M4 Technical Reference Manual
- ARM CoreSight Components Technical Reference Manual
- ARM Debug Interface v5 Architecture Specification
- IEEE Standard for Test Access Port and Boundary-Scan Architecture, IEEE 1149.1-2013

### 5.2 Features

- Debug Access Port Serial Wire JTAG (DAP SWJ-DP)
  - Implements the ADIv5 debug interface
- Authentication Access Point (AAP)
  - Implements various user commands
- Flash Patch and Breakpoint (FPB) unit
  - Implement breakpoints and code patches
- Data Watch point and Trace (DWT) unit
  - Implement watch points, trigger resources and system profiling
- Instrumentation Trace Macrocell (ITM)
  - Application-driven trace source that supports printf style debugging

### 5.3 Functional Description

Operation of the available debug interface is described in the following sections.

### 5.3.1 Debug Pins

The following pins are the debug connections for the device:

- Serial Wire Clock Input and Test Clock Input (SWCLKTCK) : This pin is enabled after power-up and has a built-in pull down.
- Serial Wire Data Input/Output and Test Mode Select Input (SWDIOTMS) : This pin is enabled after power-up and has a built-in pull-up.
- Test Data Output (TDO): This pin is assigned to JTAG functionality after power-up. However, it remains in high-Z state until the first valid JTAG command is received.
- Test Data Input (TDI): This pin is assigned to JTAG functionality after power-up. However, it remains in high-Z state until the first valid JTAG command is received. Once enabled, the pin has a built-in pull-up.

The debug pins have pull-down and pull-up enabled by default, so leaving them enabled may increase the current consumption if left connected to supply or ground. The debug pins can be enabled and disabled through GPIO\_ROUTEEN, see [26.3.4.2.3 Disabling Debug Connections](#). Remember that upon disabling the debug pins, debug contact with the device is lost once the DAP SWJ-DP power request bits are deasserted. By default after power cycle the part's debug pins are in JTAG mode. If during debugging session the pins are switched to SWD mode, a power cycle is required to bring restore the pins to JTAG mode.

### 5.3.2 Debug and EM2 DeepSleep/EM3 Stop

Leaving the debugger connected when issuing a WFI or WFE to enter EM2 DeepSleep or EM3 Stop will make the system enter a special EM2 DeepSleep. This mode differs from regular EM2 DeepSleep and EM3 Stop in that the high frequency clocks are still enabled, and certain core functionality is still powered in order to maintain debug-functionality. Because of this, the current consumption in this mode is closer to EM1 Sleep and it is therefore important to deassert the power requests in the DAP SWJ-DP and disconnect the debugger before doing current consumption measurements.

### 5.3.3 Authentication Access Point

The Authentication Access Point (AAP) is a set of registers that provide a minimal amount of debugging and system level commands. The AAP registers contain commands to issue a FLASH erase, a system reset, a CRC of user code pages, and stalling the system bus. The user must program the APSEL bit field to 255 inside of the ARM DAP SWJ Debug Port SELECT register to access the AAP. The AAP is only accessible from a debugger and not from the core.

#### 5.3.3.1 System Bus Stall

The system bus can be stalled at any time using the SYSBUSSTALL register bit. Once the SYSBUSSTALL is set, the system bus will remain stalled until SYSBUSSTALL is cleared. While the system bus is stalled, only the registers inside the Cortex-M4, AAP and the debugger can be accessed. The SYSBUSSTALL register is available at all times through the AAP.

#### 5.3.3.2 Command Key

The AAP uses a command key to enable the DEVICEERASE and SYSRESETREQ AAP commands. The command key must be written with the correct key in order for the commands to execute.

#### 5.3.3.3 Device Erase

The device can be erased by stalling the system bus, writing AAP\_CMDKEY, and then writing the DEVICEERASE register bit. Upon writing the command bit, the ERASEBUSY bit is asserted. The ERASEBUSY bit will be de-asserted once the erase is complete. The SYSRESETREQ bit must then be set to resume a normal debugger session. The DEVICEERASE register is available at all times through the AAP once the CMDKEY is entered.

#### 5.3.3.4 System Reset

The system can be reset by writing AAP\_CMDKEY followed by writing the SYSRESETREQ register bit. This must be done after asserting DEVICEERASE or CRCREQ. Depending on the reset level setting for system reset, asserting SYSRESETREQ will either reset the entire AAP register space or just the SYSRESETREQ bit. See [8.3.1 Reset Levels](#) for more details on reset levels. The SYSRESETREQ register is available at all times through the AAP once the CMDKEY is entered.

### 5.3.3.5 User Flash Page CRC

The CRCREQ command initiates a CRC calculation on a given Flash Page. The CRC is only available on the Main, User Data, and Lock Bit pages. It is highly recommended that the system bus is stalled before any CRCREQ commands are issued. The CRC calculation uses the on chip CRC block configured in 32 bit CRC mode. The Flash Page address for the CRCREQ command is written to the CRCADDR register. After issuing the CRCREQ, the CRCBUSY flag is asserted. Once the CRCBUSY flag is de-asserted, the resulting page CRC can be found in the CRCRESULT register. Once issuing a CRC command, the CPU is stalled and remains stalled until a system reset occurs. Multiple CRC requests can occur before resetting the system. However, a CRC request that occurs while the CRCBUSY flag is asserted will be ignored. The CRC registers are available at all times through the AAP, even when the device is debug locked.

### 5.3.4 Debug Lock

The debug access to the Cortex-M4 is locked by clearing the Debug Lock Word (DLW) and resetting the device, see [6.3.2 Lock Bits \(LB\) Page Description](#).

When debug access is locked, the debugger can access the DAP SWJ-DP and AAP registers. However, the connection to the Cortex-M4 core and the whole bus-system is blocked. This mechanism is controlled by the Authentication Access Port (AAP) as illustrated by [Figure 5.1 AAP - Authentication Access Port on page 85](#).

**Figure 5.1. AAP - Authentication Access Port**

If the DLW is cleared, the device is locked. If the device is locked and the the AAP Lock Word (ALW) has not been cleared, it can be unlocked by writing a valid key to the AAP\_CMDKEY register and then setting the DEVICEERASE bit of the AAP\_CMD register via the debug interface. This operation erases the main block of flash, clears all lock bits, and debug access to the Cortex-M4 and bus-system is enabled. The operation takes tens of mili seconds to complete. Note that the SRAM contents will also be deleted during a device erase, while the UD-page is not erased.

The debugger may read the status of the device erase from the AAP\_STATUS register. When the ERASEBUSY bit is set low after DEVICEERASE of the AAP\_CMD register is set, the debugger may set the SYSRESETREQ bit in the AAP\_CMD register. After reset, the debugger may resume a normal debug session through the AHB-AP.

### 5.3.5 AAP Lock

Take extreme caution when using this feature. Once the AAP has been locked, the state of the FLASH can not be changed via the debugger.

### 5.3.6 Debugger Reads of Actionable Registers

Some peripheral registers cause particular actions when read, e.g FIFOs which pop and IFC registers which clear the IF flags when read. This can cause problems when debugging and the user wants to read the value without triggering the read action. For this reason, by default, the peripherals will not execute these triggered actions when an attached debugger is performing the read accesses through the AAP. To override this behavior, the debugger can configure the MASTERTYPE bitfield of the Cortex-M4 AHB Access Port CSW register in order to emulate a core access when performing system bus transfers.

**Note:**

- Registers with actionable reads are noted in their register descriptions. Refer to [Table 1.1 Register Access Types on page 22](#).

### 5.3.7 Debug Recovery

Debug recovery is the ability to stall the system bus before the Cortex-M4 executes code. For example, the first few instructions may disconnect the debugger pins. When this occurs it is difficult to connect the debugger and halt the Cortex-M4 before the Cortex-M4 starts to execute. By holding down pin reset, issuing the System Bus Stall AAP instruction, then releasing pin reset, the debugger can stall the system bus before the Cortex-M4 has a chance to execute. Because the system is under reset during this procedure the Debugger can not look for ACK's from the part. Once the system bus is stalled, the FLASH can be erased by issuing the AAP\_CMDKEY and then the writing the DEVICEERASE in the AAP\_CMD register.

## 5.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name          | Type | Description                 |
|--------|---------------|------|-----------------------------|
| 0x000  | AAP_CMD       | W1   | Command Register            |
| 0x004  | AAP_CMDKEY    | W1   | Command Key Register        |
| 0x008  | AAP_STATUS    | R    | Status Register             |
| 0x00C  | AAP_CTRL      | RW   | Control Register            |
| 0x010  | AAP_CRCCMD    | W1   | CRC Command Register        |
| 0x014  | AAP_CRCSTATUS | R    | CRC Status Register         |
| 0x018  | AAP_CRCADDR   | RW   | CRC Address Register        |
| 0x01C  | AAP_CRCRESULT | R    | CRC Result Register         |
| 0x0FC  | AAP_IDR       | R    | AAP Identification Register |

## 5.5 Register Description

### 5.5.1 AAP\_CMD - Command Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |             |             |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|-------------|-------------|
| 0x000  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |             |             |
| Reset  |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   | 0           | 0           |
| Access |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   | W1          | W1          |
| Name   |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   | SYSRESETREQ | DEVICEERASE |

| Bit  | Name        | Reset                                                                                                                    | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-------------|--------------------------------------------------------------------------------------------------------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:2 | Reserved    | To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a> |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1    | SYSRESETREQ | 0                                                                                                                        | W1     | <b>System Reset Request</b><br>A system reset request is generated when set to 1. This register is write enabled from the AAP_CMDKEY register.                                                                                                                                                                                                                                                                                                                              |
| 0    | DEVICEERASE | 0                                                                                                                        | W1     | <b>Erase the Flash Main Block, SRAM and Lock Bits</b><br>When set, all data and program code in the main block is erased, the SRAM is cleared and then the Lock Bit (LB) page is erased. This also includes the Debug Lock Word (DLW), causing debug access to be enabled after the next reset. The information block User Data page (UD) is left unchanged, but the User data page Lock Word (ULW) is erased. This register is write enabled from the AAP_CMDKEY register. |

### 5.5.2 AAP\_CMDKEY - Command Key Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |

### Quick Facts

#### What?

The user can perform flash memory read, read configuration and write operations through the Memory System Controller (MSC) .

#### Why?

The MSC allows the application code, user data and flash lock bits to be stored in non-volatile flash memory. Certain memory system functions, such as program memory wait-states and bus faults are also configured from the MSC peripheral register interface, giving the developer the ability to dynamically customize the memory system performance, security level, energy consumption and error handling capabilities to the requirements at hand.

#### How?

The MSC integrates a low-energy flash IP with a charge pump, enabling minimum energy consumption while eliminating the need for external programming voltage to erase the memory. An easy to use write and erase interface is supported by an internal, fixed-frequency oscillator and autonomous flash timing and control reduces software complexity while not using other timer resources.

Application code may dynamically scale between high energy optimization and high code execution performance through advanced read modes.

A highly efficient low energy instruction cache reduces the number of flash reads significantly, thus saving energy. Performance is also improved when wait-states are used, since many of the wait-states are eliminated. Built-in performance counters can be used to measure the efficiency of the instruction cache.

### 6.1 Introduction

The Memory System Controller (MSC) is the program memory unit of the EFM32 Gecko microcontroller. The flash memory is readable and writable from both the Cortex-M4 and DMA. The flash memory is divided into two blocks; the main block and the information block. Program code is normally written to the main block. Additionally, the information block is available for special user data and flash lock bits. There is also a read-only page in the information block containing system and device calibration data, and bootloader. Read and write operations are supported in the energy modes EM0 Active and EM1 Sleep.

## 6.2 Features

- AHB read interface
  - Scalable access performance to optimize the Cortex-M4 code interface
    - Zero wait-state access up to 25 MHz
    - Advanced energy optimization functionality
      - Conditional branch target prefetch suppression
      - Cortex-M4 disfolding of if-then (IT) blocks
      - Instruction Cache
  - DMA read support in EM0 Active and EM1 Sleep
- Command and status interface
  - Flash write and erase
    - Accessible from Cortex-M4 in EM0 Active
    - DMA write support in EM0 Active and EM1 Sleep
  - Core clock independent flash timing
    - Internal oscillator and internal timers for precise and autonomous flash timing
      - General purpose timers are not occupied during flash erase and write operations
  - Configurable interrupt erase abort
    - Improved interrupt predictability
  - Memory and bus fault control
- Security features
  - Lockable debug access
  - Page lock bits
  - SW mass erase lock bits
  - Authentication Access Port (AAP) lock bits
- End-of-write and end-of-erase interrupts

### 6.3 Functional Description

The size of the main block is device dependent. The largest size available is 256 KB (128 pages). The information block has 2 KB available for user data. The information block also contains chip configuration data located in a reserved area. The main block is mapped to address 0x00000000 and the information block is mapped to address 0x0FE00000. [Table 6.1 MSC Flash Memory Mapping on page 94](#) outlines how the flash is mapped in the memory space. All flash memory is organized into 2 KB pages.

**Table 6.1. MSC Flash Memory Mapping**

| Block             | Page | Base address | Write/Erase by...                           | Software Readable?           | Purpose/Name                 | Size           |

**Note:**

1. Block/page erased by a device erase.

#### 6.3.1 User Data (UD) Page Description

This is the user data page in the information block. The page can be erased and written by software. The page is erased by the ERASEPAGE command of the MSC\_WRITECMD register. Note that the page is not erased by a device erase operation. The device erase operation is described in [5.3.3 Authentication Access Point](#).

### 6.3.2 Lock Bits (LB) Page Description

This page contains the following information:

- Main block Page Lock Words (PLWs)
- User data page Lock Word (ULWs)
- Debug Lock Word (DLW)
- Mass erase Lock Word (MLW)
- Authentication Access Port (AAP) lock word (ALW)
- Bootloader enable (CLW0)
- Pin reset soft (CLW0)

The words in this page are organized as shown in [Table 6.2 Lock Bits Page Structure on page 95](#):

**Table 6.2. Lock Bits Page Structure**

|     |        |
|-----|--------|
| 127 | DLW    |
| 126 | ULW    |
| 125 | MLW    |
| 124 | ALW    |
| 122 | CLW0   |
| N   | PLW[N] |
| ... | ...    |
| 1   | PLW[1] |
| 0   | PLW[0] |

There are 32 page lock bits per page lock word (PLW). Bit 0 refers to the first page and bit 31 refers to the last page within a PLW. Thus, PLW[0] contains lock bits for page 0-31 in the main block, PLW[1] contains lock bits for page 32-63 etc. A page is locked when the bit is 0. A locked page cannot be erased or written.

Word 127 is the debug lock word (DLW). The four LSBs of this word are the debug lock bits. If these bits are 0xF, then debug access is enabled. Debug access to the core is disabled from power-on reset until the DLW is evaluated immediately before the Cortex-M4 starts execution of the user application code. If the bits are not 0xF, then debug access to the core remains blocked.

Word 126 is the user page lock word (ULW). Bit 0 of this word is the User Data Page lock bit. Bit 1 in this word locks the Lock Bits Page. The lock bits can be reset by a device erase operation initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in [5.3.3 Authentication Access Point](#). Note that the AAP is only accessible from the debug interface, and cannot be accessed from the Cortex-M4 core.

Word 125 is the mass erase lock word (MLW). Bit 0 locks the entire flash. The mass erase lock bits will not have any effect on device erases initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in [5.3.3 Authentication Access Point](#).

Word 124 is the Authentication Access Port (AAP) lock word (ALW) and the four LSBs of this word are the lock bits. If these bits are 0xF, then AAP access is enabled. If the bits are not 0xF, AAP is disabled and it is impossible to access the device through the AAP.

**NOTE - locking the AAP completely is irreversible. Once the AAP is locked, it will be impossible to perform an external mass erase and the AAP lock cannot be reset.** The only way to program the device when the AAP is locked is through a boot loader or by SW already loaded into the FLASH.

Word 122 is Configuration Lock Word 0 (CLW0). Bit 2 is the Pin Reset Soft bit. By default, a pin reset is handled as a soft reset (See [8.3.5 RESETn Pin Reset](#)). Bit 1 is the bootloader enable bit. Because the state of erased flash bits is 1, the bootloader is enabled by default.

#### 6.3.3 Device Information (DI) Page

This read-only page holds calibration data from the production test as well as a unique device ID. The page is further described in [4. Memory and Bus System](#).

### 6.3.4 Bootloader

The system is configured by default to boot from a pre-programmed bootloader automatically after system reset. The bootloader is described in *AN0003: UART Bootloader* ([www.silabs.com/32bit-appnotes](http://www.silabs.com/32bit-appnotes)). Users can bypass the bootloader by clearing bit 1 in Configuration Lock Word 0 (CLW0) at word 122 in the lock bits page.

The bootloader area is readable by software but not writeable in this device family.

### 6.3.5 Post-reset Behavior

Calibration values are automatically written to registers by the MSC before application code startup. The values are also available to read from the DI page for later reference by software. Other information such as the device ID and production date is also stored in the DI page and is readable from software.

If the bootloader is not bypassed, the system will boot up from the bootloader at address 0x0FE10000.

### 6.3.6 Flash Startup

On transitions from EM2/3 to EM0, the flash must be powered up. The time this takes depends on the current operating conditions. To have a deterministic startup-time, set STDLY0 in MSC\_STARTUP to 0x64 and clear STDLY1, ASTWAIT, STWSEN and STWS. This will result in a 10 us delay before the flash is ready. The system will wake up before this, but the Cortex will stall on the first access to the flash until it is ready. Execute code from RAM or cache to get a quicker startup.

To get the fastest possible startup when waking, i.e. a startup that depends on the current operating conditions, set STDLY0 to 0x28 and set ASTWAIT in MSC\_STARTUP. When configured this way, the system will poll the flash to determine when it is ready, and then start execution.

For even quicker startup, run code in beginning with a set of wait-states. Set STDLY0 to 0x32, STDLY1 to 0x32, and set ASTWAIT and STWSEN. Then configure STWS in MSC\_STARTUP to the number of waitstates to run with. With this setup, sampling will begin with the given number of waitstates after 5 us, and the system will run with this number of waitstates for the remaining 5 us before returning to normal operation

A recommended setting for MSC\_STARTUP register is to leave STDLY0 at its reset value and set ASTWAIT to one for active sampling Set STWSEN to zero to bypass the second delay period.

Flash wakeup on demand is supported when wakeup from EM2/3 to EM0. Set bit PWRUPONDEMAND of register MSC\_CTRL to one to enable the power up on demand. When enabled during powerup, flash will enter sleep mode and waiting for either pending flash read transaction or software command to MSC\_CMD.PWRUP bit. If software command wakeup, and interrupt of MSC\_IF.PWRUPF will be flagged if the MSC\_IEN.PWRUPF is set

### 6.3.7 Wait-states

**Table 6.3. Flash Wait-States**

| Wait-States | Frequency                            |
|-------------|--------------------------------------|
| WS0         | no more than 25 MHz                  |
| WS1         | above 25 MHz and no more than 40 MHz |

#### 6.3.7.1 One Wait-state Access

After reset, the HFCORECLK is normally 19 MHz from the HFRCO and the MODE field of the MSC\_READCTRL register is set to WS1 (one wait-state). Software must not select a zero wait-state mode unless the clock is guaranteed to be 25 MHz or below, otherwise the resulting behavior is undefined. If a HFCORECLK frequency above 25 MHz is to be set by software, the MODE field of the MSC\_READCTRL register must be set to WS1 or WS1SCBTP before the core clock is switched to the higher frequency clock source.

When changing to a lower frequency, the MODE field of the MSC\_READCTRL register must be set to WS0 or WS0SCBTP only after the frequency transition has completed. If the HFRCO is used, wait until the oscillator is stable on the new frequency. Otherwise, the behavior is unpredictable.

To run at a frequency higher than 40 MHz, WS2 or WS2SCBTP must be selected to insert two wait-states for every flash access.

### 6.3.7.2 Zero Wait-state Access

At 25 MHz and below, read operations from flash may be performed without any wait-states. Zero wait-state access greatly improves code execution performance at frequencies from 25 MHz and below. By default, the Cortex-M4 uses speculative prefetching and If-Then block folding to maximize code execution performance at the cost of additional flash accesses and energy consumption.

### 6.3.7.3 Operation Above

To run at frequencies higher than 25 MHz, MODE in MSC\_READCTRL must be set to WS1 or WS1SCBTP.

### 6.3.8 Suppressed Conditional Branch Target Prefetch (SCBTP)

MSC offers a special instruction fetch mode which optimizes energy consumption by cancelling Cortex-M4 conditional branch target prefetches. Normally, the Cortex-M4 core prefetches both the next sequential instruction and the instruction at the branch target address when a conditional branch instruction reaches the pipeline decode stage. This prefetch scheme improves performance while one extra instruction is fetched from memory at each conditional branch, regardless of whether the branch is taken or not. To optimize for low energy, the MSC can be configured to cancel these speculative branch target prefetches. With this configuration, energy consumption is more optimal, as the branch target instruction fetch is delayed until the branch condition is evaluated.

The performance penalty with this mode enabled is source code dependent, but is normally less than 1% for core frequencies from 25 MHz and below. To enable the mode at frequencies from 25 MHz and below write WS0SCBTP to the MODE field of the MSC\_READCTRL register. For frequencies above 25 MHz, use the WS1SCBTP mode, and for frequencies above 40 MHz, use the WS2SCBTP mode. An increased performance penalty per clock cycle must be expected compared to WS0SCBTP mode. The performance penalty in WS1SCBTP/WS2SCBTP mode depends greatly on the density and organization of conditional branch instructions in the code.

### 6.3.9 Cortex-M4 If-Then Block Folding

The Cortex-M4 offers a mechanism known as if-then block folding. This is a form of speculative prefetching where small if-then blocks are collapsed in the prefetch buffer if the condition evaluates to false. The instructions in the block then appear to execute in zero cycles. With this scheme, performance is optimized at the cost of higher energy consumption as the processor fetches more instructions from memory than it actually executes. To disable the mode, write a 1 to the DISFOLD bit in the NVIC Auxiliary Control Register; see the Cortex-M4 Technical Reference Manual for details. Normally, it is expected that this feature is most efficient at core frequencies above 25 MHz. Folding is enabled by default.

### 6.3.10 Instruction Cache

The MSC includes an instruction cache. The instruction cache for the internal flash memory is enabled by default, but can be disabled by setting IFCDIS in MSC\_READCTRL. When enabled, the instruction cache typically reduces the number of flash reads significantly, thus saving energy. In most cases a cache hit-rate of more than 70 % is achievable. When a 32-bit instruction fetch hits in the cache the data is returned to the processor in one clock cycle. Thus, performance is also improved when wait-states are used (i.e. running at frequencies above 25 MHz).

The instruction cache is connected directly to the ICODE bus on the ARM core and functions as a memory access filter between the processor and the memory system, as illustrated in [Figure 6.1 Instruction Cache on page 98](#). The cache consists of an access filter, lookup logic, SRAM, and two performance counters. The access filter checks that the address for the access is to on-chip flash memory (instructions in RAM are not cached). If the address matches, the cache lookup logic and SRAM is enabled. Otherwise, the cache is bypassed and the access is forwarded to the memory system. The cache is then updated when the memory access completes. The access filter also disables cache updates for interrupt context accesses if caching in interrupt context is disabled. The performance counters, when enabled, keep track of the number of cache hits and misses. The cachelines are filled up continuously one word at a time as the individual words are requested by the processor. Thus, not all words of a cacheline might be valid at a given time.

Figure 6.1. Instruction Cache

By default, the instruction cache is automatically invalidated when the contents of the flash is changed (i.e. written or erased). In many cases, however, the application only makes changes to data in the flash, not code. In this case, the automatic invalidate feature can be disabled by setting AIDIS in MSC\_READCTRL. The cache can (independent of the AIDIS setting) be manually invalidated by writing 1 to INVCACHE in MSC\_CMD.

**Note:** The instruction cache flush is not triggered at the event of a bus fault. As a result, when an instruction fetch results in a bus fault, invalid data may be cached. This means that the next time the instruction that caused the bus fault is fetched, the processor core will get the invalid cached data without any bus fault. In order to avoid invalid cached data propagation to the processor core, software should manually invalidate the instruction cache by writing 1 to INVCACHE in MSC\_CMD at the event of a bus fault.

In general it is highly recommended to keep the cache enabled all the time. However, for some sections of code with very low cache hit-rate more energy-efficient execution can be achieved by disabling the cache temporarily. To measure the hit-rate of a code-section, the built-in performance counters can be used. Before the section, start the performance counters by writing 1 to STARTPC in MSC\_CMD. This starts the performance counters, counting from 0. At the end of the section, stop the performance counters by writing 1 to STOPPC in MSC\_CMD. The number of cache hits and cache misses for that section can then be read from MSC\_CACHEHITS and MSC\_CACHEMISSIONS respectively. The total number of 32-bit instruction fetches will be MSC\_CACHEHITS + MSC\_CACHEMISSIONS. Thus, the cache hit-ratio can be calculated as  $\text{MSC\_CACHEHITS} / (\text{MSC\_CACHEHITS} + \text{MSC\_CACHEMISSIONS})$ . When MSC\_CACHEHITS overflows the CHOF interrupt flag is set. When MSC\_CACHEMISSIONS overflows the CMOF interrupt flag is set. These flags must be cleared explicitly by software. The range of the performance counters can thus be extended by increasing a counter in the MSC interrupt routine. The performance counters only count when a cache lookup is performed. If the lookup fails, MSC\_CACHEMISSIONS is increased. If the lookup is successful, MSC\_CACHEHITS is increased. For example, a cache lookup is not performed if the cache is disabled or the code is executed from RAM.

**Note:** When caching of vector fetches and instructions in interrupt routines is disabled (ICCDIS in MSC\_READCTRL is set), the performance counters do not count when these types of fetches occur (i.e. while in interrupt context).

By default, interrupt vector fetches and instructions in interrupt routines are also cached. Some applications may get better cache utilization by not caching instructions in interrupt context. This is done by setting ICCDIS in MSC\_READCTRL. You should only set this bit based on the results from a cache hit ratio measurement. In general, it is recommended to keep the ICCDIS bit cleared. Note that look-ups in the cache are still performed, regardless of the ICCDIS setting - but instructions are not cached when cache misses occur inside

the interrupt routine. So, for example, if a cached function is called from the interrupt routine, the instructions for that function will be taken from the cache.

The cache content is not retained in EM2, EM3 and EM4. The cache is therefore invalidated regardless of the setting of AIDIS in MSC\_READCTRL when entering these energy modes. Applications that switch frequently between EM0 and EM2/3 and executes the very same non-looping code almost every time will most likely benefit from putting this code in RAM. The interrupt vectors can also be put in RAM to reduce current consumption even further.

### 6.3.11 Erase and Write Operations

Both page erase and write operations require that the address is written into the MSC\_ADDRB register. For erase operations, the address may be any within the page to be erased. Load the address by writing 1 to the LADDRIM bit in the MSC\_WRITECMD register. The LADDRIM bit only has to be written once when loading the first address. After each word is written the internal address register ADDR will be incremented automatically by 4. The INVADDR bit of the MSC\_STATUS register is set if the loaded address is outside the flash and the LOCKED bit of the MSC\_STATUS register is set if the page addressed is locked. Any attempts to command erase of or write to the page are ignored if INVADDR or the LOCKED bits of the MSC\_STATUS register are set. To abort an ongoing erase, set the ERASEABORT bit in the MSC\_WRITECMD register.

When a word is written to the MSC\_WDATA register, the WDATABREADY bit of the MSC\_STATUS register is cleared. When this status bit is set, software or DMA may write the next word.

A single word write is commanded by setting the WRITEONCE bit of the MSC\_WRITECMD register. The operation is complete when the BUSY bit of the MSC\_STATUS register is cleared and control of the flash is handed back to the AHB interface, allowing application code to resume execution.

For a DMA write the software must write the first word to the MSC\_WDATA register and then set the WRITETRIG bit of the MSC\_WRITECMD register. DMA triggers when the WDATABREADY bit of the MSC\_STATUS register is set.

It is possible to write words twice between each erase by keeping at 1 the bits that are not to be changed. Let us take as an example writing two 16 bit values, 0xAAAA and 0x5555. To safely write them in the same flash word this method can be used:

- Write 0xFFFFAAAA (word in flash becomes 0xFFFFAAAA)
- Write 0x5555FFFF (word in flash becomes 0x5555AAAA)

#### Note:

- There is a maximum of two writes to the same word between each erase due to a physical limitation of the flash.
- During a write or erase, flash read accesses will be stalled, effectively halting code execution from flash. Code execution continues upon write/erase completion. Code residing in RAM may be executed during a write/erase operation.

#### 6.3.11.1 Mass Erase

A mass erase can be initiated from software using ERASEMAIN0 MSC\_WRITECMD. This command will start a mass erase of the entire flash. Prior to initiating a mass erase, MSC\_MASSLOCK must be unlocked by writing 0x631A to it. After a mass erase has been started, this register can be locked again to prevent runaway code from accidentally triggering a mass erase.

The regular flash page lock bits will not prevent a mass erase. To prevent software from initiating mass erases, use the mass erase lock bits in the mass erase lock word (MLW).

## 6.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name            | Type  | Description                      |
|--------|-----------------|-------|----------------------------------|
| 0x000  | MSC_CTRL        | RWH   | Memory System Control Register   |
| 0x004  | MSC_READCTRL    | RWH   | Read Control Register            |
| 0x008  | MSC_WRITECTRL   | RW    | Write Control Register           |
| 0x00C  | MSC_WRITECMD    | W1    | Write Command Register           |
| 0x010  | MSC_ADDRB       | RW    | Page Erase/Write Address Buffer  |
| 0x018  | MSC_WDATA       | RW    | Write Data Register              |
| 0x01C  | MSC_STATUS      | R     | Status Register                  |
| 0x030  | MSC_IF          | R     | Interrupt Flag Register          |
| 0x034  | MSC_IFS         | W1    | Interrupt Flag Set Register      |
| 0x038  | MSC_IFC         | (R)W1 | Interrupt Flag Clear Register    |
| 0x03C  | MSC_IEN         | RW    | Interrupt Enable Register        |
| 0x040  | MSC_LOCK        | RWH   | Configuration Lock Register      |
| 0x044  | MSC_CACHECMD    | W1    | Flash Cache Command Register     |
| 0x048  | MSC_CACHEHITS   | R     | Cache Hits Performance Counter   |
| 0x04C  | MSC_CACHEMISSES | R     | Cache Misses Performance Counter |
| 0x054  | MSC_MASSLOCK    | RWH   | Mass Erase Lock Register         |
| 0x05C  | MSC_STARTUP     | RW    | Startup Control                  |
| 0x074  | MSC_CMD         | W1    | Command Register                 |

## 6.5 Register Description

### 6.5.1 MSC\_CTRL - Memory System Control Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |              |               |               |             |   |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|--------------|---------------|---------------|-------------|---|
| 0x000  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3            | 2             | 1             | 0           |   |
| Reset  |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | 0            | 0             | 2             | 1           | 0 |

| 28    | SCBTP    | 0                                                                                                                        | RW     | <b>Suppress Conditional Branch Target Prefetch</b><br><br>Enable suppressed Conditional Branch Target Prefetch (SCBTP) function. SCBTP saves energy by delaying Cortex-M conditional branch target prefetches until the conditional branch instruction is in the execute stage. When the instruction reaches this stage, the evaluation of the branch condition is completed and the core does not perform a speculative prefetch or both the branch target address and the next sequential address. With the SCBTP function enabled, one instruction fetch is saved for each branch not taken, with a negligible performance penalty.                                                                                                                                                                                      |

| 25:24 | MODE     | 0x1                                                                                                                      | RWH    | <b>Read Mode</b><br><br>After reset, the core clock is 19 MHz from the HFRCO and the MODE field of MSC_READCTRL register is set to WS1. The reset value is WS1 because the HFRCO may produce a frequency above 19 MHz before it is calibrated. A large wait states is associated with high frequency. When changing to a higher frequency, this register must be set to a large wait states first before the core clock is switched to the higher frequency. When changing to a lower frequency, this register should be set to lower wait states after the frequency transition has been completed. If the HFRCO is used as clock source, wait until the oscillator is stable on the new frequency to avoid unpredictable behavior. See Flash Wait-States table for the corresponding threshold for different wait-states. |

## 7. LDMA - Linked DMA Controller

### Quick Facts

#### What?

The LDMA controller can move data without CPU intervention, effectively reducing the energy consumption for a data transfer.

#### Why?

The LDMA can perform data transfers more energy efficiently than the CPU and allows autonomous operation in low energy modes. For example the LEUART can provide full UART communication in EM2 DeepSleep, consuming only a few  $\mu\text{A}$  by using the LDMA to move data between the LEUART and RAM.

#### How?

The LDMA controller has multiple highly configurable, prioritized DMA channels. A linked list of flexible descriptors makes it possible to tailor the controller to the specific needs of an application.

### 7.1 Introduction

The Linked Direct Memory Access (LDMA) controller performs memory transfer operations independently of the CPU. This has the benefit of reducing the energy consumption and the workload of the CPU, and enables the system to stay in low energy modes while still routing data to memory and peripherals. For example, moving data from the LEUART to memory or memory to LEUART. Each of the DMA channels on the EFM32 can be connected to any of the EFM32 peripherals.

### 7.1.1 Features

- Flexible Source and Destination transfers
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Peripheral-to-peripheral
- DMA transfers triggered by peripherals, software, or linked list
- Single or multiple data transfers for each peripheral or software request
- Inter-channel and hardware event synchronization via trigger and wait functions
- Supports single or multiple descriptors
  - Single descriptor
  - Linked list of descriptors
  - Circular and ping-pong buffers
  - Scatter-Gather
  - Looping
  - Pause and restart triggered by other channels
  - Sophisticated flow control which can function without CPU interaction
- Channel arbitration includes:
  - Fixed priority
  - Simple round robin
  - Round robin with programmable multiple interleaved entries for higher priority requesters
- Programmable data size and source and destination address strides
- Programmable interrupt generation at the end of each DMA descriptor execution
- Little-endian/big-endian conversion
- DMA write-immediate function

## 7.2 Block Diagram

An overview of the LDMA and the modules it interacts with is shown in [Figure 7.1 LDMA Block Diagram on page 119](#).

**Figure 7.1. LDMA Block Diagram**

The Linked DMA Controller consists of three main parts

- A DMA core that executes transfers and communicates status to the core
- A channel select block that routes peripheral DMA requests and acknowledge signals to the DMA
- A set of internal channel configuration registers for tracking the progress of each DMA channel

The DMA has access to all system memory through the AHB bus and the AHB->APB bridge. It can load channel descriptors from memory with no CPU intervention.

### 7.3 Functional Description

The Linked DMA Controller is highly flexible. It is capable of transferring data between peripherals and memory without involvement from the processor core. This can be used to increase system performance by off-loading the processor from copying large amounts of data or avoiding frequent interrupts to service peripherals needing more data or having available data. It can also be used to reduce the system energy consumption by making the LDMA work autonomously with some EM2/3 peripherals for data transfer without having to wake up the processor core from sleep.

The Linked DMA Controller has 8 independent channels. Each of these channels can be connected to any of the available peripheral DMA transfer request input sources by writing to the channel configuration registers, see [7.3.2 Channel Configuration](#). In addition, each channel can also be triggered directly by software, which is useful for memory-to-memory transfers.

The channel descriptors determine what the Linked DMA Controller will do when it receives DMA transfer request. The initial descriptor is written directly to the LDMA's channel registers. If desired, the initial descriptor can link to additional linked descriptors stored in memory (RAM or Flash). Alternatively, software may also load the initial descriptor by writing the descriptor address to the LDMA\_CHx\_LINK register and then setting the corresponding bit the LDMA\_LINKLOAD register.

Before enabling a channel, the software must take care to properly configure the channel registers including the link address and any linked descriptors. When a channel is triggered, the Linked DMA Controller will perform the memory transfers as specified by the descriptors. A descriptor contains the memory address to read from, the memory address to write to, link address of the next descriptor, the number of bytes to be transferred, etc. The channel descriptor is described in detail in [7.3.7 Channel Descriptor Data Structure](#).

The Linked DMA Controller supports both fixed priority and round robin arbitration. The number of fixed and round robin channels is programmable. For round robin channels, the number of arbitration slots requested for each channel is programmable. Using this scheme, it is possible to ensure that timing-critical transfers are serviced on time.

DMA transfers take place by reading a block of data at a time from the source, storing it in the LDMA's local FIFO, then writing the block out to the destination from the FIFO. Interrupts may optionally be signaled to the CPU's interrupt controller at the end of any DMA transfer or at the completion of a descriptor if the DONEIFSEN bit is set. An AHB error will always generate an interrupt.

#### 7.3.1 Channel Descriptor

Each DMA channel has descriptor registers. A transfer can be initialized by software writing to the registers or by the DMA itself copying a descriptor from RAM to memory. When using a linked list of descriptors the first descriptor should be initialized by the CPU. The DMA itself will then copy linked descriptors to its descriptor registers as required. In addition to manually initializing the first transfer, software may also cause the LDMA to load the initial descriptor by writing the descriptor address to the LDMA\_CHx\_LINK register and then setting the corresponding bit the LDMA\_LINKLOAD register.

The contents of the descriptor registers are dynamically updated during the DMA transfer. The contents of descriptors in memory are not edited by the controller.

Some descriptor field values are only used for linked descriptors. For example, the SRCMODE and DSTMODE bits of the LDMA\_CHx\_CTRL registers determine if a linked descriptor is using relative or absolute addressing. Software writes to the address registers will always use absolute addressing and never set these bits. Therefore, these bits are read only.

##### 7.3.1.1 DMA Transfer Size

A DMA transfer is the smallest unit of data that can be transferred by the LDMA. The LDMA supports byte, half-word and word sized transfers. The SIZE field in the LDMA\_CHx\_CTRL register specifies the data width of one DMA transfer.

##### 7.3.1.2 Source/Destination Increments

The SRCINC and DSTINC in the LDMA\_CHx\_CTRL register determines the increment between DMA transfers. The increment is in units of DMA transfers and using an increment size of 1 will transfer contiguous bytes, half-words, or words depending on the value of the SIZE field. Multiple unit increments are useful for transferring or packing/unpacking aligned data. For example using an increment of 4 with a size of BYTE will transfer word aligned bytes. An increment of 2 units with a size of HALFWORD is suitable for the transfer of word aligned half-word data. The LDMA can also pack or unpack data by using a different increment size for source and destination. For example - to convert from word aligned byte data (unpacked) to contiguous byte data (packed), set the SIZE to BYTE, SRCINC to 4, and DSTINC to 1.

SRCINC or DSTINC may also be set to NONE which will cause the LDMA to read or write the same location for every DMA transfer. This is useful for accessing peripheral FIFO or data registers.

### 7.3.1.3 Block Size

The block size defines the amount of data transferred in one arbitration. It consists of one or more DMA transfers. See [7.3.6.1 Arbitration Priority](#) for more details.

### 7.3.1.4 Transfer Count

The descriptor transfer count defines how many DMA transfers to perform. The number of bytes transferred by the descriptor will depend on both the transfer count XFERCNT and the SIZE field settings.  $TOTAL\_BYTES = XFERCNT * SIZE$

### 7.3.1.5 Descriptor List

A descriptor list consists of one or more descriptors which are executed in serially. This list may be a simple sequence of descriptors, a loop of descriptors, or a combination of the two.

Each descriptor in the list can be one of several types.

- Single Transfer descriptor: Transfers TOTAL\_BYTES of data and then stops.
- Linked Transfer descriptor: Transfers TOTAL\_BYTES of data and then loads the next linked descriptor.
- Loop Transfer descriptor: Transfers TOTAL\_BYTES of data and performs loop control (see [7.3.2.2 Loop Counter](#)).
- Sync descriptor: Handle synchronization of the list with other entities (see [7.3.7.2 SYNC Descriptor Structure](#)).
- WRI descriptor: Writes a value to a location in memory (see [7.3.7.3 WRI Descriptor Structure](#)).

### 7.3.1.6 Addresses

Before initiating a transfer, software should write the source address, destination address, and if applicable the link address to the descriptor registers. Alternatively, software may load a descriptor from memory by writing the descriptor address to the LDMA\_CHx\_LINK register and setting the corresponding bit in the LDMA\_LINKLOAD register.

During a DMA transfer, the DMA source and destination address registers are pointers to the next transfer address. The LDMA will update the SRC and DST addresses after each transfer. If software halts a DMA transfer by clearing the enable bit, the SRC and DST addresses will indicate the next transfer address.

When a descriptor is finished the DMA will either halt or load the next (linked) descriptor depending on the value of the LINK field in the LDMA\_Chx\_LINK register. After loading a linked descriptor, the descriptor registers will reflect the content of the loaded descriptor. Note that the linked descriptor must be word aligned in memory. The two least significant bits of the LDMA\_CHx\_LINK register are used by the LINK and LINKMODE bits. The two least significant bits of the link address are always zero.

### 7.3.1.7 Addressing Modes

The DMA descriptors support absolute addressing or relative addressing. When using relative addressing, the offset is relative to the current contents of the respective address registers. Regardless of the descriptor addressing modes, the address registers always indicate the absolute address. For example, when loading a descriptor using relative SRC addressing, the LDMA will add the descriptor source address (offset) to the contents of the SRCADDR register (base address). After loading, the SRCADDR register will indicate the absolute address of the loaded descriptor.

The initial descriptor must use absolute addressing. The LDMA will ignore the DSTMODE, SRCMODE, and LINKMODE bits for the initial descriptor and interpret the addresses as an absolute addresses.

Relative addressing is most useful for the link address. The initial descriptor will indicate the absolute address of the linked descriptors in memory. The linked descriptors might be an array of structures. In this case the offset between descriptors is constant and is always 4 words or 16 bytes (each descriptor has 4 words). The LINK address is not incremented or decremented after each transfer. Thus, a relative offset of 0x10 may be used for all linked descriptors.

The source and destination addresses also support relative addressing. When using relative addressing with the source or destination address registers, the LDMA adds the relative offset to the current contents of the respective address register. Since the source and destination addresses are normally incremented after each transfer, the final address will point to one unit past the last transfer. Thus, an offset of zero will give the next sequential data address.

See the example [7.4.6 2D Copy](#) for an common use of relative addressing.

### 7.3.1.8 Byte Swap

Enabling byte swap reverses the endianness of the incoming source data read into the LDMA's FIFO. Byte swap is only valid for transfer sizes of word and half-word. Note that linked structure reads are not byte swapped.

Figure 7.2. Word and Half-Word Endian Byte Swap Examples

### 7.3.1.9 DMA Size and Source/Destination Increment Programming

The DMA channels' SIZE, SRCINC, and DSTINC bit-fields are programmed to best utilize memory resources. They provide a means for memory packing and unpacking, as well as for matching the size of data being transmitted to or received from an IO peripheral. The following figure shows how 32-bit words of data are read from a memory source into the DMA's internal transfer FIFO, and then written out to the memory destination. The memory organization in bytes is shown as well as the first read to and write from the DMA's FIFO.

Figure 7.3. Memory-to-Memory Transfer WORD Size Example

The next example shows four variations of half-word sized transfers, with all possible combinations of half- and full-word source and destination increments. Note that when the size and source/destination increments are all configured for half-word, the resulting DMA transfer organization is equivalent to the full-word sized transfer in the previous example. The difference is that the half-word configuration requires twice as many DMA transfers.

Figure 7.4. Memory-to-Memory Transfer HALF Size Examples

Fields SRCINCSIGN and DSTINCSIGN allow for address decrement. These can be used to mirror an image, for example, in the pixel copy application.

### 7.3.2 Channel Configuration

Each DMA channel has associated configuration and loop counter registers for controlling direction of address increment, arbitration slots, and descriptor looping.

#### 7.3.2.1 Address Increment/Decrement

Normally DMA transfers increment the source and destination addresses after each DMA transfer. Each channel is also capable of decrementing the source and/or destination addresses after each DMA transfer. This may be useful for flipping an array or copying data from tail to head. For example, a data packet might be prepared as an array of data with increasing addresses and then transmitted from the highest address to the lowest address, from tail to head.

After reset the SRCINCSIGN and DSTINCSIGN bits in the LDMA\_CHx\_CFG register are cleared causing the source and destination addresses to increment after each transfer. If the SRCINCSIGN bit is set, the DMA will decrement the source address after each transfer. If the DSTINCSIGN bit in the LDMA\_CHx\_CFG register is set, the DMA will decrement the destination address after each transfer. Setting only one of these bits will flip the data. Setting both bits will copy from tail to head, but will not flip the data.

The SRCINCSIGN and DSTINCSIGN bits apply to all descriptors used by that channel. Software should take care to set the starting source and/or destination address to the highest data address when decrementing.

#### 7.3.2.2 Loop Counter

Each channel has a LDMA\_CHx\_LOOP register that includes a loop counter field. To use looping, software should initialize the loop counter with the desired number of repetitions before enabling the transfer. A descriptor with the DECLOOPCNT bit set to TRUE will repeat the loop and decrement the loop counter until LOOPCNT = 0.

For a looping descriptor, with DECLOOPCNT=1, the LINK address in the LDMA\_CHx\_LINK register is used as the loop address. While LOOPCNT is greater than zero, the descriptor will execute and then the LDMA will load the next descriptor using the address specified in the LDMA\_CHx\_LINK register. This feature enables looping of multiple descriptors. To repeat a single descriptor, the LINK address of the descriptor should point to itself.

After LOOPCNT reaches zero, if the LINK bit in the descriptor LINK word is clear the transfer stops. If the LINK bit is set, the LDMA will load the next sequential descriptor located immediately following the looping descriptor. The behavior of the LINK bit is different for a looping descriptor. This is necessary because the LINK address is re-purposed as the loop address for a looping descriptor.

Note that LOOPCNT sets the number of repeats, not the number of iterations. The total number of loop iterations will be LOOPCNT plus 1. Normally, the LOOPCNT should be set to one or more repeats.

Also note that because there is only one LOOPCNT per channel, software intervention is required to update the LOOPCNT if a sequence of transfers contains multiple loops. It is also possible to use a write immediate DMA data transfer to update the LDMA\_CHx\_LOOP register.

### 7.3.3 Channel Select Configuration

The channel select block determines which peripheral request signal connects to each DMA channel.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA\_CHn\_REQSEL register. SOURCESEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

#### 7.3.4 Starting a Transfer

A transfer may be started by software, a peripheral request, or a descriptor load.

Software may initiate a transfer by setting the bit for the desired channel in the LDMA\_SREQ register. In this case the channel should set SOURCESEL to NONE to prevent unintentional triggering of the channel by a peripheral.

A peripheral may trigger the channel by configuring the peripheral source and signal as described in [7.3.3 Channel Select Configuration](#)

The LDMA may also be configured to begin a transfer immediately after a new descriptor is loaded by setting the STRUCTREQ field of the LDMA\_CHx\_CTRL register or descriptor word.

This configuration is done by software through the SOURCESEL and SIGSEL fields of the LDMA\_CHn\_REQSEL register. SOURCESEL selects the peripheral and SIGSEL picks which DMA request signals to use from the selected peripheral.

### 7.3.4.1 Peripheral Transfer Requests

By default peripherals issue a Single Request (SREQ) when any data is present. For peripherals with a data buffer or FIFO this occurs any time the FIFO is not empty. Upon receiving an SREQ the LDMA will perform one DMA transfer and stop till another request is made.

It is generally more efficient to wait for a peripheral to accumulate data and transfer in a burst. This both reduces overhead of the DMA engine and allows EM2 peripherals to save power by using the LDMA less often. To enable this set the IGNORESREQ bit in the LDMA\_CHx\_CTRL register (or descriptor) which will cause the LDMA to ignore SREQ's and wait for a full Request (REQ) signal. When the REQ is received the entire descriptor will be executed. For most peripherals with a FIFO the REQ signal is set when the FIFO is full, or a predetermined threshold has been reached. See the individual peripheral chapters for more information.

### 7.3.5 Managing Transfer Errors

LDMA transfer errors are normally managed using interrupts. Software should clear the ERROR flag in the bit in the LDMA\_IF register and enable error interrupts by setting the ERROR bit in the LDMA\_IEN register before initiating a DMA transfer.

The LDMA interrupt handler should check the ERROR flag bit in the LDMA\_IF register. If the ERROR flag bit is set, it should then read the CHERROR field in the LDMA\_STATUS register to determine the errant channel. The interrupt handler should reset the channel and clear the ERROR flag bit in the LDMA\_IF register before returning.

### 7.3.6 Arbitration

While multiple channels are configured simultaneously the LDMA engine can only be actively copying data for one channel at a time. Arbitration determines which channel is being serviced at any point in time. The LDMA will choose a channel through arbitration, transfer BLOCK\_SIZE elements of that channel and then arbitrate again choosing another channel to service. This allows high priority channels to be serviced while lower priority channels are in the middle of a transfer.

#### 7.3.6.1 Arbitration Priority

There are two modes in determining priority when the controller arbitrates: fixed priority and round robin priority.

In fixed priority mode, channel 0 has the highest priority. As the channel number increases, the priority decreases. When the LDMA controller is idle or when a transfer completes, the highest priority channel with an active request is granted the transfer. This mode guarantees smallest latency for the highest priority requesters. It is best suited for systems where peak bandwidth is well below LDMA controller's maximum ability to serve. The drawback of this mode is the possibility of starvation for lowest priority requesters.

In the round robin priority mode, each active requesting channel is serviced in the order of priority. A late arriving request on a higher priority channel will not get serviced until the next round. This mode minimizes the risk of starving low-priority latency-tolerant requesters. The drawback of this mode is higher risk of starving low-latency requesters.

The NUMFIXED field in the LDMA\_CTRL register determines which channels are fixed priority and which are round robin. Channels lower than NUMFIXED are fixed priority while those above it are round robin. A value of 0x0 implies all channels are round robin. A value of 0x4 implies channels 0 through 3 are fixed priority and 4 through 7 are round robin. A value of 7 implies that channels 0 through 6 are fixed and channel 7 is round robin. This is functionally equivalent to having 8 fixed priority channels.

Fixed priority channels always take priority over round robin. As long as NUMFIXED is greater than 0, there is a possibility that a higher priority channel can starve the remaining channels.

To address the drawbacks of using fixed priority or round robin priority the LDMA implements the concept of arbitration slots. This allows for channels to have high bandwidth and low latency while preventing starvation of latency tolerant low priority channels.

Each channel has a two bit ARBSLOT field in its LDM\_CHx\_CFG register. This field only applies to channels marked as round robin (determined by NUMFIXED). The channels in the same arbitration slot are treated equally with round robin scheduling. Channels marked with a higher arbitration slot will get serviced more frequently. By default all channels are placed in arbitration slot 1.

Every time the channels in slot 1 get serviced the channels in slot 2 get serviced twice, those in slot 4 get serviced 4 times, and those in slot 8 get serviced 7 times. The specific arbitration allocation can be seen by the following table. The highest arbitration slot is serviced every other arbitration cycle, allowing for low latency response. If there are no requests from channels in arbitration slot then that slot is immediately skipped.

**Table 7.1. Arbitration Slot Order**

| Arbslot order | 8 | 4 | 8 | 2 | 8 | 4 | 8 | 1 | 8 | 4 | 8 | 2 | 8 | 4 |
|---------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Arbslot1      |   |   |   |   |   |   |   | 1 |   |   |   |   |   |   |
| Arbslot2      |   |   |   | 1 |   |   |   |   |   |   |   | 1 |   |   |
| Arbslot4      |   | 1 |   |   |   | 1 |   |   |   | 1 |   |   |   | 1 |
| Arbslot8      | 1 |   | 1 |   | 1 |   | 1 |   | 1 |   | 1 |   | 1 |   |

The top row shows the order at which the arbitration slots are executed. The remaining part of the table shows a more visual interpretation of the arbitration order.

For example, if we have one low latency channel (CHNL0) and two latency tolerant channels (CHNL1 and CHNL2). We could use the following settings.

LDMA\_CTRL.NUMFIXED = 0; set round robin for all channels.

CHNL0\_CFG.ARBSLOTS = TWO;

CHNL1\_CFG.ARBSLOTS = ONE;

CHNL2\_CFG.ARBSLOTS = ONE;

If all channels are constantly requesting transfers, then the arbitration order is: CHNL0, CHNL1, CHNL0, CHNL2, CHNL0, CHNL1, CHNL0, CHNL2, CHNL0, etc

Note, there are no channels assigned to arbitration slot four or eight in this example, so those slots are skipped and the final sequence is ARBSLOT2, ARBSLOT1, ARBSLOT2, ARBSLOT1, etc...

Channel 1 and Channel 2 are selected in round robin order when arbitration slot 1 is executed.

If we replace the ARBSLOTS value for channel 0 with EIGHT, then the sequence would look like the following:

CHNL0, CHNL0, CHNL0, CHNL0, CHNL1, CHNL0, CHNL0, CHNL0, CHNL0, CHNL2, CHNL0, CHNL0, CHNL0, CHNL0, CHNL1, etc.

### 7.3.6.2 DMA Transfer Arbitration

In addition to the inter channel arbitration, software can configure when the controller arbitrates during a DMA transfer. This provides reduced latency to higher priority channels when configuring low priority transfers with more arbitration cycles.

The LDMA provides four bits that configure how many DMA transfers occur before it re-arbitrates. These bits are known as the BLOCKSIZE bits and they map to the arbitration rate as shown below. For example, if BLOCKSIZE = 4 then the arbitration rate is 6, that is, the controller arbitrates every 6 DMA transfers.

Table 7.2 AHB Bus Transfer Arbitration Interval on page 128 lists the arbitration rates.

**Table 7.2. AHB Bus Transfer Arbitration Interval**

| BLOCKSIZE | Arbitrate After x DMA transfers |
|-----------|---------------------------------|
| 0         | x = 1                           |
| 1         | x = 2                           |
| 2         | x = 3                           |
| 3         | x = 4                           |
| 4         | x = 6                           |
| 5         | x = 8                           |
| 6         | x = 12                          |
| 7         | x = 16                          |
| 8         | x = 24                          |
| 9         | x = 32                          |
| 10        | x = 64                          |
| 11        | x = 128                         |
| 12        | x = 256                         |
| 13        | x = 512                         |
| 14        | x = 1024                        |
| 15        | x = lock                        |

**Note:** Software must take care not to assign a low-priority channel with a large BLOCKSIZE because this prevents the controller from servicing high-priority requests, until it re-arbitrates.

The number of DMA transfers that need to be done is specified by the user in XFERCNT. When XFERCNT > BLOCKSIZE and is not an integer multiple of BLOCKSIZE then the controller always performs sequences of BLOCKSIZE transfers until XFERCNT < BLOCKSIZE remain to be transferred. The controller performs the remaining XFERCNT transfers at the end of the DMA cycle.

Software must store the value of the BLOCKSIZE bits in the channel control data structure. See 7.3.7.1 XFER Descriptor Structure for more information about the location of the BLOCKSIZE bits in the data structure.

### 7.3.7 Channel Descriptor Data Structure

Each channel descriptor consists of four 32-bit words:

- CTRL - control word contains information like transfer count and block size.
- SRC - source address points to where to copy data from
- DST - destination address points to where to copy data to
- LINK - link address points to where to load the next linked descriptor

These words map directly to the LDMA\_CHx\_CTRL, LDMA\_CHx\_SRC, LDMA\_CHx\_DST, and LDMA\_CHx\_LINK registers. The usage of the SRC and DST fields may differ depending on the structure type

There are three different types of descriptor data structures: **XFER**, **SYNC**, and **WRI**

#### 7.3.7.1 XFER Descriptor Structure

This descriptor defines a typical data transfer which may be a Normal, Link, or Loop transfer.

Only this structure type can be written directly into LDMA's registers by the CPU. All descriptors may be linked to. Refer to the register descriptions for additional information.

For specifying XFER structure type, set STRUCTTYPE to 0. See the peripheral register descriptions for information on the fields in this structure.

| LINK       | DST | SRC     | CTRL       | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | Name |
|------------|-----|---------|------------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|------|
|            |     |         |            | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 |      |
| LINKADDR   |     | SRCADDR | DSTMODE    | 31           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | Name |
|            |     |         | SRCMODE    | 30           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | DSTINC     | 29           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 28           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | SIZE       | 27           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 26           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | SRCINC     | 25           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 24           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | IGNORESREQ | 23           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | DECLOOPCNT | 22           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | REQMODE    | 21           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | DONEIFSEN  | 20           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         | BLOCKSIZE  | 19           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 18           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 17           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |
|            |     |         |            | 16           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |

### 7.3.7.2 SYNC Descriptor Structure

This descriptor defines an intra-channel synchronizing structure. It allows the channel to wait for some external stimulus before continuing on to the next descriptor. This structure is also used to provide stimulus to another channel to indicate that it may continue.

For example channel 1 may be configured to transfer a header into a buffer while channel 2 is simultaneously transferring data into the same structure. When channel 1 has completed it can wait for a sync signal from channel 2 before transferring the now complete buffer to a peripheral.

Sync descriptors do nothing until a condition is met. The condition is formed by the SYNCTRIG field in the LDMA\_SYNC register and the MATCHEN and MATCHVAL fields of the descriptor. When  $(\text{SYNCTRIG} \& \text{MATCHEN}) == (\text{MATCHVAL} \& \text{MATCHEN})$  the next descriptor is loaded. In addition to waiting for the condition a Link descriptor can set or clear bits in SYNCTRIG to meet the conditions of another channel and cause it to continue. The CPU also has the ability to set and clear the SYNCTRIG bits from software.

This structure type can only be linked in from memory.

For specifying SYNC structure type, set STRUCTTYPE to 1.

| Name | Bit Position |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |         |    |    |    |    |    |   |   |          |   |            |   |      |   |          |   |

| 15:8 | SYNCCLR    | <b>Sync Trigger Clear</b><br>This bit-field is used to clear corresponding bits within the SYNCTRIG field of the SYNC LDMA_SYNC register. To clear a given bit, a one should be loaded to the corresponding bit. Set is given priority over clear if both corresponding bits are loaded with a one. The sync trigger clear function can only be used when loaded from a linked structure. Alternately, the user can directly write the SYNCTRIG bit-field if required. |
| 7:0  | SYNCSET    | <b>Sync Trigger Set</b><br>This bit-field is used to set corresponding bits within the SYNCTRIG bit-field. To set a given bit, a one should be loaded to the corresponding bit. Set is given priority over clear if both corresponding bits are loaded with a one. The sync trigger set function can only be used when loaded from a linked structure. Alternately, the user can directly write the SYNCTRIG bit-field if required.                                    |
| 15:8 | MATCHEN    | <b>Sync Trigger Match Enable</b><br>This bit-field serves as the SYNCTRIG match enable. A sync match triggers the load of the next linked DMA structure as specified by link_mode, when: $(\text{SYNCTRIG} \& \text{MATCHEN}) == (\text{MATCHVAL} \& \text{MATCHEN})$ .                                                                                                                                                                                                |
| 7:0  | MATCHVAL   | <b>Sync Trigger Match Value</b>                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Bit                                                                                                                                                                                               | Name | Description |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|
| This bit-field serves as the SYNCTRIG match value. A sync match triggers the load of the next linked DMA structure as specified by link_mode, when: (SYNCTRIG & MATCHEN) == (MATCHVAL & MATCHEN). |      |             |

### 7.3.7.3 WRI Descriptor Structure

This descriptor defines a write-immediate structure. This allows a list of descriptors to write a value to a register or memory location. For example, if a channel wishes to perform two loops in a descriptor sequence a WRI may be used to program the loop count for the second loop.

This structure type can only be linked in from memory.

For specifying WRI structure type, set STRUCTTYPE to 2.

| Name | Bit Position |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |            |   |          |

### 7.3.8 Interaction With the EMU

The LDMA interacts with the Energy Management Unit (EMU) to allow transfers from a low energy peripheral while in EM2 DeepSleep. For example, when using the LEUART in EM2 DeepSleep the EMU can wake up the LDMA sufficiently long to allow data transfers to occur. See section "DMA Support" in the LEUART documentation.

Similarly, when using the ADC in EM2 DeepSleep or EM3 Stop the EMU can wake up the LDMA as needed to allow data transfers to occur.

[Table 7.3 List of Peripherals Capable of Waking Up LDMA in EM2 DeepSleep or EM3 Stop on page 132](#) shows complete list of peripherals that are capable of waking up LDMA via EMU in EM2 DeepSleep or EM3 Stop

**Table 7.3. List of Peripherals Capable of Waking Up LDMA in EM2 DeepSleep or EM3 Stop**

| Peripheral |
|------------|
| ADC0       |
| IDAC0      |
| LEUART0    |

### 7.3.9 Interrupts

The LDMA\_IF Interrupt flag register contains one DONE bit for each channel and one combined ERROR bit. When enabled, these interrupts are available as interrupts to the Cortex-M4 core. They are combined into one interrupt vector, DMA\_INT. If the interrupt for the DMA is enabled in the ARM Cortex-M4 core, an interrupt will be made if one or more of the interrupt flags in LDMA\_IF and their corresponding bits in LDMA\_IEN are set.

When a descriptor finishes execution the interrupt flag for that channel will be set if the DONEIFSEN field of the LDMA\_CHx\_LOOP register is set. If LINK and DONEIFSEN are both set when the descriptor completes the interrupt and the linked descriptor will be immediately loaded. When the final descriptor in a linked list (LINK = 0) is finished the interrupt flag is always set regardless of the state of DONEIFSEN.

### 7.3.10 Debugging

For a peripheral request DMA transfer, if software sets a bit for a channel in the LDMA\_DBGHALT register then the DMA will halt during a debug halt and the SRC and DST registers in the debug window will show the transfer in progress. Otherwise, during debug halt the DMA will continue to run and complete the entire transfer causing the descriptor registers to indicate the transfer has completed.

## 7.4 Examples

This section provides examples of common LDMA usage. All examples assume the LDMA is in the reset state with the channel being configured disabled and LDMA\_CHx\_CFG, LDMA\_CHx\_LOOP, and LDMA\_CHx\_LINK cleared.

### 7.4.1 Single Direct Register DMA Transfer

This simple example uses only the Channel Descriptor registers directly and does not use linking. Software writes directly to the LDMA channel registers. This example does not use a memory based descriptor list.

This example is suitable for most simple transfers that are limited to transferring one block of data. It supports anything that can be done using a single descriptor. This includes endian conversion and packing/unpacking data. Channel 0 is used for this example.

The LDMA will be used to copy 127 contiguous half words (254 bytes) from 0x0 to 0x1000. It will allow arbitration every 4 transfers and is triggered by a CPU write to the LDMA\_SWREQ register. The CH0 interrupt flag will be set when the transfer completes since the descriptor does not link to another descriptor.

- Configure LDMA\_CH0\_CTRL
  - DSTMODE = 0 (absolute)
  - SRCMODE = 0 (absolute)
  - SIZE = HALFWORD (16 bits)
  - DSTINC = 0 (1 half-word)
  - SRCINC = 0 (1 half-word)
  - DECLOOPCNT=0 (unused)
  - REQMODE = 1 (one request transfers all data)
  - BLOCKSIZE = 3 (4 transfers)
  - BYTESWAP=0 (no byte swap)
  - XFERCNT=127 (transfer 127 half words)
  - STRUCTTPYE=0 (TRANSFER)
- Write source address to LDMA\_CH0\_SRC register
- Write destination address to LDMA\_CH0\_DST register
- Configure the LDMA\_CH0REQSEL register for the desired peripheral or select none for a memory-to-memory transfer
- Clear and enable interrupts.
  - Write a 1 to bit 0 of the LDMA\_IFC register to clear the CH0 DONE flag
  - Write a 1 to bit 0 of the LDMA\_IEN register to enable the CH0 interrupt
- Write a 1 to bit 0 of the LDMA\_CHEN register to enable CH0

The REQMODE field is normally cleared to zero for a peripheral request transfer and will transfer the specified block size for each peripheral request. The REQMODE may be set to 1 for a memory-to-memory transfer or any time it is desired for a single DMA request to initiate complete transfer.

## 7.4.2 Descriptor Linked List

This example shows how to use a Linked List of descriptors. Each descriptor has a link address which points to the next descriptor in the list. A descriptor may be removed from the Linked list by altering the Link address of the one before it to point to the one after it. Descriptor Linked lists are useful when handling an array of buffers for communication data. For example, a bad packet can be removed from a receiver queue by simply removing the descriptor from the linked list.

Software loads the first descriptor into the DMA by writing the descriptor address to LDMA\_CHx\_LINK and setting the bit for that channel in the LDMA\_LINKLOAD register. This method is preferred when using a linked list in memory since it treats the first descriptor just like all the others. However, it is also allowed for software to write the first descriptor directly to the LDMA registers.

In this example 4 descriptors are executed in series. the interrupt flag is set after the 2nd and 4th (last) descriptors have completed.

- Prepare a list of descriptors using the XFER structure type in RAM
- Initialize the CTRL, SRC, and DST members as desired
  - Setting STRUCTREQ in the CTRL word for descriptors 2-4 will cause them to begin transferring data as soon as they are loaded.
- Write 0x00000013 to the LINK member of all but the last descriptor
  - LINKMODE = 1 (relative addressing)
  - LINK = 1 (Link to the next descriptor)
  - LINKADDR = 0x00000010 (size of descriptor)
- Set the DONEIFSEN bit in the CTRL member of the 2nd structure so that the interrupt flag will be set when it completes
- Write 0x00000000 to the LINK member of the last descriptor
  - LINK = 0 (Do not link to the next descriptor)
  - LINKMODE = 0 (don't care)
  - LINKADDR = 0x00000000 (don't care)

Each descriptor now points to the start of the next descriptor as shown on the left in [Figure 7.5 Descriptor Linked List on page 134](#). To remove a descriptor from the linked list modify the LINK address of the descriptor of the one before to point to the one after. For example to remove the third descriptor, add 0x00000010 to the LINK register of the second descriptor. The second descriptor will now point to the forth descriptor and skip over the third descriptor as shown on the right in [Figure 7.5 Descriptor Linked List on page 134](#).

Figure 7.5. Descriptor Linked List

To start execution of the linked list of descriptors:

- Write the absolute address of the first descriptor to the LINKADR field of the LDMA\_CH0\_LINK register
- Set the LINK bit of LDMA\_CH0\_LINK register.
- Configure the LDMA\_CH0REQSEL register for the desired peripheral or select none for memory-to-memory
- Clear and enable interrupts as desired
- Set bit 0 in the LDMA\_LINKLOAD register to initiate loading and execution of the first descriptor

Alternatively, software can manually copy the first descriptor contents to the LDMA\_CH0\_CTRL, LDMA\_CH0\_SRC, LDMA\_CH0\_DST, and LDMA\_CH0\_LINK registers and then enable the channel in the LDMA\_CHEN register.

### 7.4.3 Single Descriptor Looped Transfer

This example demonstrates how to use looping using a single descriptor. This method allows a single DMA transfer to be repeated a specified number of times. The looping descriptor is stored in memory and reloaded by hardware. After a specified number of iterations, the transfer stops.

CH0 is setup to copy 4 words from the ADC FIFO into a 15 word buffer at 0x1000. It repeats 4 times to fill the entire 16 word buffer. An interrupt will fire when the entire 16 words have been transferred.

Initialize the Linked descriptor in memory as follows:

- Configure CTRL member
  - DSTMODE = 0 (absolute)
  - SRCMODE = 0 (absolute)
  - SIZE = WORD
  - DSTINC = 0 (1 WORD)
  - SRCINC = 3 (0 WORDS)
  - DECLOOPCNT=1 (decrement loop count)
  - REQMODE=1 (Use XFERCNT)
  - BLOCKSIZE = 4 (4 words)
  - BYTESWAP=0 (no swap)
  - XFERCNT= 4 (4 words)
  - STRUCTTPYE=0 (TRANSFER)
  - IGNORESREQ=1 (ignore single requests)
- Write the address ADC0\_SINGLEDATA register to the SRC member
- Write 0x1000 address to DST member
- Configure the LINKLink member
  - LINK = 0 (stop after loop)
  - MODE = 1 (relative link address)
  - LINKADDR = 0 (point to ourself)
- Configure the Channel
  - Write the desired number of repeats to the LDMA\_CH0\_LOOP register
  - SOURCESEL in LDMA\_CH0REQSEL = ADC0 (select the ADC)
  - SIG in LDMA\_CH0REQSEL = ADC0SCAN (select the scan conversion request)
- Clear and enable interrupts
- Load the descriptor using LINKLOAD as described in [7.4.2 Descriptor Linked List](#)

**Figure 7.6. Single Descriptor Looped Transfer**

Note that the looping descriptor must be stored in memory, because it must load itself from the link address in memory on each iteration.

#### 7.4.4 Descriptor List With Looping

This example uses a descriptor list in memory with looping over multiple descriptors. This example also uses the looping feature and continues on with the next sequential descriptor after looping completes.

The descriptor list in memory is shown in figure [Figure 7.7 Descriptor List With Looping on page 137](#). Descriptor A links to descriptor B. Descriptor B has the DECLOOPCNT bit enabled and loops back to the start of descriptor A. The LINK address of descriptor B is used for the loop address. The LINK bit is set to indicate that execution will continue after completion of looping. Once the LOOPCNT reaches zero, the LDMA will load descriptor C. Descriptor C must be located immediately following descriptor B.

**Figure 7.7. Descriptor List With Looping**

Initialization is similar to the single looping descriptor with the following modifications.

- Set the LINK bit in descriptors A and B
- write the address of descriptor A into the LIKADDRESS of descriptor B
- write the address of descriptor B into the LIKADDRESS of descriptor A
- Descriptor C must be located immediately after descriptor B in memory

### 7.4.5 Simple Inter-Channel Synchronization

The LDMA controller features synchronization structures which allow differing channels and/or hardware events to pause a DMA sequence, and wait for a synchronizing event to restart it.

In this example DMA channel 0 and 1 are tasked with the transfer of different sets of data. Channel 0 has two transfer structures, and channel 1 just one, but channel 0 must wait until channel 1 has completed its transfer before it starts its second transfer structure.

Pausing channel 0 is accomplished by inserting a sync wait structure between the two transfer structures. This sync structure waits on SYNCCTRL[7] to be set by a sync set/clear structure which is controlled by channel 1. Sync structures do not transfer data, they can only set, clear, or wait to match the SYNCCTRL[7:0] bits. Note that sync structures cannot decrement loop counter.

```
LDMA_SYNC
  SYNCCTRL=0x0 (at time 0)

LDMA_CH0

  Structure A @ 0x00
  CTRL
    STRUCTTYPE=XFER
  LINK
    LINKADDR[29:0]=0x00000004
    LINK=1

  Structure B @ 0x10
  CTRL
    STRUCTTYPE=SYNC
  LINK
    LINKADDR[29:0]=0x00000008
    LINK=1
  DST
    MATCHEN=0x80
    MATCHVAL=0x80 (waits for SYNCCTRL[7]=1)

  Structure C @ 0x20
  CTRL
    STRUCTTYPE=XFER
  LINK
    LINKADDR[29:0]=NA
    LINK=0

LDMA_CH1

  Structure Y @ 0x30
  CTRL
    STRUCTTYPE=XFER
  LINK
    LINKADDR[29:0]=0x00000010
    LINK=1

  Structure Z @ 0x40
  CTRL
    STRUCTTYPE=SYNC
  LINK
    LINKADDR=NA
    LINK=0
  SRC
    SRCCLR=0x0
    SRCSET=0x80 (sets SYNCCTRL[7])
```

**Figure 7.8. Simple Intra-channel Synchronization Example**

Both A and Y effectively start at the same time. A finishes earlier, then it links to B, which waits for the SYNC[7] bit to be set before loading C. Y finishes after B is loaded, and it links to sync structure Z, which sets the SYNC[7] bit. Channel 0 responds to the trigger set by loading C for the final data transfer.

## 7.4.6 2D Copy

The LDMA can easily perform a 2D copy using a descriptor list with looping. This set up is visualized in [Figure 7.9 2D Copy on page 140](#).

For an application working with graphics, this would mean the ability to copy a rectangle of a given width and height from one picture to another.

**Figure 7.9. 2D Copy**

The first descriptor will use absolute addressing mode and the source and destination addresses should point to the desired target addresses. The first descriptor will copy only the first row. The XFERCNT of the first descriptor is set to the desired width minus one.

- CTRL
  - XFERCNT = WIDTH - 1
  - SRCMD = 0 (absolute)
  - DSTMD = 0 (absolute)
- SRCADDR = target source address
- DSTADDR = target destination address
- LINK = 0x00000013
  - LINK=1
  - LINKMD=1
  - LINKADDR=0x00000010 (point to next descriptor)

The second descriptor will use relative addressing and the source and destination addresses are set to the desired offset. After the completion of the first descriptor, the address registers will point to the last address transferred. Thus, the width must be subtracted from the stride to get the offset. The second descriptor uses looping and the link register has not offset.

- CTRL
  - XFERCNT = WIDTH - 1
  - SRCMD = 1 (relative)
  - DSTMD = 1 (relative)
  - DECLOOPCNT = 1
- SRCADDR = desired source offset (SRCSTRIDE-WIDTH)
- DSTADDR = desired destination offset (DSTSTRIDE-WIDTH)
- LINK = 0x00000001
  - LINK=0
  - LINKMD=1 (relative)
  - LINKADDR=0x00000000 (no offset)

Because the first descriptor already transferred one row, the number of looping repeats should be the desired height minus two. Therefore, LOOPCNT should be set to HEIGHT minus two before initiating the transfer.

This same method is easily extended to copy multiple rectangles by linking descriptors together. To initialize the LDMA\_CHx\_LOOP register, precede each descriptor pair described above with a write immediate descriptor which writes the desired value to the LOOPCNT field of the LDMA\_CHx\_LOOP register.

### 7.4.7 Ping-Pong

Communication peripherals often use ping-pong buffers. Ping-pong buffers allow the CPU to process data in one buffer while a peripheral transmits or receives data in the other buffer.

Both transmit and receive ping-pong buffers are easily implemented using the LDMA. In either case, this requires two descriptors as shown in [Figure 7.10 Infinite Ping-Pong Example on page 142](#). The LINKADDR field of the LINK member should point to the other descriptor. Using two adjacent descriptors and relative link addressing ensures the descriptors are easily reloadable.

Figure 7.10. Infinite Ping-Pong Example

A **receiver** ping-pong buffer controller consists of two buffers and two descriptors stored in memory that point to the two buffers. Once initialized, as the peripheral receives data, it will fill the first buffer. Once the first buffer is full, it will link automatically to the second buffer and generate an interrupt. Software will then process the data in the first buffer while the LDMA is transferring data to the second buffer. For a receiver ping-pong buffer each descriptor should link to the other descriptor. The link bit should be set to provide infinite ping pong between the two buffers. The DONIFS bit in each descriptor should be set to generate an interrupt on the completion of each descriptor.

- Descriptor A
  - CTRL
    - DONEIFS = 1
    - other settings as desired
  - SRCADDR = peripheral source address
  - DSTADDR = memory destination address
  - LINK = 0x00000013
    - LINKADDR = 0x00000010 (next descriptor)
    - LINK = 1 (link to next descriptor)
    - LINKMD = 1 (relative addressing)
- Descriptor B
  - CTRL
    - DONEIFS = 1
    - other settings as desired
  - SRCADDR = peripheral source address
  - DSTADDR = memory destination address
  - LINK = 0xFFFFFFFF3
    - LINKADDR = 0xFFFFFFFF0 (previous descriptor)
    - LINK = 1 (link to previous descriptor)
    - LINKMD = 1 (relative addressing)

For **transmitter** ping-pong buffer, software will fill the first buffer and then initiate the DMA transfer. The LDMA will transmit the first buffer data while software is filling the second buffer. In this case, the two descriptors should point to each other, but not automatically

continue to the second buffer. The LINK bit should be cleared to zero. Once software has loaded the first buffer, it will use the LINK-LOAD bit to load the first descriptor and transmit the data. The DONEIFS need not be set in each descriptor. The DMA will stop and then generate an interrupt at the completion of each descriptor.

- Descriptor A
  - CTRL
    - DONEIFS = 0
    - other settings as desired
  - SRCADDR = memory source address
  - DSTADDR = peripheral destination address
  - LINK = 0x00000013
    - LINKADDR = 0x00000010 (next descriptor)
    - LINK = 0 (link to next descriptor)
    - LINKMD = 1 (relative addressing)
- Descriptor B
  - CTRL
    - DONEIFS = 0
    - other settings as desired
  - SRCADDR = memory source address
  - DSTADDR = peripheral destination address
  - LINK = 0xFFFFFFFF3
    - LINKADDR = 0xFFFFFFFF0 (previous descriptor)
    - LINK = 0 (link to previous descriptor)
    - LINKMD = 1 (relative addressing)

#### 7.4.8 Scatter-Gather

Scatter-Gather in general refers to a process that copies data from multiple locations scattered in memory and gathers the data to a single location in memory, or vice versa. A simple descriptor list allows data gathering. For example, data from a discontinuous list of buffers might be copied to a contiguous sequential array of buffers. The inverse is also possible when a sequential array of buffers is scattered to a discontinuous list of available buffers. See section [7.4.2 Descriptor Linked List](#).

Some DMAs which only have two descriptors implement scatter-gather by using one descriptor to modify the other descriptor. While it is possible to implement this same behavior using the LDMA, it is much more straight-forward to just use a simple descriptor list.

## 7.5 Register Map

The offset register address is relative to the registers base address.

| Offset | Name            | Type  | Description                                             |
|--------|-----------------|-------|---------------------------------------------------------|
| 0x000  | LDMA_CTRL       | RW    | DMA Control Register                                    |
| 0x004  | LDMA_STATUS     | R     | DMA Status Register                                     |
| 0x008  | LDMA_SYNC       | RWH   | DMA Synchronization Trigger Register (Single-Cycle RMW) |
| 0x020  | LDMA_CHEN       | RWH   | DMA Channel Enable Register (Single-Cycle RMW)          |
| 0x024  | LDMA_CHBUSY     | R     | DMA Channel Busy Register                               |
| 0x028  | LDMA_CHDONE     | RWH   | DMA Channel Linking Done Register (Single-Cycle RMW)    |
| 0x02C  | LDMA_DBGHALT    | RW    | DMA Channel Debug Halt Register                         |
| 0x030  | LDMA_SWREQ      | W1    | DMA Channel Software Transfer Request Register          |
| 0x034  | LDMA_REQDIS     | RW    | DMA Channel Request Disable Register                    |
| 0x038  | LDMA_REQPEND    | R     | DMA Channel Requests Pending Register                   |
| 0x03C  | LDMA_LINKLOAD   | W1    | DMA Channel Link Load Register                          |
| 0x040  | LDMA_REQCLEAR   | W1    | DMA Channel Request Clear Register                      |
| 0x060  | LDMA_IF         | R     | Interrupt Flag Register                                 |
| 0x064  | LDMA_IFS        | W1    | Interrupt Flag Set Register                             |
| 0x068  | LDMA_IFC        | (R)W1 | Interrupt Flag Clear Register                           |
| 0x06C  | LDMA_IEN        | RW    | Interrupt Enable Register                               |
| 0x080  | LDMA_CH0_REQSEL | RW    | Channel Peripheral Request Select Register              |
| 0x084  | LDMA_CH0_CFG    | RW    | Channel Configuration Register                          |
| 0x088  | LDMA_CH0_LOOP   | RWH   | Channel Loop Counter Register                           |
| 0x08C  | LDMA_CH0_CTRL   | RWH   | Channel Descriptor Control Word Register                |

| 25:24 | SRCINC     | 0x0      | RWH    | <b>Source Address Increment Size</b><br>This bit-field specifies the stride or number of unit data addresses to increment the source address after each unit of data is transferred. The unit data width is controlled by the SIZE bit-field and can be a byte, half-word or word. |
|       | Value      | Mode     |        | Description                                                                                                                                                                                                                                                                        |
|       | 0          | ONE      |        | Increment source address by one unit data size after each read                                                                                                                                                                                                                     |
|       | 1          | TWO      |        | Increment source address by two unit data sizes after each read                                                                                                                                                                                                                    |
|       | 2          | FOUR     |        | Increment source address by four unit data sizes after each read                                                                                                                                                                                                                   |
|       | 3          | NONE     |        | Do not increment the source address. In this mode reads are made from a fixed source address, for example reading FIFO.                                                                                                                                                            |
| 23    | IGNORESREQ | 0        | RWH    | <b>Ignore Sreq</b><br>The channel arbiter will ignore single requests (SREQ) and only respond to multiple requests (REQ) when this bit is set.                                                                                                                                     |
| 22    | DECLOOPCNT | 0        | RWH    | <b>Decrement Loop Count</b><br>When using looping, setting this bit will decrement the LOOPCNT field in the LDMA_CHx_LOOP register after each descriptor execution.                                                                                                                |

|-------|----------|------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:2  | LINKADDR | 0x00000000 | RWH    | <b>Link Structure Address</b><br><br>To use linking, write the address of the the first linked descriptor to this register. When a linked descriptor is loaded, it may also be linked to another descriptor. Reading this register will reflect the address of the next linked descriptor.                 |
| 1     | LINK     | 0          | RWH    | <b>Link Next Structure</b><br><br>After completing the initial transfer, if this bit is set, the DMA will load the next linked descriptor. If the next linked descriptor also has this bit set, the DMA will load the next linked descriptor.                                                              |
| 0     | LINKMODE | 0          | R      | <b>Link Structure Addressing Mode</b><br><br>This field specifies the addressing mode of linked descriptors. After loading a linked descriptor, reading this field will indicate the addressing mode of the loaded linked descriptor. Note that the first descriptor always uses absolute addressing mode. |
| Value |          |            |        | Mode                                                                                                                                                                                                                                                                                                       |
| 0     |          |            |        | ABSOLUTE                                                                                                                                                                                                                                                                                                   |
|       |          |            |        | Description                                                                                                                                                                                                                                                                                                |
|       |          |            |        | The LINKADDR field of LDMA_CHx_LINK contains the absolute address of the linked descriptor.                                                                                                                                                                                                                |
| 1     |          |            |        | RELATIVE                                                                                                                                                                                                                                                                                                   |
|       |          |            |        | Description                                                                                                                                                                                                                                                                                                |
|       |          |            |        | The LINKADDR field of LDMA_CHx_LINK contains the relative offset of the linked descriptor.                                                                                                                                                                                                                 |

## 8. RMU - Reset Management Unit

### Quick Facts

#### What?

The RMU ensures correct reset operation. It is responsible for connecting the different reset sources to the reset lines of the EFM32 Gecko.

#### Why?

A correct reset sequence is needed to ensure safe and synchronous startup of the EFM32 Gecko. In the case of error situations such as power supply glitches or software crash, the RMU provides proper reset and startup of the EFM32 Gecko.

#### How?

The Power-on Reset and Brown-out Detector of the EFM32 Gecko provides power line monitoring with exceptionally low power consumption. The cause of the reset may be read from a register, thus providing software with information about the cause of the reset.

### 8.1 Introduction

The RMU is responsible for handling the reset functionality of the EFM32 Gecko.

### 8.2 Features

- Reset sources
  - Power-on Reset (POR)
  - Brown-out Detection (BOD) on the following power domains:
    - Analog Unregulated Power Domain AVDD
    - Digital Unregulated Power Domain DVDD
    - Regulated Digital Domain DECOUPLE (DEC)
  - RESETn pin reset
  - Watchdog reset
  - Software triggered reset (SYSRESETREQ)
  - Core LOCKUP condition
- EM4 Hibernate/Shutoff Detection
- EM4 Hibernate/Shutoff wakeup reset from GPIO pin
- Configurable reset levels
- A software readable register indicates the cause of the last reset

### 8.3 Functional Description

The RMU monitors each of the reset sources of the EFM32 Gecko. If one or more reset sources go active, the RMU applies reset to the EFM32 Gecko. When the reset sources go inactive the EFM32 Gecko starts up. At startup the EFM32 Gecko loads the stack pointer and program entry point from memory, and starts execution. [Figure 8.1 RMU Reset Input Sources and Connections on page 164](#) shows an overview of the reset system on EFM32 Gecko.

**Figure 8.1. RMU Reset Input Sources and Connections**

### 8.3.1 Reset Levels

The reset sources on EFM32 Gecko can be divided in two main groups; Hard resets and Soft resets.

The soft resets can be configured to be either DISABLED, LIMITED, EXTENDED or FULL. The reset level for soft reset sources is configured in the xxxRMODE bitfields in RMU\_CTRL.

**Table 8.1. Reset Levels**

| RMU_CTRL_xxxRMODE | Parts of System Reset                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------|
| DISABLED          | Nothing is reset, request will not be registered in RMU_RSTCAUSE                                   |
| LIMITED           | Everything reset, with exception of CRYOTIMER, DEBUGGER, RTCC, VMON and parts of CMU, RMU and EMU. |
| EXTENDED          | Everything reset, with exception of CRYOTIMER, DEBUGGER, and parts of CMU, RMU and EMU.            |
| FULL              | Everything reset, with exception of some registers in RMU and EMU.                                 |

The reset sources resulting in a soft reset are:

- Watchdog reset
- Lockup reset
- System reset request
- Pin reset (Pin reset can be configured to be either a soft or a hard reset, see [8.3.5 RESETn Pin Reset](#) for details.)

**Note:** LIMITED and EXTENDED resets are synchronized to HFSRCCLK. If HFSRCCLK is slow, there will be latency on reset assertion. If HFSRCCLK is not running, reset will be asserted after a timeout.

Hard resets will reset the entire chip, the reset sources resulting in a hard reset are:

- Power-on reset
- Brown-out reset
- Pin reset (Pin reset can be configured to be either a soft or a hard reset, see [8.3.5 RESETn Pin Reset](#) for details.)

### 8.3.2 RMU\_RSTCAUSE Register

Whenever a reset source is active, the corresponding bit in the RMU\_RSTCAUSE register is set. At startup the program code may investigate this register in order to determine the cause of the reset. The register is cleared upon POR and software write to RMU\_CMD\_RCCLR. The register should be cleared after the value has been read at startup, otherwise the register may indicate multiple causes for the reset at next startup.

RMU\_RSTCAUSE should be interpreted according to [Table 8.2 RMU Reset Cause Register Interpretation on page 166](#). In [Table 8.2 RMU Reset Cause Register Interpretation on page 166](#), the reset causes are ordered by severity from right to left. A reset cause bit is invalidated (i.e. can not be trusted) if one of the bits to the right of it does not match the table. X bits are don't care.

**Note:** It is possible to have multiple reset causes. For example, an external reset and a watchdog reset may happen simultaneously.

**Table 8.2. RMU Reset Cause Register Interpretation**

| RMU_RSTCAUSE                         |         |           |           |                  |        |          |          |       | Reset cause             |
|--------------------------------------|---------|-----------|-----------|------------------|--------|----------|----------|-------|-------------------------|
| EM4RST                               | WDOGRST | SYSREQRST | LOCKUPRST | EXTRST           | DECBOD | DVDDDBOD | AVDDDBOD | PORST |                         |
| X                                    | X       | X         | X         | X                | X      | X        | X        | 1     | Power on reset          |
| X                                    | X       | X         | X         | X                | X      | X        | 1        | 0     | Brown-out on AVDD power |
| X                                    | X       | X         | X         | X                | X      | 1        | X        | 0     | Brown-out on DVDD power |
| X                                    | X       | X         | X         | X                | 1      | X        | X        | 0     | Brown-out on DEC power  |
| X                                    | X       | X         | X         | 1                | X      | X        | X        | 0     | Pin reset               |
| X                                    | X       | X         | 1         | 0/X <sup>1</sup> | 0      | 0        | 0        | 0     | Lockup reset            |
| X                                    | X       | 1         | X         | 0/X <sup>1</sup> | 0      | 0        | 0        | 0     | System reset request    |
| X                                    | 1       | X         | X         | 0/X <sup>1</sup> | 0      | 0        | 0        | 0     | Watchdog reset          |
| 1                                    | X       | X         | X         | 0/X <sup>1</sup> | 0      | 0        | 0        | 0     | System has been in EM4  |
| 1. Pin reset configured as hard/soft |         |           |           |                  |        |          |          |       |                         |

### 8.3.3 Power-On Reset (POR)

The POR ensures that the EFM32 Gecko does not start up before the AVDD supply voltage has reached the threshold voltage  $V_{PORthr}$  (roughly 1.2V). Before the POR threshold voltage is reached, the EFM32 Gecko is kept in reset state. The operation of the POR is illustrated in [Figure 8.2 RMU Power-on Reset Operation on page 167](#), with the active low  $POWERONn$  reset signal. The reason for the “unknown” region is that the corresponding supply voltage is too low for any reliable operation.

Figure 8.2. RMU Power-on Reset Operation

### 8.3.4 Brown-Out Detector (BOD)

The EFM32 Gecko has 3 brownout detectors, one for the unregulated power (DVDD), one for the regulated internal power (DECOUPLE), and one for the Analog Power Domain (AVDD). The BODs are constantly monitoring these supply voltages. Whenever the unregulated or regulated power drops below the  $V_{BODthr}$  value (see the Electrical Characteristics section of the data sheet for details), or if AVDD drops below the voltage at the DECOUPLE pin, the corresponding active low  $BROWNOUTn$  line is held low. The BODs also include hysteresis, which prevents instability in the corresponding  $BROWNOUTn$  line when the supply is crossing the  $V_{BODthr}$  limit or the AVDD supply drops below the DECOUPLE pin. The operation of the BOD is illustrated in [Figure 8.3 RMU Brown-out Detector Operation on page 167](#). The “unknown” regions are handled by the POR module.

Figure 8.3. RMU Brown-out Detector Operation

### 8.3.5 RESETn Pin Reset

The pin reset on EFM32 Gecko can be configured to be either hard or soft. By default, pin reset is configured as a soft reset source. To configure it as a hard reset, clear the PINRESETSOFT bit in CLW0 in the Lock bit page, see [6.3.2 Lock Bits \(LB\) Page Description](#) for details. Forcing the RESETn pin low generates a reset of the EFM32 Gecko. The RESETn pin includes an on-chip pull-up resistor, and can therefore be left unconnected if no external reset source is needed. Also connected to the RESETn line is a filter which prevents glitches from resetting the EFM32 Gecko.

### 8.3.6 Watchdog Reset

The Watchdog circuit is a timer which (when enabled) must be cleared by software regularly. If software does not clear it, a Watchdog reset is activated. This functionality provides recovery from a software stalemate. Refer to the Watchdog section for specifications and description. The Watchdog reset can be configured to cause different levels of reset as determined by WDOGRMODE in the RMU\_CTRL register.

### 8.3.7 Lockup Reset

A Cortex-M4 lockup is the result of the core being locked up because of an unrecoverable exception following the activation of the processor's built-in system state protection hardware.

A Cortex-M4 lockup gives immediate indication of seriously errant kernel software. This is the result of the core being locked up due to an unrecoverable exception following the activation of the processor's built in system state protection hardware. For more information about the Cortex-M4 lockup conditions see the Architecture Reference Manual. The Lockup reset does not reset the Debug Interface, unless configured as a FULL reset. The Lockup reset can be configured to cause different levels of reset as determined by the LOCKUPRMODE bits in the RMU\_CTRL register. This includes disabling the reset.

### 8.3.8 System Reset Request

Software may initiate a reset (e.g. if it finds itself in a non-recoverable state). By asserting the SYSRESETREQ in the Application Interrupt and Reset Control Register, a reset is issued. The SYSRESETREQ does not reset the Debug Interface, unless configured as a FULL reset. The SYSRESETREQ reset can be configured to cause different levels of reset as determined by SYSRESETRMODE bits in the RMU\_CTRL register. This includes disabling the reset.

### 8.3.9 Reset State

The RESETSTATE bitfield in RMU\_CTRL is a read-write register intended for software use only, and can be used to keep track of state throughout a reset. This bitfield is only reset by POR and hard pin reset.

### 8.3.10 Register Reset Signals

[Figure 8.1 RMU Reset Input Sources and Connections on page 164](#) shows an overview of how the different parts of the design are affected by the different levels of reset. For RMU, EMU and CMU there are some exceptions. These are given in the following tables.

### 8.3.10.1 Registers With Alternate Reset

**Table 8.3. Alternate Reset for Registers in RMU**

| RMU Reset Levels       |                      |
|------------------------|----------------------|
| POR and hard pin reset | RMU_CTRL_WDOGRMODE   |
|                        | RMU_CTRL_LOCKUPRMODE |
|                        | RMU_CTRL_SYSRMODE    |
|                        | RMU_CTRL_PINRMODE    |
|                        | RMU_CTRL_RESETSTATE  |
| FULL reset             | RMU_LOCK_LOCKKEY     |

**Table 8.4. Alternate Reset for Registers in CMU**

| CMU Reset Levels |                |
|------------------|----------------|
| FULL reset       | CMU_LFRCOCTRL  |
|                  | CMU_LFXOCTRL   |
|                  | CMU_ULFRCOCTRL |
| EXTENDED reset   | CMU_LFECLKSEL  |
|                  | CMU_LFECLKEN0  |
|                  | CMU_LFEPRESC0  |

**Table 8.5. Alternate Reset for Registers in EMU**

| EMU Reset Levels             |                     |
|------------------------------|---------------------|
| POR, BOD, and hard pin reset | EMU_DCDCLNVCTRL     |
| POR, BOD, and hard pin reset | EMU_PWRCTRL         |
|                              | EMU_DCDCCTRL        |
|                              | EMU_DCDCMISCCTRL    |
|                              | EMU_DCDCZDETCTRL    |
|                              | EMU_DCDCCLIMCTRL    |
|                              | EMU_DCDCLNCOMPCTRL  |
|                              | EMU_DCDCTIMING      |
|                              | EMU_DCDCLPVCTRL     |
|                              | EMU_DCDCLPCTRL      |
|                              | EMU_DCDCLNFREQCTRL  |
| EXTENDED reset               | EMU_VMONAVDDCTRL    |
|                              | EMU_VMONALTAVDDCTRL |

## 8.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name         | Type | Description                 |
|--------|--------------|------|-----------------------------|
| 0x000  | RMU_CTRL     | RW   | Control Register            |
| 0x004  | RMU_RSTCAUSE | R    | Reset Cause Register        |
| 0x008  | RMU_CMD      | W1   | Command Register            |
| 0x00C  | RMU_RST      | RW   | Reset Control Register      |
| 0x010  | RMU_LOCK     | RWH  | Configuration Lock Register |

## 8.5 Register Description

### 8.5.1 RMU\_CTRL - Control Register

| Offset | Bit Position |    |    |    |    |    |            |    |    |    |    |    |    |    |    |    |    |          |    |    |    |          |   |   |   |     |   |             |   |   |     |   |  |           |  |  |

## 9. EMU - Energy Management Unit

### Quick Facts

#### What?

The EMU (Energy Management Unit) handles the different low energy modes in EFM32 Gecko

#### Why?

The need for performance and peripheral functions varies over time in most applications. By efficiently scaling the available resources in real time to match the demands of the application, the energy consumption can be kept at a minimum.

#### How?

With a broad selection of energy modes, a high number of low-energy peripherals available even in EM2 DeepSleep, and short wake-up time (2  $\mu$ s from EM2 DeepSleep and EM3 Stop), applications can dynamically minimize energy consumption during program execution.

### 9.1 Introduction

The Energy Management Unit (EMU) manages all the low energy modes (EM) in EFM32 Gecko. Each energy mode manages whether the CPU and the various peripherals are available. The energy modes range from EM0 Active to EM4 Shutoff. EM0 Active mode provides the highest amount of features, enabling the CPU, and peripherals with the highest clock frequency. EM4 Shutoff Mode provides the lowest power state, allowing the part to return to EM0 Active on a wake-up condition. The EMU also controls the various power routing configurations, internal regulators settings, and voltage monitoring needed for optimal power configuration and protection.

### 9.2 Features

The primary features of the EMU are listed below:

- Energy Modes control
  - Entry into EM4 Hibernate or EM4 Shutoff
  - Configuration of regulators and clocks for each Energy Mode
  - Configuration of various EM4 Hibernate/Shutoff wake-up conditions
  - Configuration of RAM power and retention settings
  - Configuration of GPIO retention settings
- Power routing configurations
  - DCDC control
  - Internal power switches allowing for extensible system power architecture
- Temperature measurement control and status
- Brown Out Detection
- Voltage Monitoring
  - Four dedicated continuous monitor channels
  - Optional monitor features include interrupt generation and low power mode wake-up
- State Retention

### 9.3 Functional Description

The EMU is responsible for managing the wide range of energy modes available in EFM32 Gecko. The block works in harmony with the entire platform to easily transition between energy modes in the most efficient manner possible. The following diagram [Figure 9.1 EMU Overview on page 177](#), shows the relative connectivity to the various blocks in the system.

**Figure 9.1. EMU Overview**

The EMU is available on the peripheral bus. The energy management state machine controls the internal voltage regulators, oscillators, memories, and interrupt system. Events, interrupts, and resets can trigger the energy management state machine to return to the active state. This is further described in the following sections.

The power architecture is highly configurable to meet system power performance needs. Several external power configurations are supported. The EMU allows flexible control of internal DCDC, Digital LDO Regulator, and internal power switching.

### 9.3.1 Energy Modes

EFM32 Gecko features six main energy modes, referred to as Energy Mode 0 (EM0 Active) through Energy Mode 4 (EM4 Shutoff). The Cortex-M4 is only available for program execution in EM0 Active. In EM0 Active/EM1 Sleep any peripheral function can be enabled. EM2 DeepSleep through EM4 Shutoff, also referred to as low energy modes, provide a significantly reduced energy consumption while still allowing a rich set of peripheral functionality. The following [Table 9.1 table on page 178](#) shows the possible transitions between different energy modes.

**Table 9.1. Energy Mode Transitions**

| Current Mode                                                                                            | EM Transition Action |                                     |                                      |                                      |                     |                   |

| EM4 Shutoff                                                                                             | Wake Up              |                                     |                                      |                                      |                     |                   |
| <b>Note:</b><br>1. Peripheral wake-up from EM2/3 to EM1 and then automatically back to EM2/3 when done. |                      |                                     |                                      |                                      |                     |                   |

The ADC and LEUART have the ability to temporarily wake up the part from either EM2 DeepSleep or EM3 Stop to EM1 Sleep in order to transfer data. Once completed, the part is automatically placed back into the EM2 DeepSleep or EM3 Stop mode.

The Core can always request to go to EM1 Sleep with the WFI or WFE command during EM0 Active. The core will be prevented from entering EM2 DeepSleep or EM3 Stop if Flash is programming or erasing.

An overview of supported energy modes and available functionality is shown in [Table 9.2 EMU Energy Mode Overview on page 178](#). For each energy mode, the system will typically default to its lowest power configuration, with non-essential clocks and peripherals disabled. Functionality may be then selectively enabled by software.

**Table 9.2. EMU Energy Mode Overview**

|                                       | EM0 Active/EM1 Sleep | EM2 Deep-Sleep         | EM3 Stop               | EM4 Hibernate            | EM4 Shutoff              |

The different energy modes are summarized in the following sections.

#### 9.3.1.1 EM0 Active

EM0 Active provides all system features.

- Cortex-M4 is executing code
- High and low frequency clock trees are active
- All oscillators are available
- All peripheral functionality is available

#### 9.3.1.2 EM1 Sleep

EM1 Sleep disables the core but leaves the remaining system fully available.

- Cortex-M4 is in sleep mode. Clocks to the core are off
- High and low frequency clock trees are active
- All oscillators are available
- All peripheral functionality is available

### 9.3.1.3 EM2 DeepSleep

This is the first level into the low power energy modes. Most of the high frequency peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- Cortex-M4 is in sleep mode. Clocks to the core are off.
- High frequency clock tree is inactive
- Low frequency clock tree is active
- The following oscillators are available
  - LFRCO, LFXO, ULFRCO, AUXHFRCO (on demand, if used by the ADC)
- The following low frequency peripherals are available
  - RTCC, WDOG, LEUART, LETIMER, LESENSE, PCNT, CRYOTIMER
- The following analog peripherals are available (with potential limitations on functionality)
  - ADC, IDAC
- Wake-up to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- RAM and register values are preserved
  - RAM blocks may be optionally powered down for lower power
- GPIO pin state is retained
- RTCC memory is retained
- The DC-DC converter can be configured to remain on in Low Power mode.

### 9.3.1.4 EM3 Stop

In this low energy mode, all low frequency oscillators (LFXO, LFRCO) and all low frequency clocks derived from them, are stopped, as well as all high frequency clocks. Most peripherals are disabled or have reduced functionality. Memory and registers retain their values.

- Cortex-M4 is in sleep mode. Clocks to the core are off.
- High frequency clock tree is inactive
- All low frequency clock trees derived from the low frequency oscillators (LFXO, LFRCO) are inactive
- The following oscillators are available
  - ULFRCO, AUXHFRCO (on demand, if used by the ADC)
- The following low frequency peripherals are available if clocked by the ULFRCO
  - RTCC, WDOG, CRYOTIMER
- The following analog peripherals are available (with potential limitations on functionality)
  - ADC, IDAC
- Wake-up to EM0 Active through
  - Peripheral interrupt, reset pin, power on reset, asynchronous pin interrupt, I2C address recognition, or ACMP edge interrupt
- RAM and register values are preserved
  - RAM blocks may be optionally powered down for lower power
- GPIO pin state is retained
- RTCC memory is retained
- The DC-DC converter can be configured to remain on in Low Power mode.

### 9.3.1.5 EM4 Hibernate

The majority of peripherals are shutoff to reduce leakage power. A few selected peripherals are available. System memory and registers do not retain values. GPIO PAD state and RTCC RAM are retained. Wake-up from EM4 Hibernate requires a reset to the system, returning it back to EM0 Active

- Cortex-M4 is off
- High frequency clock tree is off
- Some low frequency clock trees may be active
- The following oscillators are available
  - LFRCO, LFXO, ULFRCO
- The following low frequency peripherals are available
  - RTCC, CRYOTIMER
- Wake-up to EM0 Active through
  - VMON, EMU Temperature Sensor, RTCC, CRYOTIMER, reset pin, power on reset, asynchronous pin interrupt (on GPIO\_EM4WUX pins only)
- GPIO pin state may be retained (depending on EMU->EM4CTRL.EM4IORETMODE configuration)
- RTCC memory is retained
- The DC-DC converter can be configured to remain on in Low Power mode.

### 9.3.1.6 EM4 Shutoff

EM4 Shutoff is the lowest energy mode of the part. There is no retention except for GPIO PAD state. Wake-up from EM4 Shutoff requires a reset to the system, returning it back to EM0 Active

- Cortex-M4 is off
- High frequency clock tree is off
- Low frequency clock tree may be active
- The following oscillators are available
  - LFRCO, LFXO, ULFRCO
- The following low frequency peripherals are available
  - CRYOTIMER
- Wake-up to EM0 Active through
  - CRYOTIMER, reset pin, power on reset, asynchronous pin interrupt (on GPIO\_EM4WUX pins only)
- GPIO pin state may be retained (depending on EMU->EM4CTRL.EM4IORETMODE configuration)
- The DC-DC converter configuration is reset to its default Startup configuration (DC-DC converter disabled and bypass switch is on)

## 9.3.2 Entering Low Energy Modes

The following sections describe the requirements for entering the various energy modes.

### 9.3.2.1 Entry Into EM1 Sleep

Energy mode EM1 Sleep is entered when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit in the Cortex-M4 System Control Register is cleared. The MCU can re-enter sleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

Alternately, EM1 Sleep can be entered from either EM2 DeepSleep or EM3 Stop from a Peripheral Wake-up Request allowing transfers between the Peripheral and System RAM or Flash. On EFM32, ADC, IDAC, and LEUART peripherals can request this wake-up event. Refer to their respective register specification to enable this option. The system will return back to EM2 DeepSleep or EM3 Stop once the ADC, IDAC, or LEUART have completed its transfers and processing.

### 9.3.2.2 Entry Into EM2 DeepSleep or EM3 Stop

Energy mode EM2 DeepSleep or EM3 Stop may be entered when **all** of the following conditions are true:

- IDAC is currently not updating output.
- Cortex-M4 (if present) is in DEEPSLEEP state
- Flash Program/Erase Inactive
- DMA done with all current requests
- A debugger is not currently connected.

Entry into EM2 DeepSleep and EM3 Stop can be blocked by setting the EMU\_CTRL->EM2BLOCK bit.

**Note:** When EM2 DeepSleep or EM3 Stop entry is blocked, the part is not able to enter a lower energy state. The core will be in a sleep state, similar to EM1, where it is waiting for a proper interrupt of other valid wake-up event. Once the blocking conditions are removed, then the part will automatically enter a lower energy state.

Energy mode EM2 DeepSleep is entered from EM0 Active when the Cortex-M4 executes the Wait For Interrupt (WFI) or Wait For Event (WFE) instruction while the SLEEPDEEP bit in the Cortex-M4 System Control Register is set. The MCU can re-enter DeepSleep automatically out of an Interrupt Service Routine (ISR) if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set. Refer to ARM documentation on entering Sleep modes.

### 9.3.2.3 Entry Into EM4 Hibernate or EM4 Shutoff

Energy mode EM4 Hibernate and EM4 Shutoff is entered through register access.

Software must ensure no modules are active when entering EM4 Hibernate/Shutoff. EM4CTRL->EM4STATE field must be configured to select either Hibernate (EM4H) or Shutoff (EM4S) mode prior to entering EM4.

Software may enter EM4 Hibernate/Shutoff from EM0 Active by writing the sequence 2,3,2,3,2,3,2,3,2 to EM4CTRL->EM4ENTRY bit field. If the EM4BLOCK bit in WDOGn\_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

An active debugger connection will prevent entry into EM4 Hibernate/Shutoff.

Note that upon entry into EM4 Shutoff, the DC-DC converter configuration is reset to its default (i.e. Startup) configuration. In the Startup configuration, the DC-DC converter will be disabled and the bypass switch will be turned on.

### 9.3.3 Exiting a Low Energy Mode

A system in EM2 DeepSleep and EM3 Stop can be woken up to EM0 Active through regular interrupt requests from active peripherals. Since state and RAM retention is available, the EFM32 is fully restored and can continue to operate as before it went into the Low Energy Mode.

Wake-Up from EM4 Hibernate or EM4 Shutoff is performed through reset. Wake-Up from a specific module must be enabled in that module's EM4WUEN register.

Enabled interrupts that can cause wake-up from a low energy mode are shown in [Table 9.3 EMU Wake-Up Triggers from Low Energy Modes on page 184](#). The wake-up triggers always return the EFM32 to EM0 Active/EM1 Sleep. Additionally, any reset source will return to EM0 Active. VMON-based EM4 Hibernate wake-ups also set the corresponding rise or fall interrupt flag. These flags serve as the wake-up source for EM4 Hibernate and must be cleared by software on EM4 Hibernate exit. Not doing so will result in an immediate wake-up after next EM4 Hibernate entry.

**Table 9.3. EMU Wake-Up Triggers from Low Energy Modes**

| Peripheral               | Wake-Up Trigger                                                    | EM2 Deep-Sleep | EM3 Stop         | EM4 Hibernate       | EM4 Shutoff         |
|--------------------------|--------------------------------------------------------------------|----------------|------------------|---------------------|---------------------|
| LEUART (Low Energy UART) | Receive / transmit                                                 | Yes            | —                | —                   | —                   |
| LETIMER                  | Any enabled interrupt                                              | Yes            | —                | —                   | —                   |
| WDOG                     | Any enabled interrupt                                              | Yes            | Yes              | —                   | —                   |
| LFXO                     | Ready Interrupt                                                    | Yes            | —                | —                   | —                   |
| LFRCO                    | Ready Interrupt                                                    | Yes            | —                | —                   | —                   |
| I <sup>2</sup> C         | Receive address recognition                                        | Yes            | Yes              | —                   | —                   |
| ACMP                     | Any enabled edge interrupt                                         | Yes            | Yes              | —                   | —                   |
| ADC                      | SINGLE / SCAN FIFO events, window comparator, and VREF overvoltage | Yes            | Yes              | —                   | —                   |
| PCNT                     | Any enabled interrupt                                              | Yes            | Yes <sup>1</sup> | —                   | —                   |
|                          | Any enabled interrupt                                              | Yes            | Yes              | Yes <sup>2</sup>    |                     |
| VMON                     | Rising or falling edge on any monitored power                      | Yes            | Yes              | Yes <sup>2</sup>    | —                   |
| EMU Temperature Sensor   | Measured temperature outside the defined limits                    | Yes            | Yes              | Yes <sup>2</sup>    | —                   |
| CRYOTIMER                | Timeout                                                            | Yes            | Yes              | Yes <sup>2</sup>    | Yes <sup>2</sup>    |
| Pin Interrupts           | Transition                                                         | Yes            | Yes              | Yes <sup>2, 3</sup> | Yes <sup>2, 3</sup> |
| Reset Pin                | Assertion                                                          | Yes            | Yes              | Yes                 | Yes                 |
| Power                    | Cycle Off/On                                                       | Yes            | Yes              | Yes                 | Yes                 |

**Note:**

1. When using an external clock
2. Corresponding bit in the module's EM4WUEN must be set.
3. Only available on a subset of the pins. Refer to the data sheet for details.

### 9.3.4 Power Configurations

The EFM32 Gecko allows several power configurations with additional options giving flexible power architecture selection.

In order to provide the lowest power consuming solutions, the EFM32 Gecko comes with a DC-DC module to power internal circuits. The DC-DC requires an external inductor and capacitor (refer to the data sheet for recommended values).

The EFM32 Gecko has multiple internal power domains: IO Supply (IOVDD), Analog & Flash (AVDD), Input to Digital LDO (DVDD), and Low Voltage Digital Supply (DECOUPLE). Additional detail for each configuration and option is given in the following sections.

When assigning supply sources, the following requirement must be adhered to:

- VREGVDD = AVDD (Must be the highest voltage in the system)
- VREGVDD  $\geq$  DVDD
- VREGVDD  $\geq$  IOVDD
- DVDD  $\geq$  DECOUPLE

The system boots up into a safe power state, but must be immediately programmed to the desired configuration by writing to the EMU\_PWRCFG->PWRCFG bitfield. Out of POR, the PWRCFG is set to STARTUP, locking access to various power control registers. Once written, the PWRCFG cannot be changed.

### 9.3.4.1 Power Configuration 0: STARTUP

Upon power-on reset (POR) or entry into EM4 Shutoff, the system is configured in a safe Startup Configuration that supports all of the available Power Configurations. The Startup Configuration is shown in the simplified diagram below.

In the Startup Configuration:

- The DC-DC converter's Bypass switch is ON (i.e., the VREGVDD pin is shorted internally to the DVDD pin).
- The internal digital LDO is powered from the DVDD pin.
- The analog blocks are powered from the AVDD supply pin (i.e., ANASW=0).

After power on, firmware can configure the device based on the external hardware configuration. Note that the PWRCFG register can only be written once to a valid value and is then locked. This should be done immediately out of boot to select the proper power configuration. The DCDC and PWRCTRL registers will be locked until the PWRCFG register is configured.

Figure 9.2. Startup Power Configuration

### 9.3.4.2 Power Configuration 1: No DC-DC

In Power Configuration 1, the DC-DC converter is programmed in Off mode and the Bypass switch is Off. The DVDD pin must be powered externally - typically, DVDD is connected to the main supply. IOVDD and AVDD are powered from the main supply as well.

VREGSW must be left disconnected in this configuration.

Figure 9.3. DC-DC Off Power Configuration

### 9.3.4.3 Power Configuration 2: DC-DC

For the lowest power applications, the DC-DC converter can be used to power the DVDD supply.

In Power Configuration 2, the DC-DC Output ( $V_{DCDC}$ ) is connected to DVDD. DVDD powers the internal Digital LDO which powers the digital circuits. AVDD is connected to the main supply voltage. The internal analog blocks may be powered from AVDD or DVDD, depending on the ANASW configuration. IOVDD could be connected to either the main supply (as shown below) or to  $V_{DCDC}$ , depending on the system IO requirements.

**Figure 9.4. DC-DC Standard Power Configuration**

As the Main Supply voltage approaches the DC-DC output voltage, it eventually reaches a point where becomes inefficient (or impossible) for the DC-DC module to regulate  $V_{DCDC}$ . At this point, firmware can enable bypass mode, which effectively disables the DC-DC and shorts the Main Supply voltage directly to the DC-DC output. If and when sufficient voltage margin on the Main Supply returns, the system can be switched back into DC-DC regulation mode.

### 9.3.5 DC-to-DC Interface

The EFM32 Gecko devices feature a DC-DC buck converter which requires a single external inductor and a single external capacitor. The converter takes the VREGVDD input voltage and converts it down to an output voltage between VREGVDD and 1.8 V with a peak efficiency of approximately 90% in Low Noise (LN) mode and 85% in Low Power (LP) mode. Refer to the data sheet for full DC-DC specifications.

The DC-DC converter operates in either Low Noise (LN) or Low Power (LP) mode. LN mode is intended for higher current operation (e.g., EM0), whereas LP mode is intended for very low current operation (e.g., EM2 and below).

The DC-DC may be configured to automatically transition from LN mode in EM0/EM1 to LP mode in EM2, EM3, or EM4.

In addition, the DC-DC converter supports an unregulated Bypass mode, in which the input voltage is directly shorted to the DC-DC output.

### 9.3.5.1 Bypass Mode

In Bypass mode, the VREGVDD input voltage is directly shorted to the DC-DC converter output through an internal switch. Out of reset, the DC-DC converter defaults to Bypass mode. Consult the data sheet for the Bypass switch impedance specification.

The Bypass Current Limit limits the maximum current drawn from the input supply in Bypass mode. This current limit is enabled by setting the BYPLIMEN bit in the EMU\_DCDCCLIMCTRL register, and the limit value may be adjusted between 20 mA and 320 mA using the BYPLIMSEL bitfield in the EMU\_DCDCMISCCTRL register. When the difference between the DC-DC output voltage ( $V_{DCDC}$ ) and the DC-DC input voltage (VREGVDD) is large, applications should enable the Bypass Current Limit before enabling Bypass mode. For example, if Bypass mode is enabled with VREGVDD=3.8 V and  $V_{DCDC}$ =1.8 V with a 4.7  $\mu$ F capacitor, the peak current draw may be quite large as it is limited only by the bypass switch on-resistance, which could result in drooping on the input supply voltage. For smaller input / output voltage differences (e.g., VREGVDD=2.4 V and  $V_{DCDC}$ =1.8 V), it may not be necessary to enable the Bypass Current Limit at all.

Note that the device will see an additional ~10  $\mu$ A of current draw when both the Bypass Current Limiter and Bypass Mode are enabled. Applications should therefore disable the Bypass Current Limiter (i.e., set BYPLIMEN = 0) after the DVDD voltage has reached the main supply voltage in Bypass Mode.

### 9.3.5.2 Low Power (LP) Mode

The Low Power (LP) controller operates in a hysteretic mode to keep the output voltage within a defined voltage band. Once the DC-DC output voltage drops below a programmable internal reference, the LP controller generates a pulse train to control the powertrain PFET switch, which charges up the DC-DC output capacitor. When the output voltage is at the programmed upper level, the powertrain PFET is turned off. The output ripple voltage may be quite large (>100 mV) in LP mode.

The LP controller supports load currents up to approximately 10 mA, making it suitable for EM2, EM3, or EM4 low energy modes.

### 9.3.5.3 Low Noise (LN) Mode

The Low Noise (LN) controller continuously switches the powertrain NFET and PFET switches to maintain a constant programmed voltage at the DVDD pin. The LN controller supports load current from sub-mA up to 200 mA.

The LN controller switching frequency is programmable using the RCOBAND bitfield in the EMU\_DCDCCLNFREQCTRL register. See below for recommended RCOBAND settings for each mode.

The DC-DC Low Noise controller operates in one of two modes:

1. Continuous Conduction Mode (CCM)
2. Discontinuous Conduction Mode (DCM)

#### 9.3.5.3.1 Low Noise (LN) Continuous Conduction Mode (CCM)

CCM operation is configured by setting the LNFORCECCM bit in the EMU\_DCDCMISCCTRL register. CCM can be used to improve the DC-DC converter's output transient response time to quick load current changes, which minimizes voltage transients on the DC-DC output.

Note that all references to CCM in the documentation actually refer to Forced Continuous Conduction Mode (FCCM) - that is, if the LNFORCECCM bit is set and the output load current is very low, the DC-DC will be forced to operate in CCM. In this case, the current through the inductor may be negative and current may flow back into the battery.

In CCM, the recommended DC-DC converter switching frequency is 6.4 MHz (RCOBAND = 4).

#### 9.3.5.3.2 Low Noise (LN) Discontinuous Conduction Mode (DCM)

To enable DCM, the LNFORCECCM bit in EMU\_DCDCMISCCTRL must be cleared before entering LN. Typically, this configuration would occur while the part was in Bypass mode. Once DCM is enabled, the DC-DC should operate in DCM at light load currents. However, as the load current increases, the DC-DC will automatically transition into CCM without software intervention.

The advantage of DCM is improved efficiency for light load currents. However, in DCM the DC-DC has poorer dynamic response to changes in load current, leading to potentially larger changes in the regulated output voltage. For these reasons, DCM is not recommended for applications that expect large instantaneous load current steps. For example, if the DC-DC is in DCM, firmware may need to increment the core clock frequency in small steps to prevent a large sudden load increase.

In DCM, the recommended DC-DC converter switching frequency is 3 MHz (RCOBAND = 0).

### 9.3.5.4 DC-to-DC Programming Guidelines

**Note:** Refer to Application Note *AN0948: EFM32 and EFR32 Series 1 Power Configurations and DC-DC* for detailed information on programming the DC-DC. Application Notes can be found on the Silicon Labs website ([www.silabs.com/32bit-appnotes](http://www.silabs.com/32bit-appnotes)) or using the [Application Notes] tile in Simplicity Studio.

### 9.3.6 Analog Peripheral Power Selection

The analog peripherals (e.g., ULFRCO, LFRCO, LFXO, HFRCO, AUXHFRCO, VMON, IDAC, ADC) are powered from an internal analog supply domain, VDDX\_ANA. VDDX\_ANA may be supplied from either the AVDD or DVDD supply pins, depending on the configuration of the ANASW bit in the EMU\_PWRCTRL register. Changes to the ANASW setting should be made immediately out of reset (i.e., in the Startup Configuration), before all clocks (with the exception of HFRCO and ULFRCO) are enabled. If the DCDC converter is used and ANASW is set to 1, the switch will not take effect until after the DCDC output voltage has reached its target level. To prevent supply transients, firmware should configure and enable the DCDC, configure ANASW, and then enable clocks.

Once ANASW is configured it should not be changed. Note that the flash is always powered from the AVDD pin, regardless of the state of the ANASW bit.

**Table 9.4. Analog Peripheral Power Configuration**

| ANASW       | Analog Peripheral Power Supply Source (VDDX_ANA) | Comments                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (default) | AVDD pin                                         | This configuration may provide a quieter supply to the analog modules, but is less efficient as AVDD is typically at a higher voltage than DVDD.                                                                                                                                                |
| 1           | DVDD pin                                         | This configuration may provide a noisier supply to the analog modules, but is more efficient. However, because the maximum allowable input voltage to many of the analog modules using APORT is limited to MIN(VDDX_ANA, IOVDD), this setting could artificially limit your analog input range. |

### 9.3.7 IOVDD Connection

The IOVDD supply(s) must be less than or equal to AVDD. IOVDD will typically be connected to either the DC-DC Output ( $V_{DCDC}$ ) or the main supply.

When IOVDD is powered from the  $V_{DCDC}$ , any circuit attached to IOVDD must be capable of withstanding the main supply voltage momentarily. This is because the bypass switch is on at startup, shorting the main supply to DVDD and  $V_{DCDC}$ .

Any application with powering external loads from the DC-DC converter must take into consideration the maximum allowable DC-DC load current. Refer to the data sheet for DC-DC load current specification.

### 9.3.8 Brown Out Detector (BOD)

The EFM32 Gecko contains multiple supply brown out detectors (BODs).

#### 9.3.8.1 AVDD BOD

The EFM32 Gecko has a fast response BOD on AVDD that is always active. This BOD ensures the minimal supply is provided to the AVDD supply (typically also connected to VREGVDD). Once triggered, the BOD will cause the system to reset.

**Note:** In EM4 Hibernate/Shutoff a low power version of the AVDD BOD, called EM4BOD, is available to trigger a reset at level lower than in other energy modes. All other BODs are disabled during EM4 Hibernate/Shutoff

#### 9.3.8.2 DVDD and DECOUPLE BOD

Additional BODs will monitor DVDD and DECOUPLE during EM0 Active through EM3 Stop. This can cause a reset to the internal logic, but will not cause a power-on reset or reset the EMU or RTCC.

### 9.3.9 Voltage Monitor (VMON)

The EFM32 features an extremely low energy Voltage Monitor (VMON) capable of running down to EM4 Hibernate. Trigger points are preloaded but may be reconfigured.

- AVDD X 2
- DVDD
- IOVDD0

**Table 9.5. VMON Events**

| Feature                                      | Condition    | AVDD | DVDD | IOVDD |
|----------------------------------------------|--------------|------|------|-------|
| Hysteresis (separate rise and fall triggers) | —            | Yes  | —    | —     |
| Interrupt                                    | Fall or Rise | Yes  | Yes  | Yes   |
| Wake-Up from EM4 Hibernate                   | Fall or Rise | Yes  | Yes  | Yes   |

The status of the VMON is reflected in the EMU\_STATUS register.

The status of the sticky interrupt can be found at EMU\_IF. These interrupt flags also serve as the wake-up source of EM4H when the associated RISEWU and FALLWU bits are set. This means that if these flags are set, EM4H entry will result in an immediate wake-up. To prevent this, these must be cleared by software before EM4H entry.

Note that the VMON has offset high hysteresis, specified in the device Data Sheet. For rising edge detection the threshold will be the threshold setting (as described below) +  $V_{VMON\_HST}$ , and for falling edge detection the threshold will simply be the threshold setting.

VMON channels are calibrated at two voltages: 1.86 V and 2.98 V. The calibration results (coarse thresholds and fine thresholds for 1.86 V and 2.98 V) are placed in the VMONCAL registers in the DI page. Using these thresholds it is possible to calculate thresholds for the entire supported VMON VDD range, i.e., 1.62 V to 3.4 V. Using the values given in VMONCAL registers, one can calculate  $T_{1.86}$ ,  $T_{2.98}$ ,  $V_a$  and  $V_b$ .

$$T_{1.86} = (10 \times VMONCALX\_XVDD1V86THRESCOARSE) + VMONCALX\_XVDD1V86THRESFINE,$$

$$T_{2.98} = (10 \times VMONCALX\_XVDD2V98THRESCOARSE) + VMONCALX\_XVDD2V98THRESFINE,$$

$$V_a = (1.12) / (T_{2.98} - T_{1.86}),$$

$$V_b = 1.86 - (V_a \times T_{1.86}),$$

**Figure 9.5. VMON Calibration Equations**

Now if it is required to find the coarse and fine thresholds for a certain voltage Y, following equation can be used:

$$Thres_Y = (Y - V_b) / V_a,$$

$$Y_{calib} = (Thres_Y \times V_a) + V_b,$$

**Figure 9.6. VMON Threshold Equations**

$Thres_Y$  should be rounded to the nearest integer. The least significant digit of the rounded  $Thres_Y$  gives the fine threshold and remaining digits give the coarse threshold for Y. These can now be programmed in the relevant EMU\_VMONXVDDCTRL register as the coarse and fine thresholds. It may not be possible to set threshold exactly for Y. In that case the closest possible voltage is used.  $Y_{calib}$  gives the value of this closest possible voltage.

Consider the example where it is required to set the AVDD rise threshold to 2.2 V (so  $Y=2.2$  V). This means that the EMU\_VMONXVDDCTRL\_RISETHRESCOARSE and EMU\_VMONXVDDCTRL\_RISETHRESFINE need to be programmed. Here are the steps that should be followed:

- Check VMONCAL0 register. It has the VMON AVDD channel calibrated thresholds for 1.86 V and 2.98 V. Lets assume that the following values are present in the associated bitfields:
  - AVDD1V86THRESCOARSE = 3
  - AVDD1V86THRESFINE = 5
  - AVDD2V98THRESCOARSE = 8
  - AVDD2V98THRESFINE = 7

- Using the above numbers and the VMON calibration equations:
  - $T_{1.86} = 35$
  - $T_{2.98} = 87$
  - $V_a = 21.53 \text{ mV}$
  - $V_b = 1.106 \text{ V}$
- Using the VMON threshold equations (with  $Y=2.2 \text{ V}$ ),  $\text{Thres}_Y = 51$  (rounded from 50.8) and  $Y_{\text{calib}} = 2.204 \text{ V}$

EMU\_VMONAVDDCTRL\_RISETHRESCOARSE should be programmed to 5 and EMU\_VMONAVDDCTRL\_RISETHRESFINE should be programmed to 1 (since  $\text{Thres}_Y = 51$ ). With these programmed values, VMON AVDD rise threshold is set for  $Y_{\text{calib}} = 2.204 \text{ V}$ , which is the closest programmable threshold.

### 9.3.10 Powering Off SRAM Blocks

SRAM blocks may be powered off using the EMU\_RAMxCTRL RAMPOWERDOWN and RAMHPOWERDOWN fields. Selected blocks are powered down in order from the highest to lowest address in each bank. The lowest SRAM block in RAM0 cannot be powered off and will always remain powered on for proper system functionality. The stack must be located in retained memory. Refer to the EMU\_RAMxCTRL register descriptions for power configuration options and the associated address ranges.

### 9.3.11 Temperature Sensor

EMU provides low energy periodic temperature measurement. A temperature measurement is taken every 250 ms, with the 8-bit result stored in EMU->TEMP register.

**Note:** The EMU temperature sensor is always running (except in EM4 Shutoff) and is independent from the ADC temperature sensor.

The EMU provides the following features around temperature changes

- Wake-Up from EM4 Hibernate on Temperature Change
- Interrupt from High Level Trip
- Interrupt from Low Level Trip

During production test, the EMU temperature sensor for each device is calibrated at room temperature, with the corresponding calibration temperature and reading stored off in the DI page as follows:

- DEVINFO->CAL.TEMP : This bitfield contains the temperature in degrees C at calibration
- DEVINFO->EMUTEMP : This register contains the EMU->TEMP reading at the calibration temperature stored in DEVINFO->CAL.TEMP

The current calibrated EMU temperature sensor result from EMU->TEMP may be converted to degrees C using the following equation:

$$T_{J\_EMU} [^{\circ}\text{C}] = ( \text{DEVINFO->CAL.TEMP} ) + (\text{TEMPCO}_{\text{EMxx}}) * [ (\text{DEVINFO->EMUTEMP}) - (\text{EMU->TEMP}) ]$$

**Figure 9.7. Temperature Calculation**

$\text{TEMPCO}_{\text{EMxx}}$  is a temperature coefficient that varies based on the energy mode at the time of the EMU temperature sensor reading:

- $\text{TEMPCO}_{\text{EM01}} = 0.278 + (\text{DEVINFO->EMUTEMP}) / 100$
- $\text{TEMPCO}_{\text{EM234}} = 0.268 + (\text{DEVINFO->EMUTEMP}) / 100$

For maximum accuracy when using the high/low level temperature interrupts, firmware should ensure that  $\text{TEMPCO}_{\text{EM234}}$  is used to set the temperature thresholds in EMU->TEMPLIMITS before entering EM2/3/4. Similarly, when exiting EM2/3/4, the temperature thresholds should be updated using  $\text{TEMPCO}_{\text{EM01}}$ .

Note that an increasing reading in EMU->TEMP corresponds to a decreasing temperature, and vice-versa. If enabled, the TEMPHIGH High Level Limit in EMU->TEMPLIMITS causes an interrupt flag on a increasing EMU->TEMP reading (i.e., decreasing temperature). Similarly, the TEMPLOW Low Level Limit causes a interrupt flag on a decreasing EMU->TEMP reading (i.e., increasing temperature).

The EMU temperature sensor accuracy is approximately  $\pm 10^{\circ}\text{C}$  over most of the useable temperature range, but may be  $+15^{\circ}\text{C}$  at higher temperatures. Accordingly, any use of the EMU temperature sensor should include margin to account for that accuracy.

### 9.3.12 Registers latched in EM4

The following registers will be latched when entering EM4. After wake-up from EM4, these registers will be reset and require reprogramming prior to writing the EMU\_CMD\_EM4UNLATCH command.

- CMU\_LFRCOCTRL
- CMU\_LFXOCTRL
- CMU\_ULFRCOCTRL
- CMU\_LFECLKSEL
- CMU\_LFECLKEN0
- CMU\_LFEPRESC0

### 9.3.13 Register Resets

Each EMU register requires retaining state in various energy modes and power transitions and will consequently need to be reset with a different condition. The following reset conditions will apply to the appropriate set of registers as marked in the Register Description table.

- Reset with POR or Hard Pin Reset
- Reset with POR, Hard Pin Reset, or any BOD reset
- Reset with SYSEXTENDEDRESETn
- Reset with FULLRESETn (default)

If a register field is not marked with a specific reset condition then it is assumed to be reset with FULLRESETn.

## 9.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                | Type  | Description                                                  |
|--------|---------------------|-------|--------------------------------------------------------------|
| 0x000  | EMU_CTRL            | RW    | Control Register                                             |
| 0x004  | EMU_STATUS          | R     | Status Register                                              |
| 0x008  | EMU_LOCK            | RWH   | Configuration Lock Register                                  |
| 0x00C  | EMU_RAM0CTRL        | RW    | Memory Control Register                                      |
| 0x010  | EMU_CMD             | W1    | Command Register                                             |
| 0x018  | EMU_EM4CTRL         | RW    | EM4 Control Register                                         |
| 0x01C  | EMU_TEMPLIMITS      | RW    | Temperature Limits for Interrupt Generation                  |
| 0x020  | EMU_TEMP            | R     | Value of Last Temperature Measurement                        |
| 0x024  | EMU_IF              | R     | Interrupt Flag Register                                      |
| 0x028  | EMU_IFS             | W1    | Interrupt Flag Set Register                                  |
| 0x02C  | EMU_IFC             | (R)W1 | Interrupt Flag Clear Register                                |
| 0x030  | EMU_IEN             | RW    | Interrupt Enable Register                                    |
| 0x034  | EMU_PWRLOCK         | RW    | Regulator and Supply Lock Register                           |
| 0x038  | EMU_PWRCFG          | RW    | Power Configuration Register                                 |
| 0x03C  | EMU_PWRCTRL         | RW    | Power Control Register                                       |
| 0x040  | EMU_DCDCCTRL        | RW    | DCDC Control                                                 |

Upon wakeup, these registers will be reset and can have contradictory values to the latched values. To ensure a seamless transition from EM4 to EM0, the unlatch command should be given after properly reconfiguring these latched registers. The unlatch command can be executed after any reset condition but is only needed after EM4 wakeup. |

| 26:24 | LNCLIMILIMSEL | 0x3                                                                                                                      | RW     | <b>Current Limit Level Selection for Current Limiter in LN Mode</b><br><br>High-side current limiter's current limit level selection in low noise mode. The recommended setting is calculated by LNCLIMILIMSEL=(I_MAX+40mA)*1.5/(5mA*(PFETCNT+1))-1, where I_MAX is the maximum average current allowed to the load, and 40mA represents the current ripple with some margin, and the factor of 1.5 accounts for detecting error and other variations. For strong (i.e., low internal impedance) battery, it is recommended to have I_MAX=200mA. I_MAX should never be set higher than 200mA to avoid reliability issues. Reset with POR, Hard Pin Reset, or BOD reset. |       |      |             |   |       |                                      |   |       |                                       |   |       |                                       |   |       |                                      |

| 6:4   | ZDETILIMSEL  | 0x3                                                                                                                      | RW     | <b>Reverse Current Limit Level Selection for Zero Detector</b><br><br>Zero detector is reconfigured as low-side reverse current limiter when LNFORCECCM=1 in LN mode. The configuration of this register is calculated by the allowed average reverse current $I_{RMAX}$ through the equation: $ZDETILIMSEL = (I_{RMAX} + 40mA) * 1.5 / (2.5mA * (NFETCNT + 1))$ , where 40mA represents the current ripple with some margin, and the factor of 1.5 accounts for detecting error and other variations. When the battery can tolerate large reverse current, it is recommended to have $I_{RMAX} = 160mA$ to maximize ZDETILIMSEL to 7 with NFETCNT=15. Note that when LNFORCECCM=1 but ZDETILIMSEL=0, the DCDC's behavior will be very similar to when LNFORCECCM=0 - that is, the DCDC will be in DCM mode. When LNFORCECCM=0, the zero detector will only detect zero-crossings (reverse-current limit=0 mA) and this register is ignored. Reset with POR, Hard Pin Reset, or BOD reset. |

Setting this bit limits maximum current drawn from DCDC input supply while DCDC is in BY-PASS mode. Note that the device will see an additional ~10 µA of current draw when BYPLIMEN=1 and Bypass Mode is enabled. To prevent this excess current, applications should disable the Bypass Current Limit (BYPLIMEN=0) once the DVDD voltage has reached the main supply voltage in Bypass Mode. Reset with POR, Hard Pin Reset, or BOD Reset. |

## 10. CMU - Clock Management Unit

### Quick Facts

#### What?

The CMU controls oscillators and clocks. EFM32 Gecko supports 6 different oscillators with minimized power consumption and short start-up time. The CMU has HW support for calibration of RC oscillators.

#### Why?

Oscillators and clocks contribute significantly to the power consumption of an MCU. Low power oscillators combined with a flexible clock control scheme make it possible to minimize the energy consumption in any given application.

#### How?

The CMU can configure different clock sources, enable/disable clocks to peripherals on an individual basis and set the prescaler for the different clocks. The short oscillator start-up times makes duty-cycling between active mode and the different low energy modes (EM2 DeepSleep, EM3 Stop, and EM4 Hibernate/Shutoff) very efficient. The calibration feature ensures high accuracy RC oscillators. Several interrupts are available to avoid CPU polling of flags.

### 10.1 Introduction

The Clock Management Unit (CMU) is responsible for controlling the oscillators and clocks in the EFM32 Gecko. The CMU provides the capability to turn on and off the clock on an individual basis to all peripheral modules in addition to enable/disable and configure the available oscillators. The high degree of flexibility enables software to minimize energy consumption in any specific application by not wasting power on peripherals and oscillators that do not need to be active.

### 10.2 Features

- Multiple clock sources available:
  - 38 MHz - 40 MHz High Frequency Crystal Oscillator (HFXO)
  - 1 MHz - 38 MHz High Frequency RC Oscillator (HFRCO)
  - 1 MHz - 38 MHz Auxiliary High Frequency RC Oscillator (AUXHFRCO)
  - 32768 Hz Low Frequency Crystal Oscillator (LFXO)
  - 32768 Hz Low Frequency RC Oscillator (LFRCO)
  - 1000 Hz Ultra Low Frequency RC Oscillator (ULFRCO)
- All oscillator sources are low power.
- Fast start-up times.
- Separate prescalers for High Frequency Core Clocks (HFCORECLK), and Peripheral Clocks (HPPERCLK).
- Individual clock prescaler selection for each Low Energy Peripheral.
- Clock gating on an individual basis to core modules and all peripherals.
- Selectable clock output to external pins and/or PRS.
- Wakeup interrupt for LFRCO or LFXO ready allows entry into EM2 DeepSleep while waiting for low-frequency oscillator startup. This avoids the need for software polling and saves power during oscillator startup.
- Auxiliary 1 MHz - 38 MHz RC oscillator (AUXHFRCO), which is asynchronous to the HFSRCCLK system clock, can be selected for ADC operation and debug trace.

### 10.3 Functional Description

An overview of the high frequency portion of the CMU is shown in [Figure 10.1 CMU Overview - High Frequency Portion on page 230](#). An overview of the low frequency portion is shown in [Figure 10.2 CMU Overview - Low Frequency Portion on page 230](#). These figures show the CMU for the largest device in the EFM32 family. Refer to the Configuration Summary in the device data sheet to see which core, and peripheral modules, and therefore clock connections, are present in a specific device.

Figure 10.1. CMU Overview - High Frequency Portion

Figure 10.2. CMU Overview - Low Frequency Portion

### 10.3.1 System Clocks

Available system clock sources are detailed in the following sections.

#### 10.3.1.1 HFCLK - High Frequency Clock

HFSRCCLK is the selected High Frequency Source Clock. HFCLK is an optionally prescaled version of HFSRCCLK. The HFSRCCLK, and therefore HFCLK, can be driven by a high-frequency oscillator, such as HFRCO or HFXO, or one of the low-frequency oscillators (LFRCO or LFXO). By default the HFRCO is selected. In most applications, one of the high frequency oscillators will be the preferred choice. To change the selected clock source, write to the HF bitfield in CMU\_HFCLKSEL. The high frequency clock source can also be changed automatically by hardware as explained in [10.3.2.4.1 Automatic HFXO Start](#). The currently selected source for HFSRCCLK and HFCLK can be read from CMU\_HFCLKSTATUS. The HFSRCCLK is running in EM0 Active and EM1 Sleep and is automatically stopped in EM2 DeepSleep.

**Note:** If a low frequency clock (i.e. LFRCO or LFXO) is selected as source clock for HFSRCCLK via the HF bitfield in CMU\_HFCLKSEL, then no register reads should be performed from Low Energy Peripherals for registers which can change value every clock cycle (e.g., a counter register). In addition to the peripherals on LFACLK, LFBCLK and LFECLK, this restriction applies in general to any low frequency peripheral, which is not directly or indirectly clocked from HFSRCCLK (e.g., WDOGn).

HFCLK can optionally be prescaled by setting PRESC in CMU\_HFPRESC to a non-zero value. This prescales HFCLK to all high frequency components and is typically used to save energy in applications where the system is not required to run at the highest frequency. The prescaler setting can be changed dynamically and the new setting takes effect immediately. HFCLK is used by the CMU and drives the prescalers that generate HFCORECLK and HFPERCLK allowing for flexible clock prescaling. The HFBUSCLK, used in for example the bus and memory system, is equal to HFCLK.

### 10.3.1.2 HFCORECLK - High Frequency Core Clock

HFCORECLK is a prescaled version of HFCLK. This clock drives the Core Modules, which consists of the CPU and modules that are tightly coupled to the CPU (e.g., the cache). The prescale factor for prescaling HFCLK into HFCORECLK is set using the CMU\_HFCOREPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** If HFPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. Refer to [4.2.5 Bus Matrix](#) for more details.

### 10.3.1.3 HFBUSCLK - High Frequency Bus Clock

HFBUSCLK is equal to HFCLK. This clock drives the Bus and Memory System. HFBUSCLK is also used to drive the bus interface to the Low Energy Peripherals as described further in [10.3.1.6 LFACLK - Low Frequency a Clock](#), [10.3.1.7 LFBCLK - Low Frequency B Clock](#) and [10.3.1.8 LFECLK - Low Frequency E Clock](#). Some of the modules that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific module in CMU\_HFBUSCLKEN0. The frequency of HFBUSCLK is equal to the frequency of HFCLK and can therefore only be prescaled by using the PRESC bitfield in CMU\_HFPRESC.

### 10.3.1.4 HFPERCLK - High Frequency Peripheral Clock

Like HFCORECLK, HFPERCLK is a prescaled version of HFCLK. This clock drives the High-Frequency Peripherals. All the peripherals that are driven by this clock can be clock gated individually when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU\_HFPERCLKEN0. All high frequency peripheral clocks can be universally and simultaneously gated by clearing the HFPERCLKEN bit in the CMU\_CTRL register. The prescale factor for prescaling HFCLK into HFPERCLK is set using the CMU\_HFPERPRESC register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** If HFPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. For example, if a bus-access normally takes three cycles, it will take 9 cycles of HFCORECLK if HFPERCLK runs three times as fast as HFCORECLK.

### 10.3.1.5 ADCnCLK - ADC Core Clock

ADCnCLK is a selectable core clock for ADCn. There are three selectable sources for ADCnCLK: HFSRCCLK, HFXO and AUXHFR-CO. In addition, the ADCnCLK can be disabled, which is the default setting. The selection is configured using the ADCnCLKSEL field in CMU\_ADCCTRL. The ADCnCLKINV bit in CMU\_ADCCTRL can be used to invert ADCnCLK. The ADCnCLKDIV bitfield in CMU\_ADCCTRL can be used to prescale ADCnCLK. The bus interface of ADCn is clocked with HFBUSCLK.

### 10.3.1.6 LFACLK - Low Frequency a Clock

LFACLK is the selected clock for the Low Energy A Peripherals. There are several selectable sources for LFACLK: LFRCO, LFXO and ULFRCO. In addition, the LFACLK can be disabled, which is the default setting. The selection is configured using the LFA field in CMU\_LFACLKSEL.

The bus interface to the Low Energy A Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a Low Energy (LE) peripheral.

Each Low Energy Peripheral that is clocked by LFACLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFAPRESC0 and the clock enable bits can be found in CMU\_LFACLKEN0.

When operating in oversampling mode, the pulse counters are clocked by LFACLK. This is configured for each pulse counter (n) individually by setting PCNTnCLKSEL in CMU\_PCNTCTRL.

### 10.3.1.7 LFBCLK - Low Frequency B Clock

LFBCLK is the selected clock for the Low Energy B Peripherals. There are several selectable sources for LFBCLK: LFRCO, LFXO, HFCLKLE and ULFRCO. In addition, the LFBCLK can be disabled, which is the default setting. The selection is configured using the LFB field in CMU\_LFBCLKSEL. The HFCLKLE setting allows the Low Energy B Peripherals to be used as high-frequency peripherals.

The bus interface to the Low Energy B Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a LE peripheral.

**Note:** If HFCLKLE is selected as LFBCLK, the clock will stop in EM2 DeepSleep and EM3 Stop.

Each Low Energy Peripheral that is clocked by LFBCLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFBPRESC0 and the clock enable bits can be found in CMU\_LFBCLKEN0.

### 10.3.1.8 LFECLK - Low Frequency E Clock

LFECLK is the selected clock for the Low Energy E Peripherals. There are several selectable sources for LFECLK: LFRCO, LFXO and ULFRCO. In addition, the LFECLK can be disabled, which is the default setting. The selection is configured using the LFE field in CMU\_LFECLKSEL.

The bus interface to the Low Energy E Peripherals is clocked by HFBUSCLK<sub>LE</sub> and this clock therefore needs to be enabled when programming a LE peripheral.

**Note:** LFECLK is in a different power domain than LFACLK and LFBCLK, which makes it available all the way down to EM4 Hibernate.

Each Low Energy Peripheral that is clocked by LFECLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFEPRESCO and the clock enable bits can be found in CMU\_LFECLKEN0.

### 10.3.1.9 PCNTnCLK - Pulse Counter N Clock

Each available pulse counter is driven by its own clock, PCNTnCLK where n is the pulse counter instance number. Each pulse counter can be configured to use an external pin (PCNTn\_S0) or LFACLK as PCNTnCLK.

### 10.3.1.10 WDOGnCLK - Watchdog Timer Clock

The Watchdog Timer (WDOGn) can be configured to use one of many different clock sources. Refer to CLKSEL field in WDOGn\_CTRL for a complete list.

### 10.3.1.11 CRYOCLK - CRYOTIMER Clock

The CRYOTIMER clock can be configured to use one of many different clock sources. Refer to OSCSEL field in CRYOTIMER\_CTRL for a complete list. The CRYOTIMER can also run in EM4 Hibernate/Shutoff provided that its selected clock is kept enabled as configured in EMU\_EM4CTRL.

### 10.3.1.12 AUXCLK - Auxiliary Clock

AUXCLK is a 1 MHz - 38 MHz clock driven by a separate RC oscillator, the AUXHFRCO. This clock can be used for ADC operation. When the AUXHFRCO is selected as the ADCn clock via the ADCnCLKSEL bitfield in the CMU\_ADCCTRL register this clock will become active automatically when needed. Even if the AUXHFRCO has not been enabled explicitly by software, the ADC can automatically start and stop it. The AUXHFRCO is explicitly enabled by writing a 1 to AUXHFRCOEN in CMU\_OSCENCMD. This explicit enabling is required when selecting the AUXCLK for SWO operation.

### 10.3.1.13 Debug Trace Clock

The CMU selects the clock used for debug trace via the DBGCLKSEL register. The user can use AUXHFRCO or the HFCLK. The selected debug trace clock will be used to run the Cortex-M4 trace logic.

**Note:** When using AUXHFRCO as the debug trace clock, it must be stopped before entering EM2 or EM3.

## 10.3.2 Oscillators

Control of the various oscillators available in the device is detailed in the following sections.

### 10.3.2.1 Enabling and Disabling

The different oscillators can typically be enabled and disabled via both hardware and software mechanisms. Enabling via software is done by setting the corresponding enable bit in the CMU\_OSCENCMD register. Disabling via software is done by setting the corresponding disable bit in CMU\_OSCENCMD. Enabling via hardware can be performed by various peripherals and varies per oscillator. Disabling via hardware is typically performed on entry of low energy modes. The enable and disable mechanisms for each of the oscillators are summarized in [Table 10.1 Software Based and Hardware Based Enabling and Disabling of Oscillators on page 234](#) and described in more detail below.

**Table 10.1. Software Based and Hardware Based Enabling and Disabling of Oscillators**

| Oscillator | SW Enable                       | SW Disable                       | HW Enable                                                                                                                     | HW Disable                                                                                                                                                  |
|------------|---------------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ULFRCO     | -                               | -                                | Enabled when in EM0/EM1/EM2/EM3/EM4H.                                                                                         | EM4S entry depending on configuration in EMU_EM4CTRL.                                                                                                       |

Automatic control by ADC even in EM2/EM3.                                                                                                |
| HFXO       | Via HFXOEN in CMU_OSCENCMD.     | Via HFXODIS in CMU_OSCENCMD.     | Automatic start by EM0/EM1 entry as configured in CMU_HFXOCTRL.                                                               | EM2/EM3/EM4 entry.                                                                                                                                          |

### 10.3.2.1.1 LFRCO and LFXO

The LFXO and LFRCO can be enabled and disabled by software via the CMU\_OSCENCMD register. WDOGn can be configured to force the LFXO or LFRCO to become (and remain) enabled when such an oscillator is selected as its clock source via the CLKSEL bitfield in the WDOGn\_CTRL register while SWOSCBLOCK is set. In that case LFXODIS and LFRCODIS commands are blocked. They are automatically disabled when entering EM3. Upon EM4 entry they are default turned off, but they can optionally be retained depending on the EMU\_EM4CTRL configuration. Retaining of the LFXO or LFRCO in EM4 is needed if such an oscillator is required by a specific peripheral in EM4. Retaining can also be used to guarantee quick oscillator availability after EM4 exit.

The oscillators should never be retained in case they are off before entering EM4. The following are the valid ways of using the LFXO/LFRCO retention mechanism:

- Turn on LFXO/LFRCO always (even in EM4):
  1. POR
  2. Enable LFXO/LFRCO
  3. Enable RETAINLFXO/RETAINLFRCO
  4. EM4 entry
  5. LFXO/LFRCO are retained and remain running in EM4
  6. EM4 wakeup
  7. Enable LFXO/LFRCO
  8. Set EM4UNLATCH in EMU\_CMD
- Turn off LFXO/LFRCO in EM4:
  1. POR
  2. Disable RETAINLFXO/RETAINLFRCO (default)
  3. Enable LFXO/LFRCO
  4. EM4 entry
  5. LFXO/LFRCO are off in EM4
  6. EM4 wakeup
  7. Enable LFXO/LFRCO
  8. Set EM4UNLATCH in EMU\_CMD
- Turn on LFXO/LFRCO after EM4 exit:
  1. POR
  2. Disable RETAINLFXO/RETAINLFRCO (default)
  3. Enable LFXO/LFRCO
  4. EM4 entry
  5. LFXO/LFRCO are off in EM4
  6. EM4 wakeup
  7. Enable LFXO/LFRCO
  8. Set EM4UNLATCH in EMU\_CMD
  9. Enable RETAINLFXO/RETAINLFRCO

In summary RETAINLFXO/RETAINLFRCO should either be changed once after POR and kept static, or they can be changed on-the-fly only after asserting EM4UNLATCH.

**Note:**

- In order to support usage of LFRCO and LFXO in EM4, their settings are automatically latched upon EM4 entry. These settings remain latched upon wake-up from EM4 to EM0 although the related registers (CMU\_LFRCOCTRL, CMU\_LFXOCTRL, CMU\_LFECLKSEL, CMU\_LFECLKEN0 and CMU\_LEEPPRESC0) will have been reset. The registers can be rewritten by software, but they will only affect the LFRCO and LFXO after unlatching their settings by setting EM4UNLATCH in the EMU\_CMD register.
- Turning off the LFRCO and LFXO upon EM4 Hibernate/Shutoff entry is most easily done by using the RETAINLFRCO and RETAINLFXO bitfields from the EMU\_EM4CTRL register, which are default such that the LFRCO and LFXO are turned off automatically upon EM4 Hibernate/Shutoff entry. Alternatively the LFRCO and LFXO can be disabled via the CMU\_OSCENCMD register, in which case software should wait for the oscillators to be properly disabled before executing the EM4 Hibernate/Shutoff entry routine.

After enabling the LFRCO (or LFXO), it should not be disabled before it has been signaled to be ready. Similarly, after disabling the LFRCO (or LFXO), it should not be re-enabled before it has been signaled to be non-ready. Before entering EM4, software should check that the LFRCO (or LFXO) is signaled to be ready before allowing or initiating the EM4 entry if that oscillator is required in EM4. Also, to guarantee latching the latest settings, no control write should be ongoing upon EM4 entry as can be checked via the CMU\_SYNCBUSY register. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_LFRCOEN;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) != CMU_STATUS_LFRCORDY);

CMU->OSCENCMD = CMU_OSCENCMD_LFRCODIS;
while ((CMU->STATUS & CMU_STATUS_LFRCORDY) == CMU_STATUS_LFRCORDY);
```

When the LFXO is disabled, the interface to the LFXTAL\_N and LFXTAL\_P pins are set in a high-Z state. The XTAL oscillations will not stop immediately when LFXO is disabled, but typically die out gradually over some 100 ms. If the LFXO is enabled before XTAL oscillations have had time to reach zero amplitude, startup time can be significantly shorter.

**Note:** The LFRCORDY and LFXORDY interrupts can be used to wake up the system from EM2 DeepSleep. In this way busy waiting for the LFRCO or LFXO to become ready can be avoided by going into EM2 after enabling these oscillators and sleeping until the interrupt causes a wakeup.

#### 10.3.2.1.2 ULFRCO

The ULFRCO is automatically enabled in EM0, EM1, EM2, EM3, and EM4H and cannot be controlled via CMU\_OSCENCMD. It is automatically disabled upon entering EM4S unless prevented by the configuration in EMU\_EM4CTRL.

#### 10.3.2.1.3 HFRCO

The HFRCO can be enabled and disabled by software via the CMU\_OSCENCMD register. The HFRCO is disabled automatically when entering EM2, EM3, or EM4. Further hardware based enabling and disabling can be performed by the LEUART when using automatic RX/TX DMA wakeup as controlled by the RXDMAWU and TXDMAWU bits in the LEUARTn\_CTRL register. An automatic start and selection of the HFXO will lead to an automatic HFRCO disabling.

The supported HFRCO frequency range is from 1 MHz to 38 MHz. The default HFRCO frequency is 19 MHz.

#### 10.3.2.1.4 HFXO

The HFXO can be enabled and disabled by software via the CMU\_OSCENCMD register. The HFXO is disabled automatically when entering EM2, EM3, or EM4. Hardware based HFXO enabling can be initiated by various peripherals as configured via the AUTOSTARTEM0EM1, and AUTOSTARTSELEM0EM1 bits in the CMU\_HFXOCTRL register. The interaction between hardware based and software based control of the HFXO is further explained in [10.3.2.4.1 Automatic HFXO Start](#).

The supported HFXO frequency range is from 38 MHz to 40 MHz.

After enabling the HFXO, it should not be disabled before it has been signaled to be enabled. Similarly, after disabling the HFXO it should not be re-enabled before it has been signaled to be non-enabled. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_HFXOEN;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) != CMU_STATUS_HFXOENS);

CMU->OSCENCMD = CMU_OSCENCMD_HFXODIS;
while ((CMU->STATUS & CMU_STATUS_HFXOENS) == CMU_STATUS_HFXOENS);
```

#### 10.3.2.1.5 AUXHFRCO

The AUXHFRCO can be enabled and disabled by software via the CMU\_OSCENCMD register. The AUXHFRCO is disabled automatically when entering EM2, EM3, or EM4. Hardware based AUXHFRCO enabling and disabling is however performed by the ADC module when AUXCLK is selected for its operation making it available even when being in EM2/EM3.

The supported AUXHFRCO frequency range is from 1 MHz to 38 MHz. The default AUXHFRCO frequency is 19 MHz

After enabling the AUXHFRCO, it should not be disabled before it has been signaled to be enabled. Similarly, after disabling the AUXHFRCO, it should not be re-enabled before it has been signaled to be non-enabled. Typical enable and disable sequences are as follows:

```
CMU->OSCENCMD = CMU_OSCENCMD_AUXHFRCOEN;  
while ((CMU->STATUS & CMU_STATUS_AUXHFRCOENS) != CMU_STATUS_AUXHFRCOENS);  
  
CMU->OSCENCMD = CMU_OSCENCMD_AUXHFRCODIS;  
while ((CMU->STATUS & CMU_STATUS_AUXHFRCOENS) == CMU_STATUS_AUXHFRCOENS);
```

**Note:** When using AUXHFRCO as the debug trace clock (as selected in CMU\_DBGCLKSEL), it must be stopped before entering EM2 or EM3.

### 10.3.2.2 Oscillator Start-up Time and Time-out

The start-up time differs per oscillator and the usage of an oscillator clock can further be delayed by a time-out. The LFRCO, LFXO and the HFXO have a configurable time-out which is set by software in the (various) TIMEOUT bitfields of the CMU\_LFRCTRL, CMU\_LFXOCTRL and CMU\_HFXOCTRL registers respectively. The time-out delays the assertion of the READY signal for LFRCO, LFXO and HFXO and should allow for enough time for the oscillator to stabilize. The time-out can be optimized for the chosen crystal (for LFXO and HFXO) used in the application. In case LFRCO and/or LFXO has been retained throughout EM4 Hibernate/Shut-off, such retained oscillators can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using the minimum TIMEOUT settings for them. For the other RC oscillators (HFRCO, AUXHFRCO, and ULFRCO), the start-up time is known and a fixed time-out is used.

There are individual bits in the CMU\_STATUS register for each oscillator indicating the status of the oscillator:

- ENABLED - Indicates that the oscillator is enabled
- READY - Start-up time including time-out is exceeded

These status bits are located in the CMU\_STATUS register.

Additionally, the HFXO has a second time-out counter which can be used to achieve deterministic start-up time based on timing from the LFXO, ULFRCO, or LFRCO. This second counter runs off LFECLK and can be programmed via the LFTIMEOUT bitfield in the CMU\_HFXOCTRL register. It can be used when waking up from EM2 when either ULFRCO, LFRCO or LFXO is already running and stable. In this case the HFXO ready assertion can be delayed with the number of LFECLK cycles as programmed in LFTIMEOUT. The HFXO ready signal is asserted when both the TIMEOUT counter (configured via the CMU\_HFXOCTRL register) and the LFTIMEOUT counter (configured via CMU\_HFXOCTRL register) have timed out as shown in [Figure 10.3 CMU Deterministic HFXO startup using LFTIMEOUT on page 238](#). The TIMEOUT should cover the actual crystal startup time. Typically the time base used for the TIMEOUT counter is not as accurate as the time base accuracy that can be achieved for the LFTIMEOUT counter, specifically if that one is based on the LFXO timing. If LFTIMEOUT is triggered before TIMEOUT is triggered, then the LFTIMEOUTERR bitfield in CMU\_IF will be set to 1. Note that use of LFTIMEOUT requires that the peripheral causing the wake-up is on the LFECLK domain.

**Figure 10.3. CMU Deterministic HFXO startup using LFTIMEOUT**

The startup behavior of the HFXO also depends on how and how long the HFXO is disabled.

### 10.3.2.3 Switching Clock Source

The HFRCO oscillator is a low energy oscillator with extremely short start-up time. Therefore, this oscillator is always chosen by hardware as the clock source for HFCLK when the device starts up (e.g., after reset and after waking up from EM2 DeepSleep and EM3 Stop). After reset, the HFRCO frequency is 19 MHz.

Software can switch between the different clock sources at run-time. For example, when the HFRCO is the clock source, software can switch to HFXO by writing the field HF in the CMU\_HFCLKSEL command register. See [Figure 10.4 CMU Switching from HFRCO to HFXO before HFXO is ready on page 239](#) for a description of the sequence of events for this specific operation.

**Note:** Before switching the HFCLKSRC to HFXO via the HF bitfield in CMU\_HFCLKSEL it is important to first enable the HFXO. Switching to a disabled oscillator will effectively stop HFSRCCLK and only a reset can recover the system.

When selecting an oscillator which has been enabled, but which is not ready yet, the HFSRCCLK will stop for the duration of the oscillator start-up time since the oscillator driving it is not ready. This effectively stalls the Core Modules and the High-Frequency Peripherals. It is possible to avoid this by first enabling the target oscillator (e.g., HFXO) and then waiting for that oscillator to become ready before switching the clock source. This way, the system continues to run on the HFRCO until the target oscillator (e.g., HFXO) has timed out and provides a reliable clock. This sequence of events is shown in [Figure 10.5 CMU Switching from HFRCO to HFXO after HFXO is ready on page 240](#).

A separate flag is set when the oscillator is ready. This flag can also be configured to generate an interrupt.

Figure 10.4. CMU Switching from HFRCO to HFXO before HFXO is ready

**Figure 10.5. CMU Switching from HFRCO to HFXO after HFXO is ready**

Switching clock source for LFACLK, LFBCLK, and LFECLK is done by setting the LFA, LFB and LFE bitfields in `CMU_LFACLKSEL`, `CMU_LFBCLKSEL` and `CMU_LFECLKSEL` respectively. To ensure no stalls in the Low Energy Peripherals, the clock source should be ready before switching to it.

**Note:** To save energy, remember to turn off all oscillators not in use.

### 10.3.2.4 HFXO Configuration

The High Frequency Crystal Oscillator needs to be configured to ensure safe startup for the given crystal. Refer to the device data sheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The HFXO crystal is connected to the HFXTAL\_N/HFXTAL\_P pins as shown in [Figure 10.6 HFXO Pin Connection on page 241](#)

**Figure 10.6. HFXO Pin Connection**

By default the HFXO is started in crystal mode, but it is possible to connect an active external sine wave or square wave clock source to the HFXTAL\_N pin of the HFXO. By configuring the MODE field in CMU\_HFXOCTRL to EXTCLK, the HFXO can be bypassed and the source clock can be provided through the HFXTAL\_N pin.

Upon enabling the HFXO, a hardware state machine sequentially applies the configurable startup state and steady state control settings from the CMU\_HFXOSTARTUPCTRL and CMU\_HFXOSTEADYSTATECTRL registers. Configuration is required for both the startup state and the steady state of the HFXO. After reaching the steady operation state of the HFXO, further optimization can optionally be performed to optimize the HFXO for noise and current consumption. Optimization for noise can be performed by an automatic Peak Detection Algorithm (PDA). Optimization for current can be performed by an automatic Shunt Current Optimization algorithm (SCO). HFXO operation is possible without PDA and SCO at the cost of higher noise and current consumption than required.

Upon fully disabling the HFXO, the HFXTAL\_N and HFXTAL\_P pins can optionally be automatically pulled to ground as configured via the XT12GND and XTO2GND bits respectively from the CMU\_HFXOCTRL register. Do not set XT12GND to 1 when the HFXO is in EXTCLK mode and an external wave is connected.

**Figure 10.7. CMU HFXO control state machine**

Refer to the device data sheet to find the configuration values for a given crystal. The startup state configuration needs to be written into the IBTRIMXOCORE and CTUNE bitfields of the CMU\_HFXOSTARTUPCTRL register. The duration of the startup phase is configured in the STARTUPTIMEOUT bitfield of the CMU\_HFXOTIMEOUTCTRL register. Similarly, the device data sheet provides the steady

state configuration depending on the crystal's CL, RESR and oscillation frequency. This configuration is programmed into the IBTRIMXOCORE, REGISH and CTUNE bitfields of the CMU\_HFXOSTEADYSTATECTRL register. The minimum duration of the steady phase is configured in the STEADYTIMEOUT bitfield of the CMU\_HFXOTIMEOUTCTRL register.

All HFXO configuration needs to be performed prior to enabling the HFXO via HFXOEN in CMU\_OSCENCMD unless noted otherwise. The HFXOENS flag in CMU\_STATUS indicates if the HFXO has been successfully enabled. Once the HFXO startup time (STARTUP-TIMEOUT plus STEADYTIMEOUT) has exceeded and oscillations begin, the HFXORDY flag in CMU\_STATUS. If PDA and SCO are enabled, the HFXOPEAKDETRDY and HFXOSHUNTOPTRDY flags in the CMU\_STATUS register indicate when these algorithms are ready and it is advised to also wait for these flags before using the HFXO.

The HFXO crystal bias current may be optimized and set to a value which decreases output phase noise without sacrificing PSR. This is done by programming the recommended IBTRIMXOCORE value into the CMU\_HFXOSTEADYSTATECTRL register. The built-in Peak Detector Algorithm (PDA) performs further optimization to accommodate for process variations. Once PDA is ready as indicated by the HFXOPEAKDETRDY flag, the found optimal bias current setting is available in the IBTRIMXOCORE bitfield of the CMU\_HFXO-TRIMSTATUS register. This IBTRIMXOCORE setting should be saved and can be applied directly during a future HFXO startup as a low noise setting by programming it into the corresponding bitfield in CMU\_HFXOSTEADYSTATECTRL while the HFXO is off.

If low noise is not required, the same PDA algorithm can be configured to optimize the HFXO for low current consumption by enabling LOWPOWER in the CMU\_HFXOCTRL register before starting up the HFXO. The found IBTRIMXOCORE setting can be saved as a future low current setting.

Default PDA is started automatically once the HFXO has become ready. Repeated PDA can be triggered by writing HFXOPEAKDET-START to 1 in the CMU\_CMD register. PDA can also be triggered only by the command register by configuring PEAKDETSHUNTOPT-MODE to CMD in the CMU\_HFXOCTRL register before starting the HFXO. For PDA to work correctly, the REGISHUPPER bitfield of CMU\_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The PEAKDETTIMEOUT bitfield in the CMU\_HFXOTIMEOUTCTRL register is used to time the PDA steps and needs to be configured according to the device data sheet for the given crystal. The PEAKDETEN bitfield of the CMU\_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) peak detection and is ignored during automatic or command based triggering of the PDA. Note that the manual PDA mode is not recommended for general usage and therefore it is not further described. PDA should not be used when using an external wave as clock source.

Current consumption can be (further) reduced by running Shunt Current Optimization (SCO) after PDA. Once SCO is ready as indicated by the HFXOSHUNTOPTRDY flag, the found optimal regulator output current setting is available in the REGISH bitfield of the CMU\_HFXOTRIMSTATUS register. This REGISH setting should be saved and can be applied directly during a future HFXO startup as a low current setting by programming it into the corresponding bitfield in CMU\_HFXOSTEADYSTATECTRL while the HFXO is off. Normally SCO is run only for initial HFXO start up. The amplitude of the oscillator is not strongly dependent on temperature, but further optimization may be done each time that the temperature changes significantly. In that case, run SCO again by writing HFXOSHUNTOPTSTART to 1 in the CMU\_CMD register. SCO depends on the LOWPOWER setting in the CMU\_HFXOCTRL and needs to be rerun if that value has been changed.

Default SCO is started automatically once the HFXO has become ready and PDA has finished. Repeated SCO can be triggered by writing HFXOSHUNTOPTSTART to 1 in the CMU\_CMD register. SCO can also be triggered only by the command register by configuring PEAKDETSHUNTOPTMODE to CMD in the CMU\_HFXOCTRL register before starting the HFXO. For SCO to work correctly, the REGISHUPPER bitfield of CMU\_HFXOSTEADYSTATECTRL should be programmed to the value of the steady state REGISH + 3. The SHUNTOPTTIMEOUT bitfield in the CMU\_HFXOTIMEOUTCTRL register is used to time the SCO steps and needs to be configured according to the device data sheet for the given crystal. The REGSELIOW bitfield of the CMU\_HFXOSTEADYSTATECTRL register is only used during manual (i.e. fully software controlled) shunt current optimization and is ignored during automatic or command based triggering of the SCO. Note that the manual SCO mode is not recommended for general usage and therefore it is not further described.

### 10.3.2.4.1 Automatic HFXO Start

The enabling of the HFXO and its selection as HFSRCCLK source can be performed automatically by hardware. Automatic control of the HFXO is controlled via the AUTOSTARTSELEM0EM1 and AUTOSTARTEM0EM1 bits in the CMU\_HFXOCTRL register. It further depends on the energy mode of the EFM32.

An automatic HFXO enable is performed only if any of the following conditions are met:

- EFM32 is in EM0/EM1 and AUTOSTARTEM0EM1 or AUTOSTARTSELEM0EM1 are set to 1.

An automatic HFXO select is performed only if any of the following conditions is met:

- EFM32 is in EM0/EM1 and AUTOSTARTSELEM0EM1 is set to 1.

Whenever any of the conditions for automatic HFXO enable is met, software is not allowed to disable the HFXO. An attempt to do so (e.g., by writing 1 to the HFXODIS bit) is ignored and causes the HFXODISERR bit in the CMU\_IF register to be set to 1. Similarly, whenever any of the conditions for automatic HFXO selection is met, software is not allowed to deselect the HFXO as clock source for HFSRCCLK. An attempt to do so (e.g., by selecting another clock source via CMU\_HFCLKSEL) is ignored and causes the HFXODISERR bit in the CMU\_IF register to be set to 1. Note that CMUERR is not implied by HFXODISERR. CMUERR will not get set to 1 for the above scenarios in which HFXODISERR gets set.

Software can only disable or deselect the HFXO after removing all of the HFXO automatic enable or select reasons. The HFXO is only disabled by hardware upon EM2, EM3 or EM4 entry.

In case that AUTOSTARTSELEM0EM1 is set to 1 in EM0/EM1 (irrespective of the other autostart bits), the HFXO select will occur immediately, even if HFXO is not ready yet. Upon wake-up into EM0/EM1 this can therefore lead to a relatively long startup time as the system will not start operating from the HFRCO as it would otherwise do.

Note that the user should take care that the settings in the MSC\_READCTRL and CMU\_CTRL registers, as described in [10.3.3 Configuration for Operating Frequencies](#), are compatible with HFXO frequency before enabling the HFXO automatic startup feature. A basic automatic HFXO start scenario is shown in [Figure 10.8 CMU Automatic Startup and Selection of HFXO on page 244](#).

**Figure 10.8. CMU Automatic Startup and Selection of HFXO**

If an automatic selection of HFXO is performed, which switches the clock source used for HFSRCCLK, then the HFXOAUTOSW bit in CMU\_IF is set to 1. After automatic enable and selection of the HFXO, the HFRCO is automatically disabled in case it is running. The disabling of a running HFRCO is signalled via the HFRCODIS bit in CMU\_IF. This only applies to the HFRCO. If for example the LFXO was used as HFSRCCLK at the time of automatic selection of the HFXO, the LFXO remains unaffected.

The interaction between automatic HFXO startup and selection with startup and selection of HFRCO is shown in [Figure 10.9 CMU HFRCO Startup/Selection While Awaiting Automatic HFXO Startup/Selection on page 245](#).

**Figure 10.9. CMU HFRCO Startup/Selection While Awaiting Automatic HFXO Startup/Selection**

### 10.3.2.5 LFXO Configuration

The Low Frequency Crystal Oscillator (LFXO) is default configured to ensure safe startup for all crystals. In order to optimize startup time and power consumption for a given crystal, it is possible to adjust the startup gain in the oscillator by programming the GAIN field in CMU\_LFXOCTRL. Recommendations for the GAIN setting are as follows:

1. C0 must be < 2 pF
2. For 12.5 pF < CL < 18 pF, GAIN = 3
3. For 8 pF < CL < 12.5 pF, GAIN = 2
4. For 6 pF < CL < 8 pF, GAIN = 1
5. For CL = 6 pF, GAIN = 0

Refer to the device data sheet and application notes for guidelines in selecting correct components and crystals as well as for configuration trade-offs.

The LFXO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU\_LFXOCTRL register itself will be reset. Upon EM4 exit, the CMU\_LFXOCTRL register therefore needs to be reconfigured to its original settings and the LFXO needs to be restarted via CMU\_OSCENCMD, before optionally unlatching the retained LFXO configuration by writing 1 to EM4UNLATCH in the EMU\_CMD register. The LFXO startup time is configured via the TIMEOUT bitfield of the CMU\_LFXOCTRL register. If the LFXO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK, LFBCLK or LFECLK by using its minimum TIMEOUT setting. While retained, the LFXO can be used down to EM4 Hibernate as source for LFECLK and down to EM4 Shutoff as source for CRYOCLK.

The LFXO crystal is connected to the LFXTAL\_N/LFXTAL\_P pins as shown in [Figure 10.10 LFXO Pin Connection on page 246](#).

**Figure 10.10. LFXO Pin Connection**

By configuring the MODE field in CMU\_LFXOCTRL, the LFXO can be bypassed, and an external clock source can be connected to the LFXTAL\_N pin of the LFXO oscillator. If MODE is set to BUFEXTCLK, an external active sine source can be used as clock source. If MODE is set to DIGEXTCLK, an external active CMOS source can be used as clock source.

The LFXO includes on-chip tunable capacitance, which can replace external load capacitors. The TUNING bitfield of the CMU\_LFXOCTRL register is used to tune the internal load capacitance connected between LFXTAL\_P and ground and LFXTAL\_N and ground symmetrically. The capacitance range and step size information is available in the device data sheets. Use the formula below to calculate the TUNING bitfield:

$$\text{TUNING} = ((\text{desiredTotalLoadCap} * 2 - \text{Min}(C_{\text{LFXO\_T}})) / C_{\text{LFXO\_TS}})$$

**Figure 10.11. CMU LFXO Tuning Capacitance Equation**

These tunable capacitors can also be used to compensate for temperature drift of the XTAL in software. Crystals normally have a temperature dependency which is given by a parabolic function. The crystal has highest frequency at its turnover temperature, normally 25C. The frequency is reduced following a parabola for higher and lower temperatures. The LFXO offers a mechanism to internally add capacitance on the LFXTAL\_N and LFXTAL\_P pins (in parallel to an optional external load capacitance). The variation in frequency as a function of temperature can therefore be compensated by adjusting the load capacitance. When the temperature compensation scheme is used, the maximum internal capacitance should be used to obtain good frequency matching at the turnover temperature. For higher and lower temperatures software then has the maximum range available to adjust the tuning. The external load capacitance

must then of course be reduced accordingly. Note that the ADC0 (22. [ADC - Analog to Digital Converter](#)) includes an embedded temperature sensor and that the EMU (9. [EMU - Energy Management Unit](#)) offers a temperature management interface, both of which can be used in combination with this LFXO temperature compensation scheme.

The XTAL oscillation amplitude can be controlled via the HIGHAMPL bitfield in CMU\_LFXOCTRL. Setting HIGHAMPL to 1 will result in higher amplitude, which in turn provides safer operation, somewhat improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

The AGC bit of the CMU\_LFXOCTRL register is used to turn on or off the Automatic Gain Control module that adjusts the amplitude of the XTAL. When disabled, the LFXO will run at the startup current and the XTAL will oscillate rail to rail, again providing safer operation, improved duty cycle, and lower sensitivity to noise at the cost of increased current consumption.

### 10.3.2.6 HFRCO and AUXHFRCO Configuration

It is possible to calibrate the HFRCO and AUXHFRCO to achieve higher accuracy (see the device data sheets for details on accuracy). The frequency is adjusted by changing the TUNING and FINETUNING bitfields in CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL. Changing to a higher value will result in a lower frequency. Refer to the data sheet for stepsize details.

The HFRCO can be set to one of several different frequency bands from 1 MHz to 38 MHz by setting the FREQRANGE field in CMU\_HFRCOCTRL. Similarly the AUXHFRCO can be set to one of several different frequency bands from 1 MHz to 38 MHz by setting the FREQRANGE field in CMU\_AUXHFRCOCTRL. The HFRCO and AUXHFRCO frequency bands are calibrated during production test, and the production tested calibration values can be read from the Device Information (DI) page. The DI page contains separate tuning values for various frequency bands. During reset, HFRCO and AUXHFRCO tuning values are set to the production calibrated values for the 19 MHz band, which is the default frequency band. When changing to a different HFRCO or AUXHFRCO band, make sure to also update the TUNING value and other bitfields in the CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL registers. Typically the entire register is written with a value obtained from the Device Information (DI) page. Refer to [4.6 DI Page Entry Map](#) for information on which frequency band settings are stored in the DI page.

The frequency can be tuned more accurately via the FINETUNING bitfield if fine tuning has been enabled via the FINETUNINGEN bit. Note that there will be a slight increase in the oscillator current consumption when fine tuning is enabled. Note also that changing the value of FINETUNINGEN will result in a frequency shift, regardless of the FINETUNING field value. If the oscillator is to be used at different times with fine tuning enabled and disabled, it should be tuned separately for both settings. The HFRCO and AUXHFRCO contain a local prescaler, which can be used in combination with any FREQRANGE setting. These prescalers allow the output clocks to be divided by 1, 2, or 4 as configured in the CLKDIV bitfield.

When using [10.3.2.8 RC Oscillator Calibration](#) to tune HFRCO and AUXHFRCO to the desired frequency, linear search must be used to avoid over clocking the calibration counters. Before changing the FREQRANGE field in CMU\_HFRCOCTRL, TUNING and FINETUNING fields should initially be set to the highest value (slowest frequency). After changing the FREQRANGE, linearly step TUNING value until desired frequency is reached. Likewise, before changing the TUNING field, FINETUNING field should initially be set to the highest value (lowest frequency). After changing the TUNING field, linearly step FINETUNING until accuracy is reached.

### 10.3.2.7 LFRCO Configuration

It is possible to calibrate the LFRCO to achieve higher accuracy (see the device data sheets for details on accuracy). The frequency is adjusted by changing the TUNING bitfield in CMU\_LFRCOCTRL. Changing to a higher value will result in a lower frequency. Refer to the data sheet for stepsize details.

The LFRCO can be retained on in EM4 Hibernate/Shutoff. In that case its required configuration is latched/retained throughout EM4 even though the CMU\_LFRCOCTRL register itself will be reset. Upon EM4 exit the CMU\_LFRCOCTRL register therefore needs to be reconfigured to its original settings and the LFRCO needs to be restarted via CMU\_OSCENCMD, before optionally unlatching the retained LFRCO configuration by writing 1 to EM4UNLATCH in the EMU\_CMD register. The LFRCO startup time is configured via the TIMEOUT bitfield of the CMU\_LFRCOCTRL register. Default its 16 cycle startup should be used. However, in case the LFRCO has been retained throughout EM4 Hibernate/Shutoff, it can be quickly restarted for use as LFACLK or LFBCLK by using its minimum TIMEOUT setting. While retained, the LFRCO can be used down to EM4 Hibernate as source for LFECLK and down to EM4 Shutoff as source for CRYOCLK.

The LFRCO is also calibrated in production and its TUNING values are set to the correct value during reset.

The LFRCO can be put in duty cycle mode by setting the ENVREF bit in CMU\_LFRCOCTRL to 1 before starting the LFRCO. This will reduce current consumption, but will result in slightly worse accuracy especially at high temperatures. Setting the ENCHOP and/or ENDEM bitfields to 1 in the CMU\_LFRCOCTRL register will improve the average LFRCO frequency accuracy at the cost of a worse cycle-to-cycle accuracy.

### 10.3.2.8 RC Oscillator Calibration

The CMU has built-in HW support to efficiently calibrate the RC oscillators (LFRCO, HFRCO, AUXHFRCO, etc) at run-time. For a complete list of supported oscillators, refer to DOWNSSEL and UPSEL fields in CMU\_CALCTRL. See [Figure 10.12 HW-support for RC Oscillator Calibration on page 248](#) for an illustration of this circuit. The concept is to select a reference and compare the RC frequency with the reference frequency. When the calibration circuit is started, one down-counter running on a selectable clock (DOWNSSEL in CMU\_CALCTRL) and one up-counter running on a selectable clock (UPSEL in CMU\_CALCTRL) are started simultaneously. The top value for the down-counter must be written to CMU\_CALCNT before calibration is started. The down-counter counts for CMU\_CALCNT +1 cycles. When the down-counter has reached 0, the up-counter is sampled and the CALRDY interrupt flag is set. If CONT in CMU\_CALCTRL is cleared, the counters are stopped after finishing the ongoing calibration. If continuous mode is selected by setting CONT in CMU\_CALCTRL the down-counter reloads the top value and continues counting and the up-counter restarts from 0. Software can then read out the sampled up-counter value from CMU\_CALCNT. The up-counter has counted (the sampled value)+1 cycles. The ratio between the reference and the oscillator subject to the calibration can easily be found using top+1 and sample+1. Overflows of the up-counter will not occur. If the up-counter reaches its top value before the down-counter reaches 0, the up-counter stays at its top value. Calibration can be stopped by writing CALSTOP in CMU\_CMD. With this HW support, it is simple to write efficient calibration algorithms in software.

**Figure 10.12. HW-support for RC Oscillator Calibration**

The counter operation for single and continuous mode are shown in [Figure 10.13 Single Calibration \(CONT=0\) on page 249](#) and [Figure 10.14 Continuous Calibration \(CONT=1\) on page 249](#) respectively.

Figure 10.13. Single Calibration (CONT=0)

Figure 10.14. Continuous Calibration (CONT=1)

### 10.3.3 Configuration for Operating Frequencies

The HFXO is capable of frequencies up to 40 MHz, which allows the EFM32 to run at up to this frequency. However the Memory System Controller (MSC) and the Low Energy Peripheral Interface need to be configured correctly to allow operation at higher frequencies as explained below.

The MODE bitfield in MSC\_READCTRL makes sure the flash is able to operate at the given HFCLK frequency by inserting wait states for flash accesses. The required settings for controlling flash wait states are shown in [Table 10.2 MSC Configuration for Operating Frequencies: Flash Wait States on page 250](#). The WSHFLE bitfield in CMU\_CTRL is used to ensure that the Low Energy Peripheral Interface is able to operate at the given HFBUSCLK<sub>LE</sub> frequency by inserting wait states when using this interface. The required settings are shown in [Table 10.3 LE Configuration for Operating Frequencies: Low Energy Peripheral Interface on page 250](#).

Before going to a high frequency, make sure the registers in the table have the correct values. When going down in frequency, make sure to keep the registers at the values required by the higher frequency until after the switch has been done.

**Table 10.2. MSC Configuration for Operating Frequencies: Flash Wait States**

| Condition               | MODE in MSC_READCTRL |
|-------------------------|----------------------|
| HFCLK ≤ 25 MHz          | WS0 or above         |
| 25 MHz < HFCLK ≤ 40 MHz | WS1 or above         |

**Table 10.3. LE Configuration for Operating Frequencies: Low Energy Peripheral Interface**

| Condition                       | WSHFLE in CMU_CTRL |
|---------------------------------|--------------------|
| HFBUSCLK <sub>LE</sub> ≤ 32 MHz | 0 / 1              |
| HFBUSCLK <sub>LE</sub> > 32 MHz | 1                  |

### 10.3.4 Energy Modes

The availability of oscillators and system clocks depends on the chosen energy mode. Default the high frequency oscillators (HFRCO, AUXHFRCO, and HFXO) and high frequency clocks (HFSRCLK, HFCLK, HFCORECLK, HFBUSCLK, HFPERCLK, HFCLKLE) are available down to EM1 Sleep. From EM2 DeepSleep onwards these oscillators and clocks are normally off, although special cases exist as summarized in [Table 10.4 Oscillator and Clock Availability in Energy Modes on page 251](#) and [Table 9.2 EMU Energy Mode Overview on page 178](#). The CMU overview figure in [Figure 10.1 CMU Overview - High Frequency Portion on page 230](#) and [Figure 10.2 CMU Overview - Low Frequency Portion on page 230](#) also indicate which oscillators and clocks can be used in what energy modes.

The low frequency oscillators (LFRCO and LFXO) are available in all energy modes except in EM3 Stop when they are off by definition. Default these oscillators are also off in EM4 Hibernate and EM4 Shutoff, but they can be retained on in these states as well if needed. The ultra low frequency oscillator (ULFRCO) is default on in all energy modes, except for EM4 Shutoff, but it can be retained on in that mode as well if needed. The low frequency clocks (LFACLK, LFBCLK, LFECLK, WDOGnCLK, and CRYOCLK) are in various power domains and therefore their availability not only depends on the chosen clock source, but also on the chosen energy mode as indicated in [Table 10.4 Oscillator and Clock Availability in Energy Modes on page 251](#).

**Table 10.4. Oscillator and Clock Availability in Energy Modes**

|                                                        | EM0 Active/EM1 Sleep | EM2 DeepSleep   | EM3 Stop        | EM4 Hibernate            | EM4 Shutoff              |
|--------------------------------------------------------|----------------------|-----------------|-----------------|--------------------------|--------------------------|
| HFRCO                                                  | On <sup>1</sup>      | Off             | Off             | Off                      | Off                      |
| HFXO                                                   | On <sup>1</sup>      | Off             | Off             | Off                      | Off                      |
| AUXHFRCO                                               | On <sup>1</sup>      | On <sup>2</sup> | On <sup>2</sup> | Off                      | Off                      |
| LFRCO, LFXO                                            | On <sup>1</sup>      | On <sup>1</sup> | Off             | Retained on <sup>3</sup> | Retained on <sup>3</sup> |
| ULFRCO                                                 | On                   | On              | On              | On                       | Retained on <sup>3</sup> |
| HFSRCLK, HFCLK, HFCORECLK, HFBUSCLK, HFPERCLK, HFCLKLE | On <sup>1</sup>      | Off             | Off             | Off                      | Off                      |
| AUXCLK                                                 | On <sup>1</sup>      | On <sup>2</sup> | On <sup>2</sup> | Off                      | Off                      |
| ADCnCLK                                                | On <sup>1</sup>      | On <sup>4</sup> | On <sup>4</sup> | Off                      | Off                      |
| LFACLK, LFBCLK                                         | On <sup>1</sup>      | On <sup>1</sup> | On <sup>5</sup> | Off                      | Off                      |
| LFECLK                                                 | On <sup>1</sup>      | On <sup>1</sup> | On <sup>5</sup> | Retained on <sup>3</sup> | Off                      |
| WDOGnCLK                                               | On <sup>1</sup>      | On <sup>1</sup> | On <sup>5</sup> | Off                      | Off                      |
| CRYOCLK                                                | On <sup>1</sup>      | On <sup>1</sup> | On <sup>5</sup> | Retained on <sup>3</sup> | Retained on <sup>3</sup> |

**Note:**

1. Under software control.
2. Default off, but kept active if used by the ADC.
3. Default off, but can be retained on.
4. Will be kept on if AUXHFRCO is selected as clock source.
5. On only if ULFRCO is used as clock source.

### 10.3.5 Clock Output on a Pin

It is possible to configure the CMU to output clocks on the CMU\_CLK0, CMU\_CLK1 and CMU\_CLK2 pins. This clock selection is done using the CLKOUTSEL0, CLKOUTSEL1 and CLKOUTSEL2 bitfields respectively in CMU\_CTRL. The required output pins must be enabled in the CMU\_ROUTEPEN register and the pin locations can be configured in the CMU\_ROUTELOC0 register. The following clocks can be output on a pin:

- HFSRCCLK and HFEXPCLK. The HFSRCCLK is the high frequency clock before any prescaling has been applied. The HFEXPCLK is a prescaled version of HFCLK as controlled by the HFEXPPRESC bitfield in the CMU\_HFPRESC register.
- The unqualified clock output from any of the oscillators (ULFRCO, LFRCO, LFXO, HFXO). Note that these unqualified clocks can exhibit glitches or skewed duty-cycle during startup and therefore these clock outputs are normally not used before observing the related ready flag being set to 1 in CMU\_STATUS.
- The qualified clock from any of the oscillators (ULFRCO, LFRCO, LFXO, HFXO, HFRCO, AUXHFRCO). A qualified clock will not have any glitches or skewed duty-cycle during startup. For LFRCO, LFXO and HFXO correct configuration of the TIMEOUT bitfield(s) in CMU\_LFRCOCTRL, CMU\_LFXOCTRL and CMU\_HFXOTIMEOUTCTRL respectively is required to guarantee a properly qualified clock.

HFCLK will not have a 50-50 duty cycle when any other division factor than 1 is used in CMU\_HFPRESC (i.e. if PRESC is not equal to 0). In such a case, the exported HFEXPCLK will therefore also not be 50-50 when its division factor is not set to an even number in CMU\_HFEXPPRESC.

### 10.3.6 Clock Output on PRS

The CMU can be used as a PRS producer. It can output clocks onto PRS which can be selected by a consumer as CMUCLKOUT0, CMUCLKOUT1 and CMUCLKOUT2. The clocks which can be produced via CMUCLKOUT0, CMUCLKOUT1 and CMUCLKOUT2 are selected via the CLKOUTSEL0, CLKOUTSEL1 and CLKOUTSEL2 fields respectively in CMU\_CTRL.

Note that the CLKOUTSEL0 and CLKOUTSEL1 fields are also used for selecting which clock is output onto a pin as described in [10.3.5 Clock Output on a Pin](#). In contrast with clock output on a pin however, output of a clock onto PRS does not depend on any configuration of the CMU\_ROUTEPEN and CMU\_ROUTELOC0 registers.

### 10.3.7 Error Handling

Certain restrictions apply to how and when the CMU registers can be configured as is described for the respective registers. Not adhering to these restrictions can lead to unpredictable and non-defined behaviour. Some of these software restrictions are checked in hardware and not adhering to them will cause the CMUERR interrupt flag in CMU\_IF to be set to 1. The restrictions impacting CMUERR are as follows:

- CMU\_HFRCOCTRL should not be written while HFRCOBSY in the CMU\_SYNCBUSY register is set to 1.
- CMU\_AUXHFRCOCTRL should not be written while AUXHFRCOBSY in the CMU\_SYNCBUSY register is set to 1.
- CMU\_HFXOSTARTUPCTRL, CMU\_HFXOSTEADYSTATECTRL and CMU\_HFXOTIMEOUTCTRL should not be written while HFXOBSY in the CMU\_SYNCBUSY register is set to 1. Note that writes to CMU\_HFXOCTRL do not impact CMUERR. Although most of its bitfields need to be configured before enabling the HFXO, it is allowed to change the AUTOSTART bits (i.e. AUTOSTARTSELEM0EM1 and AUTOSTARTSEM0EM1) at any time.
- HFXO should not be enabled before it has been properly disabled (so only enable HFXO when HFXOENS=0 or HFXOBSY=0). Likewise, HFXO should not be disabled before it has been properly enabled (so only disable HFXO when HFXOENS=1 or HFXOBSY=0).
- CMU\_LFRCOCTRL should not be written while LFRCOBSY in the CMU\_SYNCBUSY register is set to 1. The GMCCURTUNE bitfield should not be written with a differing value while the LFRCOVREFBSY flag is set to 1.
- CMU\_LFXOCTRL should not be written while LFXOBSY in the CMU\_SYNCBUSY register is set to 1.

### 10.3.8 Interrupts

The interrupts generated by the CMU module are combined into one interrupt vector. If CMU interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in CMU\_IF and their corresponding bits in CMU\_IEN are set.

### 10.3.9 Wake-up

The CMU can be (partially) active all the way down to EM4 Shutoff. It can wake up the CPU from EM2 upon LFRCO or LFXO becoming ready as LFRCORDY and LFXORDY can be used as wake-up interrupt.

#### 10.3.10 Protection

It is possible to lock the control- and command registers to prevent unintended software writes to critical clock settings. This is controlled by the CMU\_LOCK register.

## 10.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                    | Type  | Description                                         |
|--------|-------------------------|-------|-----------------------------------------------------|
| 0x000  | CMU_CTRL                | RW    | CMU Control Register                                |
| 0x010  | CMU_HFRCOCTRL           | RWH   | HFRCO Control Register                              |
| 0x018  | CMU_AUXHFRCOCTRL        | RW    | AUXHFRCO Control Register                           |
| 0x020  | CMU_LFRCOCTRL           | RW    | LFRCO Control Register                              |
| 0x024  | CMU_HFXOCTRL            | RW    | HFXO Control Register                               |
| 0x028  | CMU_HFXOCTRL1           | RW    | HFXO Control 1                                      |
| 0x02C  | CMU_HFXOSTARTUPCTRL     | RW    | HFXO Startup Control                                |
| 0x030  | CMU_HFXOSTEADYSTATECTRL | RW    | HFXO Steady State Control                           |
| 0x034  | CMU_HFXOTIMEOUTCTRL     | RW    | HFXO Timeout Control                                |
| 0x038  | CMU_LFXOCTRL            | RW    | LFXO Control Register                               |
| 0x03C  | CMU_ULFRCOCTRL          | RW    | ULFRCO Control Register                             |
| 0x050  | CMU_CALCTRL             | RW    | Calibration Control Register                        |

### 10.5.2 CMU\_HFRCTRL - HFRCO Control Register

Write this register to set the frequency band in which the HFRCO is to operate. Always update all fields in this register at once by writing the value for the desired band, which has been obtained from the Device Information page entry for that band. The TUNING, FINE-TUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. When changing this setting there will be no glitches on the HFRCO output, hence it is safe to change this setting

even while the system is running on the HFRCO. Only write CMU\_HFRCOCTRL when it is ready for an update as indicated by HFRCOBSY=0 in CMU\_SYNCBUSY.

### 10.5.3 CMU\_AUXHFRCTRL - AUXHFRCO Control Register

Write this register with the production calibrated values from the Device Info pages. The TUNING, FINETUNING, FINETUNINGEN and CLKDIV bitfields can be used to tune a specific band (FREQRANGE) of the oscillator to a non-preconfigured frequency. Only write CMU\_AUXHFRCTRL when it is ready for an update as indicated by AUXHFRCOBSY=0 in CMU\_SYNCBUSY.

Do not change while LFXO is enabled. When starting up the LFXO after it has been completely turned off, use the TIMEOUT setting required by the XTAL. If the LFXO has been retained on in EM4, then the TIMEOUT=2cycles configuration is also allowed when re-enabling the LFXO after EM4 exit (as it is still running). |

|      | Selects the clock source for HFCLK. Note that selecting an oscillator that is disabled will cause the system clock to stop. Check the status register and confirm that oscillator is ready before switching. If the system can deal with a temporarily stopped system clock, then it is okay to switch to an oscillator as soon as the status register indicates that the oscillator has been enabled successfully. |                                                                                                                          |        |                       |

## 11. RTCC - Real Time Counter and Calendar

### Quick Facts

#### What?

The Real Time Counter and Calendar (RTCC) is a 32-bit counter ensuring timekeeping in low energy modes. The RTCC also includes a calendar mode for easy time and date keeping. In addition, the RTCC includes 128 bytes of general purpose retention data, allowing persistent data storage in all energy modes except EM4 Shutoff.

#### Why?

Timekeeping over long time periods while using as little power as possible is required in many low power applications.

#### How?

A low frequency oscillator is used as clock signal and the RTCC has three different Capture/Compare channels which can trigger wake-up, generate PRS signalling, or capture system events. 32-bit resolution and selectable prescaling allow the system to stay in low energy modes for long periods of time and still maintain reliable timekeeping.

### 11.1 Introduction

The Real Time Counter and Calendar (RTCC) contains a 32-bit counter/calendar in combination with a 15-bit pre-counter to allow flexible prescaling of the main counter. The RTCC is available in all energy modes except EM4 Shutoff.

Three individually configurable Capture/Compare channels are available in the RTCC. These can be used to trigger interrupts, generate PRS signals, capture system events, and to wake the device up from a low energy mode. The RTCC also includes 128 bytes of general purpose storage and a Binary Coded Decimal (BCD) calendar mode, enabling easy time and date keeping.

### 11.2 Features

- 32-bit Real Time Counter.
- 15-bit pre-counter, for flexible frequency scaling or for use as an independent counter.
- EM4 Hibernate operation and wakeup.
- 128 byte general purpose retention data.
- Oscillator failure detection.
- Can continue through system reset; only reset by power loss, pin, or software reset.
- Calendar mode.
  - BCD encoding.
  - Three programmable alarms.
  - Leap year correction.
- Three Capture/Compare registers.
  - Capture of PRS events from other parts of the system.
  - Compare match or input capture can trigger interrupts.
  - Compare register 1, RTCC\_CC1\_CCV can be used as a top value for the main counter.
  - Compare register 0, RTCC\_CC0\_CCV can be used as a top value for the pre-counter.
  - Compare match events are available to other peripherals through the Peripheral Reflex System (PRS).

### 11.3 Functional Description

The RTCC is a 32-bit up-counter with three Capture/Compare channels. In addition, the RTCC includes a 15-bit pre-counter which can be used as an independent counter or to prescale the main counter. An overview of the RTCC module is shown in [Figure 11.1 RTCC Overview](#) on page 310.

Figure 11.1. RTCC Overview

### 11.3.1 Counter

The RTCC consists of two counters; the 32-bit main counter, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode), and a 15-bit pre-counter, RTCC\_PRECNT. The pre-counter can be used as an independent counter or to generate a specific frequency for the main counter. In both configurations, the pre-counter can be used to generate compare match events or be captured in the Capture/Compare channels as a result of an external PRS event. Refer to [11.3.2 Capture/Compare Channels](#) for details on how to configure the Capture/Compare channels for use with the pre-counter.

Figure 11.2. RTCC counters

The RTCC is enabled by setting the ENABLE bit in RTCC\_CTRL. When the RTCC is enabled, the pre-counter (RTCC\_PRECNT) increments upon each positive clock edge of LFCLK<sub>RTCC</sub>. If CNTTICK in RTCC\_CTRL is set to PRESC, the pre-counter will continue to count up, wrapping around to zero when it overflows. If CNTTICK in RTCC\_CTRL is set to CCV0MATCH, the pre-counter will wrap around when it hits the value configured in RTCC\_CC0\_CCV.

The main counter of the RTCC, RTCC\_CNT, has two modes; normal mode and calendar mode. In normal mode, the main counter is available in RTCC\_CNT and increments upon each tick given from the pre-counter. Refer to [11.3.1.1 Normal Mode](#) for a description on how to configure the frequency of these ticks. In calendar mode, the counter value is available in RTCC\_TIME and RTCC\_DATE, keeping track of seconds, minutes, hours, day of month, day of week, months, and years, all encoded in BCD format. Refer to [11.3.1.2 Calendar Mode](#) for details on this mode. The mode of the main counter is configured in CNTMODE in RTCC\_CTRL. The differences between the two modes are summarized below.

- **Normal mode**

- Incremental counter, RTCC\_CNT.
- RTCC\_CCx\_CCV used for Capture/Compare value.

- **Calendar mode**

- BCD counters, RTCC\_DATE, RTCC\_TIME.
- RTCC\_CCx\_TIME and RTCC\_CCx\_DATE used for Capture/Compare value.

**Note:** The mode of the RTCC must be configured for CALENDAR mode in RTCC\_CTRL\_CNTMODE before writing to the mode dependent registers, RTCC\_TIME, RTCC\_DATE, RTCC\_CCx\_TIME, and RTCC\_CCx\_DATE. Writes to these registers when in NORMAL mode will be ignored.

### 11.3.1.1 Normal Mode

The main counter can receive a tick based on different tapplings from the pre-counter, allowing the ticks to be power of 2 divisions of the  $LFCLK_{RTCC}$ . For more accurate configuration of the tick frequency,  $RTCC\_CC0\_CCV[14:0]$  can be used as a top value for  $RTCC\_PRECNT$ . When reaching the top value, the main counter receives a tick and the pre-counter wraps around. [Table 11.1 RTCC Resolution Vs Overflow,  \$F\_{LFCLK} = 32768\$  Hz on page 312](#) summarizes the resolutions available when using a 32768 Hz oscillator as source for  $LFCLK_{RTCC}$ .

**Table 11.1. RTCC Resolution Vs Overflow,  $F_{LFCLK} = 32768$  Hz**

| RTCC_CTRL_CNTTICK | RTCC_CTRL_CNTPRESC | Main counter period, $T_{CNT}$     | Overflow                       |
|-------------------|--------------------|------------------------------------|--------------------------------|

|                   | DIV512             | 15.6 ms                            | 776 days                       |
|                   | DIV1024            | 31.25 ms                           | 4.2 years                      |
|                   | DIV2048            | 62.5 ms                            | 8.5 years                      |
|                   | DIV4096            | 0.125 s                            | 17 years                       |
|                   | DIV8192            | 0.25 s                             | 34 years                       |
|                   | DIV16384           | 0.5 s                              | 68 years                       |
|                   | DIV32768           | 1 s                                | 136 years                      |

By default, the counter will keep counting until it reaches the top value, 0xFFFFFFFF, before it wraps around and continues counting from zero. By setting  $CCV1TOP$  in  $RTCC\_CTRL$ , a Capture/Compare channel 1 compare match will result in the main counter wrapping to 0. The timer will then wrap around on a channel 1 compare match ( $RTCC\_CNT = RTCC\_CC1\_CCV$ ). Before using the  $CCV1TOP$  setting, make sure to set this bit prior to or at the same time the RTCC is enabled. Setting  $CCV1TOP$  after enabling the RTCC ( $RTCC\_CTRL\_MODE \neq DISABLED$ ) may cause unintended operation (e.g. if  $RTCC\_CNT > RTCC\_CC1\_CCV$ ,  $RTCC\_CNT$  will wrap when reaching 0xFFFFFFFF rather than  $RTCC\_CC1\_CCV$ ).

**Note:** If the RTCC is being reconfigured, and capture compare channel 1 has previously been used, a  $CCV1TOP$  wrap event might be pending. This would lead to the first tick of the main counter being a wrap to 0. To clear any pending wrap events, use the following procedure before reconfiguring the RTCC:

1.  $RTCC \rightarrow CC[1].CTRL = RTCC\_CC\_CTRL\_MODE\_OFF$ ;
2.  $RTCC \rightarrow CTRL = RTCC\_CTRL\_CNTTICK\_PRESC | RTCC\_CTRL\_CNTMODE\_NORMAL | RTCC\_CTRL\_ENABLE$ ;
3.  $rtcc\_cnt\_pre = RTCC \rightarrow CNT$ ;
4.  $while(RTCC \rightarrow CNT == rtcc\_cnt\_pre)$ ;
5. Reconfigure the RTCC

### 11.3.1.2 Calendar Mode

The RTCC includes a calendar mode which implements time and date decoding in hardware. Calendar mode is enabled by configuring CNTMODE in RTCC\_CTRL to CALENDAR. When in calendar mode, the counter value is available in RTCC\_TIME and RTCC\_DATE. RTCC\_TIME shows seconds, minutes, and hours while RTCC\_DATE shows day of month, month, year, and day of week. RTCC\_TIME and RTCC\_DATE are encoded in BCD format. In calendar mode, the pre-counter should be configured to give ticks with a period of one second, i.e. RTCC\_CTRL\_CNTTICK should be set to PRESC, and the CNTPRESC bitfield of the RTCC\_CTRL register should be set to DIV32768 if a 32768 Hz clock source is used.

In calendar mode, the time and date registers of the capture compare channels, RTCC\_CCx\_TIME and RTCC\_CCx\_DATE, are used to set compare values. Compare values can be set on seconds, minutes, hours, days, and months. Whether day of week or day of month is used for a Capture/Compare channel, it is configured in RTCC\_CCx\_CTRL\_DAYCC of the respective Capture/Compare channel.

The RTCC will automatically compensate for 28-, 29- (leap year), 30-, and 31-day months. The day of week counter, RTCC\_DATE\_DAYOW, is a three bit counter incrementing when RTCC\_TIME\_HOURLT overflows, wrapping around every seventh day. Automatic leap year correction, extending the month of February from 28 to 29 days every fourth year is by default enabled, but can be disabled by setting the LYEARCHORRDIS bit in RTCC\_CTRL. The pseudo-code for leap year correction is as follows:

```
if RTCC_DATE YEART modulo 2 = 0:
    if RTCC_DATE YEARU modulo 4 = 0:
        leap_year = true
    else:
        leap_year = false
else:
    if (RTCC_DATE YEARU + 2) modulo 4 = 0:
        leap_year = true
    else:
        leap_year = false
```

The seconds, minute, hour segments are represented in 24-hour BCD format. The month segments are enumerated as shown in [Table 11.2 RTCC calendar enumeration on page 313](#).

**Table 11.2. RTCC calendar enumeration**

| Month     | RTCC_DATE_MONTHT | RTCC_DATE_MONTHU |
|-----------|------------------|------------------|
| January   | 0b0              | 0b0001           |
| February  | 0b0              | 0b0010           |
| March     | 0b0              | 0b0011           |
| April     | 0b0              | 0b0100           |
| May       | 0b0              | 0b0101           |
| June      | 0b0              | 0b0110           |
| July      | 0b0              | 0b0111           |
| August    | 0b0              | 0b1000           |
| September | 0b0              | 0b1001           |
| October   | 0b1              | 0b0000           |
| November  | 0b1              | 0b0001           |
| December  | 0b1              | 0b0010           |

### 11.3.1.3 RTCC Initialization

The counters of the RTCC, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode) and RTCC\_PRECNT, can at any time be written by software, as long as the registers are not locked using RTCC\_LOCKKEY. All RTCC registers use the immediate synchronization scheme, described in [4.3.1 Writing](#).

**Note:** Writing to the RTCC\_PRECNT register may alter the frequency of the ticks for the RTCC\_CNT register.

### 11.3.2 Capture/Compare Channels

Three capture/compare channels are available in the RTCC. Each channel can be configured as input capture or output compare, by setting the corresponding MODE in the RTCC\_CCx\_CTRL register.

**Figure 11.3. RTCC Compare match and PRS output illustration**

In input capture mode the RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode) register is captured into the RTCC\_CCx\_CCv (RTCC\_CCx\_TIME and RTCC\_CCx\_DATE in calendar mode) register when an edge is detected on the selected PRS input channel. The active capture edge is configured in the ICEDGE control bits.

In output compare mode the compare values are set by writing to the RTCC compare channel registers RTCC\_CCx\_CCv (RTCC\_CCx\_TIME and RTCC\_CCx\_DATE in calendar mode). These values will be compared to the main counter, RTCC\_CNT (RTCC\_TIME and RTCC\_DATE in calendar mode), or a mixture of the main counter and the pre-counter, as illustrated in [Figure 11.4 RTCC Compare base illustration on page 316](#). Compare base for the capture compare channels is set by configuring COMP-BASE in RTCC\_CCx\_CTRL.

**Figure 11.4. RTCC Compare base illustration**

Table 11.3 RTCC Capture/Compare Subjects on page 316 summarizes which registers being subject to comparison for different configurations of RTCC\_CTRL\_CNTMODE and RTCC\_CCx\_CTRL\_COMPBASE.

**Table 11.3. RTCC Capture/Compare Subjects**

| RTCC_CTRL_CNTMODE               | NORMAL                                              | CALENDAR                                                    |
|---------------------------------|-----------------------------------------------------|-------------------------------------------------------------|
| RTCC_CCx_CTRL_COMPBASE = CNT    | RTCC_CNT vs. RTCC_CCx_CCx                           | RTCC_TIME vs. RTCC_CCx_TIME and RTCC_DATE vs. RTCC_CCx_DATE |
| RTCC_CCx_CTRL_COMPBASE = PRECNT | {RTCC_CNT[16:0],RTCC_PRECNT[14:0]} vs. RTCC_CCx_CCx | RTCC_PRECNT vs. RTCC_CCx_CCx[14:0]                          |

Figure 11.5 RTCC Compare in calendar mode, COMPBASE = CNT on page 317 illustrates how the compare events are evaluated when in calendar mode with RTCC\_CCx\_CTRL\_COMPBASE = CNT. The SECU, SECT, MINU, MINT, HOURU, HOURS, MONTHU, and MONTHT bitfields in RTCC\_CCx\_TIME and RTCC\_CCx\_DATE are compared to the corresponding bitfields in RTCC\_DATE and RTCC\_TIME. The DAYU and DAYT bitfields in RTCC\_CCx\_DATE will be compared to {RTCC\_DATE\_DAYOMT, RTCC\_DATE\_DAYOMU} if DAYCC in RTCC\_CCx\_CTRL is set to MONTH. If DAYCC in RTCC\_CCx\_CTRL is set to WEEK, the DAYU and DAYT bitfields in RTCC\_CCx\_DATE will be compared to {0b000, RTCC\_DATE\_DAYOW}.

**Figure 11.5. RTCC Compare in calendar mode, COMPBASE = CNT**

To generate periodically recurring events, it is possible to mask out parts of the compare match values. By configuring COMPMASK in RTCC\_CCx\_CTRL, parts of the compare values will be masked out, limiting which part of the compare register being subject to comparison with the counter. [Figure 11.6 RTCC Compare mask illustration, COMPMASK=11 on page 317](#) illustrates the effect of COMPMASK when in normal mode and calendar mode.

**Figure 11.6. RTCC Compare mask illustration, COMPMASK=11**

Upon a compare match, the respective Capture/Compare interrupt flag CCx is set. Additionally, the event selected by the CMOA setting is generated on the corresponding PRS output. This is illustrated in [Figure 11.3 RTCC Compare match and PRS output illustration on page 315](#).

### 11.3.3 Interrupts and PRS Output

The RTCC has one interrupt for each of its 3 Capture/Compare channels, CC0, CC1, and CC2. Each Capture/Compare channel has a PRS output with configurable actions upon compare match.

The interrupt flag CNTTICK is set each time the main counter receives a tick (each second in calendar mode). In calendar mode, there are also interrupt flags being set each minute, hour, day, week, and month.

Upon oscillator failure detection, the OSCFAIL flag will be set.

### 11.3.3.1 Main Counter Tick PRS Output

To output the ticks for the main counter on PRS, it is possible to use a Capture/Compare channel and mask all the bits, i.e. `RTCC_CCx_CTRL_COMPBASE=CNT` and `RTCC_CCx_CTRL_COMPMASK=31`. PRS output of main counter ticks does not work if the main counter is not prescaled.

**Note:** To be able to mask all bits in the main counter, `RTCC_CTRL_CNTMODE` has to be set to `CALENDAR`. In `NORMAL` mode, the least significant bit can not be masked out.

### 11.3.4 Energy Mode Availability

The RTCC is available in all energy modes except EM4 Shutoff. To enable RTCC operation in EM4 Hibernate, the `EMU_EM4CTRL` register in the EMU has to be configured. Any enabled RTCC interrupt will wake the system up from EM4 Hibernate; if `EM4WU` in `RTCC_EM4WUEN` is set. Refer to [9. EMU - Energy Management Unit](#) for details on how to configure the EMU.

### 11.3.5 Register Lock

To prevent accidental writes to the RTCC registers, the `RTCC_LOCKKEY` register can be written to any value other than the unlock value. To unlock the register, write the unlock value to `RTCC_LOCKKEY`. Registers affected by this lock are:

- `RTCC_CTRL`
- `RTCC_PRECNT`
- `RTCC_CNT`
- `RTCC_TIME`
- `RTCC_DATE`
- `RTCC_IEN`
- `RTCC_POWERDOWN`
- `RTCC_CCx_CTRL`
- `RTCC_CCx_CCV`
- `RTCC_CCx_TIME`
- `RTCC_CCx_DATE`

### 11.3.6 Oscillator Failure Detection

To be able to detect OSC failure, the RTCC includes a security mechanism ensuring that at least three OSC cycles are detected within one period of the `ULFRCO`. If no OSC cycles are detected, the `OSCFAIL` interrupt flag is set. OSC failure detection is enabled by setting the `OSCFDETEN` bit in `RTCC_CTRL`.

### 11.3.7 Retention Registers

The RTCC includes 32 x 32 bit registers which can be retained in all energy modes except EM4 Shutoff. The registers are accessible through the `RETx_REG` registers. Retention is by default enabled in EM0 Active through EM4 Hibernate/Shutoff. The registers can be shut off to save power by setting the `RAM` bit in `RTCC_POWERDOWN`.

**Note:** The retention registers are mapped to a RAM instance and have undefined state out of reset.

### 11.3.8 Frame Controller Interface

For easy timestamping of frames, `RTCC_CC2_CCV` is directly available for the Frame Controller, `FRC`.

### 11.3.9 Debug Session

By default, the RTCC is halted when code execution is halted from the debugger. By setting the `DEBUGRUN` bit in the `RTCC_CTRL` register, the RTCC will continue to run even when the debugger has halted the system.

## 11.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                       | Type  | Description                                     |
|--------|----------------------------|-------|-------------------------------------------------|
| 0x000  | RTCC_CTRL                  | RW    | Control Register                                |
| 0x004  | RTCC_PRECNT                | RWH   | Pre-Counter Value Register                      |
| 0x008  | RTCC_CNT                   | RWH   | Counter Value Register                          |
| 0x00C  | RTCC_COMBCNT               | R     | Combined Pre-Counter and Counter Value Register |
| 0x010  | RTCC_TIME                  | RWH   | Time of Day Register                            |
| 0x014  | RTCC_DATE                  | RWH   | Date Register                                   |
| 0x018  | RTCC_IF                    | R     | RTCC Interrupt Flags                            |
| 0x01C  | RTCC_IFS                   | W1    | Interrupt Flag Set Register                     |
| 0x020  | RTCC_IFC                   | (R)W1 | Interrupt Flag Clear Register                   |
| 0x024  | RTCC_IEN                   | RW    | Interrupt Enable Register                       |
| 0x028  | RTCC_STATUS                | R     | Status Register                                 |
| 0x02C  | RTCC_CMD                   | W1    | Command Register                                |
| 0x030  | RTCC_SYNCBUSY              | R     | Synchronization Busy Register                   |
| 0x034  | RTCC_POWERDOWN             | RW    | Retention RAM Power-down Register               |
| 0x038  | RTCC_LOCK                  | RWH   | Configuration Lock Register                     |
| 0x03C  | RTCC_EM4WUEN               | RW    | Wake Up Enable                                  |
| 0x040  | RTCC_CC0_CTRL              | RW    | CC Channel Control Register                     |
| 0x044  | RTCC_CC0_CCV               | RWH   | Capture/Compare Value Register                  |
| 0x048  | RTCC_CC0_TIME              | RWH   | Capture/Compare Time Register                   |
| 0x04C  | RTCC_CC0_DATE              | RWH   | Capture/Compare Date Register                   |
| 0x050  | RTCC_CC1_CTRL              | RW    | CC Channel Control Register                     |
| 0x054  | RTCC_CC1_CCV               | RWH   | Capture/Compare Value Register                  |
| 0x058  | RTCC_CC1_TIME              | RWH   | Capture/Compare Time Register                   |
| 0x05C  | RTCC_CC1_DATE              | RWH   | Capture/Compare Date Register                   |
| 0x060  | RTCC_CC2_CTRL              | RW    | CC Channel Control Register                     |
| 0x064  | RTCC_CC2_CCV               | RWH   | Capture/Compare Value Register                  |
| 0x068  | RTCC_CC2_TIME              | RWH   | Capture/Compare Time Register                   |
| 0x06C  | RTCC_CC2_DATE              | RWH   | Capture/Compare Date Register                   |
| 0x104  | RTCC_RET0_REG              | RW    | Retention Register                              |
| ...    | RTCC_RET <sub>x</sub> _REG | RW    | Retention Register                              |
| 0x180  | RTCC_RET31_REG             | RW    | Retention Register                              |

## 11.5 Register Description

### 11.5.1 RTCC\_CTRL - Control Register (Async Reg)

For more information about asynchronous registers see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |              |         |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|--------------|---------|
| 0x000  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17           | 16      |
| Reset  |              |    |    |    |    |    |    |    |    |    |    |    |    |    | 0            | 0       |
| Access |              |    |    |    |    |    |    |    |    |    |    |    |    |    | RW           | RW      |
| Name   |              |    |    |    |    |    |    |    |    |    |    |    |    |    | LYEARCORRDIS | CNTMODE |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | OSCFDETEN    |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | CNTTICK      |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | CNTPRESC     |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    |              |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | CCV1TOP      |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | PRECCV0TOP   |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    |              |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    | DEBGRUN      |         |
|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    |              | ENABLE  |

## 12. WDOG - Watchdog Timer

### Quick Facts

#### What?

The Watchdog Timer (WDOG) resets the system in case of a fault condition, and can be enabled in all energy modes as long as the low frequency clock source is available.

#### Why?

If a software failure or external event renders the MCU unresponsive, a Watchdog timeout will reset the system to a known, safe state.

#### How?

An enabled Watchdog Timer implements a configurable timeout period. If the CPU fails to re-start the Watchdog Timer before it times out, a full system reset will be triggered. The Watchdog consumes insignificant power, and allows the device to remain safely in low energy modes for up to 256 seconds at a time.

### 12.1 Introduction

The purpose of the watchdog timer is to generate a reset in case of a system failure to increase application reliability. The failure can be caused by a variety of events, such as an ESD pulse or a software failure.

### 12.2 Features

- Clock input from selectable oscillators
  - Internal 32 kHz LFRCO oscillator
  - Internal 1 kHz ULFRCO oscillator
  - External 32.768 kHz LFXO XTAL oscillator
- Configurable timeout period from 9 to 256k watchdog clock cycles
- Individual selection to keep running or freeze when entering EM2 DeepSleep or EM3 Stop
- Selection to keep running or freeze when entering debug mode
- Selection to block the CPU from entering Energy Mode 4
- Selection to block the CMU from disabling the selected watchdog clock
- Configurable warning interrupt at 25%, 50%, or 75% of the timeout period
- Configurable window interrupt at 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, 87.5% of the timeout period
- Timeout interrupt
- PRS as a watchdog clear
- Interrupt for the event where a PRS rising edge is absent before a software reset

### 12.3 Functional Description

The watchdog is enabled by setting the EN bit in WDOGN\_CTRL. When enabled, the watchdog counts up to the period value configured through the PERSEL field in WDOGN\_CTRL. If the watchdog timer is not cleared to 0 (by writing a 1 to the CLEAR bit in WDOGN\_CMD) before the period is reached, the chip is reset. If a timely clear command is issued, the timer starts counting up from 0 again. The watchdog can optionally be locked by writing the LOCK bit in WDOGN\_CTRL. Once locked, it cannot be disabled or reconfigured by software.

When the EN bit in WDOGN\_CTRL is cleared to 0, the watchdog counter is reset.

### 12.3.1 Clock Source

Three clock sources are available for use with the watchdog, through the CLKSEL field in WDOGN\_CTRL. The corresponding clocks must be enabled in the CMU. The SWOSCBLOCK bit in WDOGN\_CTRL can be written to prevent accidental disabling of the selected clocks. Also, setting this bit will automatically start the selected oscillator source when the watchdog is enabled. The PERSEL field in WDOGN\_CTRL is used to divide the selected watchdog clock, and the timeout for the watchdog timer can be calculated with the formula:

$$T_{\text{TIMEOUT}} = (2^{3+\text{PERSEL}} + 1) / f$$

where  $f$  is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing PERSEL.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0.

### 12.3.2 Debug Functionality

The watchdog timer can either keep running or be frozen when the device is halted by a debugger. This configuration is done through the DEBUGRUN bit in WDOGN\_CTRL. When code execution is resumed, the watchdog will continue counting where it left off.

### 12.3.3 Energy Mode Handling

The watchdog timer can be configured to either keep on running or freeze when entering EM2 DeepSleep or EM3 Stop. The configuration is done individually for each energy mode in the EM2RUN and EM3RUN bits in WDOGN\_CTRL. When the watchdog has been frozen and is re-entering an energy mode where it is running, the watchdog timer will continue counting where it left off. For the watchdog there is no difference between EM0 Active and EM1 Sleep. The watchdog does not run in EM4 Hibernate/Shutoff. If EM4BLOCK in WDOGN\_CTRL is set, the CPU will be prevented from entering EM4 Hibernate/Shutoff by software request.

#### Note:

If the WDOG is clocked by the LFXO or LFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM3 Stop. When running from the ULFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM4 Hibernate/Shutoff.

### 12.3.4 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals. Note that clearing the EN bit in WDOGN\_CTRL will reset the WDOG module, which will halt any ongoing register synchronization.

#### Note:

Never write to the WDOG registers when it is disabled, except to enable the watchdog by setting the EN bitfield in WDOGN\_CTRL.

### 12.3.5 Warning Interrupt

The watchdog implements a warning interrupt which can be configured to occur at approximately 25%, 50%, or 75% of the timeout period through the WARNSEL field of the WDOGN\_CTRL register. This interrupt can be used to wake up the cpu for clearing the watchdog. The warning point for the watchdog timer can be calculated with the formula:

$$T_{\text{WARNING}} = (2^{3+\text{PERSEL}}) * (\text{WARNSEL} / 4) + 1) / f,$$

where  $f$  is the frequency of the selected clock.

When the watchdog is enabled, it is recommended to clear the watchdog before changing WARNSEL.

### 12.3.6 Window Interrupt

This interrupt occurs when the watchdog is cleared below a certain threshold. This threshold is given by the formula:

$$T_{\text{WARNING}} = (2^{3+\text{PERSEL}}) * (\text{WINSEL}/8) + 1)/f,$$

where  $f$  is the frequency of the selected clock.

This value will be approximately 12.5%, 25%, 37.5%, 50%, 62.5%, 75%, or 87.5% of the timeout value based on the WINSEL field of the WDOGn\_CTRL. [Figure 12.2 WDOG Warning, Window, and Timeout on page 340](#) illustrates the warning, the window, and the timeout interrupts. Also, it shows where the prs rising edge needs to happen. The prs edge detection feature is discussed later.

**Figure 12.2. WDOG Warning, Window, and Timeout**

When the watchdog is enabled, it is recommended to clear the watchdog before changing WINSEL.

### 12.3.7 PRS as Watchdog Clear

The first PRS channel (selected by register WDOGN\_PCH0\_PRSCTRL) can be used to clear the watchdog counter. To enable this feature, CLRSRC must be set to 1. [Figure 12.2 PRS Clearing WDOG on page 341](#) shows how the PRS channel takes over the WDOG clear function. Clearing the WDOG with the PRS is mutually exclusive of clearing the WDT by software.

Figure 12.2. PRS Clearing WDOG

### 12.3.8 PRS Rising Edge Monitoring

PRS channels can be used to monitor multiple processes. If enabled, every time the watch dog timer is cleared the PRS channels are checked and any channel which has not seen an event can trigger an interrupt.

Figure 12.3. PRS Edge Monitoring in WDOG

## 12.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                   |
|--------|--------------------|-------|-------------------------------|
| 0x000  | WDOG_CTRL          | RW    | Control Register              |
| 0x004  | WDOG_CMD           | W1    | Command Register              |
| 0x008  | WDOG_SYNCBUSY      | R     | Synchronization Busy Register |

## 13. PRS - Peripheral Reflex System

### Quick Facts

#### What?

The Peripheral Reflex System (PRS) allows configurable, fast, and autonomous communication between peripherals.

#### Why?

Events and signals from one peripheral can be used as input signals or triggered by other peripherals. Besides, PRS reduces latency and ensures predictable timing by reducing software overhead and thus current consumption.

#### How?

Without CPU intervention the peripherals can send Reflex signals (both pulses and level) to each other in single or chained steps. The peripherals can be set up to perform actions based on the incoming Reflex signals. This results in improved system performance and reduced energy consumption.

### 13.1 Introduction

The Peripheral Reflex System (PRS) is a network allowing direct communication between different peripheral modules without involving the CPU. Peripheral modules which send out Reflex signals are called producers. The PRS routes these Reflex signals through Reflex channels to consumer peripherals which perform actions depending on the Reflex signals received. The format for the Reflex signals is not given, but edge triggers and other functionality can be applied by the PRS.

### 13.2 Features

- 12 Configurable Reflex Channels
  - Each channel can be connected to any producing peripheral, including the PRS channels
  - Consumers can choose which channel to listen to
  - Selectable edge detector (Rising, falling and both edges)
  - Configurable AND and OR between channels
  - Optional channel invert
  - PRS can generate event to CPU
  - Two independent DMA requests based on PRS channels
- Software controlled channel output
  - Configurable level
  - Triggered pulses

### 13.3 Functional Description

An overview of the PRS module is shown in [Figure 13.1 PRS Overview on page 354](#). The PRS contains 12 Reflex channels. All channels can select any Reflex signal offered by the producers. The consumers can choose which PRS channel to listen to and perform actions based on the Reflex signals routed through that channel. The Reflex signals can be both edge signals and level signals.

Figure 13.1. PRS Overview

#### 13.3.1 Channel Functions

Different functions can be applied to a Reflex signal within the PRS. Each channel includes an edge detector to enable generation of pulse signals from level signals. The PRS channels can also be manually triggered by writing to PRS\_SWPULSE or PRS\_SWLEVEL. SWLEVEL[n] is a programmable level for each channel and holds the value it is programmed to. Setting SWPULSE[n] will cause the PRS channel to output a high pulse that is one HFCLK cycle wide. The SWLEVEL[n] and SWPULSE[n] signals are then XOR'ed with the selected input from the producers to form the output signal sent to the consumers listening to the channel. For example, when SWLEVEL[n] is set, if a producer produces a signal of 1, this will cause a channel output of 0.

##### 13.3.1.1 Operational Mode

Reflex channels can operate in two modes, synchronous or asynchronous. In synchronous mode Reflex signals are clocked on the HFCLK, and can be used by any Reflex consumer. However, this will not work in EM2/EM3, since the HFCLK will be turned off.

Asynchronous Reflex channels are not clocked on HFCLK, and can be used even in EM2/EM3. However, the asynchronous mode can only be used by a subset of the Reflex consumers.

The asynchronous Reflex signals generated by the producers are indicated in the SIGSEL field of PRS\_CHx\_CTRL register. The consumers capable of utilizing asynchronous Reflex signals include the LEUART and the PCNT. The USART can also utilize some particular asynchronous signals. Refer to the respective modules for details on how to configure them to use the PRS.

**Note:** If a Reflex channel with ASYNC field of PRS\_CHx\_CTRL register set to '1' is used in a consumer not supporting asynchronous reflexes, the behaviour is undefined

### 13.3.1.2 Edge Detection and Clock Domains

Using EDSEL in PRS\_CHx\_CTRL, edge detection can be applied to a PRS signal. When edge detection is enabled, changes in the PRS input will result in a pulse on the PRS channel. This requires that the ASYNC bit in PRS\_CHx\_CTRL is cleared. Signals on the PRS input must be at least one HFCLK period wide in order to be detected properly. This applies to all cases when ASYNC is not used in the PRS.

For communication between peripherals on different prescaled clocks (e.g. between peripherals on HFCLK and HFPERCLK), there are two options. One option is to use level signals. No additional action is needed for level signals, but software must make sure that the level signals are held long enough for the destination domain to detect them. The other option is to use pulse signals. For pulse signals, edge detection should be enabled (by configuring EDSEL in PRS\_CHx\_CTRL to positive edge, negative edge, or both) and STRETCH in PRS\_CHx\_CTRL should be set. When edge detection and stretch are enabled on a PRS source, the output on the PRS channel is held long enough for the destination domain to detect the pulse. This also works if there are multiple destination domains running at different frequencies.

### 13.3.1.3 Configurable PRS Logic

Each PRS channel has three logic functions that can be used by themselves or in combination. The selected PRS source can be AND'ed with the next PRS channel output, OR'ed with the previous PRS channel output and inverted. This is shown in [Figure 13.1 PRS Overview on page 354](#). The order of the functions is important. If OR and AND are enabled at the same time, AND is applied first, and then OR. Note that the previous and next channel options wrap around. Using the ORPREV option on the first PRS channel OR's with the output of the last PRS channel. Likewise, using the ANDNEXT option on the last PRS channel AND's with the output of the first PRS channel.

**Figure 13.2. Configurable PRS Logic**

In addition to the logic functions that can combine a PRS channel with one of its neighbors, a PRS channel can also select any other PRS channel as input. This can allow relatively complex logic functions to be created.

### 13.3.2 Producers

Through SOURCESEL in PRS\_CHx\_CTRL, each PRS channel selects signal producers. Each producer outputs one or more signals which can be selected by setting the SIGSEL field in PRS\_CHx\_CTRL. Setting the SOURCESEL bits to 0 (Off) leads to a constant 0 output from the input mux. An overview of the available producers can be found in the SOURCESEL and SIGSEL fields in PRS\_CHx\_CTRL. Note that GPIO producers are selected in the GPIO module using the edge interrupt configuration settings described in [26.3.5.1 Edge Interrupt Generation](#). GPIOPIN0 uses the selection for the EXTIO interrupt, GPIOPIN1 uses the selection for the EXTIO1 interrupt, and so on.

### 13.3.3 Consumers

Consumer peripherals (Listed in [Table 13.1 Reflex Consumers on page 356](#)) can be set to listen to a PRS channel and perform an action based on the signal received on that channel. While most consumers can handle either only pulse input or only level input, some can handle both pulse and level inputs.

**Table 13.1. Reflex Consumers**

| Module  | Reflex Input                                                                                         | Input Format  |
|---------|------------------------------------------------------------------------------------------------------|---------------|
| TIMER   | Compare/Capture Channel                                                                              | Pulse / Level |
|         | Alternate Input for DTI<br>(Available only in specific TIMERS<br>See data sheet for details)         | Level         |
|         | Alternate Input for DTI Fault 0<br>(Available only in specific TIMERS<br>See data sheet for details) | Level         |
|         | Alternate Input for DTI Fault 1<br>(Available only in specific TIMERS<br>See data sheet for details) | Level         |
| USART   | RX/TX Trigger                                                                                        | Pulse         |
|         | Alternate Input for IrDA                                                                             | Level         |
|         | Alternate Input for RX                                                                               | Level         |
|         | Alternate Input for CLK                                                                              | Level         |
| ADC     | Single Sample Trigger                                                                                | Pulse         |
|         | Scan Sequence Trigger                                                                                | Pulse         |
| IDAC    | Alternate Input for OUTMODE                                                                          | Level         |
| CMU     | Alternate Input for Calibration Up-Counter                                                           | Level         |

| LEUART  | Alternate Input for RX                                                                               | Level         |
| PCNT    | Compare/Clear Trigger                                                                                | Pulse/Level   |
|         | Alternate Input for S0IN                                                                             | Level         |
|         | Alternate Input for S1IN                                                                             | Level         |
| WDOG    | Peripheral Watchdog                                                                                  | Pulse         |
| LETIMER | Start LETIMER                                                                                        | Pulse         |
|         | Stop LETIMER                                                                                         | Pulse         |
|         | Clear LETIMER                                                                                        | Pulse         |
| RTCC    | Compare/Capture Channel                                                                              | Pulse/Level   |
| PRS     | Set Event                                                                                            | Pulse         |
|         | DMA Request 0                                                                                        | Pulse         |
|         | DMA Request 1                                                                                        | Pulse         |

### 13.3.4 Event on PRS

The PRS can be used to send events to the MCU. This is very useful in combination with the Wait For Event (WFE) instruction. A single PRS channel can be selected for this using SEVONPRSSEL in PRS\_CTRL, and the feature is enabled by setting SEVONPRS in the same register.

Using SEVONPRS, one can e.g. set up a timer to trigger an event to the MCU periodically, every time letting the MCU pass through a WFE instruction in its program. This can help in performance-critical sections where timing is known, and the goal is to wait for an event, then execute some code, then wait for an event, then execute some code and so on.

### 13.3.5 DMA Request on PRS

Up to two independent DMA requests can be generated by the PRS. The PRS signals triggering the DMA requests are selected using the LDMA\_CHx\_REQSEL register, by setting SOURCESEL to PRS and SIGSEL to either PRSREQ0 or PRSREQ1. The DMA requests are cleared when the DMA services the requests. The requests are set whenever the selected PRS signals are high.

The selected PRS signals must have ASYNC cleared when they are used as inputs to the DMA. Edge detection in the PRS can be enabled to only trigger transfers on edges.

### 13.3.6 Example

The example below (illustrated in [Figure 13.3 TIMER0 Overflow Starting ADC0 Single Conversions Through PRS Channel 5. on page 357](#)) shows how to set up ADC0 to start single conversions every time TIMER0 overflows (one HFPERCLK cycle high pulse), using PRS channel 5:

- Set SOURCESEL in PRS\_CH5\_CTRL to TIMER0 as input to PRS channel 5.
- Set SIGSEL in PRS\_CH5\_CTRL to select the overflow signal (TIMER0OF from TIMER0).
- Configure ADC0 with the desired conversion set-up.
- Set SINGLEPRSEN in ADC0\_SINGLECTRL to 1 to enable single conversions to be started by a high PRS input signal.
- Set SINGLEPRSSEL in ADC0\_SINGLECTRL to 0x5 to select PRS channel 5 as input to start the single conversion.
- Start TIMER0 with the desired TOP value, an overflow PRS signal is output automatically on overflow.

Note that the ADC results needs to be fetched either by the CPU or DMA.

**Figure 13.3. TIMER0 Overflow Starting ADC0 Single Conversions Through PRS Channel 5.**

## 13.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name          | Type | Description                     |
|--------|---------------|------|---------------------------------|
| 0x000  | PRS_SWPULSE   | W1   | Software Pulse Register         |
| 0x004  | PRS_SWLEVEL   | RW   | Software Level Register         |
| 0x008  | PRS_ROUTEPEN  | RW   | I/O Routing Pin Enable Register |
| 0x010  | PRS_ROUTELOC0 | RW   | I/O Routing Location Register   |
| 0x014  | PRS_ROUTELOC1 | RW   | I/O Routing Location Register   |
| 0x018  | PRS_ROUTELOC2 | RW   | I/O Routing Location Register   |
| 0x020  | PRS_CTRL      | RW   | Control Register                |
| 0x024  | PRS_DMAREQ0   | RW   | DMA Request 0 Register          |
| 0x028  | PRS_DMAREQ1   | RW   | DMA Request 1 Register          |
| 0x030  | PRS_PEEK      | R    | PRS Channel Values              |
| 0x040  | PRS_CH0_CTRL  | RW   | Channel Control Register        |
| ...    | PRS_CHx_CTRL  | RW   | Channel Control Register        |
| 0x06C  | PRS_CH11_CTRL | RW   | Channel Control Register        |

## 13.5 Register Description

### 13.5.1 PRS\_SWPULSE - Software Pulse Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |           |    |          |   |          |   |          |   |          |   |          |   |          |   |          |   |          |   |          |   |          |   |    |  |

## 14. PCNT - Pulse Counter

### Quick Facts

#### What?

The Pulse Counter (PCNT) decodes incoming pulses. The module has a quadrature mode which may be used to decode the speed and direction of a mechanical shaft. PCNT can operate in EM0 Active down to EM3 Stop.

#### Why?

The PCNT generates an interrupt after a specific number of pulses (or rotations), eliminating the need for timing or I/O interrupts and CPU processing to measure pulse widths, etc.

#### How?

PCNT uses the LFACLK or may be externally clocked from a pin. The module incorporates a 16-bit up/down-counter to keep track of incoming pulses or rotations.

### 14.1 Introduction

The Pulse Counter (PCNT) can be used for counting incoming pulses on a single input or to decode quadrature encoded inputs in EM0 Active down to EM3 Stop. It can run from the internal LFACLK while counting pulses on the PCNTn\_S0IN pin. Or, alternately, the PCNTn\_S0IN pin may be used as an external clock source that runs both the PCNT counter and register access.

### 14.2 Features

- 16-bit counter with reload register
- Auxiliary counter for counting a single direction
- Single input oversampling up/down counter mode
- Externally clocked single input pulse up/down counter mode
- Quadrature decoder modes
  - Externally clocked quadrature decoder 1X mode
  - Oversampling quadrature decoder 1X, 2X and 4X modes
- Interrupt on counter underflow and overflow
- Interrupt when a direction change is detected (quadrature decoder mode only)
- Optional pulse width filter
- Optional input inversion/edge detect select
- Optional inputs from PRS
- Asynchronously triggered compare and clear

### 14.3 Functional Description

An overview of the PCNT module is shown in [Figure 14.1 PCNT Overview on page 379](#).

**Figure 14.1. PCNT Overview**

#### 14.3.1 Pulse Counter Modes

The pulse counter can operate in single input oversampling mode (OVSSINGLE), externally clocked single input counter mode (EXTCLKSINGLE), externally clocked quadrature decoder mode (EXTCLKQUAD) and oversampling quadrature decoder modes (OVSSQUAD1X, OVSSQUAD2X and OVSSQUAD4X). The following sections describe operation of each of these modes and how they are enabled. Input timing constraints are described in [14.3.6 Clock Sources](#) and [14.3.7 Input Filter](#).

##### 14.3.1.1 Single Input Oversampling Mode

This mode is enabled by writing OVSSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter is configured by clearing PCNT0CLKSEL in the CMU\_PCNTCTRL in the Clock Management Unit (CMU).

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn\_CTRL register. Additionally, the PCNTn\_S0IN input may be inverted, so that falling edges are counted, by setting the EDGE bit in the PCNTn\_CTRL register.

If S1CDIR in the PCNTn\_CTRL register is cleared, PCNTn\_S0IN is the only observed input in this mode. The PCNTn\_S0IN input is sampled by the LFACLK and the number of detected positive or negative edges on PCNTn\_S0IN appears in PCNTn\_CNT. The counter may be configured to count down by setting the CNTDIR bit in PCNTn\_CTRL. Default is to count up.

The counting direction can also be controlled externally in this mode by setting S1CDIR. This will make the input value on PCNTn\_S1IN decide the direction counted on a PCNTn\_S0IN edge. If PCNTn\_S1IN is high, the count is done according to CNTDIR in PCNTn\_CTRL. If low, the count direction is opposite.

##### 14.3.1.2 Externally Clocked Single Input Counter Mode

This mode is enabled by writing EXTCLKSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU\_PCNTCTRL register ([10. CMU - Clock Management Unit](#)).

Positive edges on PCNTn\_S0IN are used to clock the counter. Similar to the oversampled mode, PCNTn\_S1IN is used to determine the count direction if S1CDIR is set. If not, CNTDIR in PCNTn\_CTRL solely defines count direction.

The digital pulse width filter is not available in this mode. The analog de-glitch filter in the GPIO pads is capable of removing some unwanted noise. However, this mode may be susceptible to spikes and unintended pulses from devices such as mechanical switches, and is therefore most suited to take input from electronic sensors etc. that generate single wire pulses.

### 14.3.1.3 Quadrature Decoder Modes

Two different types of quadrature decoding is supported in the pulse counter: the externally clocked (Asynchronous) quadrature decoding and the oversampling (Synchronous) quadrature decoding. The externally clocked mode supports 1X quadrature decoding whereas the oversampling mode supports 1X, 2X and 4X quadrature decoding. These modes are described in detail in [14.3.1.4 Externally Clocked Quadrature Decoder Mode](#) and [14.3.1.5 Oversampling Quadrature Decoder Mode](#).

### 14.3.1.4 Externally Clocked Quadrature Decoder Mode

This mode is enabled by writing EXTCLKQUAD to the MODE field in PCNTn\_CTRL and disabled by writing DISABLE to the same field. The external pin clock source is configured by setting PCNT0CLKSEL in the CMU\_PCNTCTRL register (10. CMU - Clock Management Unit).

In this mode, both edges on PCNTn\_S0IN pin are used to sample PCNTn\_S1IN pin, in order to decode the quadrature code. A quadrature coded signal contains information about the relative speed and direction of a rotating shaft as illustrated by Figure 14.2 PCNT Quadrature Coding on page 381, hence the direction of the counter register PCNTn\_CNT is controlled automatically.

Figure 14.2. PCNT Quadrature Coding

If PCNTn\_S0IN leads PCNTn\_S1IN in phase, the direction is clockwise, and if it lags in phase the direction is counter-clockwise. Default behavior is illustrated by Figure 14.2 PCNT Quadrature Coding on page 381.

The counter direction may be read from the DIR bit in the PCNTn\_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn\_IF register is generated when a direction change is detected. When a change is detected, the DIR bit in the PCNTn\_STATUS register must be read to determine the current new direction.

**Note:** The sector disc illustrated in the figure may be finer grained in some systems. Typically, they may generate 2-4 PCNTn\_S0IN wave periods per 360° rotation.

The direction of the quadrature code and control of the counter is generated by the simple binary function outlined by Table 14.1 PCNT QUAD Mode Counter Control Function on page 381. Note that this function also filters some invalid inputs that may occur when the shaft changes direction or temporarily toggles direction.

Table 14.1. PCNT QUAD Mode Counter Control Function

| Inputs       |              | Control/Status |                   |
|--------------|--------------|----------------|-------------------|
| S1IN posedge | S1IN negedge | Count Enable   | CNTDIR status bit |
| 0            | 0            | 0              | 0                 |

| Inputs                                                          |              | Control/Status |                   |
|-----------------------------------------------------------------|--------------|----------------|-------------------|
| S1IN posedge                                                    | S1IN negedge | Count Enable   | CNTDIR status bit |
| 0                                                               | 1            | 1              | 0                 |
| 1                                                               | 0            | 1              | 1                 |
| 1                                                               | 1            | 0              | 0                 |
| <b>Note:</b> PCNTn_S1IN is sampled on both edges of PCNTn_S0IN. |              |                |                   |

### 14.3.1.5 Oversampling Quadrature Decoder Mode

There are three Oversampling Quadrature Decoder Modes supported: 1X , 2X and 4X. These modes are enabled by writing OVSQUAD1X, OVSQUAD2X and OVSQUAD4X, respectively, to the MODE field in PCNTn\_CTRL and disabled by writing DISABLE to the same field. The LFACLK clock source to the pulse counter must be configured by clearing PCNT0CLKSEL in the CMU\_PCNTCTRL in the Clock Management Unit (CMU), [10. CMU - Clock Management Unit](#) .

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn\_CTRL register. The filter applies to both inputs PCNTn\_S0IN and PCNTn\_S1IN. The filter length is configured by FILTLEN in PCNTn\_OVSCFG register.

Based on the modes selected, the decoder updates the counter on different events. In the OVSQUAD1X mode, the counter is updated on the rising edge of the PCNTn\_S0IN input when counting up, and on the negedge of the PCNTn\_S0IN input when counting down. In the OVSQUAD2X mode, the counter is updated on both edges of PCNTn\_S0IN input. In the OVSQUAD4X mode the counter is updated on both edges of both inputs PCNTn\_S0IN and PCNTn\_S1IN. [Table 14.2 PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function on page 383](#) outlines the increment or decrement of the counter based on the Quadrature Mode selected.

**Note:** The decoding behavior of OVSQUAD1X mode is slightly different compared to EXTCLKQUAD mode(also 1X mode). In the EXTCLKQUAD mode, the counter is updated only on the posedge of S0IN input. However, in the OVSQUAD1X mode, the counter is updated on the posedge of S0IN when counting up and on the negedge of S0IN when counting down.

**Table 14.2. PCNT OVSQUAD 1X, 2X and 4X Mode Counter Control Function**

| Direction          | Previous State |      | Next State |      | OVSQUAD MODE |    |    |
|--------------------|----------------|------|------------|------|--------------|----|----|
|                    | S1IN           | S0IN | S1IN       | S0IN | 1X           | 2X | 4X |
| Clockwise          | 0              | 0    | 0          | 1    | +1           | +1 | +1 |
|                    | 0              | 1    | 1          | 1    |              |    | +1 |
|                    | 1              | 1    | 1          | 0    |              | +1 | +1 |
|                    | 1              | 0    | 0          | 0    |              |    | +1 |
| Counter Clock-wise | 1              | 0    | 1          | 1    |              | -1 | -1 |
|                    | 1              | 1    | 0          | 1    |              |    | -1 |
|                    | 0              | 1    | 0          | 0    | -1           | -1 | -1 |
|                    | 0              | 0    | 1          | 0    |              |    | -1 |

[Figure 14.3 PCNT State Transitions for Different Oversampling Quadrature Decoder Modes on page 384](#) illustrates the different states of the quadrature input and the state transitions that updates the counter for the different modes. Each cycle of the input states results in 1 update, 2 updates and 4 updates of the counter for OVSQUAD1X, OVSQUAD2X and OVSQUAD4X modes respectively.

**Figure 14.3. PCNT State Transitions for Different Oversampling Quadrature Decoder Modes**

The counter direction can be read from the DIR bit in PCNTn\_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn\_IF is generated when the direction change is detected. When a change is detected, the DIR bit in the PCNTn\_STATUS register must be read to determine the new direction.

In the oversampling quadrature decoder modes, the maximum input toggle frequency supported is 8KHz. For frequencies of 8KHz and higher, incorrect decoding occurs. The different decoding modes and the counter updates are further illustrated by [Figure 14.4 PCNT Oversampling Quadrature Decoder 1X Mode on page 384](#), [Figure 14.5 PCNT Oversampling Quadrature Decoder 2X Mode on page 385](#) and [Figure 14.6 PCNT Oversampling Quadrature Decoder 4X Mode on page 385](#).

**Figure 14.4. PCNT Oversampling Quadrature Decoder 1X Mode**

Figure 14.5. PCNT Oversampling Quadrature Decoder 2X Mode

Figure 14.6. PCNT Oversampling Quadrature Decoder 4X Mode

The above modes, by default are prone to flutter effects in the inputs PCNTn\_S0IN and PCNTn\_S1IN. When this occurs, the counter changes directions rapidly causing DIRCNG interrupts and unnecessarily waking the core. To prevent this, set FLUTERRM in PCNTn\_OVSCFG register. When enabled, flutter is removed, thus preventing unnecessary wakeup of the core. The flutter removal logic works by preventing update of the counter value if the wheel keeps changing direction as a result of flutter. The counter is only updated if the current and previous state transition of the rotation are in the same direction. These state transitions are quadrature decoder mode specific. The highlighted state transitions in [Figure 14.3 PCNT State Transitions for Different Oversampling Quadrature Decoder Modes on page 384](#) are the ones considered for the different quadrature decoder modes. [Figure 14.7 PCNT Oversampling Quadrature Decoder with Flutter Removal on page 385](#) shows how the counter is updated for the different quadrature decoder modes with flutter removal FLUTERRM enabled in PCNTn\_OVSCFG.

Figure 14.7. PCNT Oversampling Quadrature Decoder with Flutter Removal

### 14.3.2 Hysteresis

By default the pulse counter wraps to 0 when passing the configured top value, and wraps to the top value when counting down from 0. On these events, a system will likely want to wake up to store and track the overflow count. This is fine if the pulse counter is tracking a monotonic value or a value that does not change directions frequently. In the latter scenario, if the counter changes directions around the overflow/underflow point, the system will have to wake up frequently to keep track of the rotations, resulting in higher current consumption.

To solve this, the pulse counter has a way of introducing hysteresis to the counter. When HYST in PCNTn\_CTRL is set, the pulse counter will always wrap to TOP/2 on underflows and overflows. This takes the counter away from the area where it might overflow or underflow, removing the problem. [Figure 14.8 PCNT Hysteresis behavior of Counter on page 386](#) illustrates the hysteresis behavior.

**Figure 14.8. PCNT Hysteresis behavior of Counter**

Given a starting value of 0 for the counter, the absolute count value when hysteresis is enabled can be calculated with the equations [Figure 14.9 Absolute Position With Hysteresis and Even TOP Value on page 386](#) or [Figure 14.10 Absolute Position With Hysteresis and Odd TOP Value on page 386](#), depending on whether the TOP value is even or odd.

$$CNT_{abs} = CNT - UF_{CNT} \times (TOP/2+1) + OF_{CNT} \times (TOP/2+1)$$

**Figure 14.9. Absolute Position With Hysteresis and Even TOP Value**

$$CNT_{abs} = CNT - UF_{CNT} \times (TOP/2+1) + OF_{CNT} \times (TOP/2+2)$$

**Figure 14.10. Absolute Position With Hysteresis and Odd TOP Value**

### 14.3.3 Auxiliary Counter

To be able to keep explicit track of counting in one direction in addition to the regular counter which counts both up and down, the auxiliary counter can be used. The pulse counter can, for instance, be configured to keep track of the absolute rotation of the wheel, while at the same time the auxiliary counter can keep track of how much the wheel has reversed.

The auxiliary counter is enabled by configuring AUXCNTEV in PCNTn\_CTRL. It will always count up, but it can be configured whether it should count up on up-events, down-events or both, keeping track of rotation either way or general movement. The value of the auxiliary counter can be read from the PCNTn\_AUXCNT register.

Overflows on the auxiliary counter happen when the auxiliary counter passes the top value of the pulse counter, configured in PCNTn\_TOP. In that event, the AUXOF interrupt flag is set, and the auxiliary counter wraps to 0.

As the auxiliary counter, the main counter can be configured to count only on certain events. This is done through CNTEV in PCNTn\_CTRL, and it is possible like for the auxiliary counter, to make the main counter count on only up and down events. The difference between the counters is that where the auxiliary counter will only count up, the main counter will count up or down depending on the direction of the count event.

### 14.3.4 Triggered Compare and Clear

The pulse counter features triggered compare and clear. When enabled, a configurable trigger will induce a comparison between the main counter, PCNTn\_CNT, and the top value, PCNTn\_TOP. After the comparison, the counter is cleared. The trigger for a compare and clear event is configured in the TCCMODE bit-field in PCNTn\_CTRL. There are two options, LFA and PRS. If LFA is selected, the pulse counter will be compared with the top value, and cleared every  $2^N$  LFA clock cycle (where N is the value of TCCPRESC in PCNTn\_CTRL). If a PRS trigger is selected, the active PRS channel is configured in TCCPRSEL in PCNTn\_CTRL. The PRS input can be inverted by setting TCCPRSPOL, triggering the compare and clear on the negative edge of the PRS input. The PRS input can also be used as a gate for the pulse counter clock. This is enabled by setting PRSGATEEN in PCNTn\_CTRL.

**Note:** When PRSGATEEN is set, the clock to the entire pulse counter will be gated by the PRS input, meaning that register writes will not take effect while the gated clock is inactive.

Comparison with PCNTn\_TOP can be performed in three ways: range, greater than or equal, and less than or equal. TCCCOMP in PCNTn\_CTRL configures comparison mode. Upon a compare match, the TCC interrupt is set, and the PRS output from the pulse counter is set. The PRS output will remain set until the next compare and clear event. Triggered compare and clear is intended for use when the pulse counter is configured to count up. In this mode, PCNTn\_CNT will not wrap to 0 when hitting PCNTn\_TOP, it will keep counting. In addition, the counter will not overflow, it will rather stop counting, just setting the overflow interrupt flag.

Figure 14.11 PCNT Triggered Compare and Clear on page 388 shows an overview of the control circuitry for triggered compare and clear. The control circuitry includes two positive edge detectors (PED) and glitch filters, used to generate clocks for the pulse counter. The two clock outputs are mutually exclusive: If both edge detectors receive a pulse at the same time, the output pulse from one of them will be postponed until the other edge detectors output pulse has completed.

Figure 14.11. PCNT Triggered Compare and Clear

**Note:** TCCMODE, TCCPRESC, PRSGATEEN, TCCPRSPOL, and TCCPRSEL in PCNTn\_CTRL should only be altered when RSTEN in PCNTn\_CTRL is set.

### 14.3.5 Register Access

The counter-clock domain may be clocked externally. To update the counter-clock domain registers from software in this mode, 2-3 clock pulses on the external clock are needed to synchronize accesses to the externally clocked domain. Clock source switching is controlled from the registers in the CMU ([10. CMU - Clock Management Unit](#)).

When the RSTEN bit in the PCNTn\_CTRL register is set, the PCNT clock domain is asynchronously held in reset. The reset is synchronously released two PCNT clock edges after the RSTEN bit in the PCNTn\_CTRL register is cleared by software. This asynchronous reset restores the reset values in PCNTn\_TOP, PCNTn\_CNT and other control registers in the PCNT clock domain.

CNTRSTEN works in a similar manner as RSTEN, but only resetting the counter, CNT. Note that the counter is also reset by RSTEN.

AUXCNTRSTEN works in a similar manner as RSTEN, but only resetting the auxiliary counter, PCNTn\_AUXCNT. Note that the auxiliary counter is also reset by RSTEN.

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals.

**Note:** PCNTn\_TOP and PCNTn\_CNT are read-only registers. When writing to PCNTn\_TOPB, make sure that the counter value, PCNTn\_CNT, can not exceed the value written to PCNTn\_TOPB within two clock cycles.

### 14.3.6 Clock Sources

The pulse counter may be clocked from two possible clock sources: LFACLK or an external clock. The clock selection is configured by the PCNT0CLKSEL bit in the CMU\_PCNTCTRL in the Clock Management Unit (CMU), [10. CMU - Clock Management Unit](#). The default clock source is the LFACLK.

This PCNT module may also use PCNTn\_S0IN as an external clock to clock the counter (EXTCLKSINGLE mode) and to sample PCNTn\_S1IN (EXTCLKQUAD mode). Setup, hold and max frequency constraints for PCNTn\_S0IN and PCNTn\_S1IN for these modes are specified in the device data sheet.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0, in addition to the module clock in CMU\_PCNTCTRL.

**Note:** PCNT Clock Domain Reset, RSTEN, should be set when changing clock source for PCNT. If changing to an external clock source, the clock pin has to be enabled as input prior to de-asserting RSTEN. Changing clock source without asserting RSTEN results in undefined behaviour.

### 14.3.7 Input Filter

An optional pulse width filter is available in OVSSINGLE and OVSQUAD modes, when LFACLK is selected as a clock source for the Pulse Counter in CMU [10. CMU - Clock Management Unit](#). The filter is enabled by writing 1 to the FILT bit in the PCNTn\_CTRL register. When enabled, the high and low periods of PCNTn\_S0IN and PCNTn\_S1IN must be stable for a programmable number of consecutive clock cycles before the edge is passed to the edge detector. The filter length should be programmed in FILTLEN field of the PCNTn\_OVSCFG register.

The filter length is given by [Figure 14.12 PCNT Input Filter Length Equation on page 389](#):

$$\text{Filter length} = (\text{FILTLEN} + 5) \text{ LFACLK cycles}$$

**Figure 14.12. PCNT Input Filter Length Equation**

The maximum filter length configured is 260 LFACLK cycles.

In EXTCLKSINGLE and EXTCLKQUAD mode, there is no digital pulse width filter available.

### 14.3.8 Edge Polarity

The edge polarity can be set by configuring the EDGE bit in the PCNTn\_CTRL register. When this bit is cleared, the pulse counter counts positive edges of PCNTn\_S0IN input. When this bit is set, the pulse counter counts negative edges in OVSSINGLE mode. Also, when the EDGE bit is set in the OVSSINGLE and EXTCLKSINGLE modes, the PCNTn\_S1IN input is inverted. In OVSQUAD 1X-4X modes the EDGE bit inverts both inputs.

**Note:** The EDGE bit in PCNTn\_CTRL has no effect in EXTCLKQUAD mode.

### 14.3.9 PRS and PCNTn\_S0IN,PCNTn\_S1IN Inputs

It is possible to receive input from PRS on both PCNTn\_S0IN (or PCNTn\_S1IN) by setting S0PRSEN (or S1PRSEN) in PCNTn\_INPUT. The PRS channel used can be selected using S0PRSSEL (or S1PRSSEL) in PCNTn\_INPUT.

In the Oversampling quadrature decoder modes, the input frequency should be less than 8KHz to ensure correct functionality.

PCNT module generates three PRS outputs the TCC PRS output, the CNT OF/UF PRS output and the CNT DIR PRS output. The TCC PRS is generated on compare match of TCC event. The CNT OF/UF combined PRS is generated when the counter overflow or underflows. The CNT DIR PRS is a level PRS and indicates the current direction of count of counter CNT

**Note:** S0PRSEN,S1PRSEN,S0PRSSEL,S1PRSSEL should only be altered when RSTEN in PCNTn\_CTRL is set.

### 14.3.10 Interrupts

The interrupt generated by PCNT uses the PCNTn\_INT interrupt vector. Software must read the PCNTn\_IF register to determine which module interrupt that generated the vector invocation.

#### 14.3.10.1 Underflow and Overflow Interrupts

The underflow interrupt flag (UF) is set when the counter counts down from 0. I.e. when the value of the counter is 0 and a new pulse is received. The PCNTn\_CNT register is loaded with the PCNTn\_TOP value after this event.

The overflow interrupt flag (OF) is set when the counter counts up from the PCNTn\_TOP (reload) value. I.e. if PCNTn\_CNT = PCNTn\_TOP and a new pulse is received. The PCNTn\_CNT register is loaded with the value 0 after this event.

### 14.3.10.2 Direction Change Interrupt

The PCNTn\_PCNT module sets the DIRCNG interrupt flag (PCNTn\_IF register) for EXTCLKQUAD and OVSQUAD1X-4X modes when the direction of the quadrature code changes. The behavior of this interrupt in the EXTCLKQUAD mode is illustrated by [Figure 14.13 PCNT Direction Change Interrupt \(DIRCNG\) Generation on page 391](#).

**Figure 14.13. PCNT Direction Change Interrupt (DIRCNG) Generation**

### 14.3.11 Cascading Pulse Counters

When two or more Pulse Counters are available, it is possible to cascade them. For example two 16-bit Pulse Counters can be cascaded to form a 32-bit pulse counter. This can be done with the help of the CNT UF/OF PRS and CNT DIR PRS outputs. The figure [Figure 14.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 392](#) illustrates this structure.

**Figure 14.14. PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT**

For cascading of Pulse Counters to work, the PCNT1 according to the figure [Figure 14.14 PCNT Cascading to two 16-bit PCNT to form a 32-bit PCNT on page 392](#) should be programmed in EXTCLKSINGLE mode and its S0IN and S1IN inputs should be configured to prs\_ufof and prs\_dir of PCNT0 respectively. In addition to this, a strict programming sequence needs to be followed to ensure both PCNTs are in sync with each other.

- Configure PCNT0 registers. eg. PCNT0\_INPUT, PCNT0\_CTRL, PCNT0\_OVSCFG etc.
- Wait for PCNT0\_SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain.
- Hold PCNT0 in sw reset by setting PCNT0\_CTRL\_RSTEN.
- Configure PCNT1\_CTRL to EXTCLKSINGLE mode with S1CDIR and CNTDIR bit set. Configure INPUT to accept "prs\_ufof" and "prs\_dir" of PCNT0 on S0IN and S1IN respectively.
- Wait for PCNTn\_SYCNBUSY to be cleared to ensure the registers are synchronized to the asynchronous clock domain. Use three PRS\_SWPULSE on the S0IN prs channel to ensure this synchronization.
- Hold PCNT1 in sw reset by setting PCNT1\_CTRL\_RSTEN.
- Clear PCNT1\_CTRL\_RSTEN and synchronize it by asserting two PRS\_SWPULSE on the S0IN input.
- Finally clear PCNT0\_CTRL\_RSTEN and start counting.

**Note:** When RSTEN in PCNTn\_CTRL is set, the TOP value in the Pulse Counter gets cleared. Therefore, in order to update the TOP value while RSTEN is set, assert TOPBHFEN bit in PCNTn\_CTRL. This will update the TOP value with the TOPB value even without having to synchronize the TOPB value. This only works if TOPBHFEN and TOPB are configured while RSTEN in PCNTn\_CTRL is set.

## 14.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name            | Type  | Description                      |
|--------|-----------------|-------|----------------------------------|
| 0x000  | PCNTn_CTRL      | RW    | Control Register                 |
| 0x004  | PCNTn_CMD       | W1    | Command Register                 |
| 0x008  | PCNTn_STATUS    | R     | Status Register                  |
| 0x00C  | PCNTn_CNT       | R     | Counter Value Register           |
| 0x010  | PCNTn_TOP       | R     | Top Value Register               |
| 0x014  | PCNTn_TOPB      | RW    | Top Value Buffer Register        |

## 15. I<sup>2</sup>C - Inter-Integrated Circuit Interface

### Quick Facts

#### What?

The I<sup>2</sup>C interface allows communication on I<sup>2</sup>C-buses with the lowest energy consumption possible.

#### Why?

I<sup>2</sup>C is a popular serial bus that enables communication with a number of external devices using only two I/O pins.

#### How?

With the help of DMA, the I<sup>2</sup>C interface allows I<sup>2</sup>C communication with minimal CPU intervention. Address recognition is available in all energy modes (except EM4), allowing the MCU to wait for data on the I<sup>2</sup>C-bus with sub- $\mu$ A current consumption.

### 15.1 Introduction

The I<sup>2</sup>C module provides an interface between the MCU and a serial I<sup>2</sup>C-bus. It is capable of acting as both a master and a slave and supports multi-master buses. Standard-mode, fast-mode and fast-mode plus speeds are supported, allowing transmission rates all the way from 10 kbit/s up to 1 Mbit/s. Slave arbitration and timeouts are also provided to allow implementation of an SMBus compliant system. The interface provided to software by the I<sup>2</sup>C module allows precise control of the transmission process and highly automated transfers. Automatic recognition of slave addresses is provided in all energy modes (except EM4).

### 15.2 Features

- True multi-master capability
- Support for different bus speeds
  - Standard-mode (Sm) bit rate up to 100 kbit/s
  - Fast-mode (Fm) bit rate up to 400 kbit/s
  - Fast-mode Plus (Fm+) bit rate up to 1 Mbit/s
- Arbitration for both master and slave (allows SMBus ARP)
- Clock synchronization and clock stretching
- Hardware address recognition
  - 7-bit masked address
  - General call address
  - Active in all energy modes (except EM4)
- 10-bit address support
- Error handling
  - Clock low timeout
  - Clock high timeout
  - Arbitration lost
  - Bus error detection
- Separate receive/ transmit 2-level buffers, with additional separate shift registers
- Full DMA support

### 15.3 Functional Description

An overview of the I2C module is shown in [Figure 15.1 I2C Overview on page 411](#).

**Figure 15.1. I2C Overview**

### 15.3.1 I2C-Bus Overview

The I<sup>2</sup>C-bus uses two wires for communication; a serial data line (SDA) and a serial clock line (SCL) as shown in [Figure 15.2 I2C-Bus Example on page 412](#). As a true multi-master bus it includes collision detection and arbitration to resolve situations where multiple masters transmit data at the same time without data loss.

**Figure 15.2. I2C-Bus Example**

Each device on the bus is addressable by a unique address, and an I<sup>2</sup>C master can address all the devices on the bus, including other masters.

Both the bus lines are open-drain. The maximum value of the pull-up resistor can be calculated as a function of the maximal rise-time **tr** for the given bus speed, and the estimated bus capacitance **Cb** as shown in [Figure 15.3 I2C Pull-up Resistor Equation on page 412](#).

$$R_p(\text{max}) = t_r / (0.8473 \times C_b)$$

**Figure 15.3. I2C Pull-up Resistor Equation**

The maximal rise times for 100 kHz, 400 kHz and 1 MHz I<sup>2</sup>C are 1 μs, 300 ns and 120 ns respectively.

**Note:**

- The GPIO drive strength can be used to control slew rate.
- If V<sub>dd</sub> drops below the voltage on SCL and SDA lines, the MCU could become back powered and pull the SCL and SDA lines low.

### 15.3.1.1 START and STOP Conditions

START and STOP conditions are used to initiate and stop transactions on the I<sup>2</sup>C-bus. All transactions on the bus begin with a START condition (S) and end with a STOP condition (P). As shown in [Figure 15.4 I2C START and STOP Conditions on page 413](#), a START condition is generated by pulling the SDA line low while SCL is high, and a STOP condition is generated by pulling the SDA line high while SCL is high.

**Figure 15.4. I2C START and STOP Conditions**

The START and STOP conditions are easily identifiable bus events as they are the only conditions on the bus where a transition is allowed on SDA while SCL is high. During the actual data transmission, SDA is only allowed to change while SCL is low, and must be stable while SCL is high. One bit is transferred per clock pulse on the I<sup>2</sup>C-bus as shown in [Figure 15.5 I2C Bit Transfer on I<sup>2</sup>C-Bus on page 413](#).

**Figure 15.5. I2C Bit Transfer on I<sup>2</sup>C-Bus**

### 15.3.1.2 Bus Transfer

When a master wants to initiate a transfer on the bus, it waits until the bus is idle and transmits a START condition on the bus. The master then transmits the address of the slave it wishes to interact with and a single R/W bit telling whether it wishes to read from the slave (R/W bit set to 1) or write to the slave (R/W bit set to 0).

After the 7-bit address and the R/W bit, the master releases the bus, allowing the slave to acknowledge the request. During the next bit-period, the slave pulls SDA low (ACK) if it acknowledges the request, or keeps it high if it does not acknowledge it (NACK).

Following the address acknowledge, either the slave or master transmits data, depending on the value of the R/W bit. After every 8 bits (one byte) transmitted on the SDA line, the transmitter releases the line to allow the receiver to transmit an ACK or a NACK. Both the data and the address are transmitted with the most significant bit first.

The number of bytes in a bus transfer is unrestricted. The master ends the transmission after a (N)ACK by sending a STOP condition on the bus. After a STOP condition, any master wishing to initiate a transfer on the bus can try to gain control of it. If the current master wishes to make another transfer immediately after the current, it can start a new transfer directly by transmitting a repeated START condition (Sr) instead of a STOP followed by a START.

Examples of I<sup>2</sup>C transfers are shown in [Figure 15.6 I2C Single Byte Write to Slave on page 414](#), [Figure 15.7 I2C Double Byte Read from Slave on page 414](#), and [Figure 15.8 I2C Single Byte Write, then Repeated Start and Single Byte Read on page 414](#). The identifiers used are:

- ADDR - Address
- DATA - Data
- S - Start bit
- Sr - Repeated start bit
- P - Stop bit
- W/R - Read(1)/Write(0)
- A - ACK
- N - NACK

**Figure 15.6. I2C Single Byte Write to Slave**

**Figure 15.7. I2C Double Byte Read from Slave**

**Figure 15.8. I2C Single Byte Write, then Repeated Start and Single Byte Read**

### 15.3.1.3 Addresses

I<sup>2</sup>C supports both 7-bit and 10-bit addresses. When using 7-bit addresses, the first byte transmitted after the START-condition contains the address of the slave that the master wants to contact. In the 7-bit address space, several addresses are reserved. These addresses are summarized in [Table 15.1 I2C Reserved I2C Addresses on page 415](#), and include a General Call address which can be used to broadcast a message to all slaves on the I<sup>2</sup>C-bus.

**Table 15.1. I2C Reserved I2C Addresses**

| I <sup>2</sup> C Address | R/W | Description                         |
|--------------------------|-----|-------------------------------------|
| 0000-000                 | 0   | General Call address                |
| 0000-000                 | 1   | START byte                          |
| 0000-001                 | X   | Reserved for the C-Bus format       |
| 0000-010                 | X   | Reserved for a different bus format |
| 0000-011                 | X   | Reserved for future purposes        |
| 0000-1XX                 | X   | Reserved for future purposes        |
| 1111-1XX                 | X   | Reserved for future purposes        |
| 1111-0XX                 | X   | 10 Bit slave addressing mode        |

### 15.3.1.4 10-bit Addressing

To address a slave using a 10-bit address, two bytes are required to specify the address instead of one. The seven first bits of the first byte must then be 1111 0XX, where XX are the two most significant bits of the 10-bit address. As with 7-bit addresses, the eighth bit of the first byte determines whether the master wishes to read from or write to the slave. The second byte contains the eight least significant bits of the slave address.

When a slave receives a 10-bit address, it must acknowledge both the address bytes if they match the address of the slave.

When performing a master transmitter operation, the master transmits the two address bytes and then the remaining data, as shown in [Figure 15.9 I2C Master Transmitter/Slave Receiver with 10-bit Address on page 415](#).

**Figure 15.9. I2C Master Transmitter/Slave Receiver with 10-bit Address**

When performing a master receiver operation however, the master first transmits the two address bytes in a master transmitter operation, then sends a repeated START followed by the first address byte and then receives data from the addressed slave. The slave addressed by the 10-bit address in the first two address bytes must remember that it was addressed, and respond with data if the address transmitted after the repeated start matches its own address. An example of this (with one byte transmitted) is shown in [Figure 15.10 I2C Master Receiver/Slave Transmitter with 10-bit Address on page 415](#).

**Figure 15.10. I2C Master Receiver/Slave Transmitter with 10-bit Address**

### 15.3.1.5 Arbitration, Clock Synchronization, Clock Stretching

Arbitration and clock synchronization are features aimed at allowing multi-master buses. Arbitration occurs when two devices try to drive the bus at the same time. If one device drives it low, while the other drives it high, the one attempting to drive it high will not be able to do so due to the open-drain bus configuration. Both devices sample the bus, and the one that was unable to drive the bus in the desired direction detects the collision and backs off, letting the other device continue communication on the bus undisturbed.

Clock synchronization is a means of synchronizing the clock outputs from several masters driving the bus at once, and is a requirement for effective arbitration.

Slaves on the bus are allowed to force the clock output on the bus low in order to pause the communication on the bus and give themselves time to process data or perform any real-time tasks they might have. This is called clock stretching.

Arbitration is supported by the I<sup>2</sup>C module for both masters and slaves. Clock synchronization and clock stretching is also supported.

### 15.3.2 Enable and Reset

The I<sup>2</sup>C is enabled by setting the EN bit in the I2Cn\_CTRL register. Whenever this bit is cleared, the internal state of the I<sup>2</sup>C is reset, terminating any ongoing transfers.

**Note:** When enabling the I<sup>2</sup>C, the ABORT command or the Bus Idle Timeout feature must be applied prior to use even if the BUSY flag is not set.

### 15.3.3 Safely Disabling and Changing Slave Configuration

The I<sup>2</sup>C slave is partially asynchronous, and some precautions are necessary to always ensure a safe slave disable or slave configuration change. These measures should be taken, if (while the slave is enabled) the user cannot guarantee that an address match will not occur at the exact time of slave disable or slave configuration change.

Worst case consequences for an address match while disabling slave or changing configuration is that the slave may end up in an undefined state. To reset the slave back to a known state, the EN bit in I2Cn\_CTRL must be reset. This should be done regardless of whether the slave is going to be re-enabled or not.

### 15.3.4 Clock Generation

The SCL signal generated by the I<sup>2</sup>C master determines the maximum transmission rate on the bus. The clock is generated as a division of the peripheral clock, and is given by the following equation:

$$f_{SCL} = f_{HFPERCLK} / (((N_{low} + N_{high}) \times (DIV + 1)) + 8),$$

**Figure 15.11. I2C Maximum Transmission Rate**

$N_{low}$  and  $N_{high}$  in combination with the synchronization cycles (discussed below) specify the number of prescaled clock cycles in the low and high periods of the clock signal respectively. The worst case low and high periods of the signal are:

$$T_{high} \geq ((N_{high}) \times (DIV + 1) + 4) / f_{HFPERCLK},$$

$$T_{low} \geq (N_{low} \times (DIV + 1) + 4) / f_{HFPERCLK}.$$

**Figure 15.12. I2C High and Low Cycles Equations**

In worst case,  $T_{high}$  and  $T_{low}$  can be 1  $f_{HFPERCLK}$  cycle longer than the number found by above equations due to synchronization uncertainty (i.e., if the synchronization takes 3  $f_{HFPERCLK}$  cycles instead of 2). Similarly, in the worst case the number 8 in the denominator in  $f_{SCL}$  equation can be 9 (if the synchronization cycles were 3 instead of 2 in  $T_{high}$  or  $T_{low}$ ) or 10 (if synchronization cycles were 3 in both  $T_{high}$  and  $T_{low}$ ). The values of  $N_{low}$  and  $N_{high}$  and thus the ratio between the high and low parts of the clock signal is controlled by CLHR in the I2Cn\_CTRL register.

**Note:** DIV must be set to 1 during slave mode operation.

### 15.3.5 Arbitration

Arbitration is enabled by default, but can be disabled by setting the ARBDIS bit in I2Cn\_CTRL. When arbitration is enabled, the value on SDA is sensed every time the I<sup>2</sup>C module attempts to change its value. If the sensed value is different than the value the I<sup>2</sup>C module tried to output, it is interpreted as a simultaneous transmission by another device, and that the I<sup>2</sup>C module has lost arbitration.

Whenever arbitration is lost, the ARBLOST interrupt flag in I2Cn\_IF is set, any lines held are released, and the I<sup>2</sup>C device goes idle. If an I<sup>2</sup>C master loses arbitration during the transmission of an address, another master may be trying to address it. The master therefore receives the rest of the address, and if the address matches the slave address of the master, the master goes into either slave transmitter or slave receiver mode.

**Note:** Arbitration can be lost both when operating as a master and when operating as a slave.

### 15.3.6 Buffers

The I2C peripheral includes separate receive and transmit buffers and shift registers.

#### 15.3.6.1 Transmit Buffer and Shift Register

The I<sup>2</sup>C transmitter has a 2-level FIFO transmit buffer and a transmit shift register as shown in [Figure 15.1 I2C Overview on page 411](#). A byte is loaded into the transmit buffer by writing to I2Cn\_TXDATA or 2 bytes can be loaded simultaneously in the transmit buffer by writing to I2Cn\_TXDOUBLE. [Figure 15.13 I2C Transmit Buffer Operation on page 417](#) shows the basics of the transmit buffer. When the transmit shift register is empty and ready for new data, the byte from the transmit buffer is then loaded into the shift register. The byte is then kept in the shift register until it is transmitted. When a byte has been transmitted, a new byte is loaded into the shift register (if available in the transmit buffer). If the transmit buffer is empty, then the shift register also remains empty. The TXC flag in I2Cn\_STATUS and the TXC interrupt flags in I2Cn\_IF are then set, signaling that the transmit shift register is out of data. TXC is cleared when new data becomes available, but the TXC interrupt flag must be cleared by software.

**Figure 15.13. I2C Transmit Buffer Operation**

The TXBL flags in the I2Cn\_STATUS and I2Cn\_IF are used to indicate the level of the transmit buffer. TXBIL in I2Cn\_CTRL controls the level at which these flag bits are set. If TXBIL is cleared, the flags are set whenever the transmit buffer becomes empty (used when transmitting using I2Cn\_TXDOUBLE). If TXBIL is set, the flags are set whenever the transmit buffer goes from full to half-empty or empty (used when transmitting with I2Cn\_TXDATA). Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when the condition becomes false.

If an attempt is made to write more bytes to the transmit buffer than the space available, the TXOF interrupt flag in I2Cn\_IF is set, indicating the overflow. The data already in the buffer remains preserved, and no new data is written.

The transmit buffer and the transmit shift register can be cleared by setting command bit CLEAR\_TX in I2Cn\_CMD. This will prevent the I<sup>2</sup>C module from transmitting the data in the buffer and the shift register, and will make them available for new data. Any byte currently being transmitted will not be aborted. Transmission of this byte will be completed.

### 15.3.6.2 Receive Buffer and Shift Register

The I<sup>2</sup>C receiver uses a 2-level FIFO receive buffer and a receive shift register as shown in [Figure 15.14 I2C Receive Buffer Operation on page 418](#). When a byte has been fully received by the receive shift register, it is loaded into the receive buffer if there is room for it, making the shift register empty to receive another byte. Otherwise, the byte waits in the shift register until space becomes available in the buffer.

**Figure 15.14. I2C Receive Buffer Operation**

When a byte becomes available in the receive buffer, the RXDATAV in I2Cn\_STATUS and RXDATAV interrupt flag in I2Cn\_IF are set. When the buffer becomes full, RXFULL in the I2Cn\_STATUS and I2Cn\_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more byte.

The data can be fetched from the buffer in two ways. I2Cn\_RXDATA gives access to the received byte (if two bytes are received then the one received first is fetched first). I2Cn\_RXDOUBLE makes it possible to read the two received bytes simultaneously. If an attempt is made to read more bytes from the buffer than available, the RXUF interrupt flag in I2Cn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

When using I2Cn\_RXDOUBLE to pick data, AUTOACK in I2Cn\_CTRL should be set to 1. This ensures that an ACK is automatically sent out after the first byte is received so that the reception of the next byte can begin. In order to stop receiving data bytes, a NACK must be sent out through the I2Cn\_CMD register.

I2Cn\_RXDATAP and I2Cn\_RXDOUBLEP can be used to read data from the receive buffer without removing it from the buffer. The RXUF interrupt flag in I2Cn\_IF will never be set as a result of reading from I2Cn\_RXDATAP and I2Cn\_RXDOUBLEP, but the data read through I2Cn\_RXDATAP when the receive buffer is empty is still undefined.

Once a transaction is complete (STOP sent or received), the receive buffer needs to be flushed (all received data must be read) before starting a new transaction.

### 15.3.7 Master Operation

A bus transaction is initiated by transmitting a START condition (S) on the bus. This is done by setting the START bit in I2Cn\_CMD. The command schedules a START condition, and makes the I<sup>2</sup>C module generate a start condition whenever the bus becomes free.

The I<sup>2</sup>C-bus is considered busy whenever another device on the bus transmits a START condition. Until a STOP condition is detected, the bus is owned by the master issuing the START condition. The bus is considered free when a STOP condition is transmitted on the bus. After a STOP is detected, all masters that have data to transmit send a START condition and begin transmitting data. Arbitration ensures that collisions are avoided.

When the START condition has been transmitted, the master must transmit a slave address (ADDR) with an R/W bit on the bus. If this address is available in the transmit buffer, the master transmits it immediately, but if the buffer is empty, the master holds the I<sup>2</sup>C-bus while waiting for software to write the address to the transmit buffer.

After the address has been transmitted, a sequence of bytes can be read from or written to the slave, depending on the value of the R/W bit (bit 0 in the address byte). If the bit was cleared, the master has entered a master transmitter role, where it now transmits data to the slave. If the bit was set, it has entered a master receiver role, where it now should receive data from the slave. In either case, an unlimited number of bytes can be transferred in one direction during the transmission.

At the end of the transmission, the master either transmits a repeated START condition (Sr) if it wishes to continue with another transfer, or transmits a STOP condition (P) if it wishes to release the bus. When operating in the master mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 9 MHz for Fast-mode, and 20 MHz for Fast-mode Plus.

### 15.3.7.1 Master State Machine

The master state machine is shown in [Figure 15.15 I2C Master State Machine on page 420](#). A master operation starts in the far left of the state machine, and follows the solid lines through the state machine, ending the operation or continuing with a new operation when arriving at the right side of the state machine.

Branches in the path through the state machine are the results of bus events and choices made by software, either directly or indirectly. The dotted lines show where I<sup>2</sup>C-specific interrupt flags are set along the path and the full-drawn circles show places where interaction may be required by software to let the transmission proceed.

Figure 15.15. I2C Master State Machine

### 15.3.7.2 Interactions

Whenever the I<sup>2</sup>C module is waiting for interaction from software, it holds the bus clock SCL low, freezing all bus activities, and the BUSHOLD interrupt flag in I2Cn\_IF is set. The action(s) required by software depends on the current state the of the I<sup>2</sup>C module. This state can be read from the I2Cn\_STATE register.

As an example, [Table 15.3 I2C Master Transmitter on page 423](#) shows the different states the I<sup>2</sup>C goes through when operating as a Master Transmitter, i.e., a master that transmits data to a slave. As seen in the table, when a start condition has been transmitted, a requirement is that there is an address and an R/W bit in the transmit buffer. If the transmit buffer is empty, then the BUSHOLD interrupt flag is set, and the bus is held until data becomes available in the buffer. While waiting for the address, I2Cn\_STATE has a value 0x57, which can be used to identify exactly what the I<sup>2</sup>C module is waiting for.

**Note:** The bus would never stop at state 0x57 if the address was available in the transmit buffer.

The different interactions used by the I<sup>2</sup>C module are listed in [Table 15.2 I2C Interactions in Prioritized Order on page 421](#) in a prioritized order. If the I<sup>2</sup>C module is in such a state that multiple courses of action are possible, then the action chosen is the one that has the highest priority. For example, after sending out a START, if an address is present in the buffer and a STOP is also pending, then the I<sup>2</sup>C will send out the STOP since it has the higher priority.

**Table 15.2. I2C Interactions in Prioritized Order**

| Interaction      | Priority | Software action                                                  | Automatically continues if                                              |
|------------------|----------|------------------------------------------------------------------|-------------------------------------------------------------------------|
| STOP*            | 1        | Set the STOP command bit in I2Cn_CMD                             | PSTOP is set (STOP pending) in I2Cn_STATUS                              |
| ABORT            | 2        | Set the ABORT command bit in I2Cn_CMD                            | Never, the transmission is aborted                                      |
| CONT*            | 3        | Set the CONT command bit in I2Cn_CMD                             | PCONT is set in I2Cn_STATUS (CONT pending)                              |
| NACK*            | 4        | Set the NACK command bit in I2Cn_CMD                             | PNACK is set in I2Cn_STATUS (NACK pending)                              |
| ACK*             | 5        | Set the ACK command bit in I2Cn_CMD                              | AUTOACK is set in I2Cn_CTRL or PACK is set in I2Cn_STATUS (ACK pending) |
| ADDR+W -> TXDATA | 6        | Write an address to the transmit buffer with the R/W bit set     | Address is available in transmit buffer with R/W bit set                |
| ADDR+R -> TXDATA | 7        | Write an address to the transmit buffer with the R/W bit cleared | Address is available in transmit buffer with R/W bit cleared            |
| START*           | 8        | Set the START command bit in I2Cn_CMD                            | PSTART is set in I2Cn_STATUS (START pending)                            |
| TXDATA/ TXDOUBLE | 9        | Write data to the transmit buffer                                | Data is available in transmit buffer                                    |
| RXDATA/ RXDOUBLE | 10       | Read data from receive buffer                                    | Space is available in receive buffer                                    |
| None             | 11       | No interaction is required                                       |                                                                         |

The commands marked with a \* in [Table 15.2 I2C Interactions in Prioritized Order on page 421](#) can be issued before an interaction is required. When such a command is issued before it can be used/consumed by the I<sup>2</sup>C module, the command is set in a pending state, which can be read from the STATUS register. A pending START command can for instance be identified by PSTART having a high value.

Whenever the I<sup>2</sup>C module requires an interaction, it checks the pending commands. If one or a combination of these can fulfill an interaction, they are consumed by the module and the transmission continues without setting the BUSHOLD interrupt flag in I2Cn\_IF to get an interaction from software. The pending status of a command goes low when it is consumed.

When several interactions are possible from a set of pending commands, the interaction with the highest priority, i.e., the interaction closest to the top of [Table 15.2 I2C Interactions in Prioritized Order on page 421](#) is applied to the bus.

Pending commands can be cleared by setting the CLEARPC command bit in I2Cn\_CMD.

### 15.3.7.3 Automatic ACK Interaction

When receiving addresses and data, an ACK command in I2Cn\_CMD is normally required after each received byte. When AUTOACK is set in I2Cn\_CTRL, an ACK is always pending, and the ACK-pending bit PACK in I2Cn\_STATUS is thus always set, even after an ACK has been consumed. This is used when data is picked using I2Cn\_RXDOUBLE and can also be used with I2Cn\_RXDATA in order to reduce the amount of software interaction required during a transfer.

### 15.3.7.4 Reset State

After a reset, the state of the I<sup>2</sup>C-bus is unknown. To avoid interrupting transfers on the I<sup>2</sup>C-bus after a reset of the I<sup>2</sup>C module or the entire MCU, the I<sup>2</sup>C-bus is assumed to be busy when coming out of a reset, and the BUSY flag in I2Cn\_STATUS is thus set. To be able to carry through master operations on the I<sup>2</sup>C-bus, the bus must be idle.

The bus goes idle when a STOP condition is detected on the bus, but on buses with little activity, the time before the I<sup>2</sup>C module detects that the bus is idle can be significant. There are two ways of assuring that the I<sup>2</sup>C module gets out of the busy state.

- Use the ABORT command in I2Cn\_CMD. When the ABORT command is issued, the I<sup>2</sup>C module is instructed that the bus is idle. The I<sup>2</sup>C module can then initiate master operations.
- Use the Bus Idle Timeout. When SCL has been high for a long period of time, it is very likely that the bus is idle. Set BITO in I2Cn\_CTRL to an appropriate timeout period and set GIBITO in I2Cn\_CTRL. If activity has not been detected on the bus within the timeout period, the bus is then automatically assumed idle, and master operations can be initiated.

**Note:** If operating in slave mode, the above approach is not necessary.

### 15.3.7.5 Master Transmitter

To transmit data to a slave, the master must operate as a master transmitter. [Table 15.3 I2C Master Transmitter on page 423](#) shows the states the I<sup>2</sup>C module goes through while acting as a master transmitter. Every state where an interaction is required has the possible interactions listed, along with the result of the interactions. The table also shows which interrupt flags are set in the different states. The interrupt flags enclosed in parenthesis may be set. If the BUSHOLD interrupt in I2Cn\_IF is set, the module is waiting for an interaction, and the bus is frozen. The value of I2Cn\_STATE will be equal to the values given in the table when the BUSHOLD interrupt flag is set, and can be used to determine which interaction is required to make the transmission continue.

The interrupt flag START in I2Cn\_IF is set when the I<sup>2</sup>C module transmits the START.

A master operation is started by issuing a START command by setting START in I2Cn\_CMD. ADDR+W, i.e., the address of the slave + the R/W bit is then required by the I<sup>2</sup>C module. If this is not available in the transmit buffer, then the bus is held and the BUSHOLD interrupt flag is set. The value of I2Cn\_STATE will then be 0x57. As seen in the table, the I<sup>2</sup>C module also stops in this state if the address is not available after a repeated start condition.

To continue, write a byte to I2Cn\_TXDATA with the address of the slave in the 7 most significant bits and the least significant bit cleared (ADDR+W). This address will then be transmitted, and the slave will reply with an ACK or a NACK. If no slave replies to the address, the response will also be NACK. If the address was acknowledged, the master now has four choices. It can send data by placing it in I2Cn\_TXDATA/ I2Cn\_TXDOUBLE (the master should check the TXBL interrupt flag before writing to the transmit buffer), this data is then transmitted. The master can also stop the transmission by sending a STOP, it can send a repeated start by sending START, or it can send a STOP and then a START as soon as possible. If the master wishes to make another transfer immediately after the current, the preferred way is to start a new transfer directly by transmitting a repeated START instead of a STOP followed by a START. This is so because if a STOP is sent out, then any master wishing to initiate a transfer on the bus can try to gain control of it.

If a NACK was received, the master has to issue a CONT command in addition to providing data in order to continue transmission. This is not standard I<sup>2</sup>C, but is provided for flexibility. The rest of the options are similar to when an ACK was received.

If a new byte was transmitted, an ACK or NACK is received after the transmission of the byte, and the master has the same options as for when the address was sent.

The master may lose arbitration at any time during transmission. In this case, the ARBLOST interrupt flag in I2Cn\_IF is set. If the arbitration was lost during the transfer of an address, and SLAVE in I2Cn\_CTRL is set, the master then checks which address was transmitted. If it was the address of the master, then the master goes to slave mode.

After a master has transmitted a START and won any arbitration, it owns the bus until it transmits a STOP. After a STOP, the bus is released, and arbitration decides which bus master gains the bus next. The MSTOP interrupt flag in I2Cn\_IF is set when a STOP condition is transmitted by the master.

**Table 15.3. I2C Master Transmitter**

| I2Cn_STATE | Description                | I2Cn_IF                                       | Required interaction | Response                                                                             |
|------------|----------------------------|-----------------------------------------------|----------------------|--------------------------------------------------------------------------------------|
| 0x57       | Start transmitted          | START interrupt flag (BUSHOLD interrupt flag) | ADDR+W -> TXDATA     | ADDR+W will be sent                                                                  |
|            |                            |                                               | STOP                 | STOP will be sent and bus released.                                                  |
|            |                            |                                               | STOP + START         | STOP will be sent and bus released. Then a START will be sent when bus becomes idle. |
| 0x57       | Repeated start transmitted | START interrupt flag (BUSHOLD interrupt flag) | ADDR+W -> TXDATA     | ADDR+W will be sent                                                                  |
|            |                            |                                               | STOP                 | STOP will be sent and bus released.                                                  |
|            |                            |                                               | STOP + START         | STOP will be sent and bus released. Then a START will be sent when bus becomes idle. |
| -          | ADDR+W transmitted         | TXBL interrupt flag (TXC interrupt flag)      | None                 |                                                                                      |

| I2Cn_STATE | Description                       | I2Cn_IF                                     | Required interaction | Response                                                                                    |

| 0x97       | ADDR+W transmitted, ACK received  | ACK interrupt flag (BUSHOLD interrupt flag) | TXDATA               | DATA will be sent                                                                           |
|            |                                   |                                             | STOP                 | STOP will be sent. Bus will be released                                                     |
|            |                                   |                                             | START                | Repeated start condition will be sent                                                       |
|            |                                   |                                             | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |
| 0x9F       | ADDR+W transmitted, NACK received | NACK (BUSHOLD interrupt flag)               | CONT + TXDATA        | DATA will be sent                                                                           |
|            |                                   |                                             | STOP                 | STOP will be sent. Bus will be released                                                     |
|            |                                   |                                             | START                | Repeated start condition will be sent                                                       |
|            |                                   |                                             | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |
| -          | Data transmitted                  | TXBL interrupt flag (TXC interrupt flag)    | None                 |                                                                                             |
| 0xD7       | Data transmitted, ACK received    | ACK interrupt flag (BUSHOLD interrupt flag) | TXDATA               | DATA will be sent                                                                           |
|            |                                   |                                             | STOP                 | STOP will be sent. Bus will be released                                                     |
|            |                                   |                                             | START                | Repeated start condition will be sent                                                       |
|            |                                   |                                             | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |
| 0xDF       | Data transmitted, NACK received   | NACK (BUSHOLD interrupt flag)               | CONT + TXDATA        | DATA will be sent                                                                           |
|            |                                   |                                             | STOP                 | STOP will be sent. Bus will be released                                                     |
|            |                                   |                                             | START                | Repeated start condition will be sent                                                       |
|            |                                   |                                             | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |
| -          | Stop transmitted                  | MSTOP interrupt flag                        | None                 |                                                                                             |
|            |                                   |                                             | START                | START will be sent when bus becomes idle                                                    |
| -          | Arbitration lost                  | ARBLOST interrupt flag                      | None                 |                                                                                             |
|            |                                   |                                             | START                | START will be sent when bus becomes idle                                                    |

### 15.3.7.6 Master Receiver

To receive data from a slave, the master must operate as a master receiver, see [Table 15.4 I2C Master Receiver on page 425](#). This is done by transmitting ADDR+R as the address byte instead of ADDR+W, which is transmitted to become a master transmitter. The address byte loaded into the data register thus has to contain the 7-bit slave address in the 7 most significant bits of the byte, and have the least significant bit set.

When the address has been transmitted, the master receives an ACK or a NACK. If an ACK is received, the ACK interrupt flag in I2Cn\_IF is set, and if space is available in the receive shift register, reception of a byte from the slave begins. If the receive buffer and shift register is full however, the bus is held until data is read from the receive buffer or another interaction is made. Note that the STOP and START interactions have a higher priority than the data-available interaction, so if a STOP or START command is pending, the highest priority interaction will be performed, and data will not be received from the slave.

If a NACK was received, the CONT command in I2Cn\_CMD has to be issued in order to continue receiving data, even if there is space available in the receive buffer and/or shift register.

After a data byte has been received the master must ACK or NACK the received byte. If an ACK is pending or AUTOACK in I2Cn\_CTRL is set, an ACK is sent automatically and reception continues if space is available in the receive buffer.

If a NACK is sent, the CONT command must be used in order to continue transmission. If an ACK or NACK is issued along with a START or STOP or both, then the ACK/NACK is transmitted and the reception is ended. If START in I2Cn\_CMD is set alone, a repeated start condition is transmitted after the ACK/NACK. If STOP in I2Cn\_CMD is set, a stop condition is sent regardless of whether START is set. If START is set in this case, it is set as pending.

As when operating as a master transmitter, arbitration can be lost as a master receiver. When this happens the ARBLOST interrupt flag in I2Cn\_IF is set, and the master has a possibility of being selected as a slave given the correct conditions.

**Table 15.4. I2C Master Receiver**

| I2Cn_STATE | Description                       | I2Cn_IF                                       | Required interaction | Response                                                                                    |
|------------|-----------------------------------|-----------------------------------------------|----------------------|---------------------------------------------------------------------------------------------|
| 0x57       | START transmitted                 | START interrupt flag (BUSHOLD interrupt flag) | ADDR+R -> TXDATA     | ADDR+R will be sent                                                                         |
|            |                                   |                                               | STOP                 | STOP will be sent and bus released.                                                         |
|            |                                   |                                               | STOP + START         | STOP will be sent and bus released. Then a START will be sent when bus becomes idle.        |
| 0x57       | Repeated START transmitted        | START interrupt flag(BUSHOLD interrupt flag)  | ADDR+R -> TXDATA     | ADDR+R will be sent                                                                         |
|            |                                   |                                               | STOP                 | STOP will be sent and bus released.                                                         |
|            |                                   |                                               | STOP + START         | STOP will be sent and bus released. Then a START will be sent when bus becomes idle.        |
| -          | ADDR+R transmitted                | TXBL interrupt flag (TXC interrupt flag)      | None                 |                                                                                             |
| 0x93       | ADDR+R transmitted, ACK received  | ACK interrupt flag(BUSHOLD)                   | RXDATA               | Start receiving                                                                             |
|            |                                   |                                               | STOP                 | STOP will be sent and the bus released                                                      |
|            |                                   |                                               | START                | Repeated START will be sent                                                                 |
|            |                                   |                                               | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |
| 0x9B       | ADDR+R transmitted, NACK received | NACK(BUSHOLD)                                 | CONT + RXDATA        | Continue, start receiving                                                                   |
|            |                                   |                                               | STOP                 | STOP will be sent and the bus released                                                      |
|            |                                   |                                               | START                | Repeated START will be sent                                                                 |
|            |                                   |                                               | STOP + START         | STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle |

| I2Cn_STATE | Description      | I2Cn_IF                                       | Required interaction    | Response                                                                                                |
|------------|------------------|-----------------------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------|
| 0xB3       | Data received    | RXDATA interrupt flag(BUSHOLD interrupt flag) | ACK + RXDATA            | ACK will be transmitted, reception continues                                                            |
|            |                  |                                               | NACK + CONT + RXDATA    | NACK will be transmitted, reception continues                                                           |
|            |                  |                                               | ACK/NACK + STOP         | ACK/NACK will be sent and the bus will be released.                                                     |
|            |                  |                                               | ACK/NACK + START        | ACK/NACK will be sent, and then a repeated start condition.                                             |
|            |                  |                                               | ACK/NACK + STOP + START | ACK/NACK will be sent and the bus will be released. Then a START will be sent when the bus becomes idle |

### 15.3.8 Bus States

The I2Cn\_STATE register can be used to determine which state the I<sup>2</sup>C module and the I<sup>2</sup>C bus are in at a given time. The register consists of the STATE bit-field, which shows which state the I<sup>2</sup>C module is at in any ongoing transmission, and a set of single-bits, which reveal the transmission mode, whether the bus is busy or idle, and whether the bus is held by this I<sup>2</sup>C module waiting for a software response.

The possible values of the STATE field are summarized in [Table 15.5 I2C STATE Values on page 427](#). When this field is cleared, the I<sup>2</sup>C module is not a part of any ongoing transmission. The remaining status bits in the I2Cn\_STATE register are listed in [Table 15.6 I2C Transmission Status on page 427](#).

**Table 15.5. I2C STATE Values**

| Mode    | Value | Description                                                               |
|---------|-------|---------------------------------------------------------------------------|
| IDLE    | 0     | No transmission is being performed by this module.                        |
| WAIT    | 1     | Waiting for idle. Will send a start condition as soon as the bus is idle. |
| START   | 2     | Start being transmitted                                                   |
| ADDR    | 3     | Address being transmitted or has been received                            |
| ADDRACK | 4     | Address ACK/NACK being transmitted or received                            |
| DATA    | 5     | Data being transmitted or received                                        |
| DATAACK | 6     | Data ACK/NACK being transmitted or received                               |

**Table 15.6. I2C Transmission Status**

| Bit         | Description                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| BUSY        | Set whenever there is activity on the bus. Whether or not this module is responsible for the activity cannot be determined by this byte.            |
| MASTER      | Set when operating as a master. Cleared at all other times.                                                                                         |
| TRANSMITTER | Set when operating as a transmitter; either a master transmitter or a slave transmitter. Cleared at all other times                                 |
| BUSHOLD     | Set when the bus is held by this I <sup>2</sup> C module because an action is required by software.                                                 |
| NACK        | Only valid when bus is held and STATE is ADDRACK or DATAACK. In that case it is set if a NACK was received. In all other cases, the bit is cleared. |

**Note:** I2Cn\_STATE reflects the internal state of the I<sup>2</sup>C module, and therefore only held constant as long as the bus is held, i.e., as long as BUSHOLD in I2Cn\_STATUS is set.

### 15.3.9 Slave Operation

The I<sup>2</sup>C module operates in master mode by default. To enable slave operation, i.e., to allow the device to be addressed as an I<sup>2</sup>C slave, the SLAVE bit in I2Cn\_CTRL must be set. In this case the I<sup>2</sup>C module operates in a mixed mode, both capable of starting transmissions as a master, and being addressed as a slave. When operating in the slave mode, HFPERCLK frequency must be higher than 2 MHz for Standard-mode, 5 MHz for Fast-mode, and 14 MHz for Fast-mode Plus.

### 15.3.9.1 Slave State Machine

The slave state machine is shown in [Figure 15.16 I2C Slave State Machine on page 428](#). The dotted lines show where I<sup>2</sup>C-specific interrupt flags are set. The full-drawn circles show places where interaction may be required by software to let the transmission proceed.

Figure 15.16. I2C Slave State Machine

### 15.3.9.2 Address Recognition

The I<sup>2</sup>C module provides automatic address recognition for 7-bit addresses. 10-bit address recognition is not fully automatic, but can be assisted by the 7-bit address comparator as shown in [15.3.11 Using 10-bit Addresses](#). Address recognition is supported in all energy modes (except EM4).

The slave address, i.e., the address which the I<sup>2</sup>C module should be addressed with, is defined in the I2Cn\_SADDR register. In addition to the address, a mask must be specified, telling the address comparator which bits of an incoming address to compare with the address defined in I2Cn\_SADDR. The mask is defined in I2Cn\_SADDRMASK, and for every zero in the mask, the corresponding bit in the slave address is treated as a don't-care, i.e., the 0-masked bits are ignored.

An incoming address that fails address recognition is automatically replied to with a NACK. Since only the bits defined by the mask are checked, a mask with a value 0x00 will result in all addresses being accepted. A mask with a value 0x7F will only match the exact address defined in I2Cn\_SADDR, while a mask 0x70 will match all addresses where the three most significant bits in I2Cn\_SADDR and the incoming address are equal.

If GCAMEN in I2Cn\_CTRL is not set, the start-byte, i.e., the general call address with the R/W bit set is ignored unless it is included in the defined slave address and the address mask.

When an address is accepted by the address comparator, the decision of whether to ACK or NACK the address is passed to software.

### 15.3.9.3 Slave Transmitter

When SLAVE in I2Cn\_CTRL is set, the RSTART interrupt flag in I2Cn\_IF will be set when repeated START conditions are detected. After a START or repeated START condition, the bus master will transmit an address along with an R/W bit. If there is no room in the receive shift register for the address, the bus will be held by the slave until room is available in the shift register. Transmission then continues and the address is loaded into the shift register. If this address does not pass address recognition, it is automatically NACK'ed by the slave, and the slave goes to an idle state. The address byte is in this case discarded, making the shift register ready for a new address. It is not loaded into the receive buffer.

If the address was accepted and the R/W bit was set (R), indicating that the master wishes to read from the slave, the slave now goes into the slave transmitter mode. Software interaction is now required to decide whether the slave wants to acknowledge the request or not. The accepted address byte is loaded into the receive buffer like a regular data byte. If no valid interaction is pending, the bus is held until the slave responds with a command. The slave can reject the request with a single NACK command.

The slave will in that case go to an idle state, and wait for the next start condition. To continue the transmission, the slave must make sure data is loaded into the transmit buffer and send an ACK. The loaded data will then be transmitted to the master, and an ACK or NACK will be received from the master.

Data transmission can also continue after a NACK if a CONT command is issued along with the NACK. This is not standard I<sup>2</sup>C however.

If the master responds with an ACK, it may expect another byte of data, and data should be made available in the transmit buffer. If data is not available, the bus is held until data is available.

If the response is a NACK however, this is an indication of that the master has received enough bytes and wishes to end the transmission. The slave now automatically goes idle, unless CONT in I2Cn\_CMD is set and data is available for transmission. The latter is not standard I<sup>2</sup>C.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag in I2Cn\_IF is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag is not set.

**Note:** The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected.

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See [Table 15.7 I2C Slave Transmitter on page 429](#) for more information.

**Table 15.7. I2C Slave Transmitter**

| I2Cn_STATE | Description                     | I2Cn_IF                                        | Required interaction | Response                           |
|------------|---------------------------------|------------------------------------------------|----------------------|------------------------------------|
| 0x41       | Repeated START received         | RSTART interrupt flag (BUSHOLD interrupt flag) | RXDATA               | Receive and compare address        |
| 0x75       | ADDR + R received               | ADDR interrupt flag                            | ACK + TXDATA         | ACK will be sent, then DATA        |
|            |                                 | RXDATA interrupt flag                          | NACK                 | NACK will be sent, slave goes idle |
|            |                                 | (BUSHOLD interrupt flag)                       | NACK + CONT + TXDATA | NACK will be sent, then DATA.      |
| -          | Data transmitted                | TXBL interrupt flag (TXC interrupt flag)       | None                 |                                    |
| 0xD5       | Data transmitted, ACK received  | ACK interrupt flag (BUSHOLD interrupt flag)    | TXDATA               | DATA will be transmitted           |
| 0xDD       | Data transmitted, NACK received | NACK interrupt flag                            | None                 | The slave goes idle                |
|            |                                 | (BUSHOLD interrupt flag)                       | CONT + TXDATA        | DATA will be transmitted           |

| I2Cn_STATE | Description      | I2Cn_IF                | Required interaction | Response                                     |
|------------|------------------|------------------------|----------------------|----------------------------------------------|
| -          | Stop received    | SSTOP interrupt flag   | None                 | The slave goes idle                          |
|            |                  |                        | START                | START will be sent when bus becomes idle     |
| -          | Arbitration lost | ARBLOST interrupt flag | None                 | The slave goes idle                          |
|            |                  |                        | START                | START will be sent when the bus becomes idle |

### 15.3.9.4 Slave Receiver

A slave receiver operation is started in the same way as a slave transmitter operation, with the exception that the address transmitted by the master has the R/W bit cleared (W), indicating that the master wishes to write to the slave. The slave then goes into slave receiver mode.

To receive data from the master, the slave should respond to the address with an ACK and make sure space is available in the receive buffer. Transmission will then continue, and the slave will receive a byte from the master.

If a NACK is sent without a CONT, the transmission is ended for the slave, and it goes idle. If the slave issues both the NACK and CONT commands and has space available in the receive buffer, it will be open for continuing reception from the master.

When a byte has been received from the master, the slave must ACK or NACK the byte. The responses here are the same as for the reception of the address byte.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag in I2Cn\_IF is not set.

**Note:** The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See [Table 15.8 I2C - Slave Receiver on page 431](#) for more information.

**Table 15.8. I2C - Slave Receiver**

| I2Cn_STATE | Description             | I2Cn_IF                                                               | Required interaction | Response                                     |
|------------|-------------------------|-----------------------------------------------------------------------|----------------------|----------------------------------------------|
| -          | Repeated START received | RSTART interrupt flag (BUSHOLD interrupt flag)                        | RXDATA               | Receive and compare address                  |
| 0x71       | ADDR + W received       | ADDR interrupt flag<br>RXDATA interrupt flag (BUSHOLD interrupt flag) | ACK + RXDATA         | ACK will be sent and data will be received   |
|            |                         |                                                                       | NACK                 | NACK will be sent, slave goes idle           |
|            |                         |                                                                       | NACK + CONT + RXDATA | NACK will be sent and DATA will be received. |
| 0xB1       | Data received           | RXDATA interrupt flag (BUSHOLD interrupt flag)                        | ACK + RXDATA         | ACK will be sent and data will be received   |
|            |                         |                                                                       | NACK                 | NACK will be sent and slave will go idle     |
|            |                         |                                                                       | NACK + CONT + RXDATA | NACK will be sent and data will be received  |
| -          | Stop received           | SSTOP interrupt flag                                                  | None                 | The slave goes idle                          |
|            |                         |                                                                       | START                | START will be sent when bus becomes idle     |
| -          | Arbitration lost        | ARBLOST interrupt flag                                                | None                 | The slave goes idle                          |
|            |                         |                                                                       | START                | START will be sent when the bus becomes idle |

### 15.3.10 Transfer Automation

The I<sup>2</sup>C can be set up to complete transfers with a minimal amount of interaction.

### 15.3.10.1 DMA

DMA can be used to automatically load data into the transmit buffer and load data out from the receive buffer. When using DMA, software is thus relieved of moving data to and from memory after each transferred byte.

### 15.3.10.2 Automatic ACK

When AUTOACK in I2Cn\_CTRL is set, an ACK is sent automatically whenever an ACK interaction is possible and no higher priority interactions are pending.

### 15.3.10.3 Automatic STOP

A STOP can be generated automatically on two conditions. These apply only to the master transmitter.

If AUTOSN in I2Cn\_CTRL is set, the I<sup>2</sup>C module ends a transmission by transmitting a STOP condition when operating as a master transmitter and a NACK is received.

If AUTOSE in I2Cn\_CTRL is set, the I<sup>2</sup>C module always ends a transmission when there is no more data in the transmit buffer. If data has been transmitted on the bus, the transmission is ended after the (N)ACK has been received by the slave. If a START is sent when no data is available in the transmit buffer and AUTOSE is set, then the STOP condition is sent immediately following the START. Software must thus make sure data is available in the transmit buffer before the START condition has been fully transmitted if data is to be transferred.

### 15.3.11 Using 10-bit Addresses

When using 10-bit addresses in slave mode, set the I2Cn\_SADDR register to 1111 0XX where XX are the two most significant bits of the 10-bit address, and set I2Cn\_SADDRMASK to 0xFF. Address matches will now be given on all 10-bit addresses where the two most significant bits are correct.

When receiving an address match, the slave must acknowledge the address and receive the first data byte. This byte contains the second part of the 10-bit address. If it matches the address of the slave, the slave should ACK the byte to continue the transmission, and if it does not match, the slave should NACK it.

When the master is operating as a master transmitter, the data bytes will follow after the second address byte. When the master is operating as a master receiver however, a repeated START condition is sent after the second address byte. The address sent after this repeated START is equal to the first of the address bytes transmitted previously, but now with the R/W byte set, and only the slave that found a match on the entire 10-bit address in the previous message should ACK this address. The repeated start should take the master into a master receiver mode, and after the single address byte sent this time around, the slave begins transmission to the master.

### 15.3.12 Error Handling

**Note:** The setting of GCAMEN and SLAVE fields in the I2Cn\_CTRL register and the registers I2Cn\_SADDR and I2Cn\_ROUTELOC0 are considered static. This means that these need to be set before an I<sup>2</sup>C transaction starts and need to stay stable during the entire transaction.

#### 15.3.12.1 ABORT Command

Some bus errors may require software intervention to be resolved. The I<sup>2</sup>C module provides an ABORT command, which can be set in I2Cn\_CMD, to help resolve bus errors.

When the bus for some reason is locked up and the I<sup>2</sup>C module is in the middle of a transmission it cannot get out of, or for some other reason the I<sup>2</sup>C wants to abort a transmission, the ABORT command can be used.

Setting the ABORT command will make the I<sup>2</sup>C module discard any data currently being transmitted or received, release the SDA and SCL lines and go to an idle mode. ABORT effectively makes the I<sup>2</sup>C module forget about any ongoing transfers.

#### 15.3.12.2 Bus Reset

A bus reset can be performed by setting the START and STOP commands in I2Cn\_CMD while the transmit buffer is empty. A START condition will then be transmitted, immediately followed by a STOP condition. A bus reset can also be performed by transmitting a START command with the transmit buffer empty and AUTOSE set.

### 15.3.12.3 I2C-Bus Errors

An I<sup>2</sup>C-bus error occurs when a START or STOP condition is misplaced, which happens when the value on SDA changes while SCL is high during bit-transmission on the I<sup>2</sup>C-bus. If the I<sup>2</sup>C module is part of the current transmission when a bus error occurs, any data currently being transmitted or received is discarded, SDA and SCL are released, the BUSERR interrupt flag in I2Cn\_IF is set to indicate the error, and the module automatically takes a course of action as defined in [Table 15.9 I2C Bus Error Response on page 433](#).

**Table 15.9. I2C Bus Error Response**

|                             | Misplaced START                    | Misplaced STOP                        |
|-----------------------------|------------------------------------|---------------------------------------|
| In a master/slave operation | Treated as START. Receive address. | Go idle. Perform any pending actions. |

### 15.3.12.4 Bus Lockup

A lockup occurs when a master or slave on the I<sup>2</sup>C-bus has locked the SDA or SCL at a low value, preventing other devices from putting high values on the bus, and thus making communication on the bus impossible.

Many slave-only devices operating on an I<sup>2</sup>C-bus are not capable of driving SCL low, but in the rare case that SCL is stuck LOW, the advice is to apply a hardware reset signal to the slaves on the bus. If this does not work, cycle the power to the devices in order to make them release SCL.

When SDA is stuck low and SCL is free, a master should send 9 clock pulses on SCL while tristating the SDA. This procedure is performed in the GPIO module after clearing the I2C\_ROUTE register and disabling the I2C module. The device that held the bus low should release it sometime within those 9 clocks. If not, use the same approach as for when SCL is stuck, resetting and possibly cycling power to the slaves.

Lockup of SDA can be detected by keeping count of the number of continuous arbitration losses during address transmission. If arbitration is also lost during the transmission of a general call address, i.e., during the transmission of the STOP condition, which should never happen during normal operation, this is a good indication of SDA lockup.

Detection of SCL lockups can be done using the timeout functionality defined in [15.3.12.6 Clock Low Timeout](#)

### 15.3.12.5 Bus Idle Timeout

When SCL has been high for a significant amount of time, this is a good indication of that the bus is idle. On an SMBus system, the bus is only allowed to be in this state for a maximum of 50 µs before the bus is considered idle.

The bus idle timeout BITO in I2Cn\_CTRL can be used to detect situations where the bus goes idle in the middle of a transmission. The timeout can be configured in BITO, and when the bus has been idle for the given amount of time, the BITO interrupt flag in I2Cn\_IF is set. The bus can also be set idle automatically on a bus idle timeout. This is enabled by setting GIBITO in I2Cn\_CTRL.

When the bus idle timer times out, it wraps around and continues counting as long as its condition is true. If the bus is not set idle using GIBITO or the ABORT command in I2Cn\_CMD, this will result in periodic timeouts.

**Note:** This timeout will be generated even if SDA is held low.

The bus idle timeout is active as long as the bus is busy, i.e., BUSY in I2Cn\_STATUS is set. The timeout can be used to get the I<sup>2</sup>C module out of the busy-state it enters when reset, see [15.3.7.4 Reset State](#).

### 15.3.12.6 Clock Low Timeout

The clock timeout, which can be configured in CLTO in I2Cn\_CTRL, starts counting whenever SCL goes low, and times out if SCL does not go high within the configured timeout. A clock low timeout results in CLTOIF in I2Cn\_IF being set, allowing software to take action.

When the timer times out, it wraps around and continues counting as long as SCL is low. An SCL lockup will thus result in periodic clock low timeouts as long as SCL is low.

### 15.3.12.7 Clock Low Error

The I<sup>2</sup>C module can continue transmission in parallel with another device for the entire transaction, as long as the two communications are identical. A case may arise when (before an arbitration has been decided upon) the I<sup>2</sup>C module decides to send out a repeated START or a STOP condition while the other device is still sending data. In the I<sup>2</sup>C protocol specifications, such a combination results in an undefined condition. The I<sup>2</sup>C deals with this by generating a clock low error. This means that if the I<sup>2</sup>C is transmitting a repeated START or a STOP condition and another device (another master or a misbehaving slave) pulls SCL low before the I<sup>2</sup>C sends out the START/STOP condition on SDA, a clock low error is generated. The CLERR interrupt flag is then set in the I2Cn\_IF register, any held lines are released and the I<sup>2</sup>C device goes to idle.

### 15.3.13 DMA Support

The I<sup>2</sup>C module has full DMA support. A request for the DMA controller to write to the I<sup>2</sup>C transmit buffer can come from TXBL (transmit buffer has room for more data). The DMA controller can write to the transmit buffer using the I2Cn\_TXDATA or the I2Cn\_TXDOUBLE register. In order to write to the I2Cn\_TXDOUBLE register (i.e., transferring 2 bytes simultaneously to the transmit buffer using the DMA), DMA\_USEBURSTS needs to be set to 1 for the selected DMA channel. This ensures that the transfer is made to the transmit buffer only when both buffer elements are empty. For performing a DMA write to the I2Cn\_TXDATA register, DMA\_USEBURSTC needs to be set to 1 for the selected DMA channel. This ensures that a DMA transfer is made even when the transmit buffer is half-empty.

A request for the DMA controller to read from the I<sup>2</sup>C receive buffer can come from RXDATAV (data available in the receive buffer). To receive from I2Cn\_RXDOUBLE (i.e., receive only when both buffer elements are full), DMA\_USEBURSTS needs to be set to 1 for the selected DMA channel. In order to receive from I2Cn\_RXDATA through the DMA, DMA\_USEBURSTC needs to be set to 1. This ensures that the data gets picked up even when the receive buffer is half-full.

### 15.3.14 Interrupts

The interrupts generated by the I<sup>2</sup>C module are combined into one interrupt vector, I2C\_INT. If I<sup>2</sup>C interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in I2Cn\_IF and their corresponding bits in I2Cn\_IEN are set.

### 15.3.15 Wake-up

The I<sup>2</sup>C receive section can be active all the way down to energy mode EM3 Stop, and can wake up the CPU on address interrupt. All address match modes are supported.

## 15.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name           | Type  | Description                              |
|--------|----------------|-------|------------------------------------------|
| 0x000  | I2Cn_CTRL      | RW    | Control Register                         |
| 0x004  | I2Cn_CMD       | W1    | Command Register                         |
| 0x008  | I2Cn_STATE     | R     | State Register                           |
| 0x00C  | I2Cn_STATUS    | R     | Status Register                          |
| 0x010  | I2Cn_CLKDIV    | RW    | Clock Division Register                  |
| 0x014  | I2Cn_SADDR     | RW    | Slave Address Register                   |
| 0x018  | I2Cn_SADDRMASK | RW    | Slave Address Mask Register              |
| 0x01C  | I2Cn_RXDATA    | R(a)  | Receive Buffer Data Register             |
| 0x020  | I2Cn_RXDOUBLE  | R(a)  | Receive Buffer Double Data Register      |
| 0x024  | I2Cn_RXDATAP   | R     | Receive Buffer Data Peek Register        |
| 0x028  | I2Cn_RXDOUBLEP | R     | Receive Buffer Double Data Peek Register |
| 0x02C  | I2Cn_TXDATA    | W     | Transmit Buffer Data Register            |
| 0x030  | I2Cn_TXDOUBLE  | W     | Transmit Buffer Double Data Register     |
| 0x034  | I2Cn_IF        | R     | Interrupt Flag Register                  |
| 0x038  | I2Cn_IFS       | W1    | Interrupt Flag Set Register              |
| 0x03C  | I2Cn_IFC       | (R)W1 | Interrupt Flag Clear Register            |
| 0x040  | I2Cn_IEN       | RW    | Interrupt Enable Register                |
| 0x044  | I2Cn_ROUTEPEN  | RW    | I/O Routing Pin Enable Register          |
| 0x048  | I2Cn_ROUTELOC0 | RW    | I/O Routing Location Register            |

## 15.5 Register Description

### 15.5.1 I2Cn\_CTRL - Control Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |      |    |    |    |    |         |    |    |    |    |
|--------|--------------|----|----|----|----|----|----|----|----|----|------|----|----|----|----|---------|----|----|----|----|
| 0x000  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21   | 20 | 19 | 18 | 17 | 16      | 15 | 14 | 13 | 12 |
| Reset  |              |    |    |    |    |    |    |    |    |    | 0x0  |    |    |    |    | 0       |    |    |    |    |
| Access |              |    |    |    |    |    |    |    |    |    | RW   |    |    |    |    | RW      |    |    |    |    |
| Name   |              |    |    |    |    |    |    |    |    |    | CLTO |    |    |    |    | GIBITO  |    |    |    |    |
|        |              |    |    |    |    |    |    |    |    |    |      |    |    |    |    | BITO    |    |    |    |    |
|        |              |    |    |    |    |    |    |    |    |    |      |    |    |    |    |         |    |    |    |    |

|-------|------|-----|----|--------------------------|
| 18:16 | CLTO | 0x0 | RW | <b>Clock Low Timeout</b> |
|-------|------|-----|----|--------------------------|

Use to generate a timeout when CLK has been low for the given amount of time. Wraps around and continues counting when the timeout is reached. The timeout value can be calculated by

$$\text{timeout} = \text{PCC} / (\text{f}_{\text{SCL}} \times (\text{N}_{\text{low}} + \text{N}_{\text{high}}))$$

| Value | Mode    | Description                                                                                               |
|-------|---------|-----------------------------------------------------------------------------------------------------------|
| 0     | OFF     | Timeout disabled                                                                                          |
| 1     | 40PCC   | Timeout after 40 prescaled clock cycles. In standard mode at 100 kHz, this results in a 50us timeout.     |
| 2     | 80PCC   | Timeout after 80 prescaled clock cycles. In standard mode at 100 kHz, this results in a 100us timeout.    |
| 3     | 160PCC  | Timeout after 160 prescaled clock cycles. In standard mode at 100 kHz, this results in a 200us timeout.   |
| 4     | 320PCC  | Timeout after 320 prescaled clock cycles. In standard mode at 100 kHz, this results in a 400us timeout.   |
| 5     | 1024PCC | Timeout after 1024 prescaled clock cycles. In standard mode at 100 kHz, this results in a 1280us timeout. |

|    |        |   |    |                                    |
|----|--------|---|----|------------------------------------|
| 15 | GIBITO | 0 | RW | <b>Go Idle on Bus Idle Timeout</b> |
|----|--------|---|----|------------------------------------|

When set, the bus automatically goes idle on a bus idle timeout, allowing new transfers to be initiated.

| Value | Description                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------|
| 0     | A bus idle timeout has no effect on the bus state.                                                    |
| 1     | A bus idle timeout tells the I2C module that the bus is idle, allowing new transfers to be initiated. |

|    |          |                                                                                                                          |  |  |

| 13:12 | BITO     | 0x0                                                                                                                      | RW     | <b>Bus Idle Timeout</b><br><br>Use to generate a timeout when SCL has been high for a given amount time between a START and STOP condition. When in a bus transaction, i.e. the BUSY flag is set, a timer is started whenever SCL goes high. When the timer reaches the value defined by BITO, it sets the BITO interrupt flag. The BITO interrupt flag will then be set periodically as long as SCL remains high. The bus idle timeout is active as long as BUSY is set. It is thus stopped automatically on a timeout if GIBITO is set. It is also stopped a STOP condition is detected and when the ABORT command is issued. The timeout is activated whenever the bus goes BUSY, i.e. a START condition is detected. The timeout value can be calculated by<br><br>$\text{timeout} = \text{PCC} / (\text{f}_{\text{SCL}} \times (\text{N}_{\text{low}} + \text{N}_{\text{high}}))$ |
