## 16. USART - Universal Synchronous Asynchronous Receiver/Transmitter

### Quick Facts

#### What?

The USART handles high-speed UART, SPI-bus, SmartCards, and IrDA communication.

#### Why?

Serial communication is frequently used in embedded systems and the USART allows efficient communication with a wide range of external devices.

#### How?

The USART has a wide selection of operating modes, frame formats and baud rates. The multi-processor mode allows the USART to remain idle when not addressed. Triple buffering and DMA support makes high data rates possible with minimal CPU intervention and it is possible to transmit and receive large frames while the MCU remains in EM1 Sleep.

### 16.1 Introduction

The Universal Synchronous Asynchronous serial Receiver and Transmitter (USART) is a very flexible serial I/O module. It supports full duplex asynchronous UART communication as well as RS-485, SPI, MicroWire and 3-wire. It can also interface with ISO7816 SmartCards, and IrDA devices.

## 16.2 Features

- Asynchronous and synchronous (SPI) communication
- Full duplex and half duplex
- Separate TX/RX enable
- Separate receive / transmit multiple entry buffers, with additional separate shift registers
- Programmable baud rate, generated as an fractional division from the peripheral clock ( $\text{HFPERCLK}_{\text{USARTn}}$ )
- Max bit-rate
  - SPI master mode, peripheral clock rate/2
  - SPI slave mode, peripheral clock rate/8
  - UART mode, peripheral clock rate/16, 8, 6, or 4
- Asynchronous mode supports
  - Majority vote baud-reception
  - False start-bit detection
  - Break generation/detection
  - Multi-processor mode
- Synchronous mode supports
  - All 4 SPI clock polarity/phase configurations
  - Master and slave mode
- Data can be transmitted LSB first or MSB first
- Configurable number of data bits, 4-16 (plus the parity bit, if enabled)
  - HW parity bit generation and check
- Configurable number of stop bits in asynchronous mode: 0.5, 1, 1.5, 2
- HW collision detection
- Multi-processor mode
- IrDA modulator
- SmartCard (ISO7816) mode
- I2S mode
- Separate interrupt vectors for receive and transmit interrupts
- Loopback mode
  - Half duplex communication
  - Communication debugging
- PRS RX input
- 8 bit Timer
- Hardware Flow Control
- Automatic Baud Rate Detection

### 16.3 Functional Description

An overview of the USART module is shown in [Figure 16.1 USART Overview on page 460](#).

This section describes all possible USART features. Refer to the device data sheet to see what features a specific USART instance supports.

Figure 16.1. USART Overview

### 16.3.1 Modes of Operation

The USART operates in either asynchronous or synchronous mode.

In synchronous mode, a separate clock signal is transmitted with the data. This clock signal is generated by the bus master, and both the master and slave sample and transmit data according to this clock. Both master and slave modes are supported by the USART. The synchronous communication mode is compatible with the Serial Peripheral Interface Bus (SPI) standard.

In asynchronous mode, no separate clock signal is transmitted with the data on the bus. The USART receiver thus has to determine where to sample the data on the bus from the actual data. To make this possible, additional synchronization bits are added to the data when operating in asynchronous mode, resulting in a slight overhead.

Asynchronous or synchronous mode can be selected by configuring SYNC in USARTn\_CTRL. The options are listed with supported protocols in [Table 16.1 USART Asynchronous Vs. Synchronous Mode on page 461](#). Full duplex and half duplex communication is supported in both asynchronous and synchronous mode.

**Table 16.1. USART Asynchronous Vs. Synchronous Mode**

| SYNC | Communication Mode | Supported Protocols                                |
|------|--------------------|----------------------------------------------------|
| 0    | Asynchronous       | RS-232, RS-485 (w/external driver), IrDA, ISO 7816 |
| 1    | Synchronous        | SPI, MicroWire, 3-wire                             |

[Table 16.2 USART Pin Usage on page 461](#) explains the functionality of the different USART pins when the USART operates in different modes. Pin functionality enclosed in square brackets is optional, and depends on additional configuration parameters. LOOPBK and MASTER are discussed in [16.3.2.14 Local Loopback](#) and [16.3.3.3 Master Mode](#) respectively.

**Table 16.2. USART Pin Usage**

| SYNC | LOOPBK | MASTER | Pin functionality |                 |           |                     |
|------|--------|--------|-------------------|-----------------|-----------|---------------------|
|      |        |        | U(S)n_TX (MOSI)   | U(S)n_RX (MISO) | USn_CLK   | USn_CS              |
| 0    | 0      | x      | Data out          | Data in         | -         | [Driver enable]     |
| 0    | 1      | x      | Data out/in       | -               | -         | [Driver enable]     |
| 1    | 0      | 0      | Data in           | Data out        | Clock in  | Slave select        |
| 1    | 0      | 1      | Data out          | Data in         | Clock out | [Auto slave select] |
| 1    | 1      | 0      | Data out/in       | -               | Clock in  | Slave select        |
| 1    | 1      | 1      | Data out/in       | -               | Clock out | [Auto slave select] |

### 16.3.2 Asynchronous Operation

The USART operates in asynchronous mode when SYNC in USARTn\_CTRL is cleared to 0.

### 16.3.2.1 Frame Format

The frame format used in asynchronous mode consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 4 to 16 data bits and an optional parity bit. Finally, a number of stop-bits, where the line is driven high, end the frame. An example frame is shown in [Figure 16.2 USART Asynchronous Frame Format on page 462](#).

**Figure 16.2. USART Asynchronous Frame Format**

The number of data bits in a frame is set by DATABITS in USARTn\_FRAME, see [Table 16.3 USART Data Bits on page 462](#), and the number of stop-bits is set by STOPBITS in USARTn\_FRAME, see [Table 16.4 USART Stop Bits on page 462](#). Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY, also in USARTn\_FRAME. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

**Table 16.3. USART Data Bits**

| DATA BITS [3:0] | Number of Data Bits |
|-----------------|---------------------|
| 0001            | 4                   |
| 0010            | 5                   |
| 0011            | 6                   |
| 0100            | 7                   |
| 0101            | 8 (Default)         |
| 0110            | 9                   |
| 0111            | 10                  |
| 1000            | 11                  |
| 1001            | 12                  |
| 1010            | 13                  |
| 1011            | 14                  |
| 1100            | 15                  |
| 1101            | 16                  |

**Table 16.4. USART Stop Bits**

| STOP BITS [1:0] | Number of Stop Bits |
|-----------------|---------------------|
| 00              | 0.5                 |
| 01              | 1 (Default)         |
| 10              | 1.5                 |
| 11              | 2                   |

The order in which the data bits are transmitted and received is defined by MSBF in USARTn\_CTRL. When MSBF is cleared, data in a frame is sent and received with the least significant bit first. When it is set, the most significant bit comes first.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV in USARTn\_CTRL. These bits affect the entire frame, not only the data bits. An inverted frame has a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits.

### 16.3.2.2 Parity Bit Calculation and Handling

When parity bits are enabled, hardware automatically calculates and inserts any parity bits into outgoing frames, and verifies the received parity bits in incoming frames. This is true for both asynchronous and synchronous modes, even though it is mostly used in asynchronous communication. The possible parity modes are defined in [Table 16.5 USART Parity Bits on page 463](#). When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd.

**Table 16.5. USART Parity Bits**

| PARITY BITS [1:0] | Description             |
|-------------------|-------------------------|
| 00                | No parity bit (Default) |
| 01                | Reserved                |
| 10                | Even parity             |
| 11                | Odd parity              |

### 16.3.2.3 Clock Generation

The USART clock defines the transmission and reception data rate. When operating in asynchronous mode, the baud rate (bit-rate) is given by [Figure 16.3 USART Baud Rate on page 464](#).

$$br = f_{H\text{PERCLK}} / (\text{oversample} \times (1 + \text{USARTn\_CLKDIV}/256))$$

**Figure 16.3. USART Baud Rate**

where  $f_{H\text{PERCLK}}$  is the peripheral clock ( $H\text{PERCLK}_{\text{USARTn}}$ ) frequency and oversample is the oversampling rate as defined by OVS in  $\text{USARTn\_CTRL}$ , see [Table 16.6 USART Oversampling on page 464](#).

**Table 16.6. USART Oversampling**

| OVS [1:0] | Oversample |
|-----------|------------|
| 00        | 16         |
| 01        | 8          |
| 10        | 6          |
| 11        | 4          |

The USART has a fractional clock divider to allow the USART clock to be controlled more accurately than what is possible with a standard integral divider.

The clock divider used in the USART is a 20-bit value, with a 15-bit integral part and an 5-bit fractional part. The fractional part is configured in the lower 5 bits of DIV in  $\text{USART\_CLKDIV}$ .

Fractional clock division is implemented by distributing the selected fraction over thirty two baud periods. The fractional part of the divider tells how many of these periods should be extended by one peripheral clock cycle.

Given a desired baud rate  $br_{\text{desired}}$ , the clock divider  $\text{USARTn\_CLKDIV}$  can be calculated by using [Figure 16.4 USART Desired Baud Rate on page 464](#):

$$\text{USARTn\_CLKDIV} = 256 \times (f_{H\text{PERCLK}} / (\text{oversample} \times br_{\text{desired}})) - 1$$

**Figure 16.4. USART Desired Baud Rate**

[Table 16.7 USART Baud Rates @ 4MHz Peripheral Clock With 20 Bit CLKDIV on page 464](#) shows a set of desired baud rates and how accurately the USART is able to generate these baud rates when running at a 4 MHz peripheral clock, using 16x or 8x oversampling.

**Table 16.7. USART Baud Rates @ 4MHz Peripheral Clock With 20 Bit CLKDIV**

| Desired baud rate [baud/s] | USARTn_OVS =00                       |                           |         | USARTn_OVS =01                       |                           |         |
|----------------------------|--------------------------------------|---------------------------|---------|--------------------------------------|---------------------------|---------|
|                            | USARTn_CLKDIV/256 (to 32nd position) | Actual baud rate [baud/s] | Error % | USARTn_CLKDIV/256 (to 32nd position) | Actual baud rate [baud/s] | Error % |
| 600                        | 415.6563                             | 600.015                   | 0.003   | 832.3438                             | 599.9925                  | -0.001  |
| 1200                       | 207.3438                             | 1199.94                   | -0.005  | 415.6563                             | 1200.03                   | 0.003   |
| 2400                       | 103.1563                             | 2400.24                   | 0.010   | 207.3438                             | 2399.88                   | -0.005  |
| 4800                       | 51.09375                             | 4799.04                   | -0.020  | 103.1563                             | 4800.48                   | 0.010   |
| 9600                       | 25.03125                             | 9603.842                  | 0.040   | 51.09375                             | 9598.08                   | -0.020  |
| 14400                      | 16.375                               | 14388.49                  | -0.080  | 33.71875                             | 14401.44                  | 0.010   |
| 19200                      | 12.03125                             | 19184.65                  | -0.080  | 25.03125                             | 19207.68                  | 0.040   |
| 28800                      | 7.6875                               | 28776.98                  | -0.080  | 16.375                               | 28776.98                  | -0.080  |

| Desired baud rate [baud/s] | USARTn_OVS =00                       |                           |         | USARTn_OVS =01                       |                           |         |
|----------------------------|--------------------------------------|---------------------------|---------|--------------------------------------|---------------------------|---------|

| 230400                     | 0.09375                              | 228571.4                  | -0.794  | 1.15625                              | 231884.1                  | 0.644   |

#### 16.3.2.4 Auto Baud Detection

Setting AUTOBAUDEN in USARTn\_CLKDIV uses the first frame received to automatically set the baud rate provided that it contains 0x55 (IrDA uses 0x00). AUTOBAUDEN can be used in a simple LIN configuration to auto detect the SYNC byte. The receiver will measure the number of local clock cycles between the beginning of the START bit and the beginning of the 8th data bit. The DIV field in USARTn\_CLKDIV will be overwritten with the new value. The OVS in USARTn\_CTRL and the +1 count of the Baud Rate equation are already factored into the result that gets written into the DIV field. To restart autobaud detection, clear AUTOBAUDEN and set it high again. Since the auto baud detection is done over 8 baud times, only the upper 3 bits of the fractional part of the clock divider are populated.

#### 16.3.2.5 Data Transmission

Asynchronous data transmission is initiated by writing data to the transmit buffer using one of the methods described in [16.3.2.6 Transmit Buffer Operation](#). When the transmission shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available.

Transmission is enabled through the command register USARTn\_CMD by setting TXEN, and disabled by setting TXDIS in the same command register. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in USARTn\_STATUS.

When the USART transmitter is enabled and there is no data in the transmit shift register or transmit buffer, the TXC flag in USARTn\_STATUS and the TXC interrupt flag in USARTn\_IF are set, signaling that the transmission is complete. The TXC status flag is cleared when a new frame becomes available for transmission, but the TXC interrupt flag must be cleared by software.

### 16.3.2.6 Transmit Buffer Operation

The transmit-buffer is a multiple entry FIFO buffer. A frame can be loaded into the buffer by writing to USARTn\_TXDATA, USARTn\_TXDATAx, USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX. Using USARTn\_TXDATA allows 8 bits to be written to the buffer, while using USARTn\_TXDOUBLE will write 2 frames of 8 bits to the buffer. If 9-bit frames are used, the 9th bit of the frames will in these cases be set to the value of BIT8DV in USARTn\_CTRL.

To set the 9th bit directly and/or use transmission control, USARTn\_TXDATAx and USARTn\_TXDOUBLEX must be used. USARTn\_TXDATAx allows 9 data bits to be written, as well as a set of control bits regarding the transmission of the written frame. Every frame in the buffer is stored with 9 data bits and additional transmission control bits. USARTn\_TXDOUBLEX allows two frames, complete with control bits to be written at once. When data is written to the transmit buffer using USARTn\_TXDATAx and USARTn\_TXDOUBLEX, the 9th bit(s) written to these registers override the value in BIT8DV in USARTn\_CTRL, and alone define the 9th bits that are transmitted if 9-bit frames are used. [Figure 16.5 USART Transmit Buffer Operation on page 466](#) shows the basics of the transmit buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits.

**Figure 16.5. USART Transmit Buffer Operation**

When writing more frames to the transmit buffer than there is free space for, the TXOF interrupt flag in USARTn\_IF will be set, indicating the overflow. The data already in the transmit buffer is preserved in this case, and no data is written.

In addition to the interrupt flag TXC in USARTn\_IF and status flag TXC in USARTn\_STATUS which are set when the transmission is complete, TXBL in USARTn\_STATUS and the TXBL interrupt flag in USARTn\_IF are used to indicate the level of the transmit buffer. TXBIL in USARTn\_CTRL controls the level at which these bits are set. If TXBIL is cleared, they are set whenever the transmit buffer becomes empty, and if TXBIL is set, they are set whenever the transmit buffer goes from full to half-full or empty. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when their condition becomes false.

There is a TXIDLE status bit in USARTn\_STATUS to provide an indication of when the transmitter is idle. The combined count of TX buffer element 0, TX buffer element 1, and TX shift register is called TXBUFCNT in USARTn\_STATUS. For large frames, the count is only of TX buffer entry 0 and the TX shifter register.

The transmit buffer, including the transmit shift register can be cleared by setting CLEARTX in USARTn\_CMD. This will prevent the USART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed.

### 16.3.2.7 Frame Transmission Control

The transmission control bits, which can be written using USARTn\_TXDATAx and USARTn\_TXDOUBLEX, affect the transmission of the written frame. The following options are available:

- **Generate break:** By setting TXBREAK, the output will be held low during the stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than a USART frame are thus not supported by the USART. GPIO can be used for this.
- **Disable transmitter after transmission:** If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- **Enable receiver after transmission:** If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.
- **Unblock receiver after transmission:** If UBRXAT is set, the receiver is unblocked and RXBLOCK is cleared after the frame has been fully transmitted.
- **Tristate transmitter after transmission:** If TXTRIAT is set, TXTRI is set after the frame has been fully transmitted, tristating the transmitter output. Tristating of the output can also be performed automatically by setting AUTOTRI. If AUTOTRI is set TXTRI is always read as 0.

**Note:** When in SmartCard mode with repeat enabled, none of the actions, except generate break, will be performed until the frame is transmitted without failure. Generation of a break in SmartCard mode with repeat enabled will cause the USART to detect a NACK on every frame.

### 16.3.2.8 Data Reception

Data reception is enabled by setting RXEN in USARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start baud of a new frame. When a start baud is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start baud. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available. If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the shift register is overwritten, and the RXOF interrupt flag in USARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in USARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in USARTn\_STATUS.

### 16.3.2.9 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in USARTn\_STATUS, and the RXDATAV interrupt flag in USARTn\_IF are set, and when the buffer becomes full, RXFULL in USARTn\_STATUS and the RXFULL interrupt flag in USARTn\_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more frame.

Data can be read from the receive buffer in a number of ways. USARTn\_RXDATA gives access to the 8 least significant bits of the received frame, and USARTn\_RXDOUBLE makes it possible to read the 8 least significant bits of two frames at once, pulling two frames from the buffer. To get access to the 9th, most significant bit, USARTn\_RXDATA\_X must be used. This register also contains status information regarding the frame. USARTn\_RXDOUBLE\_X can be used to get two frames complete with the 9th bits and status bits.

When a frame is read from the receive buffer using USARTn\_RXDATA or USARTn\_RXDATA\_X, the frame is pulled out of the buffer, making room for a new frame. USARTn\_RXDOUBLE and USARTn\_RXDOUBLE\_X pull two frames out of the buffer. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in USARTn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can be read from the receive buffer without removing the data by using USARTn\_RXDATA\_XP and USARTn\_RXDOUBLE\_XP. USARTn\_RXDATA\_XP gives access the first frame in the buffer with status bits, while USARTn\_RXDOUBLE\_XP gives access to both frames with status bits. The data read from these registers when the receive buffer is empty is undefined. If the receive buffer contains one valid frame, the first frame in USARTn\_RXDOUBLE\_XP will be valid. No underflow interrupt is generated by a read using these registers, i.e. RXUF in USARTn\_IF is never set as a result of reading from USARTn\_RXDATA\_XP or USARTn\_RXDOUBLE\_XP.

The basic operation of the receive buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits is shown in [Figure 16.6 USART Receive Buffer Operation on page 468](#).

**Figure 16.6. USART Receive Buffer Operation**

The receive buffer, including the receive shift register can be cleared by setting CLEARRX in USARTn\_CMD. Any frame currently being received will not be discarded.

### 16.3.2.10 Blocking Incoming Data

When using hardware frame recognition, as detailed in [16.3.2.20 Multi-Processor Mode](#) and [16.3.2.21 Collision Detection](#), it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in USARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV flag in USARTn\_STATUS or the RXDATAV interrupt flag in USARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in USARTn\_CMD and disabled by setting RXBLOCKDIS also in USARTn\_CMD. There is one exception where data is loaded into the receive buffer even when RXBLOCK is set. This is when an address frame is received when operating in multi-processor mode. See [16.3.2.20 Multi-Processor Mode](#) for more information.

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in USARTn\_IF being set while RXBLOCK in USARTn\_STATUS is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

**Note:**

- If a frame is received while RXBLOCK in USARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.
- The overflow interrupt flag RXOF in USARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK in USARTn\_STATUS is set.

### 16.3.2.11 Clock Recovery and Filtering

The receiver samples the incoming signal at a rate 16, 8, 6 or 4 times higher than the given baud rate, depending on the oversampling mode given by OVS in USARTn\_CTRL. Lower oversampling rates make higher baud rates possible, but give less room for errors.

When a high-to-low transition is registered on the input while the receiver is idle, this is recognized as a start-bit, and the baud rate generator is synchronized with the incoming frame.

For oversampling modes 16, 8 and 6, every bit in the incoming frame is sampled three times to gain a level of noise immunity. These samples are aimed at the middle of the bit-periods, as visualized in [Figure 16.7 USART Sampling of Start and Data Bits on page 470](#). With OVS=0 in USARTn\_CTRL, the start and data bits are thus sampled at locations 8, 9 and 10 in the figure, locations 4, 5 and 6 for OVS=1 and locations 3, 4, and 5 for OVS=2. The value of a sampled bit is determined by majority vote. If two or more of the three bit-samples are high, the resulting bit value is high. If the majority is low, the resulting bit value is low.

Majority vote is used for all oversampling modes except 4x oversampling. In this mode, a single sample is taken at position 3 as shown in [Figure 16.7 USART Sampling of Start and Data Bits on page 470](#).

Majority vote can be disabled by setting MVDIS in USARTn\_CTRL.

If the value of the start bit is found to be high, the reception of the frame is aborted, filtering out false start bits possibly generated by noise on the input.

**Figure 16.7. USART Sampling of Start and Data Bits**

If the baud rate of the transmitter and receiver differ, the location each bit is sampled will be shifted towards the previous or next bit in the frame. This is acceptable for small errors in the baud rate, but for larger errors, it will result in transmission errors.

When the number of stop bits is 1 or more, stop bits are sampled like the start and data bits as seen in [Figure 16.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 471](#). When a stop bit has been detected by sampling at positions 8, 9 and 10 for normal mode, or 4, 5 and 6 for smart mode, the USART is ready for a new start bit. As seen in [Figure 16.8 USART Sampling of Stop Bits when Number of Stop Bits are 1 or More on page 471](#), a stop-bit of length 1 normally ends at c, but the next frame will be received correctly as long as the start-bit comes after position a for OVS=0 and OVS=3, and b for OVS=1 and OVS=2.

**Figure 16.8. USART Sampling of Stop Bits when Number of Stop Bits are 1 or More**

When working with stop bit lengths of half a baud period, the above sampling scheme no longer suffices. In this case, the stop-bit is not sampled, and no framing error is generated in the receiver if the stop-bit is not generated. The line must still be driven high before the next start bit however for the USART to successfully identify the start bit.

#### 16.3.2.12 Parity Error

When parity bits are enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in an incoming frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR in USARTn\_IF. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATA, USARTn\_RXDATAEXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on received parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

#### 16.3.2.13 Framing Error and Break Detection

A framing error is the result of an asynchronous frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected in an incoming frame, the framing error bit FERR in the frame is set. The interrupt flag FERR in USARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATA, USARTn\_RXDATAEXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

### 16.3.2.14 Local Loopback

The USART receiver samples U(S)n\_RX by default, and the transmitter drives U(S)n\_TX by default. This is not the only option however. When LOOPBK in USARTn\_CTRL is set, the receiver is connected to the U(S)n\_TX pin as shown in [Figure 16.9 USART Local Loopback on page 472](#). This is useful for debugging, as the USART can receive the data it transmits, but it is also used to allow the USART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the U(S)n\_TX pin must be enabled as an output in the GPIO.

Figure 16.9. USART Local Loopback

### 16.3.2.15 Asynchronous Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

### 16.3.2.16 Single Data-link

In this setup, the USART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in USARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the USART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. This is done by setting the command bit TXTRIEN in USARTn\_CMD, which tristates the transmitter. Before transmitting data, the command bit TXTRIDIS, also in USARTn\_CMD, must be set to enable transmitter output again. Whether or not the output is tristated at a given time can be read from TXTRI in USARTn\_STATUS. If TXTRI is set when transmitting data, the data is shifted out of the shift register, but is not put out on U(S)n\_TX.

When operating a half duplex data bus, it is common to have a bus master, which first transmits a request to one of the bus slaves, then receives a reply. In this case, the frame transmission control bits, which can be set by writing to USARTn\_TXDATAx, can be used to make the USART automatically disable transmission, tristate the transmitter and enable reception when the request has been transmitted, making it ready to receive a response from the slave.

The timer, [16.3.10 Timer](#), can also be used to add delay between the RX and TX frames so that the interrupt service routine has time to process data that was just received before transmitting more data. Also hardware flow control is another method to insert time for processing the frame. RTS and CTS can be used to halt either the link partner's transmitter or the local transmitter. See the section on hardware flow control, [16.3.4 Hardware Flow Control](#), for more details.

Tristating the transmitter can also be performed automatically by the USART by using AUTOTRI in USARTn\_CTRL. When AUTOTRI is set, the USART automatically tristates U(S)n\_TX whenever the transmitter is idle, and enables transmitter output when the transmitter goes active. If AUTOTRI is set TXTRI is always read as 0.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

### 16.3.2.17 Single Data-link With External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of tristating the transmitter when receiving data, the external driver must be disabled.

This can be done manually by assigning a GPIO to turn the driver on or off, or it can be handled automatically by the USART. If AUTOCS in USARTn\_CTRL is set, the USn\_CS output is automatically activated a configurable number of baud periods before the transmitter starts transmitting data, and deactivated a configurable number of baud periods after the last bit has been transmitted and there is no more data in the transmit buffer to transmit. The number of baud periods are controlled by CSSETUP and CSHOLD in USARTn\_TIMING. This feature can be used to turn the external driver on when transmitting data, and turn it off when the data has been transmitted.

The timer, [16.3.10 Timer](#), can also be used to configure CSSETUP and CSHOLD values between 1 to 256 baud-times by using TCMPVAL0, TCMPVAL1, or TCMPVAL2 for the TX sequencer.

USn\_CS is immediately deasserted when the transmitter becomes disabled.

[Figure 16.10 USART Half Duplex Communication with External Driver on page 473](#) shows an example configuration where USn\_CS is used to automatically enable and disable an external driver.

**Figure 16.10. USART Half Duplex Communication with External Driver**

The USn\_CS output is active low by default, but its polarity can be changed with CSINV in USARTn\_CTRL. AUTOCS works regardless of which mode the USART is in, so this functionality can also be used for automatic chip/slave select when in synchronous mode (e.g. SPI).

### 16.3.2.18 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

TXARXnEN in USARTn\_TRIGCTRL may be used to automatically start transmission after the end of the RX frame plus any TXSTDE-LAY and CSSETUP delay in USARTn\_TIMING. For enabling the receiver either use RXENAT in USARTn\_TXDATA or RXATXnEN in USARTn\_TRIGCTRL.

### 16.3.2.19 Large Frames

As each frame in the transmit and receive buffers holds a maximum of 9 bits, both the elements in the buffers are combined when working with USART-frames of 10 or more data bits.

To transmit such a frame, at least two elements must be available in the transmit buffer. If only one element is available, the USART will wait for the second element before transmitting the combined frame. Both the elements making up the frame are consumed when transmitting such a frame.

When using large frames, the 9th bits in the buffers are unused. For an 11 bit frame, the 8 least significant bits are thus taken from the first element in the buffer, and the 3 remaining bits are taken from the second element as shown in [Figure 16.11 USART Transmission of Large Frames on page 474](#). The first element in the transmit buffer, i.e. element 0 in [Figure 16.11 USART Transmission of Large Frames on page 474](#) is the first element written to the FIFO, or the least significant byte when writing two bytes at a time using USARTn\_TXDOUBLE.

**Figure 16.11. USART Transmission of Large Frames**

As shown in [Figure 16.11 USART Transmission of Large Frames on page 474](#), frame transmission control bits are taken from the second element in FIFO.

The two buffer elements can be written at the same time using the USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX register. The TXDATAx0 bitfield then refers to buffer element 0, and TXDATAx1 refers to buffer element 1.

**Figure 16.12. USART Transmission of Large Frames, MSBF**

[Figure 16.12 USART Transmission of Large Frames, MSBF on page 474](#) illustrates the order of the transmitted bits when an 11 bit frame is transmitted with MSBF set. If MSBF is set and the frame is smaller than 10 bits, only the contents of transmit buffer 0 will be transmitted.

When receiving a large frame, `BYTESWAP` in `USARTn_CTRL` determines the order the way the large frame is split into the two buffer elements. If `BYTESWAP` is cleared, the least significant 8 bits of the received frame are loaded into the first element of the receive buffer, and the remaining bits are loaded into the second element, as shown in [Figure 16.13 USART Reception of Large Frames on page 475](#). The first byte read from the buffer thus contains the 8 least significant bits. Set `BYTESWAP` to reverse the order.

The status bits are loaded into both elements of the receive buffer. The frame is not moved from the receive shift register before there are two free spaces in the receive buffer.

**Figure 16.13. USART Reception of Large Frames**

The two buffer elements can be read at the same time using the `USARTn_RXDOUBLE` or `USARTn_RXDOUBLEX` register. `RXDATA0` then refers to buffer element 0 and `RXDATA1` refers to buffer element 1.

Large frames can be used in both asynchronous and synchronous modes.

### 16.3.2.20 Multi-Processor Mode

To simplify communication between multiple processors, the USART supports a special multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of `MPAB` in `USARTn_CTRL` is identified as an address frame. When an address frame is detected, the `MPAF` interrupt flag in `USARTn_IF` is set, and the address frame is loaded into the receive register. This happens regardless of the value of `RXBLOCK` in `USARTn_STATUS`.

Multi-processor mode is enabled by setting `MPM` in `USARTn_CTRL`, and the value of the 9th bit in address frames can be set in `MPAB`. Note that the receiver must be enabled for address frames to be detected. The receiver can be blocked however, preventing data from being loaded into the receive buffer while looking for address frames.

Basic usage of the multi-processor mode is as follows:

1. All slaves enable multi-processor mode and, enable and block the receiver. They will now not receive data unless it is an address frame. `MPAB` in `USARTn_CTRL` is set to identify frames with the 9th bit high as address frames.
2. The master sends a frame containing the address of a slave and with the 9th bit set
3. All slaves receive the address frame and get an interrupt. They can read the address from the receive buffer. The selected slave unblocks the receiver to start receiving data from the master.
4. The master sends data with the 9th bit cleared
5. Only the slave with `RX` enabled receives the data. When transmission is complete, the slave blocks the receiver and waits for a new address frame.

When a slave has received an address frame and wants to receive the following data, it must make sure the receiver is unblocked before the next frame has been completely received in order to prevent data loss.

`BIT8DV` in `USARTn_CTRL` can be used to specify the value of the 9th bit without writing to the transmit buffer with `USARTn_TXDATAx` or `USARTn_TXDOUBLEX`, giving higher efficiency in multi-processor mode, as the 9th bit is only set when writing address frames, and 8-bit writes to the USART can be used when writing the data frames.

### 16.3.2.21 Collision Detection

The USART supports a basic form of collision detection. When the receiver is connected to the output of the transmitter, either by using the LOOPBK bit in USARTn\_CTRL or through an external connection, this feature can be used to detect whether data transmitted on the bus by the USART did get corrupted by a simultaneous transmission by another device on the bus.

For collision detection to be enabled, CCEN in USARTn\_CTRL must be set, and the receiver enabled. The data sampled by the receiver is then continuously compared with the data output by the transmitter. If they differ, the CCF interrupt flag in USARTn\_IF is set. The collision check includes all bits of the transmitted frames. The CCF interrupt flag is set once for each bit sampled by the receiver that differs from the bit output by the transmitter. When the transmitter output is disabled, i.e. the transmitter is tristated, collisions are not registered.

### 16.3.2.22 SmartCard Mode

In SmartCard mode, the USART supports the ISO 7816 I/O line T0 mode. With exception of the stop-bits (guard time), the 7816 data frame is equal to the regular asynchronous frame. In this mode, the receiver pulls the line low for one baud, half a baud into the guard time to indicate a parity error. This NAK can for instance be used by the transmitter to re-transmit the frame. SmartCard mode is a half duplex asynchronous mode, so the transmitter must be tristated whenever not transmitting data.

To enable SmartCard mode, set SCMODE in USARTn\_CTRL, set the number of databits in a frame to 8, and configure the number of stopbits to 1.5 by writing to STOPBITS in USARTn\_FRAME.

The SmartCard mode relies on half duplex communication on a single line, so for it to work, both the receiver and transmitter must work on the same line. This can be achieved by setting LOOPBK in USARTn\_CTRL or through an external connection. The TX output should be configured as open-drain in the GPIO module.

When no parity error is identified by the receiver, the data frame is as shown in [Figure 16.14 USART ISO 7816 Data Frame Without Error on page 477](#). The frame consists of 8 data bits, a parity bit, and 2 stop bits. The transmitter does not drive the output line during the guard time.

**Figure 16.14. USART ISO 7816 Data Frame Without Error**

If a parity error is detected by the receiver, it pulls the line I/O line low after half a stop bit, see [Figure 16.15 USART ISO 7816 Data Frame With Error on page 477](#). It holds the line low for one bit-period before it releases the line. In this case, the guard time is extended by one bit period before a new transmission can start, resulting in a total of 3 stop bits.

**Figure 16.15. USART ISO 7816 Data Frame With Error**

On a parity error, the NAK is generated by hardware. The NAK generated by the receiver is sampled as the stop-bit of the frame. Because of this, parity errors when in SmartCard mode are reported with both a parity error and a framing error.

When transmitting a T0 frame, the USART receiver on the transmitting side samples position 16, 17 and 18 in the stop-bit to detect the error signal when in 16x oversampling mode as shown in [Figure 16.16 USART SmartCard Stop Bit Sampling on page 478](#). Sampling at this location places the stop-bit sample in the middle of the bit-period used for the error signal (NAK).

If a NAK is transmitted by the receiver, it will thus appear as a framing error at the transmitter, and the FERR interrupt flag in USARTn\_IF will be set. If SCRETRANS USARTn\_CTRL is set, the transmitter will automatically retransmit a NACK'ed frame. The transmitter will retransmit the frame until it is ACK'ed by the receiver. This only works when the number of databits in a frame is configured to 8.

Set SKIPERRF in USARTn\_CTRL to make the receiver discard frames with parity errors. The PERR interrupt flag in USARTn\_IF is set when a frame is discarded because of a parity error.

**Figure 16.16. USART SmartCard Stop Bit Sampling**

For communication with a SmartCard, a clock signal needs to be generated for the card. This clock output can be generated using one of the timers. See the ISO 7816 specification for more info on this clock signal.

SmartCard T1 mode is also supported. The T1 frame format used is the same as the asynchronous frame format with parity bit enabled and one stop bit. The USART must then be configured to operate in asynchronous half duplex mode.

### 16.3.3 Synchronous Operation

Most of the features in asynchronous mode are available in synchronous mode. Multi-processor mode can be enabled for 9-bit frames, loopback is available and collision detection can be performed.

#### 16.3.3.1 Frame Format

The frames used in synchronous mode need no start and stop bits since a single clock is available to all parts participating in the communication. Parity bits cannot be used in synchronous mode.

The USART supports frame lengths of 4 to 16 bits per frame. Larger frames can be simulated by transmitting multiple smaller frames, i.e. a 22 bit frame can be sent using two 11-bit frames, and a 21 bit frame can be generated by transmitting three 7-bit frames. The number of bits in a frame is set using DATABITS in USARTn\_FRAME.

The frames in synchronous mode are by default transmitted with the least significant bit first like in asynchronous mode. The bit-order can be reversed by setting MSBF in USARTn\_CTRL.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV, also in USARTn\_CTRL.

### 16.3.3.2 Clock Generation

The bit-rate in synchronous mode is given by [Figure 16.17 USART Synchronous Mode Bit Rate on page 479](#). As in the case of asynchronous operation, the clock division factor have a 15-bit integral part and a 5-bit fractional part.

$$br = f_{HPERCLK} / (2 \times (1 + USARTn\_CLKDIV/256))$$

**Figure 16.17. USART Synchronous Mode Bit Rate**

Given a desired baud rate  $br_{desired}$ , the clock divider  $USARTn\_CLKDIV$  can be calculated using [Figure 16.18 USART Synchronous Mode Clock Division Factor on page 479](#)

$$USARTn\_CLKDIV = 256 \times (f_{HPERCLK} / (2 \times br_{desired}) - 1)$$

**Figure 16.18. USART Synchronous Mode Clock Division Factor**

When the USART operates in master mode, the highest possible bit rate is half the peripheral clock rate. When operating in slave mode however, the highest bit rate is an eighth of the peripheral clock:

- Master mode:  $br_{max} = f_{HPERCLK}/2$
- Slave mode:  $br_{max} = f_{HPERCLK}/8$

On every clock edge data on the data lines, MOSI and MISO, is either set up or sampled. When  $CLKPHA$  in  $USARTn\_CTRL$  is cleared, data is sampled on the leading clock edge and set-up is done on the trailing edge. If  $CLKPHA$  is set however, data is set-up on the leading clock edge, and sampled on the trailing edge. In addition to this, the polarity of the clock signal can be changed by setting  $CLKPOL$  in  $USARTn\_CTRL$ , which also defines the idle state of the clock. This results in four different modes which are summarized in [Table 16.8 USART SPI Modes on page 479](#). [Figure 16.19 USART SPI Timing on page 479](#) shows the resulting timing of data set-up and sampling relative to the bus clock.

**Table 16.8. USART SPI Modes**

| SPI mode | CLKPOL | CLKPHA | Leading Edge    | Trailing Edge   |
|----------|--------|--------|-----------------|-----------------|
| 0        | 0      | 0      | Rising, sample  | Falling, set-up |
| 1        | 0      | 1      | Rising, set-up  | Falling, sample |
| 2        | 1      | 0      | Falling, sample | Rising, set-up  |
| 3        | 1      | 1      | Falling, set-up | Rising, sample  |

**Figure 16.19. USART SPI Timing**

If  $CPHA=1$ , the TX underflow flag,  $TXUF$ , will be set on the first setup clock edge of a frame in slave mode if TX data is not available. If  $CPHA=0$ ,  $TXUF$  is set if data is not available in the transmit buffer three  $HPERCLK$  cycles prior to the first sample clock edge. The

RXDATAV flag is updated on the last sample clock edge of a transfer, while the RX overflow interrupt flag, RXOF, is set on the first sample clock edge if the receive buffer overflows. When a transfer has been performed, interrupt flags TXBL and TXC are updated on the first setup clock edge of the succeeding frame, or when CS is deasserted.

### 16.3.3.3 Master Mode

When in master mode, the USART is in full control of the data flow on the synchronous bus. When operating in full duplex mode, the slave cannot transmit data to the master without the master transmitting to the slave. The master outputs the bus clock on USn\_CLK.

Communication starts whenever there is data in the transmit buffer and the transmitter is enabled. The USART clock then starts, and the master shifts bits out from the transmit shift register using the internal clock.

When there are no more frames in the transmit buffer and the transmit shift register is empty, the clock stops, and communication ends. When the receiver is enabled, it samples data using the internal clock when the transmitter transmits data. Operation of the RX and TX buffers is as in asynchronous mode.

### 16.3.3.4 Operation of USn\_CS Pin

When operating in master mode, the USn\_CS pin can have one of two functions, or it can be disabled.

If USn\_CS is configured as an output, it can be used to automatically generate a chip select for a slave by setting AUTOCS in USARTn\_CTRL. If AUTOCS is set, USn\_CS is activated before a transmission begins, and deactivated after the last bit has been transmitted and there is no more data in the transmit buffer.

The time between when CS is asserted and the first bit is transmitted can be controlled using the USART Timer and with CSSETUP in USARTn\_TIMING. Any of the three comparators can be used to set this delay. If new data is ready for transmission before CS is deasserted, the data is sent without deasserting CS in between. CSHOLD in USARTn\_TIMING keeps CS asserted after the end of frame for the number of baud-times specified.

By default, USn\_CS is active low, but its polarity can be inverted by setting CSINV in USARTn\_CTRL.

When USn\_CS is configured as an input, it can be used by another master that wants control of the bus to make the USART release it. When USn\_CS is driven low, or high if CSINV is set, the interrupt flag SSM in USARTn\_IF is set, and if CSMA in USARTn\_CTRL is set, the USART goes to slave mode.

### 16.3.3.5 AUTOTX

A synchronous master is required to transmit data to a slave in order to receive data from the slave. In some cases, only a few words are transmitted and a lot of data is then received from the slave. In that case, one solution is to keep feeding the TX with data to transmit, but that consumes system bandwidth. Instead AUTOTX can be used.

When AUTOTX in USARTn\_CTRL is set, the USART transmits data as long as there is available space in the RX shift register for the chosen frame size. This happens even though there is no data in the TX buffer. The TX underflow interrupt flag TXUF in USARTn\_IF is set on the first word that is transmitted which does not contain valid data.

During AUTOTX the USART will always send the previous sent bit, thus reducing the number of transitions on the TX output. So if the last bit sent was a 0, 0's will be sent during AUTOTX and if the last bit sent was a 1, 1's will be sent during AUTOTX.

### 16.3.3.6 Slave Mode

When the USART is in slave mode, data transmission is not controlled by the USART, but by an external master. The USART is therefore not able to initiate a transmission, and has no control over the number of bytes written to the master.

The output and input to the USART are also swapped when in slave mode, making the receiver take its input from USn\_TX (MOSI) and the transmitter drive USn\_RX (MISO).

To transmit data when in slave mode, the slave must load data into the transmit buffer and enable the transmitter. The data will remain in the USART until the master starts a transmission by pulling the USn\_CS input of the slave low and transmitting data. For every frame the master transmits to the slave, a frame is transferred from the slave to the master. After a transmission, MISO remains in the same state as the last bit transmitted. This also applies if the master transmits to the slave and the slave TX buffer is empty.

If the transmitter is enabled in synchronous slave mode and the master starts transmission of a frame, the underflow interrupt flag TXUF in USARTn\_IF will be set if no data is available for transmission to the master.

If the slave needs to control its own chip select signal, this can be achieved by clearing CSPEN in the ROUTE register. The internal chip select signal can then be controlled through CSINV in the CTRL register. The chip select signal will be CSINV inverted, i.e. if CSINV is cleared, the chip select is active and vice versa.

### 16.3.3.7 Synchronous Half Duplex Communication

Half duplex communication in synchronous mode is very similar to half duplex communication in asynchronous mode as detailed in [16.3.2.15 Asynchronous Half Duplex Communication](#). The main difference is that in this mode, the master must generate the bus clock even when it is not transmitting data, i.e. it must provide the slave with a clock to receive data. To generate the bus clock, the master should transmit data with the transmitter tristated, i.e. TXTR1 in USARTn\_STATUS set, when receiving data. If 2 bytes are expected from the slave, then transmit 2 bytes with the transmitter tristated, and the slave uses the generated bus clock to transmit data to the master. TXTR1 can be set by setting the TXTRIEN command bit in USARTn\_CMD.

**Note:** When operating as SPI slave in half duplex mode, TX has to be tristated (not disabled) during data reception if the slave is to transmit data in the current transfer.

### 16.3.3.8 I2S

I2S is a synchronous format for transmission of audio data. The frame format is 32-bit, but since data is always transmitted with MSB first, an I2S device operating with 16-bit audio may choose to only process the 16 msb of the frame, and only transmit data in the 16 msb of the frame.

In addition to the bit clock used for regular synchronous transfers, I2S mode uses a separate word clock. When operating in mono mode, with only one channel of data, the word clock pulses once at the start of each new word. In stereo mode, the word clock toggles at the start of new words, and also gives away whether the transmitted word is for the left or right audio channel; A word transmitted while the word clock is low is for the left channel, and a word transmitted while the word clock is high is for the right.

When operating in I2S mode, the CS pin is used as a the word clock. In master mode, this is automatically driven by the USART, and in slave mode, the word clock is expected from an external master.

### 16.3.3.9 Word Format

The general I2S word format is 32 bits wide, but the USART also supports 16-bit and 8-bit words. In addition to this, it can be specified how many bits of the word should actually be used by the USART. These parameters are given by FORMAT in USARTn\_I2SCTRL.

As an example, configuring FORMAT to using a 32-bit word with 16-bit data will make each word on the I2S bus 32-bits wide, but when receiving data through the USART, only the 16 most significant bits of each word can be read out of the USART. Similarly, only the 16 most significant bits have to be written to the USART when transmitting. The rest of the bits will be transmitted as zeroes.

### 16.3.3.10 Major Modes

The USART supports a set of different I2S formats as shown in [Table 16.9 USART I2S Modes on page 482](#), but it is not limited to these modes. MONO, JUSTIFY and DELAY in USARTn\_I2SCTRL can be mixed and matched to create an appropriate format. MONO enables mono mode, i.e. one data stream instead of two which is the default. JUSTIFY aligns data within a word on the I2S bus, either left or right which can be seen in figures [Figure 16.22 USART Left-Justified I2S Waveform on page 483](#) and [Figure 16.23 USART Right-Justified I2S Waveform on page 483](#). Finally, DELAY specifies whether a new I2S word should be started directly on the edge of the word-select signal, or one bit-period after the edge.

**Table 16.9. USART I2S Modes**

| Mode            | MONO | JUSTIFY | DELAY | CLKPOL |
|-----------------|------|---------|-------|--------|
| Regular I2S     | 0    | 0       | 1     | 0      |
| Left-Justified  | 0    | 0       | 0     | 1      |
| Right-Justified | 0    | 1       | 0     | 1      |
| Mono            | 1    | 0       | 0     | 0      |

The regular I2S waveform is shown in [Figure 16.20 USART Standard I2S Waveform on page 482](#) and [Figure 16.21 USART Standard I2S Waveform \(Reduced Accuracy\) on page 482](#). The first figure shows a waveform transmitted with full accuracy. The wordlength can be configured to 32-bit, 16-bit or 8-bit using FORMAT in USARTn\_I2SCTRL. In the second figure, I2S data is transmitted with reduced accuracy, i.e. the data transmitted has less bits than what is possible in the bus format.

Note that the msb of a word transmitted in regular I2S mode is delayed by one cycle with respect to word select

**Figure 16.20. USART Standard I2S Waveform**

**Figure 16.21. USART Standard I2S Waveform (Reduced Accuracy)**

A left-justified stream is shown in [Figure 16.22 USART Left-Justified I2S Waveform on page 483](#). Note that the MSB comes directly after the edge on the word-select signal in contradiction to the regular I2S waveform where it comes one bit-period after.

**Figure 16.22. USART Left-Justified I2S Waveform**

A right-justified stream is shown in [Figure 16.23 USART Right-Justified I2S Waveform on page 483](#). The left and right justified streams are equal when the data-size is equal to the word-width.

**Figure 16.23. USART Right-Justified I2S Waveform**

In mono-mode, the word-select signal pulses at the beginning of each word instead of toggling for each word. Mono I2S waveform is shown in [Figure 16.24 USART Mono I2S Waveform on page 483](#).

**Figure 16.24. USART Mono I2S Waveform**

### 16.3.3.11 Using I2S Mode

When using the USART in I2S mode, `DATABITS` in `USARTn_FRAME` must be set to 8 or 16 data-bits. 8 databits can be used in all modes, and 16 can be used in the modes where the number of bytes in the I2S word is even. In addition to this, `MSBF` in `USARTn_CTRL` should be set, and `CLKPOL` and `CLKPHA` in `USARTn_CTRL` should be cleared.

The USART does not have separate TX and RX buffers for left and right data, so when using I2S in stereo mode, the application must keep track of whether the buffers contain left or right data. This can be done by observing `TXBLRIGHT`, `RXDATAVRIGHT` and `RXFULLRIGHT` in `USARTn_STATUS`. `TXBLRIGHT` tells whether TX is expecting data for the left or right channel. It will be set with `TXBL` if right data is expected. The receiver will set `RXDATAVRIGHT` if there is at least one right element in the buffer, and `RXFULLRIGHT` if the buffer is full of right elements.

When using I2S with DMA, separate DMA requests can be used for left and right data by setting `DMASPLIT` in `USARTn_I2SCTRL`.

In both master and slave mode the USART always starts transmitting on the LEFT channel after being enabled. In master mode, the transmission will stop if TX becomes empty. In that case, `TXC` is set. Continuing the transmission in this case will make the data-stream continue where it left off. To make the USART start on the LEFT channel after going empty, disable and re-enable TX.

### 16.3.4 Hardware Flow Control

Hardware flow control can be used to hold off the link partner's transmission until RX buffer space is available. Use `RTSPEN` and `CTSPEN` in `USARTn_ROUTEEN` to allocate the hardware flow control to GPIOs. `RTS` is an out going signal which indicates that RX buffer space is available to receive a frame. The link partner is being requested to send its data when `RTS` is asserted. `CTS` is an incoming signal to stop the next TX data from going out. When `CTS` is negated, the frame currently being transmitted is completed before stopping. `CTS` indicates that the link partner has RX buffer space available, and the local transmitter is clear to send. Also use `CTSEN` in `USARTn_CTRLX` to enable the `CTS` input into the TX sequencer. For debug use set `DBGHALT` in `USARTn_CTRLX` which will force the `RTS` to request one frame from the link partner when the CPU core single steps.

### 16.3.5 Debug Halt

When `DBGHALT` in `USARTn_CTRLX` is clear, `RTS` is only dependent on the RX buffer having space available to receive data. Incoming data is always received until both the RX buffer is full and the RX shift register is full regardless of the state of `DBGHALT` or chip halt. Additional incoming data is discarded. When `DBGHALT` is set, `RTS` deasserts on RX buffer full or when chip halt is high. However, a low pulse detected on chip halt will keep `RTS` asserted when no frame is being received. At the start of frame reception, `RTS` will deassert if chip halt is high and `DBGHALT` is set. This behavior allows single stepping to pulse the chip halt low for a cycle, and receive the next frame. The link partner must stop transmitting when `RTS` is deasserted, or the RX buffer could overflow. All data in the transmit buffer is sent out even when chip halt is asserted; therefore, the DMA will need to be set to stop sending the USART TX data during chip halt.

### 16.3.6 PRS-triggered Transmissions

If a transmission must be started on an event with very little delay, the PRS system can be used to trigger the transmission. The PRS channel to use as a trigger can be selected using `TSEL` in `USARTn_TRIGCTRL`. When a positive edge is detected on this signal, the receiver is enabled if `RXTEN` in `USARTn_TRIGCTRL` is set, and the transmitter is enabled if `TXTEN` in `USARTn_TRIGCTRL` is set. Only one signal input is supported by the USART.

The `AUTOTX` feature can also be enabled via PRS. If an external SPI device sets a pin high when there is data to be read from the device, this signal can be routed to the USART through the PRS system and be used to make the USART clock data out of the external device. If `AUTOTXTEN` in `USARTn_TRIGCTRL` is set, the USART will transmit data whenever the PRS signal selected by `TSEL` is high given that there is enough room in the RX buffer for the chosen frame size. Note that if there is no data in the TX buffer when using `AUTOTX`, the TX underflow interrupt will be set.

`AUTOTXTEN` can also be combined with `TXTEN` to make the USART transmit a command to the external device prior to clocking out data. To do this, disable TX using the `TXDIS` command, load the TX buffer with the command and enable `AUTOTXTEN` and `TXTEN`. When the selected PRS input goes high, the USART will now transmit the loaded command, and then continue clocking out while both the PRS input is high and there is room in the RX buffer.

### 16.3.7 PRS RX Input

The USART can be configured to receive data directly from a PRS channel by setting `RXPRES` in `USARTn_INPUT`. The PRS channel used is selected using `RXPRESSEL` in `USARTn_INPUT`. This way, for example, a differential RX signal can be input to the ACMP and the output routed via PRS to the USART.

### 16.3.8 PRS CLK Input

The USART can be configured to receive clock directly from a PRS channel by setting CLKPRS in USARTn\_INPUT. The PRS channel used is selected using CLKPRSEL in USARTn\_INPUT. This is useful in synchronous slave mode and can together with RX PRS input be used to input data from PRS.

### 16.3.9 DMA Support

The USART has full DMA support. The DMA controller can write to the transmit buffer using the registers USARTn\_TXDATA, USARTn\_TXDATAx, USARTn\_TXDOUBLE and USARTn\_TXDOUBLEX, and it can read from the receive buffer using the registers USARTn\_RXDATA, USARTn\_RXDATAx, USARTn\_RXDOUBLE and USARTn\_RXDOUBLEX. This enables single byte transfers, 9 bit data + control/status bits, double byte and double byte + control/status transfers both to and from the USART.

A request for the DMA controller to read from the USART receive buffer can come from the following source:

- Data available in the receive buffer
- Data available in the receive buffer and data is for the RIGHT I2S channel. Only used in I2S mode.

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- Transmit buffer has room for more data. This does not check the TXBIL for half full. For DMA use, it is either full or empty.
- Transmit buffer has room for RIGHT I2S data. Only used in I2S mode

Even though there are two sources for write requests to the DMA, only one should be used at a time, since the requests from both sources are cleared even though only one of the requests are used.

In some cases, it may be sensible to temporarily stop DMA access to the USART when an error such as a framing error has occurred. This is enabled by setting ERRSDMA in USARTn\_CTRL.

For Synchronous mode full duplex operation, if both receive buffer and transmit buffer are served by DMA, to make sure receive buffer is not overflowed the settings below should be followed.

- The DMA channel that serves receive buffer should have higher priority than the DMA channel that serves transmit buffer.
- TXBL should be used as write request for transmit buffer DMA channel.
- IGNORESREQ should be set for both DMA channel.

### 16.3.10 Timer

In addition to the TX sequence timer, there is a versatile 8 bit timer that can generate up to three event pulses. These pulses can be used to create timing for a variety of uses such as RX timeout, break detection, response timeout, and RX enable delay. Transmission delay, CS setup, inter-character spacing, and CS hold use the TX sequence counter. The TX sequencer counter can use the three 8 bit compare values or preset values for delays. There is one general counter with three comparators. Each comparator has a start source, a stop source, a restart enable, and a timer compare value. The start source enables the comparator, resets the counter, and starts the counter. If the counter is already running, the start source will reset the counter and restart it.

Any comparator could start the counter using the same start source but have different timing events programmed into TCMPVALn in USARTn\_TIMECMPn. The TCMP0, TCMP1, or TCMP2 events can be preempted by using the comparator stop source to disable the comparator before the counter reaches TCMPVAL0, TCMPVAL1, or TCMPVAL2. If one comparator gets disabled while the other comparator is still enabled, the counter continues counting. By default the counter will count up to 256 and stop unless a RESTARTEN is set in one of the USARTn\_TIMECMPn registers. By using RESTARTEN and an interval programmed into TCMPVAL, an interval timer can be set up. The TSTART field needs to be changed to DISABLE to stop the interval timer. The timer stops running once all of the comparators are disabled. If a comparator's start and stop sources both trigger the same cycle, the TCMPn event triggers, the comparator stays enabled, and the counter begins counting from zero.

The TXDELAY, CSSETUP, ICS, and CSHOLD in USARTn\_TIMING are used to program start of transmission delay, chip select setup delay, inter-character space, and chip select hold delay. Either a preset value of 0, 1, 2, 3, or 7 can be used for any of these delays; or the value in TCMPVALn may be used to set the delay. Using the preset values leaves the TCMPVALn free for other uses. The same TCMPVALn may be used for multiple events that require the same timing. The transmit sequencer's counter can run in parallel with the timer's counter. The counters and controls are shown in [Figure 16.25 USART Timer Block Diagram on page 487](#).

**Figure 16.25. USART Timer Block Diagram**

The following sections will go into more details on programming the various usage cases.

**Table 16.10. USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn**

| Application            | TSTARTn                | TSTOPn         | TCMPVALn        | Other                                                                                            |

Table 16.10 USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn on page 487 shows some examples of how the USART timer can be programmed for various applications. The following sections will describe more details for each applications shown in the table.

#### 16.3.10.1 Response Timeout

Response Timeout is when a UART master sends a frame and expects the slave to respond within a certain number of baud-times. Refer to Table 16.10 USART Application Settings for USARTn\_TIMING and USARTn\_TIMECMPn on page 487 for specific register settings. Comparator 0 will be looking for TX end of frame to use as the timer start source. For this example, a receiver start of frame RXACT has not been detected for 8 baud-times, and the TCMP0 interrupt in USARTn\_IF is set. If an RX start bit is detected before the 8 baud-times, comparator 0 is disabled before the TCMP0 event can trigger.

Figure 16.26. USART Response Timeout

### 16.3.10.2 RX Timeout

A receiver timeout function can be implemented by using the RX end of frame to start comparator 1 and look for the RX start bit RXACT to disable the comparator. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example. As long as the next RX start bit occurs before the counter reaches the comparator 1 value TCMPVAL1, the interrupt will not get set. In this example the RX Timeout was set to 8 baud-times. To get an RX timeout larger than 256 baud-times, RESTART1EN in USARTn\_TIMER can be used to restart the counter when it reaches TCMPVAL1. By setting TCMPVAL1 in USARTn\_TIMING to 0xFF, an interrupt will be generated after 256 baud-times. An interrupt service routine can then increment a memory location until the desired timeout is reached. Once the RX start bit is detected, comparator 1 will be disabled. If TIMERRESTARTED in USARTn\_STATUS is clear, the TCMP1 interrupt is the first interrupt after RXEOF.

Figure 16.27. USART RX Timeout

### 16.3.10.3 Break Detect

LIN bus and half-duplex UARTs can take advantage of the timer configured for break detection where RX is held low for a number of baud-times to indicate a break condition. [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) shows the settings for this mode. Each time RX is active (default of low) such as for a start bit, the timer begins counting. If the counter reaches 12 baud-times before RX goes to inactive RXACTN (default of high), an interrupt is asserted.

Figure 16.28. USART Break Detection

### 16.3.10.4 TX Start Delay

Some applications may require a delay before the start of transmission. This example in [Figure 16.29 USART TXSEQ Timing on page 490](#) shows the TXSEQ timer used to delay the start of transmission by 4 baud times before the start of CS, and by 2 baud times with CS asserted. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on how to configure this mode. The TX sequencer could be enabled on PRS and start the TXSEQ counter running for 4 baud times as programmed in TCMPVAL0. Then CS is asserted for 2 baud times before the transmitter begins sending TX data. TXDELAY in USARTn\_TIMING is the initial delay before any CS assertion, and CSSETUP is the delay during CS assertion. There are several small preset timing values such as 1, 2, 3, or 7 that can be used for some of the TX sequencer timing which leaves TCMPVAL0, TCMPVAL1, and TCMPVAL2 free for other uses.

Figure 16.29. USART TXSEQ Timing

### 16.3.10.5 Inter-Character Space

In addition to delaying the start of frame transmission, it is sometimes necessary to also delay the time between each transmit character (inter-character space). After the first transmission, the inter-character space will delay the start of all subsequent transmissions until the transmit buffer is empty. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example. For this example in [Figure 16.29 USART TXSEQ Timing on page 490](#) ICS is set to TCMP2 in USARTn\_TIMING. To keep CS asserted during the inter-character space, set AUTOCS in USARTn\_CTRL. There are a few small preset timing values provided for TX sequence timing. Using these preset timing values can free up the TCMPVALn for other uses. For this example, the inter-character space is set to 0x03 and a preset value could be used.

### 16.3.10.6 TX Chip Select End Delay

The assertion of CS can be extended after the final character of the frame by using CSHOLD in USARTn\_TIMING. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example. AUTOCS in USARTn\_CTRL needs to be set to extend the CS assertion after the last TX character is transmitted as shown in [Figure 16.29 USART TXSEQ Timing on page 490](#).

### 16.3.10.7 Response Delay

A response delay can be used to hold off the transmitter until a certain number of baud-times after the RX frame. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example. TXARX1EN in USARTn\_TRIGCTRL tells the TX sequencer to trigger after RX EOF plus cmp1val baud times.

Figure 16.30. USART Response Delay

### 16.3.10.8 Combined TX and RX Example

This example describes how to alternate between TX and RX frames. This has a 28 baud-time space after RX and a 16 baud-time space after TX. The TSTART1 in USARTn\_TIMECMP1 is set to RXEOF which uses the the receiver end of frame to start the timer. The TSTOP1 is set to TCMP1 to generate an event after 28 baud times. Set TXARX1EN in USARTn\_TRIGCTRL, and the transmitter is held off until 28 baud times. TCMPVAL in USARTn\_TIMECMP1 is set to 0x1C for 28 baud times. By setting TSTART0 in USARTn\_TIMECMP0 to TXEOF, the timer will be started after the transmission has completed. RXATX0EN in USARTn\_TRIGCTRL is used to delay enabling of the receiver until 16 baud times after the transmitter has completed. Write 0x10 into TCMPVAL of USARTn\_TIMECMP0 for a 16 baud time delay. CS is also asserted 7 baud-times before start of transmission by setting CSSETUP to 0x7 in USARTn\_TIMING. To keep CS asserted for 3 baud-times after transmission completes, CSHOLD is set to 0x3 in USARTn\_TIMING. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example.

### 16.3.10.9 Combined TX Delay and RX Break Detect

This example describes how to delay TX transmission after an RX frame and how to have a break condition signal an interrupt. See [Table 16.10 USART Application Settings for USARTn\\_TIMING and USARTn\\_TIMECMPn on page 487](#) for details on setting up this example. The TX delay is set up by using transmit after RX, TXARX0EN in USARTn\_TRIGCTRL to start the timer. TSTART0 in USARTn\_TIMECMP0 is set to RXEOF which enables the transitter of the timer delay. For this example TCMPVAL in USARTn\_TIMECMP0 is set to 0x20 to create a 32 baud-time delay between the end of the RX frame and the start of the TX frame. The break detect is configured by setting TSTART1 to RXACT to detect the start bit, and setting TSTOP1 to RXACTN to detect RX going high. In this case the interrupt asserts after RX stays low for 12 baud-times, so TCMPVAL1 is set to 0x0C.

### 16.3.10.10 Other Stop Conditions

There is also a timer stop on TX start using the TXST setting in TSTOP of USARTn\_TIMECMPn. This can be used to see that the DMA has not written to the TXBUFFER for a given time.

### 16.3.11 Interrupts

The interrupts generated by the USART are combined into two interrupt vectors. Interrupts related to reception are assigned to one interrupt vector, and interrupts related to transmission are assigned to the other. Separating the interrupts in this way allows different priorities to be set for transmission and reception interrupts.

The transmission interrupt vector groups the transmission-related interrupts generated by the following interrupt flags:

- TXC
- TXBL
- TXOF
- CCF
- TXIDLE

The reception interrupt on the other hand groups the reception-related interrupts, triggered by the following interrupt flags:

- RXDATAV
- RXFULL
- RXOF
- RXUF
- PERR
- FERR
- MPAF
- SSM
- TCMPn

If USART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in USART\_IF and their corresponding bits in USART\_IEN are set.

### 16.3.12 IrDA Modulator/ Demodulator

The IrDA modulator implements the physical layer of the IrDA specification, which is necessary for communication over IrDA. The modulator takes the signal output from the USART module, and modulates it before it leaves the USART. In the same way, the input signal is demodulated before it enters the actual USART module. The modulator implements the original Rev. 1.0 physical layer and one high speed extension which supports speeds from 2.4 kbps to 1.152 Mbps.

The data from and to the USART is represented in a NRZ (Non Return to Zero) format, where the signal value is at the same level through the entire bit period. For IrDA, the required format is RZI (Return to Zero Inverted), a format where a “1” is signalled by holding the line low, and a “0” is signalled by a short high pulse. An example is given in [Figure 16.31 USART Example RZI Signal for a given Asynchronous USART Frame on page 492](#).

**Figure 16.31. USART Example RZI Signal for a given Asynchronous USART Frame**

The IrDA module is enabled by setting IREN. The USART transmitter output and receiver input is then routed through the IrDA modulator.

The width of the pulses generated by the IrDA modulator is set by configuring IRPW in USARTn\_IRCTRL. Four pulse widths are available, each defined relative to the configured bit period as listed in [Table 16.11 USART IrDA Pulse Widths on page 492](#).

**Table 16.11. USART IrDA Pulse Widths**

| IRPW | Pulse width OVS=0 | Pulse width OVS=1 | Pulse width OVS=2 | Pulse width OVS=3 |
|------|-------------------|-------------------|-------------------|-------------------|
| 00   | 1/16              | 1/8               | 1/6               | 1/4               |
| 01   | 2/16              | 2/8               | 2/6               | N/A               |
| 10   | 3/16              | 3/8               | N/A               | N/A               |
| 11   | 4/16              | N/A               | N/A               | N/A               |

By default, no filter is enabled in the IrDA demodulator. A filter can be enabled by setting IRFILT in USARTn\_IRCTRL. When the filter is enabled, an incoming pulse has to last for 4 consecutive clock cycles to be detected by the IrDA demodulator.

Note that by default, the idle value of the USART data signal is high. This means that the IrDA modulator generates negative pulses, and the IrDA demodulator expects negative pulses. To make the IrDA module use RZI signalling, both TXINV and RXINV in USARTn\_CTRL must be set.

The IrDA module can also modulate a signal from the PRS system, and transmit a modulated signal to the PRS system. To use a PRS channel as transmitter source instead of the USART, set IRPRSEN in USARTn\_IRCTRL high. The channel is selected by configuring IRPRSSEL in USARTn\_IRCTRL.

## 16.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name              | Type  | Description                                    |
|--------|-------------------|-------|------------------------------------------------|
| 0x000  | USARTn_CTRL       | RW    | Control Register                               |
| 0x004  | USARTn_FRAME      | RW    | USART Frame Format Register                    |

|-----|----------|--------------------------------------------------------------------------------------------------------------------------|--------|-------------|
| 31  | Reserved | To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a> |        |             |

|       |        |     |    |                         |
|-------|--------|-----|----|-------------------------|
| 30:28 | CSHOLD | 0x0 | RW | <b>Chip Select Hold</b> |
|-------|--------|-----|----|-------------------------|

Chip Select will be asserted after the end of frame transmission. When using TCMPn, normally set TIMECMPn\_TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.

| Value | Mode  | Description                                                          |
|-------|-------|----------------------------------------------------------------------|
| 0     | ZERO  | Disable CS being asserted after the end of transmission              |
| 1     | ONE   | CS is asserted for 1 baud-times after the end of transmission        |
| 2     | TWO   | CS is asserted for 2 baud-times after the end of transmission        |
| 3     | THREE | CS is asserted for 3 baud-times after the end of transmission        |
| 4     | SEVEN | CS is asserted for 7 baud-times after the end of transmission        |
| 5     | TCMP0 | CS is asserted after the end of transmission for TCMPVAL0 baud-times |
| 6     | TCMP1 | CS is asserted after the end of transmission for TCMPVAL1 baud-times |
| 7     | TCMP2 | CS is asserted after the end of transmission for TCMPVAL2 baud-times |

|    |          |                                                                                                                          |  |  |
|----|----------|--------------------------------------------------------------------------------------------------------------------------|--|--|
| 27 | Reserved | To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a> |  |  |
|----|----------|--------------------------------------------------------------------------------------------------------------------------|--|--|

|       |     |     |    |                                |
|-------|-----|-----|----|--------------------------------|
| 26:24 | ICS | 0x0 | RW | <b>Inter-character Spacing</b> |
|-------|-----|-----|----|--------------------------------|

Inter-character spacing after each TX frame while the TX buffer is not empty. When using USART\_TIMECMPn, normally set TSTART to DISABLE to stop general timer and to prevent unwanted interrupts.

| Value | Mode  | Description                                                                |
|-------|-------|----------------------------------------------------------------------------|
| 0     | ZERO  | There is no space between characters                                       |
| 1     | ONE   | Create a space of 1 baud-times before start of transmission                |
| 2     | TWO   | Create a space of 2 baud-times before start of transmission                |
| 3     | THREE | Create a space of 3 baud-times before start of transmission                |
| 4     | SEVEN | Create a space of 7 baud-times before start of transmission                |
| 5     | TCMP0 | Create a space of before the start of transmission for TCMPVAL0 baud-times |

| Bit                                                                                                                                                                                      | Name     | Reset                                                                                                                    | Access | Description                                                                |

## 17. LEUART - Low Energy Universal Asynchronous Receiver/Transmitter

### Quick Facts

#### What?

The LEUART provides full UART communication using a low frequency 32.768 kHz clock, and has special features for communication without CPU intervention.

#### Why?

It allows UART communication to be performed in low energy modes, using only a few  $\mu\text{A}$  during active communication and only 150 nA when waiting for incoming data.

#### How?

A low frequency clock signal allows communication with less energy. Using DMA, the LEUART can transmit and receive data with minimal CPU intervention. Special UART-frames can be configured to help control the data flow, further automating data transmission.

### 17.1 Introduction

The unique Low Energy UART (LEUART) is a UART that allows two-way UART communication on a strict power budget. Only a 32.768 kHz clock is needed to allow UART communication up to 9600 baud.

Even when the system is in low energy mode EM2 DeepSleep (with most core functionality turned off), the LEUART can wait for an incoming UART frame while having an extremely low energy consumption. When a UART frame is completely received, the CPU can quickly be woken up. Alternatively, multiple frames can be transferred via the Direct Memory Access (DMA) module into RAM memory before waking up the CPU.

Received data can optionally be blocked until a configurable start frame is detected. A signal frame can be configured to generate an interrupt indicating the end of a data transmission. The start frame and signal frame can be used in combination to handle higher level communication protocols.

Similarly, data can be transmitted in EM2 DeepSleep either on a frame-by-frame basis with data from the CPU or through use of the DMA.

The LEUART includes all necessary hardware support to make asynchronous serial communication possible with minimal software overhead and low energy consumption.

## 17.2 Features

- Low energy asynchronous serial communications
- Full/half duplex communication
- Separate TX / RX enable
- Separate double buffered transmit buffer and receive buffer
- Programmable baud rate, generated as a fractional division of the LFBCLK
  - Supports baud rates from 300 baud to 9600 baud
- Can use a high frequency clock source for even higher baud rates
- Configurable number of data bits: 8 or 9 (plus parity bit, if enabled)
- Configurable parity: off, even or odd
  - HW parity bit generation and check
- Configurable number of stop bits, 1 or 2
- Capable of sleep-mode wake-up on received frame
  - Either wake-up on any received byte or
  - Wake up only on specified start and signal frames
- Supports transmission and reception in EM0 Active, EM1 Sleep and EM2 DeepSleep with
  - Full DMA support
  - Specified start-frame can start reception automatically
- IrDA modulator (pulse generator, pulse extender)
- Multi-processor mode
- Loopback mode
  - Half duplex communication
  - Communication debugging
- PRS RX input

### 17.3 Functional Description

An overview of the LEUART module is shown in [Figure 17.1 LEUART Overview on page 549](#).

**Figure 17.1. LEUART Overview**

### 17.3.1 Frame Format

The frame format used by the LEUART consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 8 or 9 data bits and an optional parity bit. The data is transmitted with the least significant bit first. Finally, a number of stop-bits, where the line is driven high, end the frame. The frame format is shown in [Figure 17.2 LEUART Asynchronous Frame Format on page 550](#).

**Figure 17.2. LEUART Asynchronous Frame Format**

The number of data bits in a frame is set by DATABITS in LEUARTn\_CTRL, and the number of stop-bits is set by STOPBITS in LEUARTn\_CTRL. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY in LEUARTn\_CTRL. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

The frame format used by the LEUART can be inverted by setting INV in LEUARTn\_CTRL. This affects the entire frame, resulting in a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits. INV should only be changed while the receiver is disabled.

#### 17.3.1.1 Parity Bit Calculation and Handling

Hardware automatically inserts parity bits into outgoing frames and checks the parity bits of incoming frames. The possible parity modes are defined in [Table 17.1 LEUART Parity Bit on page 550](#). When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd. When parity bits are disabled, which is the default configuration, the parity bit is omitted.

**Table 17.1. LEUART Parity Bit**

| PARITY [1:0] | Description         |
|--------------|---------------------|
| 00           | No parity (default) |
| 01           | Reserved            |
| 10           | Even parity         |
| 11           | Odd parity          |

See [17.3.5.4 Parity Error](#) for more information on parity bit handling.

### 17.3.2 Clock Source

The LEUART clock source is selected by the LFB bit field the CMU\_LFBCLKSEL register. The clock is prescaled by the LEUARTn bitfield in the CMU\_LFBPRESC0 register and enabled by the LEUARTn bit in the CMU\_LFBCLKEN0. See [Figure 10.2 CMU Overview - Low Frequency Portion on page 230](#) for a diagram of the clocking structure.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0, in addition to the module clock.

### 17.3.3 Clock Generation

The LEUART clock defines the transmission and reception data rate. The clock generator employs a fractional clock divider to allow baud rates that are not attainable by integral division of the 32.768 kHz clock that drives the LEUART.

The clock divider used in the LEUART is a 14-bit value, with a 9-bit integral part and a 5-bit fractional part. The baud rate of the LEUART is given by :

$$br = fLEUARTn / (1 + LEUARTn\_CLKDIV / 256)$$

**Figure 17.3. LEUART Baud Rate Equation**

where  $fLEUARTn$  is the clock frequency supplied to the LEUART. The value of  $LEUARTn\_CLKDIV$  thus defines the baud rate of the LEUART. The integral part of the divider is right-aligned in the upper 24 bits of  $LEUARTn\_CLKDIV$  and the fractional part is left-aligned in the lower 8 bits. The divider is thus a 256th of  $LEUARTn\_CLKDIV$  as seen in the equation.

As an example let us assume  $fLEUART = 22.5$  kHz and the value of  $DIV$  in  $LEUARTn\_CLKDIV$  is  $0x0028$  ( $LEUARTn\_CLKDIV = 0x00000140$ ). The baud rate =  $22.5$  kHz /  $(1 + 0x140 / 256) = 22.5$  kHz /  $2.25 = 10$  kHz.

For a desired baud rate  $br_{DESIRED}$ ,  $LEUARTn\_CLKDIV$  can be calculated by using:

$$LEUARTn\_CLKDIV = 256 \times (fLEUARTn / br_{DESIRED} - 1)$$

**Figure 17.4. LEUART CLKDIV Equation**

It's important to note that this equation results in a 32bit value for the  $LEUARTn\_CLKDIV$  register but only bits [16:3] are valid and all others must be 0. For example if we have a 32 kHz clock and wish to achieve a baud rate of 10 kHz the equation above results in a  $LEUARTn\_CLKDIV$  value of  $0x233$ . However, the actual value of the register will be  $0x230$  since bits [2:0] cannot be set. This limits the best achievable accuracy. In this example the actual baud rate will be  $32$  kHz /  $(1 + 0x230 / 255) = 10.039$  kHz instead of  $32$  kHz /  $(1 + 0x233 / 255) = 10.002$  kHz.

[Table 17.2 LEUART Baud Rates on page 551](#) lists a set of desired baud rates and the closest baud rates reachable by the LEUART with a 32.768 kHz clock source. It also shows the average baud rate error.

**Table 17.2. LEUART Baud Rates**

| Desired baud rate | LEUARTn_CLKDIV | LEUARTn_CLKDIV/256 | Actual Baud Rate | Error [%] |
|-------------------|----------------|--------------------|------------------|-----------|
| 300               | 27704          | 108.21875          | 300.0217         | 0.01      |
| 600               | 13728          | 53.625             | 599.8719         | -0.02     |
| 1200              | 6736           | 26.3125            | 1199.744         | -0.02     |
| 2400              | 3240           | 12.65625           | 2399.487         | -0.02     |
| 4800              | 1488           | 5.8125             | 4809.982         | 0.21      |
| 9600              | 616            | 2.40625            | 9619.963         | 0.21      |

### 17.3.4 Data Transmission

Data transmission is initiated by writing data to the transmit buffer using one of the methods described in [17.3.4.1 Transmit Buffer Operation](#). When the transmit shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available. Transmission is enabled through the command register  $LEUARTn\_CMD$  by setting  $TXEN$ , and disabled by setting  $TXDIS$ . When the transmitter is disabled using  $TXDIS$ , any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from  $TXENS$  in  $LEUARTn\_STATUS$ . After a transmission, when there is no more data in the shift register or transmit buffer, the  $TXC$  flag in  $LEUARTn\_STATUS$  and the  $TXC$  interrupt flag in  $LEUARTn\_IF$  are set, signaling that the transmitter is idle. The  $TXC$  status flag is cleared when a new byte becomes available for transmission, but the  $TXC$  interrupt flag must be cleared by software.

### 17.3.4.1 Transmit Buffer Operation

A frame can be loaded into the transmit buffer by writing to LEUARTn\_TXDATA or LEUARTn\_TXDATAX. Using LEUARTn\_TXDATA allows 8 bits to be written to the buffer. If 9 bit frames are used, the 9th bit will in that case be set to the value of BIT8DV in LEUARTn\_CTRL. To set the 9th bit directly and/or use transmission control, LEUARTn\_TXDATAX must be used. When writing data to the transmit buffer using LEUARTn\_TXDATAX, the 9th bit written to LEUARTn\_TXDATAX overrides the value in BIT8DV, and alone defines the 9th bit that is transmitted if 9-bit frames are used.

If a write is attempted to the transmit buffer when it is not empty, the TXOF interrupt flag in LEUARTn\_IF is set, indicating the overflow. The data already in the buffer is in that case preserved, and no data is written.

In addition to the interrupt flag TXC in LEUARTn\_IF and the status flag TXC in LEUARTn\_STATUS which are set when the transmitter becomes idle, TXBL in LEUARTn\_STATUS and the TXBL interrupt flag in LEUARTn\_IF are used to indicate the level of the transmit buffer. Whenever the transmit buffer becomes empty, these flags are set high. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when data is written to the transmit buffer.

There is also TXIDLE status in LEUART\_STATUS which can be used to detect when the transmit state machine is in the idle state.

The transmit buffer, including the TX shift register can be cleared by setting command bit CLEAR\_TX in LEUARTn\_CMD. This will prevent the LEUART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed. An overview of the operation of the transmitter is shown in [Figure 17.5 LEUART Transmitter Overview on page 552](#).

Figure 17.5. LEUART Transmitter Overview

### 17.3.4.2 Frame Transmission Control

The transmission control bits, which can be written using LEUARTn\_TXDATAx, affect the transmission of the written frame. The following options are available:

- **Generate break:** By setting TXBREAK, the output will be held low during the first stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high for one bit period before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than an UART frame are thus not supported by the LEUART. GPIO can be used for this. Note that when AUTOTRI in LEUARTn\_CTRL is used, the transmitter is not tristated before the high-bit after the break has been transmitted.
- **Disable transmitter after transmission:** If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- **Enable receiver after transmission:** If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.

The transmission control bits in the LEUART cannot tristate the transmitter. This is performed automatically by hardware if AUTOTRI in LEUARTn\_CTRL is set. See [17.3.7 Half Duplex Communication](#) for more information on half duplex operation.

### 17.3.5 Data Reception

Data reception is enabled by setting RXEN in LEUARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start bit of a new frame. When a start bit is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start bit. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available.

If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the receive shift register is overwritten, and the RXOF interrupt flag in LEUARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in LEUARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in LEUARTn\_STATUS.

The receive buffer can be cleared by setting command bit CLEARRX in LEUARTn\_CMD. This will make it available for new data. Any frame currently being received will not be aborted and will become the first received frame when complete.

#### 17.3.5.1 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in LEUARTn\_STATUS and the RXDATAV interrupt flag in LEUARTn\_IF are set. Both the RXDATAV status flag and the RXDATAV interrupt flag are cleared by hardware when data is no longer available, i.e. when data has been read out of the buffer.

Data can be read from receive buffer using either LEUARTn\_RXDATA or LEUARTn\_RXDATAx. LEUARTn\_RXDATA gives access to the 8 least significant bits of the received frame, while LEUARTn\_RXDATAx must be used to get access to the 9th, most significant bit. The LEUARTn\_RXDATAx register also contains status information regarding the frame.

When a frame is read from the receive buffer using LEUARTn\_RXDATA or LEUARTn\_RXDATAx, the frame is removed from the buffer, making room for a new one. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in LEUARTn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can also be read from the receive buffer without removing the data by using LEUARTn\_RXDATAxp, which gives access to the frame in the buffer including control bits. Data read from this register when the receive buffer is empty is undefined. No underflow interrupt is generated by a read using LEUARTn\_RXDATAxp, i.e. the RXUF interrupt flag is never set as a result of reading from LEUARTn\_RXDATAxp.

An overview of the operation of the receiver is shown in [Figure 17.6 LEUART Receiver Overview on page 553](#).

Figure 17.6. LEUART Receiver Overview

### 17.3.5.2 Blocking Incoming Data

When using hardware frame recognition, as detailed in [17.3.5.6 Programmable Start Frame](#), [17.3.5.7 Programmable Signal Frame](#), and [17.3.5.8 Multi-Processor Mode](#), it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in LEUARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV bit in LEUARTn\_STATUS or the RXDATAV interrupt flag in LEUARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in LEUARTn\_CMD and disabled by setting RXBLOCKDIS also in LEUARTn\_CMD. There are two exceptions where data is loaded into the receive buffer even when RXBLOCK is set. The first is when an address frame is received when in operating in multi-processor mode as shown in [17.3.5.8 Multi-Processor Mode](#). The other case is when receiving a start-frame when SFUBRX in LEUARTn\_CTRL is set; see [17.3.5.6 Programmable Start Frame](#).

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in LEUARTn\_IF being set while RXBLOCK is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

#### Note:

- If a frame is received while RXBLOCK in LEUARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.
- The overflow interrupt flag RXOF in LEUARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK is set.

### 17.3.5.3 Data Sampling

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Except for the start-bit, only a single sample is taken of each of the incoming bits.

The length of a bit-period is given by  $1 + \text{LEUARTn\_CLKDIV}/256$ , as a number of 32.768 kHz clock periods. Let the clock cycle where a start-bit is first detected be given the index 0. The optimal sampling point for each bit in the UART frame is then given by the following equation:

$$S_{\text{opt}}(n) = n (1 + \text{LEUARTn\_CLKDIV}/256) + \text{LEUARTn\_CLKDIV}/512$$

**Figure 17.7. LEUART Optimal Sampling Point**

where n is the bit-index.

Since samples are only done on the positive edges of the 32.768 kHz clock, the actual samples are performed on the closest positive edge, i.e. the edge given by the following equation:

$$S(n) = \text{floor}(n \times (1 + \text{LEUARTn\_CLKDIV}/256) + \text{LEUARTn\_CLKDIV}/512)$$

**Figure 17.8. LEUART Actual Sampling Point**

The sampling location will thus have jitter according to difference between  $S_{\text{opt}}$  and S. The start-bit is found at  $n=0$ , then follows the data bits, any parity bit, and the stop bits.

If the value of the start-bit is found to be high, then the start-bit is discarded, and the receiver waits for a new start-bit.

### 17.3.5.4 Parity Error

When the parity bit is enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in a frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATA register.

### 17.3.5.5 Framing Error and Break Detection

A framing error is the result of a received frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected, the framing error bit FERR in the received frame is set. The interrupt flag FERR in LEUARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATA or LEUARTn\_RXDATAEXP registers.

### 17.3.5.6 Programmable Start Frame

The LEUART can be configured to start receiving data when a special start frame is detected on the input. This can be useful when operating in low energy modes, allowing other devices to gain the attention of the LEUART by transmitting a given frame.

When SFUBRX in LEUARTn\_CTRL is set, an incoming frame matching the frame defined in LEUARTn\_STARTFRAME will result in RXBLOCK in LEUARTn\_STATUS being cleared. This can be used to enable reception when a specified start frame is detected. If the receiver is enabled and blocked, i.e. RXENS and RXBLOCK in LEUARTn\_STATUS are set, the receiver will receive all incoming frames, but unless an incoming frame is a start frame it will be discarded and not loaded into the receive buffer. When a start frame is detected, the block is cleared, and frames received from that point, including the start frame, are loaded into the receive buffer.

An incoming start frame results in the STARTF interrupt flag in LEUARTn\_IF being set, regardless of the value of SFUBRX in LEUARTn\_CTRL. This allows an interrupt to be made when the start frame is detected.

When 8 data-bit frame formats are used, only the 8 least significant bits of LEUARTn\_STARTFRAME are compared to incoming frames. The full length of LEUARTn\_STARTFRAME is used when operating with frames consisting of 9 data bits.

**Note:** The receiver must be enabled for start frames to be detected. In addition, a start frame with a parity error or framing error is not detected as a start frame.

### 17.3.5.7 Programmable Signal Frame

As well as the configurable start frame, a special signal frame can be specified. When a frame matching the frame defined in LEUARTn\_SIGFRAME is detected by the receiver, the SIGF interrupt flag in LEUARTn\_IF is set. As for start frame detection, the receiver must be enabled for signal frames to be detected.

One use of the programmable signal frame is to signal the end of a multi-frame message transmitted to the LEUART. An interrupt will then be triggered when the packet has been completely received, allowing software to process it. Used in conjunction with the programmable start frame and DMA, this makes it possible for the LEUART to automatically begin the reception of a packet on a specified start frame, load the entire packet into memory, and give an interrupt when reception of a packet has completed. The device can thus wait for data packets in EM2 DeepSleep, and only be woken up when a packet has been completely received.

A signal frame with a parity error or framing error is not detected as a signal frame.

### 17.3.5.8 Multi-Processor Mode

To simplify communication between multiple processors and maintain compatibility with the USART, the LEUART supports a multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in LEUARTn\_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in LEUARTn\_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in LEUARTn\_STATUS.

Multi-processor mode is enabled by setting MPM in LEUARTn\_CTRL. The mode can be used in buses with multiple slaves, allowing the slaves to be addressed using the special address frames. An addressed slave, which was previously blocking reception using RXBLOCK, would then unblock reception, receive a message from the bus master, and then block reception again, waiting for the next message. See the USART for a more detailed example.

**Note:** The programmable start frame functionality can be used for automatic address matching, enabling reception on a correctly configured incoming frame.

An address frame with a parity error or a framing error is not detected as an address frame. The Start, Signal, and address frames should not be set to match the same frame since each of these uses separate synchronization to the peripheral clock domain.

### 17.3.6 Loopback

The LEUART receiver samples LEUn\_RX by default, and the transmitter drives LEUn\_TX by default. This is not the only configuration however. When LOOPBK in LEUARTn\_CTRL is set, the receiver is connected to the LEUn\_TX pin as shown in [Figure 17.9 LEUART Local Loopback on page 556](#). This is useful for debugging, as the LEUART can receive the data it transmits, but it is also used to allow the LEUART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the LEUn\_TX pin must be enabled as an output in the GPIO.

**Figure 17.9. LEUART Local Loopback**

### 17.3.7 Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

#### 17.3.7.1 Single Data-link

In this setup, the LEUART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in LEUARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the LEUART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. If AUTOTRI in LEUARTn\_CTRL is set, the LEUART automatically tristates LEUn\_TX whenever the transmitter is inactive. It is then the responsibility of the software protocol to make sure the transmitter is not transmitting data whenever incoming data is expected.

The transmitter can also be tristated from software by configuring the GPIO pin as an input and disabling the LEUART output on LEUn\_TX.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

### 17.3.7.2 Single Data-link With External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of Tristating the transmitter when receiving data, the external driver must be disabled. The USART has hardware support for automatically turning the driver on and off. When using the LEUART in such a setup, the driver must be controlled by a GPIO. [Figure 17.10 LEUART Half Duplex Communication with External Driver](#) on page 557 shows an example configuration using an external driver.

**Figure 17.10. LEUART Half Duplex Communication with External Driver**

### 17.3.7.3 Two Data-links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

### 17.3.8 Transmission Delay

By configuring TXDELAY in LEUARTn\_CTRL, the transmitter can be forced to wait a number of bit-periods from when it is ready to transmit data, to when it actually transmits the data. This delay is only applied to the first frame transmitted after the transmitter has been idle. When transmitting frames back-to-back the delay is not introduced between the transmitted frames.

This is useful on half duplex buses, because the receiver always returns received frames to software during the first stop-bit. The bus may still be driven for up to 3 bit periods, depending on the current frame format. Using the transmission delay, a transmission can be started when a frame is received, and it is possible to make sure that the transmitter does not begin driving the output before the frame on the bus is completely transmitted.

To route the UART TX and RX signals to a pin first select the desired pins using the RXLOC and TXLOC fields in the LEUARTn\_ROUTELOC0 register. Then enable the connection using TXPEN and RXPEN in the LEUARTnROUTPEN register. See the device data sheet for mappings between UART locations (LOC0, LOC1, etc.) and device pins (PA0, PA1, etc.).

### 17.3.9 PRS RX Input

In addition to receiving data on an external pin the LEUART can be configured to receive data directly from a PRS channel by setting RX\_PRS in LEUARTn\_INPUT. The PRS channel used can be selected using RX\_PRS\_SEL in LEUARTn\_INPUT. See the PRS chapter for more details on the PRS block.

For example the output of a comparator could be routed to the LEUART through the PRS to allow for receiving a signal with low peak-to-peak voltage or a significant DC offset.

### 17.3.10 DMA Support

The LEUART has full DMA support in energy modes EM0 Active – EM2 DeepSleep. The DMA controller can write to the transmit buffer using the registers LEUARTn\_TXDATA and LEUARTn\_TXDATAx, and it can read from receive buffer using the registers LEUARTn\_RXDATA and LEUARTn\_RXDATAx. This enables single byte transfers and 9 bit data + control/status bits transfers both to and from the LEUART. The DMA will start up the HFRCO and run from this when it is waken by the LEUART in EM2. The HFRCO is disabled once the transaction is done.

A request for the DMA controller to read from the receive buffer can come from one of the following sources:

- Receive buffer full

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- Transmit buffer empty

In some cases, it may be sensible to temporarily stop DMA access to the LEUART when a parity or framing error has occurred. This is enabled by setting ERRSDMA in LEUARTn\_CTRL. When this bit is set, the DMA controller will not get requests from the receive buffer if a framing error or parity error is detected in the received byte. The ERRSDMA bit applies only to the RX DMA.

When operating in EM2 DeepSleep, the DMA controller must be powered up in order to perform the transfer. This is automatically performed for read operations if RXDMAWU in LEUARTn\_CTRL is set and for write operations if TXDMAWU in LEUARTn\_CTRL is set. To make sure the DMA controller still transfers bits to and from the LEUART in low energy modes, these bits must thus be configured accordingly.

**Note:** When RXDMAWU or TXDMAWU is set, the system will not be able to go to EM2 DeepSleep/EM3 Stop before all related LEUART DMA requests have been processed. This means that if RXDMAWU is set and the LEUART receives a frame, the system will not be able to go to EM2 DeepSleep/EM3 Stop before the frame has been read from the LEUART. In order for the system to go to EM2 during the last byte transmission, LEUARTn\_CTRL\_TXDMAWU must be cleared in the DMA interrupt service routine. This is because TXBL will be high during that last byte transfer.

### 17.3.11 Pulse Generator/ Pulse Extender

The LEUART has an optional pulse generator for the transmitter output, and a pulse extender on the receiver input. These are enabled by setting PULSEEN in LEUARTn\_PULSECTRL, and with INV in LEUARTn\_CTRL set, they will change the output/input format of the LEUART from NRZ to RZI as shown in [Figure 17.11 LEUART - NRZ vs. RZI on page 558](#).

Figure 17.11. LEUART - NRZ vs. RZI

If PULSEEN in LEUARTn\_PULSECTRL is set while INV in LEUARTn\_CTRL is cleared, the output waveform will look like RZI shown in [Figure 17.11 LEUART - NRZ vs. RZI on page 558](#), only inverted.

The width of the pulses from the pulse generator can be configured using PULSEW in LEUARTn\_PULSECTRL. The generated pulse width is PULSEW + 1 cycles of the 32.768 kHz clock, which makes pulse width from 31.25µs to 500µs possible.

Since the incoming signal is only sampled on positive clock edges, the width of the incoming pulses must be at least two 32.768 kHz clock periods wide for reliable detection by the LEUART receiver. They must also be shorter than half a UART bit period.

At 2400 baud or lower, the pulse generator is able to generate RZI pulses compatible with the IrDA physical layer specification. The external IrDA device must generate pulses of sufficient length for successful two-way communication.

PULSEFILT in the LEUARTn\_PULSECTRL register can be used to extend the minimum receive pulse width from 2 clock periods to 3 clock periods.

### 17.3.11.1 Interrupts

The interrupts generated by the LEUART are combined into one interrupt vector. If LEUART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in LEUARTn\_IF and their corresponding bits in LEUART\_IEN are set.

### 17.3.12 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Refer to [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#) for a description on how to perform register accesses to Low Energy Peripherals.

The registers LEUARTn\_FREEZE and LEUARTn\_SYNCBUSY are used for synchronization of this peripheral.

## 17.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                                |
|--------|--------------------|-------|--------------------------------------------|
| 0x000  | LEUARTn_CTRL       | RW    | Control Register                           |
| 0x004  | LEUARTn_CMD        | W1    | Command Register                           |
| 0x008  | LEUARTn_STATUS     | R     | Status Register                            |
| 0x00C  | LEUARTn_CLKDIV     | RW    | Clock Control Register                     |
| 0x010  | LEUARTn_STARTFRAME | RW    | Start Frame Register                       |
| 0x014  | LEUARTn_SIGFRAME   | RW    | Signal Frame Register                      |
| 0x018  | LEUARTn_RXDATAx    | R(a)  | Receive Buffer Data Extended Register      |
| 0x01C  | LEUARTn_RXDATA     | R(a)  | Receive Buffer Data Register               |
| 0x020  | LEUARTn_RXDATAxP   | R     | Receive Buffer Data Extended Peek Register |
| 0x024  | LEUARTn_TXDATAx    | W     | Transmit Buffer Data Extended Register     |
| 0x028  | LEUARTn_TXDATA     | W     | Transmit Buffer Data Register              |
| 0x02C  | LEUARTn_IF         | R     | Interrupt Flag Register                    |
| 0x030  | LEUARTn_IFS        | W1    | Interrupt Flag Set Register                |
| 0x034  | LEUARTn_IFC        | (R)W1 | Interrupt Flag Clear Register              |
| 0x038  | LEUARTn_IEN        | RW    | Interrupt Enable Register                  |
| 0x03C  | LEUARTn_PULSECTRL  | RW    | Pulse Control Register                     |
| 0x040  | LEUARTn_FREEZE     | RW    | Freeze Register                            |
| 0x044  | LEUARTn_SYNCBUSY   | R     | Synchronization Busy Register              |
| 0x054  | LEUARTn_ROUTEEN    | RW    | I/O Routing Pin Enable Register            |

|      | 3        | PRSCH3                                                                                                                   | PRS Channel 3 selected  |                                                                            |
|      | 4        | PRSCH4                                                                                                                   | PRS Channel 4 selected  |                                                                            |
|      | 5        | PRSCH5                                                                                                                   | PRS Channel 5 selected  |                                                                            |
|      | 6        | PRSCH6                                                                                                                   | PRS Channel 6 selected  |                                                                            |
|      | 7        | PRSCH7                                                                                                                   | PRS Channel 7 selected  |                                                                            |
|      | 8        | PRSCH8                                                                                                                   | PRS Channel 8 selected  |                                                                            |
|      | 9        | PRSCH9                                                                                                                   | PRS Channel 9 selected  |                                                                            |
|      | 10       | PRSCH10                                                                                                                  | PRS Channel 10 selected |                                                                            |
|      | 11       | PRSCH11                                                                                                                  | PRS Channel 11 selected |                                                                            |

## 18. TIMER - Timer/Counter

### Quick Facts

#### What?

The TIMER (Timer/Counter) keeps track of timing and counts events, generates output waveforms, and triggers timed actions in other peripherals.

#### Why?

Most applications have activities that need to be timed accurately with as little CPU intervention and energy consumption as possible.

#### How?

The flexible 16-bit timer can be configured to provide PWM waveforms with optional dead-time insertion (e.g. motor control) or work as a frequency generator. The timer can also count events and control other peripherals through the PRS, which offloads the CPU and reduces energy consumption.

### 18.1 Introduction

The general purpose timer has 3 or 4 compare/capture channels for input capture and compare/Pulse-Width Modulation (PWM) output.

Some timers also include a Dead-Time Insertion module suitable for motor control applications.

Refer to the device data sheet to determine the capabilities (capture/compare channel count and DTI) of each timer instance.

## 18.2 Features

- 16-bit auto reload up/down counter
  - Dedicated 16-bit reload register which serves as counter maximum
- 3 or 4 Compare/Capture channels
  - Individually configurable as either input capture or output compare/PWM
- Multiple Counter modes
  - Count up
  - Count down
  - Count up/down
  - Quadrature Decoder
  - Direction and count from external pins
- 2x Count Mode
- Counter control from PRS or external pin
  - Start
  - Stop
  - Reload and start
- Inter-Timer connection
  - Allows 32-bit counter mode
  - Start/stop synchronization between several timers
- Input Capture
  - Period measurement
  - Pulse width measurement
  - Two capture registers for each capture channel
    - Capture on either positive or negative edge
    - Capture on both edges
  - Optional digital noise filtering on capture inputs
- Output Compare
  - Compare output toggle/pulse on compare match
  - Immediate update of compare registers
- PWM
  - Up-count PWM
  - Up/down-count PWM
  - Predictable initial PWM output state (configured by SW)
  - Buffered compare register to ensure glitch-free update of compare values
- Clock sources
  - HFPERCLK<sub>TIMERn</sub>
    - 10-bit Prescaler
  - External pin
  - Peripheral Reflex System
- Debug mode
  - Configurable to either run or stop when processor is stopped (halt/breakpoint)
- Interrupts, PRS output and/or DMA request on:
  - Underflow
  - Overflow
  - Compare/Capture event

- Dead-Time Insertion Unit
  - Complementary PWM outputs with programmable dead-time
    - Dead-time is specified independently for rising and falling edge
      - 10-bit prescaler
      - 6-bit time value
  - Outputs have configurable polarity
  - Outputs can be set inactive individually by software.
- Configurable action on fault
  - Set outputs inactive
  - Clear output
  - Tristate output
- Individual fault sources
  - One or two PRS signals
  - Debugger
    - Support for automatic restart
  - Core lockup
- Configuration lock

### 18.3 Functional Description

An overview of the TIMER module is shown in [Figure 18.1 TIMER Block Overview on page 584](#) and it consists of a 16 bit up/down counter with 3 Compare/Capture channels connected to pins TIMn\_CC0, TIMn\_CC1, and TIMn\_CC2.

**Figure 18.1. TIMER Block Overview**

### 18.3.1 Counter Modes

The timer consists of a counter that can be configured to the following modes:

1. Up-count: Counter counts up until it reaches the value in `TIMERn_TOP`, where it is reset to 0 before counting up again.
2. Down-count: The counter starts at the value in `TIMERn_TOP` and counts down. When it reaches 0, it is reloaded with the value in `TIMERn_TOP`.
3. Up/Down-count: The counter starts at 0 and counts up. When it reaches the value in `TIMERn_TOP`, it counts down until it reaches 0 and starts counting up again.
4. Quadrature Decoder: Two input channels where one determines the count direction, while the other pin triggers a clock event.

In addition, to the TIMER modes listed above, the TIMER also supports a 2x Count Mode. In this mode the counter increments/decrements by 2. The 2x Count Mode intended use is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. The 2x Count Mode can be enabled by setting the `X2CNT` bitfield in the `TIMERn_CTRL` register.

The counter value can be read or written by software at any time by accessing the `CNT` field in `TIMERn_CNT`.

#### 18.3.1.1 Events

Overflow is set when the counter value shifts from `TIMERn_TOP` to the next value when counting up. In up-count mode and Quadrature Decoder mode the next value is 0. In up/down-count mode, the next value is `TIMERn_TOP-1`.

Underflow is set when the counter value shifts from 0 to the next value when counting down. In down-count mode and Quadrature Decoder mode, the next value is `TIMERn_TOP`. In up/down-count mode the next value is 1.

An update event occurs on overflow in up-count mode and on underflow in down-count or up/down count mode. Additionally, an update event also occurs on overflow and underflow in Quadrature Decoder Mode. This event is used to time updates of buffered values.

### 18.3.1.2 Operation

Figure 18.2 **TIMER Hardware Timer/Counter Control** on page 586 shows the hardware Timer/Counter control. Software can start or stop the counter by setting the START or STOP bits in TIMERN\_CMD. The counter value (CNT in TIMERN\_CNT) can always be written by software to any 16-bit value.

It is also possible to control the counter through either an external pin or PRS input. This is done through the input logic for the Compare/Capture Channel 0. The Timer/Counter allows individual actions (start, stop, reload) to be taken for rising and falling input edges. This is configured in the RISEA and FALLA fields in TIMERN\_CTRL. The reload value is 0 in up-count and up/down-count mode and TOP in down-count mode.

The RUNNING bit in TIMERN\_STATUS indicates if the timer is running or not. If the SYNC bit in TIMERN\_CTRL is set, the timer is started/stopped/reloaded (external pin or PRS) when any of the other timers are started/stopped/reloaded.

The DIR bit in TIMERN\_STATUS indicates the counting direction of the timer at any given time. The counter value can be read or written by software through the CNT field in TIMERN\_CNT. In Up/Down-Count mode the count direction will be set to up if the CNT value is written by software.

**Figure 18.2. TIMER Hardware Timer/Counter Control**

### 18.3.1.3 Clock Source

The counter can be clocked from several sources, which are all synchronized with the peripheral clock (HFPERCLK). See Figure 18.3 **TIMER Clock Selection** on page 586.

**Figure 18.3. TIMER Clock Selection**

### 18.3.1.4 Peripheral Clock (HFPERCLK)

The peripheral clock (HFPERCLK) can be used as a source with a configurable prescale factor of  $2^{\text{PRESC}}$ , where PRESC is an integer between 0 and 10, which is set in PRESC in TIMERN\_CTRL. However, if 2x Count Mode is enabled and the Compare/Capture channels are put in PWM mode, the CC output is updated on both clock edges so prescaling the peripheral clock will produce an incorrect result. The prescaler is stopped and reset when the timer is stopped.

### 18.3.1.5 Compare/ Capture Channel 1 Input

The timer can also be clocked by positive and/or negative edges on the Compare/Capture channel 1 input. This input can either come from the TIMn\_CC1 pin or one of the PRS channels. The input signal must not have a higher frequency than  $f_{\text{HFPERCLK}}/3$  when running from a pin input or a PRS input with FILT enabled in TIMERN\_CCx\_CTRL. When running from PRS without FILT, the frequency can be as high as  $f_{\text{HFPERCLK}}$ . Note that when clocking the timer from the same pulse that triggers a start (through RISEA/FALLA in TIMERN\_CTRL), the starting pulse will not update the Counter Value.

### 18.3.1.6 Underflow/Overflow From Neighboring Timer

All timers are linked together (see [Figure 18.4 TIMER Connections on page 587](#)), allowing timers to count on overflow/underflow from the lower numbered neighbouring timers to form a 32-bit or 48-bit timer. Note that all timers must be set to same count direction and less significant timer(s) can only be set to count up or down.

**Figure 18.4. TIMER Connections**

### 18.3.1.7 One-Shot Mode

By default, the counter counts continuously until it is stopped. If the OSMEN bit is set in the TIMERN\_CTRL register, however, the counter is disabled by hardware on the first *update event* (see [18.3.1.1 Events](#)). Note that when the counter is running with CC1 as clock source (0b01 in CLKSEL in TIMERN\_CTRL) and OSMEN is set, a CC1 capture event will not take place on the *update event* (CC1 rising edge) that stops the timer.

### 18.3.1.8 Top Value Buffer

The TIMERN\_TOP register can be altered either by writing it directly or by writing to the TIMER\_TOPB (buffer) register. When writing to the buffer register the TIMERN\_TOPB register will be written to TIMERN\_TOP on the next *update event*. Buffering ensures that the TOP value is not set below the actual count value. The TOPBV flag in TIMERN\_STATUS indicates whether the TIMERN\_TOPB register contains data that has not yet been written to the TIMERN\_TOP register (see [Figure 18.5 TIMER TOP Value Update Functionality on page 588](#)).

**Note:** When writing to TIMERN\_TOP register directly, the TIMERN\_TOPB register value will be invalidated and the TOPBV flag will be cleared. This prevents TIMERN\_TOP register from being immediately updated by an existing valid TIMERN\_TOPB value during the next *update event*.

**Figure 18.5. TIMER TOP Value Update Functionality**

### 18.3.1.9 Quadrature Decoder

Quadrature Decoding mode is used to track motion and determine both rotation direction and position. The Quadrature Decoder uses two input channels that are 90 degrees out of phase (see [Figure 18.6 TIMER Quadrature Encoded Inputs on page 589](#)).

**Figure 18.6. TIMER Quadrature Encoded Inputs**

In the timer these inputs are tapped from the Compare/Capture channel 0 (Channel A) and 1 (Channel B) inputs before edge detection. The Timer/Counter then increments or decrements the counter, based on the phase relation between the two inputs. The Quadrature Decoder Mode supports two channels, but if a third channel (Z-terminal) is available, this can be connected to an external interrupt and trigger a counter reset from the interrupt service routine. By connecting a periodic signal from another timer as input capture on Compare/Capture Channel 2, it is also possible to calculate speed and acceleration.

**Note:** In Quadrature Decoder mode, overflow and underflow triggers an *update event*.

**Figure 18.7. TIMER Quadrature Decoder Configuration**

The Quadrature Decoder can be set in either X2 or X4 mode, which is configured in the QDM bit in TIMERN\_CTRL. See [Figure 18.7 TIMER Quadrature Decoder Configuration on page 589](#)

### 18.3.1.10 X2 Decoding Mode

In X2 Decoding mode, the counter increments or decrements on every edge of Channel A, see [Table 18.1 TIMER Counter Response in X2 Decoding Mode on page 590](#) and [Figure 18.8 TIMER X2 Decoding Mode on page 590](#).

**Table 18.1. TIMER Counter Response in X2 Decoding Mode**

| Channel B | Channel A |           |
|-----------|-----------|-----------|
|           | Rising    | Falling   |
| 0         | Increment | Decrement |
| 1         | Decrement | Increment |

**Figure 18.8. TIMER X2 Decoding Mode**

### 18.3.1.11 X4 Decoding Mode

In X4 Decoding mode, the counter increments or decrements on every edge of Channel A and Channel B, see [Figure 18.9 TIMER X4 Decoding Mode on page 590](#) and [Table 18.2 TIMER Counter Response in X4 Decoding Mode on page 590](#).

**Table 18.2. TIMER Counter Response in X4 Decoding Mode**

| Opposite Channel | Channel A |           | Channel B |           |
|------------------|-----------|-----------|-----------|-----------|
|                  | Rising    | Falling   | Rising    | Falling   |
| Channel A = 0    |           |           | Decrement | Increment |
| Channel A = 1    |           |           | Increment | Decrement |
| Channel B = 0    | Increment | Decrement |           |           |
| Channel B = 1    | Decrement | Increment |           |           |

**Figure 18.9. TIMER X4 Decoding Mode**

### 18.3.1.12 TIMER Rotational Position

To calculate a position [Figure 18.10 TIMER Rotational Position Equation on page 591](#) can be used.

$$\text{pos}^\circ = (\text{CNT}/X \times N) \times 360^\circ$$

**Figure 18.10. TIMER Rotational Position Equation**

where X = Encoding type and N = Number of pulses per revolution.

### 18.3.2 Compare/Capture Channels

The timer contains 3 Compare/Capture channels, which can be configured in the following modes:

1. Input Capture
2. Output Compare
3. PWM

#### 18.3.2.1 Input Pin Logic

Each Compare/Capture channel can be configured as an input source for the Capture Unit or as external clock source for the timer (see [Figure 18.11 TIMER Input Pin Logic on page 591](#)). Compare/Capture channels 0 and 1 are the inputs for the Quadrature Decoder Mode. The input channel can be filtered before it is used, which requires the input to remain stable for 5 cycles in a row before the input is propagated to the output.

**Figure 18.11. TIMER Input Pin Logic**

#### 18.3.2.2 Compare/Capture Registers

The Compare/Capture channel registers are prefixed with `TIMERn_CCx_`, where the x stands for the channel number. Since the Compare/Capture channels serve three functions (input capture, compare, PWM), the behavior of the Compare/Capture registers (`TIMERn_CCx_CCV`) and buffer registers (`TIMERn_CCx_CCVB`) change depending on the mode the channel is set in.

### 18.3.2.3 Input Capture

In Input Capture Mode, the counter value (TIMERN\_CNT) can be captured in the Compare/Capture Register (TIMERN\_CCx\_CCV) (see [Figure 18.12 TIMER Input Capture on page 592](#)). The CCPOL bits in TIMERN\_STATUS indicate the polarity of the edge that triggered the capture in TIMERN\_CCx\_CCV.

**Figure 18.12. TIMER Input Capture**

The Compare/Capture Buffer Register (TIMERN\_CCx\_CCVB) and the TIMERN\_CCx\_CCV register form double-buffered capture registers allowing two subsequent capture events to take place before a read-out is required. The first capture can always be read from TIMERN\_CCx\_CCV, and reading this address will load the next capture value into TIMERN\_CCx\_CCV from TIMERN\_CCx\_CCVB if it contains valid data. The CC value can be read without altering the FIFO contents by reading TIMERN\_CCx\_CCVP. TIMERN\_CCx\_CCVB can also be read without altering the FIFO contents. The ICV flag in TIMERN\_STATUS indicates if there is a valid unread capture in TIMERN\_CCx\_CCV. In this mode, TIMERN\_CCx\_CCV is read-only.

In the case where a capture is triggered while both TIMERN\_CCx\_CCV and TIMERN\_CCx\_CCVB contain unread capture values, the buffer overflow interrupt flag (ICBOF in TIMERN\_IF) will be set. On overflow new capture values will overwrite the value in TIMERN\_CCx\_CCVB and the value of TIMERN\_CCx\_CCV will remain unchanged. TIMERN\_CCx\_CCV will always contain the oldest unread value and TIMERN\_CCx\_CCVB will always contain the newest value.

**Note:** In input capture mode, the timer will only trigger interrupts when it is running.

### 18.3.2.4 Period/Pulse-Width Capture

Period and/or pulse-width capture can only be possible with Channel 0 (CC0), because this is the only channel that can start and stop the timer. This can be done by setting the RISEA field in TIMERN\_CTRL to Clear&Start, and select the wanted input from either external pin or PRS, see [Figure 18.13 TIMER Period and/or Pulse width Capture on page 593](#). For period capture, the Compare/Capture Channel should then be set to input capture on a rising edge of the same input signal. To capture the width of a high pulse, the Compare/Capture Channel should be set to capture on a falling edge of the input signal. To measure the low pulse-width of a signal, opposite polarities should be chosen.

**Figure 18.13. TIMER Period and/or Pulse width Capture**

### 18.3.2.5 Compare

Each Compare/Capture channel contains a comparator which outputs a compare match if the contents of `TIMERn_CCx_CCV` matches the counter value, see [Figure 18.14 TIMER Block Diagram Showing Comparison Functionality on page 594](#). In compare mode, each compare channel can be configured to either set, clear or toggle the output on an event (compare match, overflow or underflow). The output from each channel is represented as an alternative function on the port it is connected to, which needs to be enabled for the CC outputs to propagate to the pins.

**Figure 18.14. TIMER Block Diagram Showing Comparison Functionality**

The compare output is delayed by one cycle to allow for full 0% to 100% PWM generation. If occurring in the same cycle, match action will have priority over overflow or underflow action.

The input selected (through `PRSEL`, `INSEL` and `FILTSEL` in `TIMERn_CCx_CTRL`) for the CC channel will also be sampled on compare match and the result is found in the `CCPOL` bits in `TIMERn_STATUS`. It is also possible to configure the `CCPOL` to always track the inputs by setting `ATI` in `TIMERn_CTRL`.

The `COIST` bit in `TIMERn_CCx_CTRL` is the initial state of the compare/PWM output. The `COIST` bit can also be used as an initial value to the compare outputs on a reload-start when `RSSCOIST` is set in `TIMERn_CTRL`. Also the resulting output can be inverted by setting `OUTINV` in `TIMERn_CCx_CTRL`. It is recommended to turn off the CC channel before configuring the output state to avoid any pulses on the output. The CC channel can be turned off by setting `MODE` to `OFF` in `TIMERn_CCx_CTRL`. The following figure shows the output logic for the TIMER module.

**Figure 18.15. TIMER Output Logic**

### 18.3.2.6 Compare Mode Registers

When running in Output Compare or PWM mode, the value in `TIMERN_CCx_CCV` will be compared against the count value. In Compare mode the output can be configured to toggle, clear or set on compare match, overflow, and underflow through the `CMOA`, `COFOA` and `CUFOA` fields in `TIMERN_CCx_CTRL`. `TIMERN_CCx_CCV` can be accessed directly or through the buffer register `TIMERN_CCx_CCVB`, see [Figure 18.16 TIMER Output Compare/PWM Buffer Functionality Detail on page 595](#). When writing to the buffer register, the value in `TIMERN_CCx_CCVB` will be written to `TIMERN_CCx_CCV` on the next *update event*. This functionality ensures glitch free PWM outputs. The `CCVBV` flag in `TIMERN_STATUS` indicates whether the `TIMERN_CCx_CCVB` register contains data that has not yet been written to the `TIMERN_CCx_CCV` register. Note that when writing 0 to `TIMERN_CCx_CCVB` in up-down count mode the `CCV` value is updated when the timer counts from 0 to 1. Thus, the compare match for the next period will not happen until the timer reaches 0 again on the way down.

**Figure 18.16. TIMER Output Compare/PWM Buffer Functionality Detail**

### 18.3.2.7 Frequency Generation (FRG)

Frequency generation (see [Figure 18.17 TIMER Up-count Frequency Generation on page 596](#)) can be achieved in compare mode by:

- Setting the counter in up-count mode
- Enabling buffering of the TOP value.
- Setting the CC channels overflow action to toggle

**Figure 18.17. TIMER Up-count Frequency Generation**

The output frequency is given by [Figure 18.18 TIMER Up-count Frequency Generation Equation on page 596](#)

$$f_{FRG} = f_{HPERCLK} / (2^{(PRESC + 1)} \times (TOP + 1) \times 2)$$

**Figure 18.18. TIMER Up-count Frequency Generation Equation**

The figure below provides cycle accurate timing and event generation information for frequency generation.

**Figure 18.19. TIMER Up-count Frequency Generation Detail**

### 18.3.2.8 Pulse-Width Modulation (PWM)

In PWM mode, TIMERN\_CCx\_CCV is buffered to avoid glitches in the output. The settings in the Compare Output Action configuration bits are ignored in PWM mode and PWM generation is only supported for up-count and up/down-count mode.

### 18.3.2.9 Up-count (Single-slope) PWM

If the counter is set to up-count and the Compare/Capture channel is put in PWM mode, single slope PWM output will be generated (see [Figure 18.20 TIMER Up-count PWM Generation on page 597](#)). In up-count mode the PWM period is TOP+1 cycles and the PWM output will be high for a number of cycles equal to TIMERN\_CCx\_CCV. This means that a constant high output is achieved by setting TIMERN\_CCx\_CCV to TOP+1 or higher. The PWM resolution (in bits) is then given by [Figure 18.21 TIMER Up-count PWM Resolution Equation on page 597](#).

**Figure 18.20. TIMER Up-count PWM Generation**

$$R_{PWM_{up}} = \log(TOP+1)/\log(2)$$

**Figure 18.21. TIMER Up-count PWM Resolution Equation**

The PWM frequency is given by [Figure 18.22 TIMER Up-count PWM Frequency Equation on page 597](#):

$$f_{PWM_{up/down}} = f_{HPERCLK} / (2^{\text{PRESC}} \times (TOP + 1))$$

**Figure 18.22. TIMER Up-count PWM Frequency Equation**

The high duty cycle is given by [Figure 18.23 TIMER Up-count Duty Cycle Equation on page 597](#)

$$DS_{up} = CCVx/(TOP+1)$$

**Figure 18.23. TIMER Up-count Duty Cycle Equation**

The figure below provides cycle accurate timing and event generation information for up-count mode.

**Figure 18.24. TIMER Up-count PWM Generation Detail**

### 18.3.2.10 2x Count Mode (Up-count)

When the timer is set in 2x mode, the TIMER will count up by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in [Figure 18.25 TIMER CC out in 2x mode on page 598](#)

**Figure 18.25. TIMER CC out in 2x mode**

The PWM resolution is given by [Figure 18.26 TIMER 2x PWM Resolution Equation on page 598](#).

$$R_{PWM_{2xmode}} = \log(TOP/2+1)/\log(2)$$

**Figure 18.26. TIMER 2x PWM Resolution Equation**

The PWM frequency is given by [Figure 18.27 TIMER 2x Mode PWM Frequency Equation\( Up-count\) on page 598](#):

$$f_{PWM_{2xmode}} = f_{HCLK} / (\text{floor}(TOP/2)+1)$$

**Figure 18.27. TIMER 2x Mode PWM Frequency Equation( Up-count)**

The high duty cycle is given by [Figure 18.28 TIMER 2x Mode Duty Cycle Equation on page 598](#)

$$DS_{2xmode} = CCVx/((\text{floor}(TOP/2)+1)*2)$$

**Figure 18.28. TIMER 2x Mode Duty Cycle Equation**

### 18.3.2.11 Up/Down-count (Dual-slope) PWM

If the counter is set to up-down count and the Compare/Capture channel is put in PWM mode, dual slope PWM output will be generated by [Figure 18.29 TIMER Up/Down-count PWM Generation on page 599](#). The resolution (in bits) is given by [Figure 18.30 TIMER Up/Down-count PWM Resolution Equation on page 599](#).

**Figure 18.29. TIMER Up/Down-count PWM Generation**

$$R_{PWM_{up/down}} = \log(TOP+1)/\log(2)$$

**Figure 18.30. TIMER Up/Down-count PWM Resolution Equation**

The PWM frequency is given by [Figure 18.31 TIMER Up/Down-count PWM Frequency Equation on page 599](#):

$$f_{PWM_{up/down}} = f_{HFPERCLK} / (2^{(PRESC+1)} \times TOP)$$

**Figure 18.31. TIMER Up/Down-count PWM Frequency Equation**

The high duty cycle is given by [Figure 18.32 TIMER Up/Down-count Duty Cycle Equation on page 599](#)

$$DS_{up/down} = CCVx/TOP$$

**Figure 18.32. TIMER Up/Down-count Duty Cycle Equation**

The figure below provides cycle accurate timing and event generation information for up-count mode.

**Figure 18.33. TIMER Up/Down-count PWM Generation**

### 18.3.2.12 2x Count Mode (Up/Down-count)

When the timer is set in 2x mode, the TIMER will count up/down by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in [Figure 18.34 TIMER CC out in 2x mode on page 600](#)

**Figure 18.34. TIMER CC out in 2x mode**

[Figure 18.35 TIMER 2x PWM Resolution Equation on page 600.](#)

$$R_{PWM_{2xmode}} = \log(TOP/2+1)/\log(2)$$

**Figure 18.35. TIMER 2x PWM Resolution Equation**

The PWM frequency is given by [Figure 18.36 TIMER 2x Mode PWM Frequency Equation\( Up/Down-count\) on page 600](#):

$$f_{PWM_{2xmode}} = f_{HCLK} / (\text{floor}(TOP/2)*2)$$

**Figure 18.36. TIMER 2x Mode PWM Frequency Equation( Up/Down-count)**

The high duty cycle is given by two equations based on the CCVx values. [Figure 18.37 TIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = even on page 600](#) and [Figure 18.38 TIMER 2x Mode Duty Cycle Equation for all other CCVx = odd values on page 600](#)

$$DS_{2xmode} = (CCVx*2)/(\text{floor}(TOP/2)*4)$$

**Figure 18.37. TIMER 2x Mode Duty Cycle Equation for CCVx = 1 or CCVx = even**

$$DS_{2xmode} = (CCVx*2 - CCVx)/(\text{floor}(TOP/2)*4)$$

**Figure 18.38. TIMER 2x Mode Duty Cycle Equation for all other CCVx = odd values**

### 18.3.2.13 Timer Configuration Lock

To prevent software errors from making changes to the timer configuration, a configuration lock is available similar to DTI configuration Lock. Writing any value but 0xCE80 to LOCKKEY in TIMERN\_LOCK results in TIMERN\_CTRL, TIMERN\_CMD, TIMERN\_TOP, TIMERN\_CNT, TIMERN\_CCx\_CTRL and TIMERN\_CCx\_CCV being locked from writing. To unlock the registers, write 0xCE80 to LOCKKEY in TIMERN\_LOCK. The value of TIMERN\_LOCK is 1 when the lock is active, and 0 when the registers are unlocked.

### 18.3.3 Dead-Time Insertion Unit

Some of the timers include a Dead-Time Insertion module suitable for motor control applications. Refer to the device data sheet to check if a timer has this feature. The example settings in this section are for TIMER0, but identical settings can be used for other timers with DTI as well. The Dead-Time Insertion Unit aims to make control of brushless DC (BLDC) motors safer and more efficient by introducing complementary PWM outputs with dead-time insertion and fault handling, see [Figure 18.39 TIMER Dead-Time Insertion Unit Overview on page 601](#).

**Figure 18.39. TIMER Dead-Time Insertion Unit Overview**

When used for motor control, the PWM outputs TIM0\_CC0, TIM0\_CC1 and TIM0\_CC2 are often connected to the high-side transistors of a triple half-bridge setup (UH, VH and WH), and the complementary outputs connected to the respective low-side transistors (UL, VL, WL shown in [Figure 18.40 TIMER Triple Half-Bridge on page 601](#)). Transistors used in such a bridge often do not open/close instantaneously, and using the exact complementary inputs for the high and low side of a half-bridge may result in situations where both gates are open. This can give unnecessary current-draw and short circuit the power supply. The DTI unit provides dead-time insertion to deal with this problem.

**Figure 18.40. TIMER Triple Half-Bridge**

For each of the 3 compare-match outputs of TIMER0, an additional complementary output is provided by the DTI unit. These outputs, named TIM0\_CDTI0, TIM0\_CDTI1 and TIM0\_CDTI2 are provided to make control of e.g. 3-channel BLDC or permanent magnet AC (PMAC) motors possible using only a single timer, see [Figure 18.41 TIMER Overview of Dead-Time Insertion Block for a Single PWM channel on page 602](#).

**Figure 18.41. TIMER Overview of Dead-Time Insertion Block for a Single PWM channel**

The DTI unit is enabled by setting DTEN in `TIMER0_DTCTRL`. In addition to providing the complementary outputs, the DTI unit then also overrides the compare match outputs from the timer.

The DTI unit gives the rising edges of the PWM outputs and the rising edges of the complementary PWM outputs a configurable time delay. By doing this, the DTI unit introduces a dead-time where both the primary and complementary outputs in a pair are inactive as seen in [Figure 18.42 TIMER Polarity of Both Signals are Set as Active-High on page 602](#).

**Figure 18.42. TIMER Polarity of Both Signals are Set as Active-High**

Dead-time is specified individually for the rising and falling edge of the original PWM. These values are shared across all the three PWM channels of the DTI unit. A single prescaler value is provided for the DTI unit, meaning that both the rising and falling edge dead-times share prescaler value. The prescaler divides the  $HFPERCLK_{TIMERn}$  by a configurable factor between 1 and 1024, which is set in the `DTPRESC` field in `TIMER0_DTTIME`. The rising and falling edge dead-times are configured in `DTRISSET` and `DTFALLT` in `TIMER0_DTTIME` to any number between 1-64  $HFPERCLK_{TIMER0}$  cycles.

The `DTAR` and `DTFATS` bits in `TIMER0_DTCTRL` control the DTI output behavior when the timer stops. By default the DTI block stops when the timer is stopped. Setting the `DTAR` bit will cause the DTI to output on channel 0 to continue when the timer is stopped. `DTAR` effects only channel 0. See [18.3.3.2 PRS Channel as a Source](#) for an example of when this can be used. While in this mode the undivided  $HFPERCLK_{TIMER0}$  (`DTPRESC=0`) is always used regardless of programmed `DTPRESC` value in `TIMER0_DTTIME`. This means that rise and fall dead times are calculated assuming `DTPRESC = 0`.

When the timer stops DTI outputs are frozen by default, preserving their last state. To allow the outputs to go to a safe state as programmed in the `DTFA` field of `TIMER0_DTFC` register and set the `DTFATS` bitfield in the `TIMER0_DTCTRL` reg. Note that when `DTAR` is also set, `DTAR` has priority over `DTFATS` for DTI channel 0 output.

The following table shows the DTI output when the timer is halted.

**Table 18.3. DTI Output When Timer Halted**

| DTAR | DTFATS | State   |
|------|--------|---------|
| 0    | 0      | frozen  |
| 0    | 1      | safe    |
| 1    | 0      | running |
| 1    | 1      | running |

### 18.3.3.1 Output Polarity

The value of the primary and complementary outputs in a pair will never be set active at the same time by the DTI unit. The polarity of the outputs can be changed if this is required by the application. The active values of the primary and complementary outputs are set by the DTIPOL and DTCINV bits in the `TIMER0_DTCTRL` register. The DTIPOL bit of this register specifies the base polarity. If DTIPOL = 0, then the outputs are active-high, and if DTIPOL = 1 they are active-low. The relative phase of the primary and complementary outputs is not changed by DTIPOL, as the polarity of both outputs is changed, see [Figure 18.43 TIMER Output Polarities on page 603](#).

In some applications, it may be required that the primary outputs are active-high, while the complementary outputs are active-low. This can be accomplished by manipulating the DTCINV bit of the `TIMER0_DTCTRL` register, which inverts the polarity of the complementary outputs relative to the primary outputs. As an example, DTIPOL = 0 and DTCINV = 0 results in outputs with opposite phase and active-high states. Similarly, DTIPOL = 1 and DTCINV = 1 results in outputs with equal phase and the primary output will be active-high while the complementary will be active-low.

**Figure 18.43. TIMER Output Polarities**

Output generation on the individual DTI outputs can be disabled by configuring `TIMER0_DTOGEN`. When output generation on an output is disabled that output will go to and stay in its inactive state.

### 18.3.3.2 PRS Channel as a Source

A PRS channel can be used as input to the DTI module instead of the PWM output from the timer for DTI channel 0. Setting DTPRSEN in `TIMER0_DTCTRL` will override the source of the first DTI channel, driving `TIM0_CC0` and `TIM0_CDTI0`, with the value on the PRS channel. The rest of the DTI channels will continue to be driven by the PWM output from the timer. The input PRS channel is chosen by configuring `DTPRSSEL` in `TIMER0_DTCTRL`. Note that the timer must be running even when PRS is used as DTI source. However, if it is required to keep the DTI channel 0 running even when the timer is stopped, set `DTAR` in `TIMER0_DTCTRL`. When this bit is set, it uses `DTPRESC=0` regardless of the value programmed in `DTPRESC` in `TIMER0_DTTIME`.

The DTI prescaler, set by `DTPRESC` in `TIMER0_DTTIME` determines the accuracy with which the DTI can insert dead-time into a PRS signal. The maximum dead-time error equals  $2^{DTPRESC}$  clock cycles. With zero prescaling, the inserted dead-times are therefore accurate, but they may be inaccurate for larger prescaler settings.

### 18.3.3.3 Fault Handling

The fault handling system of the DTI unit allows the outputs of the DTI unit to be put in a well-defined state in case of a fault. This hardware fault handling system enables a fast reaction to faults, reducing the possibility of damage to the system.

The fault sources which trigger a fault in the DTI module are determined by the bitfields of `TIMER0_DTFC` register. Any combination of the available error sources can be selected:

- PRS source 0, determined by `DTPRS0FSEL` in `TIMER0_DTFC`
- PRS source 1, determined by `DTPRS1FSEL` in `TIMER0_DTFC`
- Debugger
- Core Lockup

One or two PRS channels can be used as an error source. When PRS source 0 is selected as an error source, `DTPRS0FSEL` determines which PRS channel is used for this source. `DTPRS1FSEL` determines which PRS channel is selected as PRS source 1. Note that for Core Lockup, the `LOCKUPRDIS` in `RMU_CTRL` must be set. Otherwise this will generate a full reset of the chip.

### 18.3.3.4 Action on Fault

When a fault occurs, the bit representing the fault source is set in `TIMER0_DTFault` register, and the outputs from the DTI unit are set to a well-defined state. The following options are available, and can be enabled by configuring `DTFACT` in `TIMER0_DTFC`:

- Set outputs to inactive level
- Clear outputs
- Tristate outputs

With the first option enabled, the output state in case of a fault depends on the polarity settings for the individual outputs. An output set to be active high will be set low if a fault is detected, while an output set to be active low will be driven high.

When a fault occurs, the fault source(s) can be read out from `TIMER0_DTFault` register.

Additionally a fault action can also be triggered when the timer stops if `DTFATS` in `TIMER0_DTCTRL` is set. This allows the DTI output to go to safe state programmed in `DTFACT` in `TIMER0_DTFC` when timer stops. When `DTAR` and `DTFATS` in `TIMER0_DTCTRL` are both set, DTI channel 0 keeps running even when the timer stops. This is useful when DTI channel 0 has an input coming from PRS.

### 18.3.3.5 Exiting Fault State

When a fault is triggered by the PRS system, software intervention is required to re-enable the outputs of the DTI unit. This is done by manually clearing bits in `TIMER0_DTFault` register. If the fault source as determined by checking `TIMER0_DEFAULT` is the debugger alone, the outputs can be automatically restarted when the debugger exits. To enable automatic restart set `DTDAS` in `TIMER0_DCTRL`. When an automatic restart occurs the `DTDBGF` bit in `TIMER0_DTFault` will be automatically cleared by hardware. If any other bits in the `TIMER0_DTFault` register are set when the hardware clears `DTDBGF` the DTI module will not exit the fault state.

### 18.3.3.6 DTI Configuration Lock

To prevent software errors from making changes to the DTI configuration, a configuration lock is available. Writing any value but `0xCE80` to `LOCKKEY` in `TIMER0_DTLOCK` results in `TIMER0_DTFC`, `TIMER0_DTCTRL`, `TIMER0_DTTIME` and `TIMER0_ROUTE` being locked from writing. To unlock the registers, write `0xCE80` to `LOCKKEY` in `TIMER0_DTLOCK`. The value of `TIMER0_DTLOCK` is 1 when the lock is active, and 0 when the registers are unlocked.

### 18.3.4 Debug Mode

When the CPU is halted in debug mode, the timer can be configured to either continue to run or to be frozen. This is configured in `DEBUGRUN` in `TIMERN_CTRL`.

### 18.3.5 Interrupts, DMA and PRS Output

The timer has 3 different types of output events:

- Counter Underflow
- Counter Overflow
- Compare match or input capture (one per Compare/Capture channel)

Each of the events has its own interrupt flag. Also, there is one interrupt flag for each Compare/Capture channel which is set on buffer overflow in capture mode. Buffer overflow happens when a new capture pushes an old unread capture out of the `TIMERN_CCx_CCV/TIMERN_CCx_CCVB` register pair.

If the interrupt flags are set and the corresponding interrupt enable bits in `TIMERN_IEN` are set high, the timer will send out an interrupt request. Each of the events will also lead to a one `HPPERCLKTIMERN` cycle high pulse on individual PRS outputs. Setting `PRSOCNF` to `LEVEL` in `TIMERN_CCx_CTRL` will make the compare match PRS output follow the compare match output, instead of outputting one `HPPERCLKTIMERN` cycle high pulse. Interrupts are cleared by setting the corresponding bit in the `TIMERN_IFC` register.

Each of the events will also set a DMA request when they occur. The different DMA requests are cleared when certain acknowledge conditions are met, see [Table 18.4 TIMER DMA Events on page 605](#). Events which clear the DMA requests do not clear interrupt flags. Software must still manually clear the interrupt flag if interrupts are in use.

If `DMACLRACT` is set in `TIMERN_CTRL`, the DMA request is cleared when the triggered DMA channel is active, without having to access any timer registers. This is useful in cases where a timer event is used to trigger a DMA transfer that does not target the CCV or CCVB register.

**Table 18.4. TIMER DMA Events**

| Event              | Acknowledge/Clear                                                            |
|--------------------|------------------------------------------------------------------------------|
| Underflow/Overflow | Read or write to <code>TIMERN_CNT</code> or <code>TIMERN_TOPB</code>         |
| CC 0               | Read or write to <code>TIMERN_CC0_CCV</code> or <code>TIMERN_CC0_CCVB</code> |
| CC 1               | Read or write to <code>TIMERN_CC1_CCV</code> or <code>TIMERN_CC1_CCVB</code> |
| CC 2               | Read or write to <code>TIMERN_CC2_CCV</code> or <code>TIMERN_CC2_CCVB</code> |

### 18.3.6 GPIO Input/Output

The `TIMn_CCx` inputs/outputs and `TIM0_CDTIx` outputs are accessible as alternate functions through GPIO. Each pin connection can be enabled/disabled separately by setting the corresponding `CCxPEN` or `CDTIxPEN` bits in `TIMERN_ROUTE`. The `LOCATION` bits in the same register can be used to move all enabled pins to alternate pins. See the device data sheet for the mapping between block locations (`LOC0`, `LOC1`, etc.) and actual device pins (`PA0`, `PA1`, etc.).

## 18.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name             | Type   | Description                           |
|--------|------------------|--------|---------------------------------------|
| 0x000  | TIMERN_CTRL      | RW     | Control Register                      |
| 0x004  | TIMERN_CMD       | W1     | Command Register                      |
| 0x008  | TIMERN_STATUS    | R      | Status Register                       |
| 0x00C  | TIMERN_IF        | R      | Interrupt Flag Register               |
| 0x010  | TIMERN_IFS       | W1     | Interrupt Flag Set Register           |
| 0x014  | TIMERN_IFC       | (R)W1  | Interrupt Flag Clear Register         |
| 0x018  | TIMERN_IEN       | RW     | Interrupt Enable Register             |
| 0x01C  | TIMERN_TOP       | RWH    | Counter Top Value Register            |
| 0x020  | TIMERN_TOPB      | RW     | Counter Top Value Buffer Register     |
| 0x024  | TIMERN_CNT       | RWH    | Counter Value Register                |
| 0x02C  | TIMERN_LOCK      | RWH    | TIMER Configuration Lock Register     |
| 0x030  | TIMERN_ROUTEPEN  | RW     | I/O Routing Pin Enable Register       |
| 0x034  | TIMERN_ROUTELOC0 | RW     | I/O Routing Location Register         |
| 0x03C  | TIMERN_ROUTELOC2 | RW     | I/O Routing Location Register         |
| 0x060  | TIMERN_CC0_CTRL  | RW     | CC Channel Control Register           |

## 19. LETIMER - Low Energy Timer

### Quick Facts

#### What?

The LETIMER is a down-counter that can keep track of time and output configurable waveforms. Running on a 32768 Hz clock, the LETIMER is available in EM0 Active, EM1 Sleep, EM2 DeepSleep, and EM3 Stop.

#### Why?

The LETIMER can be used to provide repeatable waveforms to external components while remaining in EM2 DeepSleep. It is well suited for applications such as metering systems or to provide more compare values than available in the RTC.

#### How?

With buffered repeat and top value registers, the LETIMER can provide glitch-free waveforms at frequencies up to 16 kHz. It can be coupled with RTC using PRS, allowing advanced time-keeping and wake-up functions in EM2 DeepSleep and EM3 Stop.

### 19.1 Introduction

The unique LETIMER™, the Low Energy Timer, is a 16-bit timer that is available in energy mode EM0 Active, EM1 Sleep, EM2 DeepSleep, and EM3 Stop. Because of this, it can be used for timing and output generation when most of the device is powered down, allowing simple tasks to be performed while the power consumption of the system is kept at an absolute minimum.

The LETIMER can be used to output a variety of waveforms with minimal software intervention. It can also be connected to the Real Time Counter (RTC) using PRS, and can be configured to start counting on compare matches from the RTC.

### 19.2 Features

- 16-bit down count timer
- 2 Compare match registers
- Compare register 0 can be top timer top value
- Compare registers can be double buffered
- Double buffered 8-bit Repeat Register
- Same clock source as the Real Time Counter
- LETIMER can be triggered (started) by an RTC event via PRS or by software
- LETIMER can be started, stopped, and/or cleared by PRS
- 2 output pins can optionally be configured to provide different waveforms on timer underflow:
  - Toggle output pin
  - Apply a positive pulse (pulse width of one  $LFACLK_{LETIMER}$  period)
  - PWM
- Interrupt on:
  - Compare matches
  - Timer underflow
  - Repeat done
- Optionally runs during debug
- PRS Output

### 19.3 Functional Description

An overview of the LETIMER module is shown in [Figure 19.1 LETIMER Overview on page 647](#). The LETIMER is a 16-bit down-counter with two compare registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. The LETIMERn\_COMP0 register can optionally act as a top value for the counter. The repeat counter LETIMERn\_REP0 allows the timer to count a specified number of times before it stops. Both the LETIMERn\_COMP0 and LETIMERn\_REP0 registers can be double buffered by the LETIMERn\_COMP1 and LETIMERn\_REP1 registers to allow continuous operation. The timer can generate a single pin output, or two linked outputs.

Figure 19.1. LETIMER Overview

#### 19.3.1 Timer

The timer is started by setting command bit START in LETIMERn\_CMD, and stopped by setting the STOP command bit in the same register. RUNNING in LETIMERn\_STATUS is set as long as the timer is running. The timer can also be started on external signals, such as a compare match from the Real Time Counter. If START and STOP are set at the same time, STOP has priority, and the timer will be stopped.

The timer value can be read using the LETIMERn\_CNT register. The value can be written, and it can also be cleared by setting the CLEAR command bit in LETIMERn\_CMD. If the CLEAR and START commands are issued at the same time, the timer will be cleared, then start counting at the top value.

#### 19.3.2 Compare Registers

The LETIMER has two compare match registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. Each of these compare registers is capable of generating an interrupt when the counter value LETIMERn\_CNT becomes equal to their value. When LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP0, the interrupt flag COMP0 in LETIMERn\_IF is set, and when LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP1, the interrupt flag COMP1 in LETIMERn\_IF is set.

### 19.3.3 Top Value

If COMP0TOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 acts as the top value of the timer, and LETIMERn\_COMP0 is loaded into LETIMERn\_CNT on timer underflow. If COMP0TOP is cleared to 0, the timer wraps around to 0xFFFF. The underflow interrupt flag UF in LETIMERn\_IF is set when the timer reaches zero.

#### 19.3.3.1 Buffered Top Value

If BUFTOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 is buffered by LETIMERn\_COMP1. In this mode, the value of LETIMERn\_COMP1 is loaded into LETIMERn\_COMP0 every time LETIMERn\_REP0 is about to decrement to 0. This can for instance be used in conjunction with the buffered repeat mode to generate continually changing output waveforms.

Write operations to LETIMERn\_COMP0 have priority over buffer loads.

#### 19.3.3.2 Repeat Modes

By default, the timer wraps around to the top value or 0xFFFF on each underflow, and continues counting. The repeat counters can be used to get more control of the operation of the timer, including defining the number of times the counter should wrap around. Four different repeat modes are available, see [Table 19.1 LETIMER Repeat Modes on page 648](#).

**Table 19.1. LETIMER Repeat Modes**

| REPMODE | Mode         | Description                                                                                                                                                                                                                |
|---------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b00    | Free-running | The timer runs until it is stopped.                                                                                                                                                                                        |
| 0b01    | One-shot     | The timer runs as long as LETIMERn_REP0 != 0. LETIMERn_REP0 is decremented at each timer underflow.                                                                                                                        |
| 0b10    | Buffered     | The timer runs as long as LETIMERn_REP0 != 0. LETIMERn_REP0 is decremented on each timer underflow. If LETIMERn_REP1 has been written, it is loaded into LETIMERn_REP0 when LETIMERn_REP0 is about to be decremented to 0. |
| 0b11    | Double       | The timer runs as long as LETIMERn_REP0 != 0 or LETIMERn_REP1 != 0. Both LETIMERn_REP0 and LETIMERn_REP1 are decremented at each timer underflow.                                                                          |

The interrupt flags REP0 and REP1 in LETIMERn\_IF are set whenever LETIMERn\_REP0 or LETIMERn\_REP1 are decremented to 0 respectively. REP0 is also set when the value of LETIMERn\_REP1 is loaded into LETIMERn\_REP0 in buffered mode.

### 19.3.3.3 Free-Running Mode

In free-running mode, the LETIMER acts as a regular timer and the repeat counter is disabled. When started, the timer runs until it is stopped using the STOP command bit in LETIMERn\_CMD. A state machine for this mode is shown in [Figure 19.2 LETIMER State Machine for Free-running Mode on page 649](#).

**Figure 19.2. LETIMER State Machine for Free-running Mode**

Note that the CLEAR command bit in LETIMERn\_CMD always has priority over other changes to LETIMERn\_CNT. When the clear command is used, LETIMERn\_CNT is set to 0 and an underflow event will not be generated when LETIMERn\_CNT wraps around to the top value or 0xFFFF. Since no underflow event is generated, no output action is performed. LETIMERn\_REP0, LETIMERn\_REP1, LETIMERn\_COMP0 and LETIMERn\_COMP1 are also left untouched.

### 19.3.3.4 One-shot Mode

The one-shot repeat mode is the most basic repeat mode. In this mode, the repeat register LETIMERn\_REP0 is decremented every time the timer underflows, and the timer stops when LETIMERn\_REP0 goes from 1 to 0. In this mode, the timer counts down LETIMERn\_REP0 times, i.e. the timer underflows LETIMERn\_REP0 times.

**Note:** Write operations to LETIMERn\_REP0 have priority over the timer decrement event. If LETIMERn\_REP0 is assigned a new value in the same cycle as a timer decrement event occurs, the timer decrement will not occur and the new value is assigned.

LETIMERn\_REP0 can be written while the timer is running to allow the timer to run for longer periods at a time without stopping. [Figure 19.3 LETIMER One-shot Repeat State Machine on page 650](#).

Figure 19.3. LETIMER One-shot Repeat State Machine

#### 19.3.3.5 Buffered Mode

The Buffered repeat mode allows buffered timer operation. When started, the timer runs LETIMERNn\_REP0 number of times. If LETIMERNn\_REP1 has been written since the last time it was used and it is nonzero, LETIMERNn\_REP1 is then loaded into LETIMERNn\_REP0, and counting continues the new number of times. The timer keeps going as long as LETIMERNn\_REP1 is updated with a nonzero value before LETIMERNn\_REP0 is finished counting down. The timer top value (LETIMERNn\_COMP0) may also optionally be buffered by setting BUFTOP in LETIMERNn\_CTRL.

If the timer is started when both LETIMERn\_CNT and LETIMERn\_REP0 are zero but LETIMERn\_REP1 is non-zero, LETIMERn\_REP1 is loaded into LETIMERn\_REP0, and the counter counts the loaded number of times.

Used in conjunction with a buffered top value, both the top and repeat values of the timer may be buffered, and the timer can for instance be set to run 4 times with period 7 (top value 6), 6 times with period 200, then 3 times with period 50.

A state machine for the buffered repeat mode is shown in [Figure 19.4 LETIMER Buffered Repeat State Machine on page 651](#). REP1<sub>USED</sub> shown in the state machine is an internal variable that keeps track of whether the value in LETIMERn\_REP1 has been loaded into LETIMERn\_REP0 or not. The purpose of this is that a value written to LETIMERn\_REP1 should only be counted once. REP1<sub>USED</sub> is cleared whenever LETIMERn\_REP1 is written.

**Figure 19.4. LETIMER Buffered Repeat State Machine**

### 19.3.3.6 Double Mode

The Double repeat mode works much like the one-shot repeat mode. The difference is that, where the one-shot mode counts as long as LETIMERn\_REP0 is larger than 0, the double mode counts as long as either LETIMERn\_REP0 or LETIMERn\_REP1 is larger than 0. As an example, say LETIMERn\_REP0 is 3 and LETIMERn\_REP1 is 10 when the timer is started. If no further interaction is done with the timer, LETIMERn\_REP0 will now be decremented 3 times, and LETIMERn\_REP1 will be decremented 10 times. The timer counts a total of 10 times, and LETIMERn\_REP0 is 0 after the first three timer underflows and stays at 0. LETIMERn\_REP0 and LETIMERn\_REP1 can be written at any time. After a write to either of these, the timer is guaranteed to underflow at least the written number of times if the timer is running. Use the Double repeat mode to generate output on both the LETIMER outputs at the same time. The state machine for this repeat mode can be seen in [Figure 19.5 LETIMER Double Repeat State Machine on page 652](#).

Figure 19.5. LETIMER Double Repeat State Machine

### 19.3.3.7 Clock Source

The LETIMER clock source and its prescaler value are defined in the Clock Management Unit (CMU). The LFACLK<sub>LETIMERn</sub> has a frequency given by [Figure 19.6 LETIMER Clock Frequency on page 652](#).

$$f_{\text{LFACKL\_LETIMERn}} = 32768/2^{\text{LETIMERn}}$$

Figure 19.6. LETIMER Clock Frequency

where the exponent LETIMERn is a 4 bit value in the CMU\_LFAPRESC0 register.

To use this module, the LE interface clock must be enabled in CMU\_HFBUSCLKEN0, in addition to the module clock.

### 19.3.3.8 PRS Input Triggers

The LETIMER can be configured to start, stop, and/or clear based on PRS inputs. The diagram showing the functions of the PRS input triggers is shown in [Figure 19.7 LETIMER PRS Input Triggers on page 653](#).

There are 12 PRS inputs to the LETIMER. PRSSTARTSEL, PRSSTOPSEL, and PRSCLEARSEL select which PRS inputs are used to start, stop, and/or clear the LETIMER. PRSSTARTMODE, PRSSTOPMODE, and PRSCLEARMODE select which edge or edge(s) can trigger the start, stop, and/or clear action. The PRSSTARTEN, PRSSTOPEN, and PRSCLEAREN signals shown in the diagram are derived from the PRSSTARTMODE, PRSSTOPMODE, and PRSCLEARMODE fields; if the corresponding bit field is set to NONE, the feature is disabled.

Figure 19.7. LETIMER PRS Input Triggers

### 19.3.3.9 Debug

If DEBUGRUN in LETIMERn\_CTRL is cleared, the LETIMER automatically stops counting when the CPU is halted during a debug session, and resumes operation when the CPU continues. Because of synchronization, the LETIMER is halted two clock cycles after the CPU is halted, and continues running two clock cycles after the CPU continues. RUNNING in LETIMERn\_STATUS is not cleared when the LETIMER stops because of a debug-session.

Set DEBUGRUN in LETIMERn\_CTRL to allow the LETIMER to continue counting even when the CPU is halted in debug mode.

### 19.3.4 Underflow Output Action

For each of the repeat registers, an underflow output action can be set. The configured output action is performed every time the counter underflows while the respective repeat register is nonzero. In PWM mode, the output is similarly only changed on COMP1 match if the repeat register is nonzero. As an example, the timer will perform 7 output actions if LETIMERN\_REP0 is set to 7 when starting the timer in one-shot mode and leaving it untouched.

The output actions can be set by configuring UFOA0 and UFOA1 in LETIMERN\_CTRL. UFOA0 defines the action on output 0, and is connected to LETIMERN\_REP0, while UFOA1 defines the action on output 1 and is connected to LETIMERN\_REP1. The possible actions are defined in [Table 19.2 LETIMER Underflow Output Actions on page 654](#).

**Table 19.2. LETIMER Underflow Output Actions**

| UF0A0/UF0A1 | Mode   | Description                                                                                                                            |
|-------------|--------|----------------------------------------------------------------------------------------------------------------------------------------|
| 0b00        | Idle   | The output is held at its idle value                                                                                                   |
| 0b01        | Toggle | The output is toggled on LETIMERN_CNT underflow if LETIMERN_REPx is nonzero                                                            |
| 0b10        | Pulse  | The output is held active for one clock cycle on LETIMERN_CNT underflow if LETIMERN_REPx is nonzero. It then returns to its idle value |
| 0b11        | PWM    | The output is set idle on LETIMERN_CNT underflow and active on compare match with LETIMERN_COMP1 if LETIMERN_REPx is nonzero.          |

**Note:**

- For the Pulse and PWM modes, the outputs will return to their idle states regardless of the state of the corresponding LETIMERN\_REPx registers. They will only be set active if the LETIMERN\_REPx registers are nonzero however.
- For free-running mode, LETIMERN\_REP0 != 0 for output generation to be enabled.

The polarity of the outputs can be set individually by configuring OPOL0 and OPOL1 in LETIMERN\_CTRL. When these are cleared, their respective outputs have a low idle value and a high active value. When they are set, the idle value is high, and the active value is low.

When using the toggle action, the outputs can be driven to their idle values by setting their respective CTO0/CTO1 command bits in LETIMERN\_CTRL. This can be used to put the output in a well-defined state before beginning to generate toggle output, which may be important in some applications. The command bit can also be used while the timer is running.

Some simple waveforms generated with the different output modes are shown in [Figure 19.8 LETIMER Simple Waveforms Output on page 655](#). For the example, REPMODE in LETIMERN\_CTRL has been cleared, COMP0TOP also in LETIMERN\_CTRL has been set and LETIMERN\_COMP0 has been written to 3. As seen in the figure, LETIMERN\_COMP0 now decides the length of the signal periods. For the toggle mode, the period of the output signal is  $2(\text{LETIMERN\_COMP0} + 1)$ , and for the pulse modes, the periods of the output signals are  $\text{LETIMERN\_COMP0} + 1$ . Note that the pulse outputs are delayed by one period relative to the toggle output. The pulses come at the end of their periods.

**Figure 19.8. LETIMER Simple Waveforms Output**

For the example in [Figure 19.9 LETIMER Repeated Counting on page 655](#), the One-shot repeat mode has been selected, and LETIMERn\_REP0 has been written to 3. The resulting behavior is pretty similar to that shown in Figure 6, but in this case, the timer stops after counting to zero LETIMERn\_REP0 times. By using LETIMERn\_REP0 the user has full control of the number of pulses/toggles generated on the output.

### Figure 19.9. LETIMER Repeated Counting

Using the Double repeat mode, output can be generated on both the LETIMER outputs. [Figure 19.10 LETIMER Dual Output on page 656](#) shows an example of this. UFOA0 and UFOA1 in LETIMERn\_CTRL are configured for pulse output and the outputs are configured for low idle polarity. As seen in the figure, the number written to the repeat registers determine the number of pulses generated on each of the outputs.

**Figure 19.10. LETIMER Dual Output**

### 19.3.5 PRS Output

The LETIMER outputs can be routed out onto the PRS system. Enabling the PRS connection can be done by setting SOURCESEL to LETIMERx and SIGSEL to LETIMERxCHn in PRS\_CHx\_CTRL. The PRS register description can be found in [13.5 Register Description](#)

### 19.3.6 Examples

This section presents a couple of usage examples for the LETIMER.

### 19.3.6.1 Triggered Output Generation

If both LETIMERN\_CNT and LETIMERN\_REP0 are 0 in buffered mode, and COMP0TOP and BUFTOP in LETIMERN\_CTRL are set, the values of LETIMERN\_COMP1 and LETIMERN\_REP1 are loaded into LETIMERN\_CNT and LETIMERN\_REP0 respectively when the timer is started. If no additional writes to LETIMERN\_REP1 are done before the timer stops, LETIMERN\_REP1 determines the number of pulses/toggles generated on the output, and LETIMERN\_COMP1 determines the period lengths.

As the RTC can be used via PRS to start the LETIMER, the RTC and LETIMER can thus be combined to generate specific pulse-trains at given intervals. Software can update LETIMERN\_COMP1 and LETIMERN\_REP1 to change the number of pulses and pulse-period in each train, but if changes are not required, software does not have to update the registers between each pulse train.

For the example in [Figure 19.11 LETIMER Triggered Operation on page 657](#), the initial values cause the LETIMER to generate two pulses with 3 cycle periods, or a single pulse 3 cycles wide every time the LETIMER is started. After the output has been generated, the LETIMER stops, and is ready to be triggered again.

### 19.3.6.2 Continuous Output Generation

In some scenarios, it might be desired to make LETIMER generate a continuous waveform. Very simple constant waveforms can be generated without the repeat counter as shown in [Figure 19.8 LETIMER Simple Waveforms Output on page 655](#), but to generate changing waveforms, using the repeat counter and buffer registers can prove advantageous.

For the example in [Figure 19.12 LETIMER Continuous Operation on page 658](#), the goal is to produce a pulse train consisting of 3 sequences with the following properties:

- 3 pulses with periods of 3 cycles
- 4 pulses with periods of 2 cycles
- 2 pulses with periods of 3 cycles

**Figure 19.12. LETIMER Continuous Operation**

The first two sequences are loaded into the LETIMER before the timer is started.

LETIMERn\_COMP0 is set to 2 (cycles – 1), and LETIMERn\_REP0 is set to 3 for the first sequence, and the second sequence is loaded into the buffer registers, i.e. COMP1 is set to 1 and LETIMERn\_REP1 is set to 4.

The LETIMER is set to trigger an interrupt when LETIMERn\_REP0 is done by setting REP0 in LETIMERn\_IEN. This interrupt is a good place to update the values of the buffers. Last but not least REPMODE in LETIMERn\_CTRL is set to buffered mode, and the timer is started.

In the interrupt routine the buffers are updated with the values for the third sequence. If this had not been done, the timer would have stopped after the second sequence.

The final result is shown in [Figure 19.12 LETIMER Continuous Operation on page 658](#). The pulse output is grouped to show which sequence generated which output. Toggle output is also shown in the figure. Note that the toggle output is not aligned with the pulse outputs.

**Note:** Multiple LETIMER cycles are required to write a value to the LETIMER registers. The example in [Figure 19.12 LETIMER Continuous Operation on page 658](#) assumes that writes are done in advance so they arrive in the LETIMER as described in the figure.

[Figure 19.13 LETIMER LETIMERn\\_CNT Not Initialized to 0 on page 659](#) shows an example where the LETIMER is started while LETIMERn\_CNT is nonzero. In this case the length of the first repetition is given by the value in LETIMERn\_CNT.

**Figure 19.13. LETIMER LETIMERn\_CNT Not Initialized to 0**

### 19.3.6.3 PWM Output

There are several ways of generating PWM output with the LETIMER, but the most straight-forward way is using the PWM output mode. This mode is enabled by setting UFOA0 or UFOA1 in LETIMERn\_CTRL to 3. In PWM mode, the output is set idle on timer underflow, and active on LETIMERn\_COMP1 match, so if for instance COMP0TOP = 1 and OPOL0 = 0 in LETIMERn\_CTRL, LETIMERn\_COMP0 determines the PWM period, and LETIMERn\_COMP1 determines the active period.

The PWM period in PWM mode is LETIMERn\_COMP0 + 1. There is no special handling of the case where LETIMERn\_COMP1 > LETIMERn\_COMP0, so if LETIMERn\_COMP1 > LETIMERn\_COMP0, the PWM output is given by the idle output value. This means that for OPOLx = 0 in LETIMERn\_CTRL, the PWM output will always be 0 for at least one clock cycle, and for OPOLx = 1 LETIMERn\_CTRL, the PWM output will always be 1 for at least one clock cycle.

To generate a PWM signal using the full PWM range, invert OPOLx when LETIMERn\_COMP1 is set to a value larger than LETIMERn\_COMP0.

### 19.3.6.4 Interrupts

The interrupts generated by the LETIMER are combined into one interrupt vector. If the interrupt for the LETIMER is enabled, an interrupt will be made if one or more of the interrupt flags in LETIMERn\_IF and their corresponding bits in LETIMER\_IEN are set.

### 19.3.7 Register Access

This module is a Low Energy Peripheral, and supports immediate synchronization. For description regarding immediate synchronization, the reader is referred to [4.3.1 Writing](#).

## 19.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                     |
|--------|--------------------|-------|---------------------------------|
| 0x000  | LETIMERn_CTRL      | RW    | Control Register                |
| 0x004  | LETIMERn_CMD       | W1    | Command Register                |
| 0x008  | LETIMERn_STATUS    | R     | Status Register                 |
| 0x00C  | LETIMERn_CNT       | RWH   | Counter Value Register          |
| 0x010  | LETIMERn_COMP0     | RWH   | Compare Value Register 0        |
| 0x014  | LETIMERn_COMP1     | RW    | Compare Value Register 1        |
| 0x018  | LETIMERn_REP0      | RWH   | Repeat Counter Register 0       |
| 0x01C  | LETIMERn_REP1      | RWH   | Repeat Counter Register 1       |
| 0x020  | LETIMERn_IF        | R     | Interrupt Flag Register         |
| 0x024  | LETIMERn_IFS       | W1    | Interrupt Flag Set Register     |
| 0x028  | LETIMERn_IFC       | (R)W1 | Interrupt Flag Clear Register   |
| 0x02C  | LETIMERn_IEN       | RW    | Interrupt Enable Register       |
| 0x034  | LETIMERn_SYNCBUSY  | R     | Synchronization Busy Register   |
| 0x040  | LETIMERn_ROUTEPEN  | RW    | I/O Routing Pin Enable Register |
| 0x044  | LETIMERn_ROUTELOC0 | RW    | I/O Routing Location Register   |
| 0x050  | LETIMERn_PRSEL     | RW    | PRS Input Select Register       |

## 19.5 Register Description

### 19.5.1 LETIMERn\_CTRL - Control Register (Async Reg)

For more information about asynchronous registers see [4.3 Access to Low Energy Peripherals \(Asynchronous Registers\)](#).

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |   |          |        |       |       |       |     |    |       |     |    |         |     |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|---|----------|--------|-------|-------|-------|-----|----|-------|-----|----|---------|-----|

## 20. CRYOTIMER - Ultra Low Energy Timer/Counter

### Quick Facts

#### What?

The CRYOTIMER is a timer capable of providing wakeup events/interrupts after deterministic intervals in all energy modes, including EM4.

#### Why?

The CRYOTIMER enables the chip to remain in the lowest energy modes for long durations, while keeping track of time and being able to wake up at regular intervals, all with an absolute minimum current consumption.

#### How?

Using a counter running on a prescaled Low Frequency Oscillator, the CRYOTIMER can provide periodic wakeup events with a very wide period range.

### 20.1 Introduction

The CRYOTIMER is a 32 bit counter which operates on a low frequency oscillator, and is capable of running in all energy modes. It can provide periodic wakeup events and PRS signals which can be used to wake up peripherals from any energy mode. The CRYOTIMER provides a very wide range of periods for the interrupts facilitating flexible ultra-low energy operation.

Because of its simplicity, the CRYOTIMER is a lower energy solution for periodically waking up the MCU compared to the RTCC.

### 20.2 Features

- 32 bit Counter
- Works in all the energy modes
- Only External and Power-On resets reset the CRYOTIMER
- Interrupt/wake up event after deterministic intervals
- PRS Output
- Debug mode
  - Configurable to either run or stop when processor is stopped (break)

### 20.3 Functional Description

### 20.3.1 Block Diagram

An overview of the CRYOTIMER is shown in [Figure 20.1 CRYOTIMER Block Overview on page 678](#).

**Figure 20.1. CRYOTIMER Block Overview**

### 20.3.2 Operation

The desired low frequency oscillator for the CRYOTIMER operation can be selected by using OSCSEL in CRYOTIMER\_CTRL. The selection must be made before enabling the CRYOTIMER, and it must be ensured that the selected oscillator is ready. This can be checked by observing LFXORDY or LFRCORDY (depending upon the oscillator selection) in CMU\_STATUS. Note that the ULFRCO is always ready.

By default the CRYOTIMER is held in reset. It can be started by setting EN in CRYOTIMER\_CTRL. The CRYOTIMER, when running, is reset by clearing EN.

The timer counts at a frequency determined by PRESC in CRYOTIMER\_CTRL. This value should be set before the CRYOTIMER is enabled. Setting PRESC to 0 gives the maximum resolution, while higher values allow longer periods, see [Table 20.1 CRYOTIMER Resolution vs Maximum Wakeup Event/Interrupt Period](#),  $F_{CRYOCLK} = 32768 \text{ Hz}$  on page 679.

The 32-bit Counter provides 32 different options for selecting the duration between the Wakeup events. The selected duration is specified by CRYOTIMER\_PERIODSEL. It should be configured before the CRYOTIMER is enabled.

$$T_{WU} = (2^{PRESC} \times 2^{PERIODSEL}) / f_{CRYOCLK}$$

**Figure 20.2. Duration Between the CRYOTIMER Wakeup Events in Seconds**

**Table 20.1. CRYOTIMER Resolution vs Maximum Wakeup Event/Interrupt Period,  $F_{CRYOCLK} = 32768 \text{ Hz}$**

| CRYOTIMER_CTRL_PRESC | Resolution, $2^{PRESC} / f_{CRYOCLK}$ | Maximum Wakeup event/Interrupt Period |
|----------------------|---------------------------------------|---------------------------------------|
| DIV1                 | 30.5 $\mu\text{s}$                    | 36.4 hours                            |
| DIV2                 | 61 $\mu\text{s}$                      | 72.8 hours                            |
| DIV4                 | 122 $\mu\text{s}$                     | 145.6 hours                           |
| DIV8                 | 244 $\mu\text{s}$                     | 12 days                               |
| DIV16                | 488 $\mu\text{s}$                     | 24 days                               |
| DIV32                | 977 $\mu\text{s}$                     | 48 days                               |
| DIV64                | 1.95 ms                               | 97 days                               |
| DIV128               | 3.91 ms                               | 194 days                              |

The 32-bit counter value of the CRYOTIMER can be read using the CRYOTIMER\_CNT register.

The PRS output pulses of the CRYOTIMER are 1 CRYOCLK clock cycle wide. However, if the PRESC and PERIODSEL are both set to 0, the width of these pulses will be half CRYOCLK time period.

The CRYOTIMER wakeup events set the flag in the CRYOTIMER\_IF. Interrupt on this event can be enabled by using the CRYOTIMER\_IEN register.

The CRYOTIMER is always reset by the External Pin and Power-On resets. Additionally, by using EMU\_CTRL, it can also be configured to reset by Watchdog, lockup, and system request resets.

**Note:** The CRYOTIMER configuration bits/registers should only be changed when EN in CRYOTIMER\_CTRL is cleared.

### 20.3.3 Debug Mode

When the CPU is halted in debug mode, the CRYOTIMER can be configured to either continue to run or to be frozen. This is configured using DEBUGRUN in CRYOTIMER\_CTRL.

### 20.3.4 Energy Mode Availability

The CRYOTIMER is available in all energy modes. Wakeup from EM2 DeepSleep and EM3 Stop to EM0 Active can be performed using the regular interrupt as discussed in [20.3.2 Operation](#). To generate wakeup events during EM4 Hibernate/Shutoff, EM4WU in CRYOTIMER\_EM4WUEN must be set to 1. Since the interrupt flag serves as the wakeup source, it must be cleared by software after exiting a low energy mode. Refer to [9. EMU - Energy Management Unit](#) for details on how to configure the EMU.

## 20.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                | Type  | Description                   |
|--------|---------------------|-------|-------------------------------|
| 0x000  | CRYOTIMER_CTRL      | RW    | Control Register              |
| 0x004  | CRYOTIMER_PERIODSEL | RW    | Interrupt Duration            |
| 0x008  | CRYOTIMER_CNT       | R     | Counter Value                 |
| 0x00C  | CRYOTIMER_EM4WUEN   | RW    | Wake Up Enable                |
| 0x010  | CRYOTIMER_IF        | R     | Interrupt Flag Register       |
| 0x014  | CRYOTIMER_IFS       | W1    | Interrupt Flag Set Register   |
| 0x018  | CRYOTIMER_IFC       | (R)W1 | Interrupt Flag Clear Register |
| 0x01C  | CRYOTIMER_IEN       | RW    | Interrupt Enable Register     |

## 20.5 Register Description

### 20.5.1 CRYOTIMER\_CTRL - Control Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |   |        |          |    |   |   |   |   |   |   |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|---|--------|----------|----|---|---|---|---|---|---|
| 0x000  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10    | 9 | 8      | 7        | 6  | 5 | 4 | 3 | 2 | 1 | 0 |

| Access |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RW    |   | RW     | RW       | RW |   |   |   |   |   |   |
| Name   |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | PRESC |   | OSCSEL | DEBUGRUN | EN |   |   |   |   |   |   |

## 20.5.2 CRYOTIMER\_PERIODSEL - Interrupt Duration

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |           |   |   |   |   |   |   |   |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-----------|---|---|---|---|---|---|---|
| 0x004  | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7         | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reset  |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | 0x20      |   |   |   |   |   |   |   |
| Access |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | RW        |   |   |   |   |   |   |   |
| Name   |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | PERIODSEL |   |   |   |   |   |   |   |

| Bit  | Name     | Reset                                                                                                                    | Access | Description |
|------|----------|--------------------------------------------------------------------------------------------------------------------------|--------|-------------|
| 31:6 | Reserved | To ensure compatibility with future devices, always write bits to 0. More information in <a href="#">1.2 Conventions</a> |        |             |

5:0 PERIODSEL 0x20 RW **Interrupts/Wakeup Events Period Setting**

Defines the duration between the Interrupts/Wakeup events based on the pre-scaled clock.

| Value | Description                                      |
|-------|--------------------------------------------------|
| 0     | Wakeup event after every Pre-scaled clock cycle. |
| 1     | Wakeup event after 2 Pre-scaled clock cycles.    |
| 2     | Wakeup event after 4 Pre-scaled clock cycles.    |
| 3     | Wakeup event after 8 Pre-scaled clock cycles.    |
| 4     | Wakeup event after 16 Pre-scaled clock cycles.   |
| 5     | Wakeup event after 32 Pre-scaled clock cycles.   |
| 6     | Wakeup event after 64 Pre-scaled clock cycles.   |
| 7     | Wakeup event after 128 Pre-scaled clock cycles.  |
| 8     | Wakeup event after 256 Pre-scaled clock cycles.  |
| 9     | Wakeup event after 512 Pre-scaled clock cycles.  |
| 10    | Wakeup event after 1k Pre-scaled clock cycles.   |
| 11    | Wakeup event after 2k Pre-scaled clock cycles.   |
| 12    | Wakeup event after 4k Pre-scaled clock cycles.   |
| 13    | Wakeup event after 8k Pre-scaled clock cycles.   |
| 14    | Wakeup event after 16k Pre-scaled clock cycles.  |
| 15    | Wakeup event after 32k Pre-scaled clock cycles.  |
| 16    | Wakeup event after 64k Pre-scaled clock cycles.  |
| 17    | Wakeup event after 128k Pre-scaled clock cycles. |
| 18    | Wakeup event after 256k Pre-scaled clock cycles. |
| 19    | Wakeup event after 512k Pre-scaled clock cycles. |
| 20    | Wakeup event after 1M Pre-scaled clock cycles.   |
| 21    | Wakeup event after 2M Pre-scaled clock cycles.   |
| 22    | Wakeup event after 4M Pre-scaled clock cycles.   |

| Bit | Name | Reset | Access | Description                                       |
|-----|------|-------|--------|---------------------------------------------------|
| 23  |      |       |        | Wakeup event after 8M Pre-scaled clock cycles.    |
| 24  |      |       |        | Wakeup event after 16M Pre-scaled clock cycles.   |
| 25  |      |       |        | Wakeup event after 32M Pre-scaled clock cycles.   |
| 26  |      |       |        | Wakeup event after 64M Pre-scaled clock cycles.   |

## 21. ACMP - Analog Comparator

### Quick Facts

#### What?

The Analog Comparator (ACMP) compares two analog signals and returns a digital value telling which is greater.

#### Why?

Applications often do not need to know the exact value of an analog signal, only if it has passed a certain threshold. Often the voltage must be monitored continuously, which requires extremely low power consumption.

#### How?

Available down to Energy Mode 3 and using as little as 100 nA, the ACMP can wake up the system when input signals pass the threshold. The analog comparator can compare two analog signals or one analog signal and a highly configurable internal reference.

### 21.1 Introduction

The Analog Comparator compares the voltage of two analog inputs and outputs a digital signal indicating which input voltage is higher. Inputs can either be from internal references or from external pins. Response time, and thereby the current consumption, can be configured by altering the current supply to the comparator.

### 21.2 Features

- Up to 160 selectable external I/O inputs for both positive and negative inputs
  - Up to 48 I/O can be used as a dividable reference
- 3 selectable internal inputs
  - Dividable Internal 1.25 V bandgap reference voltage
  - Dividable Internal 2.5 V bandgap reference voltage
  - Dividable  $V_{ACMPVDD}$  reference voltage
- Voltage supply monitoring
- Low power mode for internal  $V_{DD}$  and bandgap references
- Selectable hysteresis
  - 8 values
  - Values can be positive or negative
  - Dividable references have scale for both both output values, allowing for even larger hysteresis
- Selectable response time
- Asynchronous interrupt generation on selectable edges
  - Rising edge
  - Falling edge
  - Both edges
- Operational in EM0 Active down to EM3 Stop
- Dedicated capacitive sense mode with up to 8 inputs
  - Adjustable internal resistor
- Configurable output when inactive
- Comparator output direct on PRS
- Comparator output on GPIO through alternate functionality
  - Output inversion available

## 21.3 Functional Description

An overview of the ACMP is shown in [Figure 21.1 ACMP Overview on page 687](#).

**Figure 21.1. ACMP Overview**

The comparator has two analog inputs: one positive and one negative. When the comparator is active, the output indicates which of the two input voltages is higher. When the voltage on the positive input is higher than the voltage on the negative input, the digital output is high and vice versa.

The output of the comparator can be read in the ACMPOUT bit in ACMPn\_STATUS. It is possible to switch inputs while the comparator is enabled, but all other configuration should only be changed while the comparator is disabled.

### 21.3.1 Power Supply

The comparator power supply ( $V_{ACMPVDD}$ ) can be configured to be AVDD, DVDD, or IOVDD using the PWRSEL bitfield in ACMPn\_CTRL. By default,  $V_{ACMPVDD}$  is set to AVDD.

### 21.3.2 Warm-up Time

The analog comparator is enabled by setting the EN bit in ACMPn\_CTRL. The comparator requires some time to stabilize after it is enabled. This time period is called the warm-up time. The warm-up period is self-timed and will complete within 5µs after EN is set.

During warm-up and when the comparator is disabled, the output level of the comparator is set to the value of the INACTVAL bit in ACMPn\_CTRL. When the warm-up time is over, the ACMPACT bit in ACMPn\_STATUS is set to 1 to indicate that the comparator is active.

An edge interrupt will be generated if the edge interrupt is enabled and the value set in INACTVAL differs from ACMPOUT when the comparator transitions from warm-up to active.

Software should wait until the warm-up period is over before entering EM2 or EM3, otherwise no comparator interrupts will be detected. EM1 can still be entered during warm-up. After the warm-up period is completed, interrupts will be detected in EM2 and EM3.

### 21.3.3 Response Time

There is a delay from when the input voltage changes polarity to when the output toggles. This delay is called the response time and can be altered by increasing or decreasing the bias current to the comparator through the BIASPROG and FULLBIAS fields in the ACMPn\_CTRL register. The current and speed of the circuit increase as the values of FULLBIAS and BIASPROG are increased from their minimum setting of FULLBIAS=0 BIASPROG=0b000000 to the maximum setting FULLBIAS=1 BIASPROG=0b111111 (maximum). The setting of FULLBIAS has a greater affect on current and speed than the setting of BIASPROG. See the part data sheet for specific current and response times related to the setting of these fields.

If FULLBIAS is set, to avoid glitches the highest hysteresis level should be used.

### 21.3.4 Hysteresis

When the hysteresis level is set to a non-zero value, the digital output will not toggle until the positive input voltage is at a voltage equal to the hysteresis level above or below the negative input voltage (see [Figure 21.3 Hysteresis on page 689](#)). This feature can be used to avoid continual comparator output changes due to noise when the positive and negative inputs are nearly equal by requiring the input difference to exceed the hysteresis threshold.

In the analog comparator, hysteresis can be configured to 8 different levels. Level 0 is no hysteresis. Hysteresis is configured through the HYST field in ACMPn\_HYSTERSIS0 and ACMPn\_HYSTERSIS1 registers. The hysteresis value can be positive or negative. The comparator will output a 1 if:

$$\text{POSSEL} - \text{NEGSEL} > \text{HYST}$$

There are two hysteresis registers, ACMPn\_HYSTERSIS0 and ACMPn\_HYSTERSIS1, as the ACMP supports asymmetric hysteresis. ACMPn\_HYSTERSIS0 are the hysteresis values used when the comparator output is 0; ACMPn\_HYSTERSIS1 are the values used when the comparator output is 1. The user must set both registers to the same values if symmetric hysteresis is desired.

Along with the HYST field, the ACMPn\_HYSTERSIS0/1 registers include the DIVVA and DIVVB fields. This allows the user to implement even larger hysteresis when comparing against VADIV or VBDIV, as the reference voltage can vary with the comparator output, also.

Figure 21.3. Hysteresis

### 21.3.5 Input Pin Considerations

For external ACMP inputs routed through the APORT, the maximum supported analog input voltage will be limited to the  $\text{MIN}(V_{\text{ACMPVDD}}, \text{IOVDD})$  (where  $V_{\text{ACMPVDD}}$  is selected by the PWRSEL bitfield in ACMPn\_CTRL). Note that pins configured as ACMP inputs should disable OVT (by setting the corresponding GPIO\_Px\_OVTDIS bit) to reduce any potential distortion introduced by the OVT circuitry.

### 21.3.6 Input Selection

The POSSEL and NEGSEL fields in ACMPn\_INPUTSEL control the input connections to the positive and negative inputs of the comparator. The user can select external GPIO pins on the chip, or select a number of internal chip voltages. Pins are selected by configuring channels on APORT buses. Not all selectable channels are available on a given device, as different devices within a family may not implement or bring out all of the I/O defined for that family. Refer to the data sheet for channel availability and pin mapping.

There are limitations on the POSSEL and NEGSEL connections that can be made. The user cannot select an X-bus for both POSSEL and NEGSEL simultaneously, nor a Y-bus for both POSSEL and NEGSEL simultaneously. The second limitation is that when using the feedback resistor only X-bus selections can be made for POSSEL. (The resistor only physically exists on the positive input of the comparator).

The user may also select from a number of internal voltages. VADIV and VBDIV are two dividable voltages. VADIV can be  $V_{\text{ACMPVDD}}$  divided, or the user can choose to select inputs from a number of APORT buses. VBDIV consists of two dividable band-gap references of either 1.25V or 2.5V. Each of these voltages have dividers in the ACMPn\_HYSTERSIS0/1 registers. The formula for the division of these voltages is:

$$\text{VADIV} = \text{VA} \times (\text{DIVVA} + 1) / 64$$

**Figure 21.3. VA Voltage Division**

$$\text{VBDIV} = \text{VB} \times (\text{DIVVB} + 1) / 64$$

**Figure 21.4. VB Voltage Division**

Either VADIV and VBDIV can also be used as an input to a lower power reference: VLP. Which of the two is used is configured via the VLPSEL field in ACMPn\_INPUTSEL. If the user selects VLP as an input source, then VADIV or VBDIV cannot be used as the source for the other input.

ACMP can be configured to operate with a selected level of accuracy depending on the setting of ACCURACY in ACMPn\_CTRL. The default is low-accuracy mode where ACMP operates with lower accuracy but consumes less current. When higher accuracy is needed the user can set ACCURACY=1 at the cost of higher current consumption.

### 21.3.7 Capacitive Sense Mode

The analog comparator includes specialized hardware for capacitive sensing of passive push buttons. Such buttons are traces on the PCB laid out in a way that creates a parasitic capacitor between the button and the ground node. Because a human finger will have a small intrinsic capacitance to ground, the capacitance of the button will increase when the button is touched. The capacitance is measured by including the capacitor in a free-running RC oscillator (see [Figure 21.5 Capacitive Sensing Setup on page 692](#)). The frequency produced will decrease when the button is touched compared to when it is not touched. By measuring the output frequency with a timer (via the PRS), the change in capacitance can be detected.

The analog comparator contains a feedback loop including an optional internal resistor. This resistor is enabled by setting the CSRESEN bit in ACMPn\_INPUTSEL. The resistance can be set to any of 8 values by configuring the CSRESSEL bits in ACMPn\_INPUTSEL. The source for VADIV is set to  $V_{ACMPVDD}$  by setting field VASEL=0 in ACMPn\_INPUTSEL. The oscillation rails are defined by the VADIV fields in registers ACMPn\_HYSTERESIS0/1. The user should select VADIV as the source for NEGSEL, and APORTXCHc for POSSEL in ACMPn\_INPUTSEL. When enabled, the comparator output will oscillate between the rails defined by VADIV in ACMPn\_HYSTERESIS0/1.

Figure 21.5. Capacitive Sensing Setup

### 21.3.8 Interrupts and PRS Output

The analog comparator includes an edge triggered interrupt flag (EDGE in ACMPn\_IF). If either IRISE and/or IFALL in ACMPn\_CTRL is set, the EDGE interrupt flag will be set on rising and/or falling edge of the comparator output respectively. An interrupt request will be sent if the EDGE interrupt flag in ACMPn\_IF is set and enabled through the EDGE bit in ACMPn\_IEN. The edge interrupt can also be used to wake up the device from EM3 Stop-EM1 Sleep.

The analog comparator includes the interrupt flag WARMUP in ACMPn\_IF which is set when a warm-up sequence has finished. An interrupt request will be sent if the WARMUP interrupt flag in ACMPn\_IF is set and enabled through the WARMUP bit in ACMPn\_IEN.

The analog comparator can also generate an interrupt if a bus conflict occurs. An interrupt request will be sent if the APORTCONFLICT interrupt flag in ACMPn\_IF is set and enabled through the APORTCONFLICT bit in ACMPn\_IEN.

The synchronized comparator output is also available as a PRS output signal.

### 21.3.9 Output to GPIO

The output from the comparator and the capacitive sense output are available as alternate functions to the GPIO pins. Set the ACMP-PEN bit in ACMPn\_ROUTE to enable the output to a pin and the LOCATION bits to select the output location. The GPIO-pin must also be set as output. The output to the GPIO can be inverted by setting the GPIOINV bit in ACMPn\_CTRL.

### 21.3.10 APORT Conflicts

The analog comparator connects to chip pins through APORT buses. It is possible that another APORT client is using a given APORT bus. To help debugging over-utilization of APORT resources the ACMP provides a number of status registers. The ACMPn\_APOR-TREQ gives the user visibility into what APORT buses the ACMP is requesting given the setting of registers ACMPn\_INPUTSEL and ACMPn\_CTRL. ACMPn\_APORTCONFLICT indicates if any of the selections are in conflict, internally or externally.

For example, if the user selects APORT1XCH0 for POSSEL and APORT3XCH1 for NEGSEL, then bits APORT1XCONFLICT and APORT3XCONFLICT would be 1 in register ACMPn\_APORTCONFLICT, as it is illegal for POSSEL and NEGSEL to both select an X-bus simultaneously.

If the user wishes the ACMP to monitor the same pin as another APORT client within the system, the ACMP can be configured to not attempt to control the switches on an APORT bus via the fields APORTXMASTERDIS, APOR TYMASTERDIS, and APORTVMAS-TERDIS in ACMPn\_CTRL. APORTXMASTERDIS and APOR TYMASTERDIS control if the X or Y bus selected via POSSEL or NEGSEL is mastered or not. APORTVMAS-TERDIS controls if either the X or Y bus selection of VASEL is mastered or not. When bus mastering is disabled, it is the other APORT client that determines which pin is connected to the APORT bus.

### 21.3.11 Supply Voltage Monitoring

The ACMP can be used to monitor supply voltages. The ACMP can select which voltage it uses via PWRSEL in ACMPn\_CTRL. This voltage can be selected for VADIV using VASEL=0 in ACMPn\_INPUTSEL and divided to a voltage with the band-gap reference range using DIVVA in registers ACMPn\_HYSTERESIS0/1. The band-gap reference voltage can also be scaled via DIVVB in registers ACMPn\_HYSTERESIS0/1 to provide a voltage higher or lower than the scaled VA voltage for comparison.

## 21.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                | Type  | Description                      |
|--------|---------------------|-------|----------------------------------|
| 0x000  | ACMPn_CTRL          | RW    | Control Register                 |
| 0x004  | ACMPn_INPUTSEL      | RW    | Input Selection Register         |
| 0x008  | ACMPn_STATUS        | R     | Status Register                  |
| 0x00C  | ACMPn_IF            | R     | Interrupt Flag Register          |
| 0x010  | ACMPn_IFS           | W1    | Interrupt Flag Set Register      |
| 0x014  | ACMPn_IFC           | (R)W1 | Interrupt Flag Clear Register    |
| 0x018  | ACMPn_IEN           | RW    | Interrupt Enable Register        |
| 0x020  | ACMPn_APORTREQ      | R     | APORT Request Status Register    |
| 0x024  | ACMPn_APORTCONFLICT | R     | APORT Conflict Status Register   |
| 0x028  | ACMPn_HYSTERESIS0   | RW    | Hysteresis 0 Register            |
| 0x02C  | ACMPn_HYSTERESIS1   | RW    | Hysteresis 1 Register            |
| 0x040  | ACMPn_ROUTEPEN      | RW    | I/O Routing Pine Enable Register |
| 0x044  | ACMPn_ROUTELOC0     | RW    | I/O Routing Location Register    |

## 21.5 Register Description

### 21.5.1 ACMPn\_CTRL - Control Register

| Offset | Bit Position |    |    |    |          |    |    |    |    |    |       |       |            |     |    |    |          |    |        |     |    |    |                 |                 |                 |   |   |   |   |        |          |   |    |    |    |   |

This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the ACMP to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the ACMP only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external device mastering the bus has configured for the APORT bus.<br><table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Bus mastering enabled</td></tr><tr><td>1</td><td>Bus mastering disabled</td></tr></table> | Value | Description | 0           | Bus mastering enabled | 1    | Bus mastering disabled                                        |   |      |                                                                |   |        |                     |   |        |                                              |

This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the ACMP to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the ACMP only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and is whatever selection the external device mastering the bus has configured for the APORT bus. <table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>Bus mastering enabled</td></tr><tr><td>1</td><td>Bus mastering disabled</td></tr></table> | Value | Description | 0           | Bus mastering enabled | 1      | Bus mastering disabled                        |   |      |                                           |

## 22. ADC - Analog to Digital Converter

### Quick Facts

#### What?

The ADC is used to convert analog signals into a digital representation and features low-power, autonomous operation.

#### Why?

In many applications there is a need to measure analog signals and record them in a digital representation, without exhausting the energy source.

#### How?

A low power ADC samples up to 32 input channels in a programmable sequence. With the help of PRS and DMA, the ADC can operate without CPU intervention in EM2 DeepSleep and EM3 Stop, minimizing the number of powered up resources. The ADC can further be duty-cycled to reduce the energy consumption.

### 22.1 Introduction

The ADC uses a Successive Approximation Register (SAR) architecture, with a resolution of up to 12 bits at up to one million samples per second (1 Msp/s). The integrated input multiplexer can select from external I/Os and several internal signals.

## 22.2 Features

- Programmable resolution (6/8/12-bit)
  - 13 conversion clock cycles for a 12-bit conversion
  - Maximum 1 Msps @ 12-bit
  - Maximum 1.6 Msps @ 6-bit
- Configurable acquisition time
- Externally controllable conversion start time using PRS in TIMED mode
- Integrated prescaler for conversion clock generation
  - Selectable clock division factor from 1 to 128
- Wide conversion clock range: 32 kHz to 16 MHz
- Can be run during EM2 DeepSleep and EM3 Stop, waking up the system upon various enabled interrupts
- Can be run during EM2 DeepSleep and EM3 Stop with DMA enabled to pull data from the FIFOs without waking up the system
- Supports up to 144 external input channels and several internal inputs
  - Includes temperature sensor and random number generator function
- Left or right adjusted results
  - Results in 2's complement representation
  - Differential results sign extended to 32-bits results
- Programmable scan sequence
  - Up to 32 configurable samples in scan sequence
  - Mask to select which pins are included in the sequence
  - Triggered by software or PRS input
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data along with channel ID and option to overwrite old data when full
  - Programmable watermark (DVL) to generate SCAN interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
  - Conversion tailgating support for predictable periodic scans
- Programmable single channel conversion
  - Triggered by software or PRS input
  - Can be interleaved between two scan sequences
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data with option to overwrite old data when full
  - programmable watermark (DVL) to generate SINGLE interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
- Hardware oversampling support
  - 1st order accumulate and dump filter
  - From 2 to 4096 oversampling ratio (OSR)
  - Results in 16-bit representation
  - Enabled individually for scan sequence and single channel mode
  - Common OSR select
- Programmable and preset input full scale (peak-to-peak) range (VFS) with selectable reference sources
  - VFS=1.25 V using internal VBGR reference
  - VFS=2.5 V using internal VBGR reference
  - VFS=AVDD with AVDD as reference source
  - VFS=5 V with internal VBGR reference
  - Single ended external reference
  - Differential external reference
  - VFS=2xAVDD with AVDD as reference source
  - User-programmable dividers for flexible VFS options from internal, external or supply voltage reference sources

- Support for offset and gain calibration
- Interrupt generation and/or DMA request when
  - Programmable number of converted data available in the single FIFO (also generates DMA request)
  - Programmable number of converted data available in the scan FIFO (also generates DMA request)
  - Single FIFO overflow or underflow
  - Scan FIFO overflow or underflow
  - Latest Single conversion tripped compare logic
  - Latest Scan conversion tripped compare logic
  - Analog over-voltage interrupt
  - Programming Error interrupt due to APORT Bus Request conflict or NEGSEL programming error

## 22.3 Functional Description

An overview of the ADC is shown in [Figure 22.1 ADC Overview on page 717](#).

Figure 22.1. ADC Overview

### 22.3.1 Clock Selection

The ADC logic is partitioned into two clock domains: HFPERCLK and ADC\_CLK. The HFPERCLK domain contains the register interface logic, APORT request logic and portions of FIFO read logic. The HFPERCLK is the default clock for the ADC peripheral. The rest of the ADC is clocked by the ADC\_CLK domain. The ADC\_CLK is chosen by ADCCLKMODE bit in the ADCn\_CTRL register.

The ADC\_CLK is the main clock for the ADC engine. If the ADCCLKMODE is set to SYNC, the ADC\_CLK is equal to the HFPERCLK and the ADC operates in synchronous mode. If the ADCCLKMODE is set to ASYNC, the ADC\_CLK is ASYNCCLK and the ADC operates in asynchronous mode. This distinction is important to understand as there are additional system restrictions and benefits to running the ADC in asynchronous mode detailed in [22.3.15 ASYNC ADC\\_CLK Usage Restrictions and Benefits](#).

**Note:** Whenever ADC is being used in asynchronous mode, then HFPERCLK must be at least 1.5 times higher than the ADC\_CLK.

The ADC has an internal clock prescaler, controlled by PRESC bits in ADCn\_CTRL, which can divide the ADC\_CLK by any factor between 1 and 128 to generate the conversion clock (adc\_clk\_sar) for the ADC. This adc\_clk\_sar is also used to generate acquisition timing. Note that the maximum clock frequency for adc\_clk\_sar is 16 MHz. The ADC warmup time is determined by ADC\_CLK and not by adc\_clk\_sar.

ASYNCCLK is a clock source from the CMU which is considered asynchronous to HFPERCLK. The CMU\_ADCCTRL register can be programmed to request and use ASYNCCLK. It has multiple choices for its source, including AUXHFRCO, HFXO and HFSRCCLK, and can optionally be inverted. If the chosen source for ASYNCCLK is not active at the time of request, the CMU enables the source oscillator upon receiving the request, and shuts down the oscillator when the ADC stops requesting the clock. Consult the CMU chapter for details of how to program the clock sources for the ASYNCCLK and oscillator start-up time details.

Software may choose a clock request generation scheme by programming the ASYNCCLKEN and WARMMODE of the ADCn\_CTRL register. If the ASYNCCLKEN is set to ASNEEDED with WARMMODE set to NORMAL, the ADC requests ASYNCCLK only when a conversion trigger is activated. The ASYNCCLK request is withdrawn after the conversion is complete. All other options keep the ASYNCCLK request "ON" until software programs these fields otherwise or changes the ADCCLKMODE to SYNC.

For EM2 DeepSleep or EM3 Stop operation of the ADC, the ADC\_CLK must be configured for AUXHFRCO as this is the only available option during EM2 DeepSleep or EM3 Stop. The ADC\_CLK source should not be changed as the system enters or exits various energy modes, otherwise measurement inaccuracies will result.

### 22.3.2 Conversions

A conversion consists of two phases: acquisition and approximation. The input is sampled in the acquisition phase before it is converted to digital representation during the approximation phase. The acquisition time can be configured independently for scan sequence and single channel conversions (see [22.3.3 ADC Modes](#)) by setting AT in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The acquisition times can be set to 1, 2, 3 or any integer power of 2 from 4 to 256 adc\_clk\_sar cycles.

**Note:** For high impedance sources the acquisition time should be adjusted to allow enough time for the internal sample capacitor to fully charge. The minimum acquisition time for sampling at 1 Msps and typical input loading is 187.5 ns.

The ADC uses one adc\_clk\_sar cycle per output bit in the approximation phase plus 1 extra adc\_clk\_sar cycle.

$$T_{\text{conv}} = (T_{\text{acq}} + (N + 1) \times T_{\text{adc\_clk\_sar}}) \times \text{OVSSEL}$$

Where  $T_{\text{acq}}$  is the acquisition time set by the AT bit field, N is the resolution (in bits), and OVSSEL is the oversampling ratio according to the OVSSEL field in ADCn\_CTRL when oversampling is enabled (see [22.3.10.6 Oversampling](#)).

**Figure 22.2. ADC Total Conversion Time Per Output**

**Figure 22.3. ADC Conversion Timing**

### 22.3.3 ADC Modes

The ADC contains two programmable modes: single channel mode and scan mode. Both modes have separate configuration registers and a four-deep FIFO for conversion results. Both modes may be set up to run only once per trigger or to automatically repeat after each operation. The scan mode has priority over the single channel mode. However by default, if scan sequence is running, a triggered single channel conversion will be interleaved between two scan samples.

#### 22.3.3.1 Single Channel Mode

Single channel mode can be used to convert a single channel either once per trigger or repetitively. The configuration of single channel mode is done using the `ADCn_SINGLECTRL` and `ADCn_SINGLECTRLX` registers and the result FIFO can be read through the `ADCn_SINGLEDATA` register. The `DVL` field of the `ADCn_SINGLECTRLX` controls the FIFO watermark crossing which sets the `SINGLEDV` bit in `ADCn_STATUS` high and is cleared when the data is read and the number of unread data samples falls below the `DVL` threshold. The user can choose to throw out new samples or overwrite the old samples when the FIFO becomes full by programming the `FIFOFACT` field of the `ADCn_SINGLECTRLX` register. Single channel results can also be read through `ADCn_SINGLEDATAP` without popping the FIFO, returning its latest element. The `DIFF` field in `ADCn_SINGLECTRL` selects whether differential or single ended inputs are used and `POSSEL` and `NEGSEL` selects the input signal(s). The `CMPEN` bit in the `ADCn_SINGLECTRL` register enables the window compare function, and the latest converted data is compared against values programmed into the `ADGT` and `ADLT` fields of the `ADCn_CMPTHR` register and generates `SINGLECMP` interrupts if enabled. The window compare function allows for compare triggering both within (if `ADGT` less than `ADLT`) or out of (if `ADGT` greater than `ADLT`) window.

#### 22.3.3.2 Scan Mode

Scan mode is used to perform conversions across multiple channels, sweeping a set of selected inputs in a sequence. The configuration of scan mode is done in the `ADCn_SCANCTRL` and `ADCn_SCANCTRLX` registers. It has similar controls and data read mechanisms to single channel mode. There are two key differences between single channel mode and scan mode: the input sequence is programmed differently, and it has additional information in the result to indicate the channel on which the conversion was acquired. [22.3.7 Input Selection](#) explains how the input sequence is chosen. When the scan sequence is triggered, the ADC samples all inputs that are included in the mask (`ADCn_SCANMASK`), starting at the lowest pin number. `DIFF` in `ADCn_SCANCTRL` selects whether single ended or differential inputs are used. The FIFO data is tagged with `SCANINPUTID` and can be read along with the scan data using `ADCn_SCANDATA` register. The `ADCn_SCANDATAXP` can be used to read the latest valid entry from the scan FIFO without popping it. There is also a `ADCn_SCANDATA` register that contains results without the `SCANINPUTID` appended.

### 22.3.4 Warm-up Time

After power-on, the ADC requires some time for internal bias currents and references to settle prior to starting a conversion. This time period is called the warm-up time. Warm-up timing is performed by hardware. Software must program the number of ADC\_CLK cycles required to count at least 1  $\mu$ s in the TIMEBASE field of the ADCn\_CTRL register. TIMEBASE only affects the timing of the warm-up sequence and is not dependent on adc\_clk\_sar. When enabling the ADC or changing references between samples, the ADC is automatically warmed up for 5  $\mu$ s (5 times the period indicated by TIMEBASE).

Normally, the ADC will be warmed up only when samples are requested and is shut off when there are no more samples waiting. However, if lower latency is needed, configuring the WARMUPMODE field in ADCn\_CTRL allows the ADC and/or reference to stay warm between samples, reducing the warm-up time or eliminating it altogether. [Figure 22.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 721](#) shows the effects on analog power consumption in scenarios using different WARMUPMODE settings.

Only the reference for scan-mode can be kept warm. Thus, if the single-mode reference setting is different than scan-mode, the single mode conversion will first warmup its reference for 5  $\mu$ s before a conversion begins. If the ADC is used only in single conversion mode, it is important to configure both the ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX and ADCn\_SCANCTRL, ADCn\_SCANCTRLX registers with the same reference to avoid this extra warm-up time.

Various warmup modes are described here:

- **NORMAL:** This is the lowest power option for general-purpose use and low sampling rates (below 35 ksp/s). The ADC and references are shut off when there are no samples waiting. The ADC does not consume any power when it is shut down. A 5  $\mu$ s warmup time will be initiated prior to every conversion. Figure a in [Figure 22.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 721](#) shows this mode.
- **KEEPINSTANDBY:** This mode is suitable for infrequent sampling of lower impedance inputs, and is the lowest power option for sampling rates between about 35 and 125 ksp/s. It may also be useful for lower sampling rates where latency is important. The reference selected for scan mode is kept warm, but the ADC is powered down. The ADC will initiate a 1  $\mu$ s warmup period before a conversion begins. Because the reference is kept warm, the ADC will consume a small amount of standby current when it is not converting. Figure b in [Figure 22.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 721](#) shows this mode.
- **KEEPINSLOWACC:** This mode is useful for high-impedance inputs which are sampled infrequently. It is similar to KEEPINSTANDBY, but continuously tracks the input, keeping the input multiplexer connected to the APORT bus. This mode consumes little more power than KEEPINSTANDBY mode (about 2  $\mu$ A extra) when a conversion is not in progress. This allows the user to avoid programming long acquisition time that would otherwise be necessary for high-impedance inputs when ADC wakes up to full power mode, thereby reducing the total current consumption per conversion.
- **KEEPADCWARM:** This mode provides the lowest latency and allows for maximum sampling rates. The ADC and reference circuitry remain powered on even when conversions are not in progress. Figure c in [Figure 22.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 721](#) shows this mode. This mode consumes the most power, but as soon as a trigger event occurs, the acquisition and conversion begin with no warm-up time. Note that if KEEPADCWARM mode is set and HFXO is selected as the ADC clock source, the HFXO will remain on in EM2.

When KEEPADCWARM is chosen, ADC is termed as being in continuous operation. When any other warmup mode is chosen, ADC is termed to be in duty-cycled operation.

When entering EM2 DeepSleep or EM3 Stop, if the ADC is not going to be used, it should be returned to an idle state and WARMUPMODE in ADCn\_CTRL written to 0. Refer to [22.3.17 ADC Programming Model](#) for more information on placing the ADC in an idle state. If the ADC is going to be used in these low energy modes, the user can use any of the WARMUPMODE settings, but should be mindful of the power consumption that comes along with the different mode settings. For EM2 DeepSleep or EM3 Stop operation, the ADC clock source must be configured to use AUXHFRCO.

Figure 22.4. ADC Analog Power Consumption With Different WARMUPMODE Settings

**Note:** When using any warm-up mode other than NORMAL, always switch back to the NORMAL mode before switching to another warm-up mode.

### 22.3.5 Power Supply

The ADC block power ( $V_{ADC}$ ) is derived from the VDDX\_ANA supply rail. VDDX\_ANA can be selected from the AVDD or DVDD supply pins using the EMU\_PWRCTRL\_ANASW bit field.

### 22.3.6 Input Pin Considerations

For external ADC inputs routed through the APORT, the maximum supported analog input voltage will be limited to the  $\text{MIN}(V_{ADC}, \text{IOVDD})$  (where  $V_{ADC}$  is VDDX\_ANA, as described in [22.3.5 Power Supply](#)). Note that pins configured as ADC inputs should disable OVT (by setting the corresponding GPIO\_Px\_OVTDIS bit) to reduce any potential distortion introduced by the OVT circuitry.

ADC external reference inputs are not routed through the APORT, and the maximum supported analog input voltage for an external reference will also be limited to the  $\text{MIN}(V_{ADC}, \text{IOVDD})$ .

### 22.3.7 Input Selection

The ADC samples and converts the analog voltage differential at its positive and negative voltage inputs. The input multiplexers of the ADC can connect these inputs to one of several internal nodes (e.g., temperature sensor) or to external signals via analog ports (APORT0, APORT1, APORT2, APORT3 or APORT4).

The analog ports APORT1, APORT2, APORT3, and APORT4 connect to external pins via analog buses (BUSAX, BUSAY, BUSBX, etc.) which are shared among other analog peripherals on the device. APORT1 through APORT4 are each 32 channels wide with connections to two sub-buses: a 16-channel X bus and a 16-channel Y bus. In the ADC module, all X buses connect to the INP\_MUX and all Y buses connect to the INN\_MUX as shown in [Figure 22.5 APORT Connection to the ADC on page 722](#). Connections to the X and Y sub-buses alternate channels on the APORT. On APORT1 and APORT3, even-numbered channels connect to the X bus, and odd-numbered channels connect to the Y bus. On APORT2 and APORT4, even-numbered channels connect to the X bus and odd-numbered channels connect to the Y bus. The APORT to BUS mappings may vary from device to device. Refer to the APORT Client Map in the device data sheet for exact mappings.

Unlike APORT1 through APORT4, APORT0 is not a shared resource. It consists of a 16-channel X bus and a 16-channel Y bus, each with dedicated I/O pin connections. Note that APORT0 is not available on all device families.

**Figure 22.5. APORT Connection to the ADC**

For differential measurements, one input must be chosen from an X bus and the other from a Y bus. Choosing both inputs from an X bus or both from a Y bus will generate a PROGERR interrupt (if enabled) of NEGSELCONF type. The PROGERR type can be checked in the ADCn\_STATUS register.

The mapping and availability for external I/O connections to ADC0 inputs is shown in device data sheet.

Multiple peripherals may request the same shared system bus (BUSAX, BUSAY, BUSBX, etc.). When this happens, a conflict status is generated and that bus is kept floating. If this happens with the ADC, the PROGERR field in ADCn\_STATUS is set to BUSCONF, and an interrupt may be generated (if enabled). When connecting dedicated I/Os through APORT0, all inputs are available to APORT0X and APORT0Y and no bus conflict is possible. Refer to [22.3.7.3 APORT Conflicts](#) for more information on identifying and resolving bus conflicts.

**Note:** The internal inputs can only be sampled in single channel, single-ended mode. NEGSEL should be fixed to VSS for these conversions.

### 22.3.7.1 Configuring ADC Inputs in Single Channel Mode

In single channel mode, the ADCn\_SINGLECTRL register provides the POSSEL and NEGSEL selection for positive and negative channel selection of the ADC. The APORT Client Map provides external pin to internal bus channel mapping enumeration for a particular device. Software can also choose internal nodes for POSSEL.

For all single-ended conversions, VSS must be selected in NEGSEL.

Note that in both the POSSEL and NEGSEL fields, it is possible to choose inputs from both X and Y buses, even though X channels are physically connected to the positive mux (INP\_MUX) and Y channels are physically connected to the negative mux (INN\_MUX). For single-ended operation (DIFF = 0), if the positive input is chosen from a Y channel the ADC performs a negative single ended conversion and automatically inverts the result at the end, producing a positive result. For differential conversions (DIFF = 1), if a Y channel is chosen for the positive input and an X channel is chosen for the negative input, the ADC result will be inverted to produce the correct polarity.

Refer to device-specific data sheet for specific pin connection options. Note that the same I/O pin may appear in multiple locations.

### 22.3.7.2 Configuring ADC Inputs in Scan Mode

In scan mode, the ADC can sample and convert up to 32 external channels on each conversion trigger. Internal channels are not available in scan mode. The ADC's scanner logic automatically changes the input mux settings between conversions, eliminating the need for firmware intervention.

The ADC scanner logic is controlled by a set of 32 logical channels called SCANINPUTIDs. The 32 SCANINPUTIDs are arranged in four groups of 8 channels each. Each channel group can point to a predefined series of 8 sequential channels on any of the available APORTs. The ADCn\_SCANINPUTSEL register is used to configure which group of physical APORT channels each of the SCANINPUTID channel groups map to. For example, selecting APORT1CH16TOCH23 in the INPUT7TO0SEL field selects APORT1CH16 for SCANINPUTID0, APORT1CH17 for SCANINPUTID1, APORT1CH18 for SCANINPUTID2, and so on.

The four SCANINPUTID groups are fully independent and may be selected from any APORT in any combination. It is possible also to repeat the same selection in multiple groups. For example, the user may select APORT2CH0TOCH7 for all four of the SCANINPUTID groups.

In many cases, the user application will not require all 32 channels of the scanner to be converted. Each of the scanner channels may be individually enabled according to the needs of the system. The ADCn\_SCANMASK register is used to enable and disable individual SCANINPUTIDs. The bits in the ADCn\_SCANMASK register correspond one-to-one with the SCANINPUTID channel numbers. During a scan operation, the ADC scanner logic will convert only the enabled SCANINPUTIDs, in order from lowest to highest.

In single-ended mode, all conversions performed by the ADC will be relative to VSS. For any enabled SCANINPUTID, the selected APORT channel will be connected to the ADC with the opposite ADC input terminal connected to VSS. Note that the channel groups selected in ADCn\_SCANINPUTSEL point to a block of 8 channels on an APORT, which includes both X and Y channels. Depending on the channels enabled by ADCn\_SCANMASK, the ADC may perform conversions on the X or the Y bus associated with that APORT.

Figure 22.6 ADC Single-ended Scan Mode Example on page 724 shows an example of a single-ended scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects six of these channels for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of six single-ended ADC conversions: PF0, PF3, PA5, PA5, PF7, and PF4.

| SCANINPUTSEL  | APORT1CH16TO23 |      |      |      |      |      |      |      | APORT1CH16TO23 |      |      |      |      |      |      |      | APORT4CH8TO15 |      |      |      |      |      |     |     | APORT1CH16TO23 |      |      |      |      |      |      |      |
|---------------|----------------|------|------|------|------|------|------|------|----------------|------|------|------|------|------|------|------|---------------|------|------|------|------|------|-----|-----|----------------|------|------|------|------|------|------|------|

| I/O Pin       | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  | none          | none | PA5  | PA4  | PA3  | PA2  | PA1 | PA0 | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  |
| SCANMASK      | 0              | 0    | 0    | 1    | 0    | 0    | 0    | 0    | 1              | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0             | 0    | 1    | 1    | 0    | 0    | 0   | 0   | 0              | 0    | 0    | 0    | 1    | 0    | 0    | 1    |
| SCANINPUTID   | 31             |      |      |      |      |      |      |      | 24 23          |      |      |      |      |      |      |      | 16 15         |      |      |      |      |      |     |     | 8 7            |      |      |      |      |      |      |      |

Figure 22.6. ADC Single-ended Scan Mode Example

In differential mode, the default operation of the ADC scanner is to perform a differential measurement between the selected APORT channel and the next channel on that APORT. For example, if the enabled SCANINPUTID points to APORT1CH6, the ADC will perform a differential conversion between APORT1CH6 and APORT1CH7.

There are two exceptions to this rule, listed in order of precedence:

1. When converting SCANINPUTID15, the differential conversion will be performed between the channel selected by SCANINPUTID15 and the channel selected by SCANINPUTID8.
2. When APORTnCH31 is the selected input, the differential conversion will be performed between APORTnCH31 and APORTnCH0.

Figure 22.7 ADC Differential Scan Mode Example on page 725 shows an example of a differential scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects three channels pairs for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of three differential ADC conversions: PF0-PF1, PF2-PF3, and PA4-PA5.

| SCANINPUTSEL                | APORT1CH16TO23 |         |         |         |         |         |         |         | APORT1CH16TO23 |         |         |         |         |         |         |         | APORT4CH8TO15 |      |          |         |         |         |         |         | APORT1CH16TO23 |         |         |         |         |         |         |         |
|-----------------------------|----------------|---------|---------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|---------|---------------|------|----------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|---------|
| APORT-Channel<br>(Positive) | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    | 4-15          | 4-14 | 4-13     | 4-12    | 4-11    | 4-10    | 4-9     | 4-8     | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    |

| SCANINPUTID                 | 31             |         |         |         |         |         |         |         | 24             | 23      |         |         |         |         |         |         | 16            | 15   |          |         |         |         |         | 8       | 7              |         |         |         |         |         |         |         |

Figure 22.7. ADC Differential Scan Mode Example

In certain applications it may be desirable to perform differential conversions on several channels against a common voltage. The ADCn\_SCANNEGSEL register allows eight of the SCANINPUTIDs to re-map the negative terminal of a differential conversion to a common channel. In the first ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 0, 2, 4, and 6 may be re-mapped to any of the odd-numbered channels in that group (SCANINPUT 1, 3, 5, or 7). Likewise, in the second ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 9, 11, 13, and 15 may be re-mapped to any of the even-numbered channels in that group (SCANINPUT 8, 10, 12, or 14).

Figure 22.8 ADC Differential Scan Mode Re-mapping Negative Input Selections on page 725 shows the effects of the ADCn\_SCANNEGSEL register on the re-mappable inputs. The left side of the figure shows the default channel mapping, and the right side of the figure shows how ADCn\_SCANNEGSEL can be programmed to map the same negative input on up to four channels.

| Default SCANNEGSEL Selections |                |         |         |         |         |         |         |         |                |         |         |         |         |         |         | Re-mapped using SCANNEGSEL |                |         |         |         |         |         |         |         |                |         |         |         |         |         |         |      |
|-------------------------------|----------------|---------|---------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|----------------------------|----------------|---------|---------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|------|

Figure 22.8. ADC Differential Scan Mode Re-mapping Negative Input Selections

### 22.3.7.3 APORT Conflicts

The ADC shares common analog buses connected to its APORTs (1-4) with other analog peripherals (see device-specific data sheet). As the ADC performs single or scan conversions, it requests the shared buses and sends selections for the control switches to connect the desired I/O pins. If another analog peripheral requests the same shared bus at the same time, there will be a collision and none of the peripherals will be granted control of that bus.

To help debug over-utilization of APORT resources, the ADC hardware provides status information in local registers. The ADCn\_APORTREQ register gives the user visibility into which APORT(s) the ADC is requesting given the setting of the input selection registers. ADCn\_APORTCONFLICT reports any conflicts that occur. If PROGERR in ADCn\_IEN is set, any conflict generates an interrupt. The PROGERR field in the ADCn\_STATUS register indicates whether the programming error happened as a result of an APORT bus conflict (BUSCONF) or from a negative-input selection conflict (NEGSELCONF). If the PROGERR interrupt occurred due to a negative selection conflict, then the interrupt can be cleared by software only after correcting the conflict. If a software clear is attempted without correcting the configuration, the interrupt will be cleared for one clock cycle but then it will trigger again as the invalid configuration still persists.

**Note:** The ADC requests shared bus connections as soon as that bus is selected in the input select registers, even if the ADC is not performing any conversions. This means that by using the APORT request, the ADC will acquire the associated shared analog bus, preventing other peripherals from using it. The bus will be released only when the input select registers are changed.

It is possible for the ADC to passively monitor shared bus signals without controlling the switches and creating bus conflicts. This can be done by setting the ADCn\_APORTMASTERDIS register. When ADCn\_APORTMASTERDIS is used, channel selection defers to the peripheral acting as the bus master for that shared bus, and no bus conflict will occur. The ADC will connect its input to the shared bus, but the specific channel will be controlled by the peripheral designated as the bus master.

### 22.3.8 Reference Selection and Input Range Definition

The full scale voltage (VFS) of the ADC is defined as the full input range, from the lowest possible input voltage to the highest. For single-ended conversions, the input range on the selected positive input is from 0 to VFS. For differential conversions, the input to the converter is the difference between the positive and negative input selections. This can range from -VFS/2 to +VFS/2.

VFS for the converter is determined by a combination of the selected voltage reference (VREF) and programmable divider circuits on the ADC input and voltage reference paths. Users have full control over the VREF and divider selections, offering a very flexible and wide selection of VFS values. In most applications however, it is not necessary to adjust VFS beyond a set of common pre-defined choices. For the simplest VFS configuration, refer to [22.3.8.1 Basic Full-Scale Voltage Configuration](#). If the application requires a VFS configuration not available in the pre-defined choices, [22.3.8.2 Advanced Full-Scale Voltage Configuration](#) covers additional configuration options.

### 22.3.8.1 Basic Full-Scale Voltage Configuration

Basic configuration of the VFS (full scale voltage) for the converter is done by programming the REF bitfield in ADCn\_SINGLECTRL (for single channel mode) or ADCn\_SCANCTRL (for scan mode) to any of the pre-defined options. The list of available pre-defined VFS options is:

- VFS = 1.25 V using internal VBGR as the reference source
- VFS = 2.5 V using internal VBGR as the reference source
- VFS = AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)
- VFS = 5 V using internal VBGR as the reference source
- VFS = ADCn\_EXTP external pin as a single-ended reference source (1.2 V - 3.6 V)
- VFS = ADCn\_EXTP - ADCn\_EXTN external pins as a differential reference source. ( 1.2 V - 3.6 V difference)
- VFS = 2 x AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and IOVDD supply voltages (where  $V_{ADC}$  is VDDX\_ANA, as described in [22.3.5 Power Supply](#)). If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn\_BIASPROG should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software may set GPBIASACC in ADCn\_BIASPROG to 1 (LOWACC) to conserve energy. Note that DC-DC usage may also switch the chip-level bias to high- accuracy mode (even if GPBIASACC is set to LOWACC), potentially impacting ADC results. DC-DC startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if DC-DC startup happens when ADC is doing a conversion (with GPBIASACC set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25  $\mu$ s. It is during this time that ADC conversions with the GPBIASACC set to LOWACC should be avoided.

If the pre-defined VFS options do not suit the particular application, refer to [22.3.8.2 Advanced Full-Scale Voltage Configuration](#) for more advanced VFS options.

### 22.3.8.2 Advanced Full-Scale Voltage Configuration

For most applications, the pre-defined VFS options described in [22.3.8.1 Basic Full-Scale Voltage Configuration](#) are suitable. Advanced VFS configurations are also possible by programming the REF bitfield in ADCn\_SINGLECTRL or ADCn\_SCANCTRL to the CONF option. Programming the REF bitfield to CONF allows the user to select the specific VREF source and adjust the programmable input and reference divider options directly.

The general procedure for programming an advanced VFS configuration is as follows:

1. Select the voltage reference source using VREFSEL.
2. Configure VREFATTFIX and VREFATT so that the reference voltage at the ADC is between 0.7 and 1.05 V.
3. Configure VINATT to achieve the desired full-scale voltage.

The VREFSEL field in ADCn\_SINGLECTRLX or ADCn\_SCANCTRLX selects the voltage reference source. The ADC can choose from the following voltage reference (VREF) sources:

- VBGR: An internal 0.83 V bandgap reference voltage. This is the most precise internal reference source available.
- VDDXWATT: An attenuated version of the AVDD supply voltage. The attenuation factor is determined by the VREFATTFIX and/or VREFATT bit fields.
- VREFPWATT: An external reference source applied to the ADCn\_EXTP pin, and attenuated by the attenuation factor (determined by the VREFATTFIX and/or VREFATT bit fields). This is the appropriate choice for external reference inputs greater than 1.05 V.
- VREFP: An external reference source applied to the ADCn\_EXTP pin, without any attenuation. This is the appropriate choice for external reference inputs between 0.7 V and 1.05 V.
- VENTROPY: A very low internal reference voltage (approx. 0.1 V). This option is intended to be used only with the ADC inputs tied internally to VSS, for generating random noise at the ADC output.
- VREFPNWATT: A differential version of VREFPWATT, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and attenuated. This is the appropriate choice where a differential reference of greater than 1.05 V is required.
- VREFPN: A differential version of VREFP, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and no attenuation. This is the appropriate choice where a differential reference of between 0.7 V and 1.05 V is required.
- VBGRLOW: An internal 0.78 V bandgap reference voltage.

The ADC reference voltage should be attenuated to a lower voltage when using AVDD or the external reference source. A simple method for a wide range of reference sources is to set VREFATTFIX to 1. The VREF attenuation factor ( $ATT_{VREF}$ ) can then be selected between 1/3 (when VREFATT is greater than 0), and 1/4 (when VREFATT is equal to 0). For reference sources between 1.2 V and 3.6 V,  $ATT_{VREF} = 1/3$  is the best choice.  $ATT_{VREF} = 1/4$  can be used with references from 1.6 V to 3.8 V, with slight performance degradation.

Finer granularity on  $ATT_{VREF}$  is possible as well, by clearing VREFATTFIX to 0, and setting the VREFATT field. For optimal performance with VREFATTFIX = 0, the attenuated ADC reference input should be limited to between 0.7 V and 1.05 V. When VREFATTFIX is cleared to 0,  $ATT_{VREF}$  is set according to the equation:

$$ATT_{VREF} = (VREFATT + 6) / 24 \text{ for } VREFATT < 13, \text{ and } (VREFATT - 3) / 12 \text{ for } VREFATT \geq 13$$

**Figure 22.9.  $ATT_{VREF}$ : VREF Attenuation Factor**

The ADC input also includes a programmable attenuator. The VIN attenuator is used to widen the available input range of the ADC beyond the reference source. The VIN attenuation factor ( $ATT_{VIN}$ ) is determined by the VINATT field according to the equation:

$$ATT_{VIN} = VINATT / 12 \text{ for } VINATT \geq 3 \text{ (settings 0, 1, and 2 are not allowable values for VINATT)}$$

**Figure 22.10.  $ATT_{VIN}$ : VIN Attenuation Factor**

VFS can be calculated by the formula given below for any given VREF source, VREF attenuation, and VIN attenuation:

$$VFS = 2 \times VREF \times ATT_{VREF} / ATT_{VIN}$$

VREF is selected in the VREFSEL bitfield, and

$ATT_{VREF}$  is the VREF attenuation factor, determined by VREFATT or VREFATTFIX

$ATT_{VIN}$  is the VIN attenuation factor, determined by VINATT

**Figure 22.11. VFS: Full-Scale Input Range**

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and  $IOVDD$  supply voltages (where  $V_{ADC}$  is  $VDDX\_ANA$ , as described in [22.3.5 Power Supply](#)). If  $VFS$  is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and  $VFS$  configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective  $VFS$  is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source,  $GPBIASACC$  in  $ADCN\_BIASPROG$  should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When  $AVDD$  or an external pin reference option is used, software may set  $GPBIASACC$  in  $ADCN\_BIASPROG$  to 1 (LOWACC) to conserve energy. Note that DC-DC usage may also switch the chip-level bias to high- accuracy mode (even if  $GPBIASACC$  is set to LOWACC), potentially impacting ADC results. DC-DC startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if DC-DC startup happens when ADC is doing a conversion (with  $GPBIASACC$  set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25  $\mu s$ . It is during this time that ADC conversions with the  $GPBIASACC$  set to LOWACC should be avoided.

The combination of  $VREF$ ,  $ATT_{VREF}$  and  $ATT_{VIN}$  can produce a wide range of full-scale voltage options for the converter. [Table 22.1 Advanced VFS Configuration:  \$VREF = AVDD\$  on page 729](#) shows some example VFS configurations using  $AVDD$  as a reference source.

**Table 22.1. Advanced VFS Configuration:  $VREF = AVDD$**

| AVDD Voltage | VREF Attenuation Settings                               | Reference Voltage at ADC | VIN Attenuation Settings          | VFS                                 |
|--------------|---------------------------------------------------------|--------------------------|-----------------------------------|-------------------------------------|
| 1.85 V       | $VREFATTFIX = 0$<br>$VREFATT = 6$<br>$ATT_{VREF} = 1/2$ | 0.925 V                  | $VINATT = 12$<br>$ATT_{VIN} = 1$  | 1.85 V<br>(+/-0.925 V differential) |
| 3.0 V        | $VREFATTFIX = 0$<br>$VREFATT = 2$<br>$ATT_{VREF} = 1/3$ | 1.0 V                    | $VINATT = 8$<br>$ATT_{VIN} = 2/3$ | 3.0 V<br>(+/-1.5 V differential)    |
| 3.0 V        | $VREFATTFIX = 0$<br>$VREFATT = 2$<br>$ATT_{VREF} = 1/3$ | 1.0 V                    | $VINATT = 4$<br>$ATT_{VIN} = 1/3$ | 6.0 V<br>(+/-3.0 V differential)    |
| 3.6 V        | $VREFATTFIX = 1$<br>$VREFATT = 0$<br>$ATT_{VREF} = 1/4$ | 0.9 V                    | $VINATT = 6$<br>$ATT_{VIN} = 1/2$ | 3.6 V<br>(+/-1.8 V differential)    |

### 22.3.9 Programming of Bias Current

The ADC uses a chip-level bias generator to provide bias current for its operation. The ADC's internal bias can be scaled by  $ADCBIASPROG$  field of the  $ADCN\_BIASPROG$  register. At lower conversion speeds, the  $ADCBIASPROG$  can be used to lower active power. Some commonly used settings are given in the  $ADCBIASPROG$  register description. For proper operation, the ADC conversion speed must be scaled accordingly. The scale factor is calculated as:

$$\text{Bias scale factor} = (1 - ADCBIASPROG[2:0]/8) / (1 + 3 \times ADCBIASPROG[3])$$

**Figure 22.12. Bias Scale Factor**

The bias programming register also includes the  $VFAULTCLR$  bit field. If  $VREFOF$  interrupt is enabled and it is triggered, then the user needs to set this bit in the ISR before clearing the interrupt flag. This bit then needs to be reset after the interrupt flag is cleared in order to enable the  $VREFOV$  flag to trigger on the next  $VREFOV$  condition.

The bias current settings should only be changed while the ADC is disabled (i.e. in NORMAL warm-up mode and no conversion in progress).

## 22.3.10 Feature Set

The following sections explain different ADC features.

### 22.3.10.1 Conversion Tailgating

Scan conversions have priority over single channel conversions. This means that if scan and single triggers are received simultaneously, or even if the scan is received later when ADC is being warmed up for performing a single conversion, the scan conversion will have priority and will be done before the single conversion. However, a scan trigger will not interrupt in the middle of a single conversion, i.e., if the single conversion is in the acquisition or approximation phase, then the scan will have to wait for the single conversion to complete. If a scan sequence is triggered by a timer on a periodic basis, single channel conversion that started just before a scan trigger can delay the start of the scan sequence, thus causing jitter in sample rate. To solve this, conversion tailgating can be chosen by setting TAILGATE in ADCn\_CTRL. When this bit is set, any triggered single channels will wait for the next scan sequence to finish before activating (see [Figure 22.13 ADC Conversion Tailgating on page 730](#)). The single channel will then follow immediately after the scan sequence. In this way, the scan sequence will always start immediately when triggered, provided that the period between the scan triggers is big enough to allow the single sample conversion that was triggered to finish before the next scan trigger arrives. Note that if tailgating is set and a single channel conversion is triggered, it will indefinitely wait for a scan conversion before starting the single channel conversion.

Figure 22.13. ADC Conversion Tailgating

### 22.3.10.2 Repetitive Mode

Both single channel and scan mode can be run as a one shot conversion or in repetitive mode. The REP bitfield in ADCn\_SINGLECTRL/ADCn\_SCANCTRL registers can be used to activate the repetitive mode for single and scan respectively. In order to achieve the maximum sampling rate of 1 Msps, repetitive mode should be used.

### 22.3.10.3 Conversion Trigger

The conversion modes can be activated by writing a 1 to the SINGLESTART or SCANSTART bit in the ADCn\_CMD register. The conversions can be stopped by writing a 1 to the SINGLESTOP or SCANSTOP bit in the ADCn\_CMD register. A START command will have priority over a STOP command. When the ADC is stopped in the middle of a conversion, the result buffer is cleared (the FIFO contents for any prior conversions are still intact). Every time a STOP command is issued, the user should wait for the corresponding status flag (SINGLEACT/SCANACT) to go low and then either read all the data in the FIFO or send the corresponding FIFOCLEAR command. The SINGLEACT and SCANACT bits in ADCn\_STATUS are set high when the modes are actively converting or have pending conversions.

It is also possible to trigger conversions from PRS signals. The PRS is treated as an asynchronous trigger. Setting PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL enables triggering from PRS input. Which PRS channel to listen to is defined by PRSSEL in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. When PRS trigger is selected, it is still possible to trigger a conversion from software. Refer to the PRS chapter for more information on how to set up the PRS channels. When the conversions are triggered using the ADCn\_CMD register, then the SINGLEACT and SCANACT bits in the ADCn\_STATUS are set as soon as the START command is written to the register. When the conversion is triggered using PRS, it takes some cycles from the time PRS trigger is received until the SINGLEACT and SCANACT bits are set due to the synchronization requirement. If SINGLEACT is already high then sending a new START command or a new PRS trigger for a single conversion will not have any impact as ADC already has a single conversion ongoing or a single conversion pending (single conversion can be pending if ADC is busy running a scan sequence). The same rules apply for SCANACT and SCAN START and PRS triggers. When software issues a SINGLE/SCAN STOP command, it must wait until SINGLEACT/SCANACT flag goes low before issuing a new START.

The PRS may trigger the ADC in two possible ways, configured by PRSMODE in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. In PULSED mode, a PRS pulse triggers the ADC to start the ADC\_CLK (if not already enabled), warm up (if not already warm), start the acquisition period, and perform the conversion. This is identical to issuing a START command from software. In this mode, the input sampling finishes at the end of the acquisition period (AT).

If the ADC\_CLK and the source of the trigger (START command or PRS pulse) are not synchronous, the frequency of the input sampling (FS), will experience a  $1\frac{1}{2}$  to  $2\frac{1}{2}$  ADC\_CLK cycle jitter due to synchronization requirements.

To precisely control the sample frequency, the PRSMODE can be set to TIMED mode. In this mode, a long PRS pulse is expected to trigger the ADC and its negative edge directly finishes input sampling and starts the approximation phase, giving precise sampling frequency management. The restriction is that the PRS pulse has to be long enough to start the ADC\_CLK (if not already enabled), and finish the acquisition period based on the AT field in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The PRS pulse needs to be high when AT event finishes. If it is not high when AT finishes, then it is ignored and input sampling finishes after AT event has ended (a two cycle latency is added to the conversion in this scenario).

If the PRS pulse is too long (e.g., FS = 32kHz), the analog ADC start can be delayed to save power. The CONVSTARTDELAY along with its EN in the ADCn\_SINGLECTRLX or ADCn\_SCANCTRLX can be programmed to implement a 0 to 8 microseconds delay. The microsecond tick is counted by TIMEBASE with ADC\_CLK similar to warmup case. This saves power as the ADC is not enabled until the last possible microsecond before the fall edge of the PRS arrives to open the sampling switch and to start the approximation phase. [Figure 22.14 ADC PRS Timed Mode with ASNEEDED ADC\\_CLK Request on page 731](#) shows PRS Timed mode triggering with CONVSTARTDELAY and ASNEEDED ADC\_CLK request. See that power is saved by both delaying the ADC EN and by requesting the ADC\_CLK only during ADC operation. This is especially useful in saving power when running the ADC in EM2 DeepSleep or EM3 Stop power mode with low sampling frequency.

**Figure 22.14. ADC PRS Timed Mode with ASNEEDED ADC\_CLK Request**

When a PRS pulse is received, if the ADC\_CLK is not running (ASNEEDED mode), then the ADC requests the clock by setting clkreq\_adc\_async high. If the chosen clock source (HFXO/ HFSRCCLK/ AUXHFRCO) is already running, then it takes 5 ADC\_CLK cycles after the clock request is asserted for the ADC\_CLK to start. HFXO and HFSRCCLK (if chosen as ADC clock source) need to be already running before ADC sends out the clock request. If AUXHFRCO is chosen as the ADC clock source, and it is not already

running, then the CMU automatically turns it on when the ADC sends a clock request. In such a case, it takes (7 ADC\_CLK cycles + the oscillator startup time) for the ADC\_CLK to start. The oscillator startup time can be found in the device data sheet.

When triggering repeat mode using PRS and then stopping the triggered mode using STOP command, ensure that the PRS pulse used to generate the repeat mode has gone low by the time the STOP command is issued. If the PRS pulse continues to stay high after ADC has stopped the ongoing conversion, then it will be picked as a new trigger to start a new conversion.

**Note:**

- The conversion settings should not be changed while the ADC is running. Doing so may lead to unpredictable behavior.
- The `adc_clk_sar` phase is always reset by a conversion trigger as long as a conversion is not in progress. This gives predictable latency from the time of the trigger to the time the conversion starts, regardless of when in the trigger occurs.
- Software should not trigger conversions if PRS Timed mode is selected and PRSEN is set to 1 in the ADCn\_SINGLECTRL/ADCn\_SCANCTRL register.
- If the PRS Timed mode is being used, the acquisition time (AT) must be set greater than 0.

#### 22.3.10.4 Output Results

ADC output results are presented in 2's complement form and the format for single ended and differential conversions are given in [Table 22.2 ADC Single Ended Conversion on page 732](#) and [Table 22.3 ADC Differential Conversion on page 732](#), respectively. If differential mode is selected, the results are sign extended up to 32-bits (shown in [Table 22.5 ADC Results Representation on page 733](#)).

**Table 22.2. ADC Single Ended Conversion**

| Input Voltage          | Output Results |           |
|------------------------|----------------|-----------|
|                        | Binary         | Hex value |
| $4095/4096 \times VFS$ | 111111111111   | FFF       |
| $0.5 \times VFS$       | 100000000000   | 800       |
| $1/4096 \times VFS$    | 000000000001   | 001       |
| 0                      | 000000000000   | 000       |

**Table 22.3. ADC Differential Conversion**

| Input                  | Output Results |           |
|------------------------|----------------|-----------|
|                        | Binary         | Hex value |
| $2047/4096 \times VFS$ | 011111111111   | 7FF       |
| $0.25 \times VFS$      | 010000000000   | 400       |
| $1/4096 \times VFS$    | 000000000001   | 001       |
| 0                      | 000000000000   | 000       |
| $-1/4096 \times VFS$   | 111111111111   | FFF       |
| $-0.25 \times VFS$     | 110000000000   | C00       |
| $-0.5 \times VFS$      | 100000000000   | 800       |

#### 22.3.10.5 Resolution

The ADC performs 12-bit conversions by default. However, if full 12-bit resolution is not needed, it is possible to speed up the conversion by selecting a lower resolution (6 or 8 bits). For more information on the accuracy of the ADC, the reader is referred to the electrical characteristics section for the device.

### 22.3.10.6 Oversampling

To achieve higher accuracy, hardware oversampling can be enabled individually for each mode (Set RES in ADCn\_SINGLECTRL/ADCn\_SCANCTRL to 0x3). The oversampling rate (OVSSEL in ADCn\_CTRL) can be set to any integer power of 2 from 2 to 4096 and the configuration is shared between the scan and single channel mode (OVSSEL field in ADCn\_CTRL).

With oversampling, each input is sampled at 12-bits of resolution a number of times (given by OVSSEL), and the results are filtered by a first order accumulate and dump filter to form the end result. The data presented in the ADCn\_SINGLEDATA and ADCn\_SCANDATA registers are the direct contents of the accumulation register (sum of samples). However, if the oversampling ratio is set higher than 16x, the accumulated results are shifted to fit the MSB in bit 15 as shown in [Table 22.4 Oversampling Result Shifting and Resolution on page 733](#).

**Table 22.4. Oversampling Result Shifting and Resolution**

| Oversampling setting | # right shifts | Result Resolution # bits |
|----------------------|----------------|--------------------------|
| 2x                   | 0              | 13                       |
| 4x                   | 0              | 14                       |
| 8x                   | 0              | 15                       |
| 16x                  | 0              | 16                       |
| 32x                  | 1              | 16                       |
| 64x                  | 2              | 16                       |
| 128x                 | 3              | 16                       |
| 256x                 | 4              | 16                       |
| 512x                 | 5              | 16                       |
| 1024x                | 6              | 16                       |
| 2048x                | 7              | 16                       |
| 4096x                | 8              | 16                       |

### 22.3.10.7 Adjustment

By default, all results are right adjusted, with the LSB of the result in bit position 0 (zero). In differential mode the signed bit is extended up to bit 31, but in single ended mode the bits above the result are read as 0. By setting ADJ in ADCn\_SINGLECTRL/ADCn\_SCANCTRL, the results are left adjusted as shown in [Table 22.5 ADC Results Representation on page 733](#). When left adjusted, the MSB is always placed on bit 15 and sign extended to bit 31. All bits below the conversion result are read as 0 (zero).

**Table 22.5. ADC Results Representation**

| Adjustment | Resolution | Bits      |    |    |    |    |    |    |   |   |   |   |   |   |   |   |     |
|------------|------------|-----------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|-----|
|            |            | 31 ... 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 0 |
| Right      | 12         | 11 ... 11 | 11 | 11 | 11 | 11 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 0 |
|            | 8          | 7 ... 7   | 7  | 7  | 7  | 7  | 7  | 7  | 7 | 7 | 7 | 6 | 5 | 4 | 3 | 2 | 1 0 |
|            | 6          | 5 ... 5   | 5  | 5  | 5  | 5  | 5  | 5  | 5 | 5 | 5 | 5 | 5 | 4 | 3 | 2 | 1 0 |
|            | OVS        | 15 ... 15 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 0 |
| Left       | 12         | 11 ... 11 | 11 | 10 | 9  | 8  | 7  | 6  | 5 | 4 | 3 | 2 | 1 | 0 | - | - | - - |
|            | 8          | 7 ... 7   | 7  | 6  | 5  | 4  | 3  | 2  | 1 | 0 | - | - | - | - | - | - | - - |
|            | 6          | 5 ... 5   | 5  | 4  | 3  | 2  | 1  | 0  | - | - | - | - | - | - | - | - | - - |
|            | OVS        | 15 ... 15 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 0 |

### 22.3.10.8 Channel Connection

The inputs are connected to the analog ADC at the beginning of the acquisition phase and are disconnected at the end of the acquisition phase. The time when the APORT switches are closed (for the next input to be converted) can be controlled by the CHCONMODE bitfield in the ADCn\_CTRL register. By default, this field is set to the MAXSETTLE option. For MAXSETTLE, APORT switches are closed on the next input as soon as the acquisition phase for the current conversion is complete. This means that the APORT switches are closed approximately 12 adc\_clk\_sar cycles (assuming 12 bit resolution) before the acquisition phase of the current conversion starts, giving APORT switches maximum time to settle. The time for which APORT switches should be closed before the acquisition phase starts, should be the same for all inputs in order to get consistent results. This means that if the ADC is warmed up with CHCONREFWARMIDLE set to 0 (scan reference warmed up and the APORT switches for the first scan channel closed) and a single trigger comes in, the single conversion will have to wait 12 adc\_clk\_sar cycles before it can start (even if single is using the same reference as scan). In this case, it might be more suitable to switch to the MAXRESP option in the CHCONMODE bitfield. In MAXRESP, the APORT switches for the upcoming conversion are closed just before the acquisition phase starts. This gives less settling time to the APORT switches but removes the extra waiting time before a conversion can start (which could be the case with MAXSETTLE as discussed above).

### 22.3.10.9 Temperature Measurement

The ADC includes an internal temperature sensor. This sensor is measured during production test and the temperature readout from the ADC at production temperature, ADC0CAL3\_TEMPREAD1V25, is given in the Device Information (DI) page. The production temperature, CAL\_TEMP, is also given in this page. The temperature sensor slope, V\_TS\_SLOPE (mV/degree Celsius), for the sensor is found in the data sheet for the device. Using the 1.25 V VFS option and 12-bit resolution, the temperature can be calculated according to the following formula (VFS in the formula is 1250 mV) :

$$T_{\text{CELSIUS}} = \text{CAL\_TEMP} - (\text{ADC0CAL3\_TEMPREAD1V25} - \text{ADC\_result}) \times \text{VFS} / (4096 \times \text{V\_TS\_SLOPE})$$

**Figure 22.15. ADC Temperature Measurement**

When reading the temperature sensor, the GPBIASACC bit in ADCn\_BIASPROG should be set to 1 to keep the bias in LOWACC mode. Note that DC-DC usage while ADC converts (with ADCn\_BIASPROG set to 1) may corrupt ADC results. See section [22.3.8 Reference Selection and Input Range Definition](#) for details.

#### Note:

- The minimum acquisition time for the temperature reference is found in the electrical characteristics for the device. If using the 1.25 V reference, extra acquisition time is required. In this case the AT field of ADCn\_SINGLECTRL or ADCn\_SCANCTRL should be set to a value of 9 or higher.
- If the device has more than one ADC, all ADCs may not be equipped with the temperature sensor. See the device data sheet.

### 22.3.10.10 ADC as a Random Number Generator

The ADC can be used as a random number generator. This is done by:

1. Choose the REF in the ADCn\_SINGLECTRL as CONF, setting the VREFSEL in the ADCn\_SINGLECTRLX as VENTROPY and VINATT in the same register to its maximum value of 15.
2. Set DIFF to 1 and RES to 0 in the ADCn\_SINGLECTRL register.
3. Trigger a single channel conversion and then read ADCn\_SINGLEDATA register when the conversion finishes.

The LSB[2:0] of each sample will be a random number. In this mode, the POSSEL or NEGSEL in ADCn\_SINGLECTRL can be connected to VSS or any other noisy input.

### 22.3.11 Interrupts, PRS Output

The single and scan modes have separate SINGLE and SCAN interrupt flags indicating whether corresponding FIFO contains DVL # of valid conversion data. Corresponding interrupt enable bit has to be set in ADCn\_IEN in order to generate interrupts. For these interrupts, there is no software clear mechanism by writing to ADCn\_IFC. The user needs to read enough data from the interrupted FIFO to ensure it contains less than DVL # of elements. The ADCn\_SINGLEFIFOCOUNT/ADCn\_SCANFIFOCOUNT can provide number of valid elements remaining in corresponding FIFO. The FIFO can also be cleared by ADCn\_SINGLEFIFOCLEAR/ADCn\_SCANFIFOCLEAR, but any existing data will be lost by this operation.

In addition to the SINGLE and SCAN interrupt flags, there is separate scan and single channel result overflow interrupt flag which signals that a result from a scan or single channel FIFO has been overwritten before being read. There is also separate scan and single channel result underflow interrupt flag which signals that a FIFO read was issued when the FIFO was empty.

There is separate scan and single compare interrupt flag which signals a compare match with latest sample if the CMPEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL is enabled.

ADC has two separate PRS outputs, one for single channel and one for scan sequence. A finished conversion results in a one ADC\_CLK cycle pulse, which is output to the Peripheral Reflex System (PRS). Note that the PRS pulse for scan is generated once after every channel conversion in the scan sequence.

### 22.3.12 DMA Request

The ADC has two DMA request lines, SINGLEREQ and SCANREQ, which are set when a single or scan FIFO receives DVL# of samples. The requests are cleared when the corresponding single or scan result register is read and corresponding FIFO count reaches lower than DVL. It also has two additional DMA Single request lines, SINGLESREQ and SCANSREQ, that are set when the corresponding FIFO is not empty.

### 22.3.13 Calibration

The ADC supports offset and gain calibration to correct errors due to process and temperature variations. This must be done individually for each reference used. For each reference, it needs to be repeated for single-ended, negative single-ended (see [22.3.7 Input Selection](#) for details) and differential measurement. The ADC calibration (ADCn\_CAL) register contains register fields for calibrating offset and gain for both single and scan mode. The gain and offset calibration are done in single channel mode, but the resulting calibration values can be used for both single and scan mode.

Gain and offset for various references and modes are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference. Others can be loaded as needed or the user can perform calibration on the fly using the particular reference and mode to be used and write the result in the ADCn\_CAL before starting the ADC conversion with them.

#### 22.3.13.1 Offset Calibration

Offset calibration must be performed prior to gain calibration. Follow these steps for the offset calibration in single mode:

1. Select the desired full scale configuration by setting the REF bit field of the ADCn\_SINGLECTRL register.
2. Set the AT bit field of the ADCn\_SINGLECTRL register to 16CYCLES.
3. Set the POSSEL and NEGSEL of the ADCn\_SINGLECTRL register to VSS, and set the DIFF to 1 for enabling differential input if calibrating for DIFF measurement. During calibration, the ADC samples represent the code coming out of the analog. Thus, since the input voltage is 0, the expected ADC output is 0b100000000000 in differential mode, 0b000000000000 in single-ended mode and 0b111111111111 in negative single-ended mode.
4. A binary search is used to find the offset calibration value. Set the CALEN to 1, and OFFSETINVMODE to 1 (if calibrating for negative single-ended conversion) in the ADCn\_CAL register. If user is performing negative single-ended calibration, the SINGLEOFFSETINV provides the offset else SINGLEOFFSET bit provides the offset (for both single-ended and differential offset calibration). Start with 0b0000 (or 0b1111 if doing calibration for differential mode) in SINGLEOFFSET or with 0b1000 in SINGLEOFFSETINV (if calibrating for negative single-ended conversion). Set the SINGLESTART bit in the ADCn\_CMD register to perform a 12-bit conversion and read the ADCn\_SINGLEDATA register. The offset is (ADCn\_SINGLEDATA - expected ADC output). Calculate this and write [3:0] of the result into SINGLEOFFSET or SCANOFFSETINV (if doing negative single-ended conversion). The user repeats till ADCn\_SINGLEDATA matches expected ADC output. The ADC has a 8LSB built in negative offset to allow for negative offset correction. So, with default offset value, which corrects for the negative offset, the converted ADCn\_SINGLEDATA would match expected ADC output if there were no offset. To get better noise immunity, the sampling phase can be repeated with Oversampling enabled. The result of the binary search is written to the SINGLEOFFSET (or SINGLEOFFSETINV) field of the ADCn\_CAL register.

### 22.3.13.2 Gain Calibration

Offset calibration must be performed prior to gain calibration. The Gain Calibration is done in the following manner:

1. Select an external ADC channel for single channel conversion (a differential channel can also be used).
2. Apply an external voltage on the selected ADC input channel. This voltage should correspond to the top of the ADC input range for the selected reference.
3. Set SINGLEGAIN[6:0] to 64 in the ADCn\_CAL and measure gain, repeat gain calibration walking the 1 in SINGLEGAIN[6] to SINGLEGAIN[0] till sampled ADCn\_SINGLEDATA matches expected value. This is done by setting CALEN in ADCn\_CAL set to 1 and performing single channel, reading in the raw ADC code from the ADCn\_SINGLEDATA and comparing it with expected code, i.e. 0b111111111111 for single-ended or differential conversion, and 0b000000000000 for negative single-ended conversion. The target value is ideally the top of the ADC input range, but it is recommended to use a value a couple of LSBs below in order to avoid overshooting. The result of the binary search is written to the SINGLEGAIN field of the ADCn\_CAL register.

For the VDD reference and external reference, there is no hardware gain calibration. Calibration can be done by software after taking a sample.

### 22.3.14 EM2 DeepSleep or EM3 Stop Operation

The ADC can operate in EM2 DeepSleep or EM3 Stop mode. For EM2 DeepSleep or EM3 Stop operation the ADC\_CLK must be selected as AUXHFRCO. The section [22.3.1 Clock Selection](#) describes how to choose AUXHFRCO as the ADC\_CLK. The AUXHFRCO can be kept on for as long as sample conversion is needed or it can be requested by trigger event and after the conversion is done, the AUXHFRCO can be shut down. The second option saves power at the expense of the delay to start the AUXHFRCO oscillator. All the trigger modes are available in EM2 DeepSleep or EM3 Stop as well.

While in EM2 DeepSleep or EM3 Stop, the ADC can wake the system to EM0 Active on enabled interrupts. Following interrupts can wake up the system to EM0 Active:

- SINGLE or SCAN interrupt indicating that the corresponding FIFO has reached the DVL watermark.
- Overflow interrupt (SINGLEOF or SCANOF)
- Underflow interrupt (SINGLEUF or SCANUF), triggered if DMA pops more data than present in the FIFO while the system is asleep
- Compare interrupt (SINGLECMP or SCANCMP)
- Over voltage interrupt (VREFOV)

The ADC can also work with the DMA so that the system does not have to wake up to consume data. This can happen if the SCAN or SINGLE interrupt is disabled and the SINGLEDMAWU or SCANDMAWU in the ADCn\_CTRL is set. The DMA will be triggered by the ADC when DVL samples become available in the corresponding FIFO. The DMA will then pop all the elements of the corresponding FIFO and put the system back into the low power state. A system-level wake up will occur upon the DMA done interrupt. Note that other enabled ADC interrupts can still wake up the system when operating with the DMA. For example, the user can configure the window compare function to trip when the result reaches a certain threshold while gathering ADC data in EM2 DeepSleep or EM3 Stop.

The ADC works with the EMU to wake up the system or the DMA. It takes 2  $\mu$ s from the time the ADC request a wakeup to start of the peripheral clocks. In this ASYNC mode of ADC\_CLK, it takes 6 HFPERCLK cycles to read a single entry from the single or scan FIFO. So, with a 20MHz HFPERCLK, it takes about 4  $\mu$ s per DMA wakeup to empty a full FIFO (4 entries). This restricts the sampling rate in EM2 DeepSleep or EM3 Stop in order to avoid FIFO overflows.

The AUXHFRCO power can be reduced by reducing the clock speed, and the user may adjust the ADCBIASPROG field in the ADCn\_BIASPROG register to reduce active power of the ADC during the conversions, thus reducing power even more in EM2 DeepSleep/EM3 Stop. Refer to the data sheet for relevant power consumption numbers.

If the ADC is not to be used in EM2 DeepSleep or EM3 Stop, then the user should ensure that the ADC is not busy before going to the low power mode. [22.3.17 ADC Programming Model](#) explains how to ensure the ADC is not busy. If the chip enters EM2 DeepSleep or EM3 Stop when ADC is busy without using AUXHFRCO, then the ADC clock will stop but the ADC will stay on, resulting in higher supply current.

### 22.3.15 ASYNC ADC\_CLK Usage Restrictions and Benefits

When the ADC\_CLK is chosen to come from ASYNCCLK, (ADCCLKMODE is set to ASYNC), the ADC\_CLK and the ADC peripheral clock are considered asynchronous and this adds some restrictions:

- Due to a synchronization delay, accessing the following registers takes extra time (up to additional 7 HFPERCLK cycles): ADCn\_SINGLEDATA, ADCn\_SCANDATA, ADCn\_SINGLEDATAP, ADCn\_SCANDATAP, ADCn\_SCANDATAX, ADCn\_SCANDATAXP, ADCn\_SINGLEFIFOCOUNT, ADCn\_SCANFIFOCOUNT, ADCn\_SINGLEFIFOCLEAR, ADCn\_SCANFIFOCLEAR.
- The safe time to change the ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLx, ADCn\_SCANINPSEL, ADCn\_SCANNEGSEL or ADCn\_SCANMASK register is when SINGLEACT/SCANACT in the ADCn\_STATUS is 0 with no pending trigger event. The user can enforce this by writing the SINGLESTOP or SCANSTOP in the ADCn\_CMD register and ensuring no trigger event can come before modifying the registers.
- When the ADC needs to run in EM2 DeepSleep or EM3 Stop, only AUXHFRCO can provide the ADC\_CLK to the ADC. Thus the user needs to set ASYNC mode of ADCCLKMODE and setup the CMU to provide the AUXHFRCO clock as ASYNCCLK.
- If the ADC needs to run on a particular adc\_clk\_sar frequency to achieve a sample rate and the HFPERCLK is not a proper multiple for such clock frequency, a higher frequency system clock, HFRCO, can be chosen to be ADC\_CLK using ASYNC mode. This allows HFPERCLK to be set to an optimum value from a system view point.
- ASYNC mode can also help with digital noise mitigation as this clock is asynchronous (not balanced) with the system clock. Moreover, the user can use the invert option to invert the source of ASYNCCLK helping in noise mitigation further.
- Whenever ADC is being used in asynchronous mode, then HFPERCLK must be at least 1.5 times higher than the ADC\_CLK.
- With ASNEEDED setting for ASYNCCLK request, the ADC\_CLK power can be reduced.

### 22.3.16 Window Compare Function

The ADC supports a window compare function on both the latest single and scan outputs. The compare thresholds, ADGT and ADLT, are defined in the ADCn\_CMPTHR register. These are 16-bit values and their format must match the type of conversion (single-ended or differential) the user is trying to compare with. For example, a 12-bit differential conversion is sign extended to 16 bits while a 12-bit single-ended conversion result would get zero padded to 16-bit result before comparing with ADGT and ADLT. If over-sampling is enabled, the conversion result could grow to 16-bits. There is a single set of ADLT and ADGT threshold for both single and scan compare. The user can however enable single or scan compare logic individually by enabling CMPEN in ADCn\_SINGLECTRL or ADCn\_SCANCTRL register.

The user can perform comparison both within or outside of the window defined by the ADGT and ADLT. If the ADLT is greater than ADGT, the ADC compares if the current sample is within the window. Otherwise, the ADC compares if the current sample is outside of the window.

### 22.3.17 ADC Programming Model

The ADC configuration registers are considered static and can only be updated when (1) ADC is in SYNC mode and (2) ADC is idle. ADC is considered busy when it is doing conversions (either the SINGLEACT or SCANACT status flag is high) or when it is warmed up (one of the following status flags is high: WARM, SINGLEREFWARM, SCANREFWARM). The following registers are considered ADC configuration registers: CMU\_ADCCTRL, ADCn\_CTRL, ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLX, ADCn\_SCANINPUTSEL, ADCn\_SCANNEGSEL, ADCn\_IEN, ADCn\_BIASPROG, ADCn\_SCANMASK, ADCn\_CAL and ADCn\_CMPTHR.

From reset, the ADC is in SYNC mode by default. The user can program the configuration registers as needed. If PRS is to be used, PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL should be set after all other configuration is complete. Once configuration is complete, the ADC is ready to receive triggers.

After the ADC has been used to perform conversions, the user must ensure that the ADC is idle before updating the configuration registers. The first step is to ensure that no new triggers (PRS) are being issued. It can take a few cycles from when a trigger is received to when SINGLEACT/SCANACT flags go high due to synchronization requirement. If it is unclear when the triggers were issued and if those are under synchronization or not, the user should add a small delay before checking the status flags. If the SINGLEACT/SCANACT status flags are high, the corresponding STOP command should be issued and the user should wait until the SINGLEACT/SCANACT flags go low. If the ADC was warmed up, then the WARMUPMODE should be changed to NORMAL and then the user should wait on WARM, SINGLEREFWARM and SCANREFWARM flags until those go low. Now the ADC is idle.

#### Note:

When switching ADCCLKMODE in the ADCn\_CTRL register, use the appropriate sequence below:

- SYNC to ASYNC:
  1. Disable ADC interrupts
  2. Clear the FIFOs
  3. Switch the ADCCLKMODE

If the ADC is to be used in ASYNC clock mode with WARMUPMODE set to KEEPADCWARM, then both ADCCLKMODE and WARMUPMODE fields in the ADCn\_CTRL register should be set to the desired values in the same register write. This will ensure that the ADC power-on sequence is valid.

- ASYNC TO SYNC:
  1. Disable ADC interrupts
  2. Switch the ADCCLKMODE
  3. Clear the FIFOs

The FIFOs are cleared by writing 1 to the ADCn\_SCANFIFOCLEAR and ADCn\_SINGLEFIFOCLEAR registers.

When switching from ASYNC to SYNC, ensure that the ASYNC clock is turned off before doing the switch.

## 22.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                 | Type  | Description                                                               |
|--------|----------------------|-------|---------------------------------------------------------------------------|
| 0x000  | ADCn_CTRL            | RW    | Control Register                                                          |

| Selects the negative input to the ADC for Single Channel Differential mode (in case of singled ended mode, the negative input is grounded). The user can choose any of the 32 channels of any of the 5 BUSES but must ensure that POSSEL and NEGSEL are chosen from different resources (X or Y) BUS. In case of an invalid configuration, the ADC will perform a single-ended sampling and issue a BUSCONFLICT IRQ. |              |       |        |                                                |

| Selects the positive input to the ADC for single channel operation. Software can choose any of the 32 channels of any BUS as positive input. In DIFF mode POSSEL and NEGSEL need to be chosen from different resources (X or Y). If an X BUS is connected to POSSEL, only a Y BUS can connect to NEGSEL, and vice-versa. The user can also select some internal nodes as positive input for single-ended sampling. These internal nodes cannot be sampled differentially. |             |       |    |                                                |

|       | 0               | PULSED                                                                                                                          |        | Single channel trigger is considered a regular asynchronous pulse that starts ADC warm-up, then acquisition/conversion sequence. The ADC_CLK controls the warmup-time.                                                                              |
|       | 1               | TIMED                                                                                                                           |        | Single channel trigger should be a pulse long enough to provide the required warm-up time for the selected ADC warmup mode. The negative edge requests sample acquisition. DELAY can be used to delay the warm-up request if the pulse is too long. |

|       | 0          | PULSED                                                                                                                   |        | Scan trigger is considered a regular async pulse that starts ADC warm-up, then acquisition/conversion sequence. The ADC_CLK controls the warmup-time.                                                                                     |
|       | 1          | TIMED                                                                                                                    |        | Scan trigger should be a pulse long enough to provide the required warm-up time for the selected ADC warmup mode. The negative edge requests sample acquisition. DELAY can be used to delay the warm-up request if the pulse is too long. |

| Set one or more bits in this mask to select which inputs are included in scan sequence in either single ended or differential mode. This works with SCANINPUTSEL register. The SCANINPUTSEL chooses 32 possible channels for single-ended or 32 pairs of possible channels for differential scanning from BUSES. These chosen channels are referred as ADCn_INPUTx in the description. Four even inputs from first group of 8 ADCn_INPUTx and four odd inputs from second group of 8 ADCn_INPUTx have programmable NEGSEL, defined in SCANNEGSEL register. If the SCANMASK is set to 0 and scan conversion is triggered, ADC will do a conversion with garbage results since no inputs were enabled for conversion. |                    |                                      |        |                                                                                       |

|-------|-----------------|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | CALEN           | 0     | RW     | <b>Calibration Mode is Enabled</b><br><br>When enabled, the adc performs conversion and sends raw data to the ADC fifos. This can also be used to debug the adc data conversion                                                                                                                                                                                                                                                                                                                      |
| 30:24 | SCANGAIN        | 0x40  | RW     | <b>Scan Mode Gain Calibration Value</b><br><br>This register contains the gain calibration value used with scan conversions. This field is set to the production gain calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is unsigned. Higher values lead to higher ADC results.                                                                                                                                     |
| 23:20 | SCANOFFSETINV   | 0x7   | RW     | <b>Scan Mode Offset Calibration Value for Negative Single-ended Mode</b><br><br>This register contains the offset calibration value used with scan conversions for negative single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.                                 |
| 19:16 | SCANOFFSET      | 0x8   | RW     | <b>Scan Mode Offset Calibration Value for Differential or Positive Single-ended Mode</b><br><br>This register contains the offset calibration value used with scan conversions for differential or positive single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results. |
| 15    | OFFSETINVMODE   | 0     | RW     | <b>Negative Single-ended Offset Calibration is Enabled</b><br><br>When enabled, along with CALEN bit, the ADC performs negative singled ended conversion. When not enabled, if CALEN is set, DIFF bit of SINGLECTRL register decides whether to do positive single-ended or differential conversion.                                                                                                                                                                                                 |
| 14:8  | SINGLEGAIN      | 0x40  | RW     | <b>Single Mode Gain Calibration Value</b><br><br>This register contains the gain calibration value used with single conversions. This field is set to the production gain calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is unsigned. Higher values lead to higher ADC results.                                                                                                                                 |
| 7:4   | SINGLEOFFSETINV | 0x7   | RW     | <b>Single Mode Offset Calibration Value for Negative Single-ended Mode</b><br><br>This register contains the offset calibration value used with single conversions for negative single-ended mode. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.                             |

## 23. IDAC - Current Digital to Analog Converter

### Quick Facts

#### What?

The IDAC can sink or source a configurable constant current.

#### Why?

The IDAC can be used to bias external circuits or (in conjunction with the ADC) measure capacitance by injecting a controlled current into a component.

#### How?

In addition to providing a constant current, the IDAC can be switched on and off with a PRS signal all the way down to EM3.

### 23.1 Introduction

The current digital to analog converter (IDAC) can source or sink a configurable constant current from APORT. The current is configurable with several ranges of various step sizes.

### 23.2 Features

- Can source and sink current
- Programmable constant output current
  - Selectable current range between 0.05  $\mu\text{A}$  and 64  $\mu\text{A}$
  - Each range is linearly programmable in 32 steps
  - Support for current calibration
- Support for manual and PRS triggered output enable
- Available in EM0-EM3

### 23.3 Functional Description

An overview of the IDAC module is shown in [Figure 23.1 IDAC Overview on page 785](#). The IDAC is designed to source or sink a programmable current which can be controlled by setting the range and the step in the RANGESEL and STEPSEL bitfields in IDAC\_CURRPROG register. The IDAC output enable can be controlled by software or PRS. The IDAC is enabled by setting EN in IDAC\_CTRL.

Figure 23.1. IDAC Overview

#### 23.3.1 Current Programming

The four different current ranges can be selected by configuring the RANGESEL bitfield in IDAC\_CURRPROG. The current output in each range is linearly programmable in 32 steps, and is controlled by the STEPSEL bitfield in IDAC\_CURRPROG. These current ranges and their step sizes are shown in [Table 23.1 Range Selection on page 785](#).

Table 23.1. Range Selection

| Range Select | Range Value [ $\mu$ A] | Step Size [nA] | Step Counts |
|--------------|------------------------|----------------|-------------|
| 0            | 0.05 - 1.6             | 50             | 32          |
| 1            | 1.6 - 4.7              | 100            | 32          |
| 2            | 0.5 - 16               | 500            | 32          |
| 3            | 2 - 64                 | 2000           | 32          |

#### 23.3.2 IDAC Enable and Warm-up

The IDAC is enabled by setting the EN bit in IDAC\_CTRL. When this bit is set, the IDAC must stabilize before its output current is stable.

It is important to wait until the IDAC is warmed up, or until any current programming is complete and the output current is stabilized, before entering EM1, EM2, or EM3.

#### 23.3.3 Output Control

The IDAC output enable is controlled by the APORTOUTENPRS bit field in IDAC\_CTRL. If APORTOUTENPRS is set, output enable is controlled by PRS, else it is controlled by software via APORTOUTEN.

### 23.3.4 APORT Configuration

The IDAC APORT outputs can be routed to pins through the APORT system. Note that the IDAC has only two local APORT interfaces APORT1X and APORT1Y, which are connected to the APORT BUSCX and BUSCY, respectively. The pins are selected by requesting an APORT channel in APORTOUTSEL in IDAC\_CTRL. For mapping between APORT channel and physical pin, please refer to data sheet. The IDAC can be in either master or slave mode when connecting to the APORT. By default the IDAC is in master mode. To enable slave mode, set APORTMASTERDIS in IDAC\_CTRL. As IDAC is only capable of driving an APORT channel, only master mode is meaningful for IDAC. If the IDAC is in master mode, and another module is currently driving the requested channel, the APORTCONFLICT bitfield in IDAC\_STATUS will be set together with APORT1XCONFLICT or APORT1YCONFLICT in IDAC\_APORTCONFLICT. The APORTCONFLICT can also be configured to trigger an interrupt, see [23.3.5 Interrupts](#) for details.

### 23.3.5 Interrupts

The APORTCONFLICT interrupt flag in the IDAC\_IF register indicates that a conflict has occurred when requesting a channel from the APORT. The APORTCONFLICT interrupt can be enabled by setting the APORTCONFLICT bit in IDAC\_IEN, or cleared by setting the APORTCONFLICT bit in IDAC\_IFC.

### 23.3.6 Minimizing Output Transition

If the internal output of the IDAC differs from the voltage at the output pin, enabling the output can cause an unwanted transition. To minimize this transition, it is possible to charge or discharge the internal output node before enabling the output to the pin. Setting MINOUTTRANS in IDAC\_CTRL when the IDAC is sourcing current connects the internal node to GND. Alternatively, setting MINOUTTRANS when the IDAC is sinking current connects the internal output node to VDD. Setting APORTOUTEN when MINOUTTRANS is set will halt the charge/discharge until either APORTOUTEN is cleared or MINOUTTRANS is cleared.

### 23.3.7 Duty Cycle Configuration

The references for the IDAC can be duty-cycled, meaning that it can source current at very low overhead current consumption at the cost of response time and accuracy. By default duty-cycling is enabled in EM2 and EM3 and disabled in EM0 and EM1. Setting EM2DUTYCYCLEDIS in IDAC\_DUTYCONFIG will disable duty cycling in EM2 and EM3. Note that sinking current can not be done with duty-cycled references so measures needs to be taken to always disable duty-cycling while sinking current.

### 23.3.8 Calibration

The IDAC can be calibrated to accurately compensate for process, supply voltage and temperature variations. During the production test, the middle step of each range is calibrated at room temperature. The TUNING bitfield in the IDAC\_CAL register can be used to do further calibration of each step with an external resistor connected to IDAC\_OUT. The calibrated tuning value for each band can be read from the Device Information (DI) page.

### 23.3.9 PRS Triggered Charge Injection

The amount of charge sourced or sunk by the IDAC can be controlled by the PRS (e.g., using a timer as producer) via the output switch. [Figure 23.2 IDAC Charge Injection Example on page 787](#) shows a case where the IDAC is configured to periodically supply charge using the PRS. The amount of charge injected is proportional to the the period the IDAC is on. The total charge injected is the current multiplied by the time the output switch is enabled.

The PRS system is enabled by setting APORTOUTENPRS in IDAC\_CTRL, and the PRS channel is selected by PRSSEL in IDAC\_CTRL. To generate the periodic control signal, the TIMER module can be used, by configuring for example a CC channel to compare match with a configurable level.

Figure 23.2. IDAC Charge Injection Example

### 23.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                       |
|--------|--------------------|-------|-----------------------------------|
| 0x000  | IDAC_CTRL          | RW    | Control Register                  |
| 0x004  | IDAC_CURPROG       | RW    | Current Programming Register      |
| 0x00C  | IDAC_DUTYCONFIG    | RW    | Duty Cycle Configuration Register |
| 0x018  | IDAC_STATUS        | R     | Status Register                   |
| 0x020  | IDAC_IF            | R     | Interrupt Flag Register           |
| 0x024  | IDAC_IFS           | W1    | Interrupt Flag Set Register       |
| 0x028  | IDAC_IFC           | (R)W1 | Interrupt Flag Clear Register     |
| 0x02C  | IDAC_IEN           | RW    | Interrupt Enable Register         |
| 0x034  | IDAC_APORTREQ      | R     | APORT Request Status Register     |
| 0x038  | IDAC_APORTCONFLICT | R     | APORT Request Status Register     |

## 23.5 Register Description

### 23.5.1 IDAC\_CTRL - Control Register

| Offset | Bit Position |    |    |    |    |    |    |    |       |    |    |    |               |    |                |    |

This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the IDAC to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the IDAC only passively looks at the bus. When 1, the selection of channel for a selected bus is ignored (the bus is not), and will be whatever selection the external device mastering the bus has configured for the APORT bus.<br><table><tr><td>Value</td><td>Description</td></tr><tr><td>0</td><td>Bus mastering enabled</td></tr><tr><td>1</td><td>Bus mastering disabled</td></tr></table> | Value      | Description | 0                 | Bus mastering enabled | 1    | Bus mastering disabled |            |      |                   |            |      |                   |            |      |                   |            |      |                   |     |     |     |             |      |                    |             |      |                    |

## 24. GPCRC - General Purpose Cyclic Redundancy Check

### Quick Facts

#### What?

The GPCRC is an error-detecting module commonly used in digital networks and storage systems to detect accidental changes to data.

#### Why?

The GPCRC module can detect errors in data, giving a higher system reliability and robustness.

#### How?

Blocks of data entering GPCRC module can have a short checksum, based on the remainder of a polynomial division of their contents; on retrieval the calculation is repeated, and corrective action can be taken against presumed data corruption if the check values do not match.

### 24.1 Introduction

The GPCRC module is a slave peripheral that implements a Cyclic Redundancy Check (CRC) function. It supports both 32-bit and 16-bit polynomials. The supported 32-bit polynomial is 0x04C11DB7(IEEE 802.3), while the 16-bit polynomial can be programmed to any value, depending on the needs of the application. Common 16-bit polynomials are 0x1021 (CCITT-16), 0x3D65 (IEC16-MBus), and 0x8005 (zigbee, 802.15.4, and USB).

### 24.2 Features

- Programmable 16-bit polynomial, fixed 32-bit polynomial
- Byte-level bit reversal for the CRC input
- Byte-order reorientation for the CRC input
- Word or half-word bit reversal of the CRC result
- Ability to configure and seed an operation in a single register write
- Single-cycle CRC computation for 32-, 16-, or 8-bit blocks
- DMA operation

An overview of the GPCRC module is shown in [Figure 24.1 GPCRC Overview on page 796](#).

### 24.3.1 Polynomial Specification

POLYSEL in GPCRC\_CTRL selects between 32-bit and 16-bit polynomial functions. When a 32-bit polynomial is selected, the fixed IEEE 802.3 polynomial(0x04C11DB7) is used. When a 16-bit polynomial is selected, any valid polynomial can be defined by the user in GPCRC\_POLY.

A valid 16-bit CRC polynomial must have an  $x^{16}$  term and an  $x^0$  term. Theoretically, a 16-bit polynomial has 17 terms total. The convention used is to omit the  $x^{16}$  term. The polynomial should be written in **reversed** (little endian) bit order. The most significant bit corresponds to the lowest order term. Thus, the most significant bit in CRC\_POLY represents the  $x^0$  term, and the least significant bit in CRC\_POLY represents the  $x^{15}$  term. The highest significant bit of CRC\_POLY should always set to 1. The polynomial representation for the CRC-16-CCIT polynomial  $x^{16} + x^{12} + x^5 + 1$ , or 0x8408 in reversed order, is shown in [Figure 24.2 Polynomial Representation on page 797](#).

CRC-16-CCITT Normal: 0x1021 Reversed: 0x8408

Figure 24.2. Polynomial Representation

### 24.3.2 Input and Output Specification

The CRC input data can be written to the GPCRC\_INPUTDATA, GPCRC\_INPUTDATAWORD or GPCRC\_INPUTDATABYTE register via the APB bus based on different data size. If BYTEMODE in GPCRC\_CTRL is set, only the least significant byte of the data word will be used for the CRC calculation no matter which input register is written. There are also three output registers for different ordering. Reading from GPCRC\_DATA will get the result based on the polynomial in reversed order, while reading from GPCRC\_DATAREV will get the result based on the polynomial in normal order. The CRC calculation needs one clock cycle, reading from GPCRC\_DATA, GPCRC\_DATAREV or GPCRC\_DATABYTEREV register or writing to GPCRC\_CMD register is halted while the calculation is in progress.

### 24.3.3 Initialization

The CRC can be pre-loaded or re-initialized by first writing a 32-bit programmable init value to INIT in GPCRC\_INIT and then setting INIT in GPCRC\_CMD. It can also be re-initialized automatically when read from DATA, DATAREV or DATABYTEREV provided that AUTOINIT in GPCRC\_CTRL is set, the CRC would be re-initialized with the stored init value.

### 24.3.4 DMA Usage

A DMA channel may be used to transfer data into the CRC engine. All bytes and half-word writes must be word-aligned. The recommended DMA usage model is to use the DMA to transfer all available words of data and use software writes to capture any remaining bytes.

### 24.3.5 Byte-Level Bit Reversal and Byte Reordering

The byte-level bit reversal and byte reordering operations occur before the data is used in the CRC calculation. Byte reordering can occur on words or half words. The hardware ignores the BYTEREVERSE field with any byte writes or operations with byte mode enabled (BYTEMODE = 1), but the bit reversal settings (BITREVERSE) are still applied to the byte. 32-bit little endian MSB-first data can be treated like 32-bit little endian LSB-first data, as shown in [Figure 24.3 Data Ordering Example - 32-bit MSB -first to LSB-first on page 798](#). In this example, 32-bit data is written to GPCRC\_INPUTDATA, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

Figure 24.3. Data Ordering Example - 32-bit MSB -first to LSB-first

When handling 16-bit data, the byte reordering function only swap the two lowest bytes and clear the two highest bytes, as shown in [Figure 24.4 Data Ordering Example - 16-bit MSB -first to LSB-first on page 799](#). In this example, 16-bit data is written to GPCRC\_INPUTDATAWORD, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

Figure 24.4. Data Ordering Example - 16-bit MSB -first to LSB-first

Assuming a word input byte order of B3 B2 B1 B0, the values used in the CRC calculation for the various settings of the byte-level bit reversal and byte reordering are shown in [Table 24.1 Byte-Level Bit Reversal and Byte Reordering Results \(B3 B2 B1 B0 Input Order\)](#) on page 799.

Table 24.1. Byte-Level Bit Reversal and Byte Reordering Results (B3 B2 B1 B0 Input Order)

| Input Width(bits) | BYTEREVERSE Setting | BITREVERSE Setting | Input to CRC Calculation |
|-------------------|---------------------|--------------------|--------------------------|
| 32                | 0                   | 0                  | B3 B2 B1 B0              |
| 32                | 1                   | 1                  | 'B0 'B1 'B2 'B3          |
| 32                | 1                   | 0                  | B0 B1 B2 B3              |
| 32                | 0                   | 1                  | 'B3 'B2 'B1 'B0          |
| 16                | 0                   | 0                  | XX XX B1 B0              |

The polynomial is defined in reversed representation, meaning that the lowest degree term is in the highest bit position of POLY. Additionally, the highest degree term in the polynomial is implicit. Further examples of the CRC configuration can be found in the documentation. |

## 25. CRYPTO - Crypto Accelerator

### Quick Facts

#### What?

A fast and energy efficient autonomous hardware accelerator for AES encryption and decryption with 128- or 256-bit keys, ECC over prime and binary Galois finite fields, SHA-1, SHA-224 and SHA-256.

#### Why?

Efficient cryptography with little or no CPU intervention helps to meet the speed and energy demands of the application. Hardware implementations are generally more secure against side-channel attacks than software implementations.

#### How?

Programmable sequences of instructions on big numbers allow fast processing with little CPU intervention.

### 25.1 Introduction

The CRYPTO module allows efficient acceleration of common cryptographic operations and allows these to be used efficiently with a low CPU load. Operations performed by CRYPTO can be set up as a sequence of instructions on a set of 128-bit, 256-bit or 512-bit registers to implement or accelerate Elliptic Curve Cryptography (ECC), SHA-1, SHA-224, SHA-256, and various block cipher modes based on the Advanced Encryption Standard, also known as AES (FIPS-197).

CRYPTO is capable of autonomously fetching data, performing cipher operations and storing data across multiple blocks. When the source data is not a multiple of 16 bytes (128 bits), Zero-padding can be included in the last block. Block operations such as Counter Mode (CTR), Electronic Code Book (ECB), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB) are easily implemented. Block Cipher modes of operation such as Electronic Code Book (ECB), Counter Mode (CTR), Cipher Block Chaining (CBC), CBC-MAC (CBC Message Authentication Code), CCM (Counter with CBC-MAC) and GCM (Galois Counter mode) are easily implemented.

CRYPTO is delivered with an extensive software library in Simplicity Studio that implements all major cryptographic algorithms, including but not limited to AES, SHA-1, SHA-2, ECC, and legacy algorithms DES, 3DES, MD4, MD5 and RC4. The implementation accelerates the algorithms using CRYPTO when possible.

## 25.2 Features

- Efficient AES core
  - Encryption/decryption using 128-bit key (54 clock cycles) or 256-bit key (75 clock cycles)
  - Key buffer
  - Supports autonomous cipher block modes (e.g. ECB, CTR, CBC, PCBC, CFB, CBC-MAC, GMAC, CCM, CCM\* and GCM) across multiple blocks
- Accelerated SHA-1, SHA-224 and SHA-256
- Accelerated Elliptic Curve Cryptography (ECC)
  - Binary and Prime fields
  - Supports NIST recommended curves: P-192, P-224, P-256, K-163, K-233, B-163, and B-233
- Galois/Counter Mode (GCM)
  - ALU operations on GCM  $GF(2^{128})$  field
- Flexible 256-bit ALU and sequencer
  - 5 general purpose 256-bit registers
  - Supports ADD, SUB, MUL, shift, XOR, etc.
  - Up to 20 instructions can be chained to implement various block cipher modes
- Efficient operation
  - DMA request signals for data read and write
  - Optional XOR Data write
  - Interrupt on finished operations
- Extensive software support
  - Extensive software library in Simplicity Studio
  - Implements all major cryptographic algorithms: AES, SHA-1, SHA-2, and ECC
  - Implements legacy algorithms: DES, 3DES, MD4, MD5, and RC4
  - Hardware accelerated when possible

## 25.3 Usage and Programming Interface

Many security systems fail due to mistakes in the implementation. Therefore implementations should be left to experts in cryptographic algorithms.

To solve this, the module is supported by an hardened cryptography software library and API delivered through Silicon Labs' Simplicity Studio. The software API is a frontend for performing all supported cryptographic operations, and must be used to receive prompt support.

## 25.4 Functional Description

A block diagram of the CRYPTO module is shown in [Figure 25.1 CRYPTO Overview on page 809](#).

**Figure 25.1. CRYPTO Overview**

### 25.4.1 Data and Key Registers

The CRYPTO module contains five 256-bit registers. Accelerators are implemented through instructions operating on these registers, either by copying data between registers and external components through DMA, or by executing instructions on the registers.

Depending on the instruction, the registers can be accessed as 128-bit, 256-bit or 512-bit registers. The registers can also be accessed through different interface registers to achieve different results.

When writing to and reading from the CRYPTO\_DATAx, CRYPTO\_KEY, CRYPTO\_KEYBUF, CRYPTO\_DDATABx and CRYPTO\_QDATABx registers, the least significant part is accessed first and the most significant part last, see [Figure 25.2 CRYPTO Data and Key Register Operation on page 811](#). The same is the case for the XOR and byte-access registers for DATA0 and DATA1. It is important to note that some of the 256-bit registers are composed of the 128-bit registers, and both the 512-bit registers are composed of the 256-bit registers.

**Note:** From here on, the 128, 256 and 512-bit registers are named DATAx, DDATABx, QDATABx, etc. And the access-points to these registers are named CRYPTO\_DATAx, CRYPTO\_DDATABx, CRYPTO\_QDATABx, etc.

DATA0 can be accessed through CRYPTO\_DATA0 (32-bit), CRYPTO\_DATA0XOR (32-bit), CRYPTO\_DATA0BYTE (8-bit) and CRYPTO\_DATA0XORBYTE (8-bit). Direct access to bytes 12 - 15 is available through CRYPTO\_DATA0BYTE12-15 (8-bit). The DATA0XOR (in CRYPTO\_DATA0XOR) is used for XOR'ing a value with the current value in DATA0. This is used in a large variety of block cipher modes. All of these registers operate on DATA0.

DATA1 can be accessed through CRYPTO\_DATA1 (32-bit) and CRYPTO\_DATA1BYTE (8-bit).

The remaining data registers have regular 32-bit access through their respective registers. Note that all data registers require a full read or write to be fully accessed. This means that the 128-bit registers need four 32-bit reads/writes, the 256-bit registers need 8 reads/writes and the 512-bit registers need 16 reads/writes. For a read, if all read accesses are not done, the register will end up as a shifted version of the original value.

**Note:** For byte-wise data accesses (DDATABxBYTE, DATAxBYTE, etc.), all reads and writes must be performed in groups of 4, due to internal buffering and shifting of 32 bits at a time. Accessing a number of bytes that is not a multiple of four can cause data incoherency in all of the data registers.

The KEY and KEYBUF registers are 256 bit wide when AES256 is set in CRYPTO\_CTRL. Else they are 128 bit wide. When used as a part of DDATABx and QDATABx, they are always 256 bit wide.

The registers DDATAB0BIG and QDATAB1BIG produce byte-swapped versions of DDATAB0 and QDATAB1 respectively. These may be used when a computation requires byte-swapping. An example of this is SHA computation, where data needs to be changed to big endian before CRYPTO can work with it. Little endian data is then loaded in through QDATAB1BIG and the resulting little endian hash can be read out from DDATAB0BIG, see [25.4.5 SHA](#).

Except for KEYBUF, the contents of all data registers are lost when going to EM2.

**Figure 25.2. CRYPTO Data and Key Register Operation**

#### 25.4.1.1 DATA0 Zero

DATA0ZERO in CRYPTO\_DSTATUS contains status flags indicating if any 32-bit blocks within DATA0 is 0. For example, if DATA0[95:64] is equal to 0x00000000, ZERO64TO95 is set.

### 25.4.1.2 DDATA0 and DDATA1 Quick Observation

DDATA0LSBS in CRYPTO\_DSTATUS shows the 4 least significant bits in DDATA0. DDATA0MSBS in CRYPTO\_DSTATUS shows the 4 most significant bits of DDATA0, while DDATA1MSB in CRYPTO\_DSTATUS shows the msb of DDATA1. These observation bitfields are useful for determining the sign of the value in the data registers without having to read out the full register data register values.

The 4 bits observed by DDATA0MSBS will change depending on RESULTWIDTH in CRYPTO\_WAC. When using 260-bit results, DDATA0MSBS shows bits 259-256, when using 256-bit results, it is bits 255-252, and for 128-bit results, bits 127-124 can be observed. When RESULTWIDTH is 260 bits, the 4 most significant bits, e.g. bits 259-256 are also available in CRYPTO\_DDATA0BYTE32, where they can also be written. Using this register is the only way of inputting the upper 4 bits of a 260-bit number to CRYPTO.

### 25.4.1.3 Result Width

RESULTWIDTH in CRYPTO\_WAC determines the width of the operation when performing arithmetic/shift instructions with CRYPTO. Using less wide results will reduce the current consumption of the CRYPTO module. The higher-order bits that are beyond the selected result width are ignored in the computation of arithmetic/shift operations, however, these higher-order bits will be undefined in the result of such instructions.

When RESULTWIDTH=260BIT, all DDATA registers effectively become 260 bits wide, so that the upper 4 bits are not lost when transferring data from DDATA0 to the other DDATA registers. Likewise, the arithmetic/shift instructions shall consider the full 260-bit values of DDATA0-DDATA4 when used as operation inputs. Note that DDATA0 is the only 260-bit register of which MSBs can be observed/written. The upper 4 bits are observed through DDATA0MSBS in CRYPTO\_DSTATUS or through CRYPTO\_DDATA0BYTE32. For all DDATAx registers, the extra MSBs are cleared when DDATAx is written. Furthermore, for a particular x, a write to DDATAx or any of its aliased registers will cause DDATAx MSBs to be cleared. Note, writing to KEY/KEYBUF will only clear MSBs of DDATA1/DDATA4 when AES256 mode is set. Likewise, writing to DATA0/DATA2 will not clear DDATA2/DDATA3 MSBs.

Since the DATA0-DATA3 registers are always 128-bit, all bit positions greater than 128 are interpreted as 0 when RESULTWIDTH is greater than 128 bits. However, the assignment instructions DATAxTODDATAy will not zero-out the upper 128 bits of the DDATAy target. Instead, those upper words become undefined after such operations.

## 25.4.2 Instructions and Execution

The CRYPTO module implements a set of instructions in order to load and manipulate data effectively. These instructions are grouped into four types:

- ALU instructions - arithmetic and logical bitwise operations
- Transfer instructions - moving data between registers and external peripherals like DMA
- Conditional instructions - conditionally execute instructions based on context
- Special instructions - various crypto and support instructions

A single instruction can be executed by writing INSTR in CRYPTO\_CMD. This will execute the instruction, and the interface of CRYPTO will be locked until the execution has completed. Multiple commands can safely be issued after each other by the CPU as long as NOBUSYSTALL in CRYPTO\_CTRL is not set. If CRYPTO gets a new command or a data access request while busy it will then stall the bus, and execute the new command as soon as it is done with the previous one. Note, there are some exceptions to this rule. For example, see [25.4.8 DMA](#).

Stalling of the bus can be disabled by setting NOBUSYSTALL in CRYPTO\_CTRL, however manipulating (reading or writing) registers while running an instruction will result in undefined behaviour. Additionally, if NOBUSYSTALL=0 and a new command or data access request is made while the CRYPTO is simultaneously performing a data transfer instruction, it is possible for system lockup due to bus stalling loops. The safest approach is to always check if an instruction is running by looking at INSTRRUNNING in CRYPTO\_STATUS.

Note that this automatic stalling feature does not apply to automated CRYPTO instruction sequences (described next), since there may be cycle delays between individual instructions for which bus accesses are not prevented. For sequences, always check the SEQRUNNING status bit or the SEQDONE interrupt flag to ensure the sequence is finished before attempting CRYPTO register accesses.

### 25.4.2.1 Sequences

For executing a set of instructions, it is more efficient to load them into the CRYPTO module and run them as a sequence. This is done by writing the instructions into CRYPTO\_SEQ0-CRYPTO\_SEQ4, and marking the end of the instruction sequence with either an END or an EXEC instruction. The END simply means end-of-instructions, while writing EXEC means end-of-instructions and execute immediately.

The five registers allow up to 20 instructions to be loaded. To start execution, either end the instructions with an EXEC instruction, or set SEQSTART in CRYPTO\_CMD. CRYPTO will then execute the instructions, starting in CRYPTO\_SEQ0, and ending at the first END instruction. SEQRUNNING in CRYPTO\_STATUS is set while the sequence is running, and the interrupt flag SEQDONE in CRYPTO\_IF will be set when the sequence has completed.

A sequence can be stopped by issuing the SEQSTOP command in the CRYPTO\_CMD register. This command also clears the state of ongoing CRYPTO instructions including DMA access. Check SEQRUNNING in CRYPTO\_STATUS after issuing the SEQSTOP command flag to make sure any ongoing sequence/transfer has completed before accessing data registers again.

### 25.4.2.2 Available Instructions

The available ALU instructions are listed in [Table 25.1 ALU Instructions on page 814](#), data transfer instructions are listed in [Table 25.2 Transfer Instructions on page 815](#), conditional instructions are listed in [Table 25.3 Conditional Instructions on page 815](#) and special instructions are listed in [Table 25.4 Special Instructions on page 816](#). The tables explain the side-effects of the instructions and shows which registers are affected. V0 and V1 in the instructions descriptions can be any of the DDATAx registers and a selection of the DATAx registers. They can be selected using the SELDDATAxDDATAy, SELDATAxDDATAy, SELDDATAxDATAY and SELDATAxDATAY instructions. The first register in the instruction will be selected for V0, and the second for V1. This configuration stays even when the sequence is complete, and can also be set up front. The currently selected V0 and V1 can be read V0 and V1 in CRYPTO\_CSTATUS.

**Table 25.1. ALU Instructions**

| Instruction | Description                                                                                          | Constraints/Notes                                                                                |

### 25.4.2.3 MULx Details

For the MULx instructions (not MMUL), MULWIDTH in CRYPTO\_WAC specifies the width of operands DDATA1 (and sometimes V1). This is useful in order to optimize performance because multiplications take the same number of cycles as the bits in the operands plus a couple of cycles for setup.

As with the other ALU instructions, RESULTWIDTH limits the width of the final result of the MULx and MMUL instructions.

### 25.4.2.4 DATA1INC and DATA1INCCLR Instructions

DATA1INC and DATA1INCCLR operate on the 1, 2, 3 or 4 most significant bytes in DATA1, depending on INCWIDTH in CRYPTO\_CTRL. DATA1INC increments these bytes in big endian, while DATA1INCCLR clears the bytes.

### 25.4.2.5 BBSWAP128 Instruction

The BBSWAP128 instruction copies the contents of the V0 operand to DDATA0 while swapping the bits of the lower 16 bytes. The operand is not changed. This operation is required for GCM. See [25.4.7 GCM and GMAC](#)

### 25.4.2.6 Carry

The carry output from most instructions can be observed through the CARRY bit in CRYPTO\_DSTATUS. Shift-instructions set CARRY to the value that is shifted out of the register, addition and multiplication set it on register overflow, and subtraction sets it on borrow, e.g. underflow.

In addition to generating carry information, some instructions also use the current value of CARRY. ADDC, SUBC, SHLC and SHRC all use carry to generate the result. For all of these instructions, carry allows a program to chain instructions together to operate on bigger numbers than allowed by CRYPTO. For example, by chaining first an ADD, and then an ADDC which uses the carry from the ADD operation, two 512-bit numbers can be added. By chaining more instructions, even larger numbers can be manipulated.

Other uses of CARRY include observation. To check if a register is 0, one can subtract 1 using the DEC instruction, and check if goes negative by checking the CARRY bit. CARRY can be set manually and in CRYPTO programs using the CSET and CCLR instructions, which set and clear the CARRY bit.

The MULC instruction does not use CARRY like the other carry instructions (i.e., instructions ending in 'C' such as 'ADDC'), but rather preserves the old contents of the multiplication register.

### 25.4.3 Repeated Sequence

To maximize efficiency, it is desirable to be able to run a set of instructions over multiple blocks of data autonomously. To repeat a sequence over a larger set of data, set LENGTHA in CRYPTO\_SEQCTRL to the number of bytes in the set, and BLOCKSIZE to the size of the blocks in the set. The sequence will then be repeated N times, where N is LENGTHA / BLOCKSIZE if LENGTHA is a multiple of BLOCKSIZE, or  $\text{ceiling}(\text{LENGTHA} / \text{BLOCKSIZE})$  if not. In the latter case, data written by DMA will be zero-padded up to BLOCKSIZE if it is written to a register which has a size equal to BLOCKSIZE. One notable exception is when LENGTHA is 0. In this case the sequence will still execute once, but the block transfer instructions will not execute.

**Note:** If DMAxRSEL in CRYPTO\_CTRL selects a register that is smaller than the specified blocksize, DATATODMAx/DMAxTODATA instructions will not use the full blocksize, but will only transfer enough data to empty/fill the register once. For example, if BLOCKSIZE is set to 64B and DMA0RSEL=DDATA0, the instruction DATATODMA0 will only read 32B instead of 64B. The processing of LENGTHA/B will continue as if all 64B had been transferred.

A repeated sequence can also be made do slightly different operations on different parts of the data set. A sequence can be divided into two parts; part A, and part B. By configuring LENGTHA in CRYPTO\_SEQCTRL to the length of part A, and LENGTHB in CRYPTO\_SEQCTRLB to the length of part B, CRYPTO will first run iterations over part A, knowing it is A, and then part B, knowing it is part B. By using the conditional instructions listed in [Table 25.3 Conditional Instructions on page 815](#), a program can execute different instructions depending on whether it is in part A or part B.

#### 25.4.4 AES

The AES core operates on data in the 128-bit register DATA0 using the either a 128-bit or 256-bit key from the KEY register. The key width is specified by AES256 in CRYPTO\_CTRL. AES operations are implemented as the AESENC and AESDEC instructions, for AES encryption and AES decryption respectively. An overview of the AES functionality is shown in [Figure 25.3 CRYPTO AES Overview on page 818](#).

AES encryption and decryption enables various block cipher modes like ECB, CTR, CBC, PCBC, CFB, OFB, CBC-MAC, GMAC, CCM, CCM\*, and GCM.

**Figure 25.3. CRYPTO AES Overview**

The input data before encryption is called the PlainText and output from the encryption is called CipherText. For encryption, the key is called PlainKey. After encryption, the resulting key in the KEY registers is the CipherKey. This key must be loaded into the KEY registers prior to the decryption. After one decryption, the resulting key will be the PlainKey. The resulting PlainKey/CipherKey is only dependent on the value in the KEY registers before encryption/decryption. The resulting keys and data are shown in [Figure 25.4 CRYPTO Key and Data Definitions on page 818](#).

**Figure 25.4. CRYPTO Key and Data Definitions**

The KEY is by default loaded from KEYBUF prior to each AESENC or AESDEC instruction. If the KEY is not to be overwritten, key buffering should be disabled (KEYBUFDIS in CRYPTO\_CTRL). Disabling key buffering also allows the use of key loading through DMA.

The data and key orientation in the CRYPTO registers are shown in [Figure 25.5 CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard on page 819](#).

**Figure 25.5. CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard**

### 25.4.5 SHA

The CRYPTO SHA instruction implements SHA-1 with a 160-bit digest or SHA-2 with a 224-bit digest (SHA-224) or 256-bit digest (SHA-256). Depending on SHAMODE in CRYPTO\_CTRL, SHA-1, SHA-224 or SHA-256 will be run on the data in QDATA1, and the result will be put on DDATA0. The contents in QDATA1 will be destroyed in the process.

To run SHA on a dataset, it must first be pre-processed by appending a bit '1' to the message, then padding the data with '0' bits until the message length in bits modulo 512 is 448. Then append the length of the message before pre-processing as a 64-bit big-endian integer. This pre-processing is known as MD-strengthening, and must be done by software before processing with the CRYPTO module.

The pre-processed data can now be run through the CRYPTO module. Begin by writing the values listed in [Table 25.5 SHA Init Values on page 820](#) to CRYPTO\_DDATA1 from top to bottom, then execute the instructions listed in [Table 25.6 SHA Preparations on page 820](#).

**Table 25.5. SHA Init Values**

| SHA-1      | SHA-224    | SHA-256    |
|------------|------------|------------|

**Table 25.6. SHA Preparations**

| STEP  | ACTION          | Description                                              |
|-------|-----------------|----------------------------------------------------------|
| STEP0 | DDATA1TODDATA0  | Copy init data to DDATA0                                 |
| STEP1 | SELDDATA0DDATA1 | Select DDATA0 and DDATA1 as operands for SHA instruction |

Then, for each 512-bit block, write the block to CRYPTO\_QDATA1BIG, execute the instructions listed in [Table 25.7 SHA for 512-bit Block on page 820](#).

**Table 25.7. SHA for 512-bit Block**

| STEP  | ACTION         | Description                             |
|-------|----------------|-----------------------------------------|
| STEP0 | SHA            | Perform SHA operation on data in QDATA1 |
| STEP1 | MADD32         | Accumulate with previous data in DDATA1 |
| STEP2 | DDATA0TODDATA1 | Copy hash to DDATA1                     |

After the last iteration, the resulting hash can be read out from CRYPTO\_DDATA0BIG.

### 25.4.6 ECC

The CRYPTO module implements support for Elliptic Curve Cryptography through the modular instructions MADD, MMUL and MSUB, which perform modular addition, multiplication and subtraction respectively. The instructions can operate on a set of both prime fields GF(p) and binary fields GF(2<sup>m</sup>).

The type of modular arithmetic used and the modulus for the modular operations are specified by MODOP and MODULUS in CRYPTO\_WAC respectively. Changing these in the middle of an operation leads to undefined behaviour.

### 25.4.7 GCM and GMAC

CRYPTO implements support for Galois/Counter Mode (GCM), and also Galois Message Authentication Code (GMAC), by providing AES instructions and allowing multiplication on the field  $GF(2^{128})$  defined by the polynomial  $x^{128} + x^7 + x^2 + x + 1$ .

**Note:** BBSWAP128 needs to be applied to both operands and the result of the MMUL instruction when using it for GCM and GMAC

Efficient sequencer programs can be set up to perform GCM authentication and encryption/decryption on data from either DMA, or CPU. To achieve a single-pass solution, LENGTHA in CRYPTO\_SEQCTRL is set to the length of the authentication part, and LENGTHB is set to the length of the rest of the message. Conditional instructions can then be used to make sure the two parts of the message are processed correctly. A similar approach is used to implement CCM.

### 25.4.8 DMA

The CRYPTO module has 5 DMA request signals (see [Table 25.8 DMA Signals on page 821](#)) split over 2 internal DMA channels: DMA0 and DMA1. These DMA channels are not associated with channel 0 and 1 of the system DMA, and any system DMA channel can serve any of the 5 DMA requests. See the DMA chapter for information on how to configure the system DMA.

The DMA signals are set through the use of DMA oriented instructions, and cleared by reading or writing the respective CRYPTO data registers.

**Table 25.8. DMA Signals**

| Name      | Set on                                                                            | Cleared on                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DMA0WR    | Instruction DMA0TODATA, and DMA0TODATA XOR if COMBDMA0WEREQ in CRYPTO_CTRL is set | Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 write, or CRYPTO_DDATA0XOR if COMBDMA0WEDMAREQ in CRYPTO_CTRL is set |
| DMA0XORWR | Instruction DMA0TODATA XOR                                                        | Full CRYPTO_DATA0XOR write                                                                                                               |
| DMA0RD    | Instructions DATATODMA0                                                           | Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 read, depending on DMA0MODE in CRYPTO_CTRL                           |
| DMA1WR    | Instructions DMA1TODATA                                                           | Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG write                                                                |
| DMA1RD    | Instructions DATATODMA1                                                           | Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG read, depending on DMA1MODE in CRYPTO_CTRL                           |

**Note:** DMAxRSEL in CRYPTO\_CTRL has to be set to the data registers that are to be read using the respective DMA channels on a DATATODMAx instruction. As an important note, DMAxRSEL in CRYPTO\_CTRL selects what is read from **any** of the selectable read registers during an ongoing DATATODMAx transfer.

When a DMA oriented CRYPTO instruction is used (either through a STEP in a Sequence or through CRYPTO\_CMD), the corresponding DMA signal is set. The instruction is complete when the entire source/destination is read/written (e.g. if DMA0TODATA is used, the operation is complete when a total of 128 valid bits have been written through the CRYPTO\_DATA0 register). DMAACTIVE in CRYPTO\_STATUS is set while CRYPTO is working on a DMA-related instruction, e.g. waiting for the DMA to read or write data to CRYPTO (see [25.4.8.1 DMA Initial Bytes Skip](#)).

Normally, when a sequence or instruction is executed, access to most CRYPTO registers will stall the CPU or DMA that is trying to access CRYPTO until the operation is done, preventing accesses to CRYPTO that could potentially interfere with an operation. During DMA operations, all non-DMA registers are writeable and readable, but progress through the DMA operation will only be tracked with the registers targeted by the DMA operation (i.e., if the DMA operation is supposed to transfer 3 words to DATA0, the DMA can first choose to transfer data to e.g. DATA3, and then fulfill the transfer to DATA0).

Because the bus interface to CRYPTO is normally locked outside of DMA transfers, a wrongly set up DMA transfer (e.g., transferring one byte too many) may lock up the interface. One way to assist in debugging such issues can be setting NOBUSYSTALL in CRYPTO\_CTRL. This will prevent any stall on CRYPTO register accesses during sequences and instructions. Use this option with care, as modifying a register that is being used by CRYPTO can lead to undefined behavior.

### 25.4.8.1 DMA Initial Bytes Skip

The DMA must be configured to use 32-bit transfer size. This normally would imply that the source data must be aligned to a 4 byte address boundary. However, it is possible to skip the initial bytes (1 to 3) when using DMA to write to DATA0 or DATA1 through a CRYPTO instruction operation. The number of bytes to skip are set in DMA0SKIP and DMA1SKIP in CRYPTO\_SEQCTRL. This implies that if DMA0SKIP is set to another value than 0, the initial DMA access will require 5 DMA transfers, even though only 4x32-bit is required.

**Note:** Any valid unused bytes from a previous DMA write will be used before new DMA data is requested. This data is invalidated by using STOP in CRYPTO\_CMD.

### 25.4.8.2 DMA Unaligned Read/Write

Except for DATA0 and DATA1, which can be loaded byte-wise using the CRYPTO\_DATA0BYTE, CRYPTO\_DATA0XORBYTE and CRYPTO\_DATA1BYTE registers, the CRYPTO data registers are loaded 32-bits at a time. Special care must be taken when using the DMA and the data buffer is not aligned to a 32-bit address, because the DMA does not directly support 32-bit unaligned accesses.

As an example, let an in-memory 16-byte data buffer start at address  $4*N + M$  and end at the byte before  $4*N + 16 + M$ , where  $M$  is between 0 and 3 inclusive. With an  $M=0$ , we have fully aligned accesses, and everything is fine. For  $M>0$  however, the access is unaligned. If  $M=1$ , that means that the first 32-bit aligned word of the memory buffer contains 1 byte before the buffer, and 3 bytes of the buffer. Similarly, the last 32-bit aligned word of the memory buffer contains the last byte of the buffer, and three bytes after the buffer.

When doing an unaligned read, we want to only pass the 16 bytes of the buffer to the CRYPTO module. Not the  $N$  bytes before in the 32-bit aligned word, and not the  $4-N$  words at the end. To achieve this, set  $DxDMAREADMODE$  in CRYPTO\_CTRL to either UNALIGNEDFULL or UNALIGNEDLENLIMIT, and set  $DATAxDMASKIP$  in CRYPTO\_SEQCTRL equal to  $N$ . When reading in data using a DMA-oriented instruction to  $DATAx$ ,  $DDATAx$  or  $QDATAx$ , the read will now only contain the 16 bytes, and not the  $N$  bytes before or  $4-N$  words after. Note that in this case, the DMA has to be set up to transfer 5 32-bit words instead of the effective 4.

Being able to read unaligned data does not solve all cases however. If data is to be written back to the buffer after passing through CRYPTO, e.g. when doing an in-place encryption or decryption, it is very undesirable to actually modify the  $N$  bytes before and  $4-N$  bytes after the buffer. This is solved using the UAR-suffixed registers in CRYPTO when reading data out from the CRYPTO module, e.g. CRYPTO\_DATA0UAR, CRYPTO\_DATA1UAR, CRYPTO\_DDATA0UAR, CRYPTO\_DDATA1UAR, CRYPTO\_QDATA0UAR, etc. When an unaligned buffer is written to a CRYPTO buffer, CRYPTO stores the  $N$  first bytes and the  $4-N$  last bytes internally. When reading out from an UAR register, these bytes are placed back into the data if  $DATAxDMAPRES$  is set in CRYPTO\_SEQCTRL.

Note that the latter case only works if the first  $N$  and the last  $4-N$  bytes are not changed while CRYPTO works on the data. Internally CRYPTO has 2 buffers for the bytes before and after. The first one is connected to read/write of the DATA0, DDATA0 and QDATA0 registers, and the second is connected to the DATA1, DDATA1 and QDATA1 registers.

If  $DMAxRMODE$  in CRYPTO\_CTRL is set to FULL or UNALIGNEDFULL and the corresponding  $DMAxPRES$  in CRYPTO\_SEQCTRL is set, then a whole number of data buffers have to be written by the DMA. In all other cases, it is enough to write the number of 32-bit words to pass all LENGTH bits to the target CRYPTO buffer.

## 25.4.9 Debugging

There are multiple ways of debugging CRYPTO sequences. The most straight-forward way is to write individual instructions to INSTR in CRYPTO\_CMD. An instruction can be written, and data can be read out and examined before running another instruction.

Running individual instructions to debug a program falls short when working with repeated sequences. In these cases, a sequence is run multiple times over a set of data. This cannot be directly replicated with individual instructions.

To debug a sequence, set HALT in CRYPTO\_SEQCTRL. When set, CRYPTO requires software or the debugger to step it through each instruction in the sequence. To step through the sequence, set SEQSTEP in CRYPTO\_CMD. This will execute the current instruction, and make CRYPTO ready to execute the next one.

When stepping through a sequence, the current instruction index can be read from SEQIP in CRYPTO\_CSTATUS. SEQSKIP, also in CRYPTO\_CSTATUS tells whether the next instruction will be executed or not, based on previous conditionals in the program. SEQPART in CRYPTO\_CSTATUS shows whether CRYPTO is currently in part A or B of a sequence. Even with NOBUSYSTALL in CRYPTO\_CTRL cleared, read and write accesses to CRYPTO will be allowed when CRYPTO is waiting to be stepped. This is to allow data registers to be inspected during debugging.

**Note:** The data registers in CRYPTO (those marked read-actionable) require shifting of data in order to return the result. For this reason, reading these registers will have no effect and will return unknown values during normal debugger read accesses (see [5.3.6 Debugger Reads of Actionable Registers](#)).

## 25.5 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                | Type       | Description                    |
|--------|---------------------|------------|--------------------------------|
| 0x000  | CRYPTO_CTRL         | RW         | Control Register               |
| 0x004  | CRYPTO_WAC          | RW         | Wide Arithmetic Configuration  |
| 0x008  | CRYPTO_CMD          | W          | Command Register               |
| 0x010  | CRYPTO_STATUS       | R          | Status Register                |
| 0x014  | CRYPTO_DSTATUS      | R          | Data Status Register           |
| 0x018  | CRYPTO_CSTATUS      | R          | Control Status Register        |
| 0x020  | CRYPTO_KEY          | RWH(nB)(a) | KEY Register Access            |
| 0x024  | CRYPTO_KEYBUF       | RWH(nB)(a) | KEY Buffer Register Access     |
| 0x030  | CRYPTO_SEQCTRL      | RWH        | Sequence Control               |
| 0x034  | CRYPTO_SEQCTRLB     | RWH        | Sequence Control B             |
| 0x040  | CRYPTO_IF           | R          | AES Interrupt Flags            |
| 0x044  | CRYPTO_IFS          | W1         | Interrupt Flag Set Register    |
| 0x048  | CRYPTO_IFC          | (R)W1      | Interrupt Flag Clear Register  |
| 0x04C  | CRYPTO_IEN          | RW         | Interrupt Enable Register      |
| 0x050  | CRYPTO_SEQ0         | RW         | Sequence Register 0            |
| 0x054  | CRYPTO_SEQ1         | RW         | Sequence Register 1            |
| 0x058  | CRYPTO_SEQ2         | RW         | Sequence Register 2            |
| 0x05C  | CRYPTO_SEQ3         | RW         | Sequence Register 3            |
| 0x060  | CRYPTO_SEQ4         | RW         | Sequence Register 4            |
| 0x080  | CRYPTO_DATA0        | RWH(nB)(a) | DATA0 Register Access          |
| 0x084  | CRYPTO_DATA1        | RWH(nB)(a) | DATA1 Register Access          |
| 0x088  | CRYPTO_DATA2        | RWH(nB)(a) | DATA2 Register Access          |
| 0x08C  | CRYPTO_DATA3        | RWH(nB)(a) | DATA3 Register Access          |
| 0x0A0  | CRYPTO_DATA0XOR     | RWH(nB)(a) | DATA0XOR Register Access       |
| 0x0B0  | CRYPTO_DATA0BYTE    | RWH(nB)(a) | DATA0 Register Byte Access     |
| 0x0B4  | CRYPTO_DATA1BYTE    | RWH(nB)(a) | DATA1 Register Byte Access     |
| 0x0BC  | CRYPTO_DATA0XORBYTE | RWH(nB)(a) | DATA0 Register Byte XOR Access |
| 0x0C0  | CRYPTO_DATA0BYTE12  | RWH(nB)    | DATA0 Register Byte 12 Access  |
| 0x0C4  | CRYPTO_DATA0BYTE13  | RWH(nB)    | DATA0 Register Byte 13 Access  |
| 0x0C8  | CRYPTO_DATA0BYTE14  | RWH(nB)    | DATA0 Register Byte 14 Access  |
| 0x0CC  | CRYPTO_DATA0BYTE15  | RWH(nB)    | DATA0 Register Byte 15 Access  |
| 0x100  | CRYPTO_DDATA0       | RWH(nB)(a) | DDATA0 Register Access         |
| 0x104  | CRYPTO_DDATA1       | RWH(nB)(a) | DDATA1 Register Access         |
| 0x108  | CRYPTO_DDATA2       | RWH(nB)(a) | DDATA2 Register Access         |
| 0x10C  | CRYPTO_DDATA3       | RWH(nB)(a) | DDATA3 Register Access         |

| Offset | Name                | Type       | Description                       |
|--------|---------------------|------------|-----------------------------------|
| 0x110  | CRYPTO_DDATA4       | RWH(nB)(a) | DDATA4 Register Access            |
| 0x130  | CRYPTO_DDATA0BIG    | RWH(nB)(a) | DDATA0 Register Big Endian Access |
| 0x140  | CRYPTO_DDATA0BYTE   | RWH(nB)(a) | DDATA0 Register Byte Access       |
| 0x144  | CRYPTO_DDATA1BYTE   | RWH(nB)(a) | DDATA1 Register Byte Access       |
| 0x148  | CRYPTO_DDATA0BYTE32 | RWH(nB)    | DDATA0 Register Byte 32 Access    |
| 0x180  | CRYPTO_QDATA0       | RWH(nB)(a) | QDATA0 Register Access            |
| 0x184  | CRYPTO_QDATA1       | RWH(nB)(a) | QDATA1 Register Access            |
| 0x1A4  | CRYPTO_QDATA1BIG    | RWH(nB)(a) | QDATA1 Register Big Endian Access |
| 0x1C0  | CRYPTO_QDATA0BYTE   | RWH(nB)(a) | QDATA0 Register Byte Access       |
| 0x1C4  | CRYPTO_QDATA1BYTE   | RWH(nB)(a) | QDATA1 Register Byte Access       |

## 25.6 Register Description

## 25.6.1 CRYPTO\_CTRL - Control Register

| Offset | Bit Position  |    |     |    |    |    |          |    |    |    |     |    |    |    |          |    |     |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |    |  |    |   |     |   |           |  |     |  |

## 26. GPIO - General Purpose Input/Output

### Quick Facts

#### What?

The General Purpose Input/Output (GPIO) is used for pin configuration, direct pin manipulation and sensing, as well as routing for peripheral pin connections.

#### Why?

Easy to use and highly configurable input/output pins are important to fit many communication protocols as well as minimizing software control overhead. Flexible routing of peripheral functions helps to ease PCB layout.

#### How?

Each pin on the device can be individually configured as either an input or an output with several different drive modes. Also, individual bit manipulation registers minimizes control overhead. Peripheral connections to pins can be routed to several different locations, thus solving congestion issues that may arise with multiple functions on the same pin. Fully asynchronous interrupts can also be generated from any pin.

### 26.1 Introduction

In the EFM32 Gecko devices the General Purpose Input/Output (GPIO) pins are organized into ports with up to 16 pins each. These GPIO pins can individually be configured as either an output or input. More advanced configurations like open-drain, open-source, and glitch filtering can be configured for each individual GPIO pin. The GPIO pins can also be overridden by peripheral pin connections, like Timer PWM outputs or USART communication, which can be routed to several locations on the device. The GPIO supports up to 16 asynchronous external pin interrupts, which enable interrupts from any pin on the device. Also, the input value of a pin can be routed through the Peripheral Reflex System to other peripherals.

**Note:** To use the GPIO, the GPIO clock must first be enabled in CMU\_HFBUSCLKEN0. Setting this bit enables the HFBUSCLK for the GPIO.

## 26.2 Features

- Individual configuration for each pin
  - Tristate (reset state)
  - Push-pull
  - Open-drain
  - Pull-up resistor
  - Pull-down resistor
  - Drive strength
    - 1 mA
    - 10 mA
  - Slewrate
  - Over Voltage Tolerance
- EM4 IO pin retention
  - Output enable
  - Output value
  - Pull enable
  - Pull direction
  - Over Voltage Tolerance
- EM4 wake-up on selected GPIO pins
- Glitch suppression input filter
- Alternate functions (e.g. peripheral outputs and inputs)
  - Routed to several locations on the device
  - Pin connections can be enabled individually
  - Output data can be overridden by peripheral
  - Output enable can be overridden by peripheral
- Toggle register for output data
- Dedicated data input register (read-only)
- Interrupts
  - 2 Interrupt lines using either levels or edges
    - EM4 wake-up pins are selectable for level interrupts
    - All GPIO pins are selectable for edge interrupts
  - Separate enable, status, set and clear registers
  - Asynchronous sensing
  - Rising, falling or both edges
  - High or low level detection
  - Wake up from EM0 Active-EM3 Stop
- Peripheral Reflex System producer
  - All GPIO pins are selectable
- Configuration lock functionality to avoid accidental changes

## 26.3 Functional Description

An overview of the GPIO module is shown in [Figure 26.1 Pin Configuration on page 861](#). The GPIO pins are grouped into 16-pin ports. Each individual GPIO pin is called Pxn where x indicates the port (A, B, C ...) and n indicates the pin number (0,1,...,15). Fewer than 16 bits may be available on some ports, depending on the total number of I/O pins on the package. After a reset, both input and output are disabled for all pins on the device, except for the Serial Wire Debug pins.

To use a pin, the Mode Register (GPIO\_Px\_MODEL/GPIO\_Px\_MODEH) must be configured for the pin to make it an input or output. These registers can also do more advanced configuration, which is covered in [26.3.1 Pin Configuration](#). When the port is configured as an input or an output, the Data In Register (GPIO\_Px\_DIN) can be used to read the level of each pin in the port (bit n in the register is connected to pin n on the port). When configured as an output, the value of the Data Out Register (GPIO\_Px\_DOUT) will be driven to the pin.

The DOUT value can be changed in 4 different ways:

- Writing to the GPIO\_Px\_DOUT register
- Writing the BITSET address of the GPIO\_Px\_DOUT register sets the DOUT bits
- Writing the BITCLEAR address of the GPIO\_Px\_DOUT register clears the DOUT bits
- Writing the GPIO\_Px\_DOUTTGL register toggles the corresponding DOUT bits

Reading the GPIO\_Px\_DOUT register will return its contents. Reading the GPIO\_Px\_DOUTTGL register will return 0.

Figure 26.1. Pin Configuration

### 26.3.1 Pin Configuration

In addition to setting the pins as either outputs or inputs, the GPIO\_Px\_MODEL and GPIO\_Px\_MODEH registers can be used for more advanced configurations. GPIO\_Px\_MODEL contains 8 bit fields named MODEn (n=0,1,..7) which control pins 0-7, while GPIO\_Px\_MODEH contains 8 bit fields named MODEn (n=8,9,..15) which control pins 8-15. In some modes GPIO\_Px\_DOUT is also used for extra configurations like pull-up/down and glitch suppression filter enable. [Table 26.1 Pin Configuration on page 862](#) shows the available configurations.

**Table 26.1. Pin Configuration**

| MODEn                   | Input                 | Output                 | DOUT | Pull-down | Pull-up | Alt Port Ctrl | Input Filter                                                      | Description                                              |
|-------------------------|-----------------------|------------------------|------|-----------|---------|---------------|-------------------------------------------------------------------|----------------------------------------------------------|
| DISABLED                | Disabled              | Disabled               | 0    |           |         |               |                                                                   | Input disabled                                           |
|                         |                       |                        | 1    |           | On      |               |                                                                   | Input disabled with pull-up                              |
| INPUT                   | Enabled if not DINDIS |                        | 0    |           |         |               |                                                                   | Input enabled                                            |
|                         |                       |                        | 1    |           |         |               | On                                                                | Input enabled with filter                                |
| INPUTPULL               |                       |                        | 0    | On        |         |               |                                                                   | Input enabled with pull-down                             |
|                         |                       |                        | 1    |           | On      |               |                                                                   | Input enabled with pull-up                               |
| INPUTPULLFILTER         |                       |                        | 0    | On        |         |               | On                                                                | Input enabled with pull-down and filter                  |
|                         |                       |                        | 1    |           | On      |               | On                                                                | Input enabled with pull-up and filter                    |
| PUSHPULL                |                       | Push-pull              | x    |           |         |               |                                                                   | Push-pull                                                |
| PUSHPULLALT             |                       |                        | x    |           |         | On            |                                                                   | Push-pull with alternate port control values             |
| WIREDOR                 |                       | Open Source (Wired-OR) | x    |           |         |               |                                                                   | Open-source                                              |
| WIREDORPULLDOWN         |                       |                        | x    | On        |         |               |                                                                   | Open-source with pull-down                               |
| WIREDAND                |                       | Open Drain (Wired-AND) | x    |           |         |               |                                                                   | Open-drain                                               |
| WIREDANDFILTER          |                       |                        | x    |           |         |               | On                                                                | Open-drain with filter                                   |
| WIREDANDPULLUP          |                       |                        | x    |           | On      |               |                                                                   | Open-drain with pull-up                                  |
| WIREDANDPULLUPFILTER    |                       |                        | x    |           | On      |               | On                                                                | Open-drain with pull-up and filter                       |
| WIREDANDALT             |                       |                        | x    |           |         | On            |                                                                   | Open-drain with alternate port control values            |
| WIREDANDALTFILTER       |                       |                        | x    |           |         | On            | On                                                                | Open-drain with alternate port control values and filter |
| WIREDANDALTPULLUP       | x                     |                        |      | On        | On      |               | Open-drain with alternate port control values and pull-up         |                                                          |
| WIREDANDALTPULLUPFILTER | x                     |                        |      | On        | On      | On            | Open-drain with alternate port control values, pull-up and filter |                                                          |

MODEn determines which mode the pin is in at a given time. Setting MODEn to DISABLED disables the pin, reducing power consumption to a minimum. When the output driver, input driver and Over Voltage Tolerance is disabled, the pin can be used as a connection for an analog module. An input is enabled by setting MODEn to any value other than DISABLED while DINDIS for the given port is cleared.

Set DINDIS to disable the input of a gpio port. The pull-up, pull-down and glitch filter function can optionally be applied to the input, see [Figure 26.2 Tristated Output With Optional Pull-up or Pull-down on page 863](#).

**Figure 26.2. Tristated Output With Optional Pull-up or Pull-down**

When MODEn is PUSH\_PULL or PUSH\_PULLALT, the pin operates in push-pull mode. In this mode, the pin can have alternate port control values and can be driven either high or low, dependent on the value of GPIO\_Px\_DOUT. The push-pull configuration is shown in [Figure 26.3 Push-Pull Configuration on page 863](#).

**Figure 26.3. Push-Pull Configuration**

When MODEn is WIRE\_DOR or WIRE\_DOR\_PULLDOWN, the pin operates in open-source mode (with a pull-down resistor for WIRE\_DOR\_PULLDOWN). When driving a high value in open-source mode, the pull-down is disconnected to save power.

When the mode is prefixed with WIRE\_DAND, the pin operates in open-drain mode as shown in [Figure 26.4 Open-drain on page 863](#). In open-drain mode, the pin can have an input filter, a pull-up, alternate port control values or any combination of these. When driving a low value in open-drain mode, the pull-up is disconnected to save power.

**Figure 26.4. Open-drain**

### 26.3.1.1 Over Voltage Tolerance

Over voltage capability is available for most pins. If available, it allows the pin to be used at the minimum of IOVDD + 2V and 5.5V (for 5V tolerant pads). The data sheet specifies which pins can be used as 5V tolerant pins. Default over voltage is enabled for each pin supporting that feature. Over voltage tolerance (OVT) can be disabled on a per pin basis. The over voltage tolerance feature applied to the selected pins is configured in the GPIO\_Px\_OVTDIS register. Disabling the over voltage tolerance for a pin will provide less distortion on that pin, which is useful when the pin is used as analog input.

### 26.3.1.2 Alternate Port Control

The Alternate Port Control allows for additional flexibility of port level settings. A user may setup two different port configurations (normal and alternate modes) and select which is applied on a pin by pin bases. For example you may configure half of port A to use the low drive strength setting (normal mode) while the other half uses high drive strength (alternate mode).

Alternate port control is enabled when MODEN is set to any of the ALT enumerated modes (ie. PUSH\_PULLALT). When MODEN is an alternate mode, the pin uses the alternate port control values specified in the DINDISALT, SLEWRATEALT, and DRIVESTRENGTHALT fields in GPIO\_Px\_CTRL. In all other modes, the port control values are used from the DINDIS, SLEWRATE, and DRIVESTRENGTH fields in GPIO\_Px\_CTRL.

### 26.3.1.3 Drive Strength

The drive strength can be applied to pins on a port-by-port basis. The drive strength applied to pins configured using normal MODEN settings can be controlled using the DRIVESTRENGTH field in GPIO\_Px\_CTRL. The drive strength applied to pins configured using alternate MODEN settings can be controlled using the DRIVESTRENGTHALT field.

### 26.3.1.4 Slewrate

The slewrate can be applied to pins on a port-by-port basis. The slewrate applied to pins configured using normal MODEN settings can be controlled using the SLEWRATE fields in GPIO\_Px\_CTRL. The slewrate applied to pins configured using the alternate MODEN settings can be controlled using the SLEWRATEALT field.

### 26.3.1.5 Input Disable

The pin inputs can be disabled on a port-by-port basis. The input of pins configured using the normal MODEN settings can be disabled by setting DINDIS in GPIO\_Px\_CTRL. The input of pins configured using the alternate MODEN settings can be disabled by setting DINDISALT.

### 26.3.1.6 Configuration Lock

GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_CTRL, GPIO\_Px\_PINLOCKN, GPIO\_Px\_OVTDIS, GPIO\_EXTIPSELL, GPIO\_EXTIPSELH, GPIO\_EXTIPINSELL, GPIO\_EXTIPINSELH, GPIO\_INSENSE, GPIO\_ROUTEOPEN, and GPIO\_ROUTELOC0 can be locked by writing any value other than 0xA534 to GPIO\_LOCK. Writing the value 0xA534 to the GPIOx\_LOCK register unlocks the configuration registers.

In addition to configuration lock, GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_DOUT, GPIO\_Px\_DOUTTGL, and GPIO\_Px\_OVTDIS can be locked individually for each pin by clearing the corresponding bit in GPIO\_Px\_PINLOCKN. When a bit in the GPIO\_Px\_PINLOCKN register is cleared, it will stay cleared until reset.

### 26.3.2 EM4 Wake-up

It is possible to trigger a wake-up from EM4 using any of the selectable EM4WU GPIO pins. The wake-up request can be triggered through the pins by enabling the corresponding bit in the GPIO\_EM4WUEN register. When EM4 wake-up is enabled for the pin, the input filter is enabled during EM4. This is done to avoid false wake-up caused by glitches. In addition, the polarity of the EM4 wake-up request can be selected using the GPIO\_EXTILEVEL register.

Figure 26.5. EM4 Wake-up Logic

The pins used for EM4 wake-up must be configured as inputs with glitch filters using the GPIO\_Px\_MODEL/GPIO\_Px\_MODEH register. If the input is disabled and the wakeup polarity is low, a false wakeup will occur when entering EM4. If the input is enabled, the glitch filtered is disabled, and the polarity is set low, a glitch will occur when going into EM4 that will cause an immediate wake-up. Before going down to EM4, it is important to clear the wake-up logic by setting the GPIO\_IFC bit, which clears the wake-up logic, including the GPIO\_IF register. It is possible to determine which pin caused the EM4WU by reading the GPIO\_IF register. The mapping between EM4WU pins and the bit indexes in the GPIO\_EM4WUEN, GPIO\_EXTILEVEL, GPIO\_IFC, GPIO\_IFS, GPIO\_IEN, and GPIO\_IF registers is as follows:

Table 26.2. EM4WU Register Bit Index to EM4WU Pin Mapping

| EM4WU Register Bit Indexes                                     | EM4WU Pin    |
|----------------------------------------------------------------|--------------|
| 16                                                             | GPIO_EM4WU0  |
| 17                                                             | GPIO_EM4WU1  |
| 18                                                             | GPIO_EM4WU2  |
| 19                                                             | GPIO_EM4WU3  |
| ...                                                            | ...          |
| 31                                                             | GPIO_EM4WU15 |
| <b>Note:</b> See the device data sheet for actual pin location |              |

### 26.3.3 EM4 Retention

By default, GPIO pins revert back to their reset state when EM4 is entered. The GPIO pins can be configured to retain the settings for output enable, output value, pull enable, pull direction and over voltage tolerance while in EM4.

EM4 GPIO retention is controlled with the EM4IORETMODE field in the EMU\_EM4CTRL register. Setting EM4IORETMODE to EM4EXIT will cause retention to persist while in EM4 and reset the GPIOs during wakeup. Setting EM4IORETMODE to SWUNLATCH will cause the retention to persist until the EM4UNLATCH bit is written by software. Note that when using SWUNLATCH, the GPIO register values are still reset on wakeup from EM4. In order to ensure that the GPIO state does not change, software must re-write the GPIO registers before setting EM4UNLATCH and ending EM4 GPIO retention. See the EMU chapter for additional documentation on its registers and the EM4UNLATCH bit.

## 26.3.4 Alternate Functions

Alternate functions are connections to pins from peripherals, i.e. Timers, USARTs, etc.. These peripherals contain route registers, where the pin connections are enabled. In addition, the route registers contain a location bit field that configures which pin an output of that peripheral will be connected to if enabled. After connecting a peripheral, the pin configuration stays as set in GPIO\_Px\_MODEL, GPIO\_Px\_MODEH and GPIO\_Px\_DOUT registers. For example, the pin configuration must be set to output enable in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH for a peripheral to be able to use the pin as an output.

It is not recommended to select two or more peripherals as output on the same pin. The reader is referred to the pin map section of the device data sheet for more information on the possible locations of each alternate function.

### 26.3.4.1 Analog Connections

When using the GPIO pin for analog functionality, it is recommended to disable the over voltage tolerance by setting the corresponding pin in the GPIO\_Px\_OVTDIS register and setting the MODEN in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH equal to DISABLE to disable the input sense, output driver and pull resistors.

### 26.3.4.2 Debug Connections

#### 26.3.4.2.1 Serial Wire Debug Connection

The SW Debug Port is routed as an alternate function and the SWDIO and SWCLK pin connections are enabled by default with internal pull up and pull down resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN and SWCLKTCKPEN bits in GPIO\_ROUTEPEN to 0.

#### 26.3.4.2.2 JTAG Debug Connection

The JTAG Debug Port is routed as an alternate function and the TMS, TCK, TDO, and TDI pin connections are enabled by default with internal pull up, pull down, no pull, and pull up resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN, SWCLKTCKPEN, TDOPEN, and TDIPEN bits in GPIO\_ROUTEPEN to 0.

#### 26.3.4.2.3 Disabling Debug Connections

When the debug pins are disabled, the device can no longer be accessed by a debugger. A reset will set the debug pins back to their enabled default state. The GPIO\_ROUTEPEN register can only be updated when the debugger is disconnected from the system. Any attempts to modify GPIO\_ROUTEPEN when the debugger is connected will not occur. If you do disable the debug pins, make sure you have at least a 3 second timeout at the start of your program code before you disable the debug pins. This way the debugger will have time to connect to the device after a reset and before the pins are disabled.

## 26.3.5 Interrupt Generation

Interrupts may be triggered on edge events for any GPIO pin, or on pin input levels for GPIO capable of EM4 wake-up.

### 26.3.5.1 Edge Interrupt Generation

The GPIO can generate an interrupt from any edge of the input of any GPIO pin on the device. The edge interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM3 Stop, see [Figure 26.6 Pin N Interrupt Generation on page 867](#).

Figure 26.6. Pin N Interrupt Generation

External pin interrupts can be represented in the form of `EXTI[index]`, where index is the external interrupt number. For example, the `EXTI7` interrupt has an index of 7. All pins within a group of four (0-3,4-7,8-11,12-15) from all ports are grouped together to trigger one interrupt. The group of pins available to trigger an interrupt is determined by the interrupt index and calculated as  $\text{int}(\text{index}/4)$ . For example the first 4 interrupts (`EXTI0` - `EXTI3`) are triggered by pins in the first group (`Px[3:0]`) and the second 4 interrupts (`EXTI4`-`EXTI7`) are triggered by pins in the second group (`Px[7:4]`).

The `EXTIPSELn` bits in `GPIO_EXTIPSELL` or `GPIO_EXTIPSELH` select which PORT in the group will trigger the interrupt. The `EXTIPINSELn` bits in `GPIO_EXTIPINSELL` or `GPIO_EXTIPINSELH` will determine which pin inside the selected group will trigger the interrupt.

For example if `EXTIPSEL11 = PORTB` and `EXTIPINSEL11 = 0` then `PB8` will be used for `EXTI11`. `EXTI11` uses the third group ( $11/4 = 2$ ) so the list of possible pins is `Px[11:8]`. The setting of `EXTIPSEL11` further narrows the selection to `PB[11:8]`. Finally `EXTIPINSEL11` selects the first pin in that group which is `PB8`.

The `GPIO_EXTIRISE[n]` and `GPIO_EXTIFALL[n]` registers enable sensing of rising and falling edges. By setting the `EXT[n]` bit in `GPIO_IEN`, a high interrupt flag `n`, will trigger one of two interrupt lines. The even interrupt line is triggered by any enabled even numbered interrupt flag index, while the odd interrupt line is triggered by odd flag indexes. The interrupt flags can be set and cleared by software when writing the `GPIO_IFS` and `GPIO_IFC` registers. Since the external interrupts are asynchronous, they are sensitive to noise. To increase noise tolerance, the `MODEL` and `MODEH` fields in the `GPIO_Px_MODEL` and `GPIO_Px_MODEH` registers, respectively, should be set to include glitch filtering for pins that have external interrupts enabled.

### 26.3.5.2 Level Interrupt Generation

GPIO can generate a level interrupt using the input of any GPIO EM4 wake-up pins on the device. The interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM4.

In order to enable the level interrupt, set the EM4WU field in the GPIO\_IEN register and the EM4WUn field in the GPIO\_EXTILEVEL register. Upon a level interrupt occurring, the corresponding EM4WU index in the GPIO\_IF register will be set along with the odd or even interrupt line depending on the index inside of GPIO\_IF. For example, by setting the EM4WU8 in GPIO\_EXTILEVEL and EM4WU[8] in GPIO\_IEN, the interrupt flag EM4WU[8] in GPIO\_IF will be triggered by a high level on pin EM4WU8 and a interrupt request will be sent on IRQ\_GPIO\_EVEN.

The wake-up granularity of the level interrupts is based on the settings of the EM4WU field in the GPIO\_IEN register and the EM4WUEN field in the GPIO\_EM4WUEN register, see [Table 26.3 Level Interrupt Energy Mode Wakeup on page 868](#)

**Table 26.3. Level Interrupt Energy Mode Wakeup**

| GPIO_IEN | GPIO_EM4WUEN | Energy Mode Wakeup    |
|----------|--------------|-----------------------|
| 0        | 0            | No Interrupt          |
| 0        | 1            | EM4H,EM4S             |
| 1        | 0            | EM1,EM2,EM3,EM4H,EM4S |
| 1        | 1            | EM1,EM2,EM3,EM4H,EM4S |

### 26.3.6 Output to PRS

All pins within a group of four(0-3,4-7,8-11,12-15) from all ports are grouped together to form one PRS producer which outputs to the PRS. The pin from which the output should be taken is selected in the same fashion as the edge interrupts.

PRS output is not affected by the interrupt edge detection logic or gated by the IEN bits. See [Figure 26.6 Pin N Interrupt Generation on page 867](#) for an illustration of where the PRS output signal is generated.

### 26.3.7 Synchronization

To avoid metastability in synchronous logic connected to the pins, all inputs are synchronized with double flip-flops. The flip-flops for the input data run on the HFBUSCLK. Consequently, when a pin changes state, the change will have propagated to GPIO\_Px\_DIN after two 2 HFBUSCLK cycles. Synchronization (also running on the HFBUSCLK) is also added for interrupt input. To save power when the external interrupts or level interrupts are not used, the synchronization flip-flops for these can be turned off by clearing INT or EM4WU, respectively, in GPIO\_INSENSE register.

## 26.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name             | Type  | Description                                      |
|--------|------------------|-------|--------------------------------------------------|
| 0x000  | GPIO_PA_CTRL     | RW    | Port Control Register                            |
| 0x004  | GPIO_PA_MODEL    | RW    | Port Pin Mode Low Register                       |
| 0x008  | GPIO_PA_MODEH    | RW    | Port Pin Mode High Register                      |
| 0x00C  | GPIO_PA_DOUT     | RW    | Port Data Out Register                           |
| 0x018  | GPIO_PA_DOUTTGL  | W1    | Port Data Out Toggle Register                    |
| 0x01C  | GPIO_PA_DIN      | R     | Port Data in Register                            |
| 0x020  | GPIO_PA_PINLOCKN | RW    | Port Unlocked Pins Register                      |

## 27. APORT - Analog Port

### Quick Facts

#### What?

The Analog Port (APORT) is a set of analog buses which are used to connect I/O pins to analog peripheral signals.

#### Why?

The APORT gives on-chip analog resources access to a large number of I/O pins, and provides the system designer with a high degree of routing flexibility.

#### How?

An analog peripheral requests a pad by simply configuring its input/output to use a channel on APORT. That selection becomes an APORT request where the APORT control switches the pad and the analog signal onto a common bus.

### 27.1 Introduction

APORT consists of wires, switches, and control logic needed to route signals between analog peripherals and I/O pins. On-chip clients can be either producers or consumers. Analog producers are active devices that drive current/voltage into an APORT, such as current or voltage DACs. Consumers are passive devices that monitor or react to the current/voltage routed to them via the APORT, such as ADCs or analog comparators (ACMP).

### 27.2 Features

- Pins are typically mapped to two different APORT buses
- Arbitration and conflict status provided to each APORT client

## 27.3 Functional Description

**Figure 27.1. Analog Bus (ABUS)**

An analog bus (ABUS) consists of analog switches connected to a common wire as shown in [Figure 27.1 Analog Bus \(ABUS\) on page 907](#). An APORT consists of multiple ABUSes. Since many clients can operate differentially, buses are grouped by pairs as X and Y. If a given client uses a single ABUS (e.g. single-ended ADC), X and Y are just labels to differentiate the two buses.

When operating differentially, most APORT clients require that one input be chosen from an X bus and the other from a Y bus. For example, the ACMP block will not allow both positive and negative inputs to be chosen from X buses.

### 27.3.1 I/O Pin Considerations

For external analog signals routed through the APORT, the maximum supported analog I/O voltage will typically be limited to the  $\text{MIN}(V_{\text{ANALOGSUPPLY}}, \text{IOVDD})$  (where  $V_{\text{ANALOGSUPPLY}}$  is the supply pin powering the analog module). Practically, this means that if  $\text{IOVDD}=1.8\text{ V}$ , the maximum supported analog IO voltage on APORT-routed signals will be limited to 1.8 V, regardless of the analog module supply voltage.

## 27.3.2 APORT ABUS Naming

**Figure 27.2. Conceptual APORT Structure**

APORT ABUSes are prefixed with "BUS" and are grouped in pairs. Each pair is uniquely identified using a letter prefix ("A", "B", "C", etc.) followed by either a "X" or "Y" to identify the ABUS in the pair. For example, "BUSDX" decodes as: "BUS"=ABUS, "D"=pair, "X"=bus. [Figure 27.2 Conceptual APORT Structure on page 908](#) illustrates this organization.

APORT clients are generally described once in this reference manual regardless of its number of instances. For example, the ACMP client is described once, but the device could contain multiple instances of the ACMP. Because of this, for APORT client descriptions in this reference manual, the ABUS connections are generalized with the prefix "APORT" followed by a number (instead of the "BUS"

followed by a letter). It is possible that different instances of an APORT client connect to different ABUSes. For example, ACMP0 APORT1X might connect to the ABUS BUSAX while ACMP1 APORT1X might connect to ABUS BUSCX. Refer to the APORT Client Map in the device data sheet to map the generalized APORT client bus name to an actual device ABUS. A given ABUS has multiple switches which need to be identified. The switches on a bus are specified with the ABUS connection ID followed by a channel ID. For example, channel switch 7 on a given APORT client might be given as APORT1XCH7. Not all APORT channels map to actual GPIO. Refer to the APORT Client Maps in the device data sheet for APORT to GPIO mapping.

**Figure 27.3. Detailed APORT Structure**

Figure 27.3 Detailed APORT Structure on page 909 shows all the possible routes between different peripherals and different pins via APORT BUS for the largest package of the EFM32PG1 device family. Note that, in the figure, the BUS $xX$  and BUS $xY$  are annotated as  $xX$  and  $xY$ , where  $x=A,B,C,D$  and the APORT $nX$  and APORT $nY$  are annotated as  $nX$  and  $nY$ , where  $n=1,2,3,4$ .

For example, the IDAC APORT output 1X can be routed to pin PB14 through BUSCX. The configuration required for this routing is as follows:

- Set `IDAC_CTRL_APORTOUTSEL = APORT1XCH30`. This selects the IDAC APORT output 1X and pin PB14.
- Set `IDAC_CTRL_APORTOUTEN = 1` and `IDAC_CTRL_APORTOUTENPRS = 0`. This enables the IDAC to ungate its output to BUSCX.

Another example, when ADC is configured to operate in single channel mode for differential inputs (see [22.3.3.1 Single Channel Mode](#) for how to configure ADC in single channel mode), the positive ADC APORT input 2X and the negative ADC APORT input 2Y can be routed to pin PC9 and PC10 via BUSBX and BUSBY respectively with the following configuration:

- Set `ADCn_SINGLECTRL_POSSEL = APORT2XCH9`. This selects the pin PC9 for the positive input to the ADC.
- Set `ADCn_SINGLECTRL_NEGSEL = APORT2YCH10`. This selects the pin PC10 for the negative input to the ADC.

For smaller packages, not all GPIO pins are available. See the pinout sections of the device data sheet for pin availability on a specific device.

### 27.3.3 Managing ABUSes

The ABUSes of an APORT are shared resources. The user needs to be mindful of this in assigning I/O for different clients throughout the chip, as it is possible to have conflicts for a given ABUS. Each ABUS has an arbiter responsible for limiting the control over the ABUS to one and only one client. If multiple clients attempt to control an ABUS, the arbiter allows no client control over the ABUS and asserts a conflict signal to the clients. The user has the ability to check for such a conflict in each client's status, as well as generate an interrupt.

Having only one client control an ABUS is not the same as having only one user of an ABUS. It is possible for multiple clients to access a single ABUS, but requires all but one client to relinquish control of the ABUS. To do this, some clients have bits to disable bus master-ship which are 0 by default. One example is the APORTXMASTERDIS bit in the ACMPn\_CTRL. When set to 1, the client will not assert control of the APORT X BUS switches, but may still connect to an APORT X BUS that is controlled by another client.

For example, the ADC and ACMP both want to use the same pin on a particular ABUS the user might set the bus master disable bit to 1 for the ACMP. The ADC is the sole master of the switch configuration on that ABUS, so switches are configured using the configuration set in the ADC. When the ACMP channel is chosen on that same bus, the actual pin connection is dictated by the ADC settings for that bus.

**Figure 27.4. APORT Example 1**

Figure 27.4 APORT Example 1 on page 911 illustrates the sharing of APORT. For illustration purposes, each ABUS is identified by a numeric index (instead of BUSAX, BUSAY, BUSBX, etc.). Also, the requests from all the APORT clients are packed into a bit-vector named **APORT\_REQ** to illustrate the request from the APORT Clients (instead of by name such as **APORT1XREQ**, **APORT1YREQ**, **APORT2XREQ**, etc.). In Figure 27.4 APORT Example 1 on page 911, ABUS and client are the same color if the client has been granted the ABUS.

In Figure 27.4 APORT Example 1 on page 911 ADC0 has requested ABUS[3:0], ACMP1 has requested ABUS[5:4], ACMP0 has requested ABUS[7], and ABUS[6] is unused. No APORT Client has requested the same ABUS as another, so there is no conflict.

Figure 27.5. APORT Example 2: Bus Conflict

In [Figure 27.5 APORT Example 2: Bus Conflict on page 912](#) is a similar example to [Figure 27.4 APORT Example 1 on page 911](#), but now both ACMP0 and ACMP1 are requesting ABUS[4]. This is a configuration error, so APORT grants neither client ABUS[4]. The user must resolve the conflict before ABUS[4] is useable.

Figure 27.6. APORT Example 3: Sharing an ABUS

[Figure 27.6 APORT Example 3: Sharing an ABUS on page 912](#) illustrates ABUS sharing. Both ACMPs are configured identically, except ACMP0 has its APORTXMASTERDIS bit-field set to 1. There is only one APORT master for ABUS[5:4] in this case, so there is no conflict.

## 28. Revision History

### Revision 1.0

April, 2020

Grammatical and typographic changes throughout.

Moved Table of Contents to page 2.

In section [1.1 Introduction](#), added reference to device errata for device specific information.

In System Overview section [2.4 Oscillators and Clocks](#), changed [Table 2.1 EFM32 Gecko Oscillators on page 27](#) to indicate HFXO is an optional feature.

In System Processor section [3.3.2 Interrupt Request Lines \(IRQ\)](#), added ACMP1 as a source for IRQ #13 in [Table 3.1 Interrupt Request Lines \(IRQ\) on page 33](#).

In Memory and Bus system section [4.1 Introduction](#):

- Clarified DMA DMEM code region access restriction.
- Added RAMn to [Figure 4.1 EFM32 Gecko Bus System on page 34](#).

In section Memory and Bus system section [4.2 Functional Description](#)

- Added Section [4.2.1 Peripheral Non-Word Access Behavior](#).
- Added CM4 memory region to [Table 4.4 Core Peripherals on page 39](#).
- Clarified peripheral access performance information in [4.2.5.2 Peripheral Access Performance](#).
- Added section [4.2.5.2.1 WS0 Mode](#).
- Added section [4.2.5.2.2 WS1 Mode](#).
- Added section [4.2.5.2.3 Core Access Latency](#).
- Added Figures 4.7, 4.8, and 4.9 in [4.2.5.2.2 WS1 Mode](#).
- Added note on icache flush and invalidating the instruction cache after a bus fault to section [4.2.5.3 Bus Faults](#).
- Updated DEVICE\_FAMILY values and descriptions in section [4.7.9 PART - Part description](#).

In Debug section [5.3 Functional Description](#):

- Clarified functionality of debug pins and descriptions in [5.3.1 Debug Pins](#).
- Moved section [5.3.3.1 System Bus Stall](#) to precede section [5.3.3.2 Command Key](#).

In MSC section [6.3 Functional Description](#):

- Added additional detail to description of CLW0 in [6.3.2 Lock Bits \(LB\) Page Description](#).
- Added mention of AN0003 in section [6.3.4 Bootloader](#).
- Removed section "Device Revision" before section [6.3.5 Post-reset Behavior](#).
- Removed mention of reset value of WS1 due to uncalibrated HFRCO in [6.3.7.1 One Wait-state Access](#).
- Changed recommended max clock speed for WS0 to 25 MHz throughout section [6.3.7 Wait-states](#).
- Added note on icache flush and invalidating the instruction cache after a bus fault to section [6.3.10 Instruction Cache](#).
- Changed format of note on performance counter behavior during fetches while in interrupt context in [6.3.10 Instruction Cache](#).

In MSC section [6.5 Register Description](#):

- Changed MSC\_CMD to MSC\_WRITECMD in [6.5.5 MSC\\_ADDRB - Page Erase/Write Address Buffer](#).
- Added note about reset value differing from value shown to STDLY1 and STDLY0 bit field descriptions in [6.5.17 MSC\\_STARTUP - Startup Control](#).

In LDMA section [7.3 Functional Description](#):

- Changed EM2 to EM2/3 in [7.3 Functional Description](#).
- Changed SIZE to SRCINC or DSTINC in [7.3.1.2 Source/Destination Increments](#).
- Changed SYNCCLR bits to [15:8] in [7.3.7.2 SYNC Descriptor Structure](#).
- Changed MATCHEN bits to [15:8] in [7.3.7.2 SYNC Descriptor Structure](#).
- In [7.3.8 Interaction With the EMU](#), added information about peripheral-requested wake up of the LDMA in EM2/3 and [Table 7.3 List of Peripherals Capable of Waking Up LDMA in EM2 DeepSleep or EM3 Stop on page 132](#).

In RMU section [8.3 Functional Description](#):

- Updated [Figure 8.1 RMU Reset Input Sources and Connections on page 164](#).

- Corrected supply voltage from VDD to AVDD in [8.3.3 Power-On Reset \(POR\)](#).
- Added information on 3 BODs in [8.3.4 Brown-Out Detector \(BOD\)](#).
- Added RMU\_LOCK\_LOCKKEY to FULL reset in Table 8.3 in [8.3.10.1 Registers With Alternate Reset](#).
- Added CMU\_ULFRCTRL to FULL reset in Table 8.4 in [8.3.10.1 Registers With Alternate Reset](#).
- Added EMU\_DCDCLNCOMPCTRL to POR, BOD, and hard pin reset in Table 8.5 in [8.3.10.1 Registers With Alternate Reset](#).

In EMU section [9.3 Functional Description](#):

- Updated [Table 9.2 EMU Energy Mode Overview on page 178](#).
- Added "All oscillators are available" bullet in [9.3.1.1 EM0 Active](#).
- Added "All oscillators are available" bullet in [9.3.1.2 EM1 Sleep](#).
- Updated bullet lists and clarifications throughout
- Updated bullet list in [9.3.1.3 EM2 DeepSleep](#).
- Updated bullet list in [9.3.1.4 EM3 Stop](#).
- Updated bullet list in [9.3.1.5 EM4 Hibernate](#).
- Updated bullet list in [9.3.1.6 EM4 Shutoff](#).
- Updates and clarifications throughout [9.3.2 Entering Low Energy Modes](#).
- Added information about VMON-based EM4H wake-up to [9.3.3 Exiting a Low Energy Mode](#).
- Updated [Table 9.3 EMU Wake-Up Triggers from Low Energy Modes on page 184](#).
- Added bullet concerning internal digital LDO to [9.3.4.1 Power Configuration 0: STARTUP](#).
- Added information on the Bypass Current Limit to [9.3.5.1 Bypass Mode](#).
- Moved [9.3.5.4 DC-to-DC Programming Guidelines](#) to before [9.3.6 Analog Peripheral Power Selection](#).
- Clarified [9.3.6 Analog Peripheral Power Selection](#).
- Updated [Table 9.4 Analog Peripheral Power Configuration on page 190](#).
- Clarified language in [9.3.7 IOVDD Connection](#) and added language concerning multiple BODs in [9.3.8 Brown Out Detector \(BOD\)](#).
- Removed DEC column from [Table 9.5 VMON Events on page 191](#).
- Added additional information to section [9.3.9 Voltage Monitor \(VMON\)](#), including text and Figures 9.5 and 9.6.
- Updated [9.3.10 Powering Off SRAM Blocks](#).
- Renamed section [9.3.11 Temperature Sensor](#) and added additional information, including text and Figure 9.7.
- Updated register list in section [9.3.12 Registers latched in EM4](#).

In EMU section [9.4 Register Map](#):

- Added EMU\_DCDCLNCOMPCTRL, EMU\_BIASCONF, EMU\_TESTLOCK, EMU\_BIASTESTCTRL registers.

In EMU section [9.5 Register Description](#):

- Changed value fields to hexadecimal format and swapped mode and value columns in [9.5.4 EMU\\_RAM0CTRL - Memory Control Register](#).
- Updated EM4STATE bit field description in [9.5.6 EMU\\_EM4CTRL - EM4 Control Register](#).
- Removed bits 13 (VMONPAVDDRISE) and 12 (VMONPAVDDFALL) from [9.5.10 EMU\\_IFS - Interrupt Flag Set Register](#), [9.5.11 EMU\\_IFC - Interrupt Flag Clear Register](#), and [9.5.12 EMU\\_IEN - Interrupt Enable Register](#).
- Updated [9.5.14 EMU\\_PWRCFG - Power Configuration Register](#).
- Clarified [9.5.16 EMU\\_DCDCCTRL - DCDC Control](#) description.
- Clarified [9.5.17 EMU\\_DCDCMISCCTRL - DCDC Miscellaneous Control Register](#), [9.5.18 EMU\\_DCDCZDETCTRL - DCDC Power Train NFET Zero Current Detector Control Register](#), and [9.5.19 EMU\\_DCDCCLIMCTRL - DCDC Power Train PFET Current Limiter Control Register](#) descriptions.
- Added section [9.5.20 EMU\\_DCDCLNCOMPCTRL - DCDC Low Noise Compensator Control Register](#).
- Removed bit 28 (PWMRETIME) from [9.5.22 EMU\\_DCDCTIMING - DCDC Controller Timing Value Register](#).
- Clarified section [9.5.27 EMU\\_VMONAVDDCTRL - VMON AVDD Channel Control](#), [9.5.28 EMU\\_VMONALTAVDDCTRL - Alternate VMON AVDD Channel Control](#), [9.5.29 EMU\\_VMONDVDDCTRL - VMON DVDD Channel Control](#), and [9.5.30 EMU\\_VMONIO0CTRL - VMON IOVDD0 Channel Control](#) descriptions.
- Added sections [9.5.31 EMU\\_BIASCONF - Configurations Related to the Bias](#), [9.5.32 EMU\\_TESTLOCK - Test Lock Register](#), and [9.5.33 EMU\\_BIASTESTCTRL - Test Control Register for Regulator and BIAS](#).

In CMU section [10.3 Functional Description](#):

- Updated [Figure 10.1 CMU Overview - High Frequency Portion on page 230](#) and [Figure 10.2 CMU Overview - Low Frequency Portion on page 230](#).
- Clarified text throughout section [10.3.1 System Clocks](#).
- Added section [10.3.1.5 ADCnCLK - ADC Core Clock](#).

- Added information on valid use of LFXO/LFRCO EM4 retention in section [10.3.2.1.1 LFRCO and LFXO](#).
- Clarified text throughout section [10.3.2 Oscillators](#).
- Added section [10.3.2.1.5 AUXHFRCO](#).
- Updated [Figure 10.5 CMU Switching from HFRCO to HFXO after HFXO is ready on page 240](#) and [Figure 10.7 CMU HFXO control state machine on page 242](#).
- Moved section [10.3.2.4.1 Automatic HFXO Start](#).
- Added text concerning RC oscillator calibration to [10.3.2.6 HFRCO and AUXHFRCO Configuration](#).
- Updated text in and removed Table 10.4 from [10.3.3 Configuration for Operating Frequencies](#).
- Added ADCnCLK and removed RFSENSECLK from [Table 10.4 Oscillator and Clock Availability in Energy Modes on page 251](#).
- Removed section "Clock Input from a Pin" after [10.3.5 Clock Output on a Pin](#).

In CMU section [10.4 Register Map](#):

- Added CMU\_ULFRCOCTRL register.
- Updated CMU\_LFEPRESC0 register description.

In CMU section [10.5 Register Description](#):

- Minor clarifications to text throughout.
- Added bit 0 (MODE) to [10.5.5 CMU\\_HFXOCTRL - HFXO Control Register](#).
- Added section [10.5.11 CMU\\_ULFRCOCTRL - ULFRCO Control Register](#).
- Added bit 21 (HFXOREQ) to [10.5.21 CMU\\_STATUS - Status Register](#).
- Added bit 10 (HFXOPEALDETERR) to [10.5.24 CMU\\_IF - Interrupt Flag Register](#).
- Updated register list in LOCKKEY description in [10.5.46 CMU\\_LOCK - Configuration Lock Register](#).

In RTCC section [11.3 Functional Description](#):

- Added note on reconfiguring the RTCC to [11.3.1.1 Normal Mode](#).

In WDOG section [12.3 Functional Description](#):

- Changed CMU\_HFCORECLKEN0 to CMU\_HFBUSCLKEN0 in [12.3.1 Clock Source](#).

In PRS section [13.3 Functional Description](#):

- Clarification of text throughout.
- Changed HFBUSCLK to HFCLK in [13.3.1.2 Edge Detection and Clock Domains](#).
- Added description of ORPREV and ANDNEXT channel wrapping functionality to [13.3.1.3 Configurable PRS Logic](#).
- Added description of GPIO producers to section [13.3.2 Producers](#).

In PRS section [13.5 Register Description](#):

- Clarification of text throughout.
- Changed HFPERCLK to HFCLK in [13.5.1 PRS\\_SWPULSE - Software Pulse Register](#).
- Changed HFPERCLK to HFCLK in [13.5.11 PRS\\_CHx\\_CTRL - Channel Control Register](#).
- Added CM4 to SOURCESEL and CM4TXEV to SIGSEL in [13.5.11 PRS\\_CHx\\_CTRL - Channel Control Register](#).

In I2C section [15.3 Functional Description](#):

- Updated equation in [Figure 15.3 I2C Pull-up Resistor Equation on page 412](#).
- Combined notes to bulleted list in section [15.3.1 I2C-Bus Overview](#).
- Added text on separate receive and transmit buffers to section [15.3.6 Buffers](#).

In USART section [16. USART - Universal Synchronous Asynchronous Receiver/Transmitter](#):

- Specified that IrDA modulator is only available on USART0
- Added text to [16.3.2 Asynchronous Operation](#)
- Added information about Synchronous, Full Duplex operation to [16.3.9 DMA Support](#)

In CRYOTIMER section [20.3.4 Energy Mode Availability](#), added information about clearing interrupt bits

In ACMP section [21.2 Features](#):

- Added list of selectable internal inputs
- Increased maximum external inputs to 160
- Corrected number of capacitive sense inputs to 8

In ACMP section [21.3.6 Input Selection](#)

- Moved APORT mapping to datasheet

In ADC section [8.3 Functional Description](#):

- Added note about HFPERCLK in Asynchronous mode
- Added note about KEEPADCWARM operation in EM2
- Added power supply and input pin considerations section
- Added note that APORT mappings can be found in the datasheet
- Added information about the DC-DC's effect on voltage configuration
- Added note about ADC ASYNC clock to Programing Model

In IDAC section [23.3.4 APORT Configuration](#), moved APORT mapping to datasheet

In GPIO section [26.3 Functional Description](#), added note about interrupt generation

In APORT section [27.3 Functional Description](#), added I/O pin considerations paragraph

## Revision 0.6

July, 2016

Initial Release

## Appendix 1. Abbreviations

This section lists abbreviations used in this document.

**Table 1.1. Abbreviations**

| Abbreviation                       | Description                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------|
| ACMP                               | Analog Comparator                                                                                  |
| ADC                                | Analog to Digital Converter                                                                        |
| AHB                                | AMBA Advanced High-performance Bus. AMBA is short for "Advanced Microcontroller Bus Architecture". |
| APB                                | AMBA Advanced Peripheral Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".       |
| ALE                                | Address Latch Enable                                                                               |
| AUXHFRCO                           | Auxiliary High Frequency RC Oscillator.                                                            |
| CC                                 | Compare / Capture                                                                                  |
| CIC                                | Cascaded Integrator Comb                                                                           |
| CLK                                | Clock                                                                                              |
| CMD                                | Command                                                                                            |
| CMU                                | Clock Management Unit                                                                              |
| CTRL                               | Control                                                                                            |
| DAC                                | Digital to Analog Converter                                                                        |
| DBG                                | Debug                                                                                              |
| DMA                                | Direct Memory Access                                                                               |
| DRD                                | Dual Role Device                                                                                   |
| DTI                                | Dead Time Insertion                                                                                |
| EBI                                | External Bus Interface                                                                             |
| EFM                                | Energy Friendly Microcontroller                                                                    |
| EM                                 | Energy Mode                                                                                        |
| EM0 Active                         | Energy Mode 0 (also called active mode)                                                            |
| EM1 Sleep to EM4 Hibernate/Shutoff | Energy Mode 1 to Energy Mode 4 (also called low energy modes)                                      |
| EMU                                | Energy Management Unit                                                                             |
| ENOB                               | Effective Number of Bits                                                                           |
| FS                                 | Full-speed                                                                                         |
| GPIO                               | General Purpose Input / Output                                                                     |
| HFRCO                              | High Frequency RC Oscillator                                                                       |
| HFXO                               | High Frequency Crystal Oscillator                                                                  |
| HW                                 | Hardware                                                                                           |
| I <sup>2</sup> C                   | Inter-Integrated Circuit interface                                                                 |
| LCD                                | Liquid Crystal Display                                                                             |
| LESENSE                            | Low Energy Sensor Interface                                                                        |

| Abbreviation | Description                                             |
|--------------|---------------------------------------------------------|
| LETIMER      | Low Energy Timer                                        |
| LEUART       | Low Energy Universal Asynchronous Receiver Transmitter  |
| LFRCO        | Low Frequency RC Oscillator                             |
| LFXO         | Low Frequency Crystal Oscillator                        |
| LS           | Low-speed                                               |
| MAC          | Media Access Controller                                 |
| NVIC         | Nested Vector Interrupt Controller                      |
| OSR          | Oversampling Ratio                                      |
| OTG          | On-the-go                                               |
| PCNT         | Pulse Counter                                           |
| PCM          | Pulse Code Modulation                                   |
| PDM          | Pulse Density Modulation                                |
| PHY          | Physical Layer                                          |
| PRS          | Peripheral Reflex System                                |
| PWM          | Pulse Width Modulation                                  |
| RC           | Resistance and Capacitance                              |
| RMU          | Reset Management Unit                                   |
| RTC          | Real Time Clock                                         |
| SAR          | Successive Approximation Register                       |
| SOF          | Start of Frame                                          |
| SPI          | Serial Peripheral Interface                             |
| SW           | Software                                                |
| TRNG         | True Random Number Generator                            |
| UART         | Universal Asynchronous Receiver Transmitter             |
| USART        | Universal Synchronous Asynchronous Receiver Transmitter |
| USB          | Universal Serial Bus                                    |
| VMON         | Voltage supply monitor                                  |
| WDOG         | Watchdog timer                                          |
| XTAL         | Crystal                                                 |

Silicon Labs

# Simplicity Studio™4

## Simplicity Studio

One-click access to MCU and wireless tools, documentation, software, source code libraries & more. Available for Windows, Mac and Linux!

### Disclaimer

Silicon Labs intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Labs products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Labs reserves the right to make changes without further notice to the product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Without prior notification, Silicon Labs may update product firmware during the manufacturing process for security or reliability reasons. Such changes will not alter the specifications or the performance of the product. Silicon Labs shall have no liability for the consequences of use of the information supplied in this document. This document does not imply or expressly grant any license to design or fabricate any integrated circuits. The products are not designed or authorized to be used within any FDA Class III devices, applications for which FDA premarket approval is required, or Life Support Systems without the specific written consent of Silicon Labs. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in significant personal injury or death. Silicon Labs products are not designed or authorized for military applications. Silicon Labs products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons. Silicon Labs disclaims all express and implied warranties and shall not be responsible or liable for any injuries or damages related to use of a Silicon Labs product in such unauthorized applications.
