27. ADC - Analog to Digital Converter

Quick Facts

**What?**

The ADC is used to convert analog signals into a digital representation and features low-power, autonomous operation.

**Why?**

In many applications there is a need to measure analog signals and record them in a digital representation, without exhausting the energy source.

**How?**

A low power ADC samples up to 32 input channels in a programmable sequence. With the help of PRS and DMA, the ADC can operate without CPU intervention in EM2 Deep Sleep and EM3 Stop, minimizing the number of powered up resources. The ADC can further be duty-cycled to reduce the energy consumption.

27.1 Introduction

The ADC uses a Successive Approximation Register (SAR) architecture, with a resolution of up to 12 bits at up to one million samples per second (1 Msp/s). The integrated input multiplexer can select from external I/Os and several internal signals.

## 27.2 Features

- Programmable resolution (6/8/12-bit)
  - 13 conversion clock cycles for a 12-bit conversion
  - Maximum 1 Msps @ 12-bit
  - Maximum 1.6 Msps @ 6-bit
- Configurable acquisition time
- Externally controllable conversion start time using PRS in TIMED mode
- Integrated prescaler for conversion clock generation
  - Selectable clock division factor from 1 to 128
- Wide conversion clock range: 32 kHz to 16 MHz
- Can be run during EM2 Deep Sleep and EM3 Stop, waking up the system upon various enabled interrupts
- Can be run during EM2 Deep Sleep and EM3 Stop with DMA enabled to pull data from the FIFOs without waking up the system
- Supports up to 144 external input channels and several internal inputs
  - Includes temperature sensor and random number generator function
- Left or right adjusted results
  - Results in 2's complement representation
  - Differential results sign extended to 32-bits results
- Programmable scan sequence
  - Up to 32 configurable samples in scan sequence
  - Mask to select which pins are included in the sequence
  - Triggered by software or PRS input
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data along with channel ID and option to overwrite old data when full
  - Programmable watermark (DVL) to generate SCAN interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
  - Conversion tailgating support for predictable periodic scans
- Programmable single channel conversion
  - Triggered by software or PRS input
  - Can be interleaved between two scan sequences
  - One shot or repetitive mode
  - Oversampling available
  - Four deep FIFO to store conversion data with option to overwrite old data when full
  - programmable watermark (DVL) to generate SINGLE interrupt
  - Supports overflow and underflow interrupt generation
  - Supports window compare function
- Hardware oversampling support
  - 1st order accumulate and dump filter
  - From 2 to 4096 oversampling ratio (OSR)
  - Results in 16-bit representation
  - Enabled individually for scan sequence and single channel mode
  - Common OSR select
- Programmable and preset input full scale (peak-to-peak) range (VFS) with selectable reference sources
  - VFS=1.25 V using internal VBGR reference
  - VFS=2.5 V using internal VBGR reference
  - VFS=AVDD with AVDD as reference source
  - VFS=5 V with internal VBGR reference
  - Single ended external reference
  - Differential external reference
  - VFS=2xAVDD with AVDD as reference source
  - User-programmable dividers for flexible VFS options from internal, external or supply voltage reference sources

- Support for offset and gain calibration
- Interrupt generation and/or DMA request when
  - Programmable number of converted data available in the single FIFO (also generates DMA request)
  - Programmable number of converted data available in the scan FIFO (also generates DMA request)
  - Single FIFO overflow or underflow
  - Scan FIFO overflow or underflow
  - Latest Single conversion tripped compare logic
  - Latest Scan conversion tripped compare logic
  - Analog over-voltage interrupt

## 27.3 Functional Description

An overview of the ADC is shown in [Figure 27.1 ADC Overview on page 885](#).

Figure 27.1. ADC Overview

### 27.3.1 Clock Selection

The ADC logic is partitioned into two clock domains: HUPERCLK and ADC\_CLK. The HUPERCLK domain contains the register interface logic, APORT request logic and portions of FIFO read logic. The HUPERCLK is the default clock for the ADC peripheral. The rest of the ADC is clocked by the ADC\_CLK domain. The ADC\_CLK is chosen by ADCCLKMODE bit in the ADCn\_CTRL register.

The ADC\_CLK is the main clock for the ADC engine. If the ADCCLKMODE is set to SYNC, the ADC\_CLK is equal to the HUPERCLK and the ADC operates in synchronous mode. If the ADCCLKMODE is set to ASYNC, the ADC\_CLK is ASYNCCLK and the ADC operates in asynchronous mode. This distinction is important to understand as there are additional system restrictions and benefits to running the ADC in asynchronous mode detailed in [27.3.15 ASYNC ADC\\_CLK Usage Restrictions and Benefits](#).

**Note:** Whenever ADC is being used in asynchronous mode, then HUPERCLK must be at least 1.5 times higher than the ADC\_CLK.

The ADC has an internal clock prescaler, controlled by PRESC bits in ADCn\_CTRL, which can divide the ADC\_CLK by any factor between 1 and 128 to generate the conversion clock (adc\_clk\_sar) for the ADC. This adc\_clk\_sar is also used to generate acquisition timing. Note that the maximum clock frequency for adc\_clk\_sar is 16 MHz. The ADC warmup time is determined by ADC\_CLK and not by adc\_clk\_sar.

ASYNCCLK is a clock source from the CMU which is considered asynchronous to HUPERCLK. The CMU\_ADCCTRL register can be programmed to request and use ASYNCCLK. It has multiple choices for its source, including AUXHFRCO, HFXO and HFSRCCLK, and can optionally be inverted. If the chosen source for ASYNCCLK is not active at the time of request, the CMU enables the source oscillator upon receiving the request, and shuts down the oscillator when the ADC stops requesting the clock. Consult the CMU chapter for details of how to program the clock sources for the ASYNCCLK and oscillator start-up time details.

Software may choose a clock request generation scheme by programming the ASYNCCLKEN and WARMMODE of the ADCn\_CTRL register. If the ASYNCCLKEN is set to ASNEEDED with WARMMODE set to NORMAL, the ADC requests ASYNCCLK only when a conversion trigger is activated. The ASYNCCLK request is withdrawn after the conversion is complete. All other options keep the ASYNCCLK request "ON" until software programs these fields otherwise or changes the ADCCLKMODE to SYNC.

For EM2 Deep Sleep or EM3 Stop operation of the ADC, the ADC\_CLK must be configured for AUXHFRCO as this is the only available option during EM2 Deep Sleep or EM3 Stop. The ADC\_CLK source should not be changed as the system enters or exits various energy modes, otherwise measurement inaccuracies will result.

### 27.3.2 Conversions

A conversion consists of two phases: acquisition and approximation. The input is sampled in the acquisition phase before it is converted to digital representation during the approximation phase. The acquisition time can be configured independently for scan sequence and single channel conversions (see [27.3.3 ADC Modes](#)) by setting AT in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The acquisition times can be set to 1, 2, 3 or any integer power of 2 from 4 to 256 adc\_clk\_sar cycles.

**Note:** For high impedance sources the acquisition time should be adjusted to allow enough time for the internal sample capacitor to fully charge. The minimum acquisition time for sampling at 1 Msps and typical input loading is 187.5 ns.

The ADC uses one adc\_clk\_sar cycle per output bit in the approximation phase plus 1 extra adc\_clk\_sar cycle.

$$T_{\text{conv}} = (T_{\text{acq}} + (N + 1) \times T_{\text{adc\_clk\_sar}}) \times \text{OVSSEL}$$

Where  $T_{\text{acq}}$  is the acquisition time set by the AT bit field, N is the resolution (in bits), and OVSSEL is the oversampling ratio according to the OVSSEL field in ADCn\_CTRL when oversampling is enabled (see [27.3.10.6 Oversampling](#)).

**Figure 27.2. ADC Total Conversion Time Per Output**

**Figure 27.3. ADC Conversion Timing**

### 27.3.3 ADC Modes

The ADC contains two programmable modes: single channel mode and scan mode. Both modes have separate configuration registers and a four-deep FIFO for conversion results. Both modes may be set up to run only once per trigger or to automatically repeat after each operation. The scan mode has priority over the single channel mode. However by default, if scan sequence is running, a triggered single channel conversion will be interleaved between two scan samples.

#### 27.3.3.1 Single Channel Mode

Single channel mode can be used to convert a single channel either once per trigger or repetitively. The configuration of single channel mode is done using the `ADCn_SINGLECTRL` and `ADCn_SINGLECTRLX` registers and the result FIFO can be read through the `ADCn_SINGLEDATA` register. The `DVL` field of the `ADCn_SINGLECTRLX` controls the FIFO watermark crossing which sets the `SINGLEDV` bit in `ADCn_STATUS` high and is cleared when the data is read and the number of unread data samples falls below the `DVL` threshold. The user can choose to throw out new samples or overwrite the old samples when the FIFO becomes full by programming the `FIFOFACT` field of the `ADCn_SINGLECTRLX` register. Single channel results can also be read through `ADCn_SINGLEDATAP` without popping the FIFO, returning its latest element. The `DIFF` field in `ADCn_SINGLECTRL` selects whether differential or single ended inputs are used and `POSSEL` and `NEGSEL` selects the input signal(s). The `CMPEN` bit in the `ADCn_SINGLECTRL` register enables the window compare function, and the latest converted data is compared against values programmed into the `ADGT` and `ADLT` fields of the `ADCn_CMPTHR` register and generates `SINGLECMP` interrupts if enabled. The window compare function allows for compare triggering both within (if `ADGT` less than `ADLT`) or out of (if `ADGT` greater than `ADLT`) window.

#### 27.3.3.2 Scan Mode

Scan mode is used to perform conversions across multiple channels, sweeping a set of selected inputs in a sequence. The configuration of scan mode is done in the `ADCn_SCANCTRL` and `ADCn_SCANCTRLX` registers. It has similar controls and data read mechanisms to single channel mode. There are two key differences between single channel mode and scan mode: the input sequence is programmed differently, and it has additional information in the result to indicate the channel on which the conversion was acquired. [27.3.7 Input Selection](#) explains how the input sequence is chosen. When the scan sequence is triggered, the ADC samples all inputs that are included in the mask (`ADCn_SCANMASK`), starting at the lowest pin number. `DIFF` in `ADCn_SCANCTRL` selects whether single ended or differential inputs are used. The FIFO data is tagged with `SCANINPUTID` and can be read along with the scan data using `ADCn_SCANDATA` register. The `ADCn_SCANDATAXP` can be used to read the latest valid entry from the scan FIFO without popping it. There is also a `ADCn_SCANDATA` register that contains results without the `SCANINPUTID` appended.

**Note:** If using scan mode with `ADCn_SCANCTRL_REP = 1` and `ADCn_SCANCTRLX_REPDELAY = NODELAY`, the last channel in the scan will report a `SCANINPUTID` of 0. Using `ADCn_SCANCTRLX_REPDELAY` with any value other than `NODELAY` will report the correct `SCANINPUTID`.

### 27.3.4 Warm-up Time

After power-on, the ADC requires some time for internal bias currents and references to settle prior to starting a conversion. This time period is called the warm-up time. Warm-up timing is performed by hardware. Software must program the number of ADC\_CLK cycles required to count at least 1  $\mu$ s in the TIMEBASE field of the ADCn\_CTRL register. TIMEBASE only affects the timing of the warm-up sequence and is not dependent on adc\_clk\_sar. When enabling the ADC or changing references between samples, the ADC is automatically warmed up for 5  $\mu$ s (5 times the period indicated by TIMEBASE).

Normally, the ADC will be warmed up only when samples are requested and is shut off when there are no more samples waiting. However, if lower latency is needed, configuring the WARMUPMODE field in ADCn\_CTRL allows the ADC and/or reference to stay warm between samples, reducing the warm-up time or eliminating it altogether. [Figure 27.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 889](#) shows the effects on analog power consumption in scenarios using different WARMUPMODE settings.

The user can program which reference should be kept warm in the CHCONREFWARMIDLE bitfield in the ADCn\_CTRL register. By default the scan mode reference is kept warm. The user can also choose to keep the single channel mode reference warm or to keep the last used reference warm. If the default setting is kept (scan mode reference is to be kept warm) and if the single-mode reference setting is different than scan-mode, then single mode conversions will first warmup its reference for 5  $\mu$ s before a conversion can begin.

Various warmup modes are described here:

- **NORMAL:** This is the lowest power option for general-purpose use and low sampling rates (below 35 ksps). The ADC and references are shut off when there are no samples waiting. The ADC does not consume any power when it is shut down. A 5  $\mu$ s warmup time will be initiated prior to every conversion. Figure a in [Figure 27.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 889](#) shows this mode.
- **KEEPINSTANDBY:** This mode is suitable for infrequent sampling of lower impedance inputs, and is the lowest power option for sampling rates between about 35 and 125 ksps. It may also be useful for lower sampling rates where latency is important. The reference selected for scan mode is kept warm, but the ADC is powered down. The ADC will initiate a 1  $\mu$ s warmup period before a conversion begins. Because the reference is kept warm, the ADC will consume a small amount of standby current when it is not converting. Figure b in [Figure 27.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 889](#) shows this mode.
- **KEEPINSLOWACC:** This mode is useful for high-impedance inputs which are sampled infrequently. It is similar to KEEPINSTANDBY, but continuously tracks the input, keeping the input multiplexer connected to the APORT bus. This mode consumes little more power than KEEPINSTANDBY mode (about 2  $\mu$ A extra) when a conversion is not in progress. This allows the user to avoid programming long acquisition time that would otherwise be necessary for high-impedance inputs when ADC wakes up to full power mode, thereby reducing the total current consumption per conversion.
- **KEEPADCWARM:** This mode provides the lowest latency and allows for maximum sampling rates. The ADC and reference circuitry remain powered on even when conversions are not in progress. Figure c in [Figure 27.4 ADC Analog Power Consumption With Different WARMUPMODE Settings on page 889](#) shows this mode. This mode consumes the most power, but as soon as a trigger event occurs, the acquisition and conversion begin with no warm-up time. Note that if KEEPADCWARM mode is set and HFXO is selected as the ADC clock source, the HFXO will remain on in EM2.

When KEEPADCWARM is chosen, ADC is termed as being in continuous operation. When any other warmup mode is chosen, ADC is termed to be in duty-cycled operation.

When entering EM2 Deep Sleep or EM3 Stop, if the ADC is not going to be used, it should be returned to an idle state and WARMUPMODE in ADCn\_CTRL written to 0. Refer to [27.3.17 ADC Programming Model](#) for more information on placing the ADC in an idle state. If the ADC is going to be used in these low energy modes, the user can use any of the WARMUPMODE settings, but should be mindful of the power consumption that comes along with the different mode settings. For EM2 Deep Sleep or EM3 Stop operation, the ADC clock source must be configured to use AUXHFRCO.

**Figure 27.4. ADC Analog Power Consumption With Different WARMUPMODE Settings**

**Note:** When using any warm-up mode other than NORMAL, always switch back to the NORMAL mode before switching to another warm-up mode.

### 27.3.5 Power Supply

The ADC block power ( $V_{ADC}$ ) is derived from the VDDX\_ANA supply rail. VDDX\_ANA can be selected from the AVDD or DVDD supply pins using the EMU\_PWRCTRL\_ANASW bit field.

### 27.3.6 Input Pin Considerations

For external ADC inputs routed through the APORT, the maximum supported analog input voltage will be limited to the  $\text{MIN}(V_{ADC}, \text{IOVDD})$  (where  $V_{ADC}$  is VDDX\_ANA, as described in [27.3.5 Power Supply](#)). Note that pins configured as ADC inputs should disable OVT (by setting the corresponding GPIO\_Px\_OVTDIS bit) to reduce any potential distortion introduced by the OVT circuitry.

ADC external reference inputs are not routed through the APORT, and the maximum supported analog input voltage for an external reference will also be limited to the  $\text{MIN}(V_{ADC}, \text{IOVDD})$ .

### 27.3.7 Input Selection

The ADC samples and converts the analog voltage differential at its positive and negative voltage inputs. The input multiplexers of the ADC can connect these inputs to one of several internal nodes (e.g., temperature sensor) or to external signals via analog ports (APORT0, APORT1, APORT2, APORT3 or APORT4).

The analog ports APORT1, APORT2, APORT3, and APORT4 connect to external pins via analog buses (BUSAX, BUSAY, BUSBX, etc.) which are shared among other analog peripherals on the device. APORT1 through APORT4 are each 32 channels wide with connections to two sub-buses: a 16-channel X bus and a 16-channel Y bus. In the ADC module, all X buses connect to the INP\_MUX and all Y buses connect to the INN\_MUX as shown in [Figure 27.5 APORT Connection to the ADC on page 890](#). Connections to the X and Y sub-buses alternate channels on the APORT. On APORT1 and APORT3, even-numbered channels connect to the X bus, and odd-numbered channels connect to the Y bus. On APORT2 and APORT4, even-numbered channels connect to the Y bus and odd-numbered channels connect to the X bus. The APORT to BUS mappings may vary from device to device. Refer to the APORT Client Map in the device data sheet for exact mappings.

Unlike APORT1 through APORT4, APORT0 is not a shared resource. It consists of a 16-channel X bus and a 16-channel Y bus, each with dedicated I/O pin connections. Note that APORT0 is not available on all device families.

**Figure 27.5. APORT Connection to the ADC**

For differential measurements, one input must be chosen from an X bus and the other from a Y bus. Choosing both inputs from an X bus or both from a Y bus will generate a PROGERR interrupt (if enabled) of NEGSELCONF type. The PROGERR type can be checked in the ADCn\_STATUS register.

The mapping and availability for external I/O connections to ADC0 inputs is shown in device data sheet.

Multiple peripherals may request the same shared system bus (BUSAX, BUSAY, BUSBX, etc.). When this happens, a conflict status is generated and that bus is kept floating. If this happens with the ADC, the PROGERR field in ADCn\_STATUS is set to BUSCONF, and an interrupt may be generated (if enabled). When connecting dedicated I/Os through APORT0, all inputs are available to APORT0X and APORT0Y and no bus conflict is possible. Refer to [27.3.7.3 APORT Conflicts](#) for more information on identifying and resolving bus conflicts.

**Note:** The internal inputs can only be sampled in single channel, single-ended mode. NEGSEL should be fixed to VSS for these conversions.

#### 27.3.7.1 Configuring ADC Inputs in Single Channel Mode

In single channel mode, the ADCn\_SINGLECTRL register provides the POSSEL and NEGSEL selection for positive and negative channel selection of the ADC. The APORT Client Map provides external pin to internal bus channel mapping enumeration for a particular device. Software can also choose internal nodes for POSSEL.

For single-ended conversions on external (APORT-connected) signals, POSSEL and NEGSEL are fully configurable. However, when performing conversions on internal signals, NEGSEL must be set to VSS. This NEGSEL reconfigurability feature in single-ended mode may not be available in all devices. If compatibility with devices that do not support this feature is desired, NEGSEL should be set to VSS for all single channel single-ended conversions.

Note that in both the POSSEL and NEGSEL fields, it is possible to choose inputs from both X and Y buses, even though X channels are physically connected to the positive mux (INP\_MUX) and Y channels are physically connected to the negative mux (INN\_MUX). For single-ended operation (DIFF = 0), if the positive input is chosen from a Y channel the ADC performs a negative single ended conversion and automatically inverts the result at the end, producing a positive result. For differential conversions (DIFF = 1), if a Y channel is chosen for the positive input and an X channel is chosen for the negative input, the ADC result will be inverted to produce the correct polarity.

Refer to device-specific data sheet for specific pin connection options. Note that the same I/O pin may appear in multiple locations.

### 27.3.7.2 Configuring ADC Inputs in Scan Mode

In scan mode, the ADC can sample and convert up to 32 external channels on each conversion trigger. Internal channels are not available in scan mode. The ADC's scanner logic automatically changes the input mux settings between conversions, eliminating the need for firmware intervention.

The ADC scanner logic is controlled by a set of 32 logical channels called SCANINPUTIDs. The 32 SCANINPUTIDs are arranged in four groups of 8 channels each. Each channel group can point to a predefined series of 8 sequential channels on any of the available APORTs. The ADCn\_SCANINPUTSEL register is used to configure which group of physical APORT channels each of the SCANINPUTID channel groups map to. For example, selecting APORT1CH16TOCH23 in the INPUT7TO0SEL field selects APORT1CH16 for SCANINPUTID0, APORT1CH17 for SCANINPUTID1, APORT1CH18 for SCANINPUTID2, and so on.

The four SCANINPUTID groups are fully independent and may be selected from any APORT in any combination. It is possible also to repeat the same selection in multiple groups. For example, the user may select APORT2CH0TOCH7 for all four of the SCANINPUTID groups.

In many cases, the user application will not require all 32 channels of the scanner to be converted. Each of the scanner channels may be individually enabled according to the needs of the system. The ADCn\_SCANMASK register is used to enable and disable individual SCANINPUTIDs. The bits in the ADCn\_SCANMASK register correspond one-to-one with the SCANINPUTID channel numbers. During a scan operation, the ADC scanner logic will convert only the enabled SCANINPUTIDs, in order from lowest to highest.

In single-ended mode, all conversions performed by the ADC will be relative to VSS. For any enabled SCANINPUTID, the selected APORT channel will be connected to the ADC with the opposite ADC input terminal connected to VSS. Note that the channel groups selected in ADCn\_SCANINPUTSEL point to a block of 8 channels on an APORT, which includes both X and Y channels. Depending on the channels enabled by ADCn\_SCANMASK, the ADC may perform conversions on the X or the Y bus associated with that APORT.

Figure 27.6 ADC Single-ended Scan Mode Example on page 892 shows an example of a single-ended scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects six of these channels for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of six single-ended ADC conversions: PF0, PF3, PA5, PA5, PF7, and PF4.

| SCANINPUTSEL  | APORT1CH16TO23 |      |      |      |      |      |      |      | APORT1CH16TO23 |      |      |      |      |      |      |      | APORT4CH8TO15 |      |      |      |      |      |     |     | APORT1CH16TO23 |      |      |      |      |      |      |      |
|---------------|----------------|------|------|------|------|------|------|------|----------------|------|------|------|------|------|------|------|---------------|------|------|------|------|------|-----|-----|----------------|------|------|------|------|------|------|------|
| APORT-Channel | 1-23           | 1-22 | 1-21 | 1-20 | 1-19 | 1-18 | 1-17 | 1-16 | 1-23           | 1-22 | 1-21 | 1-20 | 1-19 | 1-18 | 1-17 | 1-16 | 4-15          | 4-14 | 4-13 | 4-12 | 4-11 | 4-10 | 4-9 | 4-8 | 1-23           | 1-22 | 1-21 | 1-20 | 1-19 | 1-18 | 1-17 | 1-16 |
| I/O Pin       | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  | none          | none | PA5  | PA4  | PA3  | PA2  | PA1 | PA0 | PF7            | PF6  | PF5  | PF4  | PF3  | PF2  | PF1  | PF0  |
| SCANMASK      | 0              | 0    | 0    | 1    | 0    | 0    | 0    | 0    | 1              | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0             | 0    | 1    | 1    | 0    | 0    | 0   | 0   | 0              | 0    | 0    | 0    | 1    | 0    | 0    | 1    |
| SCANINPUTID   | 31             |      |      |      |      |      |      |      | 24 23          |      |      |      |      |      |      |      | 16 15         |      |      |      |      |      |     |     | 8 7            |      |      |      |      |      |      |      |

Figure 27.6. ADC Single-ended Scan Mode Example

In differential mode, the default operation of the ADC scanner is to perform a differential measurement between the selected APORT channel and the next channel on that APORT. For example, if the enabled SCANINPUTID points to APORT1CH6, the ADC will perform a differential conversion between APORT1CH6 and APORT1CH7.

There are two exceptions to this rule, listed in order of precedence:

1. When converting SCANINPUTID15, the differential conversion will be performed between the channel selected by SCANINPUTID15 and the channel selected by SCANINPUTID8.
2. When APORTnCH31 is the selected input, the differential conversion will be performed between APORTnCH31 and APORTnCH0.

Figure 27.7 ADC Differential Scan Mode Example on page 893 shows an example of a differential scan configuration. In this example, ADCn\_SCANINPUTSEL has been configured to place APORT1CH16TO23 in the first, third, and fourth channel groups. APORT4CH8TO15 has been placed in the second channel group. ADCn\_SCANMASK selects three channels pairs for inclusion in the scan. When an ADC scan is initiated with this configuration, the ADC begins at SCANINPUTID0 and converts each enabled channel in turn. This scan configuration results in a set of three differential ADC conversions: PF0-PF1, PF2-PF3, and PA4-PA5.

| SCANINPUTSEL                | APORT1CH16TO23 |         |         |         |         |         |         |         | APORT1CH16TO23 |         |         |         |         |         |         |         | APORT4CH8TO15 |      |          |         |         |         |         |         | APORT1CH16TO23 |         |         |         |         |         |         |         |      |
|-----------------------------|----------------|---------|---------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|---------|---------------|------|----------|---------|---------|---------|---------|---------|----------------|---------|---------|---------|---------|---------|---------|---------|------|
| APORT-Channel<br>(Positive) | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    | 4-15          | 4-14 | 4-13     | 4-12    | 4-11    | 4-10    | 4-9     | 4-8     | 1-23           | 1-22    | 1-21    | 1-20    | 1-19    | 1-18    | 1-17    | 1-16    |      |

Figure 27.7. ADC Differential Scan Mode Example

In certain applications it may be desirable to perform differential conversions on several channels against a common voltage. The ADCn\_SCANNEGSEL register allows eight of the SCANINPUTIDs to re-map the negative terminal of a differential conversion to a common channel. In the first ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 0, 2, 4, and 6 may be re-mapped to any of the odd-numbered channels in that group (SCANINPUT 1, 3, 5, or 7). Likewise, in the second ADCn\_SCANINPUTSEL group, the negative input for SCANINPUT 9, 11, 13, and 15 may be re-mapped to any of the even-numbered channels in that group (SCANINPUT 8, 10, 12, or 14).

Figure 27.8 ADC Differential Scan Mode Re-mapping Negative Input Selections on page 893 shows the effects of the ADCn\_SCANNEGSEL register on the re-mappable inputs. The left side of the figure shows the default channel mapping, and the right side of the figure shows how ADCn\_SCANNEGSEL can be programmed to map the same negative input on up to four channels.

Figure 27.8. ADC Differential Scan Mode Re-mapping Negative Input Selections

### 27.3.7.3 APORT Conflicts

The ADC shares common analog buses connected to its APORTs (1-4) with other analog peripherals (see device-specific data sheet). As the ADC performs single or scan conversions, it requests the shared buses and sends selections for the control switches to connect the desired I/O pins. If another analog peripheral requests the same shared bus at the same time, there will be a collision and none of the peripherals will be granted control of that bus.

To help debug over-utilization of APORT resources, the ADC hardware provides status information in local registers. The ADCn\_APOR-TREQ register gives the user visibility into which APORT(s) the ADC is requesting given the setting of the input selection registers. ADCn\_APORTCONFLICT reports any conflicts that occur. If PROGERR in ADCn\_IEN is set, any conflict generates an interrupt. The PROGERR field in the ADCn\_STATUS register indicates whether the programming error happened as a result of an APORT bus conflict (BUSCONF) or from a negative-input selection conflict (NEGSELCONF). If the PROGERR interrupt occurred due to a negative selection conflict, then the interrupt can be cleared by software only after correcting the conflict. If a software clear is attempted without correcting the configuration, the interrupt will be cleared for one clock cycle but then it will trigger again as the invalid configuration still persists.

**Note:** The ADC requests shared bus connections as soon as that bus is selected in the input select registers, even if the ADC is not performing any conversions. This means that by using the APORT request, the ADC will acquire the associated shared analog bus, preventing other peripherals from using it. The bus will be released only when the input select registers are changed.

It is possible for the ADC to passively monitor shared bus signals without controlling the switches and creating bus conflicts. This can be done by setting the ADCn\_APORTMASTERDIS register. When ADCn\_APORTMASTERDIS is used, channel selection defers to the peripheral acting as the bus master for that shared bus, and no bus conflict will occur. The ADC will connect its input to the shared bus, but the specific channel will be controlled by the peripheral designated as the bus master.

### 27.3.8 Reference Selection and Input Range Definition

The full scale voltage (VFS) of the ADC is defined as the full input range, from the lowest possible input voltage to the highest. For single-ended conversions, the input range on the selected positive input is from 0 to VFS. For differential conversions, the input to the converter is the difference between the positive and negative input selections. This can range from -VFS/2 to +VFS/2.

VFS for the converter is determined by a combination of the selected voltage reference (VREF) and programmable divider circuits on the ADC input and voltage reference paths. Users have full control over the VREF and divider selections, offering a very flexible and wide selection of VFS values. In most applications however, it is not necessary to adjust VFS beyond a set of common pre-defined choices. For the simplest VFS configuration, refer to [27.3.8.1 Basic Full-Scale Voltage Configuration](#). If the application requires a VFS configuration not available in the pre-defined choices, [27.3.8.2 Advanced Full-Scale Voltage Configuration](#) covers additional configuration options.

### 27.3.8.1 Basic Full-Scale Voltage Configuration

Basic configuration of the VFS (full scale voltage) for the converter is done by programming the REF bitfield in ADCn\_SINGLECTRL (for single channel mode) or ADCn\_SCANCTRL (for scan mode) to any of the pre-defined options. The list of available pre-defined VFS options is:

- VFS = 1.25 V using internal VBGR as the reference source
- VFS = 2.5 V using internal VBGR as the reference source
- VFS = AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)
- VFS = 5 V using internal VBGR as the reference source
- VFS = ADCn\_EXTP external pin as a single-ended reference source (1.2 V - 3.6 V)
- VFS = ADCn\_EXTP - ADCn\_EXTN external pins as a differential reference source. ( 1.2 V - 3.6 V difference)
- VFS = 2 x AVDD using AVDD as the reference source ( $AVDD \leq 3.6$  V)

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and IOVDD supply voltages (where  $V_{ADC}$  is VDDX\_ANA, as described in [27.3.5 Power Supply](#)). If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in ADCn\_BIASPROG should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software may set GPBIASACC in ADCn\_BIASPROG to 1 (LOWACC) to conserve energy. Note that VDAC and DC-DC usage may also switch the chip-level bias to high- accuracy mode (even if GPBIASACC is set to LOWACC), potentially impacting ADC results. For example, if ADC is doing a conversion with GPBIASACC set to LOWACC and VDAC also starts a conversion using the internal low noise reference, then the chip-level bias circuit will be automatically switched to high-accuracy mode (potentially corrupting results of the on-going ADC conversion). Similarly, DC-DC startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if DC-DC startup happens when ADC is doing a conversion (with GPBIASACC set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25  $\mu$ s. It is during this time that ADC conversions with the GPBIASACC set to LOWACC should be avoided.

If the pre-defined VFS options do not suit the particular application, refer to [27.3.8.2 Advanced Full-Scale Voltage Configuration](#) for more advanced VFS options.

### 27.3.8.2 Advanced Full-Scale Voltage Configuration

For most applications, the pre-defined VFS options described in [27.3.8.1 Basic Full-Scale Voltage Configuration](#) are suitable. Advanced VFS configurations are also possible by programming the REF bitfield in ADCn\_SINGLECTRL or ADCn\_SCANCTRL to the CONF option. Programming the REF bitfield to CONF allows the user to select the specific VREF source and adjust the programmable input and reference divider options directly.

The general procedure for programming an advanced VFS configuration is as follows:

1. Select the voltage reference source using VREFSEL.
2. Configure VREFATTFIX and VREFATT so that the reference voltage at the ADC is between 0.7 and 1.05 V.
3. Configure VINATT to achieve the desired full-scale voltage.

The VREFSEL field in ADCn\_SINGLECTRLX or ADCn\_SCANCTRLX selects the voltage reference source. The ADC can choose from the following voltage reference (VREF) sources:

- VBGR: An internal 0.83 V bandgap reference voltage. This is the most precise internal reference source available.
- VDDXWATT: An attenuated version of the AVDD supply voltage. The attenuation factor is determined by the VREFATTFIX and/or VREFATT bit fields.
- VREFPWATT: An external reference source applied to the ADCn\_EXTP pin, and attenuated by the attenuation factor (determined by the VREFATTFIX and/or VREFATT bit fields). This is the appropriate choice for external reference inputs greater than 1.05 V.
- VREFP: An external reference source applied to the ADCn\_EXTP pin, without any attenuation. This is the appropriate choice for external reference inputs between 0.7 V and 1.05 V.
- VENTROPY: A very low internal reference voltage (approx. 0.1 V). This option is intended to be used only with the ADC inputs tied internally to VSS, for generating random noise at the ADC output.
- VREFPNWATT: A differential version of VREFPWATT, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and attenuated. This is the appropriate choice where a differential reference of greater than 1.05 V is required.
- VREFPN: A differential version of VREFP, with the reference source applied to the ADCn\_EXTP and ADCn\_EXTN pins and no attenuation. This is the appropriate choice where a differential reference of between 0.7 V and 1.05 V is required.
- VBGRLOW: An internal 0.78 V bandgap reference voltage.

The ADC reference voltage should be attenuated to a lower voltage when using AVDD or the external reference source. A simple method for a wide range of reference sources is to set VREFATTFIX to 1. The VREF attenuation factor ( $ATT_{VREF}$ ) can then be selected between 1/3 (when VREFATT is greater than 0), and 1/4 (when VREFATT is equal to 0). For reference sources between 1.2 V and 3.6 V,  $ATT_{VREF} = 1/3$  is the best choice.  $ATT_{VREF} = 1/4$  can be used with references from 1.6 V to 3.8 V, with slight performance degradation.

Finer granularity on  $ATT_{VREF}$  is possible as well, by clearing VREFATTFIX to 0, and setting the VREFATT field. For optimal performance with VREFATTFIX = 0, the attenuated ADC reference input should be limited to between 0.7 V and 1.05 V. When VREFATTFIX is cleared to 0,  $ATT_{VREF}$  is set according to the equation:

$$ATT_{VREF} = (VREFATT + 6) / 24 \text{ for } VREFATT < 13, \text{ and } (VREFATT - 3) / 12 \text{ for } VREFATT \geq 13$$

**Figure 27.9.  $ATT_{VREF}$ : VREF Attenuation Factor**

The ADC input also includes a programmable attenuator. The VIN attenuator is used to widen the available input range of the ADC beyond the reference source. The VIN attenuation factor ( $ATT_{VIN}$ ) is determined by the VINATT field according to the equation:

$$ATT_{VIN} = VINATT / 12 \text{ for } VINATT \geq 3 \text{ (settings 0, 1, and 2 are not allowable values for VINATT)}$$

**Figure 27.10.  $ATT_{VIN}$ : VIN Attenuation Factor**

VFS can be calculated by the formula given below for any given VREF source, VREF attenuation, and VIN attenuation:

$$VFS = 2 \cdot VREF \cdot ATT_{VREF} / ATT_{VIN}$$

VREF is selected in the VREFSEL bitfield, and

$ATT_{VREF}$  is the VREF attenuation factor, determined by VREFATT or VREFATTFIX

$ATT_{VIN}$  is the VIN attenuation factor, determined by VINATT

**Figure 27.11. VFS: Full-Scale Input Range**

The maximum and minimum input voltage which the ADC can recognize at any external pin is limited to the minimum of the  $V_{ADC}$  and  $IOVDD$  supply voltages (where  $V_{ADC}$  is  $VDDX\_ANA$ , as described in [27.3.5 Power Supply](#)). If VFS is configured to be larger than the supply range, the full ADC range will not be available. For example, with a 3.3 V supply and VFS configured to 5 V, the input voltage for single-ended conversions will be limited to 0 to 3.3 V, though the effective VFS is still 5 V.

The ADC uses a chip-level bias circuit to provide bias current for its operation. For highest accuracy when using a VBGR-derived internal bandgap reference source, GPBIASACC in  $ADCn\_BIASPROG$  should be cleared to 0 (HIGHACC). This will allow the ADC to enable high-accuracy mode from the bias circuitry during conversions. When AVDD or an external pin reference option is used, software may set GPBIASACC in  $ADCn\_BIASPROG$  to 1 (LOWACC) to conserve energy. Note that VDAC and DC-DC usage may also switch the chip-level bias to high- accuracy mode (even if GPBIASACC is set to LOWACC), potentially impacting ADC results. For example, if ADC is doing a conversion with GPBIASACC set to LOWACC and VDAC also starts a conversion using the internal low noise reference, then the chip-level bias circuit will be automatically switched to high-accuracy mode (potentially corrupting results of the on-going ADC conversion). Similarly, DC-DC startup automatically switches the chip-level bias circuit to high-accuracy mode for a short time, i.e., if DC-DC startup happens when ADC is doing a conversion (with GPBIASACC set to LOWACC), ADC results may get corrupted. DC-DC startup automatically switches the bias circuit to high-accuracy mode for 25  $\mu s$ . It is during this time that ADC conversions with the GPBIASACC set to LOWACC should be avoided.

The combination of VREF,  $ATT_{VREF}$  and  $ATT_{VIN}$  can produce a wide range of full-scale voltage options for the converter. [Table 27.1 Advanced VFS Configuration: VREF = AVDD on page 897](#) shows some example VFS configurations using AVDD as a reference source.

**Table 27.1. Advanced VFS Configuration: VREF = AVDD**

| AVDD Voltage | VREF Attenuation Settings                                             | Reference Voltage at ADC | VIN Attenuation Settings                          | VFS                                 |

### 27.3.9 Programming of Bias Current

The ADC uses a chip-level bias generator to provide bias current for its operation. The ADC's internal bias can be scaled by ADCBIASPROG field of the ADCn\_BIASPROG register. At lower conversion speeds, the ADCBIASPROG can be used to lower active power. Some commonly used settings are given in the ADCBIASPROG register description. For proper operation, the ADC conversion speed must be scaled accordingly. The scale factor is calculated as:

$$\text{Bias scale factor} = (1 - \text{ADCBIASPROG}[2:0]/8) / (1 + 3 \cdot \text{ADCBIASPROG}[3])$$

**Figure 27.12. Bias Scale Factor**

The bias programming register also includes the VFAULTCLR bit field. If VREFOF interrupt is enabled and it is triggered, then the user needs to set this bit in the ISR before clearing the interrupt flag. This bit then needs to be reset after the interrupt flag is cleared in order to enable the VREFOV flag to trigger on the next VREFOV condition.

The bias current settings should only be changed while the ADC is disabled (i.e. in NORMAL warm-up mode and no conversion in progress).

### 27.3.10 Feature Set

The following sections explain different ADC features.

#### 27.3.10.1 Conversion Tailgating

Scan conversions have priority over single channel conversions. This means that if scan and single triggers are received simultaneously, or even if the scan is received later when ADC is being warmed up for performing a single conversion, the scan conversion will have priority and will be done before the single conversion. However, a scan trigger will not interrupt in the middle of a single conversion, i.e., if the single conversion is in the acquisition or approximation phase, then the scan will have to wait for the single conversion to complete. If a scan sequence is triggered by a timer on a periodic basis, single channel conversion that started just before a scan trigger can delay the start of the scan sequence, thus causing jitter in sample rate. To solve this, conversion tailgating can be chosen by setting TAILGATE in ADCn\_CTRL. When this bit is set, any triggered single channels will wait for the next scan sequence to finish before activating (see [Figure 27.13 ADC Conversion Tailgating on page 898](#)). The single channel will then follow immediately after the scan sequence. In this way, the scan sequence will always start immediately when triggered, provided that the period between the scan triggers is big enough to allow the single sample conversion that was triggered to finish before the next scan trigger arrives. Note that if tailgating is set and a single channel conversion is triggered, it will indefinitely wait for a scan conversion before starting the single channel conversion.

**Figure 27.13. ADC Conversion Tailgating**

### 27.3.10.2 Repetitive Mode

Both single channel and scan mode can be run as a one shot conversion or in repetitive mode. The REP bitfield in ADCn\_SINGLECTRL/ADCn\_SCANCTRL registers can be used to activate the repetitive mode for single and scan respectively. In order to achieve the maximum sampling rate of 1 Msps, repetitive mode should be used.

It is also possible to have a programmable delay between these repetitive conversions. The REPDELAY bitfield in the ADCn\_SINGLECTRLX and ADCn\_SCANCTRLX registers can be used to set the delay between two repeated conversions in single channel and scan mode respectively. For single channel mode when a single conversion in repetitive mode ends, the user programmed REPDELAY is inserted and then the next single conversion is re triggered after the delay period is over. For scan mode the REPDELAY is inserted after the entire scan sequence ends. Once the delay period is over, scan mode is internally re-triggered. Note that when the ADC is in SYNC mode and REPDELAY is set to generate a delay, it takes an additional 5 HPERCLK cycles after the trigger before the next conversion begins. If REPDELAY is set to NODELAY, the next conversion begins immediately, without any delay or additional HPERCLKs. The [27.3.10.1 Conversion Tailgating](#) explains how the single channel and scan mode conversions can push each other out of phase. Conversion tailgating can be chosen in repetitive mode as well in order to ensure that the scan sequence will always start immediately when triggered, provided the scan REPDELAY chosen is big enough for the single conversion to finish. The status flags SINGLEACT and SCANACT stay high throughout the repeat mode, i.e., even during the delay period. The flags show that the conversions are either active or pending. Whether the ADC turns off or stays warmed up between these repeated conversions depends on the WARMUPMODE chosen in the ADCn\_CTRL register. When using single channel mode with repeat mode and REPDELAY enabled, then once the ADC has started operation (i.e., singleact status flag has gone high) then no new single conversion triggers (software START/ PRS triggers) should be sent to the ADC until the ADC has stopped converting (i.e., singleact status flag has gone low). The same applies to scan sequence conversions.

### 27.3.10.3 Conversion Trigger

The conversion modes can be activated by writing a 1 to the SINGLESTART or SCANSTART bit in the ADCn\_CMD register. The conversions can be stopped by writing a 1 to the SINGLESTOP or SCANSTOP bit in the ADCn\_CMD register. A START command will have priority over a STOP command. When the ADC is stopped in the middle of a conversion, the result buffer is cleared (the FIFO contents for any prior conversions are still intact). Every time a STOP command is issued, the user should wait for the corresponding status flag (SINGLEACT/SCANACT) to go low and then either read all the data in the FIFO or send the corresponding FIFOCLEAR command. The SINGLEACT and SCANACT bits in ADCn\_STATUS are set high when the modes are actively converting or have pending conversions.

It is also possible to trigger conversions from PRS signals. The PRS is treated as an asynchronous trigger. Setting PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL enables triggering from PRS input. Which PRS channel to listen to is defined by PRSSEL in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. When PRS trigger is selected, it is still possible to trigger a conversion from software. Refer to the PRS chapter for more information on how to set up the PRS channels. When the conversions are triggered using the ADCn\_CMD register, then the SINGLEACT and SCANACT bits in the ADCn\_STATUS are set as soon as the START command is written to the register. When the conversion is triggered using PRS, it takes some cycles from the time PRS trigger is received until the SINGLEACT and SCANACT bits are set due to the synchronization requirement. If SINGLEACT is already high then sending a new START command or a new PRS trigger for a single conversion will not have any impact as ADC already has a single conversion ongoing or a single conversion pending (single conversion can be pending if ADC is busy running a scan sequence). The same rules apply for SCANACT and SCAN START and PRS triggers. When software issues a SINGLE/SCAN STOP command, it must wait until SINGLEACT/ SCANACT flag goes low before issuing a new START.

The PRS may trigger the ADC in two possible ways, configured by PRSMODE in ADCn\_SINGLECTRLX/ADCn\_SCANCTRLX. In PULSED mode, a PRS pulse triggers the ADC to start the ADC\_CLK (if not already enabled), warm up (if not already warm), start the acquisition period, and perform the conversion. This is identical to issuing a START command from software. In this mode, the input sampling finishes at the end of the acquisition period (AT).

If the ADC\_CLK and the source of the trigger (START command or PRS pulse) are not synchronous, the frequency of the input sampling (FS), will experience a  $1\frac{1}{2}$  to  $2\frac{1}{2}$  ADC\_CLK cycle jitter due to synchronization requirements.

To precisely control the sample frequency, the PRSMODE can be set to TIMED mode. In this mode, a long PRS pulse is expected to trigger the ADC and its negative edge directly finishes input sampling and starts the approximation phase, giving precise sampling frequency management. The restriction is that the PRS pulse has to be long enough to start the ADC\_CLK (if not already enabled), and finish the acquisition period based on the AT field in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The PRS pulse needs to be high when AT event finishes. If it is not high when AT finishes, then it is ignored and input sampling finishes after AT event has ended (a two cycle latency is added to the conversion in this scenario). In this case, the ADC sets the PRSTIMEDERR interrupt flag.

If the PRS pulse is too long (e.g., FS = 32kHz), the analog ADC start can be delayed to save power. The CONVSTARTDELAY along with its EN in the ADCn\_SINGLECTRLX or ADCn\_SCANCTRLx can be programmed to implement a 0 to 8 microseconds delay. The microsecond tick is counted by TIMEBASE with ADC\_CLK similar to warmup case. This saves power as the ADC is not enabled until the last possible microsecond before the fall edge of the PRS arrives to open the sampling switch and to start the approximation phase. [Figure 27.14 ADC PRS Timed Mode with ASNEEDED ADC\\_CLK Request on page 900](#) shows PRS Timed mode triggering with CONVSTARTDELAY and ASNEEDED ADC\_CLK request. See that power is saved by both delaying the ADC EN and by requesting the ADC\_CLK only during ADC operation. This is especially useful in saving power when running the ADC in EM2 Deep Sleep or EM3 Stop power mode with low sampling frequency.

**Figure 27.14. ADC PRS Timed Mode with ASNEEDED ADC\_CLK Request**

When a PRS pulse is received, if the ADC\_CLK is not running (ASNEEDED mode), then the ADC requests the clock by setting clkreq\_adc\_async high. If the chosen clock source (HFXO/ HFSRCCLK/ AUXHFRCO) is already running, then it takes 5 ADC\_CLK cycles after the clock request is asserted for the ADC\_CLK to start. HFXO and HFSRCCLK (if chosen as ADC clock source) need to be already running before ADC sends out the clock request. If AUXHFRCO is chosen as the ADC clock source, and it is not already

running, then the CMU automatically turns it on when the ADC sends a clock request. In such a case, it takes (7 ADC\_CLK cycles + the oscillator startup time) for the ADC\_CLK to start. The oscillator startup time can be found in the device data sheet.

When triggering repeat mode using PRS and then stopping the triggered mode using STOP command, ensure that the PRS pulse used to generate the repeat mode has gone low by the time the STOP command is issued. If the PRS pulse continues to stay high after ADC has stopped the ongoing conversion, then it will be picked as a new trigger to start a new conversion.

**Note:**

- The conversion settings should not be changed while the ADC is running. Doing so may lead to unpredictable behavior.
- The `adc_clk_sar` phase is always reset by a conversion trigger as long as a conversion is not in progress. This gives predictable latency from the time of the trigger to the time the conversion starts, regardless of when in the trigger occurs.
- Software and LESENSE should not trigger conversions if PRS Timed mode is selected and `PRSEN` is set to 1 in the `ADCN_SINGLECTRL/ADCN_SCANCTRL` register.
- If the PRS Timed mode is being used, the acquisition time (AT) must be set greater than 0.

Scan conversions can be triggered using LESENSE as well. LESENSE only triggers one input conversion at a time (not the whole sequence of 32 possible inputs). The input to be converted using LESENSE must be configured by the user in the `ADCN_SCANINPUTSEL` register before triggering the conversion, i.e., one of the 32 inputs chosen in the `ADCN_SCANINPUTSEL` register must be the one that is to be converted using LESENSE. The `ADCN_SCANMASK` is not used for LESENSE triggered conversions. Instead, the user can select which input should be converted through LESENSE inside the LESENSE settings (`LESENSE_CHX`). The results of LESENSE triggered conversions are not loaded in the FIFO/ DATA registers but are instead available in the LESENSE register. Similarly, the SCAN interrupt flag is not set on completion of a LESENSE triggered conversion (because that flag is set only when the data is written to the Scan FIFO). When there is a LESENSE triggered conversion going on or pending, the `SCANACT` status flag is set. The `SCANPEND` interrupt flag is set when a software/PRS triggered scan goes pending because a LESENSE triggered scan is running (software/PRS triggered scan will start after the currently running LESENSE scan conversion completes). Similarly, `SCANEXTPEND` interrupt flag is set when the LESENSE triggered scan conversion goes pending because a software/PRS triggered scan is running. LESENSE triggered conversions can be stopped at any time using the `SCANSTOP` command in the `ADCN_CMD` register. Note that the LESENSE triggered conversion cannot trigger the Scan repeat mode.

The `DBGHALT` bit-field in the `ADCN_CTRL` register can be used to choose the ADC behavior in debug mode. If this bit is set to 1, then in debug mode ADC completes the current conversions and then halts. This means that all conversion triggers that were received before the debug halt occurred will be serviced before the ADC halts. All conversion triggers received after the ADC was halted, will be serviced when the debug mode is not halted any more. If the repetitive mode is running (in repetitive mode ADC keeps doing conversions until the user sends a software STOP) and a debug mode halt occurs, then the ADC will gracefully complete the current on-going conversion and then halt. The repetitive mode conversions will restart as soon as the debug mode is not halted any more.

### 27.3.10.4 Output Results

ADC output results are presented in 2's complement form and the format for single ended and differential conversions are given in [Table 27.2 ADC Single Ended Conversion on page 902](#) and [Table 27.3 ADC Differential Conversion on page 902](#), respectively. If differential mode is selected, the results are sign extended up to 32-bits (shown in [Table 27.5 ADC Results Representation on page 903](#)).

**Table 27.2. ADC Single Ended Conversion**

| Input Voltage         | Output Results |           |
|-----------------------|----------------|-----------|
|                       | Binary         | Hex value |
| $4095/4096 \cdot VFS$ | 1111111111     | FFF       |
| $0.5 \cdot VFS$       | 100000000000   | 800       |
| $1/4096 \cdot VFS$    | 000000000001   | 001       |
| 0                     | 000000000000   | 000       |

**Table 27.3. ADC Differential Conversion**

| Input                 | Output Results |           |
|-----------------------|----------------|-----------|
|                       | Binary         | Hex value |
| $2047/4096 \cdot VFS$ | 0111111111     | 7FF       |
| $0.25 \cdot VFS$      | 010000000000   | 400       |
| $1/4096 \cdot VFS$    | 000000000001   | 001       |
| 0                     | 000000000000   | 000       |
| $-1/4096 \cdot VFS$   | 1111111111     | FFF       |
| $-0.25 \cdot VFS$     | 110000000000   | C00       |
| $-0.5 \cdot VFS$      | 100000000000   | 800       |

### 27.3.10.5 Resolution

The ADC performs 12-bit conversions by default. However, if full 12-bit resolution is not needed, it is possible to speed up the conversion by selecting a lower resolution (6 or 8 bits). For more information on the accuracy of the ADC, the reader is referred to the electrical characteristics section for the device.

### 27.3.10.6 Oversampling

To achieve higher accuracy, hardware oversampling can be enabled individually for each mode (Set RES in ADCn\_SINGLECTRL/ADCn\_SCANCTRL to 0x3). The oversampling rate (OVSSEL in ADCn\_CTRL) can be set to any integer power of 2 from 2 to 4096 and the configuration is shared between the scan and single channel mode (OVSSEL field in ADCn\_CTRL).

With oversampling, each input is sampled at 12-bits of resolution a number of times (given by OVSSEL), and the results are filtered by a first order accumulate and dump filter to form the end result. The data presented in the ADCn\_SINGLEDATA and ADCn\_SCANDATA registers are the direct contents of the accumulation register (sum of samples). However, if the oversampling ratio is set higher than 16x, the accumulated results are shifted to fit the MSB in bit 15 as shown in [Table 27.4 Oversampling Result Shifting and Resolution on page 903](#).

**Table 27.4. Oversampling Result Shifting and Resolution**

| Oversampling setting | # right shifts | Result Resolution # bits |
|----------------------|----------------|--------------------------|
| 2x                   | 0              | 13                       |
| 4x                   | 0              | 14                       |
| 8x                   | 0              | 15                       |
| 16x                  | 0              | 16                       |
| 32x                  | 1              | 16                       |
| 64x                  | 2              | 16                       |
| 128x                 | 3              | 16                       |
| 256x                 | 4              | 16                       |
| 512x                 | 5              | 16                       |
| 1024x                | 6              | 16                       |
| 2048x                | 7              | 16                       |
| 4096x                | 8              | 16                       |

### 27.3.10.7 Adjustment

By default, all results are right adjusted, with the LSB of the result in bit position 0 (zero). In differential mode the signed bit is extended up to bit 31, but in single ended mode the bits above the result are read as 0. By setting ADJ in ADCn\_SINGLECTRL/ADCn\_SCANCTRL, the results are left adjusted as shown in [Table 27.5 ADC Results Representation on page 903](#). When left adjusted, the MSB is always placed on bit 15 and sign extended to bit 31. All bits below the conversion result are read as 0 (zero).

**Table 27.5. ADC Results Representation**

| Adjustment | Resolution | Bits      |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|------------|------------|-----------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|            |            | 31 ... 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Right      | 12         | 11 ... 11 | 11 | 11 | 11 | 11 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|            | 8          | 7 ... 7   | 7  | 7  | 7  | 7  | 7  | 7  | 7 | 7 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|            | 6          | 5 ... 5   | 5  | 5  | 5  | 5  | 5  | 5  | 5 | 5 | 5 | 5 | 5 | 4 | 3 | 2 | 1 | 0 |
|            | OVS        | 15 ... 15 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Left       | 12         | 11 ... 11 | 11 | 10 | 9  | 8  | 7  | 6  | 5 | 4 | 3 | 2 | 1 | 0 | - | - | - | - |
|            | 8          | 7 ... 7   | 7  | 6  | 5  | 4  | 3  | 2  | 1 | 0 | - | - | - | - | - | - | - | - |
|            | 6          | 5 ... 5   | 5  | 4  | 3  | 2  | 1  | 0  | - | - | - | - | - | - | - | - | - | - |
|            | OVS        | 15 ... 15 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 27.3.10.8 Channel Connection

The inputs are connected to the analog ADC at the beginning of the acquisition phase and are disconnected at the end of the acquisition phase. The time when the APORT switches are closed (for the next input to be converted) can be controlled by the CHCONMODE bitfield in the ADCn\_CTRL register. By default, this field is set to the MAXSETTLE option. For MAXSETTLE, APORT switches are closed on the next input as soon as the acquisition phase for the current conversion is complete. This means that the APORT switches are closed approximately 12 adc\_clk\_sar cycles (assuming 12 bit resolution) before the acquisition phase of the current conversion starts, giving APORT switches maximum time to settle. The time for which APORT switches should be closed before the acquisition phase starts, should be the same for all inputs in order to get consistent results. This means that if the ADC is warmed up with CHCONREFWARMIDLE set to 0 (scan reference warmed up and the APORT switches for the first scan channel closed) and a single trigger comes in, the single conversion will have to wait 12 adc\_clk\_sar cycles before it can start (even if single is using the same reference as scan). In this case, it might be more suitable to switch to the MAXRESP option in the CHCONMODE bitfield. In MAXRESP, the APORT switches for the upcoming conversion are closed just before the acquisition phase starts. This gives less settling time to the APORT switches but removes the extra waiting time before a conversion can start (which could be the case with MAXSETTLE as discussed above).

### 27.3.10.9 Temperature Measurement

The ADC includes an internal temperature sensor. This sensor is measured during production test and the temperature readout from the ADC at production temperature, ADC0CAL3\_TEMPREAD1V25, is given in the Device Information (DI) page. The production temperature, CAL\_TEMP, is also given in this page. The temperature sensor slope, V\_TS\_SLOPE (mV/degree Celsius), for the sensor is found in the data sheet for the device. Using the 1.25 V VFS option and 12-bit resolution, the temperature can be calculated according to the following formula (VFS in the formula is 1250 mV) :

$$T_{\text{CELSIUS}} = \text{CAL\_TEMP} - (\text{ADC0CAL3\_TEMPREAD1V25} - \text{ADC\_result}) \cdot \text{VFS} / (4096 \cdot \text{V\_TS\_SLOPE})$$

**Figure 27.15. ADC Temperature Measurement**

#### Note:

- The minimum acquisition time for the temperature reference is found in the electrical characteristics for the device. If using the 1.25 V reference, extra acquisition time is required. In this case the AT field of ADCn\_SINGLECTRL or ADCn\_SCANCTRL should be set to a value of 9 or higher.
- For the most accurate temperature sensor results, GPBIASACC in ADCn\_BIASPROG should be set to 0 to keep the bias in HIGH-ACC mode.
- If the device has more than one ADC, all ADCs may not be equipped with the temperature sensor. See the device data sheet.

### 27.3.10.10 ADC as a Random Number Generator

The ADC can be used as a random number generator. This is done by:

1. Choose the REF in the ADCn\_SINGLECTRL as CONF, setting the VREFSEL in the ADCn\_SINGLECTRLX as VENTROPY and VINATT in the same register to its maximum value of 15.
2. Set DIFF to 1 and RES to 0 in the ADCn\_SINGLECTRL register.
3. Trigger a single channel conversion and then read ADCn\_SINGLEDATA register when the conversion finishes.

The LSB[2:0] of each sample will be a random number. In this mode, the POSSEL or NEGSEL in ADCn\_SINGLECTRL can be connected to VSS or any other noisy input.

### 27.3.11 Interrupts, PRS Output

The single and scan modes have separate SINGLE and SCAN interrupt flags indicating whether corresponding FIFO contains DVL # of valid conversion data. Corresponding interrupt enable bit has to be set in ADCn\_IEN in order to generate interrupts. For these interrupts, there is no software clear mechanism by writing to ADCn\_IFC. The user needs to read enough data from the interrupted FIFO to ensure it contains less than DVL # of elements. The ADCn\_SINGLEFIFOCOUNT/ADCn\_SCANFIFOCOUNT can provide number of valid elements remaining in corresponding FIFO. The FIFO can also be cleared by ADCn\_SINGLEFIFOCLEAR/ADCn\_SCANFIFOCLEAR, but any existing data will be lost by this operation.

In addition to the SINGLE and SCAN interrupt flags, there is separate scan and single channel result overflow interrupt flag which signals that a result from a scan or single channel FIFO has been overwritten before being read. There is also separate scan and single channel result underflow interrupt flag which signals that a FIFO read was issued when the FIFO was empty.

There is separate scan and single compare interrupt flag which signals a compare match with latest sample if the CMPEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL is enabled.

ADC has two separate PRS outputs, one for single channel and one for scan sequence. A finished conversion results in a one ADC\_CLK cycle pulse, which is output to the Peripheral Reflex System (PRS). Note that the PRS pulse for scan is generated once after every channel conversion in the scan sequence.

### 27.3.12 DMA Request

The ADC has two DMA request lines, SINGLEREQ and SCANREQ, which are set when a single or scan FIFO receives DVL# of samples. The requests are cleared when the corresponding single or scan result register is read and corresponding FIFO count reaches lower than DVL. It also has two additional DMA Single request lines, SINGLESREQ and SCANSREQ, that are set when the corresponding FIFO is not empty.

### 27.3.13 Calibration

The ADC supports offset and gain calibration to correct errors due to process and temperature variations. This must be done individually for each reference used. For each reference, it needs to be repeated for single-ended, negative single-ended (see [27.3.7 Input Selection](#) for details) and differential measurement. The ADC calibration (ADCn\_CAL) register contains register fields for calibrating offset and gain for both single and scan mode. The gain and offset calibration are done in single channel mode, but the resulting calibration values can be used for both single and scan mode.

Gain and offset for various references and modes are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference. Others can be loaded as needed or the user can perform calibration on the fly using the particular reference and mode to be used and write the result in the ADCn\_CAL before starting the ADC conversion with them.

#### 27.3.13.1 Offset Calibration

Offset calibration must be performed prior to gain calibration. Follow these steps for the offset calibration in single mode:

1. Select the desired full scale configuration by setting the REF bit field of the ADCn\_SINGLECTRL register.
2. Set the AT bit field of the ADCn\_SINGLECTRL register to 16CYCLES.
3. Set the POSSEL and NEGSEL of the ADCn\_SINGLECTRL register to VSS, and set the DIFF to 1 for enabling differential input if calibrating for DIFF measurement. During calibration, the ADC samples represent the code coming out of the analog. Thus, since the input voltage is 0, the expected ADC output is 0b100000000000 in differential mode, 0b000000000000 in single-ended mode and 0b111111111111 in negative single-ended mode.
4. A binary search is used to find the offset calibration value. Set the CALEN to 1, and OFFSETINVMODE to 1 (if calibrating for negative single-ended conversion) in the ADCn\_CAL register. If user is performing negative single-ended calibration, the SINGLEOFFSETINV provides the offset else SINGLEOFFSET bit provides the offset (for both single-ended and differential offset calibration). Start with 0b0000 (or 0b1111 if doing calibration for differential mode) in SINGLEOFFSET or with 0b1000 in SINGLEOFFSETINV (if calibrating for negative single-ended conversion). Set the SINGLESTART bit in the ADCn\_CMD register to perform a 12-bit conversion and read the ADCn\_SINGLEDATA register. The offset is (ADCn\_SINGLEDATA - expected ADC output). Calculate this and write [3:0] of the result into SINGLEOFFSET or SCANOFFSETINV (if doing negative single-ended conversion). The user repeats till ADCn\_SINGLEDATA matches expected ADC output. The ADC has a 8LSB built in negative offset to allow for negative offset correction. So, with default offset value, which corrects for the negative offset, the converted ADCn\_SINGLEDATA would match expected ADC output if there were no offset. To get better noise immunity, the sampling phase can be repeated with Oversampling enabled. The result of the binary search is written to the SINGLEOFFSET (or SINGLEOFFSETINV) field of the ADCn\_CAL register.

### 27.3.13.2 Gain Calibration

Offset calibration must be performed prior to gain calibration. The Gain Calibration is done in the following manner:

1. Select an external ADC channel for single channel conversion (a differential channel can also be used).
2. Apply an external voltage on the selected ADC input channel. This voltage should correspond to the top of the ADC input range for the selected reference.
3. Set SINGLEGAIN[6:0] to 64 in the ADCn\_CAL and measure gain, repeat gain calibration walking the 1 in SINGLEGAIN[6] to SINGLEGAIN[0] till sampled ADCn\_SINGLEDATA matches expected value. This is done by setting CALEN in ADCn\_CAL set to 1 and performing single channel, reading in the raw ADC code from the ADCn\_SINGLEDATA and comparing it with expected code, i.e. 0b111111111111 for single-ended or differential conversion, and 0b000000000000 for negative single-ended conversion. The target value is ideally the top of the ADC input range, but it is recommended to use a value a couple of LSBs below in order to avoid overshooting. The result of the binary search is written to the SINGLEGAIN field of the ADCn\_CAL register.

For the VDD reference and external reference, there is no hardware gain calibration. Calibration can be done by software after taking a sample.

### 27.3.14 EM2 Deep Sleep or EM3 Stop Operation

The ADC can operate in EM2 Deep Sleep or EM3 Stop mode. For EM2 Deep Sleep or EM3 Stop operation the ADC\_CLK must be selected as AUXHFRCO. The section [27.3.1 Clock Selection](#) describes how to choose AUXHFRCO as the ADC\_CLK. The AUXHFRCO can be kept on for as long as sample conversion is needed or it can be requested by trigger event and after the conversion is done, the AUXHFRCO can be shut down. The second option saves power at the expense of the delay to start the AUXHFRCO oscillator. All the trigger modes are available in EM2 Deep Sleep or EM3 Stop as well.

While in EM2 Deep Sleep or EM3 Stop, the ADC can wake the system to EM0 Active on enabled interrupts. Following interrupts can wake up the system to EM0 Active:

- SINGLE or SCAN interrupt indicating that the corresponding FIFO has reached the DVL watermark.
- Overflow interrupt (SINGLEOF or SCANOF)
- Underflow interrupt (SINGLEUF or SCANUF), triggered if DMA pops more data than present in the FIFO while the system is asleep
- Compare interrupt (SINGLECMP or SCANCMP)
- Over voltage interrupt (VREFOV)

The ADC can also work with the DMA so that the system does not have to wake up to consume data. This can happen if the SCAN or SINGLE interrupt is disabled and the SINGLEDMAWU or SCANDMAWU in the ADCn\_CTRL is set. The DMA will be triggered by the ADC when DVL samples become available in the corresponding FIFO. The DMA will then pop all the elements of the corresponding FIFO and put the system back into the low power state. A system-level wake up will occur upon the DMA done interrupt. Note that other enabled ADC interrupts can still wake up the system when operating with the DMA. For example, the user can configure the window compare function to trip when the result reaches a certain threshold while gathering ADC data in EM2 Deep Sleep or EM3 Stop.

The ADC works with the EMU to wake up the system or the DMA. It takes 2  $\mu$ s from the time the ADC request a wakeup to start of the peripheral clocks. In this ASYNC mode of ADC\_CLK, it takes 6 HFPERCLK cycles to read a single entry from the single or scan FIFO. So, with a 20MHz HFPERCLK, it takes about 4  $\mu$ s per DMA wakeup to empty a full FIFO (4 entries). This restricts the sampling rate in EM2 Deep Sleep or EM3 Stop in order to avoid FIFO overflows.

The AUXHFRCO power can be reduced by reducing the clock speed, and the user may adjust the ADCBIASPROG field in the ADCn\_BIASPROG register to reduce active power of the ADC during the conversions, thus reducing power even more in EM2 Deep Sleep/EM3 Stop. Refer to the data sheet for relevant power consumption numbers.

If the ADC is not to be used in EM2 Deep Sleep or EM3 Stop, then the user should ensure that the ADC is not busy before going to the low power mode. [27.3.17 ADC Programming Model](#) explains how to ensure the ADC is not busy. If the chip enters EM2 Deep Sleep or EM3 Stop when ADC is busy without using AUXHFRCO, then the ADC clock will stop but the ADC will stay on, resulting in higher supply current. If this occurs, the EM23ERR interrupt flag will be set. Software will see this interrupt flag only when the chip wakes up.

### 27.3.15 ASYNC ADC\_CLK Usage Restrictions and Benefits

When the ADC\_CLK is chosen to come from ASYNCCLK, (ADCCLKMODE is set to ASYNC), the ADC\_CLK and the ADC peripheral clock are considered asynchronous and this adds some restrictions:

- Due to a synchronization delay, accessing the following registers takes extra time (up to additional 7 HFPERCLK cycles): ADCn\_SINGLEDATA, ADCn\_SCANDATA, ADCn\_SINGLEDATAP, ADCn\_SCANDATAP, ADCn\_SCANDATAX, ADCn\_SCANDATAXP, ADCn\_SINGLEFIFOCOUNT, ADCn\_SCANFIFOCOUNT, ADCn\_SINGLEFIFOCLEAR, ADCn\_SCANFIFOCLEAR.
- The safe time to change the ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLx, ADCn\_SCANINPSEL, ADCn\_SCANNEGSEL or ADCn\_SCANMASK register is when SINGLEACT/SCANACT in the ADCn\_STATUS is 0 with no pending trigger event. The user can enforce this by writing the SINGLESTOP or SCANSTOP in the ADCn\_CMD register and ensuring no trigger event can come before modifying the registers.
- When the ADC needs to run in EM2 Deep Sleep or EM3 Stop, only AUXHFRCO can provide the ADC\_CLK to the ADC. Thus the user needs to set ASYNC mode of ADCCLKMODE and setup the CMU to provide the AUXHFRCO clock as ASYNCCLK.
- If the ADC needs to run on a particular adc\_clk\_sar frequency to achieve a sample rate and the HFPERCLK is not a proper multiple for such clock frequency, a higher frequency system clock, HFRCO, can be chosen to be ADC\_CLK using ASYNC mode. This allows HFPERCLK to be set to an optimum value from a system view point.
- ASYNC mode can also help with digital noise mitigation as this clock is asynchronous (not balanced) with the system clock. Moreover, the user can use the invert option to invert the source of ASYNCCLK helping in noise mitigation further.
- Whenever ADC is being used in asynchronous mode, then HFPERCLK must be at least 1.5 times higher than the ADC\_CLK.
- With ASNEEDED setting for ASYNCCLK request, the ADC\_CLK power can be reduced.

### 27.3.16 Window Compare Function

The ADC supports a window compare function on both the latest single and scan outputs. The compare thresholds, ADGT and ADLT, are defined in the ADCn\_CMPTHR register. These are 16-bit values and their format must match the type of conversion (single-ended or differential) the user is trying to compare with. For example, a 12-bit differential conversion is sign extended to 16 bits while a 12-bit single-ended conversion result would get zero padded to 16-bit result before comparing with ADGT and ADLT. If over-sampling is enabled, the conversion result could grow to 16-bits. There is a single set of ADLT and ADGT threshold for both single and scan compare. The user can however enable single or scan compare logic individually by enabling CMPEN in ADCn\_SINGLECTRL or ADCn\_SCANCTRL register.

The user can perform comparison both within or outside of the window defined by the ADGT and ADLT. If the ADLT is greater than ADGT, the ADC compares if the current sample is within the window. Otherwise, the ADC compares if the current sample is outside of the window.

### 27.3.17 ADC Programming Model

The ADC configuration registers are considered static and can only be updated when (1) ADC is in SYNC mode and (2) ADC is idle. ADC is considered busy when it is doing conversions (either the SINGLEACT or SCANACT status flag is high) or when it is warmed up (one of the following status flags is high: WARM, SINGLEREFWARM, SCANREFWARM). The following registers are considered ADC configuration registers: CMU\_ADCCTRL, ADCn\_CTRL, ADCn\_SINGLECTRL, ADCn\_SINGLECTRLX, ADCn\_SCANCTRL, ADCn\_SCANCTRLX, ADCn\_SCANINPUTSEL, ADCn\_SCANNEGSEL, ADCn\_IEN, ADCn\_BIASPROG, ADCn\_SCANMASK, ADCn\_CAL and ADCn\_CMPTHR.

From reset, the ADC is in SYNC mode by default. The user can program the configuration registers as needed. If PRS is to be used, PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL should be set after all other configuration is complete. Once configuration is complete, the ADC is ready to receive triggers. The user must ensure that no LESENSE triggers come in during the time the ADC configuration registers are being updated.

After the ADC has been used to perform conversions, the user must ensure that the ADC is idle before updating the configuration registers. The first step is to ensure that no new triggers (PRS, LESENSE) are being issued. It can take a few cycles from when a trigger is received to when SINGLEACT/SCANACT flags go high due to synchronization requirement. If it is unclear when the triggers were issued and if those are under synchronization or not, the user should add a small delay before checking the status flags. If the SINGLEACT/SCANACT status flags are high, the corresponding STOP command should be issued and the user should wait until the SINGLEACT/SCANACT flags go low. If the ADC was warmed up, then the WARMUPMODE should be changed to NORMAL and then the user should wait on WARM, SINGLEREFWARM and SCANREFWARM flags until those go low. Now the ADC is idle.

If both LESENSE scan and PRS/software scan conversions are taking place, then since there are two scans occurring, the SCAN STOP command needs to be issued twice. The user can check the SCANPENDING status flag. If the flag is set then the user needs to send out 2 SCAN STOP commands. After sending out the first SCAN STOP, the user needs to wait until the SCANPENDING flag goes low. Then the second SCAN STOP command should be issued and the user should wait on the SCANACT status flag to go low.

**Note:**

When switching ADCCLKMODE in the ADCn\_CTRL register, use the appropriate sequence below:

- SYNC to ASYNC:
  1. Disable ADC interrupts
  2. Clear the FIFOs
  3. Switch the ADCCLKMODE

If the ADC is to be used in ASYNC clock mode with WARMUPMODE set to KEEPADCWARM, then both ADCCLKMODE and WARMUPMODE fields in the ADCn\_CTRL register should be set to the desired values in the same register write. This will ensure that the ADC power-on sequence is valid.

- ASYNC TO SYNC:
  1. Disable ADC interrupts
  2. Switch the ADCCLKMODE
  3. Clear the FIFOs

The FIFOs are cleared by writing 1 to the ADCn\_SCANFIFOCLEAR and ADCn\_SINGLEFIFOCLEAR registers.

When switching from ASYNC to SYNC, ensure that the ASYNC clock is turned off before doing the switch.

## 27.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                 | Type  | Description                                                               |
|--------|----------------------|-------|---------------------------------------------------------------------------|
| 0x000  | ADCn_CTRL            | RW    | Control Register                                                          |

| Selects the negative input to the ADC for Single Channel Differential mode (in case of singled ended mode, the negative input is grounded). The user can choose any of the 32 channels of any of the 5 BUSES but must ensure that POSSEL and NEGSEL are chosen from different resources (X or Y) BUS. In case of an invalid configuration, the ADC will perform a single-ended sampling and issue a BUSCONFLICT IRQ.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |        |                               |        |                                                |      |       |             |             |   |                    |             |   |                    |     |     |       |              |    |                     |             |    |                    |             |    |                    |              |    |                     |             |    |                    |             |    |                    |     |     |       |              |    |                     |             |    |                    |             |    |                    |     |     |       |              |    |                     |             |    |                    |             |    |                    |     |     |       |              |     |                     |             |     |                    |             |     |                    |     |     |       |              |     |                     |       |     |                               |     |     |     |

| Selects the positive input to the ADC for single channel operation. Software can choose any of the 32 channels of any BUS as positive input. In DIFF mode POSSEL and NEGSEL need to be chosen from different resources (X or Y). If an X BUS is connected to POSSEL, only a Y BUS can connect to NEGSEL, and vice-versa. The user can also select some internal nodes as positive input for single-ended sampling. These internal nodes cannot be sampled differentially. |        |                    |    |                                                |      |       |             |             |   |                    |             |   |                    |

|-----|------|-------|--------|----------------------------------------------------------------------------------------------|
|     | 0    |       |        | ADC will perform one conversion per trigger in single channel mode.                          |
|     | 1    |       |        | ADC will repeat conversions in single channel mode continuously until SINGLESTOP is written. |

|       | 0               | PULSED                                                                                                                          |        | Single channel trigger is considered a regular asynchronous pulse that starts ADC warm-up, then acquisition/conversion sequence. The ADC_CLK controls the warmup-time.                                                                              |
|       | 1               | TIMED                                                                                                                           |        | Single channel trigger should be a pulse long enough to provide the required warm-up time for the selected ADC warmup mode. The negative edge requests sample acquisition. DELAY can be used to delay the warm-up request if the pulse is too long. |

|       | 0               | PULSED                                                                                                                          |        | Scan trigger is considered a regular async pulse that starts ADC warm-up, then acquisition/conversion sequence. The ADC_CLK controls the warmup-time.                                                                                     |
|       | 1               | TIMED                                                                                                                           |        | Scan trigger should be a pulse long enough to provide the required warm-up time for the selected ADC warmup mode. The negative edge requests sample acquisition. DELAY can be used to delay the warm-up request if the pulse is too long. |

| Set one or more bits in this mask to select which inputs are included in scan sequence in either single ended or differential mode. This works with SCANINPUTSEL register. The SCANINPUTSEL chooses 32 possible channels for single-ended or 32 pairs of possible channels for differential scanning from BUSES. These chosen channels are referred as ADCn_INPUTx in the description. Four even inputs from first group of 8 ADCn_INPUTx and four odd inputs from second group of 8 ADCn_INPUTx have programmable NEGSEL, defined in SCANNEGSEL register. If the SCANMASK is set to 0 and scan conversion is triggered, ADC will do a conversion with garbage results since no inputs were enabled for conversion. |             |                                     |                                                                                       |                                 |

## 28. IDAC - Current Digital to Analog Converter

### Quick Facts

#### What?

The IDAC can sink or source a configurable constant current.

#### Why?

The IDAC can be used to bias external circuits or (in conjunction with the ADC) measure capacitance by injecting a controlled current into a component.

#### How?

In addition to providing a constant current, the IDAC can be switched on and off with a PRS signal all the way down to EM3.

### 28.1 Introduction

The current digital to analog converter (IDAC) can source or sink a configurable constant current from APORT and/or main pad (OUT-PAD). The current is configurable with several ranges of various step sizes.

### 28.2 Features

- Can source and sink current
- Programmable constant output current
  - Selectable current range between 0.05  $\mu\text{A}$  and 64  $\mu\text{A}$
  - Each range is linearly programmable in 32 steps
  - Support for current calibration
- Support for manual and PRS triggered output enable
- Available in EM0-EM3

## 28.3 Functional Description

An overview of the IDAC module is shown in [Figure 28.1 IDAC Overview on page 959](#). The IDAC is designed to source or sink a programmable current which can be controlled by setting the range and the step in the RANGESEL and STEPSEL bitfields in IDAC\_CURRPROG register. The IDAC output enable can be controlled by software or PRS. The IDAC is enabled by setting EN in IDAC\_CTRL.

**Figure 28.1. IDAC Overview**

### 28.3.1 Current Programming

The four different current ranges can be selected by configuring the RANGESEL bitfield in IDAC\_CURRPROG. The current output in each range is linearly programmable in 32 steps, and is controlled by the STEPSEL bitfield in IDAC\_CURRPROG. These current ranges and their step sizes are shown in [Table 28.1 Range Selection on page 959](#).

**Table 28.1. Range Selection**

| Range Select | Range Value [ $\mu$ A] | Step Size [nA] | Step Counts |
|--------------|------------------------|----------------|-------------|
| 0            | 0.05 - 1.6             | 50             | 32          |
| 1            | 1.6 - 4.7              | 100            | 32          |
| 2            | 0.5 - 16               | 500            | 32          |
| 3            | 2 - 64                 | 2000           | 32          |

### 28.3.2 IDAC Enable and Warm-up

The IDAC is enabled by setting the EN bit in IDAC\_CTRL. When this bit is set, the IDAC must stabilize before its output current is stable.

It is important to wait until the IDAC is warmed up, or until any current programming is complete and the output current is stabilized, before entering EM1, EM2, or EM3.

### 28.3.3 Output Control

The IDAC output enable is controlled separately for APORT and main pad. If APORTOUTENPRS/MAINOUTENPRS is set, output enable is controlled by PRS, else it is controlled by software via APORTOUTEN/MAINOUTEN.

### 28.3.4 APORT Configuration

The IDAC APORT outputs can be routed to pins through the APORT system. Note that the IDAC has only two local APORT interfaces APORT1X and APORT1Y, which are connected to the APORT BUSCX and BUSCY, respectively. The pins are selected by requesting an APORT channel in APORTOUTSEL in IDAC\_CTRL. For mapping between APORT channel and physical pin, please refer to data sheet. The IDAC can be in either master or slave mode when connecting to the APORT. By default the IDAC is in master mode. To enable slave mode, set APORTMASTERDIS in IDAC\_CTRL. As IDAC is only capable of driving an APORT channel, only master mode is meaningful for IDAC. If the IDAC is in master mode, and another module is currently driving the requested channel, the APORTCONFLICT bitfield in IDAC\_STATUS will be set together with APORT1XCONFLICT or APORT1YCONFLICT in IDAC\_APORTCONFLICT. The APORTCONFLICT can also be configured to trigger an interrupt, see [28.3.5 Interrupts](#) for details.

### 28.3.5 Interrupts

The APORTCONFLICT interrupt flag in the IDAC\_IF register indicates that a conflict has occurred when requesting a channel from the APORT. The APORTCONFLICT interrupt can be enabled by setting the APORTCONFLICT bit in IDAC\_IEN, or cleared by setting the APORTCONFLICT bit in IDAC\_IFC.

### 28.3.6 Minimizing Output Transition

If the internal output of the IDAC differs from the voltage at the output pin, enabling the output can cause an unwanted transition. To minimize this transition, it is possible to charge or discharge the internal output node before enabling the output to the pin. Setting MINOUTTRANS in IDAC\_CTRL when the IDAC is sourcing current connects the internal node to GND. Alternatively, setting MINOUTTRANS when the IDAC is sinking current connects the internal output node to VDD. Setting APORTOUTEN/MAINOUTEN when MINOUTTRANS is set will halt the charge/discharge until either APORTOUTEN/MAINOUTEN is cleared or MINOUTTRANS is cleared.

### 28.3.7 Duty Cycle Configuration

The references for the IDAC can be duty-cycled, meaning that it can source current at very low overhead current consumption at the cost of response time and accuracy. By default duty-cycling is enabled in EM2 and EM3 and disabled in EM0 and EM1. Setting EM2DUTYCYCLEDIS in IDAC\_DUTYCONFIG will disable duty cycling in EM2 and EM3. Note that sinking current can not be done with duty-cycled references so measures needs to be taken to always disable duty-cycling while sinking current.

### 28.3.8 Calibration

The IDAC can be calibrated to accurately compensate for process, supply voltage and temperature variations. During the production test, the middle step of each range is calibrated at room temperature. The TUNING bitfield in the IDAC\_CAL register can be used to do further calibration of each step with an external resistor connected to IDAC\_OUT. The calibrated tuning value for each band can be read from the Device Information (DI) page.

### 28.3.9 PRS Triggered Charge Injection

The amount of charge sourced or sunk by the IDAC can be controlled by the PRS (e.g., using a timer as producer) via the output switch. [Figure 28.2 IDAC Charge Injection Example on page 961](#) shows a case where the IDAC is configured to periodically supply charge using the PRS. The amount of charge injected is proportional to the the period the IDAC is on. The total charge injected is the current multiplied by the time the output switch is enabled.

The PRS system is enabled by setting APORTOUTENPRS/MAINOUTENPRS in IDAC\_CTRL, and the PRS channel is selected by PRSSEL in IDAC\_CTRL. To generate the periodic control signal, the TIMER module can be used, by configuring for example a CC channel to compare match with a configurable level.

**Figure 28.2. IDAC Charge Injection Example**

### 28.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                       |
|--------|--------------------|-------|-----------------------------------|
| 0x000  | IDAC_CTRL          | RW    | Control Register                  |
| 0x004  | IDAC_CURPROG       | RW    | Current Programming Register      |
| 0x00C  | IDAC_DUTYCONFIG    | RW    | Duty Cycle Configuration Register |
| 0x018  | IDAC_STATUS        | R     | Status Register                   |
| 0x020  | IDAC_IF            | R     | Interrupt Flag Register           |
| 0x024  | IDAC_IFS           | W1    | Interrupt Flag Set Register       |
| 0x028  | IDAC_IFC           | (R)W1 | Interrupt Flag Clear Register     |
| 0x02C  | IDAC_IEN           | RW    | Interrupt Enable Register         |
| 0x034  | IDAC_APORTREQ      | R     | APORT Request Status Register     |
| 0x038  | IDAC_APORTCONFLICT | R     | APORT Request Status Register     |

## 28.5 Register Description

### 28.5.1 IDAC\_CTRL - Control Register

This bit allows multiple APORT connected devices to monitor the same APORT bus simultaneously by allowing the IDAC to not master the selected bus. When 1, the determination is expected to be from another peripheral, and the IDAC only passively looks at the bus. When 0, the selection of channel for a selected bus is ignored (the bus is not), and will be whatever selection the external device mastering the bus has configured for the APORT bus. |

## 29. LESENSE - Low Energy Sensor Interface

### Quick Facts

#### What?

LESENSE is a low energy sensor interface capable of autonomously collecting and processing data from multiple sensors even when in EM2. Flexible configuration makes LESENSE a versatile sensor interface compatible with a wide range of sensors and measurement schemes.

#### Why?

Capability to autonomously monitor sensors allows the EFR32xG13 Wireless Gecko to reside in a low energy mode for long periods of time while keeping track of sensor status and sensor events.

#### How?

LESENSE is highly configurable and is capable of collecting data from a wide range of sensor types. Once the data is collected, the programmable state machine, LESENSE decoder, is capable of processing sensor data without CPU intervention. A large result buffer allows the chip to remain in EM2 for long periods of time while autonomously collecting data.

### 29.1 Introduction

LESENSE is a low energy sensor interface utilizing on-chip peripherals to perform measurement of a configurable set of sensors. The sensor measurements results can be processed by the LESENSE decoder, a configurable state machine with up to 32 states. The results can also be stored in a result buffer to be collected by the CPU or DMA for further processing.

LESENSE operates from EM0 down to EM2, and can wake up the CPU on configurable events.

## 29.2 Features

- Up to 16 sensors
- Autonomous sensor monitoring in EM0, EM1, and EM2
- Highly configurable decoding of sensor results
- Interrupt on sensor events
- Configurable enable signals to external sensors
- Circular buffer for storage of up to 16 sensor results
- Multiple evaluation modes minimize the need for software interaction
- Supports ADC0 sampling and evaluation
- Support for multiple sensor types
  - LC sensors
  - Capacitive sensing
  - General analog sensors

## 29.3 Functional Description

The LESENSE module is capable of controlling on-chip peripherals in order to perform monitoring of different sensors with little or no CPU intervention. LESENSE uses the analog comparators (ACMP) or ADC0 for measurement of sensor signals. LESENSE can also control the VDAC to generate accurate reference voltages. [Figure 29.1 LESENSE Block Diagram on page 970](#) shows an overview of the LESENSE module.

The LESENSE module consists of a sequencer, an evaluation block, a decoder, and a RAM block:

- The sequencer handles interaction with other peripherals and controls timing of sensor measurements. It also includes a counter that can be used to count pulses on the ACMP output.
- The evaluation block is used to process the data collected by the sequencer.
- To autonomously analyze sensor results, the LESENSE decoder provides the ability to define a finite state machine with up to 32 states, as well as define programmable actions upon state transitions. This allows the decoder to implement a wide range of decoding schemes, such as quadrature decoding.
- A RAM block is used for storage of configuration and measurement results. This allows LESENSE to have a relatively large result buffer enabling the chip to remain in a low energy mode for long periods of time while collecting sensor data.

Figure 29.1. LESENSE Block Diagram

### 29.3.1 Channel Configuration

LESENSE has 16 individually configurable channels, each with its own set of configuration registers. Channel configuration is split into three registers; CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL. Individual timing for each sensor is configured in CHx\_TIMING, sensor interaction is configured in CHx\_INTERACT, and configurations regarding evaluation of the measurements are done in CHx\_EVAL. For improved readability, CHx\_CONF will be used to refer to the channel configuration registers (CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL) throughout this chapter.

By default, the channel configuration registers are directly mapped to the channel number. Configuring SCANCONF in CTRL makes it possible to alter this mapping.

Configuring SCANCONF to INVMAP will make channels 0-7 use the channel configuration registers for channels 8-15, and vice versa. This feature allows an application to quickly and easily switch the configuration set for the channels.

Setting SCANCONF to TOGGLE will make channel x alternate between using CHx\_CONF and CH<sub>x+8</sub>\_CONF. The configuration used is decided by the state of the corresponding bit in SCANRES. For instance, if channel 3 is performing a scan and bit 3 in SCANRES is set, CH<sub>11</sub>\_CONF will be used. Channels 8 through 15 will toggle between CHx\_CONF and CH<sub>x-8</sub>\_CONF. This mode provides an easy way to implement hysteresis on channel events, as threshold values can be changed depending on the sensor status.

Setting SCANCONF to DECDEF will make the state of the decoder define which scan configuration to be used. If the decoder state is at index 16 or higher, channel x will use CH<sub>x+8</sub>\_CONF, otherwise it will use CHx\_CONF. Similarly, channels 8 through 15 will use CHx\_CONF when the decoder state index is less than 8 and CH<sub>x-8</sub>\_CONF when the decoder state index is higher than 7. Allowing the decoder state to define which configuration to use enables easy implementation of hysteresis, for example, as different threshold values can be used for the same channel depending on the state of the application. [Table 29.1 LESENSE Scan Configuration Selection on page 971](#) summarizes how channel configuration is selected for different settings of SCANCONF.

**Table 29.1. LESENSE Scan Configuration Selection**

| LESENSE<br>channel x | SCANCONF |                         |                |                         |               |                         |
|----------------------|----------|-------------------------|----------------|-------------------------|---------------|-------------------------|
|                      | DIRMAP   | INVMAP                  | TOGGLE         |                         | DECDEF        |                         |
|                      |          |                         | SCANRES[n] = 0 | SCANRES[n] = 1          | DECSTATE < 16 | DECSTATE >= 16          |
| 0 ≤ x < 8            | CHx_CONF | CH <sub>x+8</sub> _CONF | CHx_CONF       | CH <sub>x+8</sub> _CONF | CHx_CONF      | CH <sub>x+8</sub> _CONF |
| 8 ≤ x < 16           | CHx_CONF | CH <sub>x-8</sub> _CONF | CHx_CONF       | CH <sub>x-8</sub> _CONF | CHx_CONF      | CH <sub>x-8</sub> _CONF |

Channels are enabled in the CHEN register, where bit x enables channel x. During a scan, all enabled channels are measured, starting with the lowest indexed channel. [Figure 29.3 Scan Sequence on page 972](#) illustrates a scan sequence with channels 3, 5, and 9 enabled.

### 29.3.2 Scan Sequence

LESENSE runs on  $LFACLK_{LESENSE}$ , which is a prescaled version of  $LFACLK$ . The prescaling factor for  $LFACLK_{LESENSE}$  is selected in the CMU, available prescaling factors are:

- DIV1:  $LFACLK_{LESENSE} = LFACLK/1$
- DIV2:  $LFACLK_{LESENSE} = LFACLK/2$
- DIV4:  $LFACLK_{LESENSE} = LFACLK/4$
- DIV8:  $LFACLK_{LESENSE} = LFACLK/8$

All enabled channels are scanned each scan period. How a new scan is started is configured in the SCANMODE bit field in CTRL. If set to PERIODIC, the scan frequency is generated using a counter which is clocked by  $LFACLK_{LESENSE}$ . This counter has its own prescaler. This prescaling factor is configured in PCPRESC in TIMCTRL. A new scan sequence is started each time the counter reaches the top value, PCTOP. The scan frequency is calculated using [Figure 29.2 Scan Frequency on page 972](#). If SCANMODE is set to ONE-SHOT, a single scan will be made when START in CMD is set. To start a new scan on a PRS event, set SCANMODE to PRS and configure PRS channel in PRSSEL. The PRS start signal needs to be active for at least one  $LFACLK_{LESENSE}$  cycle to make sure LESENSE is able to register it.

$$F_{scan} = LFACLK_{LESENSE} / ((1 + PCTOP) * 2^{PCPRESC})$$

**Figure 29.2. Scan Frequency**

It is possible to interleave additional sensor measurements in between the periodic scans. Issuing a start command when LESENSE is idle will immediately start a new scan, without disrupting the frequency of the periodic scans. If the period counter overflows during the interleaved scan, the periodically scheduled scan will start immediately after the interleaved scan completes.

**Figure 29.3. Scan Sequence**

### 29.3.3 Sensor Timing

For each channel in the scan sequence, the LESENSE interface goes through three phases: idle, excite, and measure. The durations of the excite and measure phases are configured in the CHx\_TIMING registers. The excite phase duration can be configured to be either a number of AUXHFRCO cycles or a number of LFACLK<sub>LESENSE</sub> cycles, depending on which one is selected by the EXCLK bit in the CHx\_INTERACT register. LESENSE includes two timers: A low frequency timer, running on LFACLK<sub>LESENSE</sub>, and a high frequency timer, running on AUXHFRCO. The low frequency or high frequency timers can be prescaled by configuring LFPRESC or AUXPRESC, respectively, in the TIMCTRL register. The duration of the measure phase is programmed via MEASUREDLY and SAMPLEDLY in the CHx\_TIMING registers. The output of the ACMP will be ignored for MEASUREDLY EXCLK cycles after start of the sensor measurement. Sampling of the sensor will happen after SAMPLEDLY LFACLK<sub>LESENSE</sub>, or AUXHFRCO cycles, depending on the configuration of the SAMPLECLK in the CHx\_INTERACT register. The configurable measure- and sample delays enables LESENSE to easily define exact time windows for sensor measurements. A start delay can be inserted before sensor measurement begin by configuring STARTDLY in TIMCTRL. This delay can be used to ensure that the VDAC conversion is done and voltages have stabilized before the sensor measurement begins. The AUXHFRCO startup can be delayed until the system enters the excite phase, by configuring AUX-STARTUP in TIMCTRL to ONDEMAND. This will reduce the time the AUXHFRCO is enabled and reduce power consumption, with the tradeoff that the starting point for high frequency timing will also be delayed the same amount as the AUXHFRCO startup time.

Figure 29.4 Timing Diagram, AUXHFRCO Based Timing on page 973 depicts a sensor sequence with AUXHFRCO based timing (EXTIME=5, MEASUREDLY=7, SAMPLEDLY=13), while Figure 29.5 Timing Diagram, LFACLK Based Timing on page 974 depicts a sequence with LFACLK<sub>LESENSE</sub> based timing (EXTIME=1, MEASUREDLY=1, SAMPLEDLY=2).

**Figure 29.4. Timing Diagram, AUXHFRCO Based Timing**

**Figure 29.5. Timing Diagram, LFACLK Based Timing**

### 29.3.4 Sensor Interaction

Many sensor types require some type of excitation in order to work. The LESENSE module can generate a variety of sensor stimuli, both on the same pin as the measurement is to be made on, as well as alternative pins.

By default, excitation is performed on the pin associated with the channel (i.e., excitation and sensor measurement is performed on the same pin). The mode of the pin during the excitation phase is configured by the EXMODE bitfield in CHx\_INTERACT. The available modes during the excite phase are:

- **DISABLED:** The pin is disabled.
- **HIGH:** The pin is driven high.
- **LOW:** The pin is driven low.
- **DACOUT:** The pin is connected to the output of a VDAC channel.

**Note:** Excitation with VDAC output is only available on some channels. Refer to [29.3.9 VDAC Interface](#) for details. If the VDAC is in opamp-mode, setting EXMODE to DACOUT will result in excitation with output from the opamp.

LESENSE is able to perform sensor excitation on a pin other than the one being measured. When ALTEX in CHx\_INTERACT is set, the excitation will occur on the alternative excite pin associated with the given channel. By default, the alternative excite pins are mapped to the LES\_ALTEX pins, but they can also be mapped to LESENSE CH<sub>X+8 mod 16</sub>. Mapping of the alternative excite pins is configured in ALTEXMAP in the CTRL register. [Table 29.2 LESENSE Excitation Pin Mapping on page 975](#) summarizes the mapping of excitation pins for different configurations.

**Table 29.2. LESENSE Excitation Pin Mapping**

| LESENSE channel | ALTEX = 0 | ALTEX = 1     |                  |
|-----------------|-----------|---------------|------------------|
|                 |           | ALTEXMAP = CH | ALTEXMAP = ALTEX |
| 0               | LES_CH0   | LES_CH8       | LES_ALTEX0       |
| 1               | LES_CH1   | LES_CH9       | LES_ALTEX1       |
| 2               | LES_CH2   | LES_CH10      | LES_ALTEX2       |
| 3               | LES_CH3   | LES_CH11      | LES_ALTEX3       |
| 4               | LES_CH4   | LES_CH12      | LES_ALTEX4       |
| 5               | LES_CH5   | LES_CH13      | LES_ALTEX5       |
| 6               | LES_CH6   | LES_CH14      | LES_ALTEX6       |
| 7               | LES_CH7   | LES_CH15      | LES_ALTEX7       |
| 8               | LES_CH8   | LES_CH0       | LES_ALTEX0       |
| 9               | LES_CH9   | LES_CH1       | LES_ALTEX1       |
| 10              | LES_CH10  | LES_CH2       | LES_ALTEX2       |
| 11              | LES_CH11  | LES_CH3       | LES_ALTEX3       |
| 12              | LES_CH12  | LES_CH4       | LES_ALTEX4       |
| 13              | LES_CH13  | LES_CH5       | LES_ALTEX5       |
| 14              | LES_CH14  | LES_CH6       | LES_ALTEX6       |
| 15              | LES_CH15  | LES_CH7       | LES_ALTEX7       |

[Figure 29.6 Pin Sequencing on page 976](#) illustrates the sequencing of the pin associated with the active channel and its alternative excite pin.

**Figure 29.6. Pin Sequencing**

The LES\_ALTEX<sub>n</sub> pins have the ability to excite regardless of what channel is active. Setting AEX<sub>n</sub> in ALTEXCONF will make LES\_ALTEX<sub>n</sub> excite for all channels using alternative excitation (i.e., ALTEX in CH<sub>x</sub>\_INTERACT is set).

**Note:** When exciting on the pin associated with the active channel, the pin will go through a tri-stated phase before returning to the idle configuration. This will not happen on pins used as alternative excitation pins.

The pin configuration for the idle phase can be configured individually for each LESENSE channel and alternative excite pin in the IDLECONF and ALTEXCONF registers. The modes available are the same as the modes available in the excitation phase. In the measure phase, the pin mode on the active channel is always disabled (analog input).

To allow the LESENSE mode to control a GPIO pin, the pin must be enabled in the ROUTEPEN register and configured as push-pull. The IDLECONF configuration should not be altered while the pin enable for a given pin is set in ROUTEPEN.

### 29.3.5 Sensor Sampling

During the measurement phase, LESENSE can sample data from sensors using either ADC0 or an ACMP. This is configured in CH<sub>x</sub>\_INTERACT\_SAMPLE. If the ACMP is used, LESENSE can evaluate the ACMP output at a single point in time (CH<sub>x</sub>\_INTERACT\_SAMPLE = ACMP), or count pulses on the ACMP output (CH<sub>x</sub>\_INTERACT\_SAMPLE = ACMPCOUNT) for a programmable period of time.

LESENSE includes the ability to sample both analog comparators simultaneously, effectively cutting the time spent on sensor interaction in some applications in half. Setting DUALSAMPLE in CTRL enables this mode. In dual sample mode, channels X and X+8 are paired, meaning they will be sampled at the same time. DUALSAMPLE mode only works when CH<sub>x</sub>\_INTERACT\_SAMPLE is set to ACMP.

If ADC0 is used, LESENSE will initiate ADC conversions and fetch the ADC data for further evaluation. If the ADC is configured in differential mode, CH<sub>x</sub>\_INTERACT\_SAMPLE must be set to ADCDIFF. In this mode, the output from the ADC and the threshold used for comparison are given in two's complement notation.

See sections [29.3.12 ADC Interface](#) and [29.3.10 ACMP Interface](#) for more details on the LESENSE interface to the ADC and ACMPs. The sampled data from ADC or ACMP will be referred to as sensor data in the remainder of this manual.

The diagram illustrates the step detector logic. It starts with three main inputs: 'ACMP sample', 'LESENSE counter', and 'ADC data'. The 'LESENSE counter' feeds into a 'COUNT' block. 'ADC data' feeds into an 'ADC, ADDDIFF' block. The 'ACMP sample' feeds into an 'ACMP' block. The 'COUNT' block outputs to a 'STEPDET' block. The 'ADC, ADDDIFF' block outputs to a 'WINDOW state' block. The 'STEPDET' block outputs to a 'SLIDINGWIN' block. The 'WINDOW state' block outputs to a 'THRES' block. The 'THRES' block outputs to a 'COUNTER, ADC, ADDDIFF' block. The 'ACMP' block outputs to a 'COUNTER, ADC, ADDDIFF' block. The 'COUNTER, ADC, ADDDIFF' block outputs to a 'SENSORSTATE\*' block. The 'SENSORSTATE\*' block outputs to a 'NEGEDGE' block. The 'NEGEDGE' block outputs to a 'POSEDGE' block. The 'POSEDGE' block outputs to a 'LEVEL' block. The 'LEVEL' block outputs to a 'NONE' block. The 'NONE' block outputs to a 'Set interrupt flag' block. A feedback loop exists from 'SENSORSTATE\*' to 'ACMP'. A note states: 'In STEPDET mode, both step direction and step/no step is stored in SENSORSTATE'.

### 29.3.6.2 Sliding Window

In sliding window mode, the sensor data is compared against the upper and lower limits of a window range. The window is defined by a base, given by `CHx_EVAL_COMPTHRES`, and a size configured in `EVALCTRL_WINSIZE`. The window size is constant and the same for all LESENSE channels, while the base is specific to each channel and will be updated by LESENSE when the sensor data is outside the current window range. If the sensor data is within the window range, the sensor evaluation will remain the same as it was for the previous measurement. If the sensor data is below the window range, the measurement will be evaluated to false. If the sensor data is above the window range, the measurement will be evaluated to true. In both cases, the window base in `CHx_EVAL_COMPTHRES` will be updated to reflect the new window range. [Figure 29.8 Sliding Window on page 978](#) shows how the sliding window evaluation mode can be used to implement a system with two self calibrating thresholds.

**Figure 29.8. Sliding Window**

### 29.3.6.3 Step Detection

Step detection is used to detect steps in the sensor data compared to sensor data from the previous measurement. The size of the step is configured in `EVALCTRL_WINSIZE`. In this mode, step up and step down are evaluated as described in [Figure 29.9 Step Detection on page 978](#):

$$\text{STEP\_UP} = \text{SENSORDATA}_i \geq \text{SENSORDATA}_{i-1} + \text{EVALCTRL\_WINSIZE}$$

$$\text{STEP\_DOWN} = \text{SENSORDATA}_i < \text{SENSORDATA}_{i-1} - \text{EVALCTRL\_WINSIZE}$$

**Figure 29.9. Step Detection**

If either a step up or a step down is detected, the `SCANRES` bit for the active channel will be set. In addition, the `STEPPDIR` bit for the channel will be updated to indicate if a step up or a step down was detected. `STEPPDIR = 1` indicates a step up. In this mode, previous sensor data is stored in `CHx_EVAL_COMPTHRES`.

### 29.3.7 Decoder

Many applications, such as quadrature decoding, require some sort of processing of the sensor readings. In quadrature decoding, the sensors repeatedly pass through a set of states which correspond to the position of the sensors. This sequence, and many other decoding schemes, can be described as a finite state machine. To support this type of decoding without CPU intervention, the LESENSE module includes a highly configurable decoder capable of decoding input from up to four sensors. The decoder is implemented as a programmable state machine with up to 32 states. When doing a sensor scan, the results from the sensors are placed in the decoder input register, SENSORSTATE, if DECODE in CHx\_INTERACT is set. The resulting position after a scan is illustrated in [Figure 29.10 Sensor Scan and Decode Sequence on page 979](#), where the bottom blocks show how the SENSORSTATE register is filled. If step detection is enabled, the step direction is placed in SENSORSTATE in the position after the sensor result. When the scan sequence is complete, the decoder evaluates the state of the sensors chosen for decoding, as depicted in [Figure 29.10 Sensor Scan and Decode Sequence on page 979](#).

**Figure 29.10. Sensor Scan and Decode Sequence**

Upon a state transition, LESENSE can generate a pulse on one or more of the decoder PRS channels. Which PRS channel to generate a pulse on is configured in the PRSACT bit field. If PRSCNT in DECCTRL is set, count signals will be generated on decoder PRS channels 0 and 1 according to the PRSACT configuration. In this mode, channel 0 will pulse each time a count event occurs, while channel 1 indicates the count direction (1 being up and 0 being down). The count direction will be kept at its previous state in between count events. The EFR32xG13 Wireless Gecko pulse counter may be used to keep track of events based on these PRS outputs.

If SETIF is set, the DECODER interrupt flag will be set when the transition occurs. If INTMAP in DECCTRL and SETIF is set, a transition from state  $x$  or  $x+16$  will set the CHx interrupt flag in addition to the DECODER flag.

Setting CHAIN in STx\_TCONFA enables the decoder to evaluate more than two possible transitions for each state. If none of the transitions defined in STx\_TCONFA or STx\_TCONFB match, the decoder will jump to the next descriptor pair and evaluate the transitions defined there. The decoder uses two L<sub>FACLK</sub><sub>LESENSE</sub> cycles for each descriptor pair to be evaluated. If ERRCHK in CTRL is set, the decoder will check that the sensor state has not changed if none of the defined transitions match. The DECERR interrupt flag will be set if none of the transitions match and the sensor state has changed. [Figure 29.11 Decoder State Transition Evaluation on page 980](#) illustrates state transitions. The "Generate PRS signals and set interrupt flag" blocks will perform actions according to the configuration in STx\_TCONFA and STx\_TCONFB.

**Note:** If only one transition from a state is used, STx\_TCONFA and STx\_TCONFB should be configured equally.

**Figure 29.11. Decoder State Transition Evaluation**

The DECODER has a PRS output named DECCMP. This output can be used to indicate which state, or subset of states, the decoder is currently in. This PRS output is enabled by setting DECCMPEN in PRSCTRL, and configured through DECCMPMASK and DECCMPVAL in PRSCTRL. The value of this PRS output is given by [Figure 29.12 DECCMP PRS Output on page 981](#),

$$\text{PRS\_DECCMP} = (\text{DECSTATE} \& \sim\text{DECCMPMASK}) == (\text{DECCMPVAL} \& \sim\text{DECCMPMASK})$$

**Figure 29.12. DECCMP PRS Output**

To prevent unnecessary interrupt requests or PRS outputs when the decoder toggles back and forth between two states, a hysteresis option is available. The hysteresis function is triggered if a type A transition is preceded by a type B transition, and vice versa. A type A transition is defined in STx\_TCONFA, and a type B transition is defined in STx\_TCONFB. When descriptor chaining is used, a jump to another descriptor will cancel out the hysteresis effect. [Figure 29.13 Decoder Hysteresis on page 981](#) illustrates how the hysteresis triggers upon state transitions.

**Figure 29.13. Decoder Hysteresis**

- When HYSTPRSx is set, PRS signal x is suppressed when the hysteresis triggers.
- When HYSTIRQ is set, interrupt requests are suppressed when the hysteresis triggers.

**Note:** The decoder error interrupt flag, DECERR, is not affected by the hysteresis.

### 29.3.8 Measurement Results

Part of the LESENSE RAM is treated as a circular buffer for storage of up to 16 sensor measurements results. Each time LESENSE writes data to the result buffer, the result write pointer (PTR\_WR) is incremented. Each time a new result is read through the BUFDATA register, the result read pointer (PTR\_RD) is incremented. The read pointer will not be incremented if there is no valid, unread data in the result buffer. By default LESENSE will not write additional data to a full result buffer until the data is read by software or DMA. Setting BUFOW in CTRL enables LESENSE to write to the result buffer even if it is full. In this mode, the result read pointer will follow the write pointer if the buffer is full. The result of this is that data read from the result read register (BUFDATA) will be the oldest unread result. The location pointers are available in PTR.

The result buffer has three flags in the STATUS register: BUFDATAV, BUFHALFFULL, and BUFFULL. The flags indicate when new data is available, when the buffer is half full, and when it is full, respectively.

The result buffer also has three interrupt flags in the IR register: BUFDATAV, BUFLEVEL, and BUFOF. BUFDATAV is set when data is available in the buffer. BUFLEVEL is set when the buffer is either full or half-full, depending on the configuration of BUFIDL in CTRL. BUFOF is set if the result buffer overflows.

During a scan, the state of each sensor is stored in SCANRES. If a sensor triggers, a 1 is stored in SCANRES, else a 0 is stored in SCANRES. Whether or not a sensor is said to be triggered depends of the configuration for the given channel. See [29.3.6 Sensor Evaluation](#) for details. If STRSAMPLE in CHx\_EVAL is set, the sensor data for each channel will be stored in the LESENSE result buffer. If STRSCANRES in CTRL is set, the result vector, SCANRES, will also be stored in the result buffer. This will be stored after each scan and will be interleaved with the counter values. The contents of the result buffer can be read from BUFDATA or from BUF[x]\_DATA. When reading from BUF[x]\_DATA, neither the result read pointer or the status flags BUFDATAV, BUFHALFFULL, or BUFFULL will be updated. When reading through the BUFDATA register, the oldest unread result will be read.

**Figure 29.14. Circular Result Buffer**

Figure 29.14 Circular Result Buffer on page 982 illustrates how the result buffer would be filled when channels 3,5, and 9 are enabled and have STRSAMPLE in CHx\_EVAL set, in addition to STRSCANRES in CTRL. The measurement result from the three channels will be sequentially written during the scan, while SCANRES is written to the result buffer upon scan completion.

### 29.3.9 VDAC Interface

LESENSE is able to drive the VDAC for generation of accurate reference voltages. This is enabled by setting DACCHxEN in PERCTRL. The refresh rate of the VDAC channels can be configured in DACCONVTRIG in PERCTRL. If DACCONVTRIG is set to CHANNELSTART, the VDAC channels are refreshed prior to each sensor measurement, as depicted in [Figure 29.4 Timing Diagram, AUXHFRCO Based Timing on page 973](#). If DACCONVTRIG is set to SCANSTART, the VDAC channels are refreshed prior to each scan. The conversion data is either taken from the data registers in the EFR32xG13 Wireless Gecko VDAC interface (VDAC0\_CH0DATA and VDAC0\_CH1DATA) or from the THRES bitfield in the CHx\_INTERACT register for the active LESENSE channel. VDAC data used is configured in DACCHxDATA in PERCTRL.

Bias configuration, calibration and reference selection is done in the EFR32xG13 Wireless Gecko VDAC module and LESENSE will not override these configurations.

LESENSE has the possibility to control switches that connect the VDAC alternate outputs. This allows LESENSE to excite sensors with output from the VDAC channels, this is done by setting CHx\_INTERACT\_EXMODE to DACOUT. The LESENSE channels can also be connected to the VDAC output when the given channel is idle, this is done by setting IDLECONF\_CHx to DAC.

**Note:** Only LESENSE channels 4, 5, 7, 10, 12, 13 have the possibility to excite using the VDAC alternate outputs, or connect to the VDAC alternate outputs during the idle phase.

The VDAC may be chosen as reference to the analog comparators for accurate reference generation. If the VDAC is configured in continuous mode this does not require any external components. If sample/off mode is used, an external capacitor is needed to maintain the voltage between samples. To configure the VDAC to use this external capacitor, connect the capacitor to the VDAC pin for the given channel and set SHORT in VDAC\_OPAX\_OUT.

**Note:** The VDAC mode should not be altered while DACACTIVE in STATUS is set

### 29.3.10 ACMP Interface

The analog comparators (ACMPs) are used to measure the sensors, and have to be configured according to the application in order for LESENSE to work properly. Depending on the configuration in the ACMP0MODE and ACMP1MODE bit-fields in PERCTRL, LESENSE will take control of the positive input mux and the voltage dividers (DIVVA, DIVVB) for ACMP0 and ACMP1. The remaining configuration of the analog comparators is done in the ACMP register interface.

If ACMPxMODE in PERCTRL is set to MUX, LESENSE will take control of the positive input mux of the ACMP, through the external override interface, described in the ACMP chapter (see [26.3.12 External Override Interface](#)). The offset given by LESENSE, EXT\_OFFSET, depends on whether one or two ACMPs are controlled by LESENSE. If only one ACMP is used, EXT\_OFFSET will have the same value as the active channel. If both ACMP0 and ACMP1 are used, LESENSE channel 0-7 will use ACMP0 with EXT\_OFFSET 0-7, and LESENSE channel 8-15 will use ACMP1 with EXT\_OFFSET 0-7.

If ACMPxMODE in PERCTRL is set to MUXTHRES, LESENSE will also take control of the voltage dividers in the ACMP, DIVVA and DIVVB. The thresholds used are individual to each channel and is configured using the 6 LSBs of CHx\_INTERACT\_THRES. By default, ACMP\_HYSTERESIS0\_DIVVX and ACMP\_HYSTERESIS1\_DIVVX will be given the same value, the 6 LSBs of CHx\_INTERACT\_THRES. To allow different values for ACMP\_HYSTERESIS0\_DIVVX and ACMP\_HYSTERESIS1\_DIVVX, ACMPxHYSTEN in PERCTRL needs to be set. This allows the hysteresis feature in the ACMP to be utilized. ACMP\_HYSTERESIS0\_DIVVX will get the value programmed in CHx\_INTERACT\_THRES[5:0], while ACMP\_HYSTERESIS1\_DIVVX will get the value programmed in CHx\_INTERACT\_THRES[11:6].

### 29.3.11 ACMP and VDAC Duty Cycling

By default, the analog comparators and the VDAC are shut down between LESENSE scans to save energy. If this is not desired, WARMUPMODE in PERCTRL can be configured to prevent them from being shut down.

Both the VDAC and analog comparators rely on a bias module for correct operation. This bias module has a low power mode which consumes less energy at the cost of reduced accuracy. BIASMODE in BIASCTRL configures how the bias module is controlled by LESENSE. When set to DUTYCYCLE, LESENSE will set the bias module in high accuracy mode whenever LESENSE is active, and keep it in the low power mode otherwise. When BIASMODE is set to HIGHACC, the high accuracy mode is always selected. When set to DONTTOUCH, LESENSE will not control the bias module.

### 29.3.12 ADC Interface

The LESENSE module can be configured to trigger conversions on ADC0 and use data from ADC0 to evaluate sensor status. In order to do this, the scan mode of the ADC has to be configured. When the sample delay configured in CHx\_TIMING\_SAMPLEDLY has expired, LESENSE will initiate an ADC sample. The active LESENSE channel determines which ADC0 channel to be sampled, where LESENSE channel X corresponds to ADC0 scan channel X.

### 29.3.13 DMA Requests

LESENSE issues a DMA request when the result buffer is either full or half full, depending on the configuration of BUFIDL in CTRL. The request is cleared when the buffer level drops below the threshold defined in BUFIDL. A single DMA request is also set whenever there is unread data in the buffer. DMAWU in CTRL configures at which buffer level LESENSE should wake-up the DMA when in EM2.

**Note:** The DMA controller should always fetch data from the BUFDATA register.

### 29.3.14 PRS Output

LESENSE is an asynchronous PRS producer and has twenty PRS outputs. The decoder has four outputs and in addition, all bits in the SCANRES register are available as PRS outputs. For further information on the decoder PRS output, refer to [29.3.7 Decoder](#).

### 29.3.15 RAM

LESENSE includes a RAM block used for storage of configuration and results. Registers mapped to the RAM include: STx\_TCONFA, STx\_TCONFB, BUFx\_DATA, BUFDATA, CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL. These registers have unknown value out of reset and have to be initialized before use.

**Note:** Read-modify-write operations on uninitialized RAM register produces undefined values.

### 29.3.16 Application Examples

The following sections detail several example applications for the LESENSE block.

### 29.3.16.1 Capacitive Sense

Figure 29.15 Capacitive Sense Setup on page 985 illustrates how the EFR32xG13 Wireless Gecko can be configured to monitor four capacitive buttons.

**Figure 29.15. Capacitive Sense Setup**

The following steps show how to configure LESENSE to scan through the four buttons 100 times per second, issuing an interrupt if one of them is pressed.

1. Assuming  $LFACLK_{LESENSE}$  is 32 kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will set the LESENSE scan frequency to 100 Hz.
2. Enable channels 0 through 3 in CHEN and set IDLECONF for these channels to DISABLED. In capacitive sense mode, the GPIO should always be disabled (i.e., analog input).
3. Configure the ACMP to operate in CAPSENSE mode (refer to the ACMP chapter for more details).
4. Configure the following bit fields in CHx\_CONF, for channels 0 through 3:
  - a. Set EXTIME to 0. No excitation is needed in this mode.
  - b. Set SAMPLE to ACMPCOUNT and COMP to LESS. This makes LESENSE interpret a sensor as active if the frequency on a channel drops below the threshold (i.e., the button is pressed).
  - c. Set SAMPLEDLY to an appropriate value - each sensor will be measured for  $SAMPLEDLY/F_{LFACLK_{LESENSE}}$  seconds. MEASUREDLY should be set to 0
5. Set CTRTHRESHOLD to an appropriate value. An interrupt will be issued if the counter value for a sensor is below this threshold after the measurement phase.
6. Enable interrupts on channels 0 through 3.
7. Start scan sequence by writing a 1 to START in CMD.

In a capacitive sense application, it might be required to calibrate the threshold values on a periodic basis, for example to compensate for humidity and other physical variations. LESENSE is able to store up to 16 counter values from a configurable number of channels, making it possible to collect sample data while in EM2. When calibration is to be performed, the CPU only has to be woken up for a short period of time as the data to be processed already lies in the result registers. To enable storing of the count value for a channel, set STRSAMPLE in the CHx\_INTERACT register.

### 29.3.16.2 LC Sensor

Figure 29.16 LC Sensor Setup on page 986 below illustrates how the EFR32xG13 Wireless Gecko can be set up to monitor four LC sensors.

Figure 29.16. LC Sensor Setup

LESENSE can be used to excite and measure the damping factor in LC sensor oscillations. To measure the damping factor, the ACMP can be used to generate a high output each time the sensor voltage exceeds a certain level. These pulses are counted using an asynchronous counter and compared with the threshold in COMPTHRES in the CHx\_EVAL register. If the number of pulses exceeds the threshold level, the sensor is said to be active, otherwise it is inactive. Figure 29.17 LC Sensor Oscillations on page 986 illustrates how the output pulses from the ACMP correspond to damping of the oscillations. The results from sensor evaluation can automatically be fed into the decoder in order to keep track of rotations.

Figure 29.17. LC Sensor Oscillations

The following steps show how to configure LESENSE to scan through the four LC sensors 100 times per second.

1. Assuming  $LFACLK_{LESENSE}$  is 32kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will set the LESENSE scan frequency to 100Hz.
2. Enable the VDAC and configure it to produce a voltage of  $V_{dd}/2$ .

3. Enable channels 0 through 3 in CHEN. Set IDLECONF for the active channels to DACOUT. The channel pins should be connected to the VDAC output (effectively shorting the LC sensor) in the idle phase to damp the oscillations.
4. Configure the ACMP to use scaled Vdd as negative input, refer to ACMP chapter for details.
5. Enable and configure PCNT and asynchronous PRS.
6. Configure the GPIOs used as PUSH/PULL.
7. Configure the following bit fields in CHx\_CONF, for channels 0 through 3:
  - a. Set EXCLK to AUXHFRCO. AUXHFRCO is needed to achieve short excitation time.
  - b. Set EXTIME to an appropriate value. Excitation will last for  $EXTIME/F_{AUXHFRCO}$  seconds.
  - c. Set EXMODE to HIGH. The LC sensors are excited by pulling the excitation pin high.
  - d. Set SAMPLE to ACMPCOUNT and COMP to LESS. Status of each sensor is evaluated based on the number of pulses generated by the ACMP. If they are less than the threshold value, the sensor is said to be active.
  - e. Set SAMPLEDLY to an appropriate value, each sensor will be measured for  $SAMPLEDLY/F_{LFACLK\_LESENSE}$  seconds.
8. Set CTRTHRESHOLD to an appropriate value. If the sensor is active, the counter value after the measurement phase should be less than the threshold. If it is inactive, the counter value should be greater than the threshold.
9. Start scan sequence by writing a 1 to START in CMD.

**Note:** Exciting the LC sensor by pulling the excitation pin high allows the ESD protection in the pads to clamp any voltage swings below the ground voltage, giving a consistent starting point for the oscillations.

### 29.3.16.3 LESENSE Decoder 1

The example below illustrates how the LESENSE module can be used for decoding using three sensors.

Figure 29.18. FSM Example 1

Figure 29.18 FSM Example 1 on page 988, configure the following LESENSE registers:

1. Configure the channels to be used, be sure to set DECODE in CHx\_EVAL.
2. Set PRSCNT to enable generation of count waveforms on PRS. Also configure a PCNT to listen to the PRS channels and count accordingly.
3. Configure the following in STx\_TCONFA and STx\_TCONFB:
  - a. Set MASK = 0b1000 in STx\_TCONFA and STx\_TCONFB for all used states. This enables three sensors to be evaluated by the decoder.
  - b. Configure the remaining bit fields in STx\_TCONFA and STx\_TCONFB as described in [Table 29.3 LESENSE Decoder Configuration for FSM Example 1 on page 988](#).
4. To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.
5. Write to START in CMD to start scanning of sensors and decoding.

Table 29.3. LESENSE Decoder Configuration for FSM Example 1

| Register | TCONFA_NEXTSTATE | TCONFA_COMP | TCONFA_PRSACT | TCONFB_NEXTSTATE | TCONFB_COMP | TCONFB_PRSACT |
|----------|------------------|-------------|---------------|------------------|-------------|---------------|
| ST0      | 1                | 0b001       | UP            | 7                | 0b100       | DOWN          |
| ST1      | 2                | 0b011       | UP            | 0                | 0b000       | DOWN          |
| ST2      | 3                | 0b010       | UP            | 1                | 0b001       | DOWN          |
| ST3      | 4                | 0b110       | UP            | 2                | 0b011       | DOWN          |
| ST4      | 5                | 0b111       | UP            | 3                | 0b010       | DOWN          |
| ST5      | 6                | 0b101       | UP            | 4                | 0b110       | DOWN          |
| ST6      | 7                | 0b100       | UP            | 5                | 0b111       | DOWN          |
| ST7      | 0                | 0b000       | UP            | 6                | 0b101       | DOWN          |

#### 29.3.16.4 LESENSE Decoder 2

The example below illustrates how the LESENSE decoder can be used to implement the state machine seen in [Figure 29.19 FSM Example 2](#) on [page 989](#).

Figure 29.19. FSM Example 2

1. Configure STx\_TCONFA and STx\_TCONFB as described in [Table 29.4 LESENSE Decoder Configuration for FSM Example 2](#) on [page 989](#).
2. To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.
3. Write to START in CMD to start scanning of sensors and decoding.

Table 29.4. LESENSE Decoder Configuration for FSM Example 2

| Register   | NEXTSTATE | COMP   | MASK   | CHAIN |
|------------|-----------|--------|--------|-------|
| ST0_TCONFA | 8         | 0b1000 | 0b0111 | 1     |
| ST0_TCONFB | 2         | 0b0001 | 0b1000 | -     |
| ST1_TCONFA | 6         | 0b0010 | 0b1000 | 0     |
| ST1_TCONFB | 6         | 0b0010 | 0b1000 | -     |
| ST2_TCONFA | 8         | 0b1000 | 0b0111 | 1     |
| ST2_TCONFB | 4         | 0b0011 | 0b1000 | -     |
| ST3_TCONFA | 0         | 0b0000 | 0b1000 | 0     |
| ST3_TCONFB | 0         | 0b0000 | 0b1000 | -     |
| ST4_TCONFA | 8         | 0b1000 | 0b0111 | 1     |
| ST4_TCONFB | 6         | 0b0010 | 0b1000 | -     |
| ST5_TCONFA | 2         | 0b0001 | 0b1000 | 0     |
| ST5_TCONFB | 2         | 0b0001 | 0b1000 | -     |
| ST6_TCONFA | 8         | 0b1000 | 0b0111 | 1     |
| ST6_TCONFB | 0         | 0b0000 | 0b1000 | -     |
| ST7_TCONFA | 4         | 0b0011 | 0b1000 | 0     |
| ST7_TCONFB | 4         | 0b0011 | 0b1000 | -     |

## 29.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                 | Type  | Description                          |
|--------|----------------------|-------|--------------------------------------|
| 0x000  | LESENSE_CTRL         | RW    | Control Register                     |
| 0x004  | LESENSE_TIMCTRL      | RW    | Timing Control Register              |
| 0x008  | LESENSE_PERCTRL      | RW    | Peripheral Control Register          |
| 0x00C  | LESENSE_DECCTRL      | RW    | Decoder Control Register             |
| 0x010  | LESENSE_BIASCTRL     | RW    | Bias Control Register                |
| 0x014  | LESENSE_EVALCTRL     | RW    | LESENSE Evaluation Control           |
| 0x018  | LESENSE_PRSCTRL      | RW    | PRS Control Register                 |
| 0x01C  | LESENSE_CMD          | W1    | Command Register                     |
| 0x020  | LESENSE_CHEN         | RW    | Channel Enable Register              |
| 0x024  | LESENSE_SCANRES      | RWH   | Scan Result Register                 |
| 0x028  | LESENSE_STATUS       | R     | Status Register                      |
| 0x02C  | LESENSE_PTR          | R     | Result Buffer Pointers               |
| 0x030  | LESENSE_BUFDATA      | R(a)  | Result Buffer Data Register          |
| 0x034  | LESENSE_CURCH        | R     | Current Channel Index                |
| 0x038  | LESENSE_DECSTATE     | RWH   | Current Decoder State                |
| 0x03C  | LESENSE_SENSORSTATE  | RWH   | Decoder Input Register               |

## 30. GPCRC - General Purpose Cyclic Redundancy Check

### Quick Facts

#### What?

The GPCRC is an error-detecting module commonly used in digital networks and storage systems to detect accidental changes to data.

#### Why?

The GPCRC module can detect errors in data, giving a higher system reliability and robustness.

#### How?

Blocks of data entering GPCRC module can have a short checksum, based on the remainder of a polynomial division of their contents; on retrieval the calculation is repeated, and corrective action can be taken against presumed data corruption if the check values do not match.

### 30.1 Introduction

The GPCRC module is a slave peripheral that implements a Cyclic Redundancy Check (CRC) function. It supports both 32-bit and 16-bit polynomials. The supported 32-bit polynomial is 0x04C11DB7(IEEE 802.3), while the 16-bit polynomial can be programmed to any value, depending on the needs of the application. Common 16-bit polynomials are 0x1021 (CCITT-16), 0x3D65 (IEC16-MBus), and 0x8005 (zigbee, 802.15.4, and USB).

### 30.2 Features

- Programmable 16-bit polynomial, fixed 32-bit polynomial
- Byte-level bit reversal for the CRC input
- Byte-order reorientation for the CRC input
- Word or half-word bit reversal of the CRC result
- Ability to configure and seed an operation in a single register write
- Single-cycle CRC computation for 32-, 16-, or 8-bit blocks
- DMA operation

### 30.3 Functional Description

An overview of the GPCRC module is shown in [Figure 30.1 GPCRC Overview on page 1038](#).

**Figure 30.1. GPCRC Overview**

30.3.1 Polynomial Specification

POLYSEL in GPCRC\_CTRL selects between 32-bit and 16-bit polynomial functions. When a 32-bit polynomial is selected, the fixed IEEE 802.3 polynomial(0x04C11DB7) is used. When a 16-bit polynomial is selected, any valid polynomial can be defined by the user in GPCRC\_POLY.

A valid 16-bit CRC polynomial must have an x^16 term and an x^0 term. Theoretically, a 16-bit polynomial has 17 terms total. The convention used is to omit the x^16 term. The polynomial should be written in **reversed** (little endian) bit order. The most significant bit corresponds to the lowest order term. Thus, the most significant bit in CRC\_POLY represents the x^0 term, and the least significant bit in CRC\_POLY represents the x^15 term. The highest significant bit of CRC\_POLY should always set to 1. The polynomial representation for the CRC-16-CCIT polynomial x^16 + x^12 + x^5 + 1, or 0x8408 in reversed order, is shown in [Figure 30.2 Polynomial Representation on page 1039](#).

Figure 30.2. Polynomial Representation

30.3.2 Input and Output Specification

The CRC input data can be written to the GPCRC\_INPUTDATA, GPCRC\_INPUTDATAWORD or GPCRC\_INPUTDATABYTE register via the APB bus based on different data size. If BYTEMODE in GPCRC\_CTRL is set, only the least significant byte of the data word will be used for the CRC calculation no matter which input register is written. There are also three output registers for different ordering. Reading from GPCRC\_DATA will get the result based on the polynomial in reversed order, while reading from GPCRC\_DATAREV will get the result based on the polynomial in normal order. The CRC calculation needs one clock cycle, reading from GPCRC\_DATA, GPCRC\_DATAREV or GPCRC\_DATABYTEREV register or writting to GPCRC\_CMD register is halted while the calculation is in progress.

30.3.3 Initialization

The CRC can be pre-loaded or re-initialized by first writing a 32-bit programmable init value to INIT in GPCRC\_INIT and then setting INIT in GPCRC\_CMD. It can also be re-initialized automatically when read from DATA, DATAREV or DATABYTEREV provided that AUTOINIT in GPCRC\_CTRL is set, the CRC would be re-initialized with the stored init value.

30.3.4 DMA Usage

A DMA channel may be used to transfer data into the CRC engine. All bytes and half-word writes must be word-aligned. The recommended DMA usage model is to use the DMA to transfer all available words of data and use software writes to capture any remaining bytes.

30.3.5 Byte-Level Bit Reversal and Byte Reordering

The byte-level bit reversal and byte reordering operations occur before the data is used in the CRC calculation. Byte reordering can occur on words or half words. The hardware ignores the BYTEREVERSE field with any byte writes or operations with byte mode enabled (BYTEMODE = 1), but the bit reversal settings (BITREVERSE) are still applied to the byte. 32-bit little endian MSB-first data can be treated like 32-bit little endian LSB-first data, as shown in [Figure 30.3 Data Ordering Example - 32-bit MSB -first to LSB-first on page 1040](#). In this example, 32-bit data is written to GPCRC\_INPUTDATA, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

Figure 30.3. Data Ordering Example - 32-bit MSB -first to LSB-first

When handling 16-bit data, the byte reordering function only swap the two lowest bytes and clear the two highest bytes, as shown in [Figure 30.4 Data Ordering Example - 16-bit MSB -first to LSB-first on page 1041](#). In this example, 16-bit data is written to GPCRC\_INPUTDATAWORD, BYTEREVERSE is set for byte ordering, and BITREVERSE is set for byte-level bit reversal.

Figure 30.4. Data Ordering Example - 16-bit MSB -first to LSB-first

Assuming a word input byte order of B3 B2 B1 B0, the values used in the CRC calculation for the various settings of the byte-level bit reversal and byte reordering are shown in [Table 30.1 Byte-Level Bit Reversal and Byte Reordering Results \(B3 B2 B1 B0 Input Order\)](#) on page 1041.

Table 30.1. Byte-Level Bit Reversal and Byte Reordering Results (B3 B2 B1 B0 Input Order)

| Input Width(bits) | BYTEREVERSE Setting | BITREVERSE Setting | Input to CRC Calculation |
|-------------------|---------------------|--------------------|--------------------------|
| 32                | 0                   | 0                  | B3 B2 B1 B0              |
| 32                | 1                   | 1                  | 'B0 'B1 'B2 'B3          |

## 31. TRNG - True Random Number Generator

### Quick Facts

#### What?

The TRNG module is a non-deterministic random number generator based on a full hardware solution.

#### Why?

Secure cryptography commonly relies on randomly-generated numbers for key generation. Software solutions for random number generation do not usually produce results with enough entropy to satisfy existing standards. Dedicated hardware can provide suitable entropy in an energy-efficient, non-intrusive manner, while also relieving software burden.

#### How?

Ring oscillators and sampling logic combine to produce non-deterministic random numbers.

### 31.1 Introduction

The TRNG module is a non-deterministic random number generator based on a full hardware solution. The TRNG output passes the NIST 800-22 and AIS31 test suites.

### 31.2 Features

- Simple bus interface to access random numbers, control, and status registers
- 64 x 32-bit FIFO for random number access
- Interrupt sources from different FIFO, error, and noise alarm events
- Passes NIST 800-22 and AIS31
- Ready for NIST 800-90B
- Health tests compliant to NIST 800-90B and AIS31

### 31.3 Functional Description

Software drivers provided by Silicon Labs offer a simple API interface to the TRNG module. It is highly recommended to use the provided software libraries to access the TRNG module. An overview of the TRNG module is shown in [Figure 31.1 TRNG Overview on page 1050](#).

**Figure 31.1. TRNG Overview**

#### 31.3.1 Built-In Tests

The TRNG module includes several built-in tests to detect issues with the noise source, ensure entropy, and meet cryptography standards. The Repetition Count Test and Adaptive Proportion Test with window sizes of 64 and 4096 bits described in section 6.5.1.2 of NIST-800-90B (<http://csrc.nist.gov/publications/drafts/800-90/draft-sp800-90b.pdf>) are implemented in hardware and run continuously on the data. All three tests have corresponding interrupt flags that can optionally be used to generate a system interrupt.

The AIS31 Online Test described in section 5.5.3 of [https://www.bsi.bund.de/SharedDocs/Downloads/DE/BSI/Zertifizierung/Interpretationen/AIS\\_31\\_Functionality\\_classes\\_for\\_random\\_number\\_generators\\_e.pdf](https://www.bsi.bund.de/SharedDocs/Downloads/DE/BSI/Zertifizierung/Interpretationen/AIS_31_Functionality_classes_for_random_number_generators_e.pdf) is also implemented in hardware, and runs continuously on the data. Both the preliminary noise alarm and the noise alarm are optionally available as interrupt sources from the TRNG module. If a noise alarm occurs, the TRNG will be shut down, and must be reset with a software reset.

Additionally, the NIST-800-90B and AIS31 startup tests may be optionally enabled or disabled by software. The NIST-800-90B startup test is enabled if the `CONTROL_BYPNIST` bit is cleared to 0. The AIS31 startup test is likewise enabled when `CONTROL_BYPAIS31` is cleared to 0. If either the NIST-800-90B or AIS31 startup tests are enabled, no data will be written to the output FIFO until the startup requirements for these tests pass.

#### 31.3.2 FIFO Interface

The TRNG module includes a 64-word output FIFO to hold the output data as it becomes available. The number of 32-bit words available in the FIFO may be checked at any time by reading the `FIFOLEVEL` register. When the FIFO is completely filled, the TRNG will be shut down, the `STATUS_FULLIF` flag will be set, and no further data will be written to the FIFO until the FIFO has been flushed. Data may be read from the FIFO one word (32-bits) at a time via the FIFO register. The `STATUS_FULLIF` flag is cleared upon reading the `FIFOLEVEL` register.

### 31.3.3 Data Format - Byte Ordering

All cryptographic data is handled following the big-endian format (AES standard). The first byte (lowest address) of the data is the Most Significant Byte (MSB). However, the bus interfaces on the core use little endian format for internal byte ordering within a 32-bit word. The Least Significant Byte (LSB) within a word is stored at the lowest address.

For example, a 128-bit block 0x00112233445566778899AABBCCDDEEFF is read from the FIFO in the following order:

Word 1 = 0x33221100

Word 2 = 0x77665544

Word 3 = 0xBBAA9988

Word 4 = 0xFFDDEECC

This is important to note when checking the conditioning function for validity. The KEY registers also follow this standard, with KEY0 holding the MSB of a 128-bit value and KEY3 holding the LSB.

### 31.3.4 TRNG Usage

It is highly recommended to use the software libraries provided by Silicon Labs to access the TRNG module. The information in the following sections are reference for users who choose to write their own low-level software drivers.

### 31.3.4.1 Checking the Conditioning Function

The conditioning function receives 512 bits from the entropy source and generates 128 bits of output. The conditioning function can be tested by writing a known key and known data into the block with test mode enabled, then validating against the expected output. The sequence of operations to test the conditioning function is as follows:

1. Apply a software reset by setting CONTROL\_SOFTRESET to 1, then clearing it to 0.
2. Configure the CONTROL register. Important configuration options include:
  - Enable test mode by setting CONTROL\_TESTEN to 1.
  - Ensure the conditioning function is used by clearing CONTROL\_CONDBYPASS to 0.
3. Write the key into registers KEY0, KEY1, KEY2, and KEY3.
4. Write the 512 bits of known data to TESTDATA 32 bits at a time, polling for STATUS\_TESTDATABUSY = 0 after each write.
5. Read the 128-bit result from the FIFO 32 bits at a time.

Table 31.1 Known-Answer Test for Conditioning Function on page 1052 shows an example with a given key, known data input, and expected output (taken from section F.2.1 in <http://csrc.nist.gov/publications/nistpubs/800-38a/sp800-38a.pdf>).

**Table 31.1. Known-Answer Test for Conditioning Function**

|                 | 128-bit Format                                                                                                                                                   | 32-bit Bus Format                                                                                                                                                                                                            |

### 31.3.4.2 Checking the Entropy Source

The entropy source may be checked using the three built in test sources: repetition count, 64-sample adaptive proportion, and 4096-sample adaptive proportion. The entropy source may be tested using the following sequence:

1. Apply a software reset by setting CONTROL\_SOFTRESET to 1, then clearing it to 0.
2. Configure the CONTROL register. Important configuration options include:
  - Disable test mode by clearing CONTROL\_TESTEN to 0.
  - Bypass the conditioning function by setting CONTROL\_CONDBYPASS to 1.
  - Enable the TRNG by setting CONTROL\_ENABLE to 1.
3. Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS\_FULLIF flag to set, indicating the FIFO is full. Note that STATUS\_FULLIF may be configured to generate an interrupt if desired.
4. When FIFOLEVEL has reached the expected value or when STATUS\_FULLIF is set, read the random numbers using the FIFO register. Those values can be discarded.
5. Continue reading and discarding the random data until at least 4097 x 2 bits (257 x 32-bit words) have been read. This ensures that enough time has passed for the longest test to run.
6. Check the STATUS register for error flags.

### 31.3.4.3 Programming a Random Key

1. Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS\_FULLIF flag to set, indicating the FIFO is full. Note that STATUS\_FULLIF may be configured to generate an interrupt if desired.
2. When FIFOLEVEL has reached the expected value or when STATUS\_FULLIF is set, read the random numbers using the FIFO register.
3. Use four 32-bit random values to program a random key to the KEY0, KEY1, KEY2, and KEY3 registers.
4. Apply a software reset by setting CONTROL\_SOFTRESET to 1, then clearing it to 0. This will flush the FIFO data.

### 31.3.4.4 Reading Samples

1. Check the FIFOLEVEL register to monitor the amount of generated random numbers or wait for the STATUS\_FULLIF flag to set, indicating the FIFO is full. Note that STATUS\_FULLIF may be configured to generate an interrupt if desired.
2. When FIFOLEVEL has reached the expected value or when STATUS\_FULLIF is set, read the random numbers using the FIFO register.

## 31.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name              | Type | Description           |
|--------|-------------------|------|-----------------------|
| 0x000  | TRNGn_CONTROL     | RW   | Main Control Register |
| 0x004  | TRNGn_FIFOLEVEL   | R(a) | FIFO Level Register   |
| 0x00C  | TRNGn_FIFODEPTH   | R    | FIFO Depth Register   |
| 0x010  | TRNGn_KEY0        | RW   | Key Register 0        |
| 0x014  | TRNGn_KEY1        | RW   | Key Register 1        |
| 0x018  | TRNGn_KEY2        | RW   | Key Register 2        |
| 0x01C  | TRNGn_KEY3        | RW   | Key Register 3        |
| 0x020  | TRNGn_TESTDATA    | RW   | Test Data Register    |
| 0x030  | TRNGn_STATUS      | RWH  | Status Register       |
| 0x034  | TRNGn_INITWAITVAL | RW   | Initial Wait Counter  |
| 0x100  | TRNGn_FIFO        | R(a) | FIFO Data             |

### 31.5 Register Description

### 31.5.1 TRNGn\_CONTROL - Main Control Register

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |         |    |         |    |          |    |        |    |        |    |           |    |         |    |            |    |          |    |             |    |            |    |        |    |    |    |        |    |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------|----|---------|----|----------|----|--------|----|--------|----|-----------|----|---------|----|------------|----|----------|----|-------------|----|------------|----|--------|----|----|----|--------|----|

32. CRYPTO - Crypto Accelerator

Quick Facts

**What?**

A fast and energy efficient autonomous hardware accelerator for AES encryption and decryption with 128- or 256-bit keys, ECC over prime and binary Galois finite fields, SHA-1, SHA-224 and SHA-256.

**Why?**

Efficient cryptography with little or no CPU intervention helps to meet the speed and energy demands of the application. Hardware implementations are generally more secure against side-channel attacks than software implementations.

**How?**

Programmable sequences of instructions on big numbers allow fast processing with little CPU intervention. Furthermore, CRYPTO is linked to the Buffer Controller (BUFC), thus enabling fast and efficient autonomous cipher operations on data buffer content.

32.1 Introduction

The CRYPTO module allows efficient acceleration of common cryptographic operations and allows these to be used efficiently with a low CPU load. Operations performed by CRYPTO can be set up as a sequence of instructions on a set of 128-bit, 256-bit or 512-bit registers to implement or accelerate Elliptic Curve Cryptography (ECC), SHA-1, SHA-224, SHA-256, and various block cipher modes based on the Advanced Encryption Standard, also known as AES (FIPS-197).

CRYPTO is capable of autonomously fetching data, performing cipher operations and storing data across multiple blocks. When the source data is not a multiple of 16 bytes (128 bits), Zero-padding can be included in the last block. Block operations such as Counter Mode (CTR), Electronic Code Book (ECB), Cipher Block Chaining (CBC), Cipher Feedback (CFB) and Output Feedback (OFB) are easily implemented. Block Cipher modes of operation such as Electronic Code Book (ECB), Counter Mode (CTR), Cipher Block Chaining (CBC), CBC-MAC (CBC Message Authentication Code), CCM (Counter with CBC-MAC) and GCM (Galois Counter mode) are easily implemented.

CRYPTO is delivered with an extensive software library in Simplicity Studio that implements all major cryptographic algorithms, including but not limited to AES, SHA-1, SHA-2, ECC, and legacy algorithms DES, 3DES, MD4, MD5 and RC4. The implementation accelerates the algorithms using CRYPTO when possible.

## 32.2 Features

- Efficient AES core
  - Encryption/decryption using 128-bit key (54 clock cycles) or 256-bit key (75 clock cycles)
  - Key buffer
  - Supports autonomous cipher block modes (e.g. ECB, CTR, CBC, PCBC, CFB, CBC-MAC, GMAC, CCM, CCM\* and GCM) across multiple blocks
- Accelerated SHA-1, SHA-224 and SHA-256
- Accelerated Elliptic Curve Cryptography (ECC)
  - Binary and Prime fields
  - Supports NIST recommended curves: P-192, P-224, P-256, K-163, K-233, B-163, and B-233
- Galois/Counter Mode (GCM)
  - ALU operations on GCM  $GF(2^{128})$  field
- Flexible 256-bit ALU and sequencer
  - 5 general purpose 256-bit registers
  - Supports ADD, SUB, MUL, shift, XOR, etc.
  - Up to 20 instructions can be chained to implement various block cipher modes
- Efficient operation
  - Automatic data loading and storing from registers (through BUFC, the buffer controller)
  - DMA request signals for data read and write
  - Optional XOR Data write
  - Interrupt on finished operations
- Extensive software support
  - Extensive software library in Simplicity Studio
  - Implements all major cryptographic algorithms: AES, SHA-1, SHA-2, and ECC
  - Implements legacy algorithms: DES, 3DES, MD4, MD5, and RC4
  - Hardware accelerated when possible

## 32.3 Usage and Programming Interface

Many security systems fail due to mistakes in the implementation. Therefore implementations should be left to experts in cryptographic algorithms.

To solve this, the module is supported by an hardened cryptography software library and API delivered through Silicon Labs' Simplicity Studio. The software API is a frontend for performing all supported cryptographic operations both for radio-protocols and applications, and must be used to receive prompt support.

32.4 Functional Description

A block diagram of the CRYPTO module is shown in [Figure 32.1 CRYPTO Overview on page 1064](#).

Figure 32.1. CRYPTO Overview

### 32.4.1 Data and Key Registers

The CRYPTO module contains five 256-bit registers. Accelerators are implemented through instructions operating on these registers, either by copying data between registers and external components like the BUFC or through DMA, or by executing instructions on the registers.

Depending on the instruction, the registers can be accessed as 128-bit, 256-bit or 512-bit registers. The registers can also be accessed through different interface registers to achieve different results.

When writing to and reading from the CRYPTO\_DATAx, CRYPTO\_KEY, CRYPTO\_KEYBUF, CRYPTO\_DDATABx and CRYPTO\_QDATABx registers, the least significant part is accessed first and the most significant part last, see [Figure 32.2 CRYPTO Data and Key Register Operation on page 1066](#). The same is the case for the XOR and byte-access registers for DATA0 and DATA1. It is important to note that some of the 256-bit registers are composed of the 128-bit registers, and both the 512-bit registers are composed of the 256-bit registers.

**Note:** From here on, the 128, 256 and 512-bit registers are named DATAx, DDATABx, QDATABx, etc. And the access-points to these registers are named CRYPTO\_DATAx, CRYPTO\_DDATABx, CRYPTO\_QDATABx, etc.

DATA0 can be accessed through CRYPTO\_DATA0 (32-bit), CRYPTO\_DATA0XOR (32-bit), CRYPTO\_DATA0BYTE (8-bit) and CRYPTO\_DATA0XORBYTE (8-bit). Direct access to bytes 12 - 15 is available through CRYPTO\_DATA0BYTE12-15 (8-bit). The DATA0XOR (in CRYPTO\_DATA0XOR) is used for XOR'ing a value with the current value in DATA0. This is used in a large variety of block cipher modes. All of these registers operate on DATA0.

DATA1 can be accessed through CRYPTO\_DATA1 (32-bit) and CRYPTO\_DATA1BYTE (8-bit).

The remaining data registers have regular 32-bit access through their respective registers. Note that all data registers require a full read or write to be fully accessed. This means that the 128-bit registers need four 32-bit reads/writes, the 256-bit registers need 8 reads/writes and the 512-bit registers need 16 reads/writes. For a read, if all read accesses are not done, the register will end up as a shifted version of the original value.

**Note:** For byte-wise data accesses (DDATABxBYTE, DATAxBYTE, etc.), all reads and writes must be performed in groups of 4, due to internal buffering and shifting of 32 bits at a time. Accessing a number of bytes that is not a multiple of four can cause data incoherency in all of the data registers.

The KEY and KEYBUF registers are 256 bit wide when AES256 is set in CRYPTO\_CTRL. Else they are 128 bit wide. When used as a part of DDATABx and QDATABx, they are always 256 bit wide.

The registers DDATAB0BIG and QDATAB1BIG produce byte-swapped versions of DDATAB0 and QDATAB1 respectively. These may be used when a computation requires byte-swapping. An example of this is SHA computation, where data needs to be changed to big endian before CRYPTO can work with it. Little endian data is then loaded in through QDATAB1BIG and the resulting little endian hash can be read out from DDATAB0BIG, see [32.4.5 SHA](#).

Except for KEYBUF, the contents of all data registers are lost when going to EM2.

**Figure 32.2. CRYPTO Data and Key Register Operation**

### 32.4.1.1 DATA0 Zero

DATA0ZERO in CRYPTO\_DSTATUS contains status flags indicating if any 32-bit blocks within DATA0 is 0. For example, if DATA0[95:64] is equal to 0x00000000, ZERO64TO95 is set.

### 32.4.1.2 DDATA0 and DDATA1 Quick Observation

DDATA0LSBS in CRYPTO\_DSTATUS shows the 4 least significant bits in DDATA0. DDATA0MSBS in CRYPTO\_DSTATUS shows the 4 most significant bits of DDATA0, while DDATA1MSB in CRYPTO\_DSTATUS shows the msb of DDATA1. These observation bitfields are useful for determining the sign of the value in the data registers without having to read out the full register data register values

The 4 bits observed by DDATA0MSBS will change depending on RESULTWIDTH in CRYPTO\_WAC. When using 260-bit results, DDATA0MSBS shows bits 259-256, when using 256-bit results, it is bits 255-252, and for 128-bit results, bits 127-124 can be observed. When RESULTWIDTH is 260 bits, the 4 most significant bits, e.g. bits 259-256 are also available in CRYPTO\_DDATA0BYTE32, where they can also be written. Using this register is the only way of inputting the upper 4 bits of a 260-bit number to CRYPTO.

### 32.4.1.3 Result Width

RESULTWIDTH in CRYPTO\_WAC determines the width of the operation when performing arithmetic/shift instructions with CRYPTO. Using less wide results will reduce the current consumption of the CRYPTO module. The higher-order bits that are beyond the selected result width are ignored in the computation of arithmetic/shift operations, however, these higher-order bits will be undefined in the result of such instructions.

When RESULTWIDTH=260BIT, all DDATA registers effectively become 260 bits wide, so that the upper 4 bits are not lost when transferring data from DDATA0 to the other DDATA registers. Likewise, the arithmetic/shift instructions shall consider the full 260-bit values of DDATA0-DDATA4 when used as operation inputs. Note that DDATA0 is the only 260-bit register of which MSBs can be observed/written. The upper 4 bits are observed through DDATA0MSBS in CRYPTO\_DSTATUS or through CRYPTO\_DDATA0BYTE32. For all DDATAx registers, the extra MSBs are cleared when DDATAx is written. Furthermore, for a particular x, a write to DDATAx or any of its aliased registers will cause DDATAx MSBs to be cleared. Note, writing to KEY/KEYBUF will only clear MSBs of DDATA1/DDATA4 when AES256 mode is set. Likewise, writing to DATA0/DATA2 will not clear DDATA2/DDATA3 MSBs.

Since the DATA0-DATA3 registers are always 128-bit, all bit positions greater than 128 are interpreted as 0 when RESULTWIDTH is greater than 128 bits. However, the assignment instructions DATAxTODDATAy will not zero-out the upper 128 bits of the DDATAy target. Instead, those upper words become undefined after such operations.

## 32.4.2 Instructions and Execution

The CRYPTO module implements a set of instructions in order to load and manipulate data effectively. These instructions are grouped into four types:

- ALU instructions - arithmetic and logical bitwise operations
- Transfer instructions - moving data between registers and external peripherals like DMA and the BUFC
- Conditional instructions - conditionally execute instructions based on context
- Special instructions - various crypto and support instructions

A single instruction can be executed by writing INSTR in CRYPTO\_CMD. This will execute the instruction, and the interface of CRYPTO will be locked until the execution has completed. Multiple commands can safely be issued after each other by the CPU as long as NOBUSYSTALL in CRYPTO\_CTRL is not set. If CRYPTO gets a new command or a data access request while busy it will then stall the bus, and execute the new command as soon as it is done with the previous one. Note, there are some exceptions to this rule. For example, see [32.4.8 DMA](#).

Stalling of the bus can be disabled by setting NOBUSYSTALL in CRYPTO\_CTRL, however manipulating (reading or writing) registers while running an instruction will result in undefined behaviour. Additionally, if NOBUSYSTALL=0 and a new command or data access request is made while the CRYPTO is simultaneously performing a data transfer instruction, it is possible for system lockup due to bus stalling loops. The safest approach is to always check if an instruction is running by looking at INSTRRUNNING in CRYPTO\_STATUS.

Note that this automatic stalling feature does not apply to automated CRYPTO instruction sequences (described next), since there may be cycle delays between individual instructions for which bus accesses are not prevented. For sequences, always check the SEQRUNNING status bit or the SEQDONE interrupt flag to ensure the sequence is finished before attempting CRYPTO register accesses.

### 32.4.2.1 Sequences

For executing a set of instructions, it is more efficient to load them into the CRYPTO module and run them as a sequence. This is done by writing the instructions into CRYPTO\_SEQ0-CRYPTO\_SEQ4, and marking the end of the instruction sequence with either an END or an EXEC instruction. The END simply means end-of-instructions, while writing EXEC means end-of-instructions and execute immediately.

The five registers allow up to 20 instructions to be loaded. To start execution, either end the instructions with an EXEC instruction, or set SEQSTART in CRYPTO\_CMD. CRYPTO will then execute the instructions, starting in CRYPTO\_SEQ0, and ending at the first END instruction. SEQRUNNING in CRYPTO\_STATUS is set while the sequence is running, and the interrupt flag SEQDONE in CRYPTO\_IF will be set when the sequence has completed.

A sequence can be stopped by issuing the SEQSTOP command in the CRYPTO\_CMD register. This command also clears the state of ongoing CRYPTO instructions including DMA and BUFC access. Check SEQRUNNING in CRYPTO\_STATUS after issuing the SEQSTOP command flag to make sure any ongoing sequence/transfer has completed before accessing data registers again.

### 32.4.2.2 Available Instructions

The available ALU instructions are listed in [Table 32.1 ALU Instructions on page 1069](#), data transfer instructions are listed in [Table 32.2 Transfer Instructions on page 1070](#), conditional instructions are listed in [Table 32.3 Conditional Instructions on page 1071](#) and special instructions are listed in [Table 32.4 Special Instructions on page 1071](#). The tables explain the side-effects of the instructions and shows which registers are affected. For instructions involving BUFC, the BUFC Buffers are defined by READBUFSEL and WRITEBUFSEL in CRYPTO\_CTRL for BUFC reads and writes respectively. V0 and V1 in the instructions descriptions can be any of the DDATx registers and a selection of the DATAx registers. They can be selected using the SELDDATxDDATy, SELDATxDDATy, SELDDATxDATy and SELDATxDATy instructions. The first register in the instruction will be selected for V0, and the second for V1. This configuration stays even when the sequence is complete, and can also be set up front. The currently selected V0 and V1 can be read V0 and V1 in CRYPTO\_CSTATUS.

**Table 32.1. ALU Instructions**

| Instruction | Description                                                                                          | Constraints/Notes                                                                                |

| DATA1INCCLR | DATA1 = clearinc(DATA1).<br>See <a href="#">32.4.2.4 DATA1INC and DATA1INCCLR Instructions</a>              |

### 32.4.2.3 MULx Details

For the MULx instructions (not MMUL), MULWIDTH in CRYPTO\_WAC specifies the width of operands DDATA1 (and sometimes V1). This is useful in order to optimize performance because multiplications take the same number of cycles as the bits in the operands plus a couple of cycles for setup.

As with the other ALU instructions, RESULTWIDTH limits the width of the final result of the MULx and MMUL instructions.

### 32.4.2.4 DATA1INC and DATA1INCCLR Instructions

DATA1INC and DATA1INCCLR operate on the 1, 2, 3 or 4 most significant bytes in DATA1, depending on INCWIDTH in CRYPTO\_CTRL. DATA1INC increments these bytes in big endian, while DATA1INCCLR clears the bytes.

### 32.4.2.5 BBSWAP128 Instruction

The BBSWAP128 instruction copies the contents of the V0 operand to DDATA0 while swapping the bits of the lower 16 bytes. The operand is not changed. This operation is required for GCM. See [32.4.7 GCM and GMAC](#)

### 32.4.2.6 Carry

The carry output from most instructions can be observed through the CARRY bit in CRYPTO\_DSTATUS. Shift-instructions set CARRY to the value that is shifted out of the register, addition and multiplication set it on register overflow, and subtraction sets it on borrow, e.g. underflow.

In addition to generating carry information, some instructions also use the current value of CARRY. ADDC, SUBC, SHLC and SHRC all use carry to generate the result. For all of these instructions, carry allows a program to chain instructions together to operate on bigger numbers than allowed by CRYPTO. For example, by chaining first an ADD, and then an ADDC which uses the carry from the ADD operation, two 512-bit numbers can be added. By chaining more instructions, even larger numbers can be manipulated.

Other uses of CARRY include observation. To check if a register is 0, one can subtract 1 using the DEC instruction, and check if goes negative by checking the CARRY bit. CARRY can be set manually and in CRYPTO programs using the CSET and CCLR instructions, which set and clear the CARRY bit.

The MULC instruction does not use CARRY like the other carry instructions (i.e., instructions ending in 'C' such as 'ADDC'), but rather preserves the old contents of the multiplication register.

### 32.4.3 Repeated Sequence

To maximize efficiency, it is desirable to be able to run a set of instructions over multiple blocks of data autonomously. To repeat a sequence over a larger set of data, set LENGTHA in CRYPTO\_SEQCTRL to the number of bytes in the set, and BLOCKSIZE to the size of the blocks in the set. The sequence will then be repeated N times, where N is LENGTHA / BLOCKSIZE if LENGTHA is a multiple of BLOCKSIZE, or ceiling( LENGTHA / BLOCKSIZE ) if not. In the latter case, data written by DMA or received from BUFC will be zero-padded up to BLOCKSIZE if it is written to a register which has a size equal to BLOCKSIZE. One notable exception is when LENGTHA is 0. In this case the sequence will still execute once, but the block transfer instructions will not execute.

**Note:** If DMAxRSEL in CRYPTO\_CTRL selects a register that is smaller than the specified blocksize, DATATODMAx/DMAxTODATA instructions will not use the full blocksize, but will only transfer enough data to empty/fill the register once. For example, if BLOCKSIZE is set to 64B and DMA0RSEL=DDATA0, the instruction DATATODMA0 will only read 32B instead of 64B. The processing of LENGTHA/B will continue as if all 64B had been transferred.

A repeated sequence can also be made do slightly different operations on different parts of the data set. A sequence can be divided into two parts; part A, and part B. By configuring LENGTHA in CRYPTO\_SEQCTRL to the length of part A, and LENGTHB in CRYPTO\_SEQCTRLB to the length of part B, CRYPTO will first run iterations over part A, knowing it is A, and then part B, knowing it is part B. By using the conditional instructions listed in [Table 32.3 Conditional Instructions on page 1071](#), a program can execute different instructions depending on whether it is in part A or part B.

### 32.4.4 AES

The AES core operates on data in the 128-bit register DATA0 using the either a 128-bit or 256-bit key from the KEY register. The key width is specified by AES256 in CRYPTO\_CTRL. AES operations are implemented as the AESENC and AESDEC instructions, for AES encryption and AES decryption respectively. An overview of the AES functionality is shown in [Figure 32.3 CRYPTO AES Overview on page 1073](#).

AES encryption and decryption enables various block cipher modes like ECB, CTR, CBC, PCBC, CFB, OFB, CBC-MAC, GMAC, CCM, CCM\*, and GCM.

**Figure 32.3. CRYPTO AES Overview**

The input data before encryption is called the PlainText and output from the encryption is called CipherText. For encryption, the key is called PlainKey. After encryption, the resulting key in the KEY registers is the CipherKey. This key must be loaded into the KEY registers prior to the decryption. After one decryption, the resulting key will be the PlainKey. The resulting PlainKey/CipherKey is only dependent on the value in the KEY registers before encryption/decryption. The resulting keys and data are shown in [Figure 32.4 CRYPTO Key and Data Definitions on page 1073](#).

**Figure 32.4. CRYPTO Key and Data Definitions**

The KEY is by default loaded from KEYBUF prior to each AESENC or AESDEC instruction. If the KEY is not to be overwritten, key buffering should be disabled (KEYBUFDIS in CRYPTO\_CTRL). Disabling key buffering also allows the use of key loading through DMA.

The data and key orientation in the CRYPTO registers are shown in [Figure 32.5 CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard on page 1074](#).

Figure 32.5. CRYPTO Data and Key Orientation as Defined in the Advanced Encryption Standard

### 32.4.5 SHA

The CRYPTO SHA instruction implements SHA-1 with a 160-bit digest or SHA-2 with a 224-bit digest (SHA-224) or 256-bit digest (SHA-256). Depending on SHAMODE in CRYPTO\_CTRL, SHA-1, SHA-224 or SHA-256 will be run on the data in QDATA1, and the result will be put on DDATA0. The contents in QDATA1 will be destroyed in the process.

To run SHA on a dataset, it must first be pre-processed by appending a bit '1' to the message, then padding the data with '0' bits until the message length in bits modulo 512 is 448. Then append the length of the message before pre-processing as a 64-bit big-endian integer. This pre-processing is known as MD-strengthening, and must be done by software before processing with the CRYPTO module.

The pre-processed data can now be run through the CRYPTO module. Begin by writing the values listed in [Table 32.5 SHA Init Values on page 1075](#) to CRYPTO\_DDATA1 from top to bottom, then execute the instructions listed in [Table 32.6 SHA Preparations on page 1075](#).

**Table 32.5. SHA Init Values**

| SHA-1      | SHA-224    | SHA-256    |
|------------|------------|------------|
| 0x67452301 | 0xC1059ED8 | 0x6A09E667 |
| 0xEFCDAB89 | 0x367CD507 | 0xBB67AE85 |
| 0x98BADCFE | 0x3070DD17 | 0x3C6EF372 |
| 0x10325476 | 0xF70E5939 | 0xA54FF53A |
| 0xC3D2E1F0 | 0xFFC00B31 | 0x510E527F |
| 0x00000000 | 0x68581511 | 0x9B05688C |
| 0x00000000 | 0x64F98FA7 | 0x1F83D9AB |
| 0x00000000 | 0xBEFA4FA4 | 0x5BE0CD19 |

**Table 32.6. SHA Preparations**

| STEP  | ACTION          | Description                                              |
|-------|-----------------|----------------------------------------------------------|
| STEP0 | DDATA1TODDATA0  | Copy init data to DDATA0                                 |
| STEP1 | SELDDATA0DDATA1 | Select DDATA0 and DDATA1 as operands for SHA instruction |

Then, for each 512-bit block, write the block to CRYPTO\_QDATA1BIG, execute the instructions listed in [Table 32.7 SHA for 512-bit Block on page 1075](#).

**Table 32.7. SHA for 512-bit Block**

| STEP  | ACTION         | Description                             |
|-------|----------------|-----------------------------------------|
| STEP0 | SHA            | Perform SHA operation on data in QDATA1 |
| STEP1 | MADD32         | Accumulate with previous data in DDATA1 |
| STEP2 | DDATA0TODDATA1 | Copy hash to DDATA1                     |

After the last iteration, the resulting hash can be read out from CRYPTO\_DDATA0BIG.

### 32.4.6 ECC

The CRYPTO module implements support for Elliptic Curve Cryptography through the modular instructions MADD, MMUL and MSUB, which perform modular addition, multiplication and subtraction respectively. The instructions can operate on a set of both prime fields GF(p) and binary fields GF(2<sup>m</sup>).

The type of modular arithmetic used and the modulus for the modular operations are specified by MODOP and MODULUS in CRYPTO\_WAC respectively. Changing these in the middle of an operation leads to undefined behaviour.

### 32.4.7 GCM and GMAC

CRYPTO implements support for Galois/Counter Mode (GCM), and also Galois Message Authentication Code (GMAC), by providing AES instructions and allowing multiplication on the field  $GF(2^{128})$  defined by the polynomial  $x^{128} + x^7 + x^2 + x + 1$ .

**Note:** BBSWAP128 needs to be applied to both operands and the result of the MMUL instruction when using it for GCM and GMAC

Efficient sequencer programs can be set up to perform GCM authentication and encryption/decryption on data from either BUFC, DMA, or CPU. To achieve a single-pass solution, LENGTHA in CRYPTO\_SEQCTRL is set to the length of the authentication part, and LENGTHB is set to the length of the rest of the message. Conditional instructions can then be used to make sure the two parts of the message are processed correctly. A similar approach is used to implement CCM.

### 32.4.8 DMA

The CRYPTO module has 5 DMA request signals (see [Table 32.8 DMA Signals on page 1076](#)) split over 2 internal DMA channels: DMA0 and DMA1. These DMA channels are not associated with channel 0 and 1 of the system DMA, and any system DMA channel can serve any of the 5 DMA requests. See the DMA chapter for information on how to configure the system DMA.

The DMA signals are set through the use of DMA oriented instructions, and cleared by reading or writing the respective CRYPTO data registers.

**Table 32.8. DMA Signals**

| Name      | Set on                                                                            | Cleared on                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DMA0WR    | Instruction DMA0TODATA, and DMA0TODATA XOR if COMBDMA0WEREQ in CRYPTO_CTRL is set | Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 write, or CRYPTO_DDATA0XOR if COMBDMA0WEDMAREQ in CRYPTO_CTRL is set |
| DMA0XORWR | Instruction DMA0TODATA XOR                                                        | Full CRYPTO_DATA0XOR write                                                                                                               |
| DMA0RD    | Instructions DATATODMA0                                                           | Full CRYPTO_DATA0, CRYPTO_DDATA0, CRYPTO_DDATA0BIG or CRYPTO_QDATA0 read, depending on DMA0MODE in CRYPTO_CTRL                           |
| DMA1WR    | Instructions DMA1TODATA                                                           | Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG write                                                                |
| DMA1RD    | Instructions DATATODMA1                                                           | Full CRYPTO_DATA1, CRYPTO_DDATA1, CRYPTO_QDATA1 or CRYPTO_QDATA1BIG read, depending on DMA1MODE in CRYPTO_CTRL                           |

**Note:** DMAxRSEL in CRYPTO\_CTRL has to be set to the data registers that are to be read using the respective DMA channels on a DATATODMAx instruction. As an important note, DMAxRSEL in CRYPTO\_CTRL selects what is read from **any** of the selectable read registers during an ongoing DATATODMAx transfer.

When a DMA oriented CRYPTO instruction is used (either through a STEP in a Sequence or through CRYPTO\_CMD), the corresponding DMA signal is set. The instruction is complete when the entire source/destination is read/written (e.g. if DMA0TODATA is used, the operation is complete when a total of 128 valid bits have been written through the CRYPTO\_DATA0 register). DMAACTIVE in CRYPTO\_STATUS is set while CRYPTO is working on a DMA-related instruction, e.g. waiting for the DMA to read or write data to CRYPTO (see [32.4.8.1 DMA Initial Bytes Skip](#)).

Normally, when a sequence or instruction is executed, access to most CRYPTO registers will stall the CPU or DMA that is trying to access CRYPTO until the operation is done, preventing accesses to CRYPTO that could potentially interfere with an operation. During DMA operations, all non-DMA registers are writeable and readable, but progress through the DMA operation will only be tracked with the registers targeted by the DMA operation (i.e., if the DMA operation is supposed to transfer 3 words to DATA0, the DMA can first choose to transfer data to e.g. DATA3, and then fulfill the transfer to DATA0).

Because the bus interface to CRYPTO is normally locked outside of DMA transfers, a wrongly set up DMA transfer (e.g., transferring one byte too many) may lock up the interface. One way to assist in debugging such issues can be setting NOBUSYSTALL in CRYPTO\_CTRL. This will prevent any stall on CRYPTO register accesses during sequences and instructions. Use this option with care, as modifying a register that is being used by CRYPTO can lead to undefined behavior.

### 32.4.8.1 DMA Initial Bytes Skip

The DMA must be configured to use 32-bit transfer size. This normally would imply that the source data must be aligned to a 4 byte address boundary. However, it is possible to skip the initial bytes (1 to 3) when using DMA to write to DATA0 or DATA1 through a CRYPTO instruction operation. The number of bytes to skip are set in DMA0SKIP and DMA1SKIP in CRYPTO\_SEQCTRL. This implies that if DMA0SKIP is set to another value than 0, the initial DMA access will require 5 DMA transfers, even though only 4x32-bit is required.

**Note:** Any valid unused bytes from a previous DMA write will be used before new DMA data is requested. This data is invalidated by using STOP in CRYPTO\_CMD.

### 32.4.8.2 DMA Unaligned Read/Write

Except for DATA0 and DATA1, which can be loaded byte-wise using the CRYPTO\_DATA0BYTE, CRYPTO\_DATA0XORBYTE and CRYPTO\_DATA1BYTE registers, the CRYPTO data registers are loaded 32-bits at a time. Special care must be taken when using the DMA and the data buffer is not aligned to a 32-bit address, because the DMA does not directly support 32-bit unaligned accesses.

As an example, let an in-memory 16-byte data buffer start at address  $4*N + M$  and end at the byte before  $4*N + 16 + M$ , where  $M$  is between 0 and 3 inclusive. With an  $M=0$ , we have fully aligned accesses, and everything is fine. For  $M>0$  however, the access is unaligned. If  $M=1$ , that means that the first 32-bit aligned word of the memory buffer contains 1 byte before the buffer, and 3 bytes of the buffer. Similarly, the last 32-bit aligned word of the memory buffer contains the last byte of the buffer, and three bytes after the buffer.

When doing an unaligned read, we want to only pass the 16 bytes of the buffer to the CRYPTO module. Not the  $N$  bytes before in the 32-bit aligned word, and not the  $4-N$  words at the end. To achieve this, set  $DxDMAREADMODE$  in CRYPTO\_CTRL to either UNALIGNEDFULL or UNALIGNEDLENLIMIT, and set  $DATAxDMASKIP$  in CRYPTO\_SEQCTRL equal to  $N$ . When reading in data using a DMA-oriented instruction to  $DATAx$ ,  $DDATAx$  or  $QDATAx$ , the read will now only contain the 16 bytes, and not the  $N$  bytes before or  $4-N$  words after. Note that in this case, the DMA has to be set up to transfer 5 32-bit words instead of the effective 4.

Being able to read unaligned data does not solve all cases however. If data is to be written back to the buffer after passing through CRYPTO, e.g. when doing an in-place encryption or decryption, it is very undesirable to actually modify the  $N$  bytes before and  $4-N$  bytes after the buffer. This is solved using the UAR-suffixed registers in CRYPTO when reading data out from the CRYPTO module, e.g. CRYPTO\_DATA0UAR, CRYPTO\_DATA1UAR, CRYPTO\_DDATA0UAR, CRYPTO\_DDATA1UAR, CRYPTO\_QDATA0UAR, etc. When an unaligned buffer is written to a CRYPTO buffer, CRYPTO stores the  $N$  first bytes and the  $4-N$  last bytes internally. When reading out from an UAR register, these bytes are placed back into the data if  $DATAxDMAPRES$  is set in CRYPTO\_SEQCTRL.

Note that the latter case only works if the first  $N$  and the last  $4-N$  bytes are not changed while CRYPTO works on the data. Internally CRYPTO has 2 buffers for the bytes before and after. The first one is connected to read/write of the DATA0, DDATA0 and QDATA0 registers, and the second is connected to the DATA1, DDATA1 and QDATA1 registers.

If  $DMAxRMODE$  in CRYPTO\_CTRL is set to FULL or UNALIGNEDFULL and the corresponding  $DMAxPRES$  in CRYPTO\_SEQCTRL is set, then a whole number of data buffers have to be written by the DMA. In all other cases, it is enough to write the number of 32-bit words to pass all LENGTH bits to the target CRYPTO buffer.

### 32.4.9 BUFC Data Transfer

To allow automatic encryption/decryption or other operations on radio data, CRYPTO has instructions for moving data from and to BUFC, the Buffer Controller. Both DATA0 and DATA1 can be loaded with data from the buffer selected by READBUFSEL (CRYPTO\_CTRL register) as shown in [Figure 32.6 CRYPTO BUFC Data Transfer on page 1078](#). Similarly, the content of DATA0 and DATA1 can be written to the buffer selected by WRITEBUFSEL (also in the CRYPTO\_CTRL register).

**Figure 32.6. CRYPTO BUFC Data Transfer**

When reading from CRYPTO to the BUFC, the number of bytes read are determined by the DMAxRMODE configuration in CRYPTO\_CTRL. If it is set to either LENLIMIT or LENLIMITBYTE, only the number of bytes given by LENGTH in CRYPTO\_SEQCTRL are transferred. Else the full width of the last buffer is also written, e.g. a full number of 16-byte buffers are written to the BUFC.

**Note:**

The buffer selected by READBUFSEL and WRITEBUFSEL in the CRYPTO\_CTRL registers must be appropriately configured in the BUFC module prior to using instructions involving BUFC.

All BUFC reads start at the current BUFC read pointer, and move the pointer according to the number of bytes read. BUFC writes normally also work in the same way, starting at the current BUFC write pointer, and moving it the right number of positions. For BUFC XOR writes, software has the option to change this by setting either of DATAxTOBUFCXOROW in CRYPTO\_CTRL. With this bit set, the BUFC write pointer will be reset to the start of the previous write before writing to the BUFC. Using this feature, BUFC data can be written with using the DATAxTOBUFC instructions, and then XOR'ed with another set of data using the DATAxTOBUFCXOR instruction.

BUFACTIVE in CRYPTO\_STATUS is set while CRYPTO is reading or writing from/to the BUFC.

### 32.4.10 Debugging

There are multiple ways of debugging CRYPTO sequences. The most straight-forward way is to write individual instructions to INSTR in CRYPTO\_CMD. An instruction can be written, and data can be read out and examined before running another instruction.

Running individual instructions to debug a program falls short when working with repeated sequences. In these cases, a sequence is run multiple times over a set of data. This cannot be directly replicated with individual instructions.

To debug a sequence, set HALT in CRYPTO\_SEQCTRL. When set, CRYPTO requires software or the debugger to step it through each instruction in the sequence. To step through the sequence, set SEQSTEP in CRYPTO\_CMD. This will execute the current instruction, and make CRYPTO ready to execute the next one.

When stepping through a sequence, the current instruction index can be read from SEQIP in CRYPTO\_CSTATUS. SEQSKIP, also in CRYPTO\_CSTATUS, tells whether the next instruction will be executed or not, based on previous conditionals in the program. SEQPART in CRYPTO\_CSTATUS shows whether CRYPTO is currently in part A or B of a sequence. Even with NOBUSYSTALL in CRYPTO\_CTRL cleared, read and write accesses to CRYPTO will be allowed when CRYPTO is waiting to be stepped. This is to allow data registers to be inspected during debugging.

**Note:** The data registers in CRYPTO (those marked read-actionable) require shifting of data in order to return the result. For this reason, reading these registers will have no effect and will return unknown values during normal debugger read accesses (see [7.3.7 Debugger Reads of Actionable Registers](#)).

### 32.4.11 Example: Cipher Block Chaining (CBC)

In the following the setup and operation of CBC is explained and illustrated. The example can easily be adjusted to perform other cipher block modes.

### 32.4.11.1 CBC Encryption

In CBC encryption, the cipher input is the PlainText XOR'ed with the previous cipher output (an initialization vector IV is used during the first block). This mode is easily implemented using the CRYPTO instruction sequence BUFTODATA0XOR, AESENC then DATA0TOBUF. The BUFTODATA0XOR reads data from the buffer set by READBUFSEL and XOR's it with the content in DATA0. Then the cipher operation is performed and subsequently the DATA0TOBUF writes the content of DATA0 to the buffer set by WRITEBUFSEL (normally the same as READBUFSEL).

Prior to the operation, the initialization vector IV and key must be loaded to DATA0 and KEYBUF, respectively. Additionally, the total number of bytes to be included in the repeated sequence must be set in LENGTHA in CRYPTO\_SEQCTRL. Finally, the buffers selected by READBUFSEL and WRITEBUFSEL must be configured correctly in the BUFC. The sequence is started by issuing the SEQ-START command in CRYPTO\_CMD.

In [Figure 32.7 CBC Encryption Operation on page 1080](#) the CBC encryption is illustrated and in [Table 32.9 CBC Encryption Steps on page 1080](#) each step in the loop is explained.

CBC Encryption

Figure 32.7. CBC Encryption Operation

Table 32.9. CBC Encryption Steps

| STEP  | ACTION        | Description                                                         |
|-------|---------------|---------------------------------------------------------------------|
| STEP0 | BUFTODATA0XOR | Move data (PlainText, $P_i$ ) from buffer to DATA0 using XOR write. |
| STEP1 | CIPHER        | The AES Cipher Core operates on DATA0                               |
| STEP2 | DATA0TOBUF    | The cipher output $C_i$ is written to the buffer.                   |

### 32.4.11.2 CBC Decryption

In CBC decryption, CipherText ( $C_i$ ) is used as input to the Cipher Core. The output from the Cipher Core is XOR'ed with the CipherText from the previous block  $C_{i-1}$  to form the PlainText  $P_i$  (an initialization vector IV is used as  $C_{i-1}$  during the first block).

Because each block requires both  $C_{i-1}$  and  $C_i$ , decryption is somewhat more complex than encryption. Nevertheless, CBC decryption can be performed in as a repeated sequence by having  $C_{i-1}$  from the previous block stored in DATA1 and then writing it to buffer without updating the write pointer (using the DATA1TOBUF instruction). Then the cipher output is XOR'ed with  $C_{i-1}$  in the buffer by using the DATA0TOBUF XOR instruction.

In [Figure 32.8 CBC Decryption Operation on page 1081](#) the CBC decryption is illustrated and in [Table 32.10 CBC Decryption Steps on page 1081](#) each step in the loop is explained.

#### CBC Decryption

Figure 32.8. CBC Decryption Operation

Table 32.10. CBC Decryption Steps

| STEP  | ACTION           | Description                                                                                                |
|-------|------------------|------------------------------------------------------------------------------------------------------------|
| STEP0 | BUFTODATA0       | Moves data (CipherText, $C_i$ ) from buffer to DATA0                                                       |
| STEP1 | DATA1TOBUF       | DATA1 (CipherText, $C_{i-1}$ ) is moved to buffer. BUFC Write pointer is not incremented!                  |
| STEP2 | DATA0TODATA1     | Value of DATA0 is copied to DATA1.                                                                         |
| STEP3 | CIPHER Operation | The AES Cipher Core operates on DATA0                                                                      |
| STEP4 | DATA0TOBUF XOR   | The cipher output is XOR'ed with $C_{i-1}$ (placed in the buffer at Step 2) to form the PlainText, $P_i$ . |

## 32.5 Register Map

The offset register address is relative to the registers base address.

| Offset | Name                | Type       | Description                    |
|--------|---------------------|------------|--------------------------------|
| 0x000  | CRYPTO_CTRL         | RW         | Control Register               |
| 0x004  | CRYPTO_WAC          | RW         | Wide Arithmetic Configuration  |
| 0x008  | CRYPTO_CMD          | W          | Command Register               |
| 0x010  | CRYPTO_STATUS       | R          | Status Register                |
| 0x014  | CRYPTO_DSTATUS      | R          | Data Status Register           |
| 0x018  | CRYPTO_CSTATUS      | R          | Control Status Register        |
| 0x020  | CRYPTO_KEY          | RWH(nB)(a) | KEY Register Access            |
| 0x024  | CRYPTO_KEYBUF       | RWH(nB)(a) | KEY Buffer Register Access     |
| 0x030  | CRYPTO_SEQCTRL      | RWH        | Sequence Control               |
| 0x034  | CRYPTO_SEQCTRLB     | RWH        | Sequence Control B             |
| 0x040  | CRYPTO_IF           | R          | AES Interrupt Flags            |
| 0x044  | CRYPTO_IFS          | W1         | Interrupt Flag Set Register    |
| 0x048  | CRYPTO_IFC          | (R)W1      | Interrupt Flag Clear Register  |
| 0x04C  | CRYPTO_IEN          | RW         | Interrupt Enable Register      |
| 0x050  | CRYPTO_SEQ0         | RW         | Sequence Register 0            |
| 0x054  | CRYPTO_SEQ1         | RW         | Sequence Register 1            |
| 0x058  | CRYPTO_SEQ2         | RW         | Sequence Register 2            |
| 0x05C  | CRYPTO_SEQ3         | RW         | Sequence Register 3            |
| 0x060  | CRYPTO_SEQ4         | RW         | Sequence Register 4            |
| 0x080  | CRYPTO_DATA0        | RWH(nB)(a) | DATA0 Register Access          |
| 0x084  | CRYPTO_DATA1        | RWH(nB)(a) | DATA1 Register Access          |
| 0x088  | CRYPTO_DATA2        | RWH(nB)(a) | DATA2 Register Access          |
| 0x08C  | CRYPTO_DATA3        | RWH(nB)(a) | DATA3 Register Access          |
| 0x0A0  | CRYPTO_DATA0XOR     | RWH(nB)(a) | DATA0XOR Register Access       |
| 0x0B0  | CRYPTO_DATA0BYTE    | RWH(nB)(a) | DATA0 Register Byte Access     |
| 0x0B4  | CRYPTO_DATA1BYTE    | RWH(nB)(a) | DATA1 Register Byte Access     |
| 0x0BC  | CRYPTO_DATA0XORBYTE | RWH(nB)(a) | DATA0 Register Byte XOR Access |

33. GPIO - General Purpose Input/Output

Quick Facts

**What?**  
The General Purpose Input/Output (GPIO) is used for pin configuration, direct pin manipulation and sensing, as well as routing for peripheral pin connections.

**Why?**  
Easy to use and highly configurable input/output pins are important to fit many communication protocols as well as minimizing software control overhead. Flexible routing of peripheral functions helps to ease PCB layout.

**How?**  
Each pin on the device can be individually configured as either an input or an output with several different drive modes. Also, individual bit manipulation registers minimizes control overhead. Peripheral connections to pins can be routed to several different locations, thus solving congestion issues that may arise with multiple functions on the same pin. Fully asynchronous interrupts can also be generated from any pin.

33.1 Introduction

In the EFR32xG13 Wireless Gecko devices the General Purpose Input/Output (GPIO) pins are organized into ports with up to 16 pins each. These GPIO pins can individually be configured as either an output or input. More advanced configurations like open-drain, open-source, and glitch filtering can be configured for each individual GPIO pin. The GPIO pins can also be overridden by peripheral pin connections, like Timer PWM outputs or USART communication, which can be routed to several locations on the device. The GPIO supports up to 16 asynchronous external pin interrupts, which enable interrupts from any pin on the device. Also, the input value of a pin can be routed through the Peripheral Reflex System to other peripherals.

**Note:** To use the GPIO, the GPIO clock must first be enabled in CMU\_HFBUSCLKEN0. Setting this bit enables the HFBUSCLK for the GPIO.

## 33.2 Features

- Individual configuration for each pin
  - Tristate (reset state)
  - Push-pull
  - Open-drain
  - Pull-up resistor
  - Pull-down resistor
  - Drive strength
    - 1 mA
    - 10 mA
  - Slewrate
  - Over Voltage Tolerance
- EM4 IO pin retention
  - Output enable
  - Output value
  - Pull enable
  - Pull direction
  - Over Voltage Tolerance
- EM4 wake-up on selected GPIO pins
- Glitch suppression input filter
- Alternate functions (e.g. peripheral outputs and inputs)
  - Routed to several locations on the device
  - Pin connections can be enabled individually
  - Output data can be overridden by peripheral
  - Output enable can be overridden by peripheral
- Toggle register for output data
- Dedicated data input register (read-only)
- Interrupts
  - 2 Interrupt lines using either levels or edges
    - EM4 wake-up pins are selectable for level interrupts
    - All GPIO pins are selectable for edge interrupts
  - Separate enable, status, set and clear registers
  - Asynchronous sensing
  - Rising, falling or both edges
  - High or low level detection
  - Wake up from EM0 Active-EM3 Stop
- Peripheral Reflex System producer
  - All GPIO pins are selectable
- Configuration lock functionality to avoid accidental changes

### 33.3 Functional Description

An overview of the GPIO module is shown in [Figure 33.1 Pin Configuration on page 1122](#). The GPIO pins are grouped into 16-pin ports. Each individual GPIO pin is called Pxn where x indicates the port (A, B, C ...) and n indicates the pin number (0,1,...,15). Fewer than 16 bits may be available on some ports, depending on the total number of I/O pins on the package. After a reset, both input and output are disabled for all pins on the device, except for the Serial Wire Debug pins.

To use a pin, the Mode Register (GPIO\_Px\_MODEL/GPIO\_Px\_MODEH) must be configured for the pin to make it an input or output. These registers can also do more advanced configuration, which is covered in [33.3.1 Pin Configuration](#). When the port is configured as an input or an output, the Data In Register (GPIO\_Px\_DIN) can be used to read the level of each pin in the port (bit n in the register is connected to pin n on the port). When configured as an output, the value of the Data Out Register (GPIO\_Px\_DOUT) will be driven to the pin.

The DOUT value can be changed in 4 different ways:

- Writing to the GPIO\_Px\_DOUT register
- Writing the BITSET address of the GPIO\_Px\_DOUT register sets the DOUT bits
- Writing the BITCLEAR address of the GPIO\_Px\_DOUT register clears the DOUT bits
- Writing the GPIO\_Px\_DOUTTGL register toggles the corresponding DOUT bits

Reading the GPIO\_Px\_DOUT register will return its contents. Reading the GPIO\_Px\_DOUTTGL register will return 0.

**Figure 33.1. Pin Configuration**

### 33.3.1 Pin Configuration

In addition to setting the pins as either outputs or inputs, the GPIO\_Px\_MODEL and GPIO\_Px\_MODEH registers can be used for more advanced configurations. GPIO\_Px\_MODEL contains 8 bit fields named MODEn (n=0,1,..7) which control pins 0-7, while GPIO\_Px\_MODEH contains 8 bit fields named MODEn (n=8,9,..15) which control pins 8-15. In some modes GPIO\_Px\_DOUT is also used for extra configurations like pull-up/down and glitch suppression filter enable. [Table 33.1 Pin Configuration on page 1123](#) shows the available configurations.

**Table 33.1. Pin Configuration**

| MODEn                   | Input                 | Output                 | DOUT | Pull-down | Pull-up | Alt Port Ctrl | Input Filter | Description                 |                                                                   |
|-------------------------|-----------------------|------------------------|------|-----------|---------|---------------|--------------|-----------------------------|-------------------------------------------------------------------|
| DISABLED                | Disabled              | Disabled               | 0    |           |         |               |              | Input disabled              |                                                                   |
|                         |                       |                        | 1    |           | On      |               |              | Input disabled with pull-up |                                                                   |
| INPUT                   | Enabled if not DINDIS |                        | 0    |           |         |               |              |                             | Input enabled                                                     |
|                         |                       |                        | 1    |           |         |               | On           |                             | Input enabled with filter                                         |
| INPUTPULL               |                       |                        | 0    | On        |         |               |              |                             | Input enabled with pull-down                                      |
|                         |                       |                        | 1    |           | On      |               |              |                             | Input enabled with pull-up                                        |
| INPUTPULLFILTER         |                       |                        | 0    | On        |         |               |              | On                          | Input enabled with pull-down and filter                           |
|                         |                       |                        | 1    |           | On      |               |              | On                          | Input enabled with pull-up and filter                             |
| PUSHPULL                |                       | Push-pull              | x    |           |         |               |              |                             | Push-pull                                                         |
| PUSHPULLALT             |                       |                        | x    |           |         | On            |              |                             | Push-pull with alternate port control values                      |
| WIREDOR                 |                       | Open Source (Wired-OR) | x    |           |         |               |              |                             | Open-source                                                       |
| WIREDORPULLDOWN         |                       |                        | x    | On        |         |               |              |                             | Open-source with pull-down                                        |
| WIREDAND                |                       | Open Drain (Wired-AND) | x    |           |         |               |              |                             | Open-drain                                                        |
| WIREDANDFILTER          |                       |                        | x    |           |         |               |              | On                          | Open-drain with filter                                            |
| WIREDANDPULLUP          |                       |                        | x    |           | On      |               |              |                             | Open-drain with pull-up                                           |
| WIREDANDPULLUPFILTER    |                       |                        | x    |           | On      |               |              | On                          | Open-drain with pull-up and filter                                |
| WIREDANDALT             |                       |                        | x    |           |         |               | On           |                             | Open-drain with alternate port control values                     |
| WIREDANDALTFILTER       |                       |                        | x    |           |         |               | On           | On                          | Open-drain with alternate port control values and filter          |
| WIREDANDALTPULLUP       |                       |                        | x    |           | On      | On            |              |                             | Open-drain with alternate port control values and pull-up         |
| WIREDANDALTPULLUPFILTER |                       |                        | x    |           | On      | On            | On           | On                          | Open-drain with alternate port control values, pull-up and filter |

MODEn determines which mode the pin is in at a given time. Setting MODEn to DISABLED disables the pin, reducing power consumption to a minimum. When the output driver, input driver and Over Voltage Tolerance is disabled, the pin can be used as a connection for an analog module. An input is enabled by setting MODEn to any value other than DISABLED while DINDIS for the given port is cleared.

Set DINDIS to disable the input of a gpio port. The pull-up, pull-down and glitch filter function can optionally be applied to the input, see [Figure 33.2 Tristated Output With Optional Pull-up or Pull-down on page 1124](#).

**Figure 33.2. Tristated Output With Optional Pull-up or Pull-down**

When MODEn is PUSH\_PULL or PUSH\_PULLALT, the pin operates in push-pull mode. In this mode, the pin can have alternate port control values and can be driven either high or low, dependent on the value of GPIO\_Px\_DOUT. The push-pull configuration is shown in [Figure 33.3 Push-Pull Configuration on page 1124](#).

**Figure 33.3. Push-Pull Configuration**

When MODEn is WIREOR or WIREORPULLDOWN, the pin operates in open-source mode (with a pull-down resistor for WIREORPULLDOWN). When driving a high value in open-source mode, the pull-down is disconnected to save power.

When the mode is prefixed with WIREDAND, the pin operates in open-drain mode as shown in [Figure 33.4 Open-drain on page 1124](#). In open-drain mode, the pin can have an input filter, a pull-up, alternate port control values or any combination of these. When driving a low value in open-drain mode, the pull-up is disconnected to save power.

**Figure 33.4. Open-drain**

### 33.3.1.1 Over Voltage Tolerance

Over voltage capability is available for most pins. If available, it allows the pin to be used at the minimum of IOVDD + 2V and 5.5V (for 5V tolerant pads). The data sheet specifies which pins can be used as 5V tolerant pins. Default over voltage is enabled for each pin supporting that feature. Over voltage tolerance (OVT) can be disabled on a per pin basis. The over voltage tolerance feature applied to the selected pins is configured in the GPIO\_Px\_OVTDIS register. Disabling the over voltage tolerance for a pin will provide less distortion on that pin, which is useful when the pin is used as analog input.

**Note:** The VDAC (and OPAMPs) can drive outputs above IOVDD and therefore the involved pads typically require OVT to be enabled.

### 33.3.1.2 Alternate Port Control

The Alternate Port Control allows for additional flexibility of port level settings. A user may setup two different port configurations (normal and alternate modes) and select which is applied on a pin by pin bases. For example you may configure half of port A to use the low drive strength setting (normal mode) while the other half uses high drive strength (alternate mode).

Alternate port control is enabled when MODEN is set to any of the ALT enumerated modes (ie. PUSH\_PULLALT). When MODEN is an alternate mode, the pin uses the alternate port control values specified in the DINDISALT, SLEWRATEALT, and DRIVESTRENGTHALT fields in GPIO\_Px\_CTRL. In all other modes, the port control values are used from the DINDIS, SLEWRATE, and DRIVESTRENGTH fields in GPIO\_Px\_CTRL.

### 33.3.1.3 Drive Strength

The drive strength can be applied to pins on a port-by-port basis. The drive strength applied to pins configured using normal MODEN settings can be controlled using the DRIVESTRENGTH field in GPIO\_Px\_CTRL. The drive strength applied to pins configured using alternate MODEN settings can be controlled using the DRIVESTRENGTHALT field.

### 33.3.1.4 Slewrate

The slewrate can be applied to pins on a port-by-port basis. The slewrate applied to pins configured using normal MODEN settings can be controlled using the SLEWRATE fields in GPIO\_Px\_CTRL. The slewrate applied to pins configured using the alternate MODEN settings can be controlled using the SLEWRATEALT field.

### 33.3.1.5 Input Disable

The pin inputs can be disabled on a port-by-port basis. The input of pins configured using the normal MODEN settings can be disabled by setting DINDIS in GPIO\_Px\_CTRL. The input of pins configured using the alternate MODEN settings can be disabled by setting DINDISALT.

### 33.3.1.6 Configuration Lock

GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_CTRL, GPIO\_Px\_PINLOCKN, GPIO\_Px\_OVTDIS, GPIO\_EXTIPSELL, GPIO\_EXTIPSELH, GPIO\_EXTIPINSELL, GPIO\_EXTIPINSELH, GPIO\_INSENSE, GPIO\_ROUTEOPEN, and GPIO\_ROUTELOC0 can be locked by writing any value other than 0xA534 to GPIO\_LOCK. Writing the value 0xA534 to the GPIOx\_LOCK register unlocks the configuration registers.

In addition to configuration lock, GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_DOUT, GPIO\_Px\_DOUTTGL, and GPIO\_Px\_OVTDIS can be locked individually for each pin by clearing the corresponding bit in GPIO\_Px\_PINLOCKN. When a bit in the GPIO\_Px\_PINLOCKN register is cleared, it will stay cleared until reset.

33.3.2 EM4 Wake-up

It is possible to trigger a wake-up from EM4 using any of the selectable EM4WU GPIO pins. The wake-up request can be triggered through the pins by enabling the corresponding bit in the GPIO\_EM4WUEN register. When EM4 wake-up is enabled for the pin, the input filter is enabled during EM4. This is done to avoid false wake-up caused by glitches. In addition, the polarity of the EM4 wake-up request can be selected using the GPIO\_EXTILEVEL register.

Figure 33.5. EM4 Wake-up Logic

The pins used for EM4 wake-up must be configured as inputs with glitch filters using the GPIO\_Px\_MODEL/GPIO\_Px\_MODEH register. If the input is disabled and the wakeup polarity is low, a false wakeup will occur when entering EM4. If the input is enabled, the glitch filtered is disabled, and the polarity is set low, a glitch will occur when going into EM4 that will cause an immediate wake-up. Before going down to EM4, it is important to clear the wake-up logic by setting the GPIO\_IFC bit, which clears the wake-up logic, including the GPIO\_IF register. It is possible to determine which pin caused the EM4WU by reading the GPIO\_IF register. The mapping between EM4WU pins and the bit indexes in the GPIO\_EM4WUEN, GPIO\_EXTILEVEL, GPIO\_IFC, GPIO\_IFS, GPIO\_IEN, and GPIO\_IF registers is as follows:

Table 33.2. EM4WU Register Bit Index to EM4WU Pin Mapping

| EM4WU Register Bit Indexes                                     | EM4WU Pin    |
|----------------------------------------------------------------|--------------|
| 16                                                             | GPIO_EM4WU0  |
| 17                                                             | GPIO_EM4WU1  |
| 18                                                             | GPIO_EM4WU2  |
| 19                                                             | GPIO_EM4WU3  |
| ...                                                            | ...          |
| 31                                                             | GPIO_EM4WU15 |
| <b>Note:</b> See the device data sheet for actual pin location |              |

33.3.3 EM4 Retention

By default, GPIO pins revert back to their reset state when EM4 is entered. The GPIO pins can be configured to retain the settings for output enable, output value, pull enable, pull direction and over voltage tolerance while in EM4.

EM4 GPIO retention is controlled with the EM4IORETMODE field in the EMU\_EM4CTRL register. Setting EM4IORETMODE to EM4EXIT will cause retention to persist while in EM4 and reset the GPIOs during wakeup. Setting EM4IORETMODE to SWUNLATCH will cause the retention to persist until the EM4UNLATCH bit is written by software. Note that when using SWUNLATCH, the GPIO register values are still reset on wakeup from EM4. In order to ensure that the GPIO state does not change, software must re-write the GPIO registers before setting EM4UNLATCH and ending EM4 GPIO retention. See the EMU chapter for additional documentation on its registers and the EM4UNLATCH bit.

### 33.3.4 Alternate Functions

Alternate functions are connections to pins from peripherals, i.e. Timers, USARTs, etc.. These peripherals contain route registers, where the pin connections are enabled. In addition, the route registers contain a location bit field that configures which pin an output of that peripheral will be connected to if enabled. After connecting a peripheral, the pin configuration stays as set in GPIO\_Px\_MODEL, GPIO\_Px\_MODEH and GPIO\_Px\_DOUT registers. For example, the pin configuration must be set to output enable in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH for a peripheral to be able to use the pin as an output.

It is not recommended to select two or more peripherals as output on the same pin. The reader is referred to the pin map section of the device data sheet for more information on the possible locations of each alternate function.

#### 33.3.4.1 Analog Connections

When using the GPIO pin for analog functionality, it is recommended to disable the over voltage tolerance by setting the corresponding pin in the GPIO\_Px\_OVTDIS register and setting the MODEN in GPIO\_Px\_MODEL or GPIO\_Px\_MODEH equal to DISABLE to disable the input sense, output driver and pull resistors.

#### 33.3.4.2 Debug Connections

##### 33.3.4.2.1 Serial Wire Debug Connection

The SW Debug Port is routed as an alternate function and the SWDIO and SWCLK pin connections are enabled by default with internal pull up and pull down resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN and SWCLKTCKPEN bits in GPIO\_ROUTEPEN to 0.

##### 33.3.4.2.2 JTAG Debug Connection

The JTAG Debug Port is routed as an alternate function and the TMS, TCK, TDO, and TDI pin connections are enabled by default with internal pull up, pull down, no pull, and pull up resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOTMSPEN, SWCLKTCKPEN, TDOPEN, and TDIPEN bits in GPIO\_ROUTEPEN to 0.

##### 33.3.4.2.3 Disabling Debug Connections

When the debug pins are disabled, the device can no longer be accessed by a debugger. A reset will set the debug pins back to their enabled default state. The GPIO\_ROUTEPEN register can only be updated when the debugger is disconnected from the system. Any attempts to modify GPIO\_ROUTEPEN when the debugger is connected will not occur. If you do disable the debug pins, make sure you have at least a 3 second timeout at the start of your program code before you disable the debug pins. This way the debugger will have time to connect to the device after a reset and before the pins are disabled.

##### 33.3.4.2.4 ETM Trace Connections

There are five trace pins available on the device. One trace clock which can be enabled by setting the ETMTCLKPEN bitfield in GPIO\_ROUTEPEN. The four data pins can be enabled individually by setting ETMTD0PEN, ETMTD1PEN, ETMTD2PEN and ETMTD3PEN respectively in GPIO\_ROUTEPEN. It is possible to choose which pins the trace data will be exported to. The lowest trace bit will be routed to the first enabled trace pin. For example, if the ETM data port size is 2 bits and TD0 and TD3 are enabled, will make bit 0 be routed to TD0 while bit 1 will be routed to TD3.

Both the TCLK and all the TD pins can also be routed to alternate locations by configuring the ETMLOC bitfield in GPIO\_ROUTELOC0.

### 33.3.5 Interrupt Generation

Interrupts may be triggered on edge events for any GPIO pin, or on pin input levels for GPIO capable of EM4 wake-up.

### 33.3.5.1 Edge Interrupt Generation

The GPIO can generate an interrupt from any edge of the input of any GPIO pin on the device. The edge interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM3 Stop, see [Figure 33.6 Pin N Interrupt Generation on page 1128](#).

**Figure 33.6. Pin N Interrupt Generation**

External pin interrupts can be represented in the form of `EXTI[index]`, where index is the external interrupt number. For example, the `EXTI7` interrupt has an index of 7. All pins within a group of four (0-3,4-7,8-11,12-15) from all ports are grouped together to trigger one interrupt. The group of pins available to trigger an interrupt is determined by the interrupt index and calculated as  $\text{int}(\text{index}/4)$ . For example the first 4 interrupts (`EXTI0 - EXTI3`) are triggered by pins in the first group (`Px[3:0]`) and the second 4 interrupts (`EXTI4-EXTI7`) are triggered by pins in the second group (`Px[7:4]`).

The `EXTIPSELn` bits in `GPIO_EXTIPSELL` or `GPIO_EXTIPSELH` select which PORT in the group will trigger the interrupt. The `EXTIPINSELn` bits in `GPIO_EXTIPINSELL` or `GPIO_EXTIPINSELH` will determine which pin inside the selected group will trigger the interrupt.

For example if `EXTIPSEL11 = PORTB` and `EXTIPINSEL11 = 0` then `PB8` will be used for `EXTI11`. `EXTI11` uses the third group ( $11/4 = 2$ ) so the list of possible pins is `Px[11:8]`. The setting of `EXTIPSEL11` further narrows the selection to `PB[11:8]`. Finally `EXTIPINSEL11` selects the first pin in that group which is `PB8`.

The `GPIO_EXTIRISE[n]` and `GPIO_EXTIFALL[n]` registers enable sensing of rising and falling edges. By setting the `EXT[n]` bit in `GPIO_IEN`, a high interrupt flag `n`, will trigger one of two interrupt lines. The even interrupt line is triggered by any enabled even numbered interrupt flag index, while the odd interrupt line is triggered by odd flag indexes. The interrupt flags can be set and cleared by software when writing the `GPIO_IFS` and `GPIO_IFC` registers. Since the external interrupts are asynchronous, they are sensitive to noise. To increase noise tolerance, the `MODEL` and `MODEH` fields in the `GPIO_Px_MODEL` and `GPIO_Px_MODEH` registers, respectively, should be set to include glitch filtering for pins that have external interrupts enabled.

33.3.5.2 Level Interrupt Generation

GPIO can generate a level interrupt using the input of any GPIO EM4 wake-up pins on the device. The interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM4.

In order to enable the level interrupt, set the EM4WU field in the GPIO\_IEN register and the EM4WUn field in the GPIO\_EXTILEVEL register. Upon a level interrupt occurring, the corresponding EM4WU index in the GPIO\_IF register will be set along with the odd or even interrupt line depending on the index inside of GPIO\_IF. For example, by setting the EM4WU8 in GPIO\_EXTILEVEL and EM4WU[8] in GPIO\_IEN, the interrupt flag EM4WU[8] in GPIO\_IF will be triggered by a high level on pin EM4WU8 and a interrupt request will be sent on IRQ\_GPIO\_EVEN.

The wake-up granularity of the level interrupts is based on the settings of the EM4WU field in the GPIO\_IEN register and the EM4WUEN field in the GPIO\_EM4WUEN register, see [Table 33.3 Level Interrupt Energy Mode Wakeup on page 1129](#)

Table 33.3. Level Interrupt Energy Mode Wakeup

| GPIO_IEN | GPIO_EM4WUEN | Energy Mode Wakeup    |
|----------|--------------|-----------------------|
| 0        | 0            | No Interrupt          |
| 0        | 1            | EM4H,EM4S             |
| 1        | 0            | EM1,EM2,EM3,EM4H,EM4S |
| 1        | 1            | EM1,EM2,EM3,EM4H,EM4S |

33.3.6 Output to PRS

All pins within a group of four(0-3,4-7,8-11,12-15) from all ports are grouped together to form one PRS producer which outputs to the PRS. The pin from which the output should be taken is selected in the same fashion as the edge interrupts.

PRS output is not affected by the interrupt edge detection logic or gated by the IEN bits. See [Figure 33.6 Pin N Interrupt Generation on page 1128](#) for an illustration of where the PRS output signal is generated.

33.3.7 Synchronization

To avoid metastability in synchronous logic connected to the pins, all inputs are synchronized with double flip-flops. The flip-flops for the input data run on the HFBUSCLK. Consequently, when a pin changes state, the change will have propagated to GPIO\_Px\_DIN after two 2 HFBUSCLK cycles. Synchronization (also running on the HFBUSCLK) is also added for interrupt input. To save power when the external interrupts or level interrupts are not used, the synchronization flip-flops for these can be turned off by clearing INT or EM4WU,respectively, in GPIO\_INSENSE register.

### 33.4 Register Map

The offset register address is relative to the registers base address.

| Offset | Name             | Type  | Description                                      |
|--------|------------------|-------|--------------------------------------------------|
| 0x000  | GPIO_PA_CTRL     | RW    | Port Control Register                            |
| 0x004  | GPIO_PA_MODEL    | RW    | Port Pin Mode Low Register                       |
| 0x008  | GPIO_PA_MODEH    | RW    | Port Pin Mode High Register                      |
| 0x00C  | GPIO_PA_DOUT     | RW    | Port Data Out Register                           |
| 0x018  | GPIO_PA_DOUTTGL  | W1    | Port Data Out Toggle Register                    |
| 0x01C  | GPIO_PA_DIN      | R     | Port Data in Register                            |
| 0x020  | GPIO_PA_PINLOCKN | RW    | Port Unlocked Pins Register                      |

## 34. APORT - Analog Port

### Quick Facts

#### What?

The Analog Port (APORT) is a set of analog buses which are used to connect I/O pins to analog peripheral signals.

#### Why?

The APORT gives on-chip analog resources access to a large number of I/O pins, and provides the system designer with a high degree of routing flexibility.

#### How?

An analog peripheral requests a pad by simply configuring its input/output to use a channel on APORT. That selection becomes an APORT request where the APORT control switches the pad and the analog signal onto a common bus.

### 34.1 Introduction

APORT consists of wires, switches, and control logic needed to route signals between analog peripherals and I/O pins. On-chip clients can be either producers or consumers. Analog producers are active devices that drive current/voltage into an APORT, such as current or voltage DACs. Consumers are passive devices that monitor or react to the current/voltage routed to them via the APORT, such as ADCs or analog comparators (ACMP).

### 34.2 Features

- Pins are typically mapped to two different APORT buses
- Arbitration and conflict status provided to each APORT client

### 34.3 Functional Description

**Figure 34.1. Analog Bus (ABUS)**

An analog bus (ABUS) consists of analog switches connected to a common wire as shown in [Figure 34.1 Analog Bus \(ABUS\) on page 1170](#). An APORT consists of multiple ABUSes. Since many clients can operate differentially, buses are grouped by pairs as X and Y. If a given client uses a single ABUS (e.g. single-ended ADC), X and Y are just labels to differentiate the two buses.

When operating differentially, most APORT clients require that one input be chosen from an X bus and the other from a Y bus. For example, the ACMP block will not allow both positive and negative inputs to be chosen from X buses.

#### 34.3.1 I/O Pin Considerations

For external analog signals routed through the APORT, the maximum supported analog I/O voltage will typically be limited to the  $\text{MIN}(V_{\text{ANALOGSUPPLY}}, \text{IOVDD})$  (where  $V_{\text{ANALOGSUPPLY}}$  is the supply pin powering the analog module). Practically, this means that if  $\text{IOVDD}=1.8\text{ V}$ , the maximum supported analog IO voltage on APORT-routed signals will be limited to 1.8 V, regardless of the analog module supply voltage.

## 34.3.2 APORT ABUS Naming

Figure 34.2. Conceptual APORT Structure

APORT ABUSes are prefixed with "BUS" and are grouped in pairs. Each pair is uniquely identified using a letter prefix ("A", "B", "C", etc.) followed by either a "X" or "Y" to identify the ABUS in the pair. For example, "BUSDX" decodes as: "BUS"=ABUS, "D"=pair, "X"=bus. [Figure 34.2 Conceptual APORT Structure on page 1171](#) illustrates this organization.

APORT clients are generally described once in this reference manual regardless of its number of instances. For example, the ACMP client is described once, but the device could contain multiple instances of the ACMP. Because of this, for APORT client descriptions in this reference manual, the ABUS connections are generalized with the prefix "APORT" followed by a number (instead of the "BUS"

followed by a letter). It is possible that different instances of an APORT client connect to different ABUSES. For example, ACMP0 APORT1X might connect to the ABUS BUSAX while ACMP1 APORT1X might connect to ABUS BUSCX. Refer to the APORT Client Map in the device data sheet to map the generalized APORT client bus name to an actual device ABUS. A given ABUS has multiple switches which need to be identified. The switches on a bus are specified with the ABUS connection ID followed by a channel ID. For example, channel switch 7 on a given APORT client might be given as APORT1XCH7. Not all APORT channels map to actual GPIO. Refer to the APORT Client Maps in the device data sheet for APORT to GPIO mapping.

**Figure 34.3. Detailed APORT Structure**

Figure 34.3 Detailed APORT Structure on page 1172 shows all the possible routes between different peripherals and different pins via APORT BUS for the largest package of the EFR32 device family. Note that, in the figure, the BUSxX and BUSxY are annotated as xX and xY, where x=A,B,C,D and the APORTnX and APORTnY are annotated as nX and nY, where n=1,2,3,4.

For example, the IDAC APORT output 1X can be routed to pin PB14 through BUSCX. The configuration required for this routing is as follows:

- Set `IDAC_CTRL_APORTOUTSEL = APORT1XCH30`. This selects the IDAC APORT output 1X and pin PB14.
- Set `IDAC_CTRL_APORTOUTEN = 1` and `IDAC_CTRL_APORTOUTENPRS = 0`. This enables the IDAC to ungate its output to BUSCX.

Another example, when ADC is configured to operate in single channel mode for differential inputs (see [27.3.3.1 Single Channel Mode](#) for how to configure ADC in single channel mode), the positive ADC APORT input 2X and the negative ADC APORT input 2Y can be routed to pin PC9 and PC10 via BUSBX and BUSBY respectively with the following configuration:

- Set `ADCn_SINGLECTRL_POSSEL = APORT2XCH9`. This selects the pin PC9 for the positive input to the ADC.
- Set `ADCn_SINGLECTRL_NEGSEL = APORT2YCH10`. This selects the pin PC10 for the negative input to the ADC.

For smaller packages, not all GPIO pins are available. See the pinout sections of the device data sheet for pin availability on a specific device.

### 34.3.3 Managing ABUSes

The ABUSes of an APORT are shared resources. The user needs to be mindful of this in assigning I/O for different clients throughout the chip, as it is possible to have conflicts for a given ABUS. Each ABUS has an arbiter responsible for limiting the control over the ABUS to one and only one client. If multiple clients attempt to control an ABUS, the arbiter allows no client control over the ABUS and asserts a conflict signal to the clients. The user has the ability to check for such a conflict in each client's status, as well as generate an interrupt.

Having only one client control an ABUS is not the same as having only one user of an ABUS. It is possible for multiple clients to access a single ABUS, but requires all but one client to relinquish control of the ABUS. To do this, some clients have bits to disable bus master-ship which are 0 by default. One example is the APORTXMASTERDIS bit in the ACMPn\_CTRL. When set to 1, the client will not assert control of the APORT X BUS switches, but may still connect to an APORT X BUS that is controlled by another client.

For example, the ADC and ACMP both want to use the same pin on a particular ABUS the user might set the bus master disable bit to 1 for the ACMP. The ADC is the sole master of the switch configuration on that ABUS, so switches are configured using the configuration set in the ADC. When the ACMP channel is chosen on that same bus, the actual pin connection is dictated by the ADC settings for that bus.

**Figure 34.4. APORT Example 1**

Figure 34.4 APORT Example 1 on page 1174 illustrates the sharing of APORT. For illustration purposes, each ABUS is identified by a numeric index (instead of BUSAX, BUSAY, BUSBX, etc.). Also, the requests from all the APORT clients are packed into a bit-vector named **APORT\_REQ** to illustrate the request from the APORT Clients (instead of by name such as **APORT1XREQ**, **APORT1YREQ**, **APORT2XREQ**, etc.). In Figure 34.4 APORT Example 1 on page 1174, ABUS and client are the same color if the client has been granted the ABUS.

In Figure 34.4 APORT Example 1 on page 1174 ADC0 has requested ABUS[3:0], ACMP1 has requested ABUS[5:4], ACMP0 has requested ABUS[7], and ABUS[6] is unused. No APORT Client has requested the same ABUS as another, so there is no conflict.

**Figure 34.5. APORT Example 2: Bus Conflict**

In [Figure 34.5 APORT Example 2: Bus Conflict on page 1175](#) is a similar example to [Figure 34.4 APORT Example 1 on page 1174](#), but now both ACMP0 and ACMP1 are requesting ABUS[4]. This is a configuration error, so APORT grants neither client ABUS[4]. The user must resolve the conflict before ABUS[4] is useable.

**Figure 34.6. APORT Example 3: Sharing an ABUS**

[Figure 34.6 APORT Example 3: Sharing an ABUS on page 1175](#) illustrates ABUS sharing. Both ACMPs are configured identically, except ACMP0 has its APORTXMASTERDIS bit-field set to 1. There is only one APORT master for ABUS[5:4] in this case, so there is no conflict.

## 35. CSEN - Capacitive Sense Module

### Quick Facts

#### What?

The capacitive sense (CSEN) module uses a capacitance-to-digital circuit to measure the capacitance of touch-sensitive switches. The module contains an advanced capacitance-to-digital converter that can be configured to take measurements on a single port pin or scan through a group of up to 64 port pins connected via the APORT buses. Port pins/channels can also be shorted together internally to measure the combined capacitance, lowering the required energy usage for wake-on-touch applications. Adjustable maximum capacitance allows for optimal dynamic range, while hardware accumulation and filtering reduce processor computation time. Interrupts can be generated when CSEN completes conversions or when the measured value crosses a threshold.

#### Why?

The CSEN module is designed to perform extremely low-power autonomous conversions of capacitive touch switches.

#### How?

The CSEN module uses charge timing techniques to compare external capacitance against internal reference capacitors.

### 35.1 Introduction

The capacitive sensing (CSEN) module uses a capacitance-to-digital circuit to determine the capacitance on an input pin. The module can take measurements from different physical pins using the APORT multiplexer. In addition, the module can measure multiple pins in sequence using the scan modes, or multiple pins at the same time (bonded together) using the multiple-channel measurement feature. CSEN is available in EM0, EM1, EM2 and EM3.

Figure 35.1. CSEN Overview

## 35.2 Features

- Up to 64 Channels, connected via APORT buses.
- Single sample, continuous single sample, single scan and continuous scan modes supported.
- Support for both SAR and Delta Modulation conversions.
  - SAR conversions are programmable to resolutions of 10, 12, 14, or 16 bits.
  - Delta Modulation conversions support dynamic or fixed gain, and are programmable to resolutions of 10, 12, 14, or 16 bits.
- Supports channel bonding to monitor multiple channels, shorted internally, with a single conversion. The maximum number of channels to be shorted is limited by the maximum capacitance that can be measured by the analog core.
- Conversions triggered by software, PRS, or dedicated timer running from LFXO, LFRCO, or ULFRCO.
- Hardware accumulation of 1, 2, 4, 8, 16, 32, or 64 samples. The result can be right-shifted to the desired resolution or collected in a 22-bit accumulator for further processing by software.
- Hardware exponential moving average (EMA) filter for candidate touch detection during low power autonomous operation.
- Automatic threshold comparison with programmable polarity.
- Low-frequency noise filter to reject noise sources such as 50/60 Hz.
- DMA interface to collect accumulated samples in on-chip RAM. The DMA interface can also be used to program starting values for delta-modulation conversions. The DMA interface can run down to EM2.

## 35.3 Timing

Conversion timing for the CSEN block is flexible, with access to several clocks and conversion trigger sources.

### 35.3.1 Clocks

The CSEN module takes two external clock sources as input. The register interface is driven by the HUPERCLK source, allowing for fast access to the control and data for the block. The local timer is driven by the LFBCLK source. The CSEN block also contains an internal, low-energy conversion clock source (CLK<sub>CSEN</sub>). Conversions are self-timed and the block only requires external clocks under certain circumstances.

For register access, HUPERCLK<sub>CSEN</sub> must be enabled to the CSEN block in the CMU\_HUPERCLKEN0 register. When register access is not required, this clock may be shut down for energy savings.

LFBCLK<sub>CSEN</sub> is used by the local CSEN timer. It should be enabled to the CSEN block in the CMU\_LFBCLKEN0 register any time the CSEN local timer is used as a conversion trigger.

### 35.3.2 Conversion Triggers

CSEN conversions can be triggered from one of three different sources, selected by CTRL\_STM: a software register write, a PRS channel, or the local CSEN timer. The selected trigger source begins a conversion cycle. Depending on the selected conversion mode, one conversion trigger may generate one or many output words from the CSEN module. See [35.6 Conversion Modes](#) for more details on the CSEN output for each mode.

#### Software Triggered Conversions

When CTRL\_STM is set to START, conversions are triggered by software. Software triggering is typically used when operating the CSEN block in a continuous mode to gather conversions as quickly as the converter allows. Software triggering may also be used in applications where a single conversion or one scan cycle is needed infrequently and sporadically by different software processes. When configured for software triggering, a write of the CMD\_START bit to logic 1 initiates conversions.

#### PRS Triggered Conversions

When CTRL\_STM is set to PRS, conversions are triggered via a PRS event. PRS triggers are typically used when it is necessary to synchronize CSEN conversions with other events in the system. For example, the LETIMER may be used in EM2 to initiate a CSEN scan operation and other events at the same time. A number of different PRS channels may be configured as the trigger source. The specific PRS channel to be used as a trigger source is selected in the PRSSEL register.

## CSEN Timer Triggered Conversions

When CTRL\_STM is set to TIMER, a local 8-bit CSEN timer is used to trigger conversions. The local timer is typically used in conjunction with non-continuous conversion modes to provide periodic conversion triggers at slow sampling rates. The local timer is clocked from LFBCLK<sub>CSEN</sub>, and configured with the TIMCTRL register. The CSEN timer has a local prescaler (set by the TIMCTRL\_PCPRESC field), which divides the LFBCLK<sub>CSEN</sub> further. The TIMCTRL\_PCTOP field sets the reload value for the CSEN timer. The CSEN timer counts down for the number of clocks specified in TIMCTRL\_PCTOP. When the counter reaches zero, a conversion cycle is triggered and the timer is reloaded.

### 35.3.3 Shutdown and Warmup

Many target applications for CSEN require low power operation and infrequent sampling. By default, the converter will power down when it is not in use to save energy. Upon receiving a conversion trigger, the CSEN block will power on and wait for (3 + TIMCTRL\_WARMPCNT) CLK<sub>CSEN</sub> clock cycles before starting conversions.

CTRL\_WARMUPMODE defines the behavior of the CSEN converter when it is not actively converting. Software may choose to keep the CSEN block powered on at all times by setting the CTRL\_WARMUPMODE bit to logic 1.

## 35.4 Conversion Types

The CSEN block offers two different types of conversions: SAR, and Delta Modulation.

### 35.4.1 SAR Conversion Type

SAR (successive approximation register) conversions are self-contained and do not depend on the results of any previous conversions. SAR conversions will be performed when CTRL\_CONVSEL is set to SAR. CTRL\_SARCR sets the SAR conversion resolution, and is selectable between 10, 12, 14, or 16 bits. SAR conversions last for N cycles of CLK<sub>CSEN</sub>, where N is the selected resolution (i.e. 12-bit conversions last for 12 CLK<sub>CSEN</sub> cycles).

Every SAR conversion consists of a set of tests, one for each bit of the converter. The MSB is tested first, followed by all other bits down to the LSB. Each test narrows the possible value by 1/2 until the final result is determined.

### 35.4.2 Delta Modulation Conversion Type

Delta modulation (DM) conversions provide significant noise, response time, and energy consumption improvements over SAR conversions. A DM conversion inherently takes longer than a SAR conversion to arrive at one result. However, it is much less susceptible to noise events in the system. Whereas a large number of SAR conversions may need to be averaged to produce a desired noise resolution, the same noise resolution can be achieved with few DM conversions. However, DM conversions require more specific knowledge of the underlying conversion process to implement effectively. Silicon Laboratories software libraries use delta modulation for the best possible performance. It is recommended to use the provided libraries in most applications. The information provided in this section is intended as a reference for CSEN module driver development.

Delta modulation conversions are performed when CTRL\_CONVSEL is set to DM. DMCFG\_DMCR sets the DM conversion resolution, and is selectable between 10, 12, 14, or 16 bits. The selected resolution does not have an impact on conversion timing.

A delta modulated conversion begins with a test against a provided initial value, known as the baseline. If the comparison is high (the external capacitor is larger than the initial value), the comparison value is increased by a specified amount (the delta). If the comparison is low, the comparison value is decreased by the delta. The cycle then repeats, testing against the new value. Each subsequent test brings the test value closer to the external capacitance value, until the desired number of tests have been performed and an output result is produced. The converter may be configured to use a fixed delta value, or to reduce the value by a factor of two at specific intervals.

The DM state machine is configured using different fields in the DMCFG register. The DMG field sets the initial delta step to be used, between 0 and 255 codes at the selected resolution (specified by DMCFG\_CRMODE). The DMCFG\_DMR field specifies how many tests in a row are to be performed using each delta step. The converter will perform ( $4 \times \text{DMCFG\_DMR}$ ) tests at each delta step for  $\text{DMCFG\_DMR} > 0$ . For  $\text{DMCFG\_DMR} = 0$ , the converter will perform 64 tests at each delta step. The number of tests performed at each delta step is referred to here as a "cycle". The DMCFG\_DMCR field specifies how many cycles the state machine will take to produce one conversion output. For  $\text{DMCFG\_DMCR} = 0$ , the number of cycles will be 16. If the DMCFG\_DMGRDIS bit is cleared to 0, the delta step will be halved after each cycle. If DMCFG\_DMGRDIS is set to 1, all cycles will use a fixed delta step value. Each test performed by the converter requires one  $\text{CLK}_{\text{CSEN}}$ , and so a full DM conversion requires  $\text{number\_of\_cycles} \times \text{tests\_per\_cycle}$  clocks of  $\text{CLK}_{\text{CSEN}}$ . [Figure 35.2 Delta Modulation Conversion With Gain Reduction \(DMCFG\\_DMGRDIS = 0\)](#) on page 1179 and [Figure 35.3 Delta Modulation Conversion With Fixed Delta Step \(DMCFG\\_DMGRDIS = 1\)](#) on page 1180 show how delta modulation conversions are performed with and without gain reduction.

**Figure 35.2. Delta Modulation Conversion With Gain Reduction (DMCFG\_DMGRDIS = 0)**

**Figure 35.3. Delta Modulation Conversion With Fixed Delta Step (DMCFG\_DMGDIS = 1)**

The initial test value (baseline) for a DM conversion can be written to the DMBASELINE register prior to the start of the conversion. DMBASELINE contains two fields: BASELINEUP and BASELINEDN. Only the BASELINEUP field is used when chopping is disabled (CTRL\_CHOPEN = 0). If chopping is enabled, software must maintain a second baseline value for the ramp-down phase, and write it to BASELINEDN.

## 35.5 Input Configuration

CSEN channel inputs are routed through the on-chip APORT bus matrix. Each APORT bus is a shared resource among certain analog peripherals on the device. Some knowledge of how the CSEN block utilizes the APORT buses is necessary to avoid conflicts with other peripherals.

Each time the CSEN module connects to an external pin to take a conversion, it uses one or two of the shared APORT buses. By default, the CSEN module charges the external capacitor through one APORT connection on the CEXT line, and senses the voltage at the capacitor through a different APORT connection on the CEXT\_SENSE line. This eliminates any errors introduced by series impedance of the APORT buses, particularly if the external capacitance is large. To conserve on-chip resources, it is possible to both charge and sense through the CEXT line, by setting CTRL\_LOCALSENS to logic 1. When CTRL\_LOCALSENS is set to 1, the CEXT\_SENSE line is not needed and the corresponding bus may be used by other peripherals.

The CSEN module has four APORT buses connected to the CEXT signal and four APORT buses connected to the CEXT\_SENSE signal. The specific buses used for each pin selection depend on the channel, according to [Table 35.1 CSEN APORT Bus Connectivity on page 1181](#). For example, if APORT1XCH4 (APORT1 channel 4) is selected in SINGLECTRL\_SINGLESEL, the CEXT signal will be connected to the shared BUSAX, channel 4. If CTRL\_LOCALSENS is set to DISABLE, then the CEXT\_SENSE signal will be connected to APORT2YCH4, and use the shared bus BUSBY, channel 4.

The same connections apply to scan mode conversions and bonded conversions. For scan mode conversions, the connection through the bus is only made on one channel at a time, when that channel is being converted in the scan. For bonded connections, all selected channel connections are made simultaneously.

**Table 35.1. CSEN APORT Bus Connectivity**

| Selected CSEN Channel | CEXT Routing          | CEXT_SENSE Routing<br>(LOCALSENS = 0) |
|-----------------------|-----------------------|---------------------------------------|
| APORT1, Even Channel  | APORT1XCHn / BUSAXCHn | APORT2YCHn / BUSBYCHn                 |
| APORT1, Odd Channel   | APORT1YCHn / BUSAYCHn | APORT2XCHn / BUSBXCHn                 |
| APORT3, Even Channel  | APORT3XCHn / BUSCXCHn | APORT4YCHn / BUSDYCHn                 |
| APORT3, Odd Channel   | APORT3YCHn / BUSCYCHn | APORT4XCHn / BUSDXCHn                 |

When the CSEN module requests an APORT bus that is already in use by another peripheral, an APORT conflict will occur. The IF\_APORTCONFLICT interrupt flag will be set to 1 (generating an interrupt if enabled), and the APORTCONFLICT register will reflect the bus(es) where the conflict occurred. Careful channel planning for the system will avoid APORT conflicts in most systems.

Channel selection for the CSEN module depends on the selected conversion mode. More details on how to select specific input pins are found in [35.6 Conversion Modes](#).

## 35.6 Conversion Modes

The CSEN module supports several conversion modes:

- Single Channel - A conversion trigger starts conversions on a single channel. One output result is produced, then the converter will halt.
- Scan - A conversion trigger starts a scan sequence, which converts a specified number of channels independently and in sequence. One output result is produced per channel, then the converter will halt.
- Bonded Channel - A conversion trigger starts conversions on a bonded channel. A bonded channel is several input channels which are shorted together internally. One output result is produced, then the converter will halt.
- Continuous Single Channel - A conversion trigger starts continuous conversions on a single channel. The single channel conversion will re-trigger automatically after each output result and repeat until halted.
- Continuous Scan - A conversion trigger starts continuous channel scanning. The scan sequence will re-trigger automatically at the end of each scan and repeat until halted.
- Continuous Bonded Channel - A conversion trigger starts continuous conversions on a bonded channel. The bonded channel conversion will re-trigger automatically after each output result and repeat until halted.

The conversion mode is selected by the CTRL\_CM and CTRL\_MCEN fields. Refer to [35.6.1 Single Channel Conversions](#), [35.6.2 Scan Conversions](#), and [35.6.3 Bonded Channel Conversions](#) for specific information on configuring the CSEN module to the desired conversion mode.

### 35.6.1 Single Channel Conversions

CSEN is configured for single channel mode when CTRL\_MCEN = DISABLE and CTRL\_CM = SGL. For continuous single channel mode, CTRL\_MCEN = DISABLE and CTRL\_CM = CONTSGL.

In single channel mode, SINGLECTRL\_SINGLESEL specifies the input channel to be converted. Firmware may select any of the pins connected to the CEXT signal via the APORT. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

When a single channel conversion is triggered, the CSEN block will use the configured conversion type (SAR or DM) to convert the capacitance seen at the selected input pin to a digital value one or more times. The hardware accumulator setting (CTRL\_ACU) determines how many times the input pin will be sampled and accumulated before an output word is produced. The IF\_CONV interrupt flag will be set to 1 by hardware when an output word is available in the DATA register.

**Note:** The auto-ground feature is typically not used in single channel conversion mode and should be disabled by software. However, if auto-grounding is enabled, it will ground the unused channels specified by the SCANINPUTSEL0/1 and SCANMASKSEL0/1 registers. See the channel selection discussion in [35.6.2 Scan Conversions](#) for more details.

### 35.6.2 Scan Conversions

CSEN is configured for scan mode when CTRL\_MCEN = DISABLE and CTRL\_CM = SCAN. For continuous scan mode, CTRL\_MCEN = DISABLE and CTRL\_CM = CONTSCAN.

In scan mode, the input channels to be converted during the scan are determined by the SCANINPUTSEL0/1 and SCANMASK0/1 registers. There are 64 available channels in the scanner logic. SCANINPUTSEL0/1 allow software to route CSEN scan channels to APORT-capable GPIO in groups of 8. SCANMASK0/1 specify which channels on those groups are to be included in the scan.

**Note:** It is possible to include the same group of 8 in more than one place in the scan sequence. However, for the majority of use cases, the SCANINPUTSEL0 register should be written to 0x07060504, and SCANINPUTSEL1 should be written to 0x0F0E0D0C. This will configure the CSEN scan channels to match their order in bonded mode.

Individual channels are included in the scan based on their bit positions in the mask registers, SCANMASK0 and SCANMASK1. A '1' in the corresponding bit of the mask register will include that channel in the scan. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

When a scan conversion is triggered, the CSEN block will convert each of the selected channels in turn, starting at channel 0 and working up to channel 63. If a channel is not configured for scan in the SCANMASK0/1 register (i.e. the bit for that channel is '0'), it will be skipped.

An example of how the scan logic progresses through channels is shown in [Figure 35.4 Scan Mode Sequencing on page 1183](#). In this simple example, SCANMASK0 = 0x00000318 and SCANMASK1 = 0x00000006, which selects channels 3, 4, 8, 9, 33, and 34 in turn.

|           | SCANMASK Values | CSEN Input Channel | DATA Output Order |
|-----------|-----------------|--------------------|-------------------|
| SCANMASK0 | 0               | 0                  |                   |
|           | 1               | 1                  |                   |
|           | 2               | 2                  |                   |
|           | 3               | 3                  | Channel 3         |
|           | 4               | 4                  | Channel 4         |
|           | 5               | 5                  |                   |
|           | 6               | 6                  |                   |
|           | 7               | 7                  |                   |
|           | 8               | 8                  | Channel 8         |
|           | 9               | 9                  | Channel 9         |
|           | 10              | 10                 |                   |
|           | 11              | 11                 |                   |
|           | 12              | 12                 |                   |
|           | 13              | 13                 |                   |
| SCANMASK1 | 27              | 27                 |                   |
|           | 28              | 28                 |                   |
|           | 29              | 29                 |                   |
|           | 30              | 30                 |                   |
|           | 31              | 31                 |                   |
|           | 0               | 32                 |                   |
|           | 1               | 33                 | Channel 33        |
|           | 2               | 34                 | Channel 34        |
|           | 3               | 35                 |                   |
|           | 4               | 36                 |                   |
|           | 27              | 59                 |                   |
|           | 28              | 60                 |                   |
|           | 29              | 61                 |                   |
|           | 30              | 62                 |                   |
|           | 31              | 63                 |                   |

**Figure 35.4. Scan Mode Sequencing**

An auto-grounding feature is available for scan mode conversions. This feature forces hardware to ground all of the non-active CSEN channels selected by SCANMASK0/1, to reduce bleed-through from measurements on other CSEN channels. Auto-grounding is enabled by setting the CTRL\_AUTOGND bit to logic 1.

CSEN will use the configured conversion type (SAR or DM) to convert the capacitance seen at each of the selected input pins to a digital value one or more times. The hardware accumulator setting (CTRL\_ACU) determines how many times each input pin will be sampled and accumulated before an output word is produced. The IF\_CONV interrupt flag will be set to 1 by hardware when each output word is available in the DATA register, and the IF\_EOS interrupt flag will be set to 1 by hardware at the completion of a scan cycle.

The DMBASELINE register provides the starting point for DM conversions. This starting point will be different for each channel in the scan, and the DMBASELINE register should be updated accordingly. This is typically done via DMA.

**Note:** DMA or software must read the output words from the DATA register before completion of the next conversion. New conversions will over-write the DATA register contents.

35.6.3 Bonded Channel Conversions

CSEN is configured for bonded mode when CTRL\_MCEN = ENABLE and CTRL\_CM = SGL. For continuous bonded mode, CTRL\_MCEN = ENABLE and CTRL\_CM = CONTSGL.

Bonded channel conversions are intended primarily for wake-on-touch applications where minimal power consumption is necessary. Bonded channel conversions operate similar to single channel conversions, except that multiple channels are shorted together and converted as a single capacitance value.

In bonded mode, the channels to be bonded are based on their bit positions in the mask registers SCANMASK0 and SCANMASK1, according to a fixed location, as shown in [Figure 35.5 CSEN Input Configuration in Bonded Mode on page 1184](#). SCANMASK0 selects channels from APORT1 and SCANMASK1 selects channels from APORT3. Even-numbered channels are connected through the X bus, and odd-numbered channels are connected through the Y bus. Channels with a '1' in the corresponding position of SCANMASK0/1 will be shorted together during the conversion and converted as a single channel. Refer to the Analog Port (APORT) Client Maps section in the product data sheet for mapping of the CEXT signal to specific pins.

|           | CSEN Input Channel | APORT Connection | Shared Bus Channel |
|-----------|--------------------|------------------|--------------------|
| SCANMASK0 | 0                  | APORT1XCH0       | BUSAX channel 0    |
|           | 1                  | APORT1YCH1       | BUSAY channel 1    |
|           | 2                  | APORT1XCH2       | BUSAX channel 2    |
|           | 3                  | APORT1YCH3       | BUSAX channel 3    |
|           | 4                  | APORT1XCH4       | BUSAY channel 4    |
|           | •                  | •                | •                  |
|           | •                  | •                | •                  |
|           | •                  | •                | •                  |
|           | 27                 | APORT1YCH27      | BUSAY channel 27   |
|           | 28                 | APORT1XCH28      | BUSAX channel 28   |
|           | 29                 | APORT1YCH29      | BUSAY channel 29   |
|           | 30                 | APORT1XCH30      | BUSAX channel 30   |
|           | 31                 | APORT1YCH31      | BUSAY channel 31   |
|           |                    |                  |                    |
|           |                    |                  |                    |
|           |                    |                  |                    |
|           | CSEN Input Channel | APORT Connection | Shared Bus Channel |
| SCANMASK1 | 0                  | APORT3XCH0       | BUSCX channel 0    |
|           | 1                  | APORT3YCH1       | BUSCY channel 1    |
|           | 2                  | APORT3XCH2       | BUSCX channel 2    |
|           | 3                  | APORT3YCH3       | BUSCX channel 3    |
|           | 4                  | APORT3XCH4       | BUSCY channel 4    |
|           | •                  | •                | •                  |
|           | •                  | •                | •                  |
|           | •                  | •                | •                  |

Figure 35.5. CSEN Input Configuration in Bonded Mode

When a bonded conversion is triggered, the CSEN block will use the configured conversion type (SAR or DM) to convert the total capacitance seen at the selected input pins to a digital value one or more times. The hardware accumulator setting (CTRL\_ACU) determines how many times the input pins will be sampled and accumulated before an output word is produced. The IF\_CONV interrupt flag will be set to 1 by hardware when an output word is available in the DATA register.

**Note:** The auto-ground feature should not be used in bonded conversion mode. Software should clear CTRL\_AUTOGND to 0 when configuring CSEN for bonded conversions.

## 35.7 Output Data

Output data from the CSEN module is posted to the DATA register. The data encoding can be affected by several configuration settings.

Figure 35.6 Data Encoding for Different Resolution Settings on page 1185 shows the effect that the resolution settings (CTRL\_SARCR for SAR conversions or DMCFG\_CRMODE for DM conversions) have on the output word. In this example, only one sample is accumulated. Regardless of the resolution setting, the MSB is always presented in bit position 15.

**Figure 35.6. Data Encoding for Different Resolution Settings**

A hardware accumulator allows the CSEN block to accumulate multiple samples on the same channel for each conversion data word produced, and automatically right-shift to normalize the data to 16 bits. This is effective as a simple noise filter. The CTRL\_ACU field sets the number of samples to be accumulated from 1, 2, 4, 8, 16, 32, or 64 samples. The right-shift operation can optionally be disabled by setting CTRL\_DRSF to 1. Figure 35.7 Data Encoding for Different Accumulator Settings on page 1185 shows the effects of the accumulator, with and without right-shifting on the output data word. In this example, the sample resolution is fixed at 12 bits, but the same principles apply to any resolution setting.

**Figure 35.7. Data Encoding for Different Accumulator Settings**

When the conversion type is delta modulation (CTRL\_CONVSEL = DM) and chopping is enabled (CTRL\_CHOPEN = ENABLE), this is a special case for the output word. In this case, both the "up" and the "down" portions of the conversion must be stored. The DATA register will hold the "up" portion in the lower 16 bits and the "down" portion in the upper 16 bits as shown in Figure 35.8 Data Encoding for Delta Modulation With Chopping on page 1186.

Figure 35.8. Data Encoding for Delta Modulation With Chopping

35.8 Low Frequency Noise Filter (Chopping)

The CSEN module includes a low-frequency noise filter, which is implemented internally using a chopping mechanism. Chopping is enabled by setting CTRL\_CHOPEN to ENABLE. In a normal conversion cycle (CTRL\_CHOPEN = DISABLE), the charge timing is always performed on a positive (up) ramp. When chopping is enabled, the converter will alternate between using a positive (up) and negative (down) ramp for each sample. While the absolute capacitance value contributes the same amount for an up or a down conversion, any low-frequency offset artifacts due to supply changes will have opposite polarity. Averaging the results of an "up" and a "down" conversion taken back-to-back effectively eliminataes the low-frequency offset differences.

When chopping is used with SAR type converisons, the accumulator performs the necessary averaging in hardware. The accumulator must be set to average at least two samples when chopping is enabled. Because the accumulator always works on multiples of two samples, an even number of "up" and "down" samples will be included in the average.

When chopping is used with DM type conversions, user software must maintain both an "up" and "down" portion of the baseline for the conversion separately. For this reason, the output word will contain both values when using DM conversions. In order to gain the benefits of chopping in DM mode, software should average the "up" and "down" results together.

### 35.9 Wake on Threshold and Exponential Moving Average

The CSEN module has the capability to operate in the energy-efficient EM2 or EM3 modes and autonomously wake the system when a predetermined threshold is crossed, either while doing single channel conversions or bonded channel conversions. This allows a system to monitor one or more input channels to implement low-energy "wait-for-touch" features. There are two different comparator threshold tests available for this purpose:

- Absolute - used to compare data outputs with "less than or equal" or "greater than" tests against a fixed value. This is useful for applications with short sleep durations, which simply want to wake quickly if a certain condition is met.
- Relative EMA - used to compare data outputs against a moving average window. This is extremely useful for applications with long-term sleep requirements. The relative comparison allows the CSEN module to adjust for slow changes in capacitance such as those due to environmental changes (temperature, supply) without waking the system.

The absolute test is used when CTRL\_CMPEN = ENABLE and CTRL\_EMACMP = DISABLE. In this mode, any output word written to the DATA register will be compared against the value in the CMPTHR register. The polarity of the comparison is configured with the CTRL\_CMPPOL field. Setting CTRL\_CMPPOL to GT means that the comparison will be true if DATA is greater than CMPTHR. Setting CTRL\_CMPPOL to LTE means that the comparison will be true if DATA is less than or equal to CMPTHR. On a true result, the IF\_CMP interrupt flag is set to 1, and any continuous conversion in progress will be halted.

The relative EMA test is used when CTRL\_EMACMP = ENABLE. In this mode, the exponential moving average (EMA) value is used to establish a low-noise average code reading. The EMA is a moving average that is re-calculated on every output data word from the converter, according to the following equation:

$$\text{EMA}[n] = \text{EMA}[n-1] - \text{EMA}[n-1]/N + \text{DATA}/N,$$

**Figure 35.9. CSEN Exponential Moving Average Calculation**

The EMA register stores the current EMA value. This register may be written by software to quickly establish a new baseline average. N in the equation above is the sample weighting of the EMA filter, and is controlled with the EMASAMPLE field. Lower values of EMASAMPLE mean less averaging, and quicker response time, while higher EMASAMPLE values will reject more noise at the expense of response time.

When relative EMA comparisons are enabled, every new sample is compared with a window around the EMA. The lower bound of this window is EMA - CMPTHR, and the upper bound of the window is EMA + CMPTHR. If the new sample written to DATA falls outside that window (lower than the lower bound or higher than the upper bound), the CMP interrupt flag is set to 1 and any continuous conversion in progress is halted. Using the EMA comparison, large jumps in the output data word will trip the comparator and wake the system, but gradual changes will not trigger false positives. [Figure 35.10 Wake on Threshold With Relative EMA on page 1188](#) shows an example of the EMA moving average filter and window.

**Figure 35.10. Wake on Threshold With Relative EMA**

### 35.10 Analog Adjustments

The analog front-end of the CSEN module has some additional controls that may be useful in certain applications.

#### 35.10.1 Current Reference and Gain

The internal current source used for charging the reference capacitor can be adjusted using the `ANACTRL_IREFPROG` field. This adjusts the ratio of the internal reference current source vs. the external drive current source, and thereby adjusts the effective gain of the converter. The lowest gain setting is when `ANACTRL_IREFPROG = 0`, and the highest is with `ANACTRL_IREFPROG = 7`. The difference between the lowest and highest setting is approximately 10x. High gain gives the best sensitivity and resolution for small capacitors, such as those typically implemented as touch-sensitive PCB features. Lower gain allows for larger capacitor values to be measured. It can also be useful to lower the gain when performing bonded channel conversions.

#### 35.10.2 Current Drive

The external capacitor is charged with a current-source DAC during conversions. The full scale output of the current DAC can be adjusted using the `ANACTRL_IDACIREFS` field. When `ANACTRL_IDACIREFS` is 0, the drive current is at its maximum setting. For `ANACTRL_IDACIREFS` settings of 1-7, the drive current is reduced by a factor of `ANACTRL_IDACIREFS / 8`. For most touch switch applications, the maximum (default) current drive (`ANACTRL_IDACIREFS = 0`) should be used. Lower current drive may be useful when there is additional series impedance between the device pin and the capacitive sensor.

#### 35.10.3 Reset (Discharge) Timing

During a conversion, the external capacitance is charged and discharged multiple times. The amount of time used for the reset (discharge) phase is controlled by the `ANACTRL_TRSTPROG` field. For most touch sensitive switch applications, the fastest (default) timing should be used. Extended reset timing may be useful in applications with additional series impedance between the device pin and the capacitive sensor.

### 35.11 DMA Interface

The CSEN module has DMA support for reads of the DATA register and writes to the DMBASELINE register. This enables the CSEN module to operate autonomously from software, either to free up software cycles during EM0 or to enable lower power operation in EM1 and EM2.

DMA transfers to and from the CSEN module are enabled by setting the CTRL\_DMAEN bit to 1. If the converter is used in SAR mode, only DMA reads (from the DATA register) are triggered. If the converter is used in delta modulation mode, both DMA reads from the DATA register and DMA writes to the DMBASELINE register are triggered.

Requests for a DATA register read occur at the end of a conversion cycle any time the CSEN module writes new output information to the DATA register. DMA may read half words (16 bits) or full words (32 bits) from the DATA register, depending on the specific CSEN configuration and the needs of the application. The CSEN module does not halt when the DMA read request is posted. It will immediately begin the next conversion. If the DMA read request is not serviced by the time the next conversion has completed, the IF\_DMAOF flag will be set to indicate an overflow event has occurred.

Requests for a data write to the DMBASELINE register occur only when using delta-modulation type conversions. The write request will be triggered at the start of a conversion, prior to the first sample comparison. The conversion will not begin until the DMA services this write request.

**Note:** If an absolute or EMA threshold interrupt is enabled when using the DMA, software must be aware that the converter will halt when the interrupt condition occurs. In this case it may be necessary to reconfigure portions of the DMA transfer before resuming conversions.

## 35.12 Register Map

The offset register address is relative to the registers base address.

| Offset | Name               | Type  | Description                        |

|      |             |            |        | Scan channel mask for CSEN channels CSEN_INPUT0 through CSEN_INPUT31. For scan mode conversions, a '1' in any bit position will include the channel specified by SCANINPUTSEL0 in a scan. For bonded channel conversions, a '1' in any bit position includes the corresponding channel from APORT1 / BUSA in the bonded conversion. If AUTOGND = ENABLE the scan mask also determines the pins that will be grounded when inactive, for both scan and single channel conversions. |

## 35.13.8 CSEN\_SCANINPUTSEL0 - Scan Input Selection 0

| 31:0 | SCANINPUTEN | 0x00000000 | RW     | <b>Scan Channel Mask.</b><br><br>Scan channel mask for CSEN channels CSEN_INPUT32 through CSEN_INPUT63. For scan mode conversions, a '1' in any bit position will include the channel specified by SCANINPUTSEL1 in a scan. For bonded channel conversions, a '1' in any bit position includes the corresponding channel from APORT3 / BUSC in the bonded conversion. If AUTOGND = ENABLE the scan mask also determines the pins that will be grounded when inactive, for both scan and single channel conversions. |

## 36. Revision History

### Revision 1.1

May, 2019

- Restored PLFRCO and associated details throughout document (re-introduced with Rev -D OPNs).
- [Table 2.3 EFR32xG13 Wireless Gecko Timers Overview on page 38](#): Added low frequency clock sources for SysTick.
- [4.7.2 MODULEINFO - Module trace information](#) ; [4.7.3 MODXOCAL - Module Crystal Oscillator Calibration](#) : Added device identification entries for modules to the DI page.
- [7.3.2 Embedded Trace Macrocell V3.5 \(ETM\)](#): Clarified clock configuration requirements for enabling ETM.
- [8.2 Features](#): Updated flash zero wait-state access max frequency.
- [8.3.2 Lock Bits \(LB\) Page Description](#): Revised configuration lock word description to include default state.
- [Table 9.3 List of Peripherals Capable of Waking Up LDMA in EM2 Deep Sleep or EM3 Stop on page 204](#): Added table of peripherals that can wake LDMA.
- [11.3.9.2.1 EM2/EM3 Voltage Scaling Guidelines](#): Appended note regarding HFRCO clock default frequency when waking to EM0/EM1 while using EM2/EM3 voltage scaling.
- [Figure 24.1 VDAC Overview on page 796](#): Added HFPERCLK and prescaler block as VDAC clock source.
- [27.3.3.2 Scan Mode](#): Added note regarding the ADC conversion scan ID in continuous scan mode with no delay between repeated conversions.
- [27.3.10.2 Repetitive Mode](#): Added note regarding the ADC in SYNC mode with repetitive conversions when using a delay between repeated conversions.

### Revision 1.0

March, 2018

- Removed PLFRCO and associated details throughout document (removed from Rev -C OPNs).
- [Figure 4.3 System Address Space With Peripheral Listing on page 47](#): Fixed to show all peripheral mappings.
- [8.5.19 MSC\\_BOOTLOADERCTRL - Bootloader Read and Write Enable, Write Once Register](#) : Corrected descriptions of BLWDIS and BLRDIS.
- [10.3.3 Power-On Reset \(POR\)](#): Clarification of Power-On Reset supply connection (AVDD) and threshold (1.2V).
- Added information about analog peripheral power connections and VDDX\_ANA supply rail throughout document.
- Added information about IOVDD and AVDD restrictions on analog input signals throughout document.
- [11.3.11 Brown Out Detector \(BOD\)](#): Included missing BOD details in paragraph.
- [Table 11.2 EMU Energy Mode Overview on page 252](#): Added footnote for GPIO Pin State Retention in EM4 modes.
- [11.3.5.1 Bypass Mode](#): Added information on when bypass mode can be used and how to do so.
- [11.3.9.1 EM0/EM1 Voltage Scaling](#): Clarification of reset effects on voltage scaling operations in progress.
- [11.3.12 Voltage Monitor \(VMON\)](#): Added note about VMON hysteresis and rising/falling thresholds.
- [12. CMU - Clock Management Unit](#) : Removed erroneous information about DPLL.
- [12.3.2.4 HFXO Configuration](#): Clarified steady state timeout and state transition to ready.
- [12.3.2.5 LFXO Configuration](#): Added recommendations for GAIN setting.
- [16.3.1.3 Configurable PRS Logic](#): Clarified ANDNEXT and ORPREV behavior for first and last PRS channels.
- [16.3.2 Producers](#): Added more detail about GPIO producer source.
- [16.3.5 DMA Request on PRS](#): Fixed incorrect bit / register names and clarified signals for DMA are PRSRQE0 and PRSRQE1.
- [27.3.17 ADC Programming Model](#): Added note about changing to ASYNC clock mode with KEEPADCWARM.

### Revision 0.5

May 3rd, 2017

- [Section 7.3.1](#): Clarified default state of debug logic from power-on is JTAG.
- [Section 8.x](#): Added language to clarify that flash erase and write are only supported in high voltage modes (Voltage Scale Level 2).
- [Section 12.x](#): Added PLFRCO to low-frequency clocking diagram, and to discussions of LFnCLKs as needed.
- [Table 12.3](#): Changed maximum frequency condition for WS2 to 20 MHz.
- [TRNGn\\_FIFOLEVEL register](#): Marked as actionable reads, because the STATUS\_FULLIF flag is cleared upon reading this register.
- [Figure 34.3](#): Updated APORT diagram to include internal signal connections between analog peripherals.
- Removed *Confidential* watermark.

## Revision 0.1

January 17th, 2017

Initial release.

## Appendix 1. Abbreviations

This section lists abbreviations used in this document.

**Table 1.1. Abbreviations**

| Abbreviation | Description                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------|
| ADC          | Analog to Digital Converter                                                                        |
| AES          | Advanced Encryption Standard                                                                       |
| AFC          | Automatic Frequency Control                                                                        |
| AGC          | Automatic Gain Control                                                                             |
| AHB          | AMBA Advanced High-performance Bus. AMBA is short for "Advanced Microcontroller Bus Architecture". |
| APB          | AMBA Advanced Peripheral Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".       |
| APC          | Automatic Power Control                                                                            |
| ASK          | Amplitude Shift Keying                                                                             |
| BLE          | Bluetooth Low Energy                                                                               |
| BLE-LR       | Bluetooth Low Energy Long Range                                                                    |
| BR           | Baud Rate                                                                                          |
| BT           | Bandwidth Time product                                                                             |
| BUFC         | Buffer Controller                                                                                  |
| BW           | Bandwidth                                                                                          |
| CBC          | Cipher Block Chaining (AES mode of operation)                                                      |
| CBC-MAC      | Cipher Block Chaining - Message Authentication Code (AES mode of operation)                        |
| CC           | Compare / Capture                                                                                  |
| CCA          | Clear Channel Assessment                                                                           |
| CFB          | Cipher Feedback (AES mode of operation)                                                            |
| CHF          | Channel Filter                                                                                     |
| CLK          | Clock                                                                                              |
| CM3          | ARM Cortex-M3                                                                                      |
| CM4          | ARM Cortex-M4                                                                                      |
| CMD          | Command                                                                                            |
| CMU          | Clock Management Unit                                                                              |
| CRC          | Cyclic Redundancy Check                                                                            |
| CTR          | Counter mode (AES mode of operation)                                                               |
| CTRL         | Control                                                                                            |
| DBG          | Debug                                                                                              |
| DC           | Direct Current                                                                                     |
| DEC          | Decimator                                                                                          |
| DEMOD        | Demodulator                                                                                        |

| Abbreviation | Description                                  |
|--------------|----------------------------------------------|
| DSA          | Detection of Signal Arrival                  |
| DSSS         | Direct Sequence Spread Spectrum              |
| ECB          | Electronic Code Book (AES mode of operation) |
| EFR32        | Wireless Gecko                               |
| EM           | Energy Mode                                  |
| EMU          | Energy Management Unit                       |
| FEC          | Forward Error Correction                     |
| FIR          | Finite Impulse Response                      |
| FRC          | Frame Controller                             |
| FSK          | Frequency Shift Keying                       |
| GFSK         | Gaussian Frequency Shift Keying              |
| GMSK         | Gaussian Minimum Shift Keying                |
| GPIO         | General Purpose Input / Output               |
| HFRCO        | High Frequency RC Oscillator                 |
| HFXO         | High Frequency Crystal Oscillator            |
| HW           | Hardware                                     |
| Hz           | Hertz                                        |
| IF           | Intermediate Frequency                       |
| ISR          | Interrupt Service Routine                    |
| LFRCO        | Low Frequency RC Oscillator                  |
| LFXO         | Low Frequency Crystal Oscillator             |
| LNA          | Low Noise Amplifier                          |
| LO           | Local Oscillator                             |
| MOD          | Modulator                                    |
| MODEM        | Modulator and Demodulator                    |
| MSK          | Minimum Shift Keying                         |
| NRZ          | Non Return to Zero                           |
| NVIC         | Nested Vector Interrupt Controller           |
| OFB          | Output Feedback Mode (AES mode of operation) |
| OOK          | On Off Keying                                |
| OQPSK        | Offset Quadrature Phase Shift Keying         |
| OSR          | Over-Sampling Ratio                          |
| PA           | Power Amplifier                              |
| PD           | Power Down                                   |
| PHY          | Physical Layer                               |
| PROTIMER     | Protocol Timer                               |
| PRS          | Peripheral Reflex System                     |

| Abbreviation | Description                        |
|--------------|------------------------------------|
| PWM          | Pulse Width Modulation             |
| RAC          | Radio Controller                   |
| RAM          | Random Access Memory               |
| RF           | Radio Frequency                    |
| RMU          | Reset Management Unit              |
| RSM          | Radio State Machine                |
| RSSI         | Received Signal Strength Indicator |
| RTC          | Real Time Counter                  |
| RX           | Receive                            |
| SEQ          | Radio Sequencer                    |
| SPI          | Serial Peripheral Interface        |
| SRC          | Sample Rate Converter              |
| STIMER       | Sequencer Timer                    |
| SW           | Software                           |
| SYNTH        | Synthesizer                        |
| TX           | Transmit                           |
| WOR          | Wake On Radio                      |
| XTAL         | Crystal                            |

Silicon Labs

# Simplicity Studio™4

## Simplicity Studio

One-click access to MCU and wireless tools, documentation, software, source code libraries & more. Available for Windows, Mac and Linux!

### Disclaimer

Silicon Labs intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Labs products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Labs reserves the right to make changes without further notice to the product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Without prior notification, Silicon Labs may update product firmware during the manufacturing process for security or reliability reasons. Such changes will not alter the specifications or the performance of the product. Silicon Labs shall have no liability for the consequences of use of the information supplied in this document. This document does not imply or expressly grant any license to design or fabricate any integrated circuits. The products are not designed or authorized to be used within any FDA Class III devices, applications for which FDA premarket approval is required or Life Support Systems without the specific written consent of Silicon Labs. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in significant personal injury or death. Silicon Labs products are not designed or authorized for military applications. Silicon Labs products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons. Silicon Labs disclaims all express and implied warranties and shall not be responsible or liable for any injuries or damages related to use of a Silicon Labs product in such unauthorized applications.
