

Description

The GM1117S is a positive low dropout regulator and is available in an adjustable version and fixed output voltage from 1.5V to 5.0V. All internal circuitry is designed to operate down to 800mV input to output differential and the dropout voltage is fully specified as a function of load current. On chip trimming adjusts the reference/output voltage to within $\pm 1\%$. Current limit is also trimmed in order to minimize the stress on both the regulator and the power source circuitry under overloaded conditions.

Features

- ◆ Adjustable or Fixed Output
- ◆ Output Current of 1.0A
- ◆ Dropout Voltage 1.5V max @ 1.0A
- ◆ Line Regulation 0.2% max.
- ◆ Load Regulation 0.4% max.
- ◆ Fast Transient Response
- ◆ Current Limit Protection
- ◆ Thermal Shutdown Protection

Application

High Efficiency Linear Regulators
Post Regulators for Switching Supplies
Microprocessor Supply

Battery Powered Equipment
Reference Voltage Sources
Hard Drive Controllers
Battery Chargers
Adjustable Power Supply

Typical Application Circuits

Adjustable Regulator

$$V_{OUT} = 1.25V \left(1 + \frac{R2}{R1} \right)$$

Fixed Output Voltage Regulator

Application Notes

GM1117S linear regulators provide fixed and adjustable output voltage at current up to 1.0A. These regulators are protected against over current conditions and include thermal shutdown protection. The GM1117S has a composite PNP-NPN output transistor and require an output capacitor for stability. A detailed procedure for selecting this capacitor follows.

Adjustable Operation

The GM1117S has an output voltage range for 1.25V to 5.5V. An external resistor divider sets the output voltage as show in Figure 1. The regulator maintains a fixed 1.25V (typical) reference between the output pin and the adjust pin. A resistor divider network R1 and R1 causes a fixed current to follow to ground. This current creates a voltage across R2 that adds to the 1.25V across R1 and sets the overall output voltage. The adjust pin current (typically 50μA) also flows through R2 and adds a small error that should be taken into account if precise adjustment of V_{OUT} is necessary.

Figure 1. Resistor Divider Scheme

The term I_{ADJ} X R2 represents the error added by the adjust pin current. R1 is chosen such that the minimum load current is at least 2mA. R1 and R2 should be the same type, e.g., metal film for best tracking over temperature. While not require, a bypass capacitor from the adjust pin to ground will improve ripple rejection and transient response. A 0.1μF tantalum capacitor is recommended.

Stability Considerations

The output compensation capacitor helps to determine three feature characteristics of a linear regulator's performance: start-up delay, load transient response, and loop stability. The capacitance and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is preferred, as a film or ceramic capacitor with almost zero ESR can cause instability. An aluminum electrolytic capacitor is the least expensive type, but when the circuit operates at low temperatures, both the capacitance and ESR will vary widely. For optimum performance over the full operating temperature range, a tantalum capacitor is best. A 22μF tantalum capacitor will work fine in most applications, but with high current regulators such as the GM1117S higher capacitance values will improve the transient response and stability. Most applications for the GM1117S involve large changes in load current, so the output capacitor must supply instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$\Delta V = \Delta I \times ESR$$

In microprocessor applications, an output capacitor network of several tantalum and ceramic capacitors in parallel is commonly used. This reduces overall ESR and minimizes the instantaneous output voltage drop under transient load conditions. The output capacitor network should be placed as close to the load as possible.

Heatsink Requirements

When an integrated circuit operates with an appreciable current, its junction temperature is elevated. It is important to consider its thermal limits in order to achieve acceptable performance and reliability. This limit is determined by summing the individual parts consisting of a series of temperature rises from the semiconductor junction to the operating environment.

The heat generated at the device junction flows through the die to the die attach pad, through the lead frame to the surrounding case material, to the printed circuit board, and eventually to the ambient environment. Below is a list of variables that may affect the thermal resistance and in turn the need to a heatsink.

Θ_{JC} , Junction to Case Thermal Resistance	Θ_{CA} , Case to Ambient Thermal Resistance
1. Lead Frame Size & Material	1. Mounting Pad Size, Material & Location
2. Number of conducting Pins	2. Placement of Mounting Pad
3. Die Size	3. PCB Size & Material
4. Die Attach Material	4. Traces Length & Width
5. Molding Compound Size & Material	5. Adjacent Heat Source
	6. Volume of Air
	7. Ambient Temperature
	8. Shape of Mounting Pad

The GM1117S regulators have internal thermal shutdown to protect the device from over heating. Under all possible operating conditions, the junction temperature of the GM1117S must be within in the range of 0°C to 125°C. A heatsink may be required depending on the maximum power dissipation and maximum ambient temperature of the application. To determine if a heatsink is needed, the power dissipated by the regulator, P_D , must be calculated according to the circuit below:

The next parameter which must be calculated is the maximum allowable temperature rise, $T_R(\max)$:

$$T_R(\max) = T_J(\max) - T_A(\max)$$

Where $T_J(\max)$ is the maximum allowable junction temperature (125°C) and $T_A(\max)$ is the maximum ambient temperature which will be encountered in the application.

Using the calculated values for $T_R(\max)$ and P_D the maximum allowable value for the junction-to-ambient thermal resistance (Θ_{JA}) can be calculated:

$$\Theta_{JA}(\max) = T_R(\max) \times P_D$$

If the maximum allowable value for Θ_{JA} is found to be $\geq 136^\circ\text{C/W}$ for SOT223 packages or $\geq 79^\circ\text{C/W}$ for TO220 package or $\geq 92^\circ\text{C/W}$ for TO252 package, no heat sink is needed since the package alone will dissipate enough heat to satisfy these requirements. If the calculated value for Θ_{JA} falls below these limits, a heat sink is required.

As a design aid, the table below shows the value of the Θ_{JA} of SOT-223 and TO-252 for different heat sink area.

Layout	Copper Area		Thermal Resistance	
	* Top Side (in ²)	Bottom Side (in ²)	(Θ_{JA} , °C/W) SOT-223	(Θ_{JA} , °C/W) TO-252
