Rev.2.2 00 H

The S-24C16C H series is a high temperature operation 2-wire serial E²PROM for automotive components. The S-24C16C H series has the capacity of 16 K-bit, and the organization is 2048 words × 8-bit. Page write and sequential read are available.

Caution Before using the product in automobile control unit or medical equipment, contact to SII is indispensable.

■ Features

- Operation voltage range: Read 2.5 V to 5.5 V
Write 2.5 V to 5.5 V
- Page write: 16 bytes / page
- Sequential read
- Operation frequency: 400 kHz ($V_{CC} = 2.5\text{ V to }5.5\text{ V}$)
- Write time: 5.0 ms max.
- Noise suppression Schmitt trigger and noise filter on input pins (SCL, SDA)
- Write protect function during the low power supply voltage
- Endurance: 10^6 cycles / word*1 ($T_a = +25^\circ\text{C}$)
 3×10^5 cycles / word*1 ($T_a = +85^\circ\text{C}$)
 2×10^5 cycles / word*1 ($T_a = +105^\circ\text{C}$)
- Data retention: 100 years ($T_a = +25^\circ\text{C}$)
30 years ($T_a = +85^\circ\text{C}$)
25 years ($T_a = +105^\circ\text{C}$)
- Memory capacity: 16 K-bit
- Write protect: 100%
- Initial delivery state: FFh
- Operation temperature range: $T_a = -40^\circ\text{C to }+105^\circ\text{C}$
- Lead-free (Sn 100%), halogen-free*2
- AEC-Q100 qualified*3

■ AEC-Q100 Qualified

This IC supports AEC-Q100 for operation temperature grade 2.
 Contact our sales office for details of AEC-Q100 reliability specification.

■ Absolute Maximum Ratings

Table 3

Item	Symbol	Absolute Maximum Rating	Unit
Power supply voltage	V _{CC}	−0.3 to +6.5	V
Input voltage	V _{IN}	−0.3 to +6.5	V
Output voltage	V _{OUT}	−0.3 to +6.5	V
Operation ambient temperature	T _{opr}	−40 to +105	°C
Storage temperature	T _{stg}	−65 to +150	°C

Caution The absolute maximum ratings are rated values exceeding which the product could suffer physical damage. These values must therefore not be exceeded under any conditions.

■ Recommended Operating Conditions

Table 4

Item	Symbol	Condition	Ta = −40°C to +105°C		Unit
			Min.	Max.	
Power supply voltage	V _{CC}	Read	2.5	5.5	V
		Write	2.5	5.5	V
High level input voltage	V _{IH}	V _{CC} = 2.5 V to 5.5 V	0.7 × V _{CC}	5.5	V
Low level input voltage	V _{IL}	V _{CC} = 2.5 V to 5.5 V	−0.3	0.3 × V _{CC}	V

■ Pin Capacitance

Table 5

(Ta = +25°C, f = 1.0 MHz, V_{CC} = 5.0 V)

Item	Symbol	Condition	Min.	Max.	Unit
Input capacitance	C _{IN}	V _{IN} = 0 V (SCL, A2, WP)	—	10	pF
I/O capacitance	C _{I/O}	V _{I/O} = 0 V (SDA)	—	10	pF

■ Endurance

■ Pin Functions

1. A2 (TEST) pin

The slave address can not be assigned in the S-24C16C since addressing function is removed.
The A2 pin should be connected to the GND pin.

2. SDA (Serial data input / output) pin

The SDA pin is used for the bi-directional transmission of serial data. This pin is a signal input pin, and an Nch open-drain output pin.

In use, generally, connect the SDA line to any other device which has the open-drain or open-collector output with Wired-OR connection by pulling up to V_{CC} by a resistor (**Figure 7** shows the relation with an output load).

3. SCL (Serial clock input) pin

The SCL pin is used for the serial clock input. Since the signals are processed at a rising or falling edge of the SCL clock, pay attention to the rising and falling time and comply with the specification.

4. WP (Write protect input) pin

The write protect is enabled by connecting the WP pin to V_{CC} . When not using the write protect, connect this pin to the GND pin or set in open.

Figure 7 Output Load

■ Initial Delivery State

Initial delivery state of all addresses is "FFh".

■ Operation

1. Start condition

Start is identified by a high to low transition of the SDA line while the SCL line is stable at high. Every operation begins from a start condition.

2. Stop condition

Stop is identified by a low to high transition of the SDA line while the SCL line is stable at high. When a device receives a stop condition during a read sequence, the read operation is interrupted, and the device enters standby mode. When a device receives a stop condition during a write sequence, the reception of the write data is halted, and the S-24C16C initiates a write cycle.

Figure 8 Start / Stop Conditions

3. Data transmission

Changing the SDA line while the SCL line is low, data is transmitted.

Changing the SDA line while the SCL line is high, a start or stop condition is recognized.

Figure 9 Data Transmission Timing

4. Acknowledge

The unit of data transmission is 8 bits. During the 9th clock cycle period the receiver on the bus pulls down the SDA line to acknowledge the receipt of the 8-bit data.

When an internal write cycle is in progress, the device does not generate an acknowledge.

Figure 10 Acknowledge Output Timing

5. Device addressing

To start communication, the master device on the system generates a start condition to the bus line. Next, the master device sends 7-bit device address and a 1-bit read / write instruction code on to the SDA bus.

The upper 4 bits of the device address are the "Device Code", and are fixed to "1010".

Successive 3 bits (P2, P1, and P0) are "Page Address". Choose the 8 memory blocks of 256-byte (Address 000h to 0FFh, 100h to 1FFh, 200h to 2FFh, 300h to 3FFh, 400h to 4FFh, 500h to 5FFh, 600h to 6FFh, 700h to 7FFh).

Figure 11 Device Address

6. Write

6. 1 Byte write

When the master sends a 7-bit device address and a 1-bit read / write instruction code set to "0", following a start condition, the S-24C16C acknowledges it. And the S-24C16C receives 8-bit word address and responds with an acknowledge. After the S-24C16C receives 8-bit write data and responds with an acknowledge, it receives a stop condition and that initiates the write cycle at the addressed memory.
During the write cycle all operations are forbidden and no acknowledge is generated.

Figure 12 Byte Write

6.2 Page write

The page write mode allows up to 16 bytes to be written in a single write operation in the S-24C16C.

Its basic process to transmit data is as same as byte write, but it operates page write by sequentially receiving 8-bit write data as much data as the page size has.

When the S-24C16C receives a 7-bit device address and a 1-bit read / write instruction code set to "0", following a start condition, it generates an acknowledge. And the S-24C16C receives 8-bit word address and responds with an acknowledge. After the S-24C16C receives 8-bit write data and responds with an acknowledge, it receives 8-bit write data corresponding to the next word address, and generates an acknowledge. The S-24C16C repeats reception of 8-bit write data and generation of acknowledge in succession. The S-24C16C can receive as many write data as the maximum page size.

Receiving a stop condition initiates a write cycle of the area starting from the designated memory address and having the page size equal to the received write data.

Figure 13 Page Write

In the S-24C16C, the lower 4 bits of the word address are automatically incremented every time when the S-24C16C receives 8-bit write data. If the size of the write data exceeds 16 bytes, the upper 4 bits of the word address and page address (P2, P1, and P0) remain unchanged, and the lower 4 bits are rolled over and the last 16-byte data that the S-24C16C received will be overwritten.

6.3 Write protect

Write protect is available in the S-24C16C. When the WP pin is connected to the VCC pin, write operation to memory area is inhibited.

When the WP pin is connected to the GND pin or set in open, the write protect is invalid, and write operation in all memory area is available.

Fix the level of the WP pin from start condition in the write operation (byte write, page write) until stop condition. If the WP pin changes during this time, the address data being written at this time is not guaranteed. Regarding the timing of write protect, refer to **Figure 6**.

In not using the write protect, connect the WP pin to the GND pin or set it open. The write protect is valid in the range of operation power supply voltage.

As seen in **Figure 14** when the write protect is valid, the S-24C16C does not generate an acknowledgment signal after data input.

Figure 14 Write Protect

6.4 Acknowledge polling

Acknowledge polling is used to know the completion of the write cycle in the S-24C16C.

After the S-24C16C receives a stop condition and once starts the write cycle, all operations are inhibited and no response is made to the signal transmitted by the master device.

Accordingly the master device can recognize the completion of the write cycle in the S-24C16C by detecting a response from the slave device after transmitting the start condition, the device address and the read / write instruction code to the S-24C16C (slave device).

That is, if the S-24C16C does not generate an acknowledgment signal, the write cycle is in progress and if the S-24C16C generates an acknowledgment signal, the write cycle has been completed.

It is recommended to use the read instruction "1" as the read / write instruction code transmitted by the master device.

Acknowledge polling during write

Acknowledge polling during read

Remark Users are able to input word address and data after ACK output in acknowledge polling during write. Users are able to read data after ACK output in acknowledge polling during read. However, after that users input the write instruction, a start condition may not be input during data output. Input a stop condition and the next instruction after data output and ACK output.

Figure 15 Usage Example of Acknowledge Polling

7. Read

7.1 Current address read

Either in writing or in reading the S-24C16C holds the last accessed memory address. The memory address is maintained as long as the power voltage does not decrease less than the operation voltage.

The master device can read the data at the memory address of the current address pointer without assigning the word address as a result, when it recognizes the position of the address pointer in the S-24C16C. This is called "Current Address Read".

In the following the address counter in the S-24C16C is assumed to be "n".

When the S-24C16C receives a 7-bit device address and a 1-bit read / write instruction code set to "1" following a start condition, it responds with an acknowledge.

Next, an 8-bit data at the address "n" is sent from the S-24C16C synchronous to the SCL clock. The address counter is incremented and the content of the address counter becomes $n + 1$.

The master device outputs stop condition not an acknowledge, the reading of the S-24C16C is ended.

Figure 16 Current Address Read

Attention should be paid to the following point on the recognition of the address pointer in the S-24C16C.

In Read, the memory address counter in the S-24C16C is automatically incremented after output of the 8th bit of the data. In Write, on the other hand, the upper bits of the memory address (the upper bits of the word address and the page address^{*1}) are left unchanged and are not incremented.

^{*1}. The upper 4 bits of the word address and the page address P2, P1 and P0.

7.2 Random read

Random read is used to read the data at an arbitrary memory address.

A dummy write is performed to load the memory address into the address counter.

When the S-24C16C receives a 7-bit device address and a 1-bit read / write instruction code set to "0" following a start condition, it responds with an acknowledge.

And the S-24C16C receives 8-bit word address and responds with an acknowledge. The memory address is loaded to the address counter in the S-24C16C by these operations. Reception of write data does not follow in a dummy write whereas reception of write data follows in byte write and in page write.

Since the memory address is loaded into the memory address counter by dummy write, the master device can read the data starting from the arbitrary memory address by transmitting a new start condition and performing the same operation in the current address read.

That is, when the S-24C16C receives a 7-bit device address and a 1-bit read / write instruction code set to "1", following a start condition signal, it responds with an acknowledge. Next, 8-bit data is transmitted from the S-24C16C in synchronous to the SCL clock. The master device outputs stop condition not an acknowledge, the reading of the S-24C16C is ended.

Figure 17 Random Read

7.3 Sequential read

When the S-24C16C receives a 7-bit device address and a 1-bit read / write instruction code set to "1" following a start condition both in current address read and random read, it responds with an acknowledge.

When an 8-bit data is output from the S-24C16C synchronous to the SCL clock, the address counter is automatically incremented.

When the master device responds with an acknowledge, the data at the next memory address is transmitted. Response with an acknowledge by the master device has the memory address counter in the S-24C16C incremented and makes it possible to read data in succession. This is called "Sequential Read".

The master device outputs stop condition not an acknowledge, the reading of the S-24C16C is ended.

Data can be read in succession in the sequential read mode. When the memory address counter reaches the last word address, it rolls over to the first word address.

Figure 18 Sequential Read

■ Write Protect Function during the Low Power Supply Voltage

The S-24C16C has a built-in detection circuit which operates with the low power supply voltage, cancels Write when the power supply voltage drops and power-on. Its detection and release voltages are 1.20 V typ. (Refer to **Figure 19**).

The S-24C16C cancels Write by detecting a low power supply voltage when it receives a stop condition.

In the data transmission and the Write operation, data in the address written during the low power supply voltage is not assurable.

Figure 19 Operation during Low Power Supply Voltage

■ Using S-24C16C

1. Adding a pull-up resistor to SDA I/O pin and SCL input pin

In consideration of I²C-bus protocol function, the SDA I/O pins should be connected with a pull-up resistor. The S-24C16C cannot transmit normally without using a pull-up resistor.

In case that the SCL input pin of the S-24C16C is connected to the Nch-open drain output pin of the master device, connect the SCL pin with a pull-up resistor. As well, in case the SCL input pin of the S-24C16C is connected to the tri-state output pin of the master device, connect the SCL pin with a pull-up resistor in order not to set it in "High-Z". This prevents the S-24C16C from error caused by an uncertain output ("High-Z") from the tri-state pin when resetting the master device during the voltage drop.

2. Equivalent circuit of input and I/O pin

The SCL pin and the SDA pin do not have a built-in pull-down or pull-up resistor.
 The WP pin has a built-in pull-down resistor. The SDA pin has an open-drain output.
 The followings are equivalent circuits of the pins.

Figure 20 SCL Pin

Figure 21 SDA Pin

Figure 22 WP Pin

3. Phase adjustment during S-24C16C access

The S-24C16C does not have a pin to reset (the internal circuit). The users cannot forcibly reset it externally. If the communication to the S-24C16C interrupted, the users need to handle it as you do for software.

In the S-24C16C, users are able to reset the internal circuit by inputting a start condition and a stop condition.

Although the reset signal is input to the master device, the S-24C16C's internal circuit does not go in reset, but it does by inputting a stop condition to the S-24C16C. The S-24C16C keeps the same status thus cannot do the next operation. Especially, this case corresponds to that only the master device is reset when the power supply voltage drops.

If the power supply voltage restored in this status, input the instruction after resetting (adjusting the phase with the master device) the S-24C16C. How to reset is shown below.

[How to reset S-24C16C]

The S-24C16C is able to be reset by a start and stop instructions. When the S-24C16C is reading data "0" or is outputting the acknowledgment signal, outputs "0" to the SDA line. In this status, the master device cannot output an instruction to the SDA line. In this case, terminate the acknowledgment output operation or the Read operation, and then input a start instruction. **Figure 23** shows this procedure.

First, input a start condition. Then transmit 9 clocks (dummy clock) of SCL. During this time, the master device sets the SDA line to "H". By this operation, the S-24C16C interrupts the acknowledgment output operation or data output, so input a start condition^{*1}. When a start condition is input, the S-24C16C is reset. To make doubly sure, input the stop condition to the S-24C16C. The normal operation is then possible.

Figure 23 Resetting S-24C16C

^{*1}. After 9 clocks (dummy clock), if the SCL clock continues to being output without inputting a start condition, the S-24C16C may go in the write operation when it receives a stop condition. To prevent this, input a start condition after 9 clocks (dummy clock).

Remark Regarding this reset procedure with dummy clock, it is recommended to perform at the system initialization after applying the power supply voltage.

4. Acknowledge check

The I²C-bus protocol includes an acknowledge check function as a handshake function to prevent a communication error. This function allows detection of a communication failure during data communication between the master device and the S-24C16C. This function is effective to prevent malfunction, so it is recommended to perform an acknowledge check with the master device.

5. Built-in power-on-clear circuit

The S-24C16C has a built-in power-on-clear circuit that initializes itself at the same time during power-on. Unsuccessful initialization may cause a malfunction. To operate the power-on-clear circuit normally, the following conditions must be satisfied to raise the power supply voltage.

5.1 Raising power supply voltage

Shown in **Figure 24**, raise the power supply voltage from 0.2 V max., within the time defined as t_{RISE} which is the time required to reach the power supply voltage to be set.

For example, if the power supply voltage is 5.0 V, $t_{\text{RISE}} = 200$ ms seen in **Figure 25**. The power supply voltage must be raised within 200 ms.

*1. 0 V means there is no difference in potential between the VCC pin and the GND pin of the S-24C16C.

*2. t_{INIT} is the time required to initialize the S-24C16C. No instructions are accepted during this time.

Figure 24 Raising Power Supply Voltage

For example: If the supply voltage = 5.0 V, raise the power supply voltage to 5.0 V within 200 ms.

Figure 25 Rise Time of Power Supply Voltage

When initialization is successfully completed by the power-on-clear circuit, the S-24C16C enters the standby status.

If the power-on-clear circuit does not operate;

The S-24C16C has not completed initialization, an instruction previously input is still valid or an instruction may be inappropriately recognized. In this case, the S-24C16C may perform the Write operation.

The voltage drops due to power off while the S-24C16C is being accessed. Even if the master device is reset due to the low power voltage, the S-24C16C may malfunction unless the power-on-clear operation conditions of the S-24C16C are satisfied.

When not using this rise time seen in **Figure 25**, adjust the phase (reset) to reset the internal circuit in the S-24C16C normally.

5.2 Initialization time

The S-24C16C initializes at the same time when the power supply voltage is raised. Input instructions to the S-24C16C after initialization. The S-24C16C does not accept any instruction during initialization.

Figure 26 shows the initialization time of the S-24C16C.

Figure 26 Initialization Time of S-24C16C

6. Data hold time ($t_{HD,DAT} = 0 \text{ ns}$)

If SCL and SDA of the S-24C16C are changed at the same time, it is necessary to prevent a start / stop condition from being mistakenly recognized due to the effect of noise.

The S-24C16C may error if it does not recognize a start / stop condition correctly during transmission.

It is recommended to set the delay time of $0.3 \mu\text{s}$ minimum from a falling edge of SCL for the SDA.

This is to prevent the S-24C16C from going in a start / stop condition due to the time lag caused by the load of the bus line.

Figure 27 S-24C16C Data Hold Time

7. SDA pin and SCL pin noise suppression time

The S-24C16C includes a built-in low-pass filter at the SDA pin and the SCL pin to suppress noise. This means that if the power supply voltage is 5.0 V, noise with a pulse width of 130 ns or less can be suppressed.

For details of the assurable value, refer to noise suppression time (t_i) in **Table 12**.

Figure 28 Noise Suppression Time for SDA Pin and SCL Pin

8. Operation when input stop condition during input write data

The S-24C16C does the write operation only when it receives data of 1 byte or more and receives a stop condition immediately after ACK output.

Refer to **Figure 29** regarding details.

Figure 29 Write Operation by Inputting Stop Condition during Write

9. Command cancel by start condition

By a start condition, users are able to cancel command which is being input. However, adjust the phase while the S-24C16C is outputting "L" because users are not able to input a start condition. When users cancel the command, there may be a case that the address will not be identified. Use random read for the read operation, not current address read.

10. Precaution for use

Do not operate these ICs in excess of the absolute maximum ratings. Attention should be paid to the power supply voltage, especially. The surge voltage which exceeds the absolute maximum ratings can cause latch-up and malfunction. Perform operations after confirming the detailed operation condition in the data sheet.

Operations with moisture on the S-24C16C pins may occur malfunction by short-circuit between pins. Especially, in occasions like picking the S-24C16C up from low temperature tank during the evaluation. Be sure that not remain frost on the S-24C16C's pins to prevent malfunction by short-circuit.

Also attention should be paid in using on environment, which is easy to dew for the same reason.

■ Precautions

- Do not apply an electrostatic discharge to this IC that exceeds the performance ratings of the built-in electrostatic protection circuit.
- SII claims no responsibility for any and all disputes arising out of or in connection with any infringement of the products including this IC upon patents owned by a third party.

■ Product Name Structure

1. Product name

Remark Please contact our sales office for products with product name structure other than those specified above.

2. Packages

Package name	Drawing code		
	Package	Tape	Reel
8-Pin SOP (JEDEC)	FJ008-A-P-SD	FJ008-D-C-SD	FJ008-D-R-S1
8-Pin TSSOP	FT008-A-P-SD	FT008-E-C-SD	FT008-E-R-S1

No. FJ008-A-P-SD-2.1

TITLE	SOP8J-D-PKG Dimensions
No.	FJ008-A-P-SD-2.1
SCALE	
UNIT	mm
Seiko Instruments Inc.	

No. FJ008-D-C-SD-1.1

TITLE	SOP8J-D-Carrier Tape
No.	FJ008-D-C-SD-1.1
SCALE	
UNIT	mm
Seiko Instruments Inc.	

Enlarged drawing in the central part

No. FJ008-D-R-S1-1.0

TITLE	SOP8J-D-Reel		
No.	FJ008-D-R-S1-1.0		
SCALE		QTY.	4,000
UNIT	mm		
Seiko Instruments Inc.			

No. FT008-A-P-SD-1.1

TITLE	TSSOP8-E-PKG Dimensions
No.	FT008-A-P-SD-1.1
SCALE	
UNIT	mm
Seiko Instruments Inc.	

No. FT008-E-C-SD-1.0

TITLE	TSSOP8-E-Carrier Tape
No.	FT008-E-C-SD-1.0
SCALE	
UNIT	mm
Seiko Instruments Inc.	

Enlarged drawing in the central part

No. FT008-E-R-S1-1.0

TITLE	TSSOP8-E-Reel		
No.	FT008-E-R-S1-1.0

- The information described herein is subject to change without notice.
- Seiko Instruments Inc. is not responsible for any problems caused by circuits or diagrams described herein whose related industrial properties, patents, or other rights belong to third parties. The application circuit examples explain typical applications of the products, and do not guarantee the success of any specific mass-production design.
- When the products described herein are regulated products subject to the Wassenaar Arrangement or other agreements, they may not be exported without authorization from the appropriate governmental authority.
- Use of the information described herein for other purposes and/or reproduction or copying without the express permission of Seiko Instruments Inc. is strictly prohibited.
- The products described herein cannot be used as part of any device or equipment affecting the human body, such as exercise equipment, medical equipment, security systems, gas equipment, vehicle equipment, in-vehicle equipment, aviation equipment, aerospace equipment, and nuclear-related equipment, without prior written permission of Seiko Instruments Inc.
- The products described herein are not designed to be radiation-proof.
- Although Seiko Instruments Inc. exerts the greatest possible effort to ensure high quality and reliability, the failure or malfunction of semiconductor products may occur. The user of these products should therefore give thorough consideration to safety design, including redundancy, fire-prevention measures, and malfunction prevention, to prevent any accidents, fires, or community damage that may ensue.
