Return to the [Summary Table](#).

This register contains one bit for each of the bus comparator modules and the counter modules that are present in a device. Each bit directly acts as a global enable for the corresponding module. This bit has to be set to 1 for the module to be functional.

#### 11.6.2.4 GLBL\_CTM\_RESET Register (Offset = 6h) [reset = 0h]

GLBL\_CTM\_RESET is shown in [Figure 11-6](#) and described in [Table 11-8](#).

Return to the [Summary Table](#).

This register contains one bit for each of the counter modules that are present in a device. Each bit directly acts as a reset for the counters for the corresponding module. (It does not affect anything else except resetting the counter.

Example: If the counter was previously incrementing before reset, then on a reset event the counter gets reset and continues to increment again).

**Figure 11-6. GLBL\_CTM\_RESET Register**

### 11.6.3 ERAD\_HWBP\_REGS Registers

Table 11-10 lists the ERAD\_HWBP\_REGS registers. All register offset addresses not listed in Table 11-10 should be considered as reserved locations and the register contents should not be modified.

**Table 11-10. ERAD\_HWBP\_REGS Registers**

| Offset | Acronym     | Register Name           | Write Protection | Section            |
|--------|-------------|-------------------------|------------------|--------------------|
| 0h     | HWBP_MASK   | HWBP Mask Register      | EALLOW           | <a href="#">Go</a> |
| 2h     | HWBP_REF    | HWBP Reference Register | EALLOW           | <a href="#">Go</a> |
| 4h     | HWBP_CLEAR  | HWBP Clear Register     | EALLOW           | <a href="#">Go</a> |
| 6h     | HWBP_CNTL   | HWBP Control Register   | EALLOW           | <a href="#">Go</a> |
| 7h     | HWBP_STATUS | HWBP Status Register    | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 11-11 shows the codes that are used for access types in this section.

**Table 11-11. ERAD\_HWBP\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

| 7-1   | RESERVED    | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                    |
| 0     | EVENT_FIRED | R    | 0h    | This is a sticky bit which gets set every time the HWBP unit generates a match event. This will be used by software to figure out whether this HWBP module fired an event or not. This bit will get cleared by writing a '1' to bit 0 of the HWBP_CLEAR register.<br>Reset type: ERAD_RESET |

### 11.6.4 ERAD\_COUNTER\_REGS Registers

Table 11-17 lists the ERAD\_COUNTER\_REGS registers. All register offset addresses not listed in Table 11-17 should be considered as reserved locations and the register contents should not be modified.

**Table 11-17. ERAD\_COUNTER\_REGS Registers**

| Offset | Acronym       | Register Name                    | Write Protection | Section            |
|--------|---------------|----------------------------------|------------------|--------------------|
| 0h     | CTM_CNTL      | Counter Control Register         | EALLOW           | <a href="#">Go</a> |
| 1h     | CTM_STATUS    | Counter Status Register          | EALLOW           | <a href="#">Go</a> |
| 2h     | CTM_REF       | Counter Reference Register       | EALLOW           | <a href="#">Go</a> |
| 4h     | CTM_COUNT     | Counter Current Value Register   | EALLOW           | <a href="#">Go</a> |
| 6h     | CTM_MAX_COUNT | Counter Max Count Value Register | EALLOW           | <a href="#">Go</a> |
| 8h     | CTM_INPUT_SEL | Counter Input Select Register    | EALLOW           | <a href="#">Go</a> |
| 9h     | CTM_CLEAR     | Counter Clear Register           | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 11-18 shows the codes that are used for access types in this section.

**Table 11-18. ERAD\_COUNTER\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

## ***Analog Subsystem***

---

---

---

This analog subsystem module is described in this chapter.

| Topic                                        | Page        |
|----------------------------------------------|-------------|
| <b>12.1 Introduction .....</b>               | <b>1449</b> |
| <b>12.2 Analog Subsystem Registers .....</b> | <b>1458</b> |

## 12.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Programmable Gain Amplifier (PGA), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

### 12.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references
  - The ADCs are referenced to VREFHlx and VSSA pins
    - VREFHlx pin voltage can be driven in externally or can be generated by an internal bandgap voltage reference
    - The internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V
  - The buffered DACs are referenced to VREFHlx and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
  - The comparator DACs are referenced to VDDA and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC outputs, comparator subsystem inputs, PGA functions, and digital inputs are multiplexed with ADC inputs
  - Internal connection to  $V_{REFLO}$  on all ADCs for offset self-calibration

### 12.1.2 Block Diagram

The subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The analog pins are organized into analog groups around a PGA and CMPSS module. The block diagram shows which pins connect to each group, but does not show the specific connections from the pins to the ADC, DAC, CMPSS, or PGA modules.

The block diagram for the analog subsystem is presented in the following graphics.

The following note applies to all packages.

#### NOTES:

- Not all analog pins are available on all devices. Consult the datasheet for your specific device to determine which pins are available.
- Consult the datasheet for your device to determine the allowable voltage range for VREFHI and VREFLO
- An external capacitor is required on the VREFHI pins. Consult the datasheet for the specific value required.
- For buffered DAC modules, VSSA will be the low reference whether VREFHlx or VDAC is selected as the high reference.
- For CMPSS modules, VSSA will be the low reference whether VDAC or VDDA is selected as the high reference.

### **12.1.3 Lock Registers**

Setting one of the bits in the lock registers prevents further writes to the associated analog subsystem configuration register. This lock can only be cleared by a device reset.

## 12.2 Analog Subsystem Registers

This section describes the Analog Subsystem Registers.

### 12.2.1 Analog Subsystem Base Addresses

**Table 12-4. Analog Subsystem Base Address Table**

| Device Registers | Register Name      | Start Address | End Address |
|------------------|--------------------|---------------|-------------|
| AnalogSubsysRegs | ANALOG_SUBSYS_REGS | 0x0005_D700   | 0x0005_D7FF |

## 12.2.2 ANALOG\_SUBSYS\_REGS Registers

Table 12-5 lists the ANALOG\_SUBSYS\_REGS registers. All register offset addresses not listed in Table 12-5 should be considered as reserved locations and the register contents should not be modified.

**Table 12-5. ANALOG\_SUBSYS\_REGS Registers**

| Offset | Acronym    | Register Name                                                                                                 | Write Protection | Section            |
|--------|------------|---------------------------------------------------------------------------------------------------------------|------------------|--------------------|
| 1Eh    | ANAREFPP   | ADC Analog Reference Peripheral Properties register. The value of this register is populated during boot rom. | EALLOW           | <a href="#">Go</a> |
| 60h    | TSNSCTL    | Temperature Sensor Control Register                                                                           | EALLOW           | <a href="#">Go</a> |
| 68h    | ANAREFCTL  | Analog Reference Control Register                                                                             | EALLOW           | <a href="#">Go</a> |
| 70h    | VMONCTL    | Voltage Monitor Control Register                                                                              | EALLOW           | <a href="#">Go</a> |
| 78h    | DCDCCTL    | DC-DC control register.                                                                                       | EALLOW           | <a href="#">Go</a> |
| 7Ah    | DCDCSTS    | DC-DC status register.                                                                                        |                  | <a href="#">Go</a> |
| 82h    | CMPPHMXSEL | Bits to select one of the many sources on CopmHP inputs. Refer to Pimux diagram for details.                  | EALLOW           | <a href="#">Go</a> |
| 84h    | CMPLPMXSEL | Bits to select one of the many sources on CopmLP inputs. Refer to Pimux diagram for details.                  | EALLOW           | <a href="#">Go</a> |
| 86h    | CMPHNMXSEL | Bits to select one of the many sources on CopmHN inputs. Refer to Pimux diagram for details.                  | EALLOW           | <a href="#">Go</a> |
| 87h    | CMPLNMXSEL | Bits to select one of the many sources on CopmLN inputs. Refer to Pimux diagram for details.                  | EALLOW           | <a href="#">Go</a> |
| 8Eh    | LOCK       | Lock Register                                                                                                 | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 12-6 shows the codes that are used for access types in this section.

**Table 12-6. ANALOG\_SUBSYS\_REGS Access Type Codes**

| Access Type                     | Code   | Description                            |
|---------------------------------|--------|----------------------------------------|

**Table 12-6. ANALOG\_SUBSYS\_REGS Access Type Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 12.2.2.1 ANAREFPP Register (Offset = 1Eh) [reset = 0h]

ANAREFPP is shown in [Figure 12-5](#) and described in [Table 12-7](#).

Return to the [Summary Table](#).

ADC Analog Reference Peripheral Properties register. The value of this register is populated during boot rom.

If the check shows that inductor is functional then this bit will be set.<br><br>This status of this bit should be checked after DCDCSTS.SWSEQDONE is set.<br>Reset type: XRSn                        |

### 12.2.2.7 CMPHPMXSEL Register (Offset = 82h) [reset = 0h]

CMPHPMXSEL is shown in [Figure 12-11](#) and described in [Table 12-13](#).

Return to the [Summary Table](#).

Bits to select one of the many sources on CopmHP inputs. Refer to Pimux diagram for details.

## Analog-to-Digital Converter (ADC)

The analog-to-digital converter module described in this chapter is a Type 5 ADC. See the *TMS320C28xx, 28xxx DSP Peripheral Reference Guide* ([SPRU566](#)) for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 13.1 Introduction

The ADC module is a 12-bit successive approximation (SAR) style ADC. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (s/h) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see [Section 13.5](#)).

## 13.2 ADC Features

Each ADC has the following features:

- 12-bit resolution
- Ratiometric external reference set by VREFHI and VREFLO pins
- Selectable internal reference of 2.5V or 3.3V
- Single-ended signal conversions
- Input multiplexer with up to 16 channels
- 16 configurable SOC's
- 16 individually addressable result registers
- Multiple trigger sources
  - S/W - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2
  - ADCINT1/2
- Four flexible PIE interrupts
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from setpoint calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture

---

**NOTE:** Not every channel may be pinned out from all ADCs. Check the datasheet for your device to determine which channels are available.

---

### 13.3 ADC Block Diagram

The block diagram for the ADC core and ADC wrapper are presented in [Figure 13-1](#).

Figure 13-1. ADC Module Block Diagram

### 13.4 ADC Configurability

Some ADC configurations are individually controlled by the SOCx, while others are globally controlled per ADC module. [Table 13-1](#) summarizes the basic ADC options and their level of configurability. The subsequent sections discuss these configurations.

Table 13-1. ADC Options and Configuration Levels

| Options    | Configurability                |
|------------|--------------------------------|
| Clock      | Per module <sup>(1)</sup>      |
| Resolution | Not configurable (12-bit only) |

<sup>(1)</sup> Writing these values differently to different ADC modules could cause the ADCs to operate asynchronously. See [Section 13.15.1](#) for guidance on when the ADCs are operating synchronously or asynchronously.

**Table 13-1. ADC Options and Configuration Levels (continued)**

| Options                     | Configurability                      |
|-----------------------------|--------------------------------------|
| Signal mode                 | Not configurable (single-ended only) |
| Reference voltage source    |                                      |
| Trigger source              | Per SOC <sup>(1)</sup>               |
| Converted channel           | Per SOC                              |
| Acquisition window duration | Per SOC <sup>(1)</sup>               |
| EOC location                | Per module                           |
| Burst Mode                  | Per module <sup>(1)</sup>            |

### 13.4.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). This clock is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field which determines the ADCCLK. The ADCCLK is used to clock the converter.

The core requires approximately 10.5 ADCCLK cycles to process a voltage into a conversion result. It is necessary for the user to determine the required duration of the acquisition window, see [Section 13.15.2](#).

---

**NOTE:** To determine an appropriate value for ADCCTL2.PRESCALE, consult the datasheet of your device to determine the maximum SYSCLK and ADCCLK frequency.

---

### 13.4.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. This ADC supports a resolution of 12 bits.

### 13.4.3 Voltage Reference

#### 13.4.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode these pins are used as a ratiometric reference to determine the ADC conversion input range.

See [Section 13.15.4](#) for information on how to supply the reference voltage.

**NOTES:**

- On devices with no external VREFLO signals, VREFLO has been internally connected to the device analog ground, VSSA.
- Consult the datasheet for your device to determine the allowable voltage range for VREFHI and VREFLO.
- The external reference mode requires an external capacitor on the VREFHI pin. Consult the device datasheet for the specific value required.

#### 13.4.3.2 Internal Reference Mode

In internal reference mode the device drives a voltage out onto the VREFHI pin. The VREFHI and VREFLO pins then set the ADC conversion range.

The internal reference voltage can be configured to be either 2.5V or 1.65V. When a 1.65V internal reference voltage is selected, the effective ADC conversion input range will be VREFLO to 3.3V.

**NOTES:**

- The internal reference mode also requires an external capacitor on the VREFHI pin. Consult the device datasheet for the specific value required.

### 13.4.3.3 Ganged References

On some packages, the voltage reference pins for multiple ADCs may be combined. In this case, it is necessary to configure the ganged references identically when selecting external vs. internal reference mode and for selecting an internal reference voltage range of 3.3V or 2.5V.

For example, if ADC B and ADC C reference pins are combined and the desired reference mode is 2.5V internal reference mode, the following reference configuration code should be run:

```
//ADCB VREFHI and ADCC VREFHI share a pin
//ADCB VREFLO and ADCC VREFLO share a pin
//Both references must be explicitly configured
//Both references must be configured identically
SetVREF(ADC_ADCB, ADC_INTERNAL, ADC_VREF2P5);
SetVREF(ADC_ADCC, ADC_INTERNAL, ADC_VREF2P5);
```

Internal device hardware will ensure multiple references don't drive conflicting voltages onto the same pin. Because of this, references can be configured in any order or over any amount of time.

### 13.4.3.4 Selecting Reference Mode

The voltage reference mode should be configured by using either SetVREF or ADC\_setVREF function provided in C2000Ware. Using any of these functions ensures that the correct trim is loaded in the ADC trim registers. This function must be called at least once after a device reset. Do not configure the voltage reference mode by directly writing to the ANAREFCTL register.

### 13.4.4 Signal Mode

The ADC supports single-ended signaling.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCINx), referenced to VREFLO.

### 13.4.5 Expected Conversion Results

Based on a given analog input voltage, the ideal expected digital conversion is given by the tables below. Fractional values are truncated.

**Table 13-2. Analog to 12-bit Digital Formulas**

| Analog Input                    | Digital Result                                                             |
|---------------------------------|----------------------------------------------------------------------------|
| when $ADCINy \leq VREFLO$       | $ADCRESULTx = 0$                                                           |
| when $VREFLO < ADCINy < VREFHI$ | $ADCRESULTx = 4096 \left( \frac{ADCINy - VREFLO}{VREFHI - VREFLO} \right)$ |
| when $ADCINy \geq VREFHI$       | $ADCRESULTx = 4095$                                                        |

### 13.4.6 Interpreting Conversion Results

Based on a given ADC conversion result, the ideal corresponding analog input is given by the following tables. This corresponds to the center of the possible range of analog voltages that could have produced this conversion result.

**Table 13-3. 12-Bit Digital-to-Analog Formulas**

| Digital Value                | Analog Equivalent                                                            |
|------------------------------|------------------------------------------------------------------------------|
| when $ADCRESULTy = 0$        | $ADCINx \leq VREFLO$                                                         |
| when $0 < ADCRESULTy < 4095$ | $ADCINx = (VREFHI - VREFLO) \left( \frac{ADCRESULTy}{4096} \right) + VREFLO$ |
| when $ADCRESULTy = 4095$     | $ADCINx \geq VREFHI$                                                         |

## 13.5 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper will ensure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and/or acquisition window as desired. Configuring multiple SOCs to use the same trigger will allow the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel will allow for oversampling.

**Figure 13-2. SOC Block Diagram**

### 13.5.1 SOC Configuration

Each SOC has its own configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, and acquisition (sample) window duration.

### 13.5.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCA from each ePWM module

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

### 13.5.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in their ability to drive an analog signal quickly and effectively. In order to achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

Acquisition window = (ACQPS + 1) · (System Clock (SYSCLK) cycle time)

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The datasheet will specify a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

### 13.5.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see [Figure 13-3](#)) can be found in the device data manual.

**Figure 13-3. Single-Ended Input Model**

These input models should be used along with actual signal source impedance to determine the acquisition window duration. See [Section 13.15.2](#) for more information.

### 13.5.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. This is summarized in [Table 13-4](#).

**Table 13-4. Channel Selection of Input Pins**

| Input Mode   | CHSEL | Input   |
|--------------|-------|---------|
| Single-Ended | 0     | ADCIN0  |
|              | 1     | ADCIN1  |
|              | 2     | ADCIN2  |
|              | 3     | ADCIN3  |
|              | 4     | ADCIN4  |
|              | 5     | ADCIN5  |
|              | 6     | ADCIN6  |
|              | 7     | ADCIN7  |
|              | 8     | ADCIN8  |
|              | 9     | ADCIN9  |
|              | 10    | ADCIN10 |
|              | 11    | ADCIN11 |
|              | 12    | ADCIN12 |
|              | 13    | ADCIN13 |
|              | 14    | ADCIN14 |
|              | 15    | ADCIN15 |

## 13.6 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOC5s to produce some conversions.

### 13.6.1 Single Conversion from ePWM Trigger

To configure ADC5 to perform a single conversion on channel ADCIN1 when the ePWM timer reaches its period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOC5s could be used.

Assuming a 100ns sample window is desired with a SYSCLK frequency of 100MHz, then the acquisition window duration should be  $100\text{ns}/10\text{ns} = 10$  cycles. The ACQPS field should therefore be set to  $10 - 1 = 9$ .

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 will convert ADCIN1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 9;      //SOC5 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 will begin conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCIN1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCIN1 will begin sampling when SOC5 gains priority (see [Section 13.7](#)). The ADC control logic will sample ADCIN1 with the specified acquisition window width of 100 ns. Immediately after the acquisition is complete, the ADC will begin converting the sampled voltage to a digital value. When the ADC conversion is complete, the results will be available in the ADCRESULT5 register (see [Section 13.14](#) for exact sample, conversion, and result latch timings).

### 13.6.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCIN1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 will convert ADCIN1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 9;      //SOC5 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;      //SOC6 will convert ADCIN1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 9;      //SOC6 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;   //SOC6 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;      //SOC7 will convert ADCIN1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 9;      //SOC7 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;   //SOC7 will begin conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;      //SOC8 will convert ADCIN1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 9;      //SOC8 will use sample duration of 10 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;   //SOC8 will begin conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches its period and generates the SOCB signal, the ADC will begin sampling channel ADCIN1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCIN1 will begin sampling when SOC5 gains priority (see [ADC Conversion Priority](#)). Once the conversion is complete for SOC5, SOC6 will begin converting ADCIN1 and the results for SOC5 will be placed in the ADCRESULT5 register. All four conversions will eventually be completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

---

**NOTE:** It is possible, but unlikely, that the ADC could begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See [ADC Conversion Priority](#) to understand how the next SOC to be converted is chosen.

---

### 13.6.3 Multiple Conversions from CPU Timer Trigger

This example will show how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 will be used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and their required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in [Table 13-5](#), where a SYCLK of 100MHz is assumed ( 10ns cycle time).

**Table 13-5. Example Requirements for Multiple Signal Sampling**

| Signal Name | Acquisition Window Requirement (ns) | Acquisition Window SYSCLK Cycles | ACQPS Register Value |
|-------------|-------------------------------------|----------------------------------|----------------------|
| Signal 1    | >240ns                              | 240ns/10ns = 24                  | 24 – 1 = 23          |
| Signal 2    | >883.333ns                          | 883.333ns/10ns = 89 (round up)   | 89 – 1 = 88          |
| Signal 3    | >220 ns                             | 220ns/10ns = 22                  | 22 – 1 = 21          |
| Signal 4    | >585ns                              | 585ns/10ns = 59 (round up)       | 59 – 1 = 58          |

Next decide which ADC pins to connect to each signal. This will be highly dependent on application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see [Table 13-6](#)).

**Table 13-6. Example Connections for Multiple Signal Sampling**

| Signal Name | ADC PIN | CHSEL Register Value |
|-------------|---------|----------------------|
| Signal 1    | ADCINA5 | 5                    |
| Signal 2    | ADCINA0 | 0                    |
| Signal 3    | ADCINA3 | 3                    |
| Signal 4    | ADCINA2 | 2                    |

With the information tabulated, it is easy to generate the SOC configurations:

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;          //SOC0 will use sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;         //SOC0 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;           //SOC1 will convert ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;          //SOC1 will use sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;         //SOC1 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;           //SOC2 will convert ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;          //SOC2 will use sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;         //SOC2 will begin conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;           //SOC3 will convert ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;          //SOC3 will use sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;         //SOC3 will begin conversion on CPU1 Timer 2
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 will eventually be sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) will be in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) will be in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

---

**NOTE:** It is possible, but unlikely, that the ADC could begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See [ADC Conversion Priority](#) to understand how the next SOC to be converted is chosen.

---

### 13.6.4 Software Triggering of SOC's

At any point, whether or not the SOC's have been configured to accept a specific trigger, a software trigger can set the SOC's to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger could be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;           //set SOC flags for SOC0 to SOC3
```

### 13.7 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the order in which they are converted. The default priority method is round robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset by a device reset, when the ADCCTL1.RESET bit is set, or when the SOCPRICTL register is written.

An example of the round robin priority method is given in [Figure 13-4](#).

**Figure 13-4. Round Robin Priority Example**

- A** After reset, SOC0 is highest priority SOC ;  
SOC7 receives trigger;  
SOC7 configured channel is converted immediately.
- B** RRPOINTER changes to point to SOC 7;  
SOC8 is now highest priority SOC .
- C** SOC2 & SOC12 triggers rcvd. simultaneously ;  
SOC12 is first on round robin wheel ;  
SOC12 configured channel is converted while  
SOC2 stays pending.
- D** RRPOINTER changes to point to SOC 12;  
SOC2 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 2;  
SOC3 is now highest priority SOC .

The SOC PRIORITY field in the ADCSOC PRIORITY CTL register can be used to assign high priority from a single to all of the SOC s. When configured as high priority, an SOC will interrupt the round robin wheel after any current conversion completes and insert itself in as the next conversion. After its conversion completes, the round robin wheel will continue where it was interrupted. If two high priority SOC s are triggered at the same time, the SOC with the lower number will take precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOC PRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOC PRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in [Figure 13-5](#).

**Figure 13-5. High Priority Example**

Example when SOC PRIORITY = 4

- A** After reset, SOC4 is 1<sup>st</sup> on round robin wheel ;  
SOC7 receives trigger ;  
SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ;  
SOC8 is now 1<sup>st</sup> on round robin wheel .
- C** SOC2 & SOC12 triggers rcvd. simultaneously ;  
SOC2 interrupts round robin wheel and SOC 2 configured channel is converted while SOC 12 stays pending .
- D** RRPOINTER stays pointing to 7 ;  
SOC12 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 12 ;  
SOC13 is now 1<sup>st</sup> on round robin wheel .

## 13.8 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOC's one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOC's that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOC's are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper will not set all round-robin SOC's to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOC's. The first SOC to be set will be that with the highest priority based on the round-robin pointer, and subsequent SOC's will be set until BURSTSIZE SOC's have been set.

---

**NOTE:** When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received.

---

### 13.8.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ADCIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations could be configured for each SOC as desired.

```
AdcaRegs.BURSTCTL.BURSTEN = 1;           //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;          //CPU1 Timer 2 will trigger burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;          //conversion bursts are 1 + 1 = 2 conversions long

AdcaRegs.SOCPRCTL.bit.SOCPRIORITY = 12;   //SOC0 to SOC11 are high priority

AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;        //SOC12 will convert ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;       //SOC12 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;        //SOC13 will convert ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;       //SOC13 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;        //SOC14 will convert ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;       //SOC14 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;        //SOC15 will convert ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;       //SOC15 will use sample duration of 20 SYSCLK cycles
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 will be converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 will be converted once their SOC's gain priority. The results for SOC12 and SOC13 will be in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round robin pointer will give highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 will be set as pending and eventually be converted. The results for SOC14 and SOC15 will be in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers will continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions could be achieved using a similar approach.

### 13.8.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOC's is presented in [Figure 13-6](#).

Figure 13-6. Burst Priority Example

Example when SOC PRIORITY = 4, BURSTEN = 1, and BURSTSIZE = 1

- A** After reset, SOC4 is 1<sup>st</sup> on round robin wheel;  
BURSTTRIG trigger is received;  
SOC4 & SOC5 are set and configured channels converted immediately.
- B** RRPOINTER changes to point to SOC5;  
SOC6 is now 1<sup>st</sup> on round robin wheel.
- C** BURSTTRIG & SOC1 triggers rcvd. simultaneously;  
SOC1, SOC6, and SOC7 are set;  
SOC1 interrupts round robin wheel and SOC1 configured channel is converted while SOC6 and SOC7 stay pending.
- D** RRPOINTER stays pointing to 5;  
SOC6/SOC7 configured channels are now converted.
- E** RRPOINTER changes to point to SOC7;  
SOC8 is now 1<sup>st</sup> on round robin wheel, waiting for BURSTTRIG.

## 13.9 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit `INTPULSEPOS` in the `ADCCTL1` register. See [Section 13.14](#), for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each `ADCINT` can be read directly or the interrupt can be passed on to the PIE.

Figure 13-7 shows a block diagram of the ADC interrupt structure.

Figure 13-7. ADC EOC Interrupts

### 13.9.1 Interrupt Overflow

If the EOC signal would set a flag in the `ADCINTFLG` register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts will not be passed on to the PIE module. When an overflow occurs on a given flag in the `ADCINTFLG` register, the corresponding flag in the `ADCINTOVF` register is set. This overflow flag is only used to detect that an overflow has occurred; it does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow could occur, the application should check the appropriate `ADCINTOVF` flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippet demonstrates how to check the `ADCINTOVF` flag inside the ISR after attempting to clear the `ADCINT` flag.

```
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;    //clear INT1 flag for ADC-A
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)    //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1 //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1 //Re-clear ADCINT flag
}
```

### 13.9.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts will not be issued to the PIE. By activating this mode ADC interrupts will always reach the PIE. The ADCINTOVF register will still be set if an interrupts occur while ADCINTFLG is still set regardless of this configuration.

### 13.9.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when they become available. However, the timing of the early interrupt may be too early and the application may need to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable via the OFFSET field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The OFFSET value of the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of OFFSET goes beyond EOC, the ADC interrupt will be generated along with EOC.
- Writing values to OFFSET when INTPULSEPOS is set to 1 will not have any effect on the interrupt generation.

## 13.10 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. Each PPB can simultaneously remove an offset associated with the ADCIN channel, subtract out a reference value, flag a zero-crossing point, and flag a high or low compare limit. Furthermore, the zero-crossing and compare flags can trip a PWM and/or generate an interrupt. A PPB is also capable of recording the delay between when the SOC associated with the PPB is triggered and when it actually begins to be sampled. [Figure 13-8](#) presents the structure of each PPB. Subsequent sections explain the use of each submodule.

Figure 13-8. ADC PPB Block Diagram

### 13.10.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCBPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCBPBxOFFCAL.OFFCAL register. The post-processing block will automatically add or subtract the value in the OFFCAL register from the raw conversion result and store it in the ADCRESULT register. This addition/subtraction will saturate at 0 on the low end and 4095 on the high end.

#### NOTES:

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
- It is possible to point multiple PPBs to the same SOC. In this case, the OFFCAL value that will actually be applied will be that of the PPB with the highest number.
- In particular, care needs to be taken when using the PPB on SOC0, as all the PPB point to this SOC by default. This may cause unintentional overwriting of offset correction of a lower numbered PPB by a higher numbered PPB.

### 13.10.2 PPB Error Calculation

In many applications, an error from a setpoint or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these function automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block will automatically subtract the value in the OFFREF register from the ADCRESULT value and store it in the ADCPPBxRESULT register. This subtraction will produce a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

#### NOTES:

- Do not write a value larger than 12 bits to the OFFREF register.
- Since the PPBxRESULT register is unique for each PPB, it is possible to point multiple PPBs to the same SOC and get different results for each PPB.
- Writing a 0 to the OFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.

### 13.10.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against a high and low limit or whenever ADCPPBxRESULT changes sign. Based on these comparisons, it can generate a trip to the PWM and/or an interrupt automatically, lowering the sample to ePWM latency and reducing software overhead. This functionality also enables safety conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zerocrossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit will be set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by EOC and not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCINTSEL register has corresponding bits which allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in [Figure 13-9](#).

**Figure 13-9. ADC PPB Interrupt Event**

**NOTES:**

- Zero-crossing and limit compare reference the ADCPPBxRESULT register. This will include any correction applied by the OFFCAL and OFFREF registers. TRIPHI and TRIPLO do NOT perform a signed comparison. It is recommended to leave OFFREF as 0 when using limit compare functionality.
- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR will have to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and/or zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.

#### 13.10.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops will collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field will contain the number of SYSCLK cycles between when the associate SOC was triggered and when it began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

---

**NOTE:** If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register may overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

---

---

**NOTE:** The sample delay capture will not function if the associated SOC is triggered via software. It will, however, correctly record the delay if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

---

### 13.11 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in [Figure 13-10](#).

#### NOTES:

- The divider resistance tolerances can vary widely, hence this feature should not be used to check for conversion accuracy.
- Consult the device data manual for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum will be needed .

**Figure 13-10. Opens/Shorts Detection Circuit**

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This will cause the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in [Table 13-7](#).

**Table 13-7. DETECTCFG Settings**

| ADCOSDETECT.DETECTCFG | Source Voltage | S4     | S3     | S2     | S1     | Drive Impedance |
|-----------------------|----------------|--------|--------|--------|--------|-----------------|
| 0                     | Off            | Open   | Open   | Open   | Open   | Open            |
| 1                     | Zero Scale     | Closed | Open   | Open   | Closed | 5K    7K        |

### 13.11.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance  $R_S$ , shunt capacitor  $C_P$ , the equivalent OSDETECT resistance  $R_{OSDETECT}$  and voltage  $V_{OSDETECT}$  is shown in Figure 13-11 and can be used as a basis to calculate the signal level going in to the sampling capacitor.  $R_{OSDETECT}$  and  $V_{OSDETECT}$  are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 13-7 for the different configuration settings. Refer to Figure 13-11 when deriving the input signal to S/H if signal source  $V_S$  is driving while the OSDETECT feature is enabled.

Figure 13-11. Input Circuit Equivalent with OSDETECT Enabled

The input impedance  $R_S$  and  $C_P$  may be integral parts of the signal source or these could have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature as this would affect the conversion results. For instance, driving an input signal when this feature is enabled would connect signal  $V_S$  to the OSDETECT circuit through  $R_S$  and affecting the ADC results. Larger  $C_P$  values (in the order greater than hundreds of pF) would require using higher ACQPS to ensure that signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 13-7.
3. Initiate a conversion and inspect the conversion result.

**Note:** You must interpret the results based on what is driving on the input side and what are the values of  $R_S$  and  $C_P$ . If the  $V_S$  signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

first then

### 13.11.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with good drive strength (pin not open) will be minimally affected. However, if the pin is open, the sampled voltages will be close to the source voltages specified in Table 13-7.

### 13.11.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal will be pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) will be pulled toward each sourced voltage. However, if the pin is shorted, the signal will remain at the same voltage.

## 13.12 Power-Up Sequence

Upon device power-up or system level reset, the ADC will be powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data manual for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as it occurs after all the ADCs have begun powering up.

### 13.13 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs and the gain and offset of the PGAs.. These trim settings are embedded into TI reserved OTP memory as part of C-callable functions.

- The Device\_cal() function copies the trim values for ADC and PGA gain and offset from OTP memory to their respective trim registers.
- The trim functions in Device\_cal() are callable in C2000Ware as ADC\_setOFFSETTRIM() and ADC\_setINLTRIM() and PGA\_setGAINTRIM(). These functions fetch trim values from the TI reserved OTP memory source locations where the values are stored during test process as well as the analog module register destinations where the trim values are copied to.

Until the appropriate factory trim is loaded, the ADC (and other modules) will not be guaranteed to operate within datasheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) will not be guaranteed to operate within datasheet specifications.

The boot ROM will call the calibration functions, so trim values should be initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user can call the calibration functions (defined in the headerfiles).

#### 13.13.1 ADC Zero Offset Calibration

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO. The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register will be applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results will not be affected and the full dynamic range of the ADC will be maintained for any trim value.

Using the GetAdcOffsetTrimOTP(Uint16) function, the ADCOFFTRIM register can be loaded with the factory calibrated offset error correction. The user can modify the ADCOFFTRIM register to compensate for additional offset error induced by the application environment if desired, but this is not typically necessary to achieve datasheet specified performance.

---

**NOTE:** Regardless of the converter resolution, the size of each ADCOFFTRIM step is (VREFHI-VREFLO)/65536.

---

Use the following procedure to re-calibrate the ADC offset in 12-bit, single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that may reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32\*16 conversions = 512 conversions).
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

### 13.14 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must ensure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the datasheet. The conversion time is approximately 10.5 ADCCLK cycles. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in [Section 13.14.1](#) for exact timings.

### 13.14.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOC's given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOC's are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

The following parameters are identified in the timing diagrams:

**Table 13-8. ADC Timing Parameters**

| PARAMETER | DESCRIPTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $t_{SH}$  | <p>The duration of the S+H window.</p> <p>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by <math>(ACQPS + 1)</math> SYSCLK cycles. ACQPS can be configured individually for each SOC, so <math>t_{SH}</math> will not necessarily be the same for different SOCs.</p> <p><b>Note:</b> The value on the S+H capacitor will be captured approximately 5ns before the end of the S+H window regardless of device clock settings.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| $t_{LAT}$ | <p>The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.</p> <p>If the ADCRESULTx register is read before this time, the previous conversion results will be returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $t_{EOC}$ | <p>The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. The subsequent sample can start before the conversion results are latched. The subsequent sample can start before the conversion results are latched.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $t_{INT}$ | <p>The time from the end of the S+H window until an ADCINT flag is set (if configured).</p> <p>If the INTPULSEPOS bit in the ADCCTL1 register is set, <math>t_{INT}</math> will coincide with the conversion results being latched into the result register.</p> <p>If the INTPULSEPOS bit is 0, <math>t_{INT}</math> will coincide with the end of the S+H window. If <math>t_{INT}</math> triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to ensure the read occurs after the results latch (otherwise, the previous results will be read).</p> <p>If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there will be a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the DMA at exactly the time the sample is ready.</p> |

## 13.15 Additional Information

The following sections contain additional practical information.

### 13.15.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device should be operated synchronously. The device datasheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To ensure synchronous operation, all ADCs on the device should operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration).

### 13.15.1.1 Basic Synchronous Operation

The below example configures two SOC's each on ADCA and ADCB with identical trigger select and ACQPS values. This will result in synchronous operation between ADCA and ADCB. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

#### Example: Basic Synchronous Operation

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;    //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOC0B
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;    //SOC0 will convert ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOC0B

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;    //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOC0B
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;    //SOC1 will convert ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOC0B
```

**Figure 13-14. Example: Basic Synchronous Operation**

Several things should be noted from [Figure 13-14](#). First, while the ACQPS values must be the same for SOC's with the same number, different ACQPS values can be used for SOC's with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high priority SOC's are to be used, the priority must be configured the same on all ADCs.

### 13.15.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOC's has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The below example demonstrates synchronous operation between ADCA and ADCB while using three SOC's and two trigger sources. [Figure 13-15](#) demonstrates that any combination of relative trigger timings still results in synchronous operation.

**Example: Synchronous Operation With Multiple Trigger Sources**

```

AdcaRegs.ADCS0C0CTL.bit.CHSEL = 4;    //SOC0 will convert ADCINA4
AdcaRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCS0C0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCS0C0CTL.bit.CHSEL = 0;    //SOC0 will convert ADCINB0
AdcbRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCS0C0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCS0C1CTL.bit.CHSEL = 4;    //SOC1 will convert ADCINA4
AdcaRegs.ADCS0C1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCS0C1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCS0C1CTL.bit.CHSEL = 1;    //SOC1 will convert ADCINB1
AdcbRegs.ADCS0C1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCS0C1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCS0C2CTL.bit.CHSEL = 0;    //SOC2 will convert ADCINA0
AdcaRegs.ADCS0C2CTL.bit.ACQPS = 19;   //SOC2 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCS0C2CTL.bit.TRIGSEL = 2;  //SOC2 will begin conversion on CPU Timer1
AdcbRegs.ADCS0C2CTL.bit.CHSEL = 2;    //SOC2 will convert ADCINB2
AdcbRegs.ADCS0C2CTL.bit.ACQPS = 19;   //SOC2 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCS0C2CTL.bit.TRIGSEL = 2;  //SOC2 will begin conversion on CPU Timer1

```

**Figure 13-15. Example: Synchronous Operation with Multiple Trigger Sources**

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so it will likely result in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

**13.15.1.3 Synchronous Operation with Uneven SOC Numbers**

If only one trigger source is used, one ADC can use more SOCs than the other ADCs while still operating synchronously.

**Example: Synchronous Operation With Uneven SOC Numbers**

```

AdcaRegs.ADCS0C0CTL.bit.CHSEL = 4;    //SOC0 will convert ADCINA4
AdcaRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCS0C0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCS0C0CTL.bit.CHSEL = 0;    //SOC0 will convert ADCINB0
AdcbRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCS0C0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCS0C1CTL.bit.CHSEL = 4;    //SOC1 will convert ADCINA4
AdcaRegs.ADCS0C1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCS0C1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCS0C1CTL.bit.CHSEL = 1;    //SOC1 will convert ADCINB1
AdcbRegs.ADCS0C1CTL.bit.ACQPS = 30;   //SOC1 will use sample duration of 31 SYSCLK cycles
AdcbRegs.ADCS0C1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCS0C2CTL.bit.CHSEL = 0;    //SOC2 will convert ADCINA0
AdcaRegs.ADCS0C2CTL.bit.ACQPS = 19;   //SOC2 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCS0C2CTL.bit.TRIGSEL = 10; //SOC2 will begin conversion on ePWM3 SOCB

```

**Figure 13-16. Example: Synchronous Operation with Uneven SOC Numbers**

Note that if the trigger comes again before all SOC's have completed their conversions, ADCB will begin converting immediately on SOC0 while ADCA will not start converting SOC0 again until SOC2 is complete. This will result in asynchronous operation, so care must be taken to not overflow the trigger.

**Figure 13-17. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow**

### 13.15.1.4 Non-overlapping Conversions

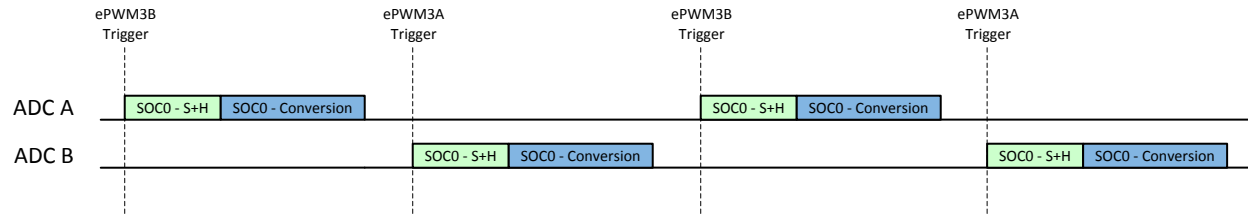

If conversion timings can be guaranteed to not overlap by the user, then it is not necessary to configure all SOC's identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources which are always 180 degrees out-of-phase, then SOC0 could be used for both ADCA and ADCB with different trigger sources and different ACQPS values.

**Example: Operation with Non-overlapping Conversions**

```

//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCS0C0CTL.bit.CHSEL = 4;    //SOC0 will convert ADCINA4
AdcaRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCS0C0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCS0C0CTL.bit.CHSEL = 0;    //SOC0 will convert ADCINB0
AdcbRegs.ADCS0C0CTL.bit.ACQPS = 19;   //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCS0C0CTL.bit.TRIGSEL = 9;  //SOC0 will begin conversion on ePWM3 SOCA

```

**Figure 13-18. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions**

### 13.15.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor will be charged to within ½ LSB or ¼ LSB of the final value, depending on the tolerable settling error.

An approximation of the required settling time can be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_s + R_{on}) \cdot C_h + R_s \cdot (C_s + C_p)$$

And the number of time constants needed is given by the equation:

$$k = \ln \left( \frac{2^n}{\text{settling error}} \right) - \ln \left( \frac{C_s + C_p}{C_h} \right)$$

So the total S+H time should be set to at least:

$$t = k \cdot \tau$$

Where the following parameters are provided by the ADC input model in the device data manual:

- n = ADC resolution (in bits)
- R<sub>ON</sub> = ADC sampling switch resistance (in Ohms)
- C<sub>H</sub> = ADC sampling capacitor (in pF)
- C<sub>p</sub> = ADC channel parasitic input capacitance (in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- R<sub>s</sub> = ADC driving circuit source impedance (in Ohms)
- C<sub>s</sub> = capacitance on ADC input pin (in pF)

For example, assuming the following parameters:

- n = 12-bits
- R<sub>ON</sub> = 500Ω
- C<sub>H</sub> = 12.5pF
- C<sub>p</sub> = 12.7pF
- settling error = ¼ LSB
- R<sub>s</sub> = 180Ω
- C<sub>s</sub> = 150pF

The time constant would be calculated as:

$$\tau = (180\Omega + 500\Omega) \cdot 12.5pF + 180\Omega \cdot (150pF + 12.7pF) = 8.5ns + 29.3ns = 37.8ns$$

And the number of required time constants would be:

$$k = \ln\left(\frac{2^{12}}{0.25}\right) - \ln\left(\frac{150pF + 12.7pF}{12.5pF}\right) = 9.70 - 2.57 = 7.13$$

So the S+H time should be set to at least:

$$37.8ns \cdot 7.13 = 270ns$$

If SYSCLK = 100 MHz, then each SYSCLK is 10ns. S+H duration should be 270ns/10ns = 27.0 SYSCLKs so ACQPS for this input should be set to at least CEILING(27.0) – 1 = 26.

While this gives a rough estimate of the required acquisition window, a better method would be to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

---

**NOTE:** The device datasheet will specify a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

---

### 13.15.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, it is easy to achieve simultaneous sampling. This is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The example below demonstrates x3 simultaneous sampling based on an ePWM3 event. ADCINA3, ADCINB5, and ADCINC5 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;           //SOC0 will convert ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINB5
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
```

When the ePWM3 trigger is received, all three ADCs will begin converting in parallel immediately. All results will be in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples will not happen at exactly the same time.

### 13.15.4 Designing an External Reference Circuit

shows the basic organization of the external voltage reference generation circuitry. A single reference voltage generation source should be shared by all ADC modules. This will minimize reference voltage mismatch between ADC modules. The reference voltage should then be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the reference pin. A capacitor between the high and low reference pins should be placed on the PCB as close to the pins as practical to help absorb high frequency currents. A series resistor (typically <1Ω ) in series with this capacitor may be necessary to ensure op-amp stability.

It is also possible to share two reference pins between one op-amp driver. This organization is shown in . This will give slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but it should still be possible to achieve all ADC specifications in the data manual.

Figure 13-19. ADC Shared Reference System

**Figure 13-20. ADC Shared Reference**

### 13.15.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN14 on ADCB by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the `GetTemperatureC()` function in `F28004x_TempSensorConv.c`.

Note that this function assumes that the temperature reading was taken with  $VREFHI = 2.5V$ . If a different reference voltage is used, the sample should be scaled appropriately before passing it to the function by using the below formula.

$$\text{adjusted sensor reading} = \text{raw sensor reading} * (VREFHI / 2.5V)$$

## 13.16 ADC Registers

This section describes the Analog-to-Digital Converter Registers.

### 13.16.1 ADC Base Addresses

**Table 13-10. ADC Base Address Table**

| Device Registers | Register Name   | Start Address | End Address |
|------------------|-----------------|---------------|-------------|
| AdcaResultRegs   | ADC_RESULT_REGS | 0x0000_0B00   | 0x0000_0B1F |
| AdcbResultRegs   | ADC_RESULT_REGS | 0x0000_0B20   | 0x0000_0B3F |
| AdccResultRegs   | ADC_RESULT_REGS | 0x0000_0B40   | 0x0000_0B5F |
| AdcaRegs         | ADC_REGS        | 0x0000_7400   | 0x0000_747F |
| AdcbRegs         | ADC_REGS        | 0x0000_7480   | 0x0000_74FF |
| AdccRegs         | ADC_REGS        | 0x0000_7500   | 0x0000_757F |

### 13.16.2 ADC\_REGS Registers

Table 13-11 lists the ADC\_REGS registers. All register offset addresses not listed in Table 13-11 should be considered as reserved locations and the register contents should not be modified.

**Table 13-11. ADC\_REGS Registers**

| Offset | Acronym       | Register Name                             | Write Protection | Section            |
|--------|---------------|-------------------------------------------|------------------|--------------------|
| 0h     | ADCCTL1       | ADC Control 1 Register                    | EALLOW           | <a href="#">Go</a> |

| <b>Reset or Default Value</b>   |         |                                        |
| -n                              |         | Value after reset or the default value |
| <b>Register Array Variables</b> |         |                                        |

**Table 13-12. ADC\_REGS Access Type Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 13.16.2.1 ADCCTL1 Register (Offset = 0h) [reset = 0h]

ADCCTL1 is shown in [Figure 13-21](#) and described in [Table 13-13](#).

Return to the [Summary Table](#).

### 13.16.2.20 ADCSOC3CTL Register (Offset = 16h) [reset = 0h]

ADCSOC3CTL is shown in [Figure 13-40](#) and described in [Table 13-32](#).

Return to the [Summary Table](#).

ADC SOC3 Control Register

### 13.16.2.21 ADCSOC4CTL Register (Offset = 18h) [reset = 0h]

ADCSOC4CTL is shown in [Figure 13-41](#) and described in [Table 13-33](#).

Return to the [Summary Table](#).

ADC SOC4 Control Register

### 13.16.2.22 ADCSOC5CTL Register (Offset = 1Ah) [reset = 0h]

ADCSOC5CTL is shown in [Figure 13-42](#) and described in [Table 13-34](#).

Return to the [Summary Table](#).

ADC SOC5 Control Register

### 13.16.2.23 ADCSOC6CTL Register (Offset = 1Ch) [reset = 0h]

ADCSOC6CTL is shown in [Figure 13-43](#) and described in [Table 13-35](#).

Return to the [Summary Table](#).

ADC SOC6 Control Register

### 13.16.2.24 ADCSOC7CTL Register (Offset = 1Eh) [reset = 0h]

ADCSOC7CTL is shown in [Figure 13-44](#) and described in [Table 13-36](#).

Return to the [Summary Table](#).

ADC SOC7 Control Register

### 13.16.2.25 ADCSOC8CTL Register (Offset = 20h) [reset = 0h]

ADCSOC8CTL is shown in [Figure 13-45](#) and described in [Table 13-37](#).

Return to the [Summary Table](#).

ADC SOC8 Control Register

### 13.16.2.26 ADCSOC9CTL Register (Offset = 22h) [reset = 0h]

ADCSOC9CTL is shown in [Figure 13-46](#) and described in [Table 13-38](#).

Return to the [Summary Table](#).

ADC SOC9 Control Register

| 15-0 | OFFREF | R/W  | 0h    | <p>ADC Post Processing Block 1 Offset Correction. This bit field can be used to either calculate the feedback error or convert a unipolar signal to bipolar by subtracting a reference value. This 16-bit unsigned value is subtracted from the ADCRESULT register before being passed through an optional two's complement function and stored in the ADCPPB1RESULT register. This subtraction is not saturated.</p> <p>0000h No change. The ADCRESULT value is passed on.<br/> 0001h ADCRESULT - 1 is passed on.<br/> 0002h ADCRESULT - 2 is passed on.<br/> ...<br/> 8000h ADCRESULT - 32,768 is passed on.<br/> ...<br/> FFFFh ADCRESULT - 65,535 is passed on.</p> <p>NOTE: In 12-bit mode the size of this register does not change from 16-bits. It is the user's responsibility to ensure that only a 12-bit value is written to this register when in 12-bit mode.</p> <p>Reset type: SYSRSn</p> |

### 13.16.2.45 ADCPPB1TRIPHI Register (Offset = 44h) [reset = 0h]

ADCPPB1TRIPHI is shown in [Figure 13-65](#) and described in [Table 13-57](#).

Return to the [Summary Table](#).

## Programmable Gain Amplifier (PGA)

The Programmable Gain Amplifier (PGA) is used to amplify an input voltage for the purpose of increasing the dynamic range of the downstream ADC and CMPSS modules.

## 14.1 Programmable Gain Amplifier (PGA) Overview

The integrated PGA helps to reduce cost and design effort for many control applications that traditionally require external, standalone amplifiers. On-chip integration ensures that the PGA is compatible with the downstream ADC and CMPSS modules. Software selectable gain and filter settings make the PGA adaptable to various performance needs.

### 14.1.1 Features

Features available to PGA modules are:

- Four programmable gain modes: 3x, 6x, 12x, 24x
- Internally powered by VDDA and VSSA
- Hardware-based trims to reduce offset and gain errors
- Support for Kelvin ground connections using PGA\_GND pin
- Embedded series resistors for RC filtering

### 14.1.2 Block Diagram

The active component in the PGA is an embedded operational amplifier (op-amp) that is configured as a non-inverting amplifier with internal feedback resistors. These internal feedback resistor values are paired to produce software selectable voltage gains.

Three PGA signals are available at the device pins:

- PGA\_IN is the positive input to the PGA op-amp. The signal applied to this pin will be amplified by the PGA.
- PGA\_GND is the Kelvin ground reference for the PGA\_IN signal. Ideally, the PGA\_GND reference is equal to VSSA, however the PGA can tolerate small voltage offsets from VSSA. See the device data manual for more information.
- PGA\_OF supports op-amp output filtering with RC components. The filtered signal is available for sampling and monitoring by internal ADC and CMPSS modules.

PGA\_OUT is an internal signal at the op-amp output. It is available for sampling and monitoring by the internal ADC and CMPSS modules.

**Figure 14-1. PGA Block Diagram**

## 14.2 Linear Output Range

The absolute output range of the PGA is bounded by the analog VDDA and VSSA supplies – the PGA cannot produce output voltages greater than VDDA or less than VSSA.

Although the PGA can produce full-scale output across the absolute voltage range of VSSA to VDDA, the amplifier output is only linear within a subset of the absolute range. This reduced range is referred to as the linear output range.

The PGA performance specifications in the device data manual only apply to the linear output range. For best performance, the input signal should be conditioned in such a way that the PGA stays within the linear output range during normal system operation.

---

**NOTE:** The voltage input range required to operate the PGA in the linear output range is unique for each gain mode. See the device data manual for the linear output range.

---

## 14.3 Gain Modes

Gain modes of 3x, 6x, 12x, and 24x are software-selectable via the PGACTL[GAIN] register field. The gain of the PGA is determined by a preset ratio between resistors  $R_{OUT}$  and  $R_{GND}$ :

$$\text{Gain} = 1 + \frac{R_{OUT}}{R_{GND}}$$

The ideal target values for the gain resistors by mode are shown in [Table 14-1](#).

**Table 14-1. Ideal Gain Resistor Values**

| Gain Mode | Ideal $R_{OUT}$ | Ideal $R_{GND}$ |
|-----------|-----------------|-----------------|
| 3x        | 20k $\Omega$    | 10k $\Omega$    |
| 6x        | 25k $\Omega$    | 5k $\Omega$     |
| 12x       | 27.5k $\Omega$  | 2.5k $\Omega$   |
| 24x       | 28.75k $\Omega$ | 1.25k $\Omega$  |

Changing the gain mode during normal operation is allowed, but a minimum configuration settling time should be observed when doing so. See the device data manual for the gain switch settling time.

## 14.4 External Filtering

The PGA output may be routed to a pin through an embedded series resistor for the purpose of low-pass filtering the amplified signal. The filter resistance is software selectable via the PGACTL[FILTRESSEL] register field. The default selection of PGACTL[FILTRESSEL]=0 will disable the filter path.

The cutoff frequency can be estimated using the standard low-pass RC equation of:

$$f_c = \frac{1}{2\pi RC}$$

Each gain mode requires a minimum amount of series resistance when filtering is enabled. The values are shown in [Table 14-2](#).

**Table 14-2. Minimum Filter Resistance**

| Gain Mode | Minimum $R_{FILTER}$ |
|-----------|----------------------|
| 3x        | 50 $\Omega$          |
| 6x        | 50 $\Omega$          |
| 12x       | 80 $\Omega$          |
| 24x       | 100 $\Omega$         |

The choice of  $C_{\text{FILTER}}$  value may also influence the ADC sampling performance. See [Section 14.10.1.2](#) for more information.

## 14.5 Error Calibration

Inherent offset and gain errors can be reduced through the use of built-in hardware trim circuitry. Factory-generated values are written to the trim registers by calling the `Device_cal()` function that is located in TI reserved OTP.

### 14.5.1 Offset Error

The offset error appears as a constant DC offset across the PGA output range. The hardware trim will reduce the offset error so that it falls within data manual specifications.

**Figure 14-2. PGA Offset Trim**

D001

### 14.5.2 Gain Error

After the offset error has been removed, the remaining error, gain error appears as a scaled error that increases in magnitude with increasing PGA output voltage. The hardware trim will target the gain performance so that it falls within data manual specifications.

Figure 14-3. PGA Gain Trim

D002

## 14.6 Ground Routing

PGA\_GND should be connected to the source signal ground reference when possible. Routing the PGA\_IN and PGA\_GND signals in close proximity (especially in parallel) may also help to reduce sensitivity to external noise.

Figure 14-4. PGA\_GND to Remote Ground

PGA\_GND may also be connected to VSSA if the source signal ground reference is not available.

Figure 14-5. PGA\_GND to VSSA

PGA\_GND should not be biased with an intentional DC offset with respect to VSSA.

## **14.7 Enabling and Disabling the PGA Clock**

If the clock to the PGA is disabled while the PGA is outputting a voltage, the output voltage remains unaffected but the PGA registers will no longer be updated with register writes. Enabling the clock resumes register writes.

## **14.8 Lock Register**

The PGALOCK register provides the ability to block writes to certain PGA configuration registers. Locking register writes can prevent spurious or malicious code from modifying critical register settings. Once a register has been locked via the PGALOCK register, only a module- or device-level reset can restore write functionality.

## 14.9 Examples

### 14.9.1 Direct Amplifier

Given a small positive signal, the PGA can be used to amplify the signal to increase the dynamic range of ADC sampling and comparator trip monitoring. For example, an input signal with a valid range between 0.25V and 0.75V can be amplified in 3x mode to produce an output signal between 0.75V and 2.25V.

**Figure 14-6. PGA Amplifier Example**

The amplified output voltage is calculated as:

$$V_{PGA\_OUT} = \left(1 + \frac{R_{OUT}}{R_{GND}}\right) \times V_{PGA\_IN}$$

### 14.9.2 RC Filter

If low-pass filtering is desired, an external capacitor can be added to the PGA\_OF pin in the following topology.

**Figure 14-7. PGA Filter Example**

The amplified voltage is calculated as:

$$V_{PGA\_OUT} = \left(1 + \frac{R_{OUT}}{R_{GND}}\right) \times V_{PGA\_IN}$$

The filter cutoff frequency is estimated as:

$$f_{CUTOFF} = \frac{1}{2\pi R_{FILTER} C_{FILTER}}$$

## 14.10 Analog Front End Integration

The PGAs operate in concert with the other embedded analog modules (ADC, CMPSS, Buffered DAC) as an analog front end system.

### 14.10.1 ADC

In its simplest application, the PGA amplifies small input signals in order to increase the ADC dynamic range. The PGA also provides the additional benefit of buffering input signals from the ADC sample and hold capacitor, which further reduces sampling error.

Both the filtered and unfiltered PGA output paths are available for ADC sampling. Minimum ADC acquisition windows are recommended when sampling the PGA paths.

#### 14.10.1.1 Unfiltered Acquisition Window

The device data manual provides a minimum estimated ADC acquisition window for sampling the PGA\_OUT signal with one ADC. This estimated value should provide sampling accuracy close to the specified performance parameters of the ADC. A longer acquisition window may be used for better performance.

#### 14.10.1.2 Filtered Acquisition Window

The minimum ADC acquisition window for sampling the PGA\_OF filtered signal with one ADC will vary based on the values of  $R_{\text{FILTER}}$  and  $C_{\text{FILTER}}$ . To ensure good performance, choose a  $C_{\text{FILTER}}$  capacitor that is large enough to satisfy most of the ADC sample and hold capacitor ( $C_h$ ) charge requirements by itself. The  $C_{\text{FILTER}}$  value can be sized based on the acceptable amount of ADC sampling error ( $\text{LSB}_{\text{Err}}$ ):

$$C_{\text{FILTER}} = C_h \times 4096 / \text{LSB}_{\text{Err}}$$

See the *Analog-to-Digital Converter (ADC)* chapter to determine the optimal ADC acquisition window, where the ADC source resistance ( $R_s$ ) is equal to  $R_{\text{FILTER}}$ .

### 14.10.2 CMPSS

The PGA output can be monitored by a CMPSS module for trips above or below a reference voltage. Up to two independent reference thresholds per CMPSS can be used for trip detection.

Both the filtered and unfiltered PGA output paths are available for CMPSS trip monitoring.

See the *Comparator Subsystem (CMPSS)* chapter for CMPSS usage information.

### 14.10.3 Buffered DAC

As a best practice, the PGA input signal should be conditioned so that the PGA output is centered within its linear range. The input signal may require some combination of offset and attenuation in order to achieve this goal.

For example, an external resistor divider can attenuate the input signal while the embedded buffered DAC can provide a positive voltage offset.

Figure 14-8. Buffered DAC Offset

With the topology shown above, the voltage seen at the PGA\_IN pin can be calculated as follows:

$$V_{\text{PGA\_IN}} = \frac{20 \text{ k}\Omega \times (V_{\text{SIGNAL}} - V_{\text{DAC\_OUT}})}{10 \text{ k}\Omega + 20 \text{ k}\Omega} + V_{\text{DAC\_OUT}}$$

Supplying a  $V_{\text{DAC\_OUT}}$  of 1.65V would transform a bipolar  $V_{\text{SIGNAL}}$  range of -0.5V to +0.5V into a  $V_{\text{PGA\_IN}}$  range of 0.22V to 0.88V, which is ideal for the 3x gain mode.

See the *Buffered Digital to Analog Converter (DAC)* chapter for buffered DAC usage information.

#### 14.10.4 Alternate Functions

Each PGA has up to three device terminals for operation: ground, input, and output filter. Alternate paths at the device level allow the input and output filter terminals to take on alternate functions. This can be especially valuable if the respective PGA resource is not used for an application. The ground terminal should be tied to VSSA if the PGA is not used.

**Figure 14-9. PGA Pin Alternate Functions**

See the *Analog Subsystem* chapter for more information.

## 14.11 PGA Registers

### 14.11.1 PGA Base Addresses

**Table 14-3. I2C Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| Pga1Regs         | PGA_REGS      | 0000 5B00     | 0000 5B0F   |
| Pga2Regs         | PGA_REGS      | 0000 5B10     | 0000 5B1F   |
| Pga3Regs         | PGA_REGS      | 0000 5B20     | 0000 5B2F   |
| Pga4Regs         | PGA_REGS      | 0000 5B30     | 0000 5B3F   |
| Pga5Regs         | PGA_REGS      | 0000 5B40     | 0000 5B4F   |
| Pga6Regs         | PGA_REGS      | 0000 5B50     | 0000 5B5F   |
| Pga7Regs         | PGA_REGS      | 0000 5B60     | 0000 5B6F   |

### 14.11.2 PGA\_REGS Registers

Table 14-4 lists the PGA\_REGS registers. All register offset addresses not listed in Table 14-4 should be considered as reserved locations and the register contents should not be modified.

**Table 14-4. PGA\_REGS Registers**

| Offset | Acronym       | Register Name                                   | Write Protection | Section            |
|--------|---------------|-------------------------------------------------|------------------|--------------------|
| 0h     | PGACTL        | PGA Control Register                            | EALLOW           | <a href="#">Go</a> |
| 2h     | PGALOCK       | PGA Lock Register                               | EALLOW           | <a href="#">Go</a> |
| 4h     | PGAGAIN3TRIM  | PGA Gain Trim Register for a gain setting of 3  | EALLOW           | <a href="#">Go</a> |
| 5h     | PGAGAIN6TRIM  | PGA Gain Trim Register for a gain setting of 6  | EALLOW           | <a href="#">Go</a> |
| 6h     | PGAGAIN12TRIM | PGA Gain Trim Register for a gain setting of 12 | EALLOW           | <a href="#">Go</a> |
| 7h     | PGAGAIN24TRIM | PGA Gain Trim Register for a gain setting of 24 | EALLOW           | <a href="#">Go</a> |
| 8h     | PGATYPE       | PGA Type Register                               |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 14-5 shows the codes that are used for access types in this section.

**Table 14-5. PGA\_REGS Access Type Codes**

| Access Type                     | Code       | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |            |                                                                                                                                                                                                                                                                                      |
| R                               | R          | Read                                                                                                                                                                                                                                                                                 |
| <b>Write Type</b>               |            |                                                                                                                                                                                                                                                                                      |
| W                               | W          | Write                                                                                                                                                                                                                                                                                |
| WSonce                          | W<br>Sonce | Write<br>Set once                                                                                                                                                                                                                                                                    |
| <b>Reset or Default Value</b>   |            |                                                                                                                                                                                                                                                                                      |
| -n                              |            | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |            |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |            | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |            | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 14.11.2.1 PGACTL Register (Offset = 0h) [reset = 0h]

PGACTL is shown in [Figure 14-10](#) and described in [Table 14-6](#).

Return to the [Summary Table](#).

PGA Control Register

**Figure 14-10. PGACTL Register**

## ***Buffered Digital-to-Analog Converter (DAC)***

---

---

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

| <b>Topic</b>                     | <b>Page</b> |
|----------------------------------|-------------|
| <b>15.1 Introduction .....</b>   | <b>1675</b> |
| <b>15.2 Using the DAC .....</b>  | <b>1675</b> |
| <b>15.3 Lock Registers .....</b> | <b>1677</b> |
| <b>15.4 DAC Registers .....</b>  | <b>1678</b> |

## 15.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. For driving even higher loads than typical, a trade-off can be made between load size and output voltage swing. For the load conditions of the buffered DAC, see the device-specific data manual. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

### 15.1.1 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- x1 and x2 gain modes when using internal VREFHI
- Ability to synchronize with EPWMSYNCPER

### 15.1.2 Block Diagram

The block diagram for the buffered DAC is shown in [Figure 15-1](#).

### Figure 15-1. DAC Module Block Diagram

## 15.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI. The x2 gain mode is only available when VREFHI is set as DACREF and internal reference mode is used (see the *Analog Subsystem* chapter on how to switch to internal reference mode). Even though the buffered DAC has an x2 gain mode, the maximum output voltage from the buffered DAC will not be greater than VDDA. [Table 15-1](#) lists the gain mode combinations supported by the buffered DAC. In this table, x = A or B. X = Don't Care. VDAC/VREFHI = 2.5v, VDDA = 3.3v, and DACVAL = 4095.

**Table 15-1. DAC Supported Gain Mode Combinations**

| DACREFSEL | ANAREF <sub>x</sub> SEL | ANAREF <sub>x</sub> 2P5 | REF SOURCE | REF VOLTAGE (V) | MODE | MAXIMUM DAC OUTPUT (V) | SUPPORT STATUS |
|-----------|-------------------------|-------------------------|------------|-----------------|------|------------------------|----------------|
| 0         | X                       | X                       | EXTERNAL   | VDAC            | 0    | 2.5                    | SUPPORTED      |
| 0         | X                       | X                       | EXTERNAL   | VDAC            | 1    | 2.5                    | NOT SUPPORTED  |
| 1         | 0                       | 0                       | INTERNAL   | 1.65            | 0    | 1.65                   | NOT SUPPORTED  |
| 1         | 0                       | 0                       | INTERNAL   | 1.65            | 1    | 3.3                    | SUPPORTED      |
| 1         | 0                       | 1                       | INTERNAL   | 2.5             | 0    | 2.5                    | SUPPORTED      |
| 1         | 0                       | 1                       | INTERNAL   | 2.5             | 1    | 3.3                    | NOT SUPPORTED  |
| 1         | 1                       | X                       | EXTERNAL   | VREFHI          | 0    | 2.5                    | SUPPORTED      |
| 1         | 1                       | X                       | EXTERNAL   | VREFHI          | 1    | 2.5                    | NOT SUPPORTED  |

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS will no longer be updated with register writes. Enabling the clock to the buffered DAC restores it to the state before the clock was disabled.

The ideal output of the internal DAC can be calculated as shown in [Equation 1](#).

(1)

$$DACOUT = \frac{DACVALA * DACREF}{4096}$$

The buffered DAC can be used to level-shift the PGA's input signal (see the PGA section for details). The output buffer of the buffered DAC may exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data manual.

### 15.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device-specific data manual.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS should be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device-specific data manual.

### 15.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25v (for 2.5v reference voltage). DAC offset error is calibrated at 2.5v reference voltage and loaded into the DAC offset trim register as part of the Device\_cal() function. If the DAC is used at any reference voltage other than 2.5v, the offset trim must be adjusted to ensure the offset error performance stays within the device-specific data manual limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC\_tuneOffsetTrim() found in C2000Ware to adjust the offset.

### 15.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the Time-Base submodule chapter of the EPWM.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACVALA will be loaded immediately from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, it is recommended to configure the EPWM first before setting DACCTL [LOADMODE] to 1.

---

**NOTE:** The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what these signals are, see the EPWM chapter.

---

## 15.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access will be locked out until the device is reset.

## 15.4 DAC Registers

This section describes the Buffered Digital to Analog Converter registers.

### 15.4.1 DAC Base Addresses

**Table 15-2. DAC Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| DacaRegs         | DAC_REGS      | 0x0000_5C00   | 0x0000_5C0F |
| DacbRegs         | DAC_REGS      | 0x0000_5C10   | 0x0000_5C1F |

## 15.4.2 DAC\_REGS Registers

Table 15-3 lists the DAC\_REGS registers. All register offset addresses not listed in Table 15-3 should be considered as reserved locations and the register contents should not be modified.

**Table 15-3. DAC\_REGS Registers**

| Offset | Acronym  | Register Name               | Write Protection | Section            |
|--------|----------|-----------------------------|------------------|--------------------|
| 0h     | DACREV   | DAC Revision Register       |                  | <a href="#">Go</a> |
| 1h     | DACCTL   | DAC Control Register        | EALLOW           | <a href="#">Go</a> |
| 2h     | DACVALA  | DAC Value Register - Active |                  | <a href="#">Go</a> |
| 3h     | DACVALS  | DAC Value Register - Shadow |                  | <a href="#">Go</a> |
| 4h     | DACOUTEN | DAC Output Enable Register  | EALLOW           | <a href="#">Go</a> |
| 5h     | DACLOCK  | DAC Lock Register           | EALLOW           | <a href="#">Go</a> |
| 6h     | DACTRIM  | DAC Trim Register           | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 15-4 shows the codes that are used for access types in this section.

**Table 15-4. DAC\_REGS Access Type Codes**

| Access Type                     | Code  | Description                                                                                                                                                                                                                                                                          |

## Comparator Subsystem (CMPSS)

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

## 16.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, two digital filters and one ramp generator. Comparators are denoted "H" or "L" within each module where "H" and "L" represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin or by the PGA (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC. Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required. A ramp generator circuit is optionally available to control the reference 12-bit DAC value for the high comparator in the subsystem.

## 16.2 Features

Each CMPSS includes:

- Two analog comparators
- Two programmable reference 12-bit DACs
- One ramp generator
- Two digital filters
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to extend clear signal with EPWMBLANK
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for positive input of comparator to be driven by an external signal or by the PGA
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- Option to choose between VDDA or VDACC to be the DAC reference voltage

### 16.2.1 Block Diagram

The block diagram for the CMPSS is shown in [Figure 16-1](#).

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *ePWM* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *GPIO* chapter for more details on the Output X-BAR mux configuration.

Figure 16-1. CMPSS Module Block Diagram

### 16.3 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 16-2.

Figure 16-2. Comparator Block Diagram

| Voltages              | Output |
|-----------------------|--------|
| Voltage A > Voltage B | 1      |
| Voltage A < Voltage B | 0      |

### 16.4 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of its respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high reference 12-bit DAC (DACH) can optionally source its DACHVALA value from the ramp generator instead of DACHVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high voltage reference is VDDA by default, but it can be configured to be VDAC. The reference 12-bit DAC is illustrated in [Figure 16-3](#).

**Figure 16-3. Reference DAC Block Diagram**

The ideal output of the reference 12-bit DAC can be calculated as follows:

**Figure 16-4. Output Voltage Calculation**

$$DACOUT = \frac{DACVALA * DACREF}{4096}$$

## 16.5 Ramp Generator

This section discusses the characteristics of the ramp generator and its behavior.

### 16.5.1 Ramp Generator Overview

The ramp generator produces a falling-ramp input for the high reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most significant 12 bits of the RAMPSTS countdown register as its input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling-ramp rate configurable with RAMPDECVALA.

The ramp generator is enabled by setting DACSOURCE = 1. On setting DACSOURCE = 1, the value of RAMPSTS is loaded from RAMPMAXREFS and the register remains static until the selected EPWMSYNCPER signal is received. After receiving the selected EPWMSYNCPER signal, the value of RAMPDECVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a EPWMSYNCPER event, the RAMPDLA register which serves as a delay counter can be used to hold off the RAMPSTS subtraction. On receiving a EPWMSYNCPER event, the value of RAMPDLA is decremented by one on every SYSCLK cycle until the register reaches zero. The RAMPSTS subtraction will only begin when RAMPDLA is zero.

### 16.5.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, EPWMSYNCPER and COMPHSTS.

On the rising edge of DACSOURCE, RAMPMAXREFA, RAMPDECVALA and RAMPDLA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS.

On the rising edge of the selected EPWMSYNCPER, RAMPMAXREFA, RAMPDECVALA and RAMPDLA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and starts decrementing when RAMPDLA counter reaches zero.

On the rising edge of COMPHSTS with RAMPLOADSEL = 1, RAMPMAXREFA, RAMPDECVALA and RAMPDLA are loaded with their shadow registers. RAMPSTS is loaded with RAMPMAXREFS and stops decrementing.

On the rising edge of COMPHSTS with RAMPLOADSEL = 0, RAMPSTS is loaded with RAMPMAXREFA and stops decrementing.

Additionally, if the value of RAMPSTS reaches zero, the RAMPSTS register will remain static at zero until the next EPWMSYNCPER is received. These state changes are illustrated in the ramp generator block diagram in [Figure 16-5](#).

Figure 16-6. Ramp Generator Behavior

## 16.6 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$  and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 16-7.

Figure 16-7. Digital Filter Behavior

Equivalent C code of the filter implementation is shown below:

```
if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
```

### 16.6.1 Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation
2. Configure the digital filter parameters for operation
  - Set SAMPWIN for the number of samples to monitor in the FIFO window
  - Set THRESH for the threshold required for majority qualification
  - Set CLKPRESCALE for the digital filter clock prescale value
3. Initialize the sample values in the digital FIFO window by setting FILINIT
4. Clear COMPSTS latch via COMPSTSCLR if the latched path is desired
5. Configure the CTRIP and CTRIPOUT signal paths
6. If desired, configure the ePWM and GPIO modules to accept the filtered signals

## 16.7 Using the CMPSS

### 16.7.1 LATCHCLR, EPWMSYNCPER and EPWMBLANK Signals

The LATCHCLR signal initializes the digital filter to the output of the synchronization block and holds the latch output in reset (0) with the output of the synchronization block reflecting the async output of the comparator. It is activated in software using xLATCHCLR(x= "H" or "L"). It can also be activated by EPWMSYNCPER when xSYNCCLEN(x= "H" or "L") is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend it by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM respectively. For a detailed description of how these two signals are generated, refer to the respective submodule chapter of the EPWM.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL [SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER will be held at level high and DACxVALA will be loaded immediately from DACxVALS irrespective of the value of COMPDACCTL [SWLOADSEL]. Due to this, it is recommended to configure the EPWM first before setting COMPDACCTL [SWLOADSEL] to 1.

---

**NOTE:** The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what these signals are, see the EPWM chapter.

---

### 16.7.2 Synchronizer, Digital Filter and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter will add a delay of 2 sysclks. The latch adds 1 sysclk delay.

### 16.7.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data manual, the comparator offset error is referred to as **Input referred offset error** and compdac offset error is referred to as **Static offset error**. See the device specific data manual for their values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, it is recommended that the CMPSS be calibrated to ensure trips happen at the expected levels. The flow below outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis should be disabled for calibration. It can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult so it is recommended to use the latch with non-zero filter settings depending on how noisy the signal on the non-inverting input is.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFF.
  - Optional: Instead of setting the starting compdac value to max, it can be set to **Vtarget + Static offset error + Margin**. Where **Vtarget** is the approximate DC voltage on the non-inverting input, **Static offset error** is the compdac offset error specification and **Margin** is some amount of guard band. This can lead to a faster calibration but will only work if **Vtarget** is known. Alternatively if **Vtarget** is unknown, the ADC can be used to convert it.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
  - Optional: The trip code can be double checked by:
    - I. Increasing compdac value by 1.
    - II. Clear latch.
    - III. Wait for possible latch set.
    - IV. Latch should be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

### 16.7.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and will continue to trip from voltages on its inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA would no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on their current states.

Enabling the clock to the CMPSS restores it to the state before the clock was disabled.

## 16.8 CMPSS Registers

This section describes the CMPSS Registers.

### 16.8.1 CMPSS Base Addresses

**Table 16-1. CMPSS Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| Cmpss1Regs       | CMPSS_REGS    | 0x0000_5C80   | 0x0000_5C9F |
| Cmpss2Regs       | CMPSS_REGS    | 0x0000_5CA0   | 0x0000_5CBF |
| Cmpss3Regs       | CMPSS_REGS    | 0x0000_5CC0   | 0x0000_5CDF |
| Cmpss4Regs       | CMPSS_REGS    | 0x0000_5CE0   | 0x0000_5CFF |
| Cmpss5Regs       | CMPSS_REGS    | 0x0000_5D00   | 0x0000_5D1F |
| Cmpss6Regs       | CMPSS_REGS    | 0x0000_5D20   | 0x0000_5D3F |
| Cmpss7Regs       | CMPSS_REGS    | 0x0000_5D40   | 0x0000_5D5F |

## 16.8.2 CMPSS\_REGS Registers

Table 16-2 lists the CMPSS\_REGS registers. All register offset addresses not listed in Table 16-2 should be considered as reserved locations and the register contents should not be modified.

**Table 16-2. CMPSS\_REGS Registers**

| Offset | Acronym         | Register Name                                | Write Protection | Section            |
|--------|-----------------|----------------------------------------------|------------------|--------------------|
| 0h     | COMPCTL         | CMPSS Comparator Control Register            | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 16-3 shows the codes that are used for access types in this section.

**Table 16-3. CMPSS\_REGS Access Type Codes**

| Access Type                     | Code  | Description                            |
|---------------------------------|-------|----------------------------------------|
| <b>Read Type</b>                |       |                                        |
| R                               | R     | Read                                   |
| R-0                             | R-0   | Read Returns 0s                        |
| <b>Write Type</b>               |       |                                        |
| W                               | W     | Write                                  |
| W1S                             | W1S   | Write 1 to set                         |
| WOnce                           | WOnce | Write Set once                         |
| <b>Reset or Default Value</b>   |       |                                        |
| -n                              |       | Value after reset or the default value |
| <b>Register Array Variables</b> |       |                                        |

**Table 16-3. CMPSS\_REGS Access Type  
Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 16.8.2.1 COMPCTL Register (Offset = 0h) [reset = 0h]

COMPCTL is shown in [Figure 16-8](#) and described in [Table 16-4](#).

Return to the [Summary Table](#).

## Sigma Delta Filter Module (SDFM)

This chapter describes the sigma delta filter module (SDFM). The SDFM is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma ( $\Delta\Sigma$ ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

## 17.1 Introduction

Figure 17-1 shows the SDFM CPU Interface.

**Figure 17-1. Sigma Delta Filter Module (SDFM) CPU Interface**

### 17.1.1 SDFM Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Four different configurable modulator clock modes:
  - Mode 0: Modulator clock rate equals the modulator data rate.
  - Mode 1: Modulator clock rate running at half the modulator data rate.
  - Mode 2: Modulator data is Manchester-encoded. Modulator clock is not required.
  - Mode 3: Modulator clock rate is double that of the modulator data rate
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/Sincfast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/Sincfast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256
  - Ability to enable or disable (or both) individual filter module

- Ability to synchronize all four independent filters of an SDFM module by using the Master Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- Data filter unit has a programmable mode FIFO to reduce interrupt overhead. The FIFO has the following features:
  - The primary filter (data filter) has a 16-deep x 32-bit FIFO.
  - The FIFO can interrupt the CPU after programmable number of data-ready events.
  - FIFO Wait-for-Sync feature: Ability to ignore data-ready events until the PWM synchronization signal (SDSYNC) is received. Once the SDSYNC event is received, the FIFO is populated on every data-ready event.
  - Data filter output can be represented in either 16 bits or 32 bits.
- PWMx.SOCA/SOCB can be configured to serve as SDSYNC source on a per-data-filter-channel basis.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.

### 17.1.2 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

[Figure 17-2](#) shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in .

**Figure 17-2. Sigma Delta Filter Module (SDFM) Block Diagram**

Each filter module shown in [Figure 17-3](#) has a primary (data) filter and a secondary (comparator) filter pair which receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

Figure 17-3. Block Diagram of One Filter Module

## 17.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, following GPIO input qualification can be used. Other GPIO qualifications are not supported.

- If GPIO Input qualification is ASYNC, please make sure to check SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware of the warning message posted below.
- If GPIO Input qualification is SYNC, please make sure to check SDFM Electrical Data and Timing (Using SYNC) requirement is met and be aware of the warning message and note posted below.

### WARNING

The SDFM clock inputs (SDx\_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions should be taken on these signals to ensure a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

**NOTE:** The SDFM Synchronized GPIO (SYNC) option provides protection against SDFM module corruption due to occasional random noise glitches on the SDx\_Cy pin that may result in a false comparator trip and filter output.

The SDFM Synchronized GPIO (SYNC) option does not provide protection against persistent violations of the above timing requirements. Timing violations will result in data corruption proportional to the number of bits which violate the requirements

See the *GPIO* chapter for more details on GPIO mux and settings.

## 17.3 Input Control Unit

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in four different modes. [Table 17-1](#) and [Figure 17-4](#) show how SDCTLPARMx.MOD bits can be configured in these four different modes.

**Table 17-1. Modulator Clock Modes**

| MODULATOR MODE [MOD] | DESCRIPTION                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                    | The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock.         |
| 1                    | The modulator clock is running with half of the modulator data rate. The modulator data is strobed at every edge of the modulator clock.        |
| 2                    | The modulator clock is off and the modulator data is Manchester-encoded.                                                                        |
| 3                    | The modulator clock is running with double the modulator data rate. The modulator data is strobed at every other positive modulator clock edge. |

**NOTE:** In order to achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

**Figure 17-4. Different Modulator Modes Supported**

When MOD=2, data and modulated clock signals are encoded into modulated data as shown in Mode 2 of Figure 17-4. In this mode, the clock input SD-Cx pin should be left floating. The input control unit performs continuous automatic calibration to achieve optimum decoding performance.

## 17.4 Sinc Filter

Both comparator filter and data filter available in SDFM have the Sinc<sup>N</sup> filter as its core. The Sinc<sup>N</sup> filter is essentially a low pass filter which converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc<sup>N</sup> architecture consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 17-6. The Z-transfer function of the Sinc filter of order N is shown below.

**Figure 17-5. Z-Transform of Sinc Filter of Order N**

$$H(Z) = \left[ \frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^N$$

N = Order of Sinc filter

OSR = Over Sampling Ratio

**Figure 17-6. Simplified Sinc Filter Architecture**

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution (or) ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator datasheet to determine the effective resolution for a given Sinc filter configuration. The figure below shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10 MHz.

**Figure 17-7. Frequency Response of different Sinc Filters**

The order of different sinc filter is shown in the table below.

**Table 17-2. Order of Sinc Filter**

| filter Type | Order of Sinc Filter |
|-------------|----------------------|
| Sinc1       | 1                    |
| Sinc2       | 2                    |
| Sinc3       | 3                    |
| SincFast    | 3                    |

### 17.4.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec can be calculated by the formula shown here:

$$\text{Data rate of Sinc filter} = \frac{\text{Modulator data rate}}{OSR}$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency can be calculated as shown in this equation:

$$\text{Latency of Sinc filter} = \frac{\text{Order of Sinc filter}}{\text{Data rate of Sinc filter}}$$

#### Example configuration:

|                          |                                       |
|--------------------------|---------------------------------------|
| Sinc filter type         | = sinc3                               |
| Modulator data rate      | = 10 MHz                              |
| OSR                      | = 256                                 |
| Data rate of Sinc Filter | = 10 MHz / 256 = 39.1 K samples / sec |
| Sinc filter latency      | = 76.8 $\mu$ s                        |

|                          |                                       |
|--------------------------|---------------------------------------|
| Sinc filter type         | = sinc2                               |
| Modulator data rate      | = 10 MHz                              |
| OSR                      | = 256                                 |
| Data rate of Sinc Filter | = 10 MHz / 256 = 39.1 K samples / sec |
| Sinc filter latency      | =51.2 $\mu$ s                         |

## 17.5 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3 and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDPARMx.FEN = 1 enables the data filter. The data filter output is represented in 26-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. [Table 17-3](#) shows the different full scale values that the data filter can store using different OSRs.

See [Section 17.4.1](#) to understand how to calculate data rate and latency of data filter.

**Table 17-3. Peak Data Values for Different DOSR/Filter Combinations**

| DOSR | Sinc1       | Sinc2             | Sinc3                     | Sincfast            |
|------|-------------|-------------------|---------------------------|---------------------|
| x    | x           | $x^2$             | $x^3$                     | $2x^2$              |
| 4    | -4 to 4     | -16 to 16         | -64 to 64                 | -32 to 32           |
| 8    | -8 to 8     | -64 to 64         | -512 to 512               | -128 to 128         |
| 16   | -16 to 16   | -256 to 256       | -4096 to 4096             | -512 to 512         |
| 32   | -32 to 32   | -1024 to 1024     | -32,768 to 32,768         | -2048 to 2048       |
| 64   | -64 to 64   | -4096 to 4096     | -262,144 to 262,144       | -8192 to 8192       |
| 128  | -128 to 128 | -16,384 to 16,384 | -2,097,152 to 2,097,152   | -32,768 to 32,768   |
| 256  | -256 to 256 | -65,536 to 65,536 | -16,777,216 to 16,777,216 | -131,072 to 131,072 |

### 17.5.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

#### 32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

#### 16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

For example, for the data filter configuration below:

- Filter type = Sinc3
- OSR = 128
- SDDPARMx.DR = 0

The data filter with a 26-bit signed output value can be in the range of -16,777,216 to 16,777,216. But, 16-bit signed output supports values only from -32,768 to 32,767. Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. The table below shows the configuration settings of shift control bits for different OSR and filter types.

**Table 17-4. Shift Control Bit Configuration Settings**

| OSR        | SINC1 | SINC2 | SINCFast | SINC3 |
|------------|-------|-------|----------|-------|
| 1 to 31    | 0     | 0     | 0        | 0     |
| 32 to 40   | 0     | 0     | 0        | 1     |
| 41 to 50   | 0     | 0     | 0        | 2     |
| 51 to 63   | 0     | 0     | 0        | 3     |
| 64 to 80   | 0     | 0     | 0        | 4     |
| 81 to 101  | 0     | 0     | 0        | 5     |
| 102 to 127 | 0     | 0     | 0        | 6     |
| 128 to 161 | 0     | 0     | 1        | 7     |
| 162 to 181 | 0     | 0     | 1        | 8     |
| 182 to 203 | 0     | 1     | 2        | 8     |
| 204 to 255 | 0     | 1     | 2        | 9     |
| 256        | 0     | 2     | 3        | 10    |

### **WARNING**

**Configuring shift control bits incorrectly will result in getting incorrect 16-bit data filter output.**

## **17.5.2 Data FIFO**

Each primary (data) filter channel has a 16-level deep, 32-bit FIFO.

FIFOs can be configured to collect a programmable number of data filter samples before issuing data-ready interrupt. This reduces the number of data-ready interrupts generated and resulting interrupt overhead for managed data flow.

By default, FIFO operation is disabled. FIFOs can be enabled by setting SDFIFOCTLx.FFEN = 1. When FIFO is enabled, each data-ready event from the data filter will populate the FIFO, and the status of the FIFO at any given time is updated in the SDFIFOCTLx.SDFFST bit field.

### **Setting up FIFO to interrupt after receiving programmable number of data ready events:**

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Configure SDFIFOCTLx.SDFFIL bit field to any value between 0 to 16
- Configure SDFM data ready event to interrupt on FIFO interrupt (SDFFINT) (Set SDFFINTx = 1)
- Select data-ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

When the SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met, the SDIFLG.SDFFINTx bit is set and an interrupt is generated on the DRINTx. SDIFLG.SDFFINTx flag can be cleared by setting the SDIFLGCLR. SDFFINTx bit field.

### **Wait for Sync feature:**

The FIFO wait for sync feature can be used to ignore data-ready events from the data filter until the SDSYNC (from PWM) event is triggered.

By default, the Wait for Sync feature is disabled. This feature can be enabled by setting SDSYNcx.WTSYNCEN = 1

### **When the wait for sync feature is disabled:**

FIFOs get populated on every data ready event until the FIFO gets full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL.

### **When the wait for sync feature enabled:**

FIFOs will not be get populated on every data ready event until it receives a SDSYNC event. On a SYSYNC event, it sets SDSYNCLx.WTSYNFLG = 1 and data ready events from primary filter will start populating FIFO until either the FIFOs get full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL. WTSYNFLG can be cleared either automatically (or) manually.

When WTSYNFLG = 0, FIFOs contents are frozen and subsequent data ready events don't get populate FIFO until next SDSYNC event.

#### WTSYNFLG automatic clear mode:

By default, this mode is enabled. When SDSYNCLx.WTSCLEN = 1, WTSYNFLG is automatically cleared on SDFFINT event.

#### WTSYNFLG manual clear mode:

Setting SDSYNCLx.WTSYNCLR = 1 can be used to clear WTSYNFLG manually.

#### Clearing FIFO contents:

FIFO contents can cleared by any of the following methods:-

- Disabling FIFO clear FIFO contents. This can be done by clearing SDFIFOCTLx.FFEN = 0.
- Disabling Primary filter clear FIFO contents. This can done by either clearing SDDFPARMx.FEN = 0 (or) by clearing SDMMFILEN.MFE = 0.
- FIFO contents can also be automatically cleared upon receiving the SDSYNC event. By default, this feature is disabled and this feature can be enabled by setting FIFO Clear-on-SDSYNC enable (SDSYNCLx.FFSYNCCLEN = 1).

**Note:** The above feature is only enabled when wait for sync feature is enabled (SDSYNCLx.WTSYNCLN = 1).

#### FIFO debug access behavior:

Debug access of SDDATFIFOx registers does not affect FIFO pointers. On a CPU / CLA / DMA access to SDDATFIFOx register, FIFO read pointers would be advanced to next available entry in FIFO.

### 17.5.3 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting SDDFPARMx.SDSYNCLN = 1. Each primary filter can be synchronized from any of the available PWMx. SOCA / SOCB signals. (see [Table 17-5](#)). The SDSYNCLx.SDSYNCSSEL bits allow the user to configure which PWM signal provides the SDSYNC pulse to the primary filter.

**Table 17-5. SDSYNCLx.SDSYNCSSEL**

| SDSYNCLx.SDSYNCSSEL[1:0] |           |           |      |      |
|--------------------------|-----------|-----------|------|------|
| SDSYNCSSEL[5:2]          | 0         | 1         | 2    | 3    |
| 0                        | PWM1.SOCA | PWM1.SOCB | Rsvd | Rsvd |
| 1                        | PWM2.SOCA | PWM2.SOCB | Rsvd | Rsvd |
| 2                        | PWM3.SOCA | PWM3.SOCB | Rsvd | Rsvd |
| 3                        | PWM4.SOCA | PWM4.SOCB | Rsvd | Rsvd |
| 4                        | PWM5.SOCA | PWM5.SOCB | Rsvd | Rsvd |
| 5                        | PWM6.SOCA | PWM6.SOCB | Rsvd | Rsvd |
| 6                        | PWM7.SOCA | PWM7.SOCB | Rsvd | Rsvd |
| 7                        | PWM8.SOCA | PWM8.SOCB | Rsvd | Rsvd |
| 8                        | Rsvd      | Rsvd      | Rsvd | Rsvd |
| 9                        | Rsvd      | Rsvd      | Rsvd | Rsvd |
| 10                       | Rsvd      | Rsvd      | Rsvd | Rsvd |
| 11                       | Rsvd      | Rsvd      | Rsvd | Rsvd |
| 12                       | Rsvd      | Rsvd      | Rsvd | Rsvd |

**Table 17-5. SDSYNcx.SYNCSEL (continued)**

| SDSNYx.SYNCSEL[1:0] |      |      |      |      |
|---------------------|------|------|------|------|
| 13                  | Rsvd | Rsvd | Rsvd | Rsvd |
| 14                  | Rsvd | Rsvd | Rsvd | Rsvd |
| 15                  | Rsvd | Rsvd | Rsvd | Rsvd |

Figure 17-8 shows how the PWM signals are connected to SDFM.

**Figure 17-8. SDSYNC Event**

**NOTE:** Ensure that ONLY ONE SDSYNC event will be generated per PWM timer period. Using PWM in up-count or down-count mode would automatically ensure that you get ONLY SDSYNC event. But, if up-down count mode is used, then make sure that only one SDSYNC event per PWM cycle is generated; otherwise, the filter synchronizer will corrupt SDFM timing by providing two pulses per PWM cycle.

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type will be incorrect. Table 17-6 shows the number of incorrect samples on the following conditions:-

- When Sinc filter is enabled / configured for first time.
- When Sinc filter is disabled / re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

**Table 17-6. Number of Incorrect Samples Tabulated**

| Filter type | Number of incorrect samples after the filter is enabled and configured |
|-------------|------------------------------------------------------------------------|
| Sinc1       | No incorrect sample                                                    |
| Sinc2       | The first sample of the Sinc2 filter is incorrect                      |
| SincFast    | The first two samples of the SincFast filter are incorrect             |
| Sinc3       | The first two samples of the Sinc3 filter are incorrect                |

## **WARNING**

**SDFM comparator interrupts should be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (IELx and IEHx) should be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and five SD-Cx clock cycles.**

## **17.6 Comparator (Secondary) Filter Unit**

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

**NOTE:** The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

The comparator filter is a configurable Sinc filter which supports the following filter types: - Sinc1, Sinc2, Sinc3 and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is disabled and setting SDCPARMx.CEN = 1 enables the comparator filter. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as '0' and a high input signal as '1'. The resulting calculations give only positive values for the output of the comparator filter. [Table 17-7](#) shows the different full-scale values that the comparator filter can store using different OSRs.

**Table 17-7. Peak Data Values for Different OSR/Filter Combinations**

| OSR | Sinc1   | Sinc2     | Sinc3       | Sincfast  |
|-----|---------|-----------|-------------|-----------|
| x   | 0 to x  | 0 to x2   | 0 to x3     | 0 to 2x2  |
| 4   | 0 to 4  | 0 to 16   | 0 to 64     | 0 to 32   |
| 8   | 0 to 8  | 0 to 64   | 0 to 512    | 0 to 128  |
| 16  | 0 to 16 | 0 to 256  | 0 to 4096   | 0 to 512  |
| 32  | 0 to 32 | 0 to 1024 | 0 to 32,768 | 0 to 2048 |

See [Section 17.4.1](#) to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is memory-mapped and can be read in the SDCDATAx register. This register, SDCDATAx, is updated every COSR number of SD-Cx cycles. The comparator filter digital output is connected to digital comparators explained below.

**Figure 17-9. Comparator Unit Structure**

### 17.6.1 Higher threshold (HLT) comparators

- High threshold comparator can be used to detect over-value condition.
- When comparator data  $\geq$  higher threshold register, a high threshold event is generated.
- Higher threshold comparator events except for COMPHZx can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Higher threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of threshold crossing
- This device has two High Threshold comparators.
  - **Higher Threshold (HLT) comparator:**
    - The high threshold register (SDCMPHx.HLT) can be used to configure this comparator.
    - When SDCTL.MIE = 1 and SDCPARMx.IEH = 1, a high threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IEHx flag showing an over-value condition is triggered. This SDIFLG.IEHx flag can be reset if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.
  - **Higher Threshold (HTLZ) comparator :**
    - The high threshold Register (SDCMPHx.HTLZ) can be used to configure this comparator.
    - When comparator data  $\geq$  SDCMPHx.HTLZ, it can generate a higher threshold (B) event (COMPHZx) and sets the corresponding SDSTATUS.HZx flag. But, this event cannot be configured to generate an SDFM interrupt (SDINT). The high threshold (HTLZ) comparator can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing events.

#### Example

To measure the frequency / duty cycle of zero crossing event, the user needs to configure SDCMPHx.HTLZ = 0x4000 and enable High level (B) Threshold crossing (SDCPARMx.HZEN =

- 1). The ECCTL0.INPUTSEL register bit field should also be configured to pass on the COMPHZx signal to eCAP for frequency / duty cycle measurement.

### 17.6.2 Lower Threshold (LLT) comparators

- The low threshold comparator can be used to detect under-value condition.
- When comparator data  $\leq$  Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Lower threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing
- This device has one low threshold comparators.
  - **Lower Threshold (LLT) Comparator** : When SDCTL.MIE = 1 and SDCPARMx.IEL = 1, the low threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IELx flag showing an under-value condition is triggered. This SDIFLG.IELx flag can be reset if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.

## 17.7 Interrupt Unit

Each SDFM can generate five CPU interrupts such as SDFM Error (SDy\_ERR) and SDFM data ready (SDy\_DRINT1 / SDy\_DRINT2, SDy\_DRINT3, SDy\_DRINT4) interrupts for each filter module.

### 17.7.1 SDFM (SDyERR) Interrupt sources:

Figure 17-10 shows the structure of SDy\_ERR interrupt. SDy\_ERR interrupt can be triggered by any of these 16 events.

**Figure 17-10. SDFM Error (SD\_ERR) interrupt sources**

#### 1. Comparator Lower Threshold events (COMPLx)

COMPL events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable master interrupt enable (SDCTL.MIE = 1)

- Enable comparator filter lower threshold interrupt (SDCPARMx.IEL = 1)

On a COMPL event, SDIFLG.IELx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 2. Comparator High Threshold events (COMPHx)

COMPH events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable master interrupt enable (SDCTL.MIE = 1)
- Enable comparator filter lower threshold interrupt (SDCPARMx.IEH = 1)

On a COMPH event, SDIFLG.IEHx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable master Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 4. FIFO overflow (SDFFOVFx) event

The number of filter data available in FIFO at any given point can be tracked in SDFIFOCTLx.SDFFST. If the number of words received in FIFO is greater than Max FIFO depth (16), SDFFOVFx event is generated. SDFFOVFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO overflow interrupt (Set SDFIFOCTLx.OVFIEN = 1) and
- Enable Master interrupt enable (Set SDCTL.MIE = 1)

On a SDFFOVFx event, all subsequent data (primary) filter data is lost and is not stored in FIFO. SDIFLG.SDFFOVFx flag bit is set on a FIFO overflow event and this bit can be cleared if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

### 17.7.2 Data Ready (DRINT) Interrupt sources:

Figure 17-11 shows the structure of interrupt SDy\_DRINTx interrupt. Each SDy\_DRINTx interrupt is triggered by corresponding Data Filter channel.

### Figure 17-11. SDFM Data Ready (SDy\_DRINTx) Interrupt

## 1. Data Acknowledge (AFx)

When the primary filter is ready with a new filter data, AFx event is generated. AFx events from each filter can generate its own SDy\_DRINTx interrupt. This event can be configured to trigger SDy\_DRINTx interrupt only if below configurations are made:

- Enable individual filter interrupts (SDDFPARMx.AE = 1)
- Select data-ready interrupt source AFx (DRINTx = AFx) (SDFIFOCTLx.DRINTSEL = 0)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 2. Four FIFO Data ready interrupt (SDFFINTx)

FIFO Data Ready event is generated whenever `SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL` condition is met. FIFO data ready events from each filter can generate its own `SDy_DRINTx` interrupt. This event can be configured to trigger `SDy_DRINTx` interrupt only if below configurations are made:

Table 17-8 shows how the DRINTx output is selected.

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1) and
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Select data-Ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

### Table 17-8. SDFM Data-Ready Interrupt (SDy\_DRINTx) Output Selection

| DRINTSEL | AE | FFIEN | FFEN | DRINTx  |
|----------|----|-------|------|---------|
| 0        | 0  | x     | X    | 0       |
| 0        | 1  | x     | X    | AFx     |
| 1        | x  | 0     | X    | 0       |
| 1        | x  | x     | 0    | 0       |
| 1        | x  | 1     | 1    | SDFINTx |

## 17.8 SDFM Registers

This section describes the Sigma Delta Filter registers.

### 17.8.1 SDFM Base Addresses

**Table 17-9. SDFM Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| Sdfm1Regs        | SDFM_REGS     | 0x0000_5E00   | 0x0000_5E7F |

## 17.8.2 SDFM\_REGS Registers

Table 17-10 lists the SDFM\_REGS registers. All register offset addresses not listed in Table 17-10 should be considered as reserved locations and the register contents should not be modified.

**Table 17-10. SDFM\_REGS Registers**

| Offset | Acronym    | Register Name                                   | Write Protection | Section            |
|--------|------------|-------------------------------------------------|------------------|--------------------|
| 0h     | SDIFLG     | SD Interrupt Flag Register                      |                  | <a href="#">Go</a> |
| 2h     | SDIFLGCLR  | SD Interrupt Flag Clear Register                |                  | <a href="#">Go</a> |
| 4h     | SDCTL      | SD Control Register                             | EALLOW           | <a href="#">Go</a> |
| 6h     | SDMFILEN   | SD Master Filter Enable                         | EALLOW           | <a href="#">Go</a> |
| 7h     | SDSTATUS   | SD Status Register                              |                  | <a href="#">Go</a> |
| 10h    | SDCTLPARM1 | Control Parameter Register for Ch1              | EALLOW           | <a href="#">Go</a> |
| 11h    | SDDFPARM1  | Data Filter Parameter Register for Ch1          | EALLOW           | <a href="#">Go</a> |
| 12h    | SDDPARM1   | Data Parameter Register for Ch1                 | EALLOW           | <a href="#">Go</a> |
| 13h    | SDCMPH1    | High-level Threshold Register for Ch1           | EALLOW           | <a href="#">Go</a> |
| 14h    | SDCMPL1    | Low-level Threshold Register for Ch1            | EALLOW           | <a href="#">Go</a> |
| 15h    | SDCPARM1   | Comparator Filter Parameter Register for Ch1    | EALLOW           | <a href="#">Go</a> |
| 16h    | SDDATA1    | Data Filter Data Register (16 or 32bit) for Ch1 |                  | <a href="#">Go</a> |

### 17.8.2.2 SDIFLGCLR Register (Offset = 2h) [reset = 0h]

SDIFLGCLR is shown in [Figure 17-13](#) and described in [Table 17-13](#).

Return to the [Summary Table](#).

SD Module Interrupt Flag Clear Bits:

Writing a "1" will clear the respective flag bit in the SDIFLG register.

Writes of "0" are ignored.

Note: If user writes a "1" to clear a bit on the same cycle that the hardware is trying to set the bit to "1", then hardware has priority and the bit will not be cleared.

**Figure 17-13. SDIFLGCLR Register**

## Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral performs a digital to analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 4 with added register protection capability. See the [TMS320x28xx, 28xxx DSP Peripheral Reference Guide](#) for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

Further information about this device can be found in the following document(s):

- [Flexible PWMs Enable Multi-Axis Drives, Multi-Level Inverters](#)

## 18.1 Introduction

This chapter includes an overview and information about each submodule:

- Time-Base Submodule
- Counter Compare Submodule
- Action Qualifier Submodule
- Dead-Band Generator Submodule
- PWM Chopper (PC) Submodule
- Trip Zone Submodule
- Event Trigger Submodule
- Digital Compare Submodule

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map**

Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.

- **Delayed Trip Functionality**

Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event ( Events T1 and T2 ). If comparator T1 / T2 events are used to edit the PWM , changes to the PWM waveform will not take place immediately . Instead , they will synchronize to the next TBCLK.

- **Dead-Band Generator Submodule Enhancements**

Shadowing of the DBCTL register to allow dynamic configuration changes.

- **One Shot and Global Load of Registers**

The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multi-phase applications. It also allows a programmable prescale of shadow to active load events.

- **Trip Zone Submodule Enhancements**

Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip zone submodule to support certain power converter switching techniques like valley switching.

- **Digital Compare Submodule Enhancements**

Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.

- **PWM SYNC Related Enhancements**

The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High Resolution Dead-Band Capability**

High resolution capability is added to dead-band RED and FED in half-cycle clocking mode.

- **Dead-Band Generator Submodule Enhancements**

The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed

- **High Resolution Extension available on ePWMxB outputs**

Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in [Section 18.15](#).

- **Counter Compare Submodule Enhancements**

The ePWM Type 2 allows Interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.

- **Event Trigger Submodule Enhancements**

Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. It allows software initialization of event counters on SYNC event.

- **Digital Compare Submodule Enhancements**

Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.

- **Simultaneous Writes to TBPRD and CMPx Registers**

This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.

- **Shadow to Active Load on SYNC of TBPRD and CMP Registers**

This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

### Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution**

Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.

- **Enhanced Interrupt and SOC Generation**

Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.

- **High Resolution Period Capability**

Provides the ability to enable high-resolution period. This is discussed in more detail in the device-specific *High-Resolution Pulse Width Modulator (HRPWM)* document..

- **Digital Compare Submodule**

The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

---

**NOTE:** The name of the sync signal that goes to the CMPSS and GPDAC has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what these signals are, see [Table 18-2](#).

---

### 18.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instantiated within a device as shown in [Figure 18-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 18.15](#). See the device-specific data manual to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 18-1](#). The signals are described in detail in subsequent sections.

Figure 18-1. Multiple ePWM Modules

Copyright © 2017, Texas Instruments Incorporated

A This signal exists only on devices with an eQEP submodule.

The order in which the ePWM modules are connected may differ from what is shown in [Figure 18-1](#). See [Section 18.4.3.3](#) for the synchronization scheme for a particular device. Each ePWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 18-2](#).

**Figure 18-2. Submodules and Signal Connections for an ePWM Module**

Figure 18-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

The PWM output signals are made available external to the device through the GPIO peripheral described in the *System Control and Interrupts* chapter for your device.

- **Trip-zone signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The  $\overline{TZ1}$  to  $\overline{TZ3}$  trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 18-49.  $\overline{TZ4}$  is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module).  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is connected to the EMUSTOP output from the CPU. This allows you to configure a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCI), output (EPWMxSYNCO) and peripheral (EPWMxSYNCPER) signals.**

The synchronization signals daisy chain the ePWM module together. Each module can be configured via INPUTXBAR6 to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The ePWM module are separate into groups of three for syncing purposes. An external sync signal (EXTSYNIN1 or EXTSYNIN2) may be used to issue a sync signal to the first ePWM module in each chain. These same module can also send their EPWMxSYNCO signal to a GPIO. For more information, see Section 18.4.3.3.

Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. It is configured using the HRPCTL register but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see their respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT).**

Output signals from the comparator module can be fed through the Input X-BAR to one or all of the 12 trip inputs [TRIPIN1 - TRIPIN12] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral Bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

**Figure 18-3. ePWM modules and Critical Internal Signal Interconnects**

Copyright © 2017, Texas Instruments Incorporated

A --\*These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs.

## 18.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR must be used. Some examples of when an external signal may be needed are TZx, TRIPx, and EXTSYNClN. Any GPIO on the device can be configured as an input. The GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals. Additionally, some TRIPx (TRIP4-12 excluding TRIP6) signals must be routed through the ePWM X-Bar in addition to the Input X-Bar.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *GPIO* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 18.3 ePWM Modules Overview

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

[Table 18-1](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 18.5](#) for relevant details.

**Table 18-1. Submodule Configuration Parameters**

| Submodule            | Configuration Parameter or Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 18.4 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 18-4 illustrates the time-base module's place within the ePWM.

**Figure 18-4. Time-Base Submodule**

### 18.4.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - *CTR = PRD*: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - *CTR = Zero*: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

**Table 18-2. Key Time-Base Signals (continued)**

| Signal     | Description                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CTR = Zero | Time-base counter equal to zero<br>This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.                                                                                |
| CTR = CMPB | Time-base counter equal to active counter-compare B register (TBCTR = CMPB).<br>This event is generated by the counter-compare submodule and used by the synchronization out logic                             |
| CTR_dir    | Time-base counter direction.<br>Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.                             |
| CTR_max    | Time-base counter equal max value. (TBCTR = 0xFFFF)<br>Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit                                           |
| TBCLK      | Time-base clock.<br>This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements. |

### 18.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. [Figure 18-6](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

**Figure 18-6. Time-Base Frequency and Period**

#### 18.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDL] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in [Section 18.4.3.3](#).

The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in [Section 18.4.7](#).

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 18.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

### 18.4.3.3 Time-Base Counter Synchronization

The ePWM type 4 introduces a new synchronization scheme that allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCl), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In [Figure 19-8](#), EXTSYNCl is sourced from INPUTXBAR5 and EXTSYNCO2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. When configuring the sync chain propagation path using the SYNCSEL registers, make sure that the longest path does not exceed four ePWM/eCAP modules.

### Figure 18-7. Time-Base Counter Synchronization Scheme

**NOTE:** See the data manual for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS  $\rightarrow$  TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

The delay from internal master module to slave modules is given by:

- if ( TBCLK = EPWMCLK): 2 x EPWMCLK
- if ( TBCLK < EPWMCLK): 1 x TBCLK

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 18-8](#) through [Figure 18-11](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master. See [Section 18.13](#) for more details on synchronization strategies.

#### 18.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

#### 18.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

For a particular ePWM module # A, user code writes "B+1", to the linked register bit-field in EPWMXLINK. "B" is the ePWM module # being linked to (that is, writes to the ePWM module "B" TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, or CMPC will simultaneously be written to corresponding register in ePWM module "A"). For instance if ePWM3 EPWMXLINK register is configured so that CMPA:CMPAHR are linked to ePWM1, then a write to CMPA:CMPAHR in ePWM 1 will simultaneously write the same value to CMPA:CMPAHR in ePWM3. If ePWM4 also has its CMPA:CMPAHR registers linked to ePWM1, then a write to ePWM 1 will write the same value to the CMPA:CMPAHR registers in both ePWM3 and ePWM4.

The register description for EPWMXLINK clearly explains the linked register bit-field values for corresponding ePWM.

#### 18.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical
- Down-count mode which is asymmetrical
- Up-down-count which is symmetrical

- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

**Figure 18-8. Time-Base Up-Count Mode Waveforms**

**Figure 18-9. Time-Base Down-Count Mode Waveforms**

**Figure 18-10. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event**

**Figure 18-11. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event**

#### 18.4.7 Global Load

Figure 18-12 illustrates the signals and registers associated with the global load feature.

**Figure 18-12. Global Load: Signals and Registers**

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = '1', shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = '1' and GLDCFG[REGx] = '0' global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

#### 18.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = '0' or GLDCFG[REGx] = '0').

#### 18.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When GLDCTL2[OSHTLD] = '1' the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by GLDCTL[GLDMODE].

Software force loading of contents from shadow register to active register is possible by using GLDCTL2[GFRCLD]. The GLDCTL2 register can also be linked across multiple PWM modules by using EPWMXLINK[GLDCTL2LINK]. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

## 18.5 Counter-Compare (CC) Submodule

Figure 18-13 illustrates the counter-compare submodule within the ePWM.

Figure 18-13. Counter-Compare Submodule

### 18.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) counter-compare B (CMPB) counter-compare C (CMPC) and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC and CMPD registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) & counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 18.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 18-14.

Figure 18-14. Detailed View of the Counter-Compare Submodule

A These events are generated by the type 4 ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and  $\overline{TZ}$  signals).

### 18.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events which can be used in the action-qualifier and/or event-trigger submodules. There are four independent compare events described below:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event

can be used to generate an event in the event trigger submodule only

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode each event occurs twice per cycle if the compare value is between 0x00-TBPRD and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 18.6.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

#### Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] CMPCTL[LOADBMODE] CMPCTL[LOADASYNC] & CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

#### Immediate Mode:

If immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

#### Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule :

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D ” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

#### Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE] CMPCTL2[LOADDMODE] CMPCTL2[LOADCSYNC] & CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

#### Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register will go directly to the active register.

#### Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 18.4.7](#).

### 18.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 18-15](#) through [Figure 18-18](#) show when events are generated and how the EPWMxSYNCl signal interacts.

**Figure 18-15. Counter-Compare Event Waveforms in Up-Count Mode**

NOTE: An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 18-16. Counter-Compare Events in Down-Count Mode**

**Figure 18-17. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event**

**Figure 18-18. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event**

## 18.6 Action-Qualifier (AQ) Submodule

The figure below shows the action-qualifier (AQ) submodule in the ePWM system.

**Figure 18-19. Action-Qualifier Submodule**

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

### 18.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

### 18.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in the figure below and monitored via the registers in [Section 18.16](#).

**Figure 18-20. Action-Qualifier Submodule Inputs and Outputs**

For convenience, the possible input events are summarized again in the table below.

**Table 18-3. Action-Qualifier Submodule Possible Input Events**

| Signal                | Description                                      | Registers Compared |
|-----------------------|--------------------------------------------------|--------------------|
| CTR = PRD             | Time-base counter equal to the period value      | TBCTR = TBPRD      |
| CTR = Zero            | Time-base counter equal to zero                  | TBCTR = 0x00       |
| CTR = CMPA            | Time-base counter equal to the counter-compare A | TBCTR = CMPA       |
| CTR = CMPB            | Time-base counter equal to the counter-compare B | TBCTR = CMPB       |
| T1 event              | Based on comparator, trip or syncin events       | None               |
| T2 event              | Based on comparator, trip or syncin events       | None               |
| Software forced event | Asynchronous event initiated by software         |                    |

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**  
Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**  
Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**  
If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**  
Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option

prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in the [Section 18.10](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in [Figure 18-21](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

**Figure 18-21. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

| SW<br>force | TB Counter equals |           |           |        | Trigger Events |    | Actions    |
|-------------|-------------------|-----------|-----------|--------|----------------|----|------------|
|             | Zero              | Comp<br>A | Comp<br>B | Period | T1             | T2 |            |
|             |                   |           |           |        |                |    | Do Nothing |
|             |                   |           |           |        |                |    | Clear Lo   |
|             |                   |           |           |        |                |    | Set Hi     |
|             |                   |           |           |        |                |    | Toggle     |

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event may or may not be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

### 18.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in the table below. A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 18-4. Action-Qualifier Event Priority for Up-Down-Count Mode**

| Priority Level | Event If TBCTR is Incrementing<br>TBCTR = Zero up to TBCTR = TBPRD | Event If TBCTR is Decrementing<br>TBCTR = TBPRD down to TBCTR = 1 |
|----------------|--------------------------------------------------------------------|-------------------------------------------------------------------|
| 1 (Highest)    | Software forced event                                              | Software forced event                                             |
| 2              | T1 on up-count (T1U)                                               | T1 on down-count (T1D)                                            |
| 3              | T2 on up-count (T2U)                                               | T2 on down-count (T2D)                                            |
| 4              | Counter equals CMPB on up-count (CBU)                              | Counter equals CMPB on down-count (CBD)                           |
| 5              | Counter equals CMPA on up-count (CAU)                              | Counter equals CMPA on down-count (CAD)                           |
| 6              | Counter equals zero                                                | Counter equals period (TBPRD)                                     |
| 7              | T1 on down-count (T1D)                                             | T1 on up-count (T1U)                                              |
| 8              | T2 on down-count (T2D)                                             | T2 on up-count (T2U)                                              |
| 9              | Counter equals CMPB on down-count (CBD)                            | Counter equals CMPB on up-count (CBU)                             |
| 10 (Lowest)    | Counter equals CMPA on down-count (CAD)                            | Counter equals CMPA on up-count (CBU)                             |

The table below shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and therefore, down-count events will never be taken.

**Table 18-5. Action-Qualifier Event Priority for Up-Count Mode**

| Priority Level | Event                                   |
|----------------|-----------------------------------------|
| 1 (Highest)    | Software forced event                   |
| 2              | Counter equal to period (TBPRD)         |
| 3              | T1 on up-count (T1U)                    |
| 4              | T2 on up-count (T2U)                    |
| 5              | Counter equal to CMPB on up-count (CBU) |
| 6              | Counter equal to CMPA on up-count (CAU) |
| 7 (Lowest)     | Counter equal to Zero                   |

The table below shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 18-6. Action-Qualifier Event Priority for Down-Count Mode**

| Priority Level | Event                                     |
|----------------|-------------------------------------------|
| 1 (Highest)    | Software forced event                     |
| 2              | Counter equal to Zero                     |
| 3              | T1 on down-count (T1D)                    |
| 4              | T2 on down-count (T2D)                    |
| 5              | Counter equal to CMPB on down-count (CBD) |
| 6              | Counter equal to CMPA on down-count (CAD) |
| 7 (Lowest)     | Counter equal to period (TBPRD)           |

It is possible to set the compare value greater than the period. In this case the action will take place as shown in the table below.

**Table 18-7. Behavior if CMPA/CMPB is Greater than the Period**

| Counter Mode       | Compare on Up-Count Event<br>CAD/CBD                                                                                                                                                                                                        | Compare on Down-Count Event<br>CAD/CBD                                                                                                                                                                                                |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Up-Count Mode      | <p>If <math>CMPA/CMPB \leq TBPRD</math> period, then the event occurs on a compare match (TBCTR=CMPA or CMPB).</p> <p>If <math>CMPA/CMPB &gt; TBPRD</math>, then the event will not occur.</p>                                              | Never occurs.                                                                                                                                                                                                                         |
| Down-Count Mode    | Never occurs.                                                                                                                                                                                                                               | <p>If <math>CMPA/CMPB &lt; TBPRD</math>, the event will occur on a compare match (TBCTR=CMPA or CMPB).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event will occur on a period match (TBCTR=TBPRD).</p>                         |
| Up-Down-Count Mode | <p>If <math>CMPA/CMPB &lt; TBPRD</math> and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event will occur on a period match (TBCTR = TBPRD).</p> | <p>If <math>CMPA/CMPB &lt; TBPRD</math> and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).</p> <p>If <math>CMPA/CMPB \geq TBPRD</math>, the event occurs on a period match (TBCTR=TBPRD).</p> |

#### 18.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is described below:

##### Shadow Mode:

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE] AQCTL[LDAQBMODE] AQCTL[LDAQASYNC] & AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

##### Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2 and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 18.4.7](#).

##### Immediate Load Mode:

If immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register will go directly to the active register. See [Figure 18-22](#) and [Figure 18-23](#).

**NOTE:** Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA & AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA=0 and AQCTLA shadow to active load on TBCTR=0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention and it is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.

Figure 18-22. AQCTL[SHDWAQAMODE]

Figure 18-23. AQCTL[SHDWAQBMODE]

## 18.6.5 Waveforms for Common Configurations

**NOTE:** The waveforms in this document show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

### Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

### Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report (literature number [SPRAA11](#))

The figure below shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 18-24. Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 18-25](#) through [Figure 18-30](#) show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

**Figure 18-25. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

- A PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- B Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- D The "Do Nothing" actions ( X ) are shown for completeness, but will not be shown on subsequent diagrams.
- E Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 18-26. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low**

- A PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 18-27. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**

- A PWM frequency =  $1 / (TBPRD + 1) \times T_{TBCLK}$
- B Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C High time duty proportional to (CMPB - CMPA)

**Figure 18-28. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low**

- A PWM period =  $2 \times TBPRD \times T_{TBCLK}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D Outputs EPWMxA and EPWMxB can drive independent power switches.

**Figure 18-29. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary**

- A PWM period =  $2 \times \text{TBPRD} \times T_{\text{TBCLK}}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
- C Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
- D Outputs EPWMx can drive upper/lower (complementary) power switches.
- E Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

**Figure 18-30. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low**

- A PWM period =  $2 \times \text{TBPRD} \times \text{TBCLK}$
- B Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- C Duty modulation for EPWMxA is set by CMPA and CMPB.
- D Low time duty for EPWMxA is proportional to (CMPA + CMPB).
- E To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
- F Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

**Figure 18-31. Up-Down-Count, PWM Waveform Generation Utilizing T1 and T2 Events**

- A PWM period =  $2 \times \text{TBPRD} \times \text{TTBCLK}$
- B Independent T1 event actions when counter is counting up and when it is counting down are used to generate EPWMxA output.
- C Independent T2 event actions when counter is counting up and when it is counting down are used to generate EPWMxB output.
- D TZ1 is selected as the source for T1.
- E TZ2 is selected as the source for T2.

## 18.7 Dead-Band Generator (DB) Submodule

Figure 18-32 illustrates the dead-band submodule within the ePWM module.

Figure 18-32. Dead\_Band Submodule

### 18.7.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how it is possible to generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs ( $EPWMxA$  and  $EPWMxB$ ) with dead-band relationship from a single  $EPWMxA$  input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

### 18.7.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED could appear on one channel output and FED could appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in Figure 18-33, RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

**Note:** Phase shifting B-channel with respect to the A-channel using the dead-band submodule

additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

- The dead-band counters have also been increased to 14 bits
- Dead-band and dead-band High-resolution registers are now shadowed.
- High-resolution dead-band RED and FED have been enabled using the DBREDHR and DBFEDHR registers

---

**NOTE:** The PWM chopper will not be enabled when high-resolution dead band is enabled.

---

**NOTE:** High-resolution dead-band RED and FED requires Half-Cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

---

**NOTE:** Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB\_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. It is recommended to make sure the duty cycle value of the current waveform fed to the dead-band module is greater than the required phase shift amount.

---

**NOTE:** The Type 4 action qualifier and deadband outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

---

### Shadow Mode:

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDMODE] & DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

### Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in [Section 18.4.7](#).

**NOTE:** When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED / DBFED value only affects the NEXT PWMx edge and not the current edge.

### 18.7.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in [Figure 18-33](#).

**Figure 18-33. Configuration Options for the Dead-Band Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 18-8](#) documents some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 18-8](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**  
Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:**  
These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 18-34](#). Note that to generate equivalent waveforms to [Figure 18-34](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**  
Finally the last two entries in [Table 18-8](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 18-8. Classical Dead-Band Operating Modes**

| Mode | Mode Description                               | DBCTL[POLSEL] |        | DBCTL[OUT_MODE] |    |
|------|------------------------------------------------|---------------|--------|-----------------|----|
|      |                                                | S3            | S2     | S1              | S0 |
| 1    | EPWMxA and EPWMxB Passed Through (No Delay)    | X             | X      | 0               | 0  |
| 2    | Active High Complementary (AHC)                | 1             | 0      | 1               | 1  |
| 3    | Active Low Complementary (ALC)                 | 0             | 1      | 1               | 1  |
| 4    | Active High (AH)                               | 0             | 0      | 1               | 1  |
| 5    | Active Low (AL)                                | 1             | 1      | 1               | 1  |
| 6    | EPWMxA Out = EPWMxA In (No Delay)              | 0 or 1        | 0 or 1 | 0               | 1  |
|      | EPWMxB Out = EPWMxA In with Falling Edge Delay |               |        |                 |    |
| 7    | EPWMxA Out = EPWMxA In with Rising Edge Delay  | 0 or 1        | 0 or 1 | 1               | 0  |
|      | EPWMxB Out = EPWMxB In with No Delay           |               |        |                 |    |

**Table 18-9. Additional Dead-Band Operating Modes**

| Mode Description                                                                                                                                 | DBCTL[DEDB-MODE] | DBCTL[OUTSWAP] |    |
|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------|----------------|----|
|                                                                                                                                                  | S8               | S6             | S7 |
| EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.                                                                                       | 0                | 0              | 0  |
| EPWMxA = A-path as defined by OUT-MODE bits.                                                                                                     | 0                | 0              | 1  |
| EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)                                                  |                  |                |    |
| EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)                                                 | 0                | 1              | 0  |
| EPWMxB = B-path as defined by OUT-MODE bits                                                                                                      |                  |                |    |
| EPWMxA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B-signal path)                                                 | 0                | 1              | 1  |
| EPWMxB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A-signal path)                                                  |                  |                |    |
| Rising edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only.                                      | 0                | X              | X  |
| Falling edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.                                     |                  |                |    |
| Rising edge delay and falling edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only. <sup>(1)</sup> | 1                | X              | X  |

<sup>(1)</sup> When this bit is set to 1, user should always either set OUT\_MODE bits such that Apath = InA **or** OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA will be invalid.

Figure 18-34 shows waveforms for typical cases where  $0\% < \text{duty} < 100\%$ .

**Figure 18-34. Dead-Band Waveforms for Typical Cases ( $0\% < \text{Duty} < 100\%$ )**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}$$

Where  $T_{\text{TBCLK}}$  is the period of TBCLK, the prescaled version of EPWMCLK.

For convenience, delay values for various TBCLK options are shown in [Table 18-10](#). The ePWM input clock frequency that these delay values been computed by is 100 MHz.

**Table 18-10. Dead-Band Delay Values in  $\mu\text{S}$  as a Function of DBFED and DBRED**

| Dead-Band Value | Dead-Band Delay in $\mu\text{S}$ |                     |                     |
|-----------------|----------------------------------|---------------------|---------------------|
| DBFED, DBRED    | TBCLK = EPWMCLK/1                | TBCLK = EPWMCLK /2  | TBCLK = EPWMCLK/4   |
| 1               | 0.01 $\mu\text{S}$               | 0.02 $\mu\text{S}$  | 0.04 $\mu\text{S}$  |
| 5               | 0.05 $\mu\text{S}$               | 0.10 $\mu\text{S}$  | 0.20 $\mu\text{S}$  |
| 10              | 0.10 $\mu\text{S}$               | 0.20 $\mu\text{S}$  | 0.40 $\mu\text{S}$  |
| 100             | 1.00 $\mu\text{S}$               | 2.00 $\mu\text{S}$  | 4.00 $\mu\text{S}$  |
| 200             | 2.00 $\mu\text{S}$               | 4.00 $\mu\text{S}$  | 8.00 $\mu\text{S}$  |
| 400             | 4.00 $\mu\text{S}$               | 8.00 $\mu\text{S}$  | 16.00 $\mu\text{S}$ |
| 500             | 5.00 $\mu\text{S}$               | 10.00 $\mu\text{S}$ | 20.00 $\mu\text{S}$ |
| 600             | 6.00 $\mu\text{S}$               | 12.00 $\mu\text{S}$ | 24.00 $\mu\text{S}$ |
| 700             | 7.00 $\mu\text{S}$               | 14.00 $\mu\text{S}$ | 28.00 $\mu\text{S}$ |
| 800             | 8.00 $\mu\text{S}$               | 16.00 $\mu\text{S}$ | 32.00 $\mu\text{S}$ |
| 900             | 9.00 $\mu\text{S}$               | 18.00 $\mu\text{S}$ | 36.00 $\mu\text{S}$ |
| 1000            | 10.00 $\mu\text{S}$              | 20.00 $\mu\text{S}$ | 40.00 $\mu\text{S}$ |

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}/2$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}/2$$

## 18.8 PWM Chopper (PC) Submodule

Figure 18-35 illustrates the PWM chopper (PC) submodule within the ePWM module.

**Figure 18-35. PWM Chopper Submodule**

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

### 18.8.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### 18.8.2 Operational Highlights for the PWM Chopper Submodule

Figure 18-36 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

**Figure 18-36. PWM Chopper Submodule Operational Details**

### 18.8.3 Waveforms

Figure 18-37 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 18-37. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only**

### 18.8.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where  $T_{EPWMCLK}$  is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 18-38 shows the first and subsequent sustaining pulses and Table 18-11 gives the possible pulse width values for a EPWMCLK = 80 MHz.

**Figure 18-38. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

**Table 18-11. Possible Pulse Width Values for EPWMCLK = 80 MHz**

| OSHTWTHz<br>(hex) | Pulse Width<br>(nS) |
|-------------------|---------------------|
| 0                 | 100                 |
| 1                 | 200                 |
| 2                 | 300                 |
| 3                 | 400                 |
| 4                 | 500                 |
| 5                 | 600                 |
| 6                 | 700                 |
| 7                 | 800                 |
| 8                 | 900                 |
| 9                 | 1000                |
| A                 | 1100                |
| B                 | 1200                |
| C                 | 1300                |
| D                 | 1400                |
| E                 | 1500                |
| F                 | 1600                |

### 18.8.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 18-39 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

**Figure 18-39. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

## 18.9 Trip-Zone (TZ) Submodule

Figure 18-40 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Figure 18-40. Trip-Zone Submodule

Each ePWM module is connected to six  $\overline{TZn}$  signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).  $\overline{TZ1}$  to  $\overline{TZ3}$  are sourced from the GPIO mux.  $\overline{TZ4}$  is sourced from an inverted EQEPxERR signal on those devices with an EQEP module.  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

### 18.9.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZ6}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or  $\overline{TZ1}$  to  $\overline{TZ3}$  signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

### 18.9.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals  $\overline{TZ1}$  to  $\overline{TZ6}$  (also collectively referred to as  $\overline{TZn}$ ) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of  $3 \cdot TBCLK$  low pulse width on  $\overline{TZn}$  inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on  $\overline{TZn}$  inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the device-specific version of the *System Control and Interrupts* chapter.

Each  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB outputs. [Table 18-12](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits will remain set until they are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and/or TZCBCFLG register bits are cleared, then these bits will again be immediately set..

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 18-12](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, TZOSTFLG register bit should be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the

DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRISEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see [Section 18.11](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 18-12](#) lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and/or while it is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCA register. Actions specified in TZCTLDCA and TZCTLDCA registers take effect only when ETZE bit in TZCTL2 is set.

In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and PIE peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCA register bit fields. Some of the possible actions, shown in the table below, can be taken on a trip event.

**Table 18-12. Possible Actions On a Trip Event**

| TZCTL Register bit-field Settings | EPWMxA and/or EPWMxB | Comment                                         |
|-----------------------------------|----------------------|-------------------------------------------------|
| 0,0                               | High-Impedance       | Tripped                                         |
| 0,1                               | Force to High State  | Tripped                                         |
| 1,0                               | Force to Low State   | Tripped                                         |
| 1,1                               | No Change            | Do Nothing.<br>No change is made to the output. |

### Example 18-1. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.

**Example 18-1. Trip-Zone Configurations (continued)**

- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

**18.9.3 Generating Trip Event Interrupts**

[Figure 18-41](#) and [Figure 18-42](#) illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in [Section 18.11](#).

**Figure 18-41. Trip-Zone Submodule Mode Control Logic**

Figure 18-42. Trip-Zone Submodule Interrupt Logic

## 18.10 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. [Figure 18-43](#) illustrates where the event-trigger submodule fits within the ePWM system.

**Figure 18-43. Event-Trigger Submodule**

### 18.10.1 Operational Overview of the ePWM Type 4 Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of [Figure 18-44](#)) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to Every fifteenth event

**Figure 18-44. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- **ETSEL** - This selects which of the possible events will trigger an interrupt or start an ADC conversion.
- **ETPS** - This programs the event prescaling options mentioned above.
- **ETFLG** - These are flag bits indicating status of the selected and prescaled events.
- **ETCLR** - These bits allow you to clear the flag bits in the ETFLG register via software.
- **ETFRC** - These bits allow software forcing of an event. Useful for debugging or software intervention.
- **ETINTPS** - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- **ETSOCPS** - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- **ETCNTINITCTL** - These bits enable ETCNTINIT initialization via SYNC event OR via software force.
- **ETCNTINIT** - These bits allow you to initialize INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 18-45](#), [Figure 18-46](#), and [Figure 18-47](#).

[Figure 18-45](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

On ePWM type 4, in order to enable event generation capability up to 15 events the following changes have been made. The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until they reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the PIE.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behavior will occur [The below behavior is also applicable to ETINTPS[INTCNT2] & ETINTPS[INTPRD2] :

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ETFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] & ETINTPS[INTPRD2]

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD. You can generate an interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then it enables initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force determined by ETCNTINITCTL[INTINITFRC] .

The diagram illustrates the internal architecture of the ETB module. Key components include:

- Clear Latch Set:** Receives  $ETCLR[INT]$  and controls the  $Clear\ CNT$  block.
- Generate Interrupt Pulse When Input = 1:** Receives  $ETSEL[INT]$  and outputs  $EPWMxINT$ .
- 4-bit Counter:** Contains  $Clear\ CNT$  and  $Inc\ CNT$  logic. It receives  $ETPS[INTPRD]$  and  $ETINTPS[INTPRD2]$  as inputs and outputs  $ETPS[INTCNT]$  and  $ETINTPS[INTCNT2]$ . It also receives  $ETPS[INTPSEL]$  via a multiplexer.
- ETSEL Multiplexer:** Selects between different control signals based on  $ETSEL[INTSEL]$ . It has eight inputs:
  - 000: 0
  - 001:  $CTR = Zero$
  - 010:  $CTR = PRD$
  - 011:  $CTR = CMPA$  (selected via OR gate)
  - 100:  $CTR = CMPB$
  - 101:  $CTR = CMPC$
  - 101:  $CTR = CMPD$
  - 111:  $CTR = CMPB$  (selected via OR gate)
  - 111:  $CTR = CMPD$
- ETCNTINIT[INTINIT]:** Provides a 4-bit initial value to the counter.
- ETCNTINITCTL[INTINITFRC] and ETCNTINITCTL[INTINITEN]:** Control the initial value loading via multiplexers and an AND gate.
- ETPSEL Multiplexer:** Selects between  $ETPS[INTPRD]$  and  $ETINTPS[INTPRD2]$  based on  $ETPS[INTPSEL]$ .
- ETFRFC[INT]:** Receives  $ETSEL[INTSEL]$  and  $ETPS[INTPSEL]$  via an OR gate.

**Figure 18-46. Event-Trigger SOCA Pulse Generator**

A The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule in [Section 18.11](#).

[Figure 18-47](#) shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

**Figure 18-47. Event-Trigger SOCB Pulse Generator**

A The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule in [Section 18.11](#).

## 18.11 Digital Compare (DC) Submodule

Figure 18-48 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

**Figure 18-48. Digital-Compare Submodule High-Level Block Diagram**

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 18-49.

zone, event-trigger, and time-base submodules to:

- generate a trip zone interrupt
- generate an ADC start of conversion
- force an event
- generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

### 18.11.2 Enhanced Trip Action Using CMPSS

In order to allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

The user has a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

### 18.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps should be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification will be introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition will remain active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition will not be cleared until after the following PWM cycle has started. Thus, the new PWM cycle will detect a trip condition as soon as it begins.

To avoid this undesired trip condition, the user application should take steps to ensure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip will not be asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal via the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (via COMPSTCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (via HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

### 18.11.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

### 18.11.4.1 Digital Compare Events

As illustrated in [Section 18.11.4.2](#) earlier in this section, trip zone inputs ( $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$ ) and CMPSSx signals from the analog comparator (COMP) module can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

---

**NOTE:** The  $\overline{TZn}$  signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. ePWM outputs are asynchronously tripped when either the  $\overline{TZn}$ , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3\*TBCLK sync pulse width is required. If pulse width is < 3\*TBCLK sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

---

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 18.11.4.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

Output EPWMxA:

- TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
- TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
- TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

Output EPWMxB:

- TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
- TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
- TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)

- **interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the PIE. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

The diagrams below show how the DCAEVT1, DCAEVT2 or DCEVTFILT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

Figure 18-50. DCAEVT1 Event Triggering

Figure 18-51. DCAEVT2 Event Triggering

Figure 18-52 and Figure 18-53 show how the DCBEVT1, DCBEVT2 or DCEVTFLT signals are processed to generate the digital compare B event force, interrupt, soc and sync signals.

Figure 18-52. DCBEVT1 Event Triggering

Figure 18-53. DCBEVT2 Event Triggering

#### 18.11.4.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. The following figure shows the details of the event filtering logic.

**Figure 18-54. Event Filtering**

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

The diagram below illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

**Figure 18-55. Blanking Window Timing Diagram**

#### 18.11.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in [Section 18.11.4.2](#). This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEVty signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEVty events as input to the valley switching block (DCFCTL[SRCSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that will indicate the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEGE]) that will indicate the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
  - The STOPEGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEVty signal. The CNTVAL value may be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay may be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])

8. Configure VCAPCTL[EDGEFILTDLSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in the figure below.

**NOTE:** A specific application example showcasing the usage of valley switching hardware and software is available on the controlSuite.

**Figure 18-56. Valley Switching**

## 18.12 ePWM X-BAR

The figure below shows the architecture of the ePWM X-Bar. This module enables selection of various trigger sources into any of the eight dedicated ETWPM trips inputs, namely the TRIP4, TRIP5, TRIP7, TRIP8, TRIP9, TRIP10, TRIP11 and TRIP12.

**NOTE:** Please refer to the X-BAR chapter for more information on the X-BAR modules, including X-BAR flags.

**Figure 18-57. ePWM X-BAR**

The ePWM X-BAR has eight outputs which are routed to each ePWM module. The following figure represents the architecture of a single output but it is identical to the architecture of all of the other outputs:

**Figure 18-58. ePWM XBAR Architecture - Single Output**

First, determine the signal(s) which should be passed to the ePWM by referencing the ePWM X-Bar Input Table. You may select up to one signal per mux (31 total muxes) for each TRIPx output. Select the inputs to each mux via the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. In order to pass any signal through to the EPWM, you must also enable the mux in the TRIPxMUXENABLE register. All muxes which are enabled will be logically OR'd before being passed on to the respective TRIPx signal on the EPWM. You may also optionally invert the signal via the TRIPxOUTINV register.

**Table 18-13. ePWM X-BAR Mux Configuration Table**

| Mux | 1             | 2                       | 3         | 4         |

| 23  |               | INPUT10                 |           |           |
| 24  |               |                         |           |           |
| 25  |               | INPUT11                 |           |           |
| 26  |               |                         |           |           |
| 27  |               | INPUT12                 |           |           |
| 28  |               |                         |           |           |
| 29  |               | INPUT13                 |           |           |
| 30  |               |                         |           |           |
| 31  |               | INPUT14                 |           |           |

**Note:** All unused and reserved positions are tied to '0'.

## 18.13 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 18.13.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 18-59](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

**Figure 18-59. Simplified ePWM Module**

### 18.13.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it (that is, via the enable switch). Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 18-60](#).

**Figure 18-60. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 18.13.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. [Figure 18-61](#) shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. [Figure 18-62](#) shows the waveforms generated by the setup shown in [Figure 18-61](#); note that only three waveforms are shown, although there are four stages.

**Figure 18-61. Control of Four Buck Stages. Here  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

**Figure 18-62. Buck Waveforms for Figure 18-61 (Note: Only three bucks shown here)**

### 18.13.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 18-63 shows such a configuration; Figure 18-64 shows the waveforms generated by the configuration.

**Figure 18-63. Control of Four Buck Stages. (Note:  $F_{PWM2} = N \times F_{PWM1}$ )**

NOTE:  $\phi = X$  indicates value in phase register is a "don't care"

Figure 18-64. Buck Waveforms for Figure 18-63 (Note:  $F_{PWM2} = F_{PWM1}$ )

A Starts ADC conversion.

### 18.13.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 18-65 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 18-66 shows the waveforms generated by the configuration shown in Figure 18-65.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

[illegible]

**Figure 18-66. Half-H Bridge Waveforms for Figure 18-65 (Note: Here  $F_{PWM2} = F_{PWM1}$ )**

### 18.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 18-67 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 18-67), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

**Figure 18-67. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control**

Figure 18-68. 3-Phase Inverter Waveforms for Figure 18-67 (Only One Inverter Shown)

**Figure 18-70. Timing Waveforms Associated With Phase Control Between Two Modules**

### 18.13.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 18-71](#). This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master 1 module.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$\text{TBPHS}(N,M) = (\text{TBPRD}/N) \times (M-1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N=3), TBPRD = 600,

$$\text{TBPHS}(3,2) = (600/3) \times (2-1) = 200 \text{ (that is, Phase value for Slave module 2)}$$

$$\text{TBPHS}(3,3) = 400 \text{ (that is, Phase value for Slave module 3)}$$

[Figure 18-72](#) shows the waveforms for the configuration in [Figure 18-71](#).

**Figure 18-71. Control of a 3-Phase Interleaved DC/DC Converter**

**Figure 18-72. 3-Phase Interleaved DC/DC Converter Waveforms for Figure 18-71**

### 18.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in the figure below assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. [Figure 18-74](#) shows a master/slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave's phase register (TBPHS). The master's phase register is not used and therefore can be initialized to zero.

**Figure 18-73. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )**

Figure 18-74. ZVS Full-H Bridge Waveforms

### 18.13.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 18-75 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 10-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference could be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 18-76 shows the waveforms generated by the configuration.

Figure 18-75. Peak Current Mode Control of a Buck Converter

Figure 18-76. Peak Current Mode Control Waveforms for Figure 18-75

### 18.13.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multi channel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is frequency. Although the deadband is not controlled and kept constant as 300ns (that is, 30 @100MHz TBCLK), it is up to user to update it in real time to enhance the efficiency by adjusting enough time delay for soft switching.

Figure 18-77. Control of Two Resonant Converter Stages

NOTE:  $\Theta = X$  indicates value in phase register is 'don't care'

Figure 18-78. H-Bridge LLC Resonant Converter PWM Waveforms

## 18.14 Register Lock Protection

The register lock protection mechanism is added to protect the critical ePWM registers from being corrupted by accidental writes in case of runaway code. The register EPWMLOCK contains the definition of Lock bits (Table 18-14 shows the lock bits and the corresponding registers). This register also has a KEY field; writes to this register will succeed only if the KEY field is written with a value of 0xa5a5. Refer to the register descriptions for more details.

**Table 18-14. Lock Bits and Corresponding Registers**

| Bit Field | Definition                        | Registers Locked                                                                                |
|-----------|-----------------------------------|-------------------------------------------------------------------------------------------------|
| HRLOCK    | HRPWM Register Set Lock           | HRCNFG, HRPWR, HRMSTEP, HRPCTL                                                                  |
| GLLOCK    | Global Load Register Set Lock     | GLDCTL, GLDCFG                                                                                  |
| TZCFGLOCK | TripZone Register Set Lock        | TZSEL, TZDCSEL, TZCTL, TZCTL2, TZCTLDCA, TZCTLDCB, TZEINT                                       |
| TZCLRLOCK | TripZone Clear Register Set Lock  | TZCLR, TZCBCCLR, TZOSTCLR, TZFRC                                                                |
| DCLOCK    | Digital Compare Register Set Lock | DCTRIPSEL, DCACTL, DCBCTL, DCFCTL, DCCAPCTL, DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, DCBLTRIPSEL |

**NOTE:** Due to the presence of the KEY field in the same register, only 32-bit writes will succeed if the KEY matches. The 16-bit writes to the upper or lower half of this register will be ignored.

## 18.15 High-Resolution Pulse Width Modulator (HRPWM)

This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~ 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A & B signal path of PWM, that is, on the EPWMxA and EPWMxB output.
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running optimally
- Enables high resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output via inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module. See the device-specific data manual to determine if your device has an ePWM module for high-resolution period support.

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in [Figure 18-79](#), the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 18-79. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, the table below shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180 ps. See the device-specific data sheet for typical and maximum performance specifications for the MEP.

**Table 18-15. Resolution for PWM and HRPWM**

| PWM Freq<br><br>(kHz) | Regular Resolution (PWM) |      | High Resolution (HRPWM) |       |
|-----------------------|--------------------------|------|-------------------------|-------|
|                       | 100 MHz EPWMCLK          |      |                         |       |
|                       | Bits                     | %    | Bits                    | %     |
| 20                    | 12.3                     | 0.02 | 18.1                    | 0.000 |
| 50                    | 11                       | 0.05 | 16.8                    | 0.001 |
| 100                   | 10                       | 0.1  | 15.8                    | 0.002 |
| 150                   | 9.4                      | 0.15 | 15.2                    | 0.003 |
| 200                   | 9                        | 0.2  | 14.8                    | 0.004 |
| 250                   | 8.6                      | 0.25 | 14.4                    | 0.005 |
| 500                   | 7.6                      | 0.5  | 13.4                    | 0.009 |
| 1000                  | 6.6                      | 1    | 12.4                    | 0.018 |
| 1500                  | 6.1                      | 1.5  | 11.9                    | 0.027 |
| 2000                  | 5.6                      | 2    | 11.4                    | 0.036 |

Although each application may differ, typical low frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 18.15.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. See the device-specific data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions. Details on software diagnostics and functions are in [Section 18.15.1.7](#).

The figure below shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

**Figure 18-80. Operating Logic Using MEP**

<sup>†</sup> For MEP range and rounding adjustment. (0x0080 in Q8 format)

To generate an HRPWM waveform, configure the ePWM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in [Section 18.15.1.8](#).

#### 18.15.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM & DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Deadband Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Deadband Generator Falling Edge Delay High Resolution Register

**NOTE:** TBPHSHR must not be used. Instead TRREM (translator remainder register) must be used to mimic the functionality of TBPHSHR.

**Figure 18-81. HRPWM Extension Registers and Memory Configuration**

- A Dependant upon your device, these registers may be mirrored and can be written to at two different memory locations. Check the device-specific Technical Reference Manual's *ePWM* chapter for more details on how to read and write to these locations.

**NOTE:** HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during Dead Band half cycle clocking Operation. The number of MEP steps is half in size [ bits 15:9 ]than duty and phase high resolution registers for the same reason

HRPWM capabilities are controlled using the Channel A & B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. The following figure shows how the HRPWM interfaces with the 8-bit extension registers.

**Figure 18-82. HRPWM System Interface**

A These events are generated by the ePWM digital compare (DC) submodule.

Figure 18-83. HRPWM Block Diagram

#### 18.15.1.2 HRPWM Source Clock

The HRPWM module and HRCAL module are clocked from the EPWM1CLK. Therefore EPWM1CLK must be enabled for the HRCAL or any of the HRPWM modules to be enabled. The figure Figure 18-84 shows the HRCAL and HRPWM modules are sourced from ePWM1 clock source.

Figure 18-84. HRPWM and HRCAL Source Clock

#### 18.15.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

**Edge Mode** — The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).

**Control Mode** — The MEP is programmed to be controlled either from the CMPAHR / CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR or CMPBHR register. BE control mode should be used with TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control) the duty cycle and phase can also be controlled via their respective high-resolution registers.

**Shadow Mode** — This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR and TBPRDHR registers and should be chosen to be the same as the regular load option for the CMPA, CMPB register. If TBPHSHR is used, then this option has no effect.

**High-Resolution B Signal Control** — The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2, or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.

**Swap ePWMxA and ePWMxB Outputs** — This mode enables the swapping of the high resolution A & B outputs. The mode selection allows either A & B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A

**Auto-conversion Mode** — This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled,  $\text{CMPAHR} = \text{fraction}(\text{PWMduty} * \text{PWMperiod}) < 8$ . The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and  $\text{CMPAHR} = (\text{fraction}(\text{PWMduty} * \text{PWMperiod}) * \text{MEP Scale Factor} + 0.5) < 8$ . All calculations will need to be performed by user code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

---

**NOTE:** Auto-conversion Mode performs the calculation for CMPBHR, DBREDHR and DBFEDHR as well. The scale factor optimization software will calculate the MEP scale factor in background code and automatically update the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module will then use the values in the HRMSTEP and CMPBHR or DBREDHR / DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and move the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves same as CMPAHR.  $\text{CMPBHR} = (\text{fraction}(\text{PWMduty} * \text{PWMperiod}) * \text{MEP Scale Factor} + 0.5) < 8$ .

---

#### 18.15.1.4 Configuring Hi-Res in Deadband Rising Edge and Falling Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity and deadband enabled in half cycle clocking mode, the high resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module's register space. This register provides the following configuration options:

**Edge Mode** — The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED) or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

**Control Mode** — Selects the time event that loads the shadow value in active register for DBRED and DBFED in high resolution mode. The user needs to select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] & DBCTL[LOADFEDMODE] bits .

#### 18.15.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see device-specific data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 18-16](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 18-16. Relationship Between MEP Steps, PWM Frequency and Resolution**

| System (MHz) | MEP Steps Per EPWMCLK <sup>(1)(2)(3)</sup> | PWM MIN (Hz) <sup>(4)</sup> | PWM MAX (MHz) | Res. @ MAX (Bits) <sup>(5)</sup> |
|--------------|--------------------------------------------|-----------------------------|---------------|----------------------------------|
| 60.0         | 93                                         | 916                         | 3.00          | 10.9                             |
| 70.0         | 79                                         | 1068                        | 3.50          | 10.6                             |
| 80.0         | 69                                         | 1221                        | 4.00          | 10.4                             |
| 90.0         | 62                                         | 1373                        | 4.50          | 10.3                             |
| 100.0        | 56                                         | 1526                        | 5.00          | 10.1                             |

<sup>(1)</sup> TBCLK = EPWMCLK.

<sup>(2)</sup> Table data based on a MEP time resolution of 180 ps (this is an example value. See the device-specific data sheet for MEP limits)

<sup>(3)</sup> MEP steps applied =  $T_{EPWMCLK}/180$  ps in this example.

<sup>(4)</sup> PWM minimum frequency is based on a maximum period value, (TBPRD = 65535). PWM mode is asymmetrical up-count.

<sup>(5)</sup> Resolution in bits is given for the maximum PWM frequency stated.

### 18.15.1.5.1 Edge Positioning

**NOTE:** The below example is presented using [CMPA:CMPAHR] register combination. The theory of operation and equations is same if the user intends to use [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 18-85, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 18-17.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 18-17 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ps.

**Figure 18-85. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 18-17. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)**

| CMPA (count) <sup>(1) (2) (3)</sup> | DUTY %      | High Time (ns) | CMPA (count) | CMPAHR (count) | Duty (%)      | High Time (ns) |
|-------------------------------------|-------------|----------------|--------------|----------------|---------------|----------------|
| 28                                  | <b>35.0</b> | 280            | 32           | 18             | <b>40.405</b> | 323.24         |
| 29                                  | <b>36.3</b> | 290            | 32           | 19             | <b>40.428</b> | 323.42         |
| 30                                  | <b>37.5</b> | 300            | 32           | 20             | <b>40.450</b> | 323.60         |
| 31                                  | <b>38.8</b> | 310            | 32           | 21             | <b>40.473</b> | 323.78         |
| 32                                  | <b>40.0</b> | 320            | 32           | 22             | <b>40.495</b> | 323.96         |
| 33                                  | <b>41.3</b> | 330            | 32           | 23             | <b>40.518</b> | 324.14         |
| 34                                  | <b>42.5</b> | 340            | 32           | 24             | <b>40.540</b> | 324.32         |
|                                     |             |                | 32           | 25             | <b>40.563</b> | 324.50         |
| Required                            |             |                | 32           | 26             | <b>40.585</b> | 324.68         |
| 32.40                               | <b>40.5</b> | 324            | 32           | 27             | <b>40.608</b> | 324.86         |

<sup>(1)</sup> TBCLK = 100 MHz, 10 ns

<sup>(2)</sup> For a PWM Period register value of 80 counts, PWM Period = 80 x 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

<sup>(3)</sup> Assumed MEP step size for the above example = 180 ps  
See the device-specific data manual for typical and maximum MEP values.

### 18.15.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

**Assumptions for this example:**

|                                                                                                 |                            |
|-------------------------------------------------------------------------------------------------|----------------------------|
| TBCLK                                                                                           | = 10 ns (100 MHz)          |
| PWM frequency                                                                                   | = 1.25 MHz (1/800 ns)      |
| Required PWM duty cycle, <b>PWMDuty</b>                                                         | = 0.405 (40.5%)            |
| PWM period in terms of coarse steps, <b>PWMPeriod</b> (800 ns/10 ns)                            | = 80                       |
| Number of MEP steps per coarse step at 180 ps (10 n/180 ps ), <b>MEP_ScaleFactor</b>            | = 55                       |
| Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) | = 0.5 (0080h in Q8 format) |

**Step 1: Percentage Integer Duty value conversion for CMPA register**

|                     |                                                                            |
|---------------------|----------------------------------------------------------------------------|
| CMPA register value | = $\text{int}(\text{PWMDuty} * \text{PWMPeriod})$ ; int means integer part |
|                     | = $\text{int}(0.405 * 80)$                                                 |
|                     | = $\text{int}(32.4)$                                                       |
| CMPA register value | = 32 (20h)                                                                 |

**Step 2: Fractional value conversion for CMPAHR register**

|        |                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------|
| CMPAHR | = $(\text{frac}(\text{PWMDuty} * \text{PWMPeriod}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ ; frac means fractional part |
|        | = $(\text{frac}(32.4) * 55 + 0.5) \ll 8$ ; Shifting is to move the value to the high byte of CMPAHR.                    |
|        | = $(0.4 * 55 + 0.5) \ll 8$                                                                                              |
|        | = $(22 + 0.5) \ll 8$                                                                                                    |
|        | = $22.5 * 256$ ; Shifting left by 8 is the same as multiplying by 256.                                                  |
|        | = 5760 (1680h)                                                                                                          |
| CMPAHR | = 1680h CMPAHR value = 1600h (lower 8 bits will be ignored by hardware).                                                |

---

**NOTE:** If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value =  $\text{frac}(\text{PWMDuty} * \text{PWMperiod} \ll 8)$ . The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

---

**NOTE:** The MEP scale factor (MEP\_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the 28x CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in [Section 18.15.1.8](#). The actual implementation takes advantage of the 32-bit CPU architecture of the 28xx, and is somewhat different from the steps shown in [Section 18.15.1.5.2](#).

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles ) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

### 18.15.1.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high resolution period (TBPRDHR) control is enabled via the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED and/or DBFED (the register corresponding to the edge with hi-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in [Figure 18-86](#) to [Figure 18-89](#). This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see [Table 18-18](#). When high-resolution period control is enabled (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there may be undefined behavior on the ePWMxA output.

**Figure 18-86. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)**

**Table 18-18. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles**

| PWM Frequency <sup>(1)</sup><br>(kHz) | 3 Cycles<br>Minimum Duty | 3 Cycles<br>Maximum Duty <sup>(2)</sup> |
|---------------------------------------|--------------------------|-----------------------------------------|
| 200                                   | 0.6%                     | 99.4%                                   |
| 400                                   | 1.2%                     | 98.8%                                   |
| 600                                   | 1.8%                     | 98.2%                                   |
| 800                                   | 2.4%                     | 97.6%                                   |
| 1000                                  | 3%                       | 97%                                     |
| 1200                                  | 3.6%                     | 96.4%                                   |
| 1400                                  | 4.2%                     | 95.8%                                   |
| 1600                                  | 4.8%                     | 95.2%                                   |
| 1800                                  | 5.4%                     | 94.6%                                   |
| 2000                                  | 6%                       | 94%                                     |

<sup>(1)</sup> EPWMCLK = TBCLK = 100 MHz

<sup>(2)</sup> This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in [Figure 18-87](#). In this configuration, the minimum duty cycle limitation is no longer an issue. However, there will be a maximum duty limitation with same percent numbers as given in [Table 18-18](#).

Figure 18-87. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Figure 18-88. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)

**Figure 18-89. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1)**

**NOTE:** If the application has enabled high-resolution period control (HRPCTL[HRPE]=1), the duty cycle must not fall within the restricted range. Otherwise, there will be undefined behavior on the ePWM output.

#### 18.15.1.5.4 High Resolution Period

High resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

---

**NOTE:** When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and vice versa, the non hi-res output will have +/- 1 TBCLK cycle jitter in up-count mode and +/- 2 TBCLK cycle jitter in up-down count mode.

---

The scaling procedure described for duty cycle in [Section 18.15.1.5.2](#) applies for high-resolution period as well:

##### Assumptions for this example:

|                                                                                              |                               |
|----------------------------------------------------------------------------------------------|-------------------------------|
| TBCLK                                                                                        | = 10 ns (100 MHz)             |
| Required PWM frequency                                                                       | = 175 kHz (period of 571.428) |
| Number of MEP steps per coarse step at 180 ps (MEP_ScaleFactor)                              | = 55 (10 ns / 180 ps)         |
| Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value) | = 0.5 (0080h in Q8 format)    |

##### Problem:

In up-count mode:

If TBPRD = 571, then PWM frequency = 174.82 kHz (period =  $(571+1) * T_{TBCLK}$ ).

If TBPRD = 570, then PWM frequency = 175.13 kHz (period =  $(570+1) * T_{TBCLK}$ ).

In up-down count mode:

If TBPRD = 286, then PWM frequency = 174.82 kHz (period =  $(286*2) * T_{TBCLK}$ ).

If TBPRD = 285, then PWM frequency = 175.44 kHz (period =  $(285*2) * T_{TBCLK}$ ).

##### Solution:

With 55 MEP steps per coarse step at 180 ps each:

##### Step 1: Percentage Integer Period value conversion for TBPRD register

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| Integer period value   | $= 571 * T_{TBCLK}$<br>$= \text{int}(571.428) * T_{TBCLK}$<br>$= \text{int}(\text{PWMperiod}) * T_{TBCLK}$ |
| In up-count mode:      |                                                                                                            |
| TBPRD                  | $= 570$ (TBPRD = period value - 1)<br>$= 023Ah$                                                            |
| In up-down count mode: |                                                                                                            |
| TBPRD                  | $= 285$ (TBPRD = period value / 2)<br>$= 011Dh$                                                            |

##### Step 2: Fractional value conversion for TBPRDHR register

|                                                                      |                                                                                                     |
|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| TBPRDHR register value                                               | $= (\text{frac}(\text{PWMperiod}) * \text{MEP\_ScaleFactor} + 0.5)$                                 |
| If auto-conversion enabled and HRMSTEP = MEP_ScaleFactor value (55): | $= \text{frac}(\text{PWMperiod}) \ll 8$ (Shifting is to move the value to the high byte of TBPRDHR) |
| TBPRDHR register value                                               | $= \text{frac}(571.428) \ll 8$<br>$= 0.428 \times 256$<br>$= 6D00h$                                 |

The autoconversion will then automatically perform the calculation such that TBPRDHR MEP delay is scaled by hardware to:

$$\begin{aligned} &= ((\text{TBPRDHR}(15:0) \gg 8) \times \text{HRMSTEP} + 80h) \ll 8 \\ &= (006Dh \times 55 + 80h) \gg 8 \\ &= (17EBh) \gg 8 \\ \text{Period MEP delay} &= 0017h \text{ MEP Steps} \end{aligned}$$

#### 18.15.1.5.4.1 High-Resolution Period Configuration

To use High Resolution Period, the ePWMx module must be initialized in the exact order presented.

The steps below use CMPA with shadow registers and the corresponding HRCNFG bits for hi-resolution operation on EPWMxA. For hi-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
  - ePWMx may only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
  - TBPRD and CC registers must be configured for shadow loads.
  - CMPCTL[LOADAMODE]
    - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
    - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR=0 or CTR=PRD)
5. Configure the HRCNFG register such that:
  - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
  - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
  - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired via the SFO() function described in [Section 18.15.2](#).
11. To control high-resolution period, write to the TBPRDHR(M) registers.

**NOTE:** When high-resolution period mode is enabled, an EPWMxSYNC pulse will introduce +/- 1 - 2 cycle jitter to the PWM (+/- 1 cycle in up-count mode and +/- 2 cycle in up-down count mode). For this reason, TBCTL[SYNCOSEL] should not be set to 1 (CTR = 0 is EPWMxSYNCO source) or 2 (CTR = CMPB is EPWMxSYNCO source). Otherwise, the jitter will occur on every PWM cycle with the synchronization pulse.

When TBCTL[SYNCOSEL] = 0 (EPWMxSYNCL is EPWMxSYNCO source), a software synchronization pulse should be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter will appear on the PWM output at the time of the sync pulse.

### 18.15.1.6 Deadband High Resolution Operation

#### Assumptions for this example:

|                                                      |                             |
|------------------------------------------------------|-----------------------------|
| System clock                                         | = 10 ns (100 MHz) &         |
| Deadband Enabled in half cycle mode, TBCLK = EPWMCLK |                             |
| Required PWM frequency                               | 1.33MHz (1 / 750 ns)        |
| Required PWM duty cycle                              | 0.5 (50%)                   |
| Required Dead band Rising Edge Delay                 | 5% over duty                |
| Required Dead band Rising Edge Delay in ns           | (0.05 * 375 ns ) = 18.75 ns |

---

**NOTE:** Just like the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use hi-res deadband.

---

#### Deadband Delay Values as a Function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED * TBCLK / 2$$

$$RED = DBRED * TBCLK / 2$$

#### DBRED and DBFED Calculated Values:

Required Dead band Rising Edge Delay in ns = 18.75 ns

$$DBRED = RED / (TBCLK / 2)$$

$$DBRED = 18.75 \text{ ns} / 5 \text{ ns}$$

$$DBRED \text{ Required} = 3.75 \text{ ns}$$

With 55 MEP steps per coarse step at 180 ps each:

#### Step 1: Integer Dead band value conversion for DBREDM register

|                     |                           |
|---------------------|---------------------------|
| Integer DBRED value | = int (RED / (TBCLK / 2)) |
|                     | = int (3.75)              |
| DBRED               | = 3                       |

#### Step 2: Fractional value conversion for Dead band high resolution register DBREDHR

|                        |                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| DBREDHR register value | = (frac(DBRED Required) * MEP_ScaleFactor + 0.5) << 8 (Shifting is to move the value to the high byte of DBREDHR) |
|                        | = (frac (3.75) * 55 + 0.5) << 8                                                                                   |
|                        | = ( 0.75 * 55 + 0.5 ) << 8                                                                                        |
|                        | = (41.75) * 256 Shifting left by 8 is the same as multiplying by 256.                                             |
| DBREDHR value          | = 29C0h MEP Steps                                                                                                 |
|                        | Hardware will ignore lower 9 bits in the above calculated DBREDHR value                                           |

---

**NOTE:** If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED =  $\text{frac}((\text{required DB value}) < <8)$ . The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

---

#### 18.15.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150 ps (see device-specific data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature should use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO\_TI\_Build\_V8.lib software can be found in [Section 18.15.2](#).

#### 18.15.1.8 HRPWM Examples Using Optimized Assembly Code.

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used. Note, #defines introduced in the device-specific *Pulse Width Modulator (ePWM) Module Reference Guide* are also used.

[Example 18-2](#) This example assumes MEP step size of 150 ps and does not use the SFO library.

**Example 18-2. #Defines for HRPWM Header Files**

```
// HRPWM (High Resolution PWM) //
=====
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1          // Rising Edge position
#define HR_FEP 0x2          // Falling Edge position
#define HR_BEP 0x3          // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1          // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1      // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B 0x0       // Normal ePWMxB output
#define HR_INVERT_B 0x1     // ePWMxB is inverted ePWMxA output
```

**18.15.1.8.1 Implementing a Simple Buck Converter**

In this example, the PWM requirements are:

- PWM frequency = 1 MHz (that is, TBPRD = 100 )
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150 ps)

Figure 18-90 and Figure 18-91 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 18-90. Simple Buck Controlled Converter Using a Single PWM**

**Figure 18-91. PWM Waveform Generated for Simple Buck Controlled Converter**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

[Example 18-3](#) shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150 ps and does not use the SFO library.

### **Example 18-3. HRPWM Buck Converter Initialization Code**

```
void HrBuckDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // set Immediate load
EPwm1Regs.TBPRD = 100;                             // Period set for 1000 kHz PWM
hrbuck_period = 200;                                // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;             // EPWM1 is the Master
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;       // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;         // optional

EPwm1Regs.AQCTLA.bit.ZR0 = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZR0 = AQ_SET;                 // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;               // optional
// Now configure the HRPWM resources
EALLOW;                                             // Note these registers are protected
                                                    // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                        // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;             // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;             // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;         // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                          // Start with typical Scale Factor
                                                    // value for 100 MHz
                                                    // Note: Use SFO functions to update
                                                    // MEP_ScaleFactor dynamically
}
```

[Example 18-4](#) shows an assembly example of run-time code for the HRPWM buck converter.

**Example 18-4. HRPWM Buck Converter Run-Time Code**

```

EPWM1_BASE .set 0x6800

```

**18.15.1.8.2 Implementing a DAC function Using an R+C Reconstruction Filter**

In this example, the PWM requirements are:

- PWM frequency = 400 kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150 ps)

Figure 18-92 and Figure 18-93 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 18-92. Simple Reconstruction Filter for a PWM-based DAC**

**Figure 18-93. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP\_SP and does not use the SFO library.

[Example 18-5](#) shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

#### **Example 18-5. PWM DAC Function Initialization Code**

```
void HrPwmDacDrvCnf(void)
{
    // Config for conventional PWM first
    EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;    // Set Immediate load
    EPwm1Regs.TBPRD = 250;                      // Period set for 400 kHz PWM
    hrDAC_period = 250;                         // Used for Q15 to Q0 scaling
    EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
    EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;      // EPWM1 is the Master
    EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
    EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
    EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
    // Note: ChB is initialized here only for comparison purposes, it is not required

    EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
    EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // optional
    EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;  // optional

    EPwm1Regs.AQCTLA.bit.ZR0 = AQ_SET;
    EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
    EPwm1Regs.AQCTLB.bit.ZR0 = AQ_SET;          // optional
    EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;        // optional
    // Now configure the HRPWM resources
    EALLOW;                                     // Note these registers are protected
                                              // and act only on ChA.
    EPwm1Regs.HRCNFG.all = 0x0; // Clear all bits first
    EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;      // Control falling edge position
    EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;      // CMPAHR controls the MEP.
    EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;  // Shadow load on CTR=Zero.
    EDIS;
    MEP_ScaleFactor = 66*256;                   // Start with typical Scale Factor
                                              // value for 100 MHz.
                                              // Use SFO functions to update MEP_ScaleFactor
                                              // dynamically.
}
```

[Example 18-6](#) shows an assembly example of run-time code that can execute in a high-speed ISR loop.

**Example 18-6. PWM DAC Function Run-Time Code**

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, #_HRDAC_In
    MOVL XAR2,@_HRDAC_In          ; Pointer to input Q15 duty (XAR2)
    MOVL XAR3,#CMPAHR1           ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM
    MOV T,*XAR2                  ; T <= duty
    MPY ACC,T,@_hrDAC_period      ; Q15 to Q0 scaling based on period
    ADD ACC,@_hrDAC_period<<15 ; Offset for bipolar operation
    MOV T,@_MEP_ScaleFactor       ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL                 ; P <= T * AL, optimizer scaling
    MOVB @AL,P                   ; AL <= P, move result back to ACC
    ADD ACC, #0x080              ; MEP range and rounding adjustment
    MOVL *XAR3,ACC               ; CMPA:CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH             ; Store ACCH to regular CMPB

```

### 18.15.2 Appendix A: SFO Library Software - SFO\_TI\_Build\_V8.lib

The following table lists several features of the SFO\_TI\_Build\_V8.lib library.

**Table 18-19. SFO Library Features**

|                                                                                                       | <b>SFO_TI_Build_V8.lib</b> | <b>Unit</b>           |
|-------------------------------------------------------------------------------------------------------|----------------------------|-----------------------|
| Completion-checking?                                                                                  | Yes                        | Function return value |
| Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts | 130,000                    | EPWMCLK cycles        |

A functional description of the SFO library routine, SFO(), is found below.

#### 18.15.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100 MHz and assuming the MEP step size is 150 ps, the typical scale factor value at 100 MHz = 66 MEP steps per TBCLK unit (10 ns)

The function returns a MEP scale factor value:

MEP\_ScaleFactor = Number of MEP steps per EPWMCLK.

##### Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50 MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50 MHz, with device process variation, the MEP step size may decrease under cold temperature and high core voltage conditions to such a point, that 255 MEP steps will not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module

##### Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated, or a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP\_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register will maintain the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3-EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see [Section 18.15.1.5.3](#)).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR = fraction(PWMduty\*PWMperiod) << 8 or CMPBHR = fraction(PWMduty\*PWMperiod) << 8 or TBPRDHR = fraction(PWMperiod) while running SFO() in the background. The MEP Calibration Module will then use the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software will need to perform the necessary calculations manually so that:
  - $CMPAHR = (\text{fraction}(\text{PWMduty} * \text{PWMperiod}) * \text{MEP Scale Factor}) \ll 8 + 0x080$ .
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore it is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution may have to be performed more frequently to match the application. Note, there is no high limit restriction on the SFO function repetition rate, hence it can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic will not be active for the first three EPWMCLK cycles of the PWM period (and the last three EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE=0]) and the CMPA/CMPB register value is less than three cycles, then its CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE=1]), the CMPA register value must not fall below three or above TBPRD-3. This would avoid any unexpected transitions on the PWM signal.

### 18.15.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP\_ScaleFactor. For example, see [Table 18-20](#).

**Table 18-20. Factor Values**

| Software Function call | Functional Description                           | Updated Variables                     |
|------------------------|--------------------------------------------------|---------------------------------------|
| SFO()                  | Returns MEP scale factor in the HRMSTEP register | MEP_ScaleFactor and HRMSTEP register. |

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

#### Step 1. Add "Include" Files

The SFO\_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)\_Device.h and (Device)\_Epwm\_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

#### Example 18-7. A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h"           // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h"    // init defines
#include "SFO_V8.h"                  // SFO lib functions (needed for HRPWM)
```

#### Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

**Example 18-8. Declaring an Element**

```
int MEP_ScaleFactor = 0;    //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

**Step 3. MEP\_ScaleFactor Initialization**

The SFO() function does not require a starting scale factor value in MEP\_ScaleFactor. Prior to using the MEP\_ScaleFactor variable in application code, SFO() should be called to drive the MEP calibration module to calculate an MEP\_ScaleFactor value.

As part of the one-time initialization code prior to using MEP\_ScaleFactor, include the following:

**Example 18-9. Initializing With a Scale Factor Value**

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

**Step 4. Application Code**

While the application is running, fluctuations in both device temperature and supply voltage may be expected. To be sure that optimal Scale Factors are used for each ePWM module, the SFO function should be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

---

**NOTE:** See the HRPWM\_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

---

**Example 18-10. SFO Function Calls**

```
main ()
{
    int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.

    status = SFO();
    if(status==2) {ESTOP0;} // The function returns a 2 if MEP_ScaleFactor is greater
                          // than the maximum 255 allowed (error condition)
}
```

## 18.16 ePWM Registers

This section describes the Enhanced Pulse Width Modulator registers.

### 18.16.1 ePWM Base Addresses

**Table 18-21. ePWM Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| EPwm1Regs        | EPWM_REGS     | 0x0000_4000   | 0x0000_40FF |
| EPwm2Regs        | EPWM_REGS     | 0x0000_4100   | 0x0000_41FF |
| EPwm3Regs        | EPWM_REGS     | 0x0000_4200   | 0x0000_42FF |
| EPwm4Regs        | EPWM_REGS     | 0x0000_4300   | 0x0000_43FF |
| EPwm5Regs        | EPWM_REGS     | 0x0000_4400   | 0x0000_44FF |
| EPwm6Regs        | EPWM_REGS     | 0x0000_4500   | 0x0000_45FF |
| EPwm7Regs        | EPWM_REGS     | 0x0000_4600   | 0x0000_46FF |
| EPwm8Regs        | EPWM_REGS     | 0x0000_4700   | 0x0000_47FF |
| SyncSocRegs      | SYNC_SOC_REGS | 0x0000_7940   | 0x0000_794F |

## 18.16.2 EPWM\_REGS Registers

Table 18-22 lists the EPWM\_REGS registers. All register offset addresses not listed in Table 18-22 should be considered as reserved locations and the register contents should not be modified.

**Table 18-22. EPWM\_REGS Registers**

| Offset | Acronym   | Register Name                                                         | Write Protection | Section            |
|--------|-----------|-----------------------------------------------------------------------|------------------|--------------------|
| 0h     | TBCTL     | Time Base Control Register                                            |                  | <a href="#">Go</a> |
| 1h     | TBCTL2    | Time Base Control Register 2                                          |                  | <a href="#">Go</a> |
| 4h     | TBCTR     | Time Base Counter Register                                            |                  | <a href="#">Go</a> |
| 5h     | TBSTS     | Time Base Status Register                                             |                  | <a href="#">Go</a> |
| 8h     | CMPCTL    | Counter Compare Control Register                                      |                  | <a href="#">Go</a> |
| 9h     | CMPCTL2   | Counter Compare Control Register 2                                    |                  | <a href="#">Go</a> |
| Ch     | DBCTL     | Dead-Band Generator Control Register                                  |                  | <a href="#">Go</a> |
| Dh     | DBCTL2    | Dead-Band Generator Control Register 2                                |                  | <a href="#">Go</a> |
| 10h    | AQCTL     | Action Qualifier Control Register                                     |                  | <a href="#">Go</a> |

| -n                              |       | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |       |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 18.16.2.1 TBCTL Register (Offset = 0h) [reset = 83h]

TBCTL is shown in [Figure 18-94](#) and described in [Table 18-24](#).

Return to the [Summary Table](#).

Time Base Control Register

| 5-4 | IN_MODE       | R/W  | 0h    | <p>Dead-Band Input Mode Control</p> <p>Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays.</p> <p>00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.</p> <p>01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal.</p> <p>EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal.</p> <p>EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.</p> <p>11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.</p> <p>Reset type: SYSRSn</p> |

**Table 18-30. DBCTL Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|----------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-2 | POLSEL   | R/W  | 0h    | <p>Polarity Select Control</p> <p>Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes.</p> <p>00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).</p> <p>01: Active low complementary (ALC) mode. EPWMxA is inverted.</p> <p>10: Active high complementary (AHC). EPWMxB is inverted.</p> <p>11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.</p> <p>Reset type: SYSRSn</p> |
| 1-0 | OUT_MODE | R/W  | 0h    | <p>Dead-Band Output Mode Control</p> <p>Bit 1 controls the S1 switch and bit 0 controls the S0 switch.</p> <p>00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect.</p> <p>01: Apath = InA (delay is by-passed for A signal path)</p> <p>Bpath = FED (Falling Edge Delay in B signal path)</p> <p>10: Apath = RED (Rising Edge Delay in A signal path)</p> <p>Bpath = InB (delay is by-passed for B signal path)</p> <p>11: DBM is fully enabled (i.e. both RED and FED active)</p> <p>Reset type: SYSRSn</p>                                                                                                                                                                                                                                                                                 |

### 18.16.2.14 HRCNFG Register (Offset = 20h) [reset = 0h]

HRCNFG is shown in [Figure 18-107](#) and described in [Table 18-37](#).

Return to the [Summary Table](#).

HRPWM Configuration Register

This register is only accessible on ePWM modules with HRPWM capabilities.

### 18.16.2.16 HRMSTEP Register (Offset = 26h) [reset = 0h]

HRMSTEP is shown in [Figure 18-109](#) and described in [Table 18-39](#).

Return to the [Summary Table](#).

#### HRPWM MEP Step Register

This register is only accessible on EPWM modules with HRPWM capabilities. Only 16 bit accesses are allowed for this register. Debugger access in 32 bit mode may display incorrect values.

| 2    | TBPHSHRLOADE | R/W  | 0h    | TBPHSHR Load Enable<br><br>This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution.<br><br>0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event:<br><br>1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature.<br><br>This bit and the TBCTL[PSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled.<br>Reset type: SYSRSn |

**Table 18-41. HRPCTL Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|------------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | PWMSYNCSEL | R/W  | 0h    | <p>PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC:</p> <p>0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD)</p> <p>1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00)</p> <p>Reset type: SYSRSn</p>                                                                                                             |
| 0   | HRPE       | R/W  | 0h    | <p>High Resolution Period Enable Bit</p> <p>0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 0 ePWM.</p> <p>1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported.</p> <p>Reset type: SYSRSn</p> |

### 18.16.2.19 TRREM Register (Offset = 2Eh) [reset = 0h]

TRREM is shown in [Figure 18-112](#) and described in [Table 18-42](#).

Return to the [Summary Table](#).

Translator High Resolution Remainder Register

This register is only accessible on EPWM modules with HRPWM capabilities.

### 18.16.2.22 EPWMXLINK Register (Offset = 38h) [reset = X]

EPWMXLINK is shown in [Figure 18-115](#) and described in [Table 18-45](#).

Return to the [Summary Table](#).

#### EPWMx Link Register

This register controls which EPWMs are linked to other EPWM modules. The default reset value will vary for each module. The reset value will link each EPWM module to itself to prevent unintentional linking of modules.

**Figure 18-115. EPWMXLINK Register**

|-------|--------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | CMPA   | R/W  | 0h    | <p>Compare A Register</p> <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>- Do nothing</li> <li>- the event is ignored.</li> <li>- Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>- Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>- Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>- Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full.</li> <li>- If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p> |
| 15-0  | CMPAHR | R/W  | 0h    | <p>Compare A HRPWM Extension Register</p> <p>These 8-bits contain the high-resolution portion (least significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register.</p> <p>The lower 8 bits in this register are ignored</p> <p>Reset type: SYSRSn</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 18.16.2.37 CMPB Register (Offset = 6Ch) [reset = 0h]

CMPB is shown in [Figure 18-130](#) and described in [Table 18-60](#).

Return to the [Summary Table](#).

|-------|--------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | CMPB   | R/W  | 0h    | <p>Compare B Register</p> <p>The value in the active CMPB register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>- Do nothing</li> <li>- the event is ignored.</li> <li>- Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>- Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>- Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register.</li> <li>- Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full.</li> <li>- If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p> |
| 15-0  | CMPBHR | R/W  | 0h    | <p>Compare B High Resolution Bits</p> <p>The lower 8 bits in this register are ignored</p> <p>Reset type: SYSRSn</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 18.16.2.38 CMPC Register (Offset = 6Fh) [reset = 0h]

| Bit | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|-------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | CBC   | R    | 0h    | <p>Latched Status Flag for Cycle-By-Cycle Trip Event</p> <p>0: No cycle-by-cycle trip event has occurred.</p> <p>1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The</p> <p>TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared.</p> <p>This bit is cleared by writing the appropriate value to the TZCLR register.</p> <p>Reset type: SYSRSn</p> |
| 0   | INT   | R    | 0h    | <p>Latched Trip Interrupt Status Flag</p> <p>0: Indicates no interrupt has been generated.</p> <p>1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition.</p> <p>No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register.</p> <p>Reset type: SYSRSn</p>                                                                                                                                                                                                                                                                      |

### 18.16.2.50 TZCBCFLG Register (Offset = 94h) [reset = 0h]

TZCBCFLG is shown in [Figure 18-143](#) and described in [Table 18-73](#).

Return to the [Summary Table](#).

|-----|--------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-0 | INTPRD | R/W  | 0h    | <p>ePWM Interrupt (EPWMx_INT) Period Select</p> <p>These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared.</p> <p>Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear.</p> <p>Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.</p> <p>00: Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored.</p> <p>01: Generate an interrupt on the first event INTCNT = 01 (first event)</p> <p>10: Generate interrupt on ETPS[INTCNT] = 1,0 (second event)</p> <p>11: Generate interrupt on ETPS[INTCNT] = 1,1 (third event)</p> <p>Reset type: SYSRSn</p> |

### 18.16.2.58 ETFLG Register (Offset = A8h) [reset = 0h]

ETFLG is shown in [Figure 18-151](#) and described in [Table 18-81](#).

Return to the [Summary Table](#).

| 15-0 | DCOFFSET | R/W  | 0h    | <p>Blanking Window Offset</p> <p>These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted.</p> <p>Reset type: SYSRSn</p> |

### 18.16.2.71 DCOFFSETCNT Register (Offset = CAh) [reset = 0h]

DCOFFSETCNT is shown in [Figure 18-164](#) and described in [Table 18-94](#).

Return to the [Summary Table](#).

**Table 18-94. DCOFFSETCNT Register Field Descriptions**

| Bit  | Field       | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | DCOFFSETCNT | R    | 0h    | <p>Blanking Offset Counter</p> <p>These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCFCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by a emulation stop.</p> <p>Reset type: SYSRSn</p> |

### 18.16.2.72 DCFWINDOW Register (Offset = CBh) [reset = 0h]

DCFWINDOW is shown in [Figure 18-165](#) and described in [Table 18-95](#).

Return to the [Summary Table](#).

Digital Compare Filter Window Register

|------|-------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | DCCAP | R    | 0h    | <p>Digital Compare Time-Base Counter Capture</p> <p>To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed.</p> <p>- If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value.</p> <p>- If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address.</p> <p>Reset type: SYSRSn</p> |

### 18.16.2.75 DCAHTRIPSEL Register (Offset = D2h) [reset = 0h]

DCAHTRIPSEL is shown in [Figure 18-168](#) and described in [Table 18-98](#).

Return to the [Summary Table](#).

### 18.16.3 SYNC\_SOC\_REGS Registers

Table 18-105 lists the SYNC\_SOC\_REGS registers. All register offset addresses not listed in Table 18-105 should be considered as reserved locations and the register contents should not be modified.

**Table 18-105. SYNC\_SOC\_REGS Registers**

| Offset | Acronym         | Register Name                              | Write Protection | Section            |
|--------|-----------------|--------------------------------------------|------------------|--------------------|
| 0h     | SYNCSELECT      | Sync Input and Output Select Register      | EALLOW           | <a href="#">Go</a> |
| 2h     | ADCSOCOUTSELECT | External ADCSOC Select Register            | EALLOW           | <a href="#">Go</a> |
| 4h     | SYNCSOCLOCK     | SYNCSEL and EXTADCSOC Select Lock register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 18-106 shows the codes that are used for access types in this section.

**Table 18-106. SYNC\_SOC\_REGS Access Type Codes**

| Access Type                     | Code    | Description                                                                                                                                                                                                                                                                          |

## 19.1 Introduction

This eCAP module is a Type-1 eCAP. See the [TMS320C28xx, 28xxx DSP Peripheral Reference Guide](#) for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 19.2 Features

Features for eCAP include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module described in this guide includes the following features:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type-1 eCAP is enhanced from the Type-0 eCAP with the following added features:

- Event filter reset bit
  - Writing a 1 to ECCTL2[CTRFILTRESET] will clear the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug.
- Modulo counter status bits
  - The modulo counter (ECCTL2[MODCTRSTS]) indicates which capture register will be loaded next. In the Type-0 eCAP, it was not possible to know current state of modulo counter.
- DMA trigger source
  - eCAPxDMA was added as a DMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer
  - ECCTL0[INPUTSEL] selects one of 128 input signals which are detailed in [Table 19-1](#).
- EALLOW protection
  - EALLOW protection was added to critical registers.

## 19.3 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 128:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.

- Modulo counter status register (MODCNRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Ability to reset event filter, modulo counter, and interrupt flags
- Interrupt capabilities on any of the four capture events
- Separate DMA trigger
- EALLOW protection to control registers

## 19.4 Configuring Device Pins for the eCAP

To connect the device input pins to the module, the Input X-BAR must be used. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but will affect the eCAP's accuracy by  $\pm 2$  cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

New to the Type-1 eCAP module, a 128:1 input multiplexer must also be configured (see [Figure 19-3](#)). This multiplexer can select a variety of inputs detailed in [Table 19-1](#).

**Table 19-1. eCAP Input Selection**

| Selection of eCAP Input    | Select Index |
|----------------------------|--------------|
| Reserved                   | 127          |
| CMPSS[7:1].CTRIPL          | 126:120      |
| Reserved                   | 119:115      |
| CMPSS[7:1].CTRIPL          | 114:108      |
| Reserved                   | 107:103      |
| CMPSS[7:1].CTRIPL          | 102:96       |
| Reserved                   | 95:92        |
| SD1FLT[4:1].COMPH_OR_COMPL | 91:88        |
| Reserved                   | 87:84        |
| SD1FLT[4:1].COMPH          | 83:80        |
| Reserved                   | 79:76        |
| SD1FLT[4:1].COMPZ          | 75:72        |
| Reserved                   | 71:68        |
| SD1FLT[4:1].COMPL          | 67:64        |
| Reserved                   | 63:51        |
| Reserved                   | 50           |
| Reserved                   | 49           |
| Reserved                   | 48           |
| ADCAEVT[4:1]               | 47:44        |
| ADCBVT[4:1]                | 43:40        |
| ADCCEVT[4:1]               | 39:36        |
| Reserved                   | 35:32        |
| Output X-BAR OUTPUT[8:1]   | 31:24        |
| Reserved                   | 23:22        |
| CANB_0 interrupt           | 21           |
| CANA_0 interrupt           | 20           |
| Reserved                   | 19:16        |
| Input X-BAR INPUT[16:1]    | 15:0         |

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *GPIO Chapter* for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 19.5 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 19-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

**Figure 19-1. Capture and APWM Modes of Operation**

- A A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 19-2 further describes the output of the eCAP in APWM mode based on the CMP and PRD values.

**Figure 19-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode**

## 19.6 Capture Mode Description

Figure 19-3 shows the various components that implement the capture function.

Copyright © 2015–2019, Texas Instruments Incorporated

**Figure 19-4. Event Prescale Control**

- A When a prescale value of 1 is chosen ( ECCTL1[13:9] = 0,0,0,0,0 ), the input capture signal bypasses the prescale logic completely.

**Figure 19-5. Prescale Function Waveforms**

### 19.6.2 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### 19.6.3 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

**Figure 19-6. Details of the Continuous/One-shot Block**

#### 19.6.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Figure 19-7. Details of the Counter and Synchronization Block

### 19.6.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 19.6.6 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from EPWM or eCAP or X-Bar. The SWSYNC of the eCAP module is logical OR'd with the SYNC signal as shown in Figure 19-7. The SYNC signal is defined by the selection in the SYNCSEL[ECAPxSYNCIN] bit for ECAP1 and ECAP4 as shown in Figure 19-8.

**Figure 19-8. Time-Base Counter Synchronization Scheme**

#### 19.6.6.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP3.

- Configure ECAP[1..3].ECAPSYN1INSEL.SEL = 0x0 to disable external SYN1IN coming to eCAP1.
- Configure ECAP[1..3].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

- Configure ECAP[1..3].ECCTL2.SYNCO\_SEL = 0x0, to allow the sync-in event to be the sync-out signal pass through.
- Configure ECAP[2..3].ECCTL2.SWSYNC = 0x0, to disable software synchronization for eCAP2 through eCAP4.
- The default sync signal comes from ePWM1, if TBCTL[SYNCOSEL] is not correctly configured this can cause undesired resets of the time-stamp register (TSCTR). Select an unused GPIO in InputXbarRegs.INPUT5SELECT. Configure this GPIO in output mode and Write '0' to GPIO DAT register. By default this is programmed to GPIO0 so any activity on this pin will cause problems with the SWSYNC.
- Program SYNCSEL[ECAP1SYNCCIN] = 0x5. This will take ECAPx.EXTSYNCCIN to an inactive state.
- Configure ECAP1.ECCTL2.SWSYNC=0x1, this forces Software Synchronization of TSCTR counter

To use SWSYNC with other eCAP modules, ensure that the previous eCAP chain is not generating a SYNCOUT signal which will interfere with the software synchronization.

### 19.6.7 Interrupt Control

Operation and features of eCAP Interrupt Control include:

- An Interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CTR=PRD, CTR=CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags will be cleared upon an event filter reset by writing a "1" to ECCTL2[CLRFILTRESET]. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

**Note:** The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CTR=PRD flag is valid in both modes.

Figure 19-9. Interrupts in eCAP Module

Copyright © 2018, Texas Instruments Incorporated

### 19.6.8 DMA Interrupt

On Type-0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type-1 eCAP, a separate DMA Trigger (**ECAP\_DMA\_INT**) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events (CEVT1, CEVT2, CEVT3 and CEVT4) can be selected as the trigger source for **ECAP\_DMA\_INT** using **ECCCTL2 [DMAEVTSEL]**.

### 19.6.9 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal,  $CTR[31:0] = PRD[31:0]$ .

### 19.6.10 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a  $CTR = PRD$  trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

**Figure 19-10. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active high mode ( $APWMPOL == 0$ ) is as follows:

- CMP = 0x00000000, output low for duration of period (0% duty)
- CMP = 0x00000001, output high 1 cycle
- CMP = 0x00000002, output high 2 cycles
- CMP = PERIOD, output high except for 1 cycle (<100% duty)
- CMP = PERIOD+1, output high for complete period (100% duty)
- CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode ( $APWMPOL == 1$ ) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)  
 CMP = 0x00000001, output low 1 cycle  
 CMP = 0x00000002, output low 2 cycles  
 CMP = PERIOD, output low except for 1 cycle (<100% duty)  
 CMP = PERIOD+1, output low for complete period (100% duty)  
 CMP > PERIOD+1, output low for complete period

**Figure 19-11. Time-Base Frequency and Period Calculation**

## 19.7 Application of the eCAP Module

The following sections will provide applications examples to show how to operate the eCAP module.

### 19.7.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 19-12 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), it wraps around to 00000000 (not shown in Figure 19-12), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the 4th event), hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

**Figure 19-12. Capture Sequence for Absolute Time-stamp and Rising Edge Detect**

### 19.7.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 19-13 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...and so on. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , and so on.

**Figure 19-13. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect**

### 19.7.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

This example Figure 19-14 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (Max value), before the next event, it wraps around to 00000000 and continues, a CINTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 =  $T_1$ , Period2 =  $T_2$ ,...etc. As shown in the diagram, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 19-14. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

### 19.7.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 19-15 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is:  $\text{Period1} = T_1 + T_2$ ,  $\text{Period2} = T_3 + T_4$ , ...and so on,  $\text{Duty Cycle1 (on-time \%)} = T_1 / \text{Period1} \times 100\%$ ,  $\text{Duty Cycle1 (off-time \%)} = T_2 / \text{Period1} \times 100\%$ , and so on.

**Figure 19-15. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect**

During initialization, you must write to the active registers for both period and compare. This action will automatically copy the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

## 19.8 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

### 19.8.1 Example 1 - Simple PWM Generation (Independent Channel/s)

**Figure 19-16. PWM Waveform Details of APWM Mode Operation**

**NOTE:** Values are in hexadecimal ("h") notation.

## 19.9 eCAP Registers

This section describes the Enhanced Capture Registers.

### 19.9.1 eCAP Base Addresses

**Table 19-2. eCAP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| ECap1Regs        | ECAP_REGS     | 0x0000_5200   | 0x0000_521F |
| ECap2Regs        | ECAP_REGS     | 0x0000_5240   | 0x0000_525F |
| ECap3Regs        | ECAP_REGS     | 0x0000_5280   | 0x0000_529F |
| ECap4Regs        | ECAP_REGS     | 0x0000_52C0   | 0x0000_52DF |
| ECap5Regs        | ECAP_REGS     | 0x0000_5300   | 0x0000_531F |
| ECap6Regs        | ECAP_REGS     | 0x0000_5340   | 0x0000_535F |
| ECap7Regs        | ECAP_REGS     | 0x0000_5380   | 0x0000_539F |

## 19.9.2 ECAP\_REGS Registers

Table 19-3 lists the ECAP\_REGS registers. All register offset addresses not listed in Table 19-3 should be considered as reserved locations and the register contents should not be modified.

**Table 19-3. ECAP\_REGS Registers**

| Offset | Acronym | Register Name                       | Write Protection | Section            |
|--------|---------|-------------------------------------|------------------|--------------------|
| 0h     | TSCTR   | Time-Stamp Counter                  |                  | <a href="#">Go</a> |
| 2h     | CTRPHS  | Counter Phase Offset Value Register |                  | <a href="#">Go</a> |
| 4h     | CAP1    | Capture 1 Register                  |                  | <a href="#">Go</a> |
| 6h     | CAP2    | Capture 2 Register                  |                  | <a href="#">Go</a> |
| 8h     | CAP3    | Capture 3 Register                  |                  | <a href="#">Go</a> |
| Ah     | CAP4    | Capture 4 Register                  |                  | <a href="#">Go</a> |
| 12h    | ECCTL0  | Capture Control Register 0          | EALLOW           | <a href="#">Go</a> |
| 14h    | ECCTL1  | Capture Control Register 1          | EALLOW           | <a href="#">Go</a> |
| 15h    | ECCTL2  | Capture Control Register 2          | EALLOW           | <a href="#">Go</a> |
| 16h    | ECEINT  | Capture Interrupt Enable Register   | EALLOW           | <a href="#">Go</a> |
| 17h    | ECFLG   | Capture Interrupt Flag Register     |                  | <a href="#">Go</a> |
| 18h    | ECCLR   | Capture Interrupt Clear Register    |                  | <a href="#">Go</a> |
| 19h    | ECFRC   | Capture Interrupt Force Register    | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 19-4 shows the codes that are used for access types in this section.

**Table 19-4. ECAP\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |      |                                                                                                                                                                                                                                                                                      |
| R                               | R    | Read                                                                                                                                                                                                                                                                                 |
| R-0                             | R-0  | Read Returns 0s                                                                                                                                                                                                                                                                      |
| <b>Write Type</b>               |      |                                                                                                                                                                                                                                                                                      |
| W                               | W    | Write                                                                                                                                                                                                                                                                                |

| 31-0 | CTRPHS | R/W  | 0h    | Counter phase value register that can be programmed for phase lag/lead. This register CTRPHS is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and EPWM time-bases.<br><br>This register is not applicable in HR mode.<br>Reset type: SYSRSn |

### 19.9.2.3 CAP1 Register (Offset = 4h) [reset = 0h]

CAP1 is shown in [Figure 19-19](#) and described in [Table 19-7](#).

Return to the [Summary Table](#).

Capture 1 Register

### 19.9.2.9 ECCTL2 Register (Offset = 15h) [reset = 6h]

ECCTL2 is shown in [Figure 19-25](#) and described in [Table 19-13](#).

Return to the [Summary Table](#).

Capture Control Register 2

### 19.9.2.10 ECEINT Register (Offset = 16h) [reset = 0h]

ECEINT is shown in [Figure 19-26](#) and described in [Table 19-14](#).

Return to the [Summary Table](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.

The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

## High Resolution Capture (HRCAP)

This chapter describes the operation of the high resolution capture (HRCAP) module. The HRCAP submodule described here is part of the Type-1 eCAP. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module. See the [TMS320x28xx, 28xxx DSP Peripheral Reference Guide](#) for a list of all devices with an HRCAP module of the same type, to determine the differences between types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the C2000Ware documentation .

| <b>20.5 HRCAP Registers.....</b>     | <b><a href="#">2128</a></b> |

## 20.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

The HRCAP submodule includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the above resources are available on any pin using the Input X-BAR

Improvements to the Type 0 HRCAP are as follows:

- Simplified calibration scheme
  - HRCAP is always functional; never offline to perform calibration
  - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See [Known Exceptions](#) for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

## 20.2 Description

The HRCAP enhancement has been added to eCAP 6 and eCAP 7 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

Each HRCAP-capable channel has the following independent key resources:

- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

## 20.3 Operational Details

[Figure 20-1](#) shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See [Known Exceptions](#) for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.

[illegible]

Copyright © 2015–2019, Texas Instruments Incorporated

1. Enable HRCLK using `HRCAP_enableHighResolutionClock()`
2. Delay 1uS
3. Configure the eCAP module as desired, including interrupts
4. Enable HR mode using `HRCAP_enableHighResolution()`
5. Set calibration period using `HRCAP_setCalibrationPeriod()`
6. Enable continuous calibration using `HRCAP_setCalibrationMode()`
7. Enable interrupts using `HRCAP_enableCalibrationInterrupt()`
8. Start calibration using `HRCAP_startCalibration()`

Steps 5-8 only apply for time-converted measurements. When using the HRCAP to take relative-time measurements only steps 1-4 are required.

### 20.3.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see [Section 19.6.7](#)) in addition to HRCALINT which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. SYSCLKCTR = HRCALIBPERIOD
2. SYSCLKCTR or HRCLKCTR experience an overflow condition

[Figure 20-2](#) shows this logic.

### 20.3.4 HRCAP Calibration

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, it is required to periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

**Figure 20-2. HRCAP Calibration**

The calibration block contains the following key resources:

- HRSYSCLKCNT
  - A 32-bit counter connected to SYSCLK. The counter will start counting when CALIBSTART is set.
- HRCLKCNT
  - A 32-bit counter connected to HRCLK. The counter will start counting when CALIBSTART is set.
- HRCALIBPERIOD
  - Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- HRSYSCLKCAP
  - On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP
- HRCLKCAP
  - On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP
- HRCALINT
  - An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and the other clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block will capture and reset both counter values, then trigger an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see [Equation 1](#)). A DriverLib function, HRCAP\_getScaleFactor, has been provided to determine the scale factor. This function should be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag will be set. The full details of the calibration block are described in [Figure 20-2](#).

$$\text{ScaleFactor} = \frac{\text{HRSYCLKCAP}}{\text{HRCLKCAP}} \quad (2)$$

**NOTE:** Even with calibration, noise on the 1.2V VDD supply will negatively affect the standard deviation of the HRCAP submodule. Care should be taken to ensure that the 1.2V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.

#### 20.3.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, HRCAP\_getEventTimeStampNanoseconds(). [Equation 2](#) shows how to convert a raw count to seconds without using the DriverLib function.

$$\text{Measurement} (ns) = \frac{\text{RawCount} \times \text{scaleFactor}}{128} * \text{SysClkPrd} (ns) \quad (3)$$

**Table 20-1. Scale Factor**

| Parameter       | Typical value | Explanation                                                    |
|-----------------|---------------|----------------------------------------------------------------|
| RawCount        | 9300          | Capture value as read from ECAP_REGS_CAP1-4                    |
| ScaleFactor     | 2.75          | The Scale factor as calculated from <a href="#">Equation 2</a> |
| 128             | 128           | Constant determined by the hardware of the HRCAP submodule     |
| SysClkPrd(ns)   | 10            | Period of the system clock                                     |
| Measurement(ns) | 1998.04       | Signal converted to nS                                         |

### 20.3.5 DriverLib Functions

## 20.4 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, it can be reset using ECCTL2[CTRFILTRSET]
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high resolution mode. If time difference mode is used, it may lead to inaccurate results if the fractional value is not taken into consideration for capture events which have reset the time base counter.
  - Actual Capture Value = (Capture Value) – (fractional value of reference event which reset the counter)
- For high frequency input signals, the CPU may not be able cope with the speed of the captures. In such a case, One-Shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however in that case the event filter can be used to reduce the rate of captures.

## 20.5 HRCAP Registers

This section describes the High-Resolution Capture Registers.

### 20.5.1 HRCAP Base Addresses

**Table 20-2. HRCAP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| Hrcap6Regs       | HRCAP_REGS    | 0x0000_5360   | 0x0000_537F |
| Hrcap7Regs       | HRCAP_REGS    | 0x0000_53A0   | 0x0000_53BF |

## 20.5.2 HRCAP\_REGS Registers

Table 20-3 lists the HRCAP\_REGS registers. All register offset addresses not listed in Table 20-3 should be considered as reserved locations and the register contents should not be modified.

**Table 20-3. HRCAP\_REGS Registers**

| Offset | Acronym     | Register Name                                  | Write Protection | Section            |
|--------|-------------|------------------------------------------------|------------------|--------------------|
| 0h     | HRCTL       | High-Res Control Register                      | EALLOW           | <a href="#">Go</a> |

## ***Enhanced Quadrature Encoder Pulse (eQEP)***

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type-1 eQEP. See the *TMS320x28xx, 28xxx DSP Peripheral Reference Guide* ([SPRU566](#)) for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

## 21.1 Introduction

An incremental encoder disk is patterned with a track of slots along its periphery, as shown in [Figure 21-1](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

**Figure 21-1. Optical Encoder Disk**

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 21-2](#).

**Figure 21-2. QEP Encoder Output Signal for Forward/Reverse Movement**

**Legend:** N = lines per revolution

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 21-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 21-3. Index Pulse Example**

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (4)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (5)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k-1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k-1$ "

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

Equation 4 is the conventional approach to velocity estimation and it requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on Equation 4 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 5 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 5 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 4. A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 5 at low speed and have the DSP software switch over to Equation 4 when the motor speed rises above some specified threshold.

## 21.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured via the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode should not be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 21.3 Description

This section provides the eQEP inputs, memory map, and functional description.

### 21.3.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code should enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR**

These two pins can be used in quadrature-clock mode or direction-count mode.

- **Quadrature-clock Mode**

The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase. This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

- **Direction-count Mode**

In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- *QEPI: Index or Zero Marker*

The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- QEPS: *Strobe Input*

This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

### 21.3.2 Functional Description

The eOEP peripheral contains the following major functional units (as shown in [Figure 21-4](#)):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)
- Quadrature Mode Adapter (QMA)

## 21.4 Quadrature Decoder Unit (QDU)

Figure 21-5 shows a functional block diagram of the QDU.

Figure 21-5. Functional Block Diagram of Decoder Unit

### 21.4.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

### 21.4.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding**— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 21-2 and Figure 21-6 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 21-7 shows the direction decoding and clock generation from the eQEP input signals.

**Table 21-2. Quadrature Decoder Truth Table**

| Previous Edge | Present Edge | QDIR   | QPOSCNT                |
|---------------|--------------|--------|------------------------|
| QA↑           | QB↑          | UP     | Increment              |
|               | QB↓          | DOWN   | Decrement              |
|               | QA↓          | TOGGLE | Increment or Decrement |
| QA↓           | QB↓          | UP     | Increment              |
|               | QB↑          | DOWN   | Decrement              |
|               | QA↑          | TOGGLE | Increment or Decrement |
| QB↑           | QA↑          | DOWN   | Increment              |
|               | QA↓          | UP     | Decrement              |
|               | QB↓          | TOGGLE | Increment or Decrement |
| QB↓           | QA↓          | DOWN   | Increment              |
|               | QA↑          | UP     | Decrement              |
|               | QB↑          | TOGGLE | Increment or Decrement |

**Figure 21-6. Quadrature Decoder State Machine**

Figure 21-7. Quadrature-clock and Direction Decoding

**Phase Error Flag**— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOS CNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 21-6](#) are invalid transitions that generate a phase error.

**Count Multiplication**— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 21-7](#).

**Reverse Count**— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder, thereby reversing the counting direction.

#### 21.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for the position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

### 21.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by a factor of 2x. In up-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

### 21.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Setting the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

## 21.4.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit will invert the index input.

### 21.4.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 21.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

### 21.5.1 Position Counter Operating Modes

Position-counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after "0". The Interrupt flag is set to indicate overflow/underflow in QFLG register.

### 21.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 21-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to '00' or '11' when pcrm=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOS LAT register on every index marker.

**Figure 21-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or 0xF9F)**

**NOTE:** In case of boundary condition where time period between Index Event and previous QCLK edge is less than SYSCLK period, then QPOS CNT gets reset to zero or QPOS MAX in the same SYSCLK cycle and does not wait for next QCLK edge to occur.

### 21.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOS MAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 21-9 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

**Figure 21-9. Position Counter Underflow/Overflow (QPOSMAX = 4)**

#### 21.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 21.5.1.2](#).

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

#### 21.5.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

### 21.5.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

### 21.5.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

**Latch on Rising Edge (QEPCTL[IEL]=01)**— The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

**Latch on Falling Edge (QEPCTL[IEL] = 10)**— The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

**Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)**— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 21-10 shows the position counter latch using an index event marker.

**Figure 21-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)**

### 21.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 21-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 21-12. eQEP Position-compare Unit**

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 21-13).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

**Figure 21-13. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 21-14](#).

**Figure 21-14. eQEP Position-compare Sync Output Pulse Stretcher**

## 21.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 21-15](#). This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (6)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 21-16](#))
- $\Delta T$  - Elapsed time between unit position events
- $v(k)$  - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 21-17](#) shows the capture unit operation along with the position counter.

Figure 21-15. eQEP Edge Capture Unit

**NOTE:** The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CPPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

Figure 21-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

A N - Number of quadrature periods selected using QCAPCTL[UPPS] bits

**Figure 21-17. eQEP Edge Capture Unit - Timing Details**

Velocity calculation equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (7)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k-1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k-1$ "

Unit time ( $T$ ) and unit period( $X$ ) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOS LAT and QCPRDLAT registers.

| Parameter  | Relevant Register to Configure or Read the Information                  |
|------------|-------------------------------------------------------------------------|
| T          | Unit Period Register (QUPRD)                                            |
| $\Delta X$ | Incremental Position = QPOSLAT(k) - QPOSLAT(K-1)                        |
| X          | Fixed unit position defined by sensor resolution and ZCAPCTL[Upps] bits |
| $\Delta T$ | Capture Period Latch (QCPRDLAT)                                         |

## 21.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ( $QWDPRD = QWDTMR$ ), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

**Figure 21-18. eQEP Watchdog Timer**

## 21.8 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), it resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in [Section 21.6](#).

Figure 21-19. eQEP Unit Time Base

## 21.9 QMA Module

The QEP Mode Adapter (QMA) is designed to extend the C2000 eQEP module capabilities to support the additional modes described below. [Figure 21-20](#) depicts how the QMA module is integrated into the C2000 eQEP module.

At reset, by default QMA logic is bypassed and the EQEPA and EQEPB inputs from the pins go directly into the eQEP module. When QMA module is enabled by configuring the QMACTRL[MODE] register, the EQEPA and EQEPB input are processed by this module and modified version of EQEPA and EQEPB signals are sent to the eQEP module. The QMA module requires the eQEP module to be configured in the Direction-Count mode and generates a clock signal on EQEPA input and direction signal on EQEPB input as needed for the proper operation of the intended mode.

- The xCLKMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the clock signal on the EQEPA input to the eQEP module.
- The xDIRMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the direction signal on the EQEPB input to the eQEP module.

The QMA module has error detection logic to detect illegal transitions on EQEPA and EQEPB input signals. The QMA module's error and interrupt are integrated inside the eQEP module as described in the eQEP Interrupt Structure section. In addition QMACTRL register configuration can be locked using QMALOCK register. Refer to the register description for more details.

**Figure 21-20. QMA Module Block Diagram**

### 21.9.1 Modes of Operation

The QMA module can be operated in the following modes by configuring the QMACTRL register.

#### 21.9.1.1 QMA Mode-1(QMACTRL[MODE]=1)

In this mode outputs of QMA correspond to the following as shown in [Figure 21-21](#):

- EQEPA Output of QMA is AND of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is direction signal generated by QMA based on EQEPA and EQEPB inputs

This mode is used when the default state of EQEPA and EQEPB inputs is high

Figure 21-21. QMA Mode-1

#### 21.9.1.2 QMA Mode-2(QMACTRL[MODE]=2)

In this mode, outputs of QMA correspond to the following as shown in [Figure 21-22](#):

- EQEPA Output of QMA is OR of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is direction signal generated by QMA based on EQEPA and EQEPB inputs

This mode is used when the default state of EQEPA and EQEPB inputs is low

**Figure 21-22. QMA Mode-2**

### 21.9.1.3 QMA Mode-3(QMACTRL[MODE]=3)

In this mode outputs of QMA correspond to the following as shown in [Figure 21-23](#)

- EQEPA Output of QMA is the same as EQEPB input signal coming from the pin
- EQEPB Output of QMA is direction signal generated by QMA based on EQEPA and EQEPB inputs

This mode is used when the default state of EQEPA and EQEPB inputs are in quadrature but EQEPB input alone is used for pulse counting.

Figure 21-23. QMA Mode-3

## 21.9.2 Interrupt and Error Generation

The error detection logic detects illegal transitions on EQEPA and EQEPB signals and generates an error signal. This error signal can be used to generate eQEP interrupt and error output. Refer to [Section 21.10](#) for details.

## 21.10 eQEP Interrupt Structure

[Figure 21-24](#) shows how the interrupt mechanism works in the EQEP module.

## 21.11 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

### 21.11.1 eQEP Base Addresses

**Table 21-3. eQEP Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| EQep1Regs        | EQEP_REGS     | 0x0000_5100   | 0x0000_513F |
| EQep2Regs        | EQEP_REGS     | 0x0000_5140   | 0x0000_517F |

### 21.11.2 EQEP\_REGS Registers

Table 21-4 lists the EQEP\_REGS registers. All register offset addresses not listed in Table 21-4 should be considered as reserved locations and the register contents should not be modified.

**Table 21-4. EQEP\_REGS Registers**

| Offset | Acronym      | Register Name              | Write Protection | Section            |
|--------|--------------|----------------------------|------------------|--------------------|
| 0h     | QPOSCNT      | Position Counter           |                  | <a href="#">Go</a> |
| 2h     | QPOSINIT     | Position Counter Init      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 21-5 shows the codes that are used for access types in this section.

**Table 21-5. EQEP\_REGS Access Type Codes**

| Access Type                     | Code | Description                            |
|---------------------------------|------|----------------------------------------|
| <b>Read Type</b>                |      |                                        |
| R                               | R    | Read                                   |
| R-0                             | R-0  | Read Returns 0s                        |
| <b>Write Type</b>               |      |                                        |
| W                               | W    | Write                                  |
| W1S                             | W1S  | Write 1 to set                         |
| <b>Reset or Default Value</b>   |      |                                        |
| -n                              |      | Value after reset or the default value |
| <b>Register Array Variables</b> |      |                                        |

**Table 21-5. EQEP\_REGS Access Type  
Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 21.11.2.1 QPOSCNT Register (Offset = 0h) [reset = 0h]

QPOSCNT is shown in [Figure 21-25](#) and described in [Table 21-6](#).

Return to the [Summary Table](#).

Position Counter
