## Serial Peripheral Interface (SPI)

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the master or slave operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

## 22.1 Introduction

### 22.1.1 Features

The SPI module features include:

- SPISOMI: SPI slave-output/master-input pin
- SPISIMO: SPI slave-input/master-output pin
- $\overline{\text{SPISTE}}$ : SPI slave transmit-enable pin
- SPICLK: SPI serial-clock pin

---

**NOTE:** All four pins can be used as GPIO if the SPI module is not used.

---

- Two operational modes: Master and Slave
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device-specific data manual for more details.
- Data word length: one to sixteen data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPISTE}}$  inversion for digital audio interface receive mode on devices with two SPI modules

### 22.1.2 Block Diagram

[Figure 22-1](#) shows the SPI CPU interfaces.

**Figure 22-1. SPI CPU Interface**

## 22.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

### 22.2.1 SPI Module Signals

Table 22-1 classifies and provides a summary of the SPI module signals.

**Table 22-1. SPI Module Signal Summary**

| Signal Name                | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| <b>External Signals</b>    |                                                                                |
| SPICLK                     | SPI clock                                                                      |
| SPISIMO                    | SPI slave in, master out                                                       |
| SPISOMI                    | SPI slave out, master in                                                       |
| $\overline{\text{SPISTE}}$ | SPI slave transmit enable                                                      |
| <b>Control</b>             |                                                                                |
| SPI Clock Rate             | LSPCLK                                                                         |
| <b>Interrupt Signals</b>   |                                                                                |
| SPIINT/SPIRXINT            | Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT) |
|                            | Receive interrupt in FIFO mode                                                 |
|                            | Transmit interrupt in FIFO mode                                                |
| SPITXINT                   | Transmit interrupt in FIFO mode                                                |
| <b>DMA Triggers</b>        |                                                                                |
| SPITXDMA                   | Transmit request to DMA                                                        |
| SPIRXDMA                   | Receive request to DMA                                                         |

## Special Considerations

The  $\overline{\text{SPISTE}}$  signal provides the ability to gate any spurious clock and data pulses when the SPI is in slave mode. An active  $\overline{\text{SPISTE}}$  will not allow the slave to receive data. This prevents the SPI slave from losing synchronization with the master. It is this reason that TI does not recommend that the  $\overline{\text{SPISTE}}$  always be tied to the active state.

If the SPI slave does ever lose synchronization with the master, toggling SPISWRESET will reset internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI will interpret the next clock transition as the first bit of a new transmission. The register bit fields which are reset by SPISWRESET can be found in [Section 22.5](#)

## Configuring a GPIO to emulate $\overline{\text{SPISTE}}$

In many systems, a SPI master may be connected to multiple SPI slaves using multiple instances of  $\overline{\text{SPISTE}}$ . Though this SPI module does not natively support multiple  $\overline{\text{SPISTE}}$  signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the master. Rather than using the GPIO Mux to select  $\overline{\text{SPISTE}}$ , the application would configure pins to be GPIO outputs, one GPIO per SPI slave. Before transmitting any data, the application would drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select would be driven to the inactive state. This process can be repeated for many slaves which share the SPICLK, SPISIMO, and SPISOMI lines.

## 22.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

### 22.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on all GPIO mux options. To enable the high-speed enhancements, set SPICCR.HS\_MODE to 1. Ensure that the capacitive loading on the pin does not exceed the value stated in the device Data Manual.

When not operating in high-speed mode, or if the capacitive loading on the pins exceed the value stated in the device Data Manual, SPICCR.HS\_MODE should be set to 0.

## 22.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module.

The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

### SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT\_FLAG), or there is overrun in the receiver (OVERRUN\_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT\_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT\_FLAG will generate an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN\_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN\_FLAG will generate an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN\_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) will be set. SPIRXINT will be triggered in the PIE block if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

### SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) will be set. SPITXINT will be triggered in the PIE block if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 22-2 and Table 22-2 show how these control bits influence the SPI interrupt generation.

**Figure 22-2. SPI Interrupt Flags and Enable Logic Generation**

**Table 22-2. SPI Interrupt Flag Modes**

| FIFO Options            | SPI interrupt Source | Interrupt Flags | Interrupt Enables | FIFO Enable (SPIFFENA) | Interrupt <sup>(1)</sup> Line |
|-------------------------|----------------------|-----------------|-------------------|------------------------|-------------------------------|
| <b>SPI without FIFO</b> | Receive overrun      | RXOVRN          | OVRNINTENA        | 0                      | SPIRXINT                      |
|                         | Data receive         | SPIINT          | SPIINTENA         | 0                      | SPIRXINT                      |
|                         | Transmit empty       | SPIINT          | SPIINTENA         | 0                      | SPIRXINT                      |
| <b>SPI FIFO mode</b>    | FIFO receive         | RXFFIL          | RXFFIENA          | 1                      | SPIRXINT                      |
|                         | Transmit empty       | TXFFIL          | TXFFIENA          | 1                      | SPITXINT                      |

<sup>(1)</sup> In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in 28x devices.

## 22.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers via the internal peripheral bus. This access is limited to 16-bit register read/writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled in order for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers refer to [Section 22.3.8](#).

[Figure 22-3](#) is a block diagram showing the DMA trigger generation from the SPI module.

**Figure 22-3. SPI DMA Trigger Diagram**

## 22.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

### 22.3.1 Introduction to Operation

[Figure 22-4](#) shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master transfers data by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK\_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because it controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.

### Figure 22-4. SPI Master/Slave Connection

The SPI can operate in master or slave mode. The MASTER\_SLAVE bit selects the operating mode and the source of the SPICLK signal.

### 22.3.2 Master Mode

In master mode (MASTER\_SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT\_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the Transmit Buffer Full Flag (BUFFULL\_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

Figure 22-5 is a block diagram of the SPI in master mode. It shows the basic control blocks available in SPI master mode.

The diagram illustrates the internal architecture of the SPIFFENA module. At the top, the SPIFFENA block contains two sets of 16-bit FIFOs: RX FIFO\_0, RX FIFO\_1, and RX FIFO\_15; and TX FIFO\_0, TX FIFO\_1, and TX FIFO\_15. These are connected via 16-bit buses to SPIRXBUF and SPITXBUF registers, respectively. Both buffers interface with the SPIDAT register. The SPIDAT register's output is split: one path goes through a multiplexer (controlled by TRIWIRE) to SPISOMI; another path is ANDed with TALK and sent to SPISIMO; a third path is ANDed with CLKPOLARITY from State Control and sent to SPICLK; and a fourth path is ANDed with SPIBRR from State Control and sent to SPISTE. The State Control block also receives LSPCLK as input.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network master. Data written to the SPITXBUF register will be transferred to the SPIDAT register when all bits of the character to be transmitted have been shifted out of SPIDAT. If no character is currently being transmitted when SPITXBUF is written to, the data will be transferred immediately to SPIDAT. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts the data on the SPISIMO pin into SPIDAT. If data is to be transmitted by the slave simultaneously, and SPITXBUF has not been previously loaded, the data must be written to SPITXBUF or SPIDAT before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPISOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPISOMI is forced into the high-impedance state. This ensures that the SPI is still able to receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPISOMI line.

The  $\overline{\text{SPISTE}}$  pin operates as the slave-select pin. An active-low signal on the  $\overline{\text{SPISTE}}$  pin allows the slave SPI to transfer data to the serial data line; an inactive- high signal causes the slave SPI serial shift register to stop and its serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.

Figure 22-6 is a block diagram of the SPI in slave mode. It shows the basic control blocks available in SPI slave mode.

Figure 22-6. SPI Module Slave Configuration

### 22.3.4 Data Format

The four-bit SPICHR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from

previous transmission(s) that have been shifted to the left (shown in [Example 22-1](#)).

### Example 22-1. Transmission of Bit From SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in bits SPICHR)
2. The current value of SPIDAT = 737Bh

| SPIDAT (before transmission)  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |
|-------------------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|------------------|
|                               | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1                |
| SPIDAT (after transmission)   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |
| (TXed) 0 ←                    | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | x <sup>(1)</sup> |
| SPIRXBUF (after transmission) |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                  |
|                               | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | x <sup>(1)</sup> |

<sup>(1)</sup> x = 1 if SPISOMI data is high; x = 0 if SPISOMI data is low; master mode is assumed.

## 22.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source, and can be no greater than the LSPCLK frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin, and can be no greater than the LSPCLK frequency divided by 4.

**NOTE:** The baud rate should be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device Data Manual for the maximum GPIO toggle frequency

[Example 22-2](#) shows how to determine the SPI baud rates.

### Example 22-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)} \quad (8)$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4} \quad (9)$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (which is device-specific) and the baud rate at which you will be operating.

The following example shows how to calculate the baud rate of the SPI module in standard SPI mode (HS\_MODE=0).

**Example 22-3. Baud Rate Calculation in Non-High Speed Mode (HS\_MODE=0)**

$$\begin{aligned}
 \text{SPI Baud Rate} &= \frac{LSPCLK}{SPIBRR + 1}, \quad LSPCLK = 50 \text{ MHz} \\
 &= \frac{50 \times 10^6}{3 + 1} \\
 &= 12.5 \text{ Mbps}
 \end{aligned}
 \tag{10}$$

**22.3.6 SPI Clocking Schemes**

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK\_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK\_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are as follows:

- **Falling Edge Without Delay.** The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- **Falling Edge With Delay.** The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- **Rising Edge Without Delay.** The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- **Rising Edge With Delay.** The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in [Table 22-3](#). Examples of these four clocking schemes relative to transmitted and received data are shown in [Figure 22-7](#).

**Table 22-3. SPI Clocking Scheme Selection Guide**

| SPICLK Scheme              | CLKPOLARITY | CLK_PHASE <sup>(1)</sup> |
|----------------------------|-------------|--------------------------|
| Rising edge without delay  | 0           | 0                        |
| Rising edge with delay     | 0           | 1                        |
| Falling edge without delay | 1           | 0                        |
| Falling edge with delay    | 1           | 1                        |

<sup>(1)</sup> The description of CLK\_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.

**Figure 22-7. SPICLK Signal Options**

**Note:** Previous data bit

SPICLK symmetry is retained only when the result of (SPIBRR+1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in [Figure 22-8](#).

**Figure 22-8. SPI: SPICLK-LSPCLK Characteristic When (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1**

### 22.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode will work with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of its operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT will be active.
5. **Interrupts.** FIFO mode has two interrupts one for the transmit FIFO, SPITXINT and one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI will be disabled and this interrupt will service as SPI receive FIFO interrupt. For more information, refer to [Section 22.2.3](#)

6. **Buffers.** Transmit and receive buffers are each supplemented with a 16 word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer will be loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7–0) FFTXDLY7–FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) will reset the FIFO pointers to zero when these bits are set to 1. The FIFOs will resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits will be 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

## 22.3.8 SPI DMA Transfers

### 22.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA\_BURST\_SIZE) should be no greater than 16 – TXFFIL in order to prevent the DMA from writing to an already full FIFO. This will lead to data loss and is not recommended.

For complete data transmission, please follow these steps:

1. Calculate the total number of words to be transmitted. [NUM\_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM\_WORDS: 128

TXFFIL: 8

DMA\_TRANSFER\_SIZE: (NUM\_WORDS / TXFFIL) – 1 = (128/8) – 1 = 15 (16 transfers)

DMA\_BURST\_SIZE: (16 – TXFFIL) – 1 = (16 – 8) – 1 = 7 (8 words per burst)

### 22.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST\_SIZE) should be no greater than RXFFIL in order to prevent the DMA from reading from an empty FIFO. To ensure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size should equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, please follow these steps:

1. Calculate the number of words to be received. [NUM\_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]

3. Calculate the total number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM\_WORDS = 200

RXFFIL: 4

DMA\_TRANSFER\_SIZE: (NUM\_WORDS / RXFFIL) – 1 = (200/4) – 1 = 49 (50 transfers)

DMA\_BURST\_SIZE = RXFFIL-1 = 3 (4 words per burst)

### 22.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer the device Data Manual.

In order to achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device Data Manual.

When configuring the GPIOs to support High-Speed mode, refer to [Section 22.2.2.1](#) for more information.

### 22.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOX becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOx (SPI slave in, slave out) pin, and SPISIMOX is no longer used by the SPI.

[Table 22-4](#) indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

**Table 22-4. 4-wire vs. 3-wire SPI Pin Functions**

| 4-wire SPI | 3-wire SPI (Master) | 3-wire SPI(Slave) |
|------------|---------------------|-------------------|
| SPICLKx    | SPICLKx             | SPICLKx           |
| SPISTEx    | SPISTEx             | SPISTEx           |
| SPISIMOX   | SPIMOMIx            | Free              |
| SPISOMIx   | Free                | SPISISOx          |

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received by itself. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, in order to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

[Figure 22-9](#) and [Figure 22-10](#) illustrate 3-wire master and slave mode.

**Figure 22-9. SPI 3-wire Master Mode**

**Figure 22-10. SPI 3-wire Slave Mode**

Table 22-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

**Table 22-5. 3-Wire SPI Pin Configuration**

| Pin Mode    | SPIPRI[TRIWIRE] | SPICTL[TALK] | SPISIMO             | SPISOMI             |
|-------------|-----------------|--------------|---------------------|---------------------|
| Master Mode |                 |              |                     |                     |
| 4-wire      | 0               | X            | TX                  | RX                  |
| 3-pin mode  | 1               | 0            | RX                  | Disconnect from SPI |
|             |                 | 1            | TX/RX               |                     |
| Slave Mode  |                 |              |                     |                     |
| 4-wire      | 0               | X            | RX                  | TX                  |
| 3-pin mode  | 1               | 0            | Disconnect from SPI | RX                  |
|             |                 | 1            |                     | TX/RX               |

## 22.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

### 22.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER\_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

### 22.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration may be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

To change the SPI configuration:

Step 1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.

Step 2. Configure the SPI as desired:

- Select either master or slave mode (MASTER\_SLAVE).
- Choose SPICLK polarity and phase (CLKPOLARITY and CLK\_PHASE).
- Set the desired baud rate (SPIBRR).
- Enable high speed mode if desired (HS\_MODE).
- Set the SPI character length (SPICHR).
- Clear the SPI Flags (OVERRUN\_FLAG, INT\_FLAG).
- Enable  $\overline{\text{SPISTE}}$  inversion (STEINV) if needed.
- Enable 3-wire mode (TRIWIRE) if needed.
- If using FIFO enhancements:
  - Enable the FIFO enhancements (SPIFFENA).
  - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
  - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
  - Release SPI FIFO channels from reset (SPIRST).

Step 3. If interrupts are used:

- In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
- In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).

Step 4. Set SPISWRESET to 1 to release the SPI from the reset state.

---

**NOTE:** Do not change the SPI configuration when communication is in progress.

---

### 22.4.3 Configuring the SPI for High-Speed Mode

In order to achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100 MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO\_CTRL\_REGS.

During the SPI configuration procedure:

Set HS\_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3.  $SPICLK = LSPCLK / (SPIBRR + 1) = 25\text{MHz}$

```
SpiaRegs.SPIBRR = 0x3;
```

There are no other differences in the configuration from normal SPI operation. Sending and receiving data, interrupts, and DMA operation will operate without change.

### 22.4.4 Data Transfer Example

The timing diagram shown in [Figure 22-11](#) illustrates an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical ([Figure 22-8](#)) shares similar characterizations with [Figure 22-11](#) except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

[Figure 22-11](#) is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.

**Figure 22-11. Five Bits per Character**

- A Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
- B Master sets the slave  $\overline{\text{SPISTE}}$  signal low (active).
- C Master writes 058h to SPIDAT, which starts the transmission procedure.
- D First byte is finished and sets the interrupt flags.
- E Slave reads 0Bh from its SPIRXBUF (right-justified).
- F Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
- G Master writes 06Ch to SPIDAT, which starts the transmission procedure.
- H Master reads 01Ah from the SPIRXBUF (right-justified).
- I Second byte is finished and sets the interrupt flags.
- J Master reads 89h and the slave reads 8Dh from their respective SPIRXBUF. After the user's software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
- K Master clears the slave  $\overline{\text{SPISTE}}$  signal high (inactive).

### 22.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, SPISTEx, and SPISIMOX pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, it receives the data it transmits (because SPISIMOX and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

#### Example 22-4. 3-Wire Master Mode Transmit

```

Uint16 data;
Uint16 dummy;

```

#### Example 22-4. 3-Wire Master Mode Transmit (continued)

```
SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
SpiaRegs.SPITXBUF = data; // Master transmits data
while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
dummy = SpiaRegs.SPIRXBUF;              // Clears junk data from itself
                                         // bc it rx'd same data tx'd
```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data in order to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIM0x pin, and the master does not receive its own dummy data. Instead, the data from the slave is received by the master.

#### Example 22-5. 3-Wire Master Mode Receive

```
Uint16 rdata;
Uint16 dummy;

SpiaRegs.SPICTL.bit.TALK = 0;           // Disable Transmit path
SpiaRegs.SPITXBUF = dummy;              // Send dummy to start tx
// NOTE: because TALK = 0, data does not tx onto SPISIM0A pin
while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
rdata = SpiaRegs.SPIRXBUF;              // Master reads data
```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIM0x pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data it transmits and must clear this junk data from its receive buffer.

#### Example 22-6. 3-Wire Slave Mode Transmit

```
Uint16 data;
Uint16 dummy;

SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
SpiaRegs.SPITXBUF = data;              // Slave transmits data
while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
dummy = SpiaRegs.SPIRXBUF;              // Clears junk data from itself
```

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

#### Example 22-7. - 3-Wire Slave Mode Receive

```
Uint16 rdata;

SpiaRegs.SPICTL.bit.TALK = 0;           // Disable Transmit path
while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
rdata = SpiaRegs.SPIRXBUF;              // Slave reads data
```

### 22.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low SPISTE signal stores right-channel data, and the SPI module that receives an inverted active-high SPISTE signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in [Figure 22-12](#).

**NOTE:** This configuration is only applicable to slave mode (MASTER\_SLAVE = 0). When the SPI is configured as master (MASTER\_SLAVE = 1), the STEINV bit will have no effect on the SPISTE pin.

**Figure 22-12. SPI Digital Audio Receiver Configuration Using Two SPIs**

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See your device-specific data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK\_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in [Figure 22-13](#).

**Figure 22-13. Standard Right-Justified Digital Audio Data Format**

## 22.5 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

### 22.5.1 SPI Base Addresses

**Table 22-6. SPI Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| SpiaRegs         | SPI_REGS      | 0x0000_6100   | 0x0000_610F |
| SpibRegs         | SPI_REGS      | 0x0000_6110   | 0x0000_611F |

## 22.5.2 SPI\_REGS Registers

Table 22-7 lists the SPI\_REGS registers. All register offset addresses not listed in Table 22-7 should be considered as reserved locations and the register contents should not be modified.

**Table 22-7. SPI\_REGS Registers**

| Offset | Acronym  | Register Name                      | Write Protection | Section            |
|--------|----------|------------------------------------|------------------|--------------------|
| 0h     | SPICCR   | SPI Configuration Control Register |                  | <a href="#">Go</a> |
| 1h     | SPICTL   | SPI Operation Control Register     |                  | <a href="#">Go</a> |
| 2h     | SPISTS   | SPI Status Register                |                  | <a href="#">Go</a> |
| 4h     | SPIBRR   | SPI Baud Rate Register             |                  | <a href="#">Go</a> |
| 6h     | SPIRXEMU | SPI Emulation Buffer Register      |                  | <a href="#">Go</a> |
| 7h     | SPIRXBUF | SPI Serial Input Buffer Register   |                  | <a href="#">Go</a> |
| 8h     | SPITXBUF | SPI Serial Output Buffer Register  |                  | <a href="#">Go</a> |
| 9h     | SPIDAT   | SPI Serial Data Register           |                  | <a href="#">Go</a> |
| Ah     | SPIFFTX  | SPI FIFO Transmit Register         |                  | <a href="#">Go</a> |
| Bh     | SPIFFRX  | SPI FIFO Receive Register          |                  | <a href="#">Go</a> |
| Ch     | SPIFFCT  | SPI FIFO Control Register          |                  | <a href="#">Go</a> |
| Fh     | SPIPRI   | SPI Priority Control Register      |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 22-8 shows the codes that are used for access types in this section.

**Table 22-8. SPI\_REGS Access Type Codes**

| Access Type                     | Code    | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |         |                                                                                                                                                                                                                                                                                      |
| R                               | R       | Read                                                                                                                                                                                                                                                                                 |

| <b>Reset or Default Value</b>   |         |                                                                                                                                                                                                                                                                                      |
| -n                              |         | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |         |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 22.5.2.1 SPICCR Register (Offset = 0h) [reset = 0h]

SPICCR is shown in [Figure 22-14](#) and described in [Table 22-9](#).

Return to the [Summary Table](#).

SPICCR controls the setup of the SPI for operation.

### 22.5.2.2 SPICTL Register (Offset = 1h) [reset = 0h]

SPICTL is shown in [Figure 22-15](#) and described in [Table 22-10](#).

Return to the [Summary Table](#).

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (slave or master).

| 4    | OVERRUNINTENA | R/W  | 0h    | <p>Overrun Interrupt Enable</p> <p>Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Disable RECEIVER OVERRUN interrupts.</p> <p>1h (R/W) = Enable RECEIVER_OVERRUN interrupts.</p>                                                                                                                                                                                                                         |
| 3    | CLK_PHASE     | R/W  | 0h    | <p>SPI Clock Phase Select</p> <p>This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6).</p> <p>1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.</p> |
| 2    | MASTER_SLAVE  | R/W  | 0h    | <p>SPI Network Mode Control</p> <p>This bit determines whether the SPI is a network master or slave. SLAVE During reset initialization, the SPI is automatically configured as a network slave.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPI is configured as a slave.</p> <p>1h (R/W) = SPI is configured as a master.</p>                                                                                                                                                                                                                                                                                                                                                    |

**Table 22-10. SPICTL Register Field Descriptions (continued)**

| Bit | Field     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|-----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | TALK      | R/W  | 0h    | <p>Transmit Enable</p> <p>The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Disables transmission:</p> <ul style="list-style-type: none"> <li>- Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state.</li> <li>- Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state.</li> </ul> <p>1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPISTEn input pin.</p> |
| 0   | SPIINTENA | R/W  | 0h    | <p>SPI Interrupt Enable</p> <p>This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Disables the interrupt.</p> <p>1h (R/W) = Enables the interrupt.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 22.5.2.3 SPISTS Register (Offset = 2h) [reset = 0h]

SPISTS is shown in [Figure 22-16](#) and described in [Table 22-11](#).

Return to the [Summary Table](#).

SPISTS contains interrupt and status bits.

**Figure 22-16. SPISTS Register**

| 7    | OVERRUN_FLAG | W1C  | 0h    | <p>SPI Receiver Overrun Flag</p> <p>This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Writing a 1 to this bit</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = A receive overrun condition has not occurred.</p> <p>1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application).</p> <p>Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.</p> |

**Table 22-11. SPISTS Register Field Descriptions (continued)**

| Bit | Field        | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|--------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | INT_FLAG     | RC   | 0h    | <p>SPI Interrupt Flag</p> <p>SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Reading SPIRXBUF</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No full words have been received or transmitted.</p> <p>1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.</p> |
| 5   | BUFFULL_FLAG | R    | 0h    | <p>SPI Transmit Buffer Full Flag</p> <p>This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit buffer is not full.</p> <p>1h (R/W) = Transmit buffer is full.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4-0 | RESERVED     | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

#### 22.5.2.4 SPIBRR Register (Offset = 4h) [reset = 0h]

SPIBRR is shown in [Figure 22-17](#) and described in [Table 22-12](#).

Return to the [Summary Table](#).

SPIBRR contains the bits used for baud-rate selection.

**Figure 22-17. SPIBRR Register**

| 6-0  | SPI_BIT_RATE | R/W  | 0h    | <p><b>SPI Baud Rate Control</b></p> <p>These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 master. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.)</p> <p>If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the master should not exceed the slave SPI's LSPCLK signal divided by 4.</p> <p>In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula:</p> <p>For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1)</p> <p>For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4</p> <p>Reset type: SYSRSn</p> <p>3h (R/W) = SPI Baud Rate = LSPCLK/4</p> <p>4h (R/W) = SPI Baud Rate = LSPCLK/5</p> <p>7Eh (R/W) = SPI Baud Rate = LSPCLK/127</p> <p>7Fh (R/W) = SPI Baud Rate = LSPCLK/128</p> |

### 22.5.2.5 SPIRXEMU Register (Offset = 6h) [reset = 0h]

SPIRXEMU is shown in [Figure 22-18](#) and described in [Table 22-13](#).

Return to the [Summary Table](#).

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

**Figure 22-18. SPIRXEMU Register**

|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | ERXBn | R    | 0h    | <p>Emulation Buffer Received Data</p> <p>SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set.</p> <p>This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately.</p> <p>It is recommended that you view SPIRXEMU in the normal emulator run mode.</p> <p>Reset type: SYSRSn</p> |

### 22.5.2.6 SPIRXBUF Register (Offset = 7h) [reset = 0h]

SPIRXBUF is shown in [Figure 22-19](#) and described in [Table 22-14](#).

Return to the [Summary Table](#).

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

**Figure 22-19. SPIRXBUF Register**

|      |    |    |    |    |    |   |   |

**Table 22-14. SPIRXBUF Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                      |
|------|-------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | RXBn  | R    | 0h    | <p>Received Data</p> <p>Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register.</p> <p>Reset type: SYSRSn</p> |

### 22.5.2.7 SPITXBUF Register (Offset = 8h) [reset = 0h]

SPITXBUF is shown in [Figure 22-20](#) and described in [Table 22-15](#).

Return to the [Summary Table](#).

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.

In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

**Figure 22-20. SPITXBUF Register**

When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified.<br>Reset type: SYSRSn |

### 22.5.2.8 SPIDAT Register (Offset = 9h) [reset = 0h]

SPIDAT is shown in [Figure 22-21](#) and described in [Table 22-16](#).

Return to the [Summary Table](#).

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

**Figure 22-21. SPIDAT Register**

| 4-0 | RXFFIL   | R/W  | 1Fh   | <p>Receive FIFO Interrupt Level Bits</p> <p>Receive FIFO generates an interrupt when the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The default value of these bits after reset is 11111. This avoids frequent interrupts after reset, as the receive FIFO will be empty most of the time.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = A RX FIFO interrupt request is generated when there is 0 or more words in the RX buffer.</p> <p>1h (R/W) = A RX FIFO interrupt request is generated when there are 1 or more words in the RX buffer.</p> <p>2h (R/W) = A RX FIFO interrupt request is generated when there are 2 or more words in the RX buffer.</p> <p>10h (R/W) = A RX FIFO interrupt request is generated when there are 16 words in the RX buffer.</p> <p>1Fh (R/W) = Reserved.</p> |

### 22.5.2.11 SPIFFCT Register (Offset = Ch) [reset = 0h]

SPIFFCT is shown in [Figure 22-24](#) and described in [Table 22-19](#).

Return to the [Summary Table](#).

SPIFFCT controls the FIFO transmit delay bits.

**Figure 22-24. SPIFFCT Register**

| 7-0  | TXDLY    | R/W  | 0h    | <p>FIFO Transmit Delay Bits</p> <p>These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word.</p> <p>1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word.</p> <p>2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word.</p> <p>FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.</p> |

### 22.5.2.12 SPIPRI Register (Offset = Fh) [reset = 0h]

SPIPRI is shown in [Figure 22-25](#) and described in [Table 22-20](#).

Return to the [Summary Table](#).

SPIPRI controls auxillary functions for the SPI including emulation control, SPISTE inversion, and 3-wire control.

| 5    | SOFT     | R/W  | 0h    | <p>Emulation Soft Run</p> <p>This bit only has an effect when the FREE bit is 0.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point.</p> <p>1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used.</p> <p>Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty.</p> <p>In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.</p> |
| 4    | FREE     | R/W  | 0h    | <p>Emulation Free Run</p> <p>These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Emulation mode is selected by the SOFT bit</p> <p>1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3-2  | RESERVED | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 22-20. SPIPRI Register Field Descriptions (continued)**

| Bit | Field   | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|---------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | STEINV  | R/W  | 0h    | <p>SPISTEn Inversion Bit</p> <p>On devices with 2 SPI modules, inverting the SPISTE signal on one of the modules allows the device to receive left and right- channel digital audio data.</p> <p>This bit is only applicable to slave mode. Writing to this bit while configured as master (MASTER_SLAVE = 1) has no effect</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPISTEn is active low (normal)</p> <p>1h (R/W) = SPISTE is active high (inverted)</p> |
| 0   | TRIWIRE | R/W  | 0h    | <p>SPI 3-wire Mode Enable</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Normal 4-wire SPI mode.</p> <p>1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In master mode, the SPISIMO pin becomes the SPIMOMI (master receive and transmit) pin and SPISOMI is free for non-SPI use. In slave mode, the SPISOMI pin becomes the SPISISO (slave receive and transmit) pin and SPISIMO is free for non-SPI use.</p>                           |

## 22.5.3 Register to Driverlib Function Mapping

**Table 22-21. SPI Registers to Driverlib Functions**

| File         | Driverlib Function           |

## Serial Communications Interface (SCI)

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has its own separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

## 23.1 Introduction

The SCI interfaces are shown in [Figure 23-1](#).

**Figure 23-1. SCI CPU Interface**

Features of the SCI module include:

- Two external pins:
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin
 Both pins can be used as GPIO if not used for SCI.
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags.
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

Figure 23-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 23.14 of this chapter.

**Figure 23-2. Serial Communications Interface (SCI) Module Block Diagram**

## 23.2 Architecture

The major elements used in full-duplex operation are shown in [Figure 23-2](#) and include:

- A transmitter (TX) and its major registers (upper half of [Figure 23-2](#))
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and its major registers (lower half of [Figure 23-2](#))
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

## 23.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in [Table 23-1](#).

**Table 23-1. SCI Module Signal Summary**

| Signal Name              | Description                                |
|--------------------------|--------------------------------------------|
| <b>External signals</b>  |                                            |
| SCIRXD                   | SCI Asynchronous Serial Port receive data  |
| SCITXD                   | SCI Asynchronous Serial Port transmit data |
| <b>Control</b>           |                                            |
| Baud clock               | LSPCLK Prescaled clock                     |
| <b>Interrupt signals</b> |                                            |
| TXINT                    | Transmit interrupt                         |
| RXINT                    | Receive Interrupt                          |

## 23.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 23.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see [Section 23.8](#)) and the address-bit multiprocessor mode (see [Section 23.9](#)). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see [Section 23.10](#)) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits

- An even/odd parity bit or no parity bit
- One or two stop bits

## 23.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in [Figure 23-3](#), consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with its formatting information is called a frame and is shown in [Figure 23-3](#).

**Figure 23-3. Typical SCI Data Frame Formats**

To program the data format, use the SCICCR register. The bits used to program the data format are shown in [Table 23-2](#).

**Table 23-2. Programming the Data Format Using SCICCR**

| Bit(s) | Bit Name           | Designation | Functions                                                                                                 |
|--------|--------------------|-------------|-----------------------------------------------------------------------------------------------------------|
| 2-0    | SCI CHAR2-0        | SCICCR.2:0  | Select the character (data) length (one to eight bits).                                                   |
| 5      | PARITY<br>ENABLE   | SCICCR.5    | Enables the parity function if set to 1, or disables the parity function if cleared to 0.                 |
| 6      | EVEN/ODD<br>PARITY | SCICCR.6    | If parity is enabled, selects odd parity if cleared to 0 or even parity if set to 1.                      |
| 7      | STOP BITS          | SCICCR.7    | Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1. |

## 23.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there should be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

### Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

### Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that they are interrupted only when the address byte is detected. When a processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, it does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

### 23.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode ([Section 23.8](#)) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than ten bytes of data. The idle-line mode should be used for typical non-multiprocessor SCI communication.
- The address-bit mode ([Section 23.9](#)) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, it does not have to wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

### 23.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable via the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

### 23.7.3 Receipt Sequence

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt). It reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against its device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

## 23.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in [Figure 23-4](#) (ADDR/IDLE MODE bit is bit 3 of SCICCR).

**Figure 23-4. Idle-Line Multiprocessor Communication Format**

### 23.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

- Step 1. SCI wakes up after receipt of the block-start signal.
- Step 2. The processor recognizes the next SCI interrupt.
- Step 3. The interrupt service routine compares the received address (sent by a remote transmitter) to its own.
- Step 4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
- Step 5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute its main program without being interrupted by the SCI port until the next detection of a block start.

### 23.8.2 Block Start Signal

There are two ways to send a block-start signal:

1. **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
2. **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

### 23.8.3 Wake-UP Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in [Figure 23-5](#).

**Figure 23-5. Double-Buffered WUT and TXSHF**

#### 23.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don't care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared. Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.
3. **Write a new address value to SCITXBUF**  
A don't-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don't-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE if necessary) can be written to again because TXSHF and WUT are both double-buffered.

### 23.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt until an address frame is detected.

## 23.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see [Figure 23-6](#)).

### 23.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

- When this address value is transferred to the TXSHF register and shifted out, its address bit is sent as a 1. This flags the other processors on the serial link to read the address.
2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.)
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

**NOTE:** As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

**Figure 23-6. Address-Bit Multiprocessor Communication Format**

## 23.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in [Figure 23-7](#)). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in [Figure 23-7](#). If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. [Figure 23-7](#) illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes itself to frames, the external transmitting and receiving devices do not have to use a synchronized serial clock. The clock can be generated locally.

**Figure 23-7. SCI Asynchronous Communications Format**

### 23.10.1 Receiver Signals in Communication Modes

Figure 23-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

**Figure 23-8. SCI RX Signals in Communication Modes**

- (1) Data arrives on the SCIRXD pin, start bit detected.
- (2) Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

Notes:

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

### 23.10.2 Transmitter Signals in Communication Modes

Figure 23-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

**Figure 23-9. SCI TX Signals in Communications Mode**

**Notes:**

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

## 23.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag which is a logical OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits which are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the peripheral interrupt expansion controller section of the *External Peripheral Interface (ePIE)* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for ten bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

**NOTE:** Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

## 23.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock (LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. [Table 23-3](#) shows the baud-select values for common SCI bit rates.

**Table 23-3. Asynchronous Baud Register Values for Common SCI Bit Rates**

| Ideal Baud | LSPCLK Clock Frequency, 100 MHz |             |         |
|------------|---------------------------------|-------------|---------|
|            | BRR                             | Actual Baud | % Error |
| 2400       | 5207 (1457h)                    | 2400        | 0       |
| 4800       | 2603 (A2Bh)                     | 4800        | 0       |
| 9600       | 1301 (515h)                     | 9601        | 0.01    |
| 19200      | 650 (28Ah)                      | 19201       | 0.01    |
| 38400      | 324 (144h)                      | 38462       | 0.16    |

LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

## 23.13 SCI Enhanced Features

The 28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

### 23.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. *Reset.* At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. *Standard SCI.* The standard SCI modes will work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. *FIFO enable.* FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of its operation.
4. *Active registers.* All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. *Interrupts.* FIFO mode has two interrupts; one for transmit FIFO, TXINT and one for receive FIFO, RXINT. RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI will be disabled and this interrupt will service as SCI transmit FIFO interrupt.
6. *Buffers.* Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8 bits wide and receive FIFO registers are 10 bits wide. The one-word transmit buffer of the standard SCI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from the transmit FIFO only after the last bit of the shift register is shifted out. With the FIFO enabled, TXSHF is directly loaded after an optional delay value (SCIFFCT), TXBUF is not used. When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. *Delayed transfer.* The rate at which words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7-0) FFTXDLY7-FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define

a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.

8. *FIFO status bits.* Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12–8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to one.
9. *Programmable interrupt levels.* Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12–8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4–0 ). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits will be 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 23-10 and Table 23-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

**Figure 23-10. SCI FIFO Interrupt Flags and Enable Logic**

**Table 23-4. SCI Interrupt Flags**

| FIFO Options <sup>(1)</sup> | SCI Interrupt Source            | Interrupt Flags      | Interrupt Enables | FIFO Enable<br>SCIFFENA | Interrupt Line |
|-----------------------------|---------------------------------|----------------------|-------------------|-------------------------|----------------|
| SCI without FIFO            | Receive error                   | RXERR <sup>(2)</sup> | RXERRINTENA       | 0                       | RXINT          |
|                             | Receive break                   | BRKDT                | RX/BKINTENA       | 0                       | RXINT          |
|                             | Data receive                    | RXRDY                | RX/BKINTENA       | 0                       | RXINT          |
|                             | Transmit empty                  | TXRDY                | TXINTENA          | 0                       | TXINT          |
| SCI with FIFO               | Receive error and receive break | RXERR                | RXERRINTENA       | 1                       | RXINT          |
|                             | FIFO receive                    | RXFFIL               | RXFFIENA          | 1                       | RXINT          |
|                             | Transmit empty                  | TXFFIL               | TXFFIENA          | 1                       | TXINT          |
| Auto-baud                   | Auto-baud detected              | ABD                  | Don't care        | x                       | TXINT          |

<sup>(1)</sup> FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.

<sup>(2)</sup> RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag

### 23.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

### 23.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit should be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit has to be cleared by software. If CDC remains set even after interrupt service, there should be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (Bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500 Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud- detect hardware will detect the incoming baud rate and set the ABD bit.
4. The auto-detect hardware will update the baud rate register with the equivalent baud value hex. The logic will also generate an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit must be cleared by software.

**NOTE:** At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and 28x SCI boot loader using a lower baud rate.
- The host may then handshake with the loaded 28x application to set the SCI baud rate register to the desired higher baud rate.

## 23.14 SCI Registers

The section describes the Serial Communication Interface module Registers.

### 23.14.1 SCI Base Addresses

**Table 23-5. SCI Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| SciaRegs         | SCI_REGS      | 0x0000_7200   | 0x0000_720F |
| ScibRegs         | SCI_REGS      | 0x0000_7210   | 0x0000_721F |

### 23.14.2 SCI\_REGS Registers

Table 23-6 lists the SCI\_REGS registers. All register offset addresses not listed in Table 23-6 should be considered as reserved locations and the register contents should not be modified.

**Table 23-6. SCI\_REGS Registers**

| Offset | Acronym  | Register Name                     | Write Protection | Section            |
|--------|----------|-----------------------------------|------------------|--------------------|
| 0h     | SCICCR   | Communications control register   |                  | <a href="#">Go</a> |
| 1h     | SCICTL1  | Control register 1                |                  | <a href="#">Go</a> |
| 2h     | SCIHBAUD | Baud rate (high) register         |                  | <a href="#">Go</a> |
| 3h     | SCILBAUD | Baud rate (low) register          |                  | <a href="#">Go</a> |
| 4h     | SCICTL2  | Control register 2                |                  | <a href="#">Go</a> |
| 5h     | SCIRXST  | Receive status register           |                  | <a href="#">Go</a> |
| 6h     | SCIRXEMU | Receive emulation buffer register |                  | <a href="#">Go</a> |
| 7h     | SCIRXBUF | Receive data buffer               |                  | <a href="#">Go</a> |
| 9h     | SCITXBUF | Transmit data buffer              |                  | <a href="#">Go</a> |
| Ah     | SCIFFTX  | FIFO transmit register            |                  | <a href="#">Go</a> |
| Bh     | SCIFFRX  | FIFO receive register             |                  | <a href="#">Go</a> |
| Ch     | SCIFFCT  | FIFO control register             |                  | <a href="#">Go</a> |
| Fh     | SCIPRI   | SCI priority control              |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 23-7 shows the codes that are used for access types in this section.

**Table 23-7. SCI\_REGS Access Type Codes**

| Access Type                     | Code    | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |         |                                                                                                                                                                                                                                                                                      |
| R                               | R       | Read                                                                                                                                                                                                                                                                                 |
| R-0                             | R<br>-0 | Read<br>Returns 0s                                                                                                                                                                                                                                                                   |
| <b>Write Type</b>               |         |                                                                                                                                                                                                                                                                                      |
| W                               | W       | Write                                                                                                                                                                                                                                                                                |
| W1S                             | W<br>1S | Write<br>1 to set                                                                                                                                                                                                                                                                    |
| <b>Reset or Default Value</b>   |         |                                                                                                                                                                                                                                                                                      |
| -n                              |         | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |         |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 23.14.2.1 SCICCR Register (Offset = 0h) [reset = 0h]

SCICCR is shown in [Figure 23-11](#) and described in [Table 23-8](#).

Return to the [Summary Table](#).

SCICCR defines the character format, protocol, and communications mode used by the SCI.

**Figure 23-11. SCICCR Register**

| 7    | STOPBITS  | R/W  | 0h    | SCI number of stop bits.<br>This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit.<br>Reset type: SYSRSn<br>0h (R/W) = One stop bit<br>1h (R/W) = Two stop bits                                                                                                                                                                                                                                                                                                                           |
| 6    | PARITY    | R/W  | 0h    | SCI parity odd/even selection.<br>If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters).<br>Reset type: SYSRSn<br>0h (R/W) = Odd parity<br>1h (R/W) = Even parity                                                                                                                                                                                                                                |
| 5    | PARITYENA | R/W  | 0h    | SCI parity enable.<br>This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation.<br>Reset type: SYSRSn<br>0h (R/W) = Parity disabled<br>no parity bit is generated during transmission or is expected during reception<br>1h (R/W) = Parity is enabled |
| 4    | LOOPBKENA | R/W  | 0h    | Loop Back test mode enable.<br>This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin.<br>Reset type: SYSRSn<br>0h (R/W) = Loop Back test mode disabled<br>1h (R/W) = Loop Back test mode enabled                                                                                                                                                                                                                                                                                            |

**Table 23-8. SCICCR Register Field Descriptions (continued)**

| Bit | Field         | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|---------------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | ADDRIDLE_MODE | R/W  | 0h    | <p>SCI multiprocessor mode control bit.</p> <p>This bit selects one of the multiprocessor protocols. Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Idle-line mode protocol selected</p> <p>1h (R/W) = Address-bit mode protocol selected</p> |
| 2-0 | SCICCHAR      | R/W  | 0h    | <p>Character-length control bits 2-0.</p> <p>These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn't need to be padded with leading zeros.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCICCHAR_LENGTH_1</p> <p>1h (R/W) = SCICCHAR_LENGTH_2</p> <p>2h (R/W) = SCICCHAR_LENGTH_3</p> <p>3h (R/W) = SCICCHAR_LENGTH_4</p> <p>4h (R/W) = SCICCHAR_LENGTH_5</p> <p>5h (R/W) = SCICCHAR_LENGTH_6</p> <p>6h (R/W) = SCICCHAR_LENGTH_7</p> <p>7h (R/W) = SCICCHAR_LENGTH_8</p>                    |

### 23.14.2.2 SCICTL1 Register (Offset = 1h) [reset = 0h]

SCICTL1 is shown in [Figure 23-12](#) and described in [Table 23-9](#).

Return to the [Summary Table](#).

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

| 5    | SWRESET     | R/W  | 0h    | <p>SCI software reset (active low).</p> <p>Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. The SW RESET bit does not affect any of the configuration bits.</p> <p>All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit. Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST, bit 5).</p> <p>SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values. Once SW RESET is asserted, the flags are frozen until the bit is deasserted.</p> <p>The affected flags are as follows:</p> <p>Value After SW SCI Flag Register Bit</p> <p>RESET</p> <p>1 TXRDY SCICTL2, bit 7</p> <p>1 TX EMPTY SCICTL2, bit 6</p> <p>0 RXWAKE SCIRXST, bit 1</p> <p>0 PE SCIRXST, bit 2</p> <p>0 OE SCIRXST, bit 3</p> <p>0 FE SCIRXST, bit 4</p> <p>0 BRKDT SCIRXST, bit 5</p> <p>0 RXRDY SCIRXST, bit 6</p> <p>0 RX ERROR SCIRXST, bit 7</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition.</p> <p>1h (R/W) = After a system reset, re-enable the SCI by writing a 1 to this bit.</p> |

**Table 23-9. SCICTL1 Register Field Descriptions (continued)**

| Bit | Field    | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|----------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | RESERVED | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3   | TXWAKE   | R/W  | 0h    | <p>SCI transmitter wake-up method select.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1</p> <p>1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5) it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.</p>                               |
| 2   | SLEEP    | R/W  | 0h    | <p>SCI sleep.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode disabled</p> <p>1h (R/W) = Sleep mode enabled</p>                                                  |
| 1   | TXENA    | R/W  | 0h    | <p>SCI transmitter enable.</p> <p>Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmitter disabled</p> <p>1h (R/W) = Transmitter enabled</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| 0   | RXENA    | R/W  | 0h    | <p>SCI receiver enable.</p> <p>Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers).</p> <p>Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, the receiver shift register can continue to assemble characters. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers</p> <p>1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF</p> |

### 23.14.2.3 SCIHBAUD Register (Offset = 2h) [reset = 0h]

SCIHBAUD is shown in [Figure 23-13](#) and described in [Table 23-10](#).

Return to the [Summary Table](#).

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

**Figure 23-13. SCIHBAUD Register**

#### 23.14.2.4 SCILBAUD Register (Offset = 3h) [reset = 0h]

SCILBAUD is shown in [Figure 23-14](#) and described in [Table 23-11](#).

Return to the [Summary Table](#).

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

### 23.14.2.5 SCICTL2 Register (Offset = 4h) [reset = C0h]

SCICTL2 is shown in [Figure 23-15](#) and described in [Table 23-12](#).

Return to the [Summary Table](#).

SCICTL2 enables the receive-ready, break-detect, and transmit-ready interrupts as well as transmitter-ready and -empty flags.

| 0   | TXINTENA | R/W  | 0h    | <p>SCITXBUF-register interrupt enable.</p> <p>This bit controls the interrupt request caused by the setting of TXRDY flag bit (SCICTL2.7). However, it does not prevent the TXRDY flag from being set (which indicates SCITXBUF is ready to receive another character).</p> <p>0 Disable TXRDY interrupt<br/>1 Enable TXRDY interrupt.</p> <p>In non-FIFO mode, a dummy (or a valid) data has to be written to SCITXBUF for the first transmit interrupt to occur. This is the case when you enable the transmit interrupt for the first time and also when you re-enable (disable and then enable) the transmit interrupt. If TXINTENA is enabled after writing the data to SCITXBUF, it will not generate an interrupt.</p> <p>Reset type: SYSRSn<br/>0h (R/W) = Disable TXRDY interrupt<br/>1h (R/W) = Enable TXRDY interrupt</p> |

### 23.14.2.6 SCIRXST Register (Offset = 5h) [reset = 0h]

SCIRXST is shown in [Figure 23-16](#) and described in [Table 23-13](#).

Return to the [Summary Table](#).

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated.

**Figure 23-16. SCIRXST Register**

| 15-8 | RESERVED | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 7    | RXERROR  | R    | 0h    | <p>SCI receiver error flag.</p> <p>The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE).</p> <p>A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly</p> <p>it is cleared by an active SW RESET or by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No error flags set</p> <p>1h (R/W) = Error flag(s) set</p>                                                                                                                                                                     |
| 6    | RXRDY    | R    | 0h    | <p>SCI receiver-ready flag.</p> <p>When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, or by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No new character in SCIRXBUF</p> <p>1h (R/W) = Character ready to be read from SCIRXBUF</p>                                                                                                                                                                                                                                                                                                                                                                                        |
| 5    | BRKDT    | R    | 0h    | <p>SCI break-detect flag.</p> <p>The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least ten bits, beginning after a missing first stop bit. The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET or by a system reset. It is not cleared by receipt of a character after the break is detected. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit or by a system reset.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No break condition</p> <p>1h (R/W) = Break condition occurred</p> |

**Table 23-13. SCIRXST Register Field Descriptions (continued)**

### 23.14.2.7 SCIRXEMU Register (Offset = 6h) [reset = 0h]

SCIRXEMU is shown in [Figure 23-17](#) and described in [Table 23-14](#).

Return to the [Summary Table](#).

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented  
it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

### 23.14.2.8 SCIRXBUF Register (Offset = 7h) [reset = 0h]

SCIRXBUF is shown in [Figure 23-18](#) and described in [Table 23-15](#).

Return to the [Summary Table](#).

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

### 23.14.2.9 SCITXBUF Register (Offset = 9h) [reset = 0h]

SCITXBUF is shown in [Figure 23-19](#) and described in [Table 23-16](#).

Return to the [Summary Table](#).

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

### 23.14.2.10 SCIFFTX Register (Offset = Ah) [reset = A000h]

SCIFFTX is shown in [Figure 23-20](#) and described in [Table 23-17](#).

Return to the [Summary Table](#).

SCIFFTX controls the transmit FIFO interrupt, FIFO enhancements, and reset for the SCI transmit and receive channels.

This interrupt is triggered whenever the transmit FIFO status (TXFFST) bits match (equal to or less than) the interrupt trigger level bits TXFFIL (bits 4-0).                                                                                                                                                                                                                                                                        |
| 4-0 | TXFFIL     | R/W     | 0h    | TXFFIL4-0 Transmit FIFO interrupt level bits.<br><br>The transmit FIFO generates an interrupt whenever the FIFO status bits (TXFFST4-0) are less than or equal to the FIFO level bits (TXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the TX FIFO. The default value of these bits after reset is 00000b. Users should set TXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of SCI bus bandwidth.<br>Reset type: SYSRSn |

### 23.14.2.11 SCIFFRX Register (Offset = Bh) [reset = 201Fh]

SCIFFRX is shown in [Figure 23-21](#) and described in [Table 23-18](#).

Return to the [Summary Table](#).

SCIFFTX controls the receive FIFO interrupt, receive FIFO reset, and status of the receive FIFO overflow.

This interrupt is triggered whenever the receive FIFO status (RXFFST) bits match (equal to or greater than) the interrupt trigger level bits RXFFIL (bits 4-0).                                                                                                                                                                                                                                                             |
| 4-0 | RXFFIL     | R/W  | 1Fh   | Receive FIFO interrupt level bits<br><br>The receive FIFO generates an interrupt whenever the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the RX FIFO. The default value of these bits after reset is 11111b. Users should set RXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of received SCI data.<br>Reset type: SYSRSn |

### 23.14.2.12 SCIFFCT Register (Offset = Ch) [reset = 0h]

SCIFFCT is shown in [Figure 23-22](#) and described in [Table 23-19](#).

Return to the [Summary Table](#).

SCIFFCT contains the status of auto-baud detect, clears the auto-baud flag, and calibrate for A-detect bit.

| 7-0  | FFTXDLY  | R/W  | 0h    | FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles<br><br>In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS.<br><br>When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to.<br><br>When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1.<br>Reset type: SYSRSn |

### 23.14.2.13 SCIPRI Register (Offset = Fh) [reset = 0h]

SCIPRI is shown in [Figure 23-23](#) and described in [Table 23-20](#).

Return to the [Summary Table](#).

SCIPRI determines what happens when an emulation suspend event occurs.

**Figure 23-23. SCIPRI Register**

## ***Inter-Integrated Circuit Module (I2C)***

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1 to 8-bit data to/from the device through the I2C module. This guide assumes the reader is familiar with the I2C bus specification.

---

**NOTE:** A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this document. The number of bits in a data byte is selectable via the BC bits of the mode register, I2CMR.

---

## 24.1 Introduction

The I2C module supports any slave or master I2C-compatible device. [Figure 24-1](#) shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

**Figure 24-1. Multiple I2C Modules Connected**

### 24.1.1 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10 kbps up to 400 kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the below events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx\_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable/disable capability
- Free data format mode

### 24.1.2 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

### 24.1.3 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in [Section 24.6](#). These two pins carry information between the 28x device and other devices connected to the I2C bus. The SDA and SCL pins both are bidirectional. They each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques: .

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See [Section 24.6](#) for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See *Registers* for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

[Figure 24-2](#) shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 24-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 24.1.5 for the master clock frequency equation.

### 24.1.5 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 24.1.4, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 24-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCLKH. For each master clock cycle, ICCH determines the amount of time the signal is high.

**Figure 24-4. The Roles of the Clock Divide-Down Values (ICCL and ICCH)**

#### 24.1.5.1 Formula for the Master Clock Period

The master clock period ( $T_{\text{mst}}$ ) is a multiple of the period of the I2C Module Clock ( $T_{\text{mod}}$ ):

$$\text{Master Clock period } (T_{\text{mst}}) = \frac{[(\text{ICCH} + d) + (\text{ICCL} + d)]}{\text{I2C Module Clock } (F_{\text{mod}})}$$

where  $d$  depends on the divide-down value IPSC, as shown in Table 24-1. IPSC is described in the I2CPSC register.

**Table 24-1. Dependency of Delay  $d$  on the Divide-Down Value IPSC**

| IPSC           | $d$ |
|----------------|-----|
| 0              | 7   |
| 1              | 6   |
| Greater than 1 | 5   |

## 24.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 24.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

### 24.3.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{DD}$ . For details, see the data manual for your particular device.

### 24.3.2 Data Validity

The data on SDA must be stable during the high period of the clock (see [Figure 24-5](#)). The high or low state of the data line, SDA, should change only when the clock signal on SCL is low.

**Figure 24-5. Bit Transfer on the I2C bus**

### 24.3.3 Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See [Table 24-2](#) for the names and descriptions of the modes.

If the I2C module is a master, it begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, it begins as a slave-receiver and typically sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

**Table 24-2. Operating Modes of the I2C Module**

| Operating Mode       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slave-receiver modes | <p>The I2C module is a slave and receives data from a master.</p> <p>All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (<math>RSFULL = 1</math> in <math>I2CSTR</math>) after a byte has been received. See <a href="#">Section 25.4</a> for more details.</p> |

**Table 24-2. Operating Modes of the I2C Module (continued)**

| Operating Mode           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slave-transmitter mode   | <p>The I2C module is a slave and transmits data to a master.</p> <p>This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its slave-transmitter mode if the slave address byte is the same as its own address (in I2COAR) and the master has transmitted <math>R/\overline{W} = 1</math>. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (<math>XSMT = 0</math> in I2CSTR) after a byte has been transmitted. See section <a href="#">Section 25.4</a> for more details.</p> |
| Master-receiver mode     | <p>The I2C module is a master and receives data from a slave.</p> <p>This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its master-receiver mode after transmitting the slave address byte and <math>R/\overline{W} = 1</math>. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (<math>RSFULL = 1</math> in I2CSTR) after a byte has been received.</p>                                                                                                                                                                              |
| Master-transmitter modes | <p>The I2C module is a master and transmits control information and data to a slave.</p> <p>All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (<math>XSMT = 0</math> in I2CSTR) after a byte has been transmitted.</p>                                                                                                                                                                                                                                                                                                                                                                   |

To summarize, SCL will be held low in the following conditions:

- When an overrun condition is detected ( $RSFULL = 1$ ), in Slave-receiver mode.
- When an underflow condition is detected ( $XSMT = 0$ ), in Slave-transmitter mode.

I2C slave nodes have to accept and provide data when the I2C master node requests it.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

**Table 24-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR**

| RM | STT | STP | Bus Activity <sup>(1)</sup> | Description                                                                                                                  |
|----|-----|-----|-----------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 0  | 0   | 0   | None                        | No activity                                                                                                                  |
| 0  | 0   | 1   | P                           | STOP condition                                                                                                               |

<sup>(1)</sup> S = START condition; A = Address; D = Data byte; P = STOP condition;

### 24.3.4 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in [Figure 24-6](#):

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.

- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

**Figure 24-6. I2C Module START and STOP Conditions**

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and its bits (including MST, STT, and STP), see *Registers Section 24.6*.

The I2C peripheral cannot detect a START or STOP condition while it is in reset (IRS = 0). The BB bit will remain in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1) the BB bit will not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

- After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, users can ensure that at least one START or STOP condition will have occurred on the I2C bus and been captured by the BB bit. After this period, the BB bit will correctly reflect the state of the I2C bus.
- Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
- Begin data transfers.

Not resetting the I2C peripheral in between transfers ensures that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

### 24.3.5 Serial Data Formats

Figure 24-7 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 24-7, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 24-7 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 24-8 through Figure 24-10 and described in the paragraphs that follow the figures.

**NOTE:** In Figure 24-7 through Figure 24-10, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

**Figure 24-7. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)**

### 24.3.5.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 24-8), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/W bit. R/W determines the direction of the data:

- $R/\overline{W} = 0$ : The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- $R/\overline{W} = 1$ : The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

**Figure 24-8. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)**

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/W bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

### 24.3.5.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 24-9) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/W. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

**Figure 24-9. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)**

### 24.3.5.3 Free Data Format

The free data format can be enabled by setting I2CMDR.FDF = 1.

In this format (see [Figure 24-10](#)), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

**Figure 24-10. I2C Module Free Data Format (FDF = 1 in I2CMDR)**

**NOTE:** The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

**Table 24-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR**

| MST | FDF | I2C Module State                             | Function of TRX                                                                                                                                                                                                                                               |
|-----|-----|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0   | In slave mode but not free data format mode  | TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter.                                                                                                                                        |
| 0   | 1   | In slave mode and free data format mode      | The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module:<br><br>TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver. |
| 1   | 0   | In master mode but not free data format mode | TRX = 1: The I2C module is a transmitter.<br>TRX = 0: The I2C module is a receiver.                                                                                                                                                                           |
| 1   | 1   | In master mode and free data format mode     | TRX = 0: The I2C module is a receiver.<br>TRX = 1: The I2C module is a transmitter.                                                                                                                                                                           |

#### 24.3.5.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, and free data formats. [Figure 24-11](#) shows a repeated START condition in the 7-bit addressing format.

**Figure 24-11. Repeated START Condition (in This Case, 7-Bit Addressing Format)**

**NOTE:** In [Figure 24-11](#), n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

#### 24.3.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. [Table 24-5](#) summarizes the various ways you can tell the I2C module to send a NACK bit.

**Table 24-5. Ways to Generate a NACK Bit**

| I2C Module Condition                                       | NACK Bit Generation Options                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Master-receiver mode AND Repeat mode (RM = 1 in I2CMDR)    | <ul style="list-style-type: none"> <li>Generate a STOP condition (STP = 1 in I2CMDR)</li> <li>Reset the module (IRS = 0 in I2CMDR)</li> <li>Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive</li> </ul>                                                                                                                                                             |
| Master-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR) | <ul style="list-style-type: none"> <li>If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition</li> <li>If STP = 0, make STP = 1 to generate a STOP condition</li> <li>Reset the module (IRS = 0 in I2CMDR). = 1 to generate a STOP condition</li> <li>Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive</li> </ul> |

### 24.3.7 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. [Figure 24-12](#) illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for SCL to be released, before starting their high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

**Figure 24-12. Synchronization of Two I2C Clock Generators During Arbitration**

### 24.3.8 Arbitration

If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. [Figure 24-13](#) illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

**Figure 24-13. Arbitration Procedure Between Two Master-Transmitters**

### 24.3.9 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

$$n = 8 * (\text{SYSCLK}) / (\text{I2C module clock (Fmod)})$$

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. [Figure 24-14](#) shows the signal routing in digital loopback mode.

**Figure 24-14. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit**

**NOTE:** The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

## 24.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources which can trigger this interrupt are described in [Section 24.4.1](#).
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources which can trigger this interrupt are described in [Section 24.4.2](#)

### 24.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in [Table 24-6](#). As shown in [Figure 24-15](#), all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, its flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if it is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A\_ISR). The I2CINT1A\_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A\_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to it.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

**Table 24-6. Descriptions of the Basic I2C Interrupt Requests**

| I2C Interrupt Request | Interrupt Source                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XRDYINT               | Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXHR).<br>As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead. |
| RRDYINT               | Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR.<br>As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.                                              |
| ARDYINT               | Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used.<br>The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR.<br>As an alternative to using ARDYINT, the CPU can poll the ARDY bit.                               |
| NACKINT               | No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not receive acknowledgment from the slave-receiver.<br>As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.                                                                                                                                                |
| ARBLINT               | Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter.<br>As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.                                                                                                                                                                                  |
| SCDINT                | Stop condition detected: A STOP condition was detected on the I2C bus.<br>As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.                                                                                                                                                                                                    |
| AASINT                | Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus.<br>As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.                                                                                                                                                              |

**Figure 24-15. Enable Paths of the I2C Interrupt Requests**

The normal transmit interrupt timing makes it possible for stale data to remain in the transmit buffer if a transaction is aborted in the middle of a byte. To avoid this, set the FCM bit in the I2CEMDR register. When this bit is set, the transmit data ready interrupt is generated only when data is required for a bus transaction. In master mode, the interrupt is first generated when the ACK of the address byte is received. In slave mode, the interrupt is first generated when the address is matched. Further interrupts are generated when the data is ACKed. In this mode XRDY is asserted at the same time as the transmit ready interrupt.

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in [Figure 24-16](#) demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

**Figure 24-16. Backwards Compatibility Mode Bit, Slave Transmitter**

Slave-Transmitter

## 24.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. [Figure 24-17](#) shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

Figure 24-17. I2C\_FIFO\_interrupt

## 24.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to their default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the  $\overline{\text{XRS}}$  pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the  $\overline{\text{XRS}}$  pin is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

## 24.6 I2C Registers

This section describes the C28x I2C Module Registers.

### 24.6.1 I2C Base Addresses

**Table 24-7. I2C Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| I2caRegs         | I2C_REGS      | 0x0000_7300   | 0x0000_733F |

## 24.6.2 I2C\_REGS Registers

Table 24-8 lists the I2C\_REGS registers. All register offset addresses not listed in Table 24-8 should be considered as reserved locations and the register contents should not be modified.

**Table 24-8. I2C\_REGS Registers**

| Offset | Acronym | Register Name               | Write Protection | Section            |
|--------|---------|-----------------------------|------------------|--------------------|
| 0h     | I2COAR  | I2C Own address             |                  | <a href="#">Go</a> |
| 1h     | I2CIER  | I2C Interrupt Enable        |                  | <a href="#">Go</a> |
| 2h     | I2CSTR  | I2C Status                  |                  | <a href="#">Go</a> |
| 3h     | I2CCLKL | I2C Clock low-time divider  |                  | <a href="#">Go</a> |
| 4h     | I2CCLKH | I2C Clock high-time divider |                  | <a href="#">Go</a> |
| 5h     | I2CCNT  | I2C Data count              |                  | <a href="#">Go</a> |

| -n                              |         | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |         |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 24.6.2.1 I2COAR Register (Offset = 0h) [reset = 0h]

I2COAR is shown in [Figure 24-18](#) and described in [Table 24-10](#).

Return to the [Summary Table](#).

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used write 0s to bits 9-7.

### 24.6.2.3 I2CSTR Register (Offset = 2h) [reset = 0h]

I2CSTR is shown in [Figure 24-20](#) and described in [Table 24-12](#).

Return to the [Summary Table](#).

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

**Table 24-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field    | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|----------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11  | RSFULL   | R     | 0h    | <p>Receive shift register full bit.</p> <p>RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Overrun detected</p>                            |
| 10  | XSMT     | R     | 0h    | <p>Transmit shift register empty bit.</p> <p>XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Underflow detected (empty)</p> <p>1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events:</p> <ul style="list-style-type: none"> <li>- Data is written to I2CDXR.</li> <li>- The I2C module is reset</li> </ul> |
| 9   | AAS      | R     | 0h    | <p>Addressed-as-slave bit</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the 7-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or by a slave address different from the I2C peripheral's own slave address.</p> <p>1h (R/W) = The I2C module has recognized its own slave address or an address of all zeros (general call).</p>                                                                                                                                                                                                                                                                    |
| 8   | AD0      | R     | 0h    | <p>Address 0 bits</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = AD0 has been cleared by a START or STOP condition.</p> <p>1h (R/W) = An address of all zeros (general call) is detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7   | RESERVED | R     | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 6   | BYTESENT | R/W1C | 0h    | <p>Byte Transmit over indication.</p> <p>BYTESENT is set when the master/slave has successfully sent the byte on SCL/SDA lines. This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- It is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The I2C module has completed the transmission of a byte.</p>                        |

**Table 24-12. I2CSTR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|-------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | SCD   | R/W1C | 0h    | <p>Stop condition detected bit.</p> <p>SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit.</li> <li>- SCD is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = A STOP condition has been detected on the I2C bus.</p>                                                                                      |
| 4   | XRDY  | R     | 0h    | <p>Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data.</p> <p>FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead.</p> <p>FCM=1: XRDY is asserted only when next data is required it gets de asserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR.</p> <p>1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR.</p> <p>XRDY is also forced to 1 when the I2C module is reset.</p> |
| 3   | RRDY  | R/W1C | 0h    | <p>Receive-data-ready interrupt flag bit.</p> <p>When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. See the Clock Divider Registers section of the Introduction for details.</p> <p>Note: These bits must be set to a non-zero value for proper I2C clock generation.</p> <p>Reset type: SYSRSn</p> |

### 24.6.2.6 I2CCNT Register (Offset = 5h) [reset = 0h]

I2CCNT is shown in [Figure 24-23](#) and described in [Table 24-15](#).

Return to the [Summary Table](#).

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.

The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

**Figure 24-23. I2CCNT Register**

### 24.6.2.7 I2CDRR Register (Offset = 6h) [reset = 0h]

I2CDRR is shown in [Figure 24-24](#) and described in [Table 24-16](#).

Return to the [Summary Table](#).

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.

If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.

When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

### 24.6.2.8 I2CSAR Register (Offset = 7h) [reset = 3FFh]

I2CSAR is shown in [Figure 24-25](#) and described in [Table 24-17](#).

Return to the [Summary Table](#).

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used write 0s to bits 9-7.

### 24.6.2.9 I2CDXR Register (Offset = 8h) [reset = 0h]

I2CDXR is shown in [Figure 24-26](#) and described in [Table 24-18](#).

Return to the [Summary Table](#).

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR.

After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.

When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

#### 24.6.2.10 I2CMR Register (Offset = 9h) [reset = 0h]

I2CMR is shown in [Figure 24-27](#) and described in [Table 24-19](#).

Return to the [Summary Table](#).

The I2C mode register (I2CMR) is a 16-bit register that contains the control bits of the I2C module.

The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR).</p> <p>1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7   | RM    | R/W  | 0h    | <p>Repeat mode bit (only applicable when the I2C module is a master-transmitter).</p> <p>The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module.</p> <p>1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.</p>                                                                                                                             |

**Table 24-19. I2CMDR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | DLB   | R/W  | 0h    | <p>Digital loopback mode bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Digital loopback mode is disabled.</p> <p>1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1.</p> <p>In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where:</p> $n = ((I2C \text{ input clock frequency} / \text{module clock frequency}) \times 8)$ <p>The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR.</p> <p>Note: The free data format (FDF = 1) is not supported in the digital loopback mode.</p>                                                                                                                                                                                                                                                                                                 |
| 5   | IRS   | R/W  | 0h    | <p>I2C module reset bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values.</p> <p>1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 4   | STB   | R/W  | 0h    | <p>START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module is not in the START byte mode.</p> <p>1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates:</p> <ol style="list-style-type: none"> <li>1. A START condition</li> <li>2. A START byte (0000 0001b)</li> <li>3. A dummy acknowledge clock pulse</li> <li>4. A repeated START condition</li> </ol> <p>Then, as normal, the I2C module sends the slave address that is in I2CSAR.</p> |
| 3   | FDF   | R/W  | 0h    | <p>Free data format mode bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit.</p> <p>1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5.</p> <p>The free data format is not supported in the digital loopback mode (DLB=1).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Bit | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-0 | BC    | R/W  | 0h    | <p>Bit count bits.</p> <p>BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits.</p> <p>Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 8 bits per data byte<br/> 1h (R/W) = 1 bit per data byte<br/> 2h (R/W) = 2 bits per data byte<br/> 3h (R/W) = 3 bits per data byte<br/> 4h (R/W) = 4 bits per data byte<br/> 5h (R/W) = 5 bits per data byte<br/> 6h (R/W) = 6 bits per data byte<br/> 7h (R/W) = 7 bits per data byte</p> |

### 24.6.2.11 I2CISRC Register (Offset = Ah) [reset = 0h]

I2CISRC is shown in [Figure 24-28](#) and described in [Table 24-20](#).

Return to the [Summary Table](#).

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

**Figure 24-28. I2CISRC Register**

### 24.6.2.13 I2CPSC Register (Offset = Ch) [reset = 0h]

I2CPSC is shown in [Figure 24-30](#) and described in [Table 24-22](#).

Return to the [Summary Table](#).

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.

IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

**Figure 24-30. I2CPSC Register**

#### 24.6.2.14 I2CFFTX Register (Offset = 20h) [reset = 0h]

I2CFFTX is shown in [Figure 24-31](#) and described in [Table 24-23](#).

Return to the [Summary Table](#).

The I2C transmit FIFO register (I2CFFTX) is a 16-bit register that contains the I2C FIFO mode enable bit as well as the control and status bits for the transmit FIFO mode of operation on the I2C peripheral.

**Figure 24-31. I2CFFTX Register**

| 4-0 | TXFFIL | R/W  | 0h    | <p>Transmit FIFO interrupt level.</p> <p>These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels.</p> <p>Reset type: SYSRSn</p> |

### 24.6.2.15 I2CFFRX Register (Offset = 21h) [reset = 0h]

I2CFFRX is shown in [Figure 24-32](#) and described in [Table 24-24](#).

Return to the [Summary Table](#).

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

**Figure 24-32. I2CFFRX Register**

## Power Management Bus Module (PMBus)

---

---

This chapter describes the features and operation of the Power Management Bus (PMBus) module.

## 25.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. PMBus is based on SMBus, which uses a similar physical layer to I2C. This guide assumes the reader is familiar with the PMBus, SMBus, and I2C bus specifications.

### 25.1.1 Features

The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for master and slave modes
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100 kHz
  - Fast Mode: Up to 400 kHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Slave address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

### 25.1.2 Functional Description

The following figure shows the block diagram for PMBus.

**Figure 25-1. PMBus Module Conceptual Block Diagram**

The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, it also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals: SCL, SDA, CONTROL, and ALERT.

- SCL is the bus clock. It is normally controlled by the master, but may be held low by a slave to delay a transaction and allow more time for processing.
- SDA is the bidirectional data line.
- CONTROL is a slave input that can trigger an interrupt. It can be used to tell a slave device to shut down.
- ALERT is a slave output/master input that allows a slave to request attention from the master.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set via the PMBTIMCLK register to provide a bit clock of 10 MHz or less.

## 25.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 25.3 Slave Mode Operation

This section describes the configuration and operation of the PMBus module in slave mode.

### 25.3.1 Configuration

To configure the module, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate slave mode, set the SLAVE\_EN bit in the PMBCTRL register. Next, set up the PMBSC register. The following options are configurable:

- Slave address and mask (SLAVE\_ADDR and SLAVE\_MASK): Sets the slave address and mask for message acceptance.
- Manual slave address acknowledgement (MAN\_SLAVE\_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the slave address and mask.
- PEC enable (PEC\_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgement (MAN\_CMD): Similar to manual slave acknowledgement, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX\_BYTE\_ACK\_CNT): This is normally set to the max value, which allows the entire receive buffer to be used. However, smaller values may be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgement is done by writing a one to the PMBACK register. Even with automatic acknowledgement, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes must be acknowledged. The PMBus module will stretch the clock (hold it low) until an ACK is issued. The module will then pull the data line low and release the clock, providing the ACK signal to the master.

If the complete message or the last part of the message is less than 4 bytes (or the RX\_BYTE\_ACK\_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit will send a NACK. This may only be done when the module is waiting for an acknowledgement. If a zero is written at any other time, the NACK will be issued during the next message.

### 25.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in slave mode. It is oriented toward the most efficient mode of operation – with automatic address and command acknowledgment. It is also oriented toward having Packet Error Checking (PEC) enabled.

If automatic address acknowledgement is disabled, all messages will start by setting the SLAVE\_ADDR\_READY register bit high. Read commands will have two instructions one for the read, and one for the write. If automatic command acknowledgement is enabled, the DATA\_READY bit will be set high, as well. If the message has no PEC, the number of bytes available will be n-1. For example, with PEC, a QUICK COMMAND will have one byte. With no PEC, a QUICK COMMAND will have zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

#### 25.3.2.1 Quick Command

Quick Commands received by the PMBus module in slave mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMB\_HSA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

**Figure 25-2. Quick Command Message**

|   |               |    |   |   |
|---|---------------|----|---|---|
| S | Slave address | RW | A | P |
|---|---------------|----|---|---|

### 25.3.2.2 Send Byte

A Send Byte message consists of the device address, a single data byte and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBSC register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module

**Figure 25-3. Send Byte Message with and without PEC**

|   |               |    |   |         |   |   |
|---|---------------|----|---|---------|---|---|
| S | Slave address | Wr | A | Byte #0 | A | P |
|---|---------------|----|---|---------|---|---|

|   |               |    |   |         |   |     |   |   |
|---|---------------|----|---|---------|---|-----|---|---|
| S | Slave address | Wr | A | Byte #0 | A | PEC | A | P |
|---|---------------|----|---|---------|---|-----|---|---|

The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte will be stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register will indicate one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register will indicate two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD\_BYTE\_COUNT) register will contain a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

### 25.3.2.3 Receive Byte

A Receive Byte message consists of the device address, a single data byte and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the slave address. The data byte to be sent to the master is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBSC register are set to a value of one. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBSC register is set to '1', along with the Enable PEC bit (bit 15). The module will automatically append the calculated PEC byte at the completion of the message.

**Figure 25-4. Receive Byte Message with and without PEC**

|   |               |    |   |         |    |   |
|---|---------------|----|---|---------|----|---|
| S | Slave address | Rd | A | Byte #0 | NA | P |
|---|---------------|----|---|---------|----|---|

|   |               |    |   |         |   |     |    |   |
|---|---------------|----|---|---------|---|-----|----|---|
| S | Slave address | Rd | A | Byte #0 | A | PEC | NA | P |
|---|---------------|----|---|---------|---|-----|----|---|

### 25.3.2.4 Write Byte/Word

The Write Byte and Write Word messages consist of a slave address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBSC register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

**Figure 25-5. Write Byte and Write Word Messages with and without PEC**

|   |               |    |   |         |   |         |   |   |
|---|---------------|----|---|---------|---|---------|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | P |
|---|---------------|----|---|---------|---|---------|---|---|

|   |               |    |   |         |   |         |   |     |   |   |
|---|---------------|----|---|---------|---|---------|---|-----|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | PEC | A | P |
|---|---------------|----|---|---------|---|---------|---|-----|---|---|

|   |               |    |   |         |   |         |   |         |   |   |
|---|---------------|----|---|---------|---|---------|---|---------|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | Byte #1 | A | P |
|---|---------------|----|---|---------|---|---------|---|---------|---|---|

|   |               |    |   |         |   |         |   |         |   |     |   |   |
|---|---------------|----|---|---------|---|---------|---|---------|---|-----|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | Byte #1 | A | PEC | A | P |
|---|---------------|----|---|---------|---|---------|---|---------|---|-----|---|---|

In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the master. The PMBus module holds SCL low until the firmware responds to the received data.

In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgement back to the master.

The Write Byte message will look exactly the same as the Send Byte, except the RD\_BYTE\_COUNT register will contain a 3. The Write Word message will have a RD\_BYTE\_COUNT of 4.

### 25.3.2.5 Read Byte/Word

The Read Byte and Read Word messages consist of a slave address, a command word, received data bytes from a slave, and an optional PEC byte. Address and command acknowledgment is configured through the PMBSC register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and slave address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBSC register. If PEC processing is enabled, the Transmit PEC bit should also be asserted. An EOM interrupt indicates completion of the message to the Master.

**Figure 25-6. Read Byte and Read Word Messages with and without PEC**

|   |               |    |   |         |   |    |               |    |   |
|---|---------------|----|---|---------|---|----|---------------|----|---|
| S | Slave address | Wr | A | Command | A | Sr | Slave address | Rd | A |
|---|---------------|----|---|---------|---|----|---------------|----|---|

|         |    |   |
|---------|----|---|
| Byte #0 | NA | P |
|---------|----|---|

|   |               |    |   |         |   |    |               |    |   |
|---|---------------|----|---|---------|---|----|---------------|----|---|
| S | Slave address | Wr | A | Command | A | Sr | Slave address | Rd | A |
|---|---------------|----|---|---------|---|----|---------------|----|---|

|         |   |     |    |   |
|---------|---|-----|----|---|
| Byte #0 | A | PEC | NA | P |
|---------|---|-----|----|---|

|   |               |    |   |         |   |    |               |    |   |
|---|---------------|----|---|---------|---|----|---------------|----|---|
| S | Slave address | Wr | A | Command | A | Sr | Slave address | Rd | A |
|---|---------------|----|---|---------|---|----|---------------|----|---|

|         |   |         |    |   |
|---------|---|---------|----|---|
| Byte #0 | A | Byte #1 | NA | P |
|---------|---|---------|----|---|

|   |               |    |   |         |   |    |               |    |   |
|---|---------------|----|---|---------|---|----|---------------|----|---|
| S | Slave address | Wr | A | Command | A | Sr | Slave address | Rd | A |
|---|---------------|----|---|---------|---|----|---------------|----|---|

|         |   |         |   |     |    |   |
|---------|---|---------|---|-----|----|---|
| Byte #0 | A | Byte #1 | A | PEC | NA | P |
|---------|---|---------|---|-----|----|---|

When the repeated start (Sr) signal is received, the Data Ready bit will be asserted with a RD\_BYTE\_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit will be asserted. If data has already been written to the PMTXBUF register before the Device Addr is received, the Data Request bit will not be asserted. So if group commands are also expected, it is necessary to read the Data Ready with a RD\_BYTE\_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If it is an EOM, the command should be processed as a group send byte. If it is a Data Request, the command should be processed as a read. Depending on the command, it could be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits could possibly be set between polling intervals. This should be considered in the design of the firmware.

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. It is also necessary to make sure that the values in the PMBSC register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX\_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes should be written to PMBTXBUF at the same time. After the master receives the message, it will NACK the last byte to indicate that the correct number of bytes have been received. This will cause the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

### 25.3.2.6 Process Call

The Process Call protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgement is configured through the PMBSC register. In automatic mode, following receipt of the repeated start and slave address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the master can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the master. If PEC processing is enabled, the Transmit PEC bit within the PMBSC register is asserted. The EOM interrupt will indicate the read word portion of the Process Call message has been completed by the module

**Figure 25-7. Process Call Message with and without PEC**

### 25.3.2.7 Block Write

The Block Write protocol is similar to Write Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module will drive the clock line low, stalling the bus. The data ready interrupts will continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

**Figure 25-8. Block Write Message with and without PEC**

### 25.3.2.8 Block Read

The Block Read protocol is similar to a Read Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated slave address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the master can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module will issue a data request interrupt and hold SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

Block read starts the same as Read Word or Read Byte, but TX\_COUNT is loaded with a 4 the first time, and TX\_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the master is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX\_COUNT and then writes the 4 bytes to PMBTXBUF. TX\_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX\_PEC bit, and writes the data to PMBTXBUF. The PMBus module will write out the data, followed by the PEC, and then the EOM bit will be set when the master NACKs the PEC.

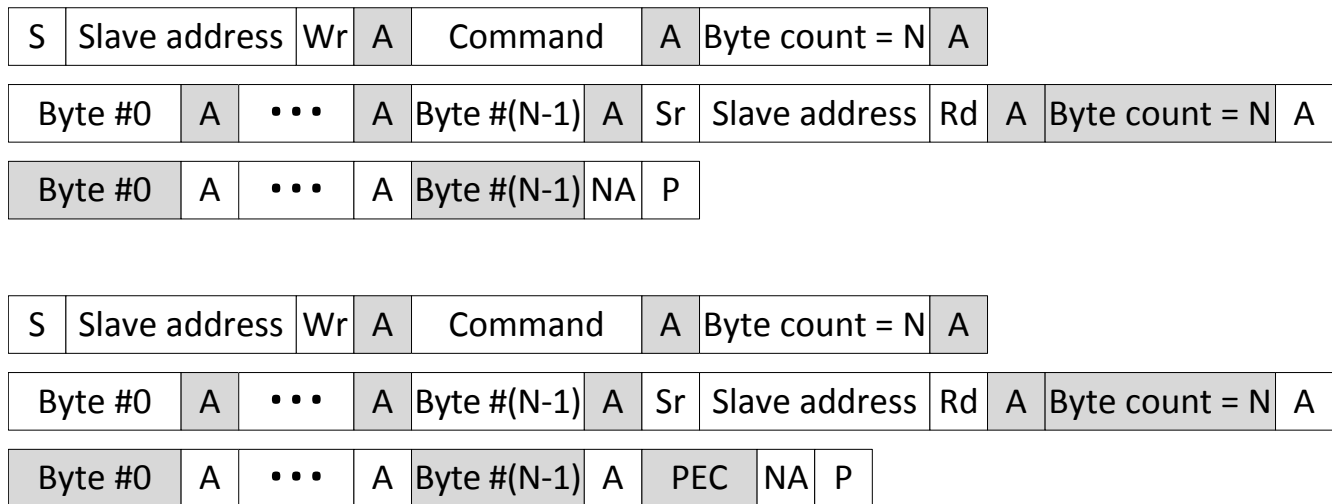

**Figure 25-9. Block Read Message with and without PEC**

### 25.3.2.9 Block Write-Block Read Process Call

The Block Read-Block Write Process Call protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgement of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware will be required to load transmit data to send to the master. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the master.

**Figure 25-10. Block Write-Block Read Process Call Message with and without PEC**

#### 25.3.2.10 Alert Response

The Alert Response Message is utilized when the master detects an alert condition from a slave on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgement to the master and sends the programmed slave address within the PMBSC register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module will clear the alert condition and enable bit within the PMBCTRL register.

**Figure 25-11. Alert Response Message**

In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired slave address back to the master. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the master.

#### 25.3.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte/Write Word messages, the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte should hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

**Figure 25-12. Extended Command Write Byte and Write Word Messages with and without PEC**

|----|---------------|----|---|---------|---|---------|---|-----|----|---|

For the Extended Command Read Byte/Read Word messages, the module will generate a data ready and data request interrupt following reception of the repeated device address. The two command bytes will be found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware will be required to load transmit data to complete the message back to the master.

### 25.3.2.12 Group Command

The PMBus module supports the Group Command Protocol. The Group Command Protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware should wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

**Figure 25-14. Group Command Message with and without PEC**

For Group Commands, the data ready bit will be set as soon as the repeated start is received. The data can then be read into memory. But the data should not be acted upon until the EOM bit is set, which will occur when all of the messages have been received. Other than this delayed EOM, there is no difference for the slave firmware in receiving a Group Command than any other write message.

## 25.4 Master Mode Operation

This section describes the configuration and operation of the PMBus module in master mode.

## 25.4.1 Configuration

First, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate master mode, set the MASTER\_EN bit and clear the SLAVE\_EN bit in the PMBCTRL register. For each transaction, set up the PMBMC register. The following options are configurable:

- Slave address (SLAVE\_ADDR): Sets the slave address for the next transaction.
- PEC enable (PEC\_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT\_CMD): When set, uses two bytes for commands.
- Command code enable (CMD\_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE\_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP\_CMD and PRC\_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBMC register will start a transfer.

Manual acknowledgement of received data is not needed.

## 25.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

### 25.4.2.1 Quick Command

Quick commands are initiated in master mode by simply programming the desired slave device address into the PMBMC. The byte count within the PMBMC register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module will monitor the slave acknowledgement of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

**Figure 25-15. Quick Command Message**

### 25.4.2.2 Send Byte

A Send Byte message consists of the device address, a single data byte and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the slave is loaded into bits 7-0 of the PMBTXBUF register. The PMBMC register is configured with the device address. To transmit a PEC byte with the message, the PEC\_EN bit within the PMBMC register is asserted high when the address is programmed.

**Figure 25-16. Send Byte Message with and without PEC**

After programming the PMBMC register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the slave properly acknowledged the transmitted data.

### 25.4.2.3 Receive Byte

A Receive Byte message consists of the device address, a single data byte and an optional PEC byte. Data is being read from the slave in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC\_EN into the PMBMC register. The R/W bit is enabled high to indicate a read message type (data transmitted from slave to master).

**Figure 25-17. Receive Byte Message with and without PEC**

|   |               |    |   |         |    |   |
|---|---------------|----|---|---------|----|---|
| S | Slave address | Rd | A | Byte #0 | NA | P |
|---|---------------|----|---|---------|----|---|

|   |               |    |   |         |   |     |    |   |
|---|---------------|----|---|---------|---|-----|----|---|
| S | Slave address | Rd | A | Byte #0 | A | PEC | NA | P |
|---|---------------|----|---|---------|---|-----|----|---|

After programming the PMBMC register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper slave acknowledgement of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC\_EN was asserted in the PMBMC register, the PEC\_VALID bit in the PMBSTS register is also checked to ensure a proper PEC byte was received from the slave with the received data.

### 25.4.2.4 Write Byte/Word

The Write Byte and Write Word messages consist of a device address, a command byte, transmitted data bytes and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding slave module. Similar to the Send Byte protocol, the PMBMC register is configured to send 1 or 2 bytes, the CMD\_EN bit is set to enable command byte transmission and the optional PEC\_EN bit is set.

**Figure 25-18. Write Byte and Write Word Messages with and without PEC**

|   |               |    |   |         |   |         |   |   |
|---|---------------|----|---|---------|---|---------|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | P |
|---|---------------|----|---|---------|---|---------|---|---|

|   |               |    |   |         |   |         |   |     |   |   |
|---|---------------|----|---|---------|---|---------|---|-----|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | PEC | A | P |
|---|---------------|----|---|---------|---|---------|---|-----|---|---|

|   |               |    |   |         |   |         |   |         |   |   |
|---|---------------|----|---|---------|---|---------|---|---------|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | Byte #1 | A | P |
|---|---------------|----|---|---------|---|---------|---|---------|---|---|

|   |               |    |   |         |   |         |   |         |   |     |   |   |
|---|---------------|----|---|---------|---|---------|---|---------|---|-----|---|---|
| S | Slave address | Wr | A | Command | A | Byte #0 | A | Byte #1 | A | PEC | A | P |
|---|---------------|----|---|---------|---|---------|---|---------|---|-----|---|---|

With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the slave. The data byte(s) are programmed into bits 15-8 and bits 23-16.

After programming the PMBMC register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the slave acknowledged the message properly.

### 25.4.2.5 Read Byte/Word

The Read Byte and Read Word messages consist of a device address, a command byte, received data bytes from a slave and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the slave. Similar to the Receive Byte Protocol, the PMBMC register is configured to receive 1 or 2 bytes, the CMD\_EN bit is set and the PEC\_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module will automatically terminate the message after the expected number of bytes is received from the slave or if the slave does not properly acknowledge any portion of the message.

**Figure 25-19. Read Byte and Read Word Messages with and without PEC**

In addition to programming the PMBMC register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the slave will be found in the PMBRXBUF register.

### 25.4.2.6 Process Call

The Process Call protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the slave as an option to the message protocol. The PMBMC register includes a PRC\_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module will automatically generate a repeated start condition and initiate the Read Word portion of the message when the process call bit is enabled.

**Figure 25-20. Process Call Message with and without PEC**

To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBMC register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register should indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the Slave acknowledgment of the transmit data. If PEC processing is enabled, the PEC\_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the slave during the Read Word part of the message.

The PRC\_CALL bit within the PMBMC register must be disabled for the next non-Process Call message. Please note that any write to the PMBMC register initiates a message, so reconfiguration of the master is not recommended until the firmware requires a new message to be transmitted.

#### 25.4.2.7 Block Write

The Block Write protocol is similar to a Write Word in its structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the slave.

To initiate a Block Write message on the bus, the PMBMC register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module will automatically insert the block length into the message if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first three data bytes following the block length.

**Figure 25-21. Block Write Message with and without PEC**

Following programming of the PMBMC register, the Block Write message is transmitted. If the block length exceeds three bytes, the PMBus module will provide a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware will utilize all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the slave accepted the block of write data.

#### 25.4.2.8 Block Read

The Block Read protocol is similar to a Read Word in its structure, with the exception that there are more than 2 data bytes received from the slave. The first data byte transmitted by the slave represents the block length of the data being written by the slave. If PEC processing is enabled, the slave appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBMC register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any slave address and the block length bytes in the message. The command byte to be transmitted to the slave is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBMC register.

**Figure 25-22. Block Read Message with and without PEC**

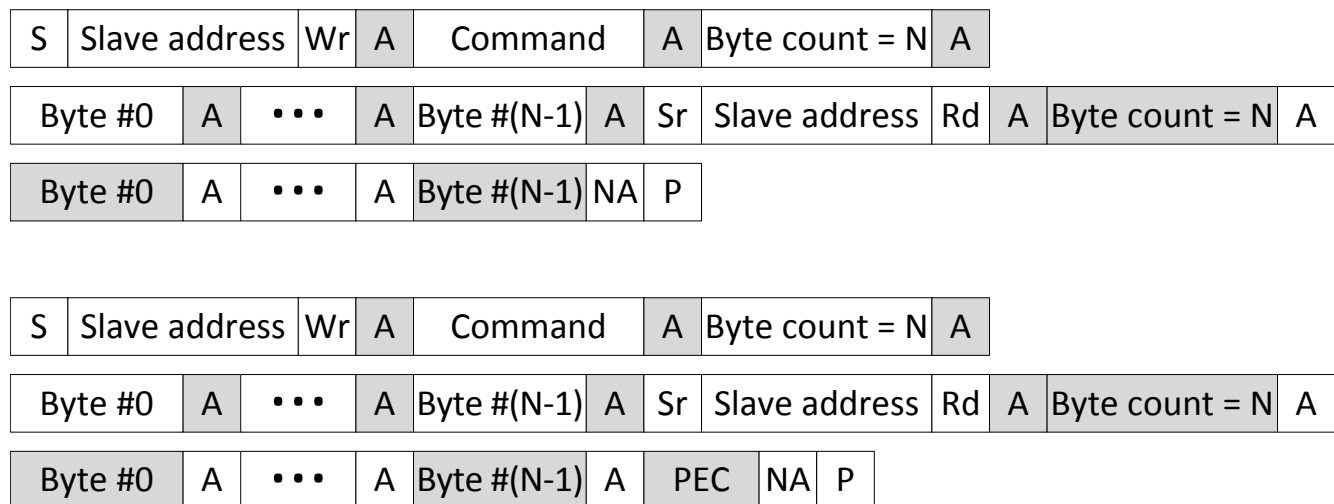

After configuring the PMBMC register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the slave. If the block length is 3, the EOM interrupt will be received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware may verify the received PEC upon detection of the End of Message interrupt.

#### 25.4.2.9 Block Write-Block Read Process Call

The Block Read-Block Write Process Call protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the master is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBMC register provides the length of the Block Write portion of the message. In addition, the PRC\_CALL bit within the PMBMC register must be enabled. Upon completion of the Block Write part of the message, the PMBus module will automatically issue a Repeated Start condition on the PMBus and start transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as it would be in a simple Block Read Message.

**Figure 25-23. Block Write-Block Read Process Call Message with and without PEC**

#### 25.4.2.10 Alert Response

The Alert Response Message is utilized when the master detects an alert condition from a slave. In master mode, the Alert Response Message is simply a Receive Byte message with PEC disable and the slave address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (slave desires to communicate with master). Programming the PMBMC register with the Alert Response address initiates the Alert Response message and provides the device address of the slave requesting service. The device address will be found in the PMBRXBUF register following receipt of the EOM interrupt.

**Figure 25-24. Alert Response Message**

#### 25.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT\_CMD bit within the PMBMC register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Read Byte, Read Word, Write Byte and Write Word protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and slave address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module will interpret the EXT\_CMD bit and make the appropriate format changes.

**Figure 25-25. Extended Command Write Message with and without PEC**

### 25.4.2.12 Group Command

The Group Command Protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP\_CMD bit within the PMBMC register must be set when programming the slave address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBMC register. The PMBus module will send a repeated start on the bus and begin the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP\_CMD bit when programming the PMBMC register.

**Figure 25-27. Group Command Message with and without PEC**

## 25.5 PMBus Registers

This section describes the Power-Management Bus module Registers.

### 25.5.1 PMBus Base Addresses

**Table 25-1. PMBus Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| PmbusaRegs       | PMBUS_REGS    | 0x0000_6400   | 0x0000_641F |

## 25.5.2 PMBUS\_REGS Registers

Table 25-2 lists the PMBUS\_REGS registers. All register offset addresses not listed in Table 25-2 should be considered as reserved locations and the register contents should not be modified.

**Table 25-2. PMBUS\_REGS Registers**

| Offset | Acronym           | Register Name                           | Write Protection | Section            |
|--------|-------------------|-----------------------------------------|------------------|--------------------|
| 0h     | PMBMC             | PMBUS Master Mode Control Register      | EALLOW           | <a href="#">Go</a> |
| 2h     | PMBTXBUF          | PMBUS Transmit Buffer                   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 25-3 shows the codes that are used for access types in this section.

**Table 25-3. PMBUS\_REGS Access Type Codes**

| Access Type                     | Code   | Description                                                                                                                                                                                                                                                                          |

| -n                              |        | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |        |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |        | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |        | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 25.5.2.1 PMBMC Register (Offset = 0h) [reset = 0h]

PMBMC is shown in [Figure 25-28](#) and described in [Table 25-4](#).

Return to the [Summary Table](#).

PMBUS Master Mode Control Register

| 15-8  | BYTE_COUNT | R/W  | 0h    | Indicates number of data bytes transmitted in current message. Byte count does not include any device addresses, command words or block lengths in block messages. In block messages, the PMBus Interface automatically inserts the block length into the message based on the byte count setting. The firmware only needs to load the address, command words and data to be transmitted. PMBus Interface supports byte writes up to 255 bytes.<br>Reset type: SYSRSn |
| 7-1   | SLAVE_ADDR | R/W  | 0h    | Specifies the address of the slave to which the current message is directed towards.<br>Reset type: SYSRSn                                                                                                                                                                                                                                                                                                                                                            |

## Controller Area Network (CAN)

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol which efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information about this module can be found in the following document(s):

- [Calculator for CAN Bit Timing Parameters](#)

## 26.1 Introduction

This device uses the CAN IP known as DCAN.

### 26.1.1 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1 Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines
- DMA support

---

**NOTE:** For a CAN bit clock of 100 MHz, the smallest bit rate possible is 3.90625 kbps.

---

---

**NOTE:** Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data manual) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

---

### 26.1.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests as well as the generation of interrupts or DMA requests.

The register set of the CAN may be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

### 26.1.3 Block Diagram

Figure 26-1. CAN Block Diagram

#### 26.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 11898-1 protocol functions.

#### 26.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

### 26.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

### 26.1.3.4 Registers and Message Object Access (IFx)

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through Interface registers.

Three Interface register sets control the CPU read and write accesses to the Message RAM. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also [Section 26.14](#). The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

## 26.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

## 26.3 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses. It is recommended to only use 32-bit accesses to the CAN registers using the `HWREG_BP()` macro which uses the `__byte_peripheral_32()` intrinsic. If 16-bit accesses are to be used, the lower 16 bits should be written to the register's address, and the upper 16 bits should be written to the register's address, plus 2.

Because of the bus bridge, the view of the CAN module's register space through a Code Composer Studio (CCS) memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses should be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view.; odd addresses from the module are not displayed.

**Table 26-1. CAN Register Access From Software**

| CAN Register Space |           |            | C28x 8 Bit            |            |

## 26.4 Operating Modes

### 26.4.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN\_CTL register), by hardware reset, or by going bus-off. While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high). The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

To initialize the CAN Controller, the CPU has to configure the CAN Bit timing and those message objects which have to be used for CAN communication. Message objects which are not needed, can be deactivated with their MsgVal bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and CCE bits in the CAN Control register are set.

Clearing the Init bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before it can take part in bus activities and start the message transfer. For more details see [Section 26.13](#).

The initialization of the message objects is independent of the Init bit; however, all message objects should be configured to particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering will be applied to it when the modified message object number is same or smaller than the previously found message object. This assures data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

### 26.4.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for communication.

Received messages are stored into their appropriate message objects if they pass acceptance filtering. The whole message (MSGID, DLC, and up to eight data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority. Messages may be updated or set to 'not valid' at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

#### 26.4.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed

By default, this automatic retransmission is enabled. It can be disabled by setting the DAR bit in the CAN Control register. Further details to this mode are provided in [Section 26.12.3](#).

#### 26.4.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module will stay in bus-off state.

The CAN provides an automatic auto-bus-on feature which is enabled by the ABO bit. If set, the CAN will automatically start the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

---

**NOTE:** If the CAN module goes Bus-Off due to multiple CAN bus errors, it stops all bus activities and automatically sets the *Init* bit. Once the *Init* bit is cleared by the application (or due to the auto-bus-on feature), the device will wait for 129 occurrences of Bus Idle (equal to  $129 * 11$  consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the *Init* bit. At the end of the bus-off recovery sequence, the error counters will be reset. After the *Init* bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

---

#### 26.4.3 Test Modes

The CAN module provides several test modes which are mainly intended for self-test purposes. The diagram below aids in understanding the various test modes. It should be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. For the sake of brevity, this diagram does not include the GPIO muxing or the I/O buffers.

The diagram shows a grey rectangular block labeled **DCAN**. Inside this block, there is a blue rectangular block labeled **CAN Core**. Above the DCAN block, there are two labels: **CAN\_TX** and **CAN\_RX**. An upward-pointing arrow connects the **CAN\_TX** label to the **CAN Core** block, with a red **=1** label next to it. A downward-pointing arrow connects the **CAN\_RX** label to the **CAN Core** block. Inside the **CAN Core** block, there are two labels: **Tx** and **Rx**. A horizontal line connects the **Tx** and **Rx** labels, and a vertical line connects the **Rx** label to the downward-pointing arrow from the **CAN\_RX** label.

### 26.4.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN\_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 26-4 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in loopback mode. Loopback mode can be activated by setting bit **LBack** in the CAN\_TEST register to 1.

---

**NOTE:** In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see [Section 26.4.3.3](#).

---

**Figure 26-4. CAN Core in Loopback Mode**

### 26.4.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to the CAN Core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the **ExL** bit in Test Register to 1.

Figure 26-5 shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in external loopback mode.

---

**NOTE:** When loopback mode is active (LBack bit set), the ExL bit will be ignored.

---

**Figure 26-5. CAN Core in External Loopback Mode**

#### 26.4.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN\_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN\_TX pin.

Figure 26-6 shows the connection of the signals CAN\_TX and CAN\_RX to the CAN Core in case of the combination of loopback mode with silent mode.

**Figure 26-6. CAN Core in Loopback Combined with Silent Mode**

## 26.5 Multiple Clock Source

The CAN bit timing clock is normally derived from the system clock (SYSCLK). If desired, the bit clock can be derived directly from the external clock source (XTAL).

The System Control chapter of this document and the device data manual provide for more information on how to configure the relevant clock source registers in the system module.

---

**NOTE:** The CAN core has to be programmed to at least eight clock cycles per bit time. To achieve a transfer rate of 1 Mbps an oscillator frequency of 8 MHz or higher has to be used.

---

## 26.6 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt register. When no interrupt is pending, the register will hold the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk and LEC by reading the Error and Status Register, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID / INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine which reads the message from the interrupt source, may also read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 Command register). When IntPnd is cleared, the Interrupt register will point to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN\_GLB\_INT\_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt via CAN\_GLB\_INT\_CLR and PIEACK.

### 26.6.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in [Section 26.15.1](#). Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

### 26.6.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN\_CTL Register.

### 26.6.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN\_CTL register.

### 26.6.4 PIE Nomenclature for DCAN Interrupts

[Table 26-3](#) shows the PIE nomenclature for the interrupts.

**Table 26-3. PIE Nomenclature for Interrupts**

| Interrupt | CANA   | CANB   |
|-----------|--------|--------|
| CANINT0   | CANA_0 | CANB_0 |
| CANINT1   | CANA_1 | CANB_1 |

### 26.6.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in [Figure 26-7](#) and [Figure 26-8](#).

**Figure 26-7. CAN Interrupt Topology 1**

Figure 26-8. CAN Interrupt Topology 2

## 26.7 DMA Functionality

The CAN module provides three DMA trigger outputs, one for each of the three Interface Registers IF1, IF2 and IF3. These can be enabled using the DE1, DE2, and DE3 bits in the CAN\_CTL register.

The Update of IF1 and IF2 registers will be initiated by a write access to the IF1 and IF2 Command registers, respectively. Once enabled, setting the DMAActive bit in the IF1CMD or IF2CMD registers will cause a DMA request the next time the corresponding interface becomes available.

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update. That is, when IF3 DMA requests are enabled, all IF3 updates will trigger a DMA request.

When a DCAN internal IFx update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers; that is, DMA requests are cleared after the first read or write access to an IF register set.

## 26.8 Parity Check Mechanism

The CAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in Message RAM, one parity bit will be calculated.

Parity information is stored in the Message RAM on write accesses and will be checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN Control register. In case of a disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the CAN. A parity bit will be set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

### 26.8.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object will be checked. If a parity error is detected, the PER bit in the Error and Status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

## 26.9 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit will wait until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect. Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization (see [Section 26.15.3](#)).

---

**NOTE:** During debug mode, the Message RAM cannot be accessed via the IFx register sets.

---

---

**NOTE:** Writing to control registers in Debug mode may influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers (clear of DMA Active flag by r/w)

## 26.10 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects should be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see [Section 26.11](#).

For the configuration of the Bit Timing, see [Section 26.13.2](#).

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to '0' by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted via the CAN bus.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication may be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with `IntPnd = '1'`. It is updated even if the interrupt lines to the CPU are disabled (`IE0 / IE1` are zero).

The CPU may poll all MessageObject's `NewDat` and `TxRqst` bits in parallel from the `NewData` registers and the `Transmission Request` registers. Polling can be made easier if all `Transmit Objects` are grouped at the low numbers; all `Receive Objects` are grouped at the high numbers.

## 26.11 Configuration of Message Objects

The entire Message RAM should to be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

### 26.11.1 Configuration of a Transmit Object for Data Frames

Figure 26-9 shows how a transmit object can be initialized.

**Figure 26-9. Initialization of a Transmit Object**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE | TxIE  | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|------|-------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | 0    | appl. | 0      | appl. | 0      |

- The arbitration bits (`ID[28:0]` and `Xtd` bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (`Xtd = '0'`), it is programmed to `ID[28:18]`. In this case, `ID[17:0]` can be ignored.
- The data registers (`DLC[3:0]` and `Data0-7`) are given by the application. `TxRqst` and `RmtEn` should not be set before the data is valid.
- If the `TxIE` bit is set, the `IntPnd` bit will be set after a successful transmission of the message object.
- If the `RmtEn` bit is set, a matching received remote frame will cause the `TxRqst` bit to be set; the remote frame will autonomously be answered by a data frame.
- The Mask bits (`Msk[28:0]`, `UMask`, `MXtd`, and `MDir` bits) may be used (`UMask='1'`) to allow groups of remote frames with similar identifiers to set the `TxRqst` bit. The `Dir` bit should not be masked. For details see [Section 26.12.8](#). Identifier masking must be disabled (`UMask = '0'`) if no remote frames are allowed to set the `TxRqst` bit (`RmtEn = '0'`).

### 26.11.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting `TxRqst` for a receive object will cause the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### 26.11.3 Configuration of a Single Receive Object for Data Frames

Figure 26-10 shows how a receive object for data frames can be initialized.

**Figure 26-10. Initialization of a Single Receive Object for Data Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 0   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

- The arbitration bits (`ID[28:0]` and `Xtd` bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (`Xtd = '0'`), it is programmed to `ID[28:18]`. In this case, `ID[17:0]` can be ignored. When a data frame with an 11-bit Identifier is received, `ID[17:0]` will be set to '0'.
- When the message handler stores a data frame in the message object, it will store the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.
- The mask bits (`Msk[28:0]`, `UMask`, `MXtd`, and `MDir` bits) may be used (`UMask = '1'`) to allow groups of data frames with similar identifiers to be accepted. The `Dir` bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored data frame.

- If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = '1') for acceptance filtering.

#### 26.11.4 Configuration of a Single Receive Object for Remote Frames

Figure 26-11 shows how a receive object for remote frames can be initialized.

**Figure 26-11. Initialization of a single Receive Object for Remote Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

- Receive objects for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer, see [Section 26.11.5](#).
- UMask must be set to '1'. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details see [Section 26.12.8](#).
- The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.
- If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

#### 26.11.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to zero. The EoB bits of the last message object of a FIFO buffer is set to one, configuring it as the end of the block.

### 26.12 Message Handling

When initialization is finished, the CAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages are accepted for the same message object will be overwritten. Messages may be read interrupt-driven or after polling of NewDat.

#### 26.12.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).

- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 26.12.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 26.12.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN Control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching Transmit Object the RmtEn bit is set.

#### 26.12.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MsgVal nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see [Section 26.12.3](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

#### 26.12.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

---

**NOTE:** After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

---

#### 26.12.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

#### 26.12.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 26.12.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

1. Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'  
The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'  
The remote frame is ignored, this message object remains unchanged.
3. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'  
The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

### 26.12.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface registers, the data consistency is guaranteed by the message handler state machine.

Typically the CPU will write 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

### 26.12.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

### 26.12.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is '1'.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is '0' the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to '0', all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = '1') and therefore overwrite previous messages in this message object.

### 26.12.12 Reading from a FIFO Buffer

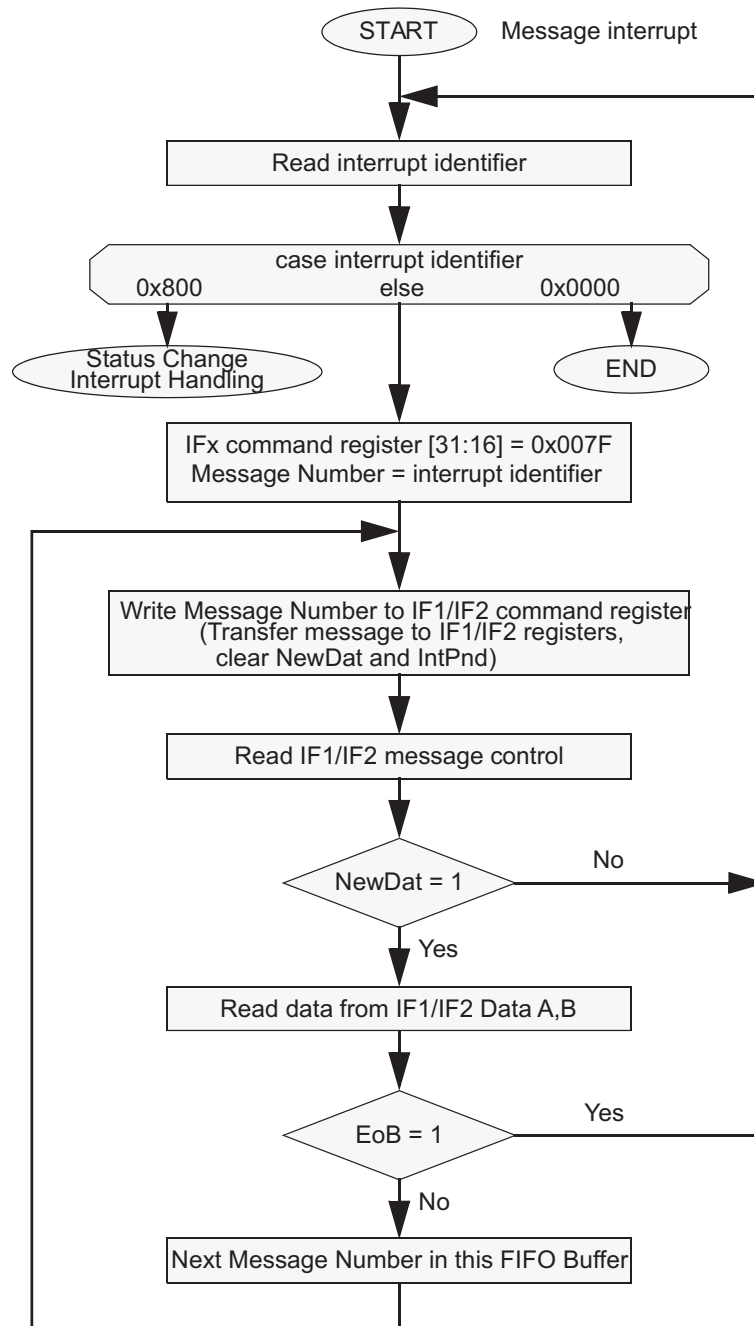

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer. A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared. A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 26-12](#).

---

**NOTE:** All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality cannot be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

---

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

**Figure 26-12. CPU Handling of a FIFO Buffer (Interrupt Driven)**

## 26.13 CAN Bit Timing

The CAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ( $F_{osc}$ ) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range ( $df$ ), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### 26.13.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 26-13):

- Synchronization Segment (Sync\_Seg)
- Propagation Time Segment (Prop\_Seg)
- Phase Buffer Segment 1 (Phase\_Seg1)
- Phase Buffer Segment 2 (Phase\_Seg2)

**Figure 26-13. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the CAN\_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate} / \text{Prescaler} / \text{CAN\_CLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 26-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

**Table 26-4. Programmable Ranges Required by CAN Protocol**

| Parameter                        | Range           | Remark                                             |
|----------------------------------|-----------------|----------------------------------------------------|
| Sync_Seg                         | 1 $t_q$ (fixed) | Synchronization of bus input to CAN_CLK            |
| Prop_Seg                         | [1 ... 8] $t_q$ | Compensates for the physical delay times           |
| Phase_Seg1                       | [1 ... 8] $t_q$ | May be lengthened temporarily by synchronization   |
| Phase_Seg2                       | [1 ... 8] $t_q$ | May be shortened temporarily by synchronization    |
| Synchronization Jump Width (SJW) | [1 ... 4] $t_q$ | May not be longer than either phase buffer segment |

**NOTE:** For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

### 26.13.1.1 Synchronization Segment

The Synchronization Segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, its distance to the Sync\_Seg is called the phase error of this edge.

### 26.13.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in [Figure 26-14](#) shows the phase shift and propagation times between two CAN nodes.

**Figure 26-14. The Propagation Time Segment**

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A\_to\_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay(B\_to\_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase\_Seg1. This condition defines the length of Prop\_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase\_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the Bit timing configuration (Prop\_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of  $1 t_q$ , requiring a longer Prop\_Seg.

### 26.13.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase\_Seg1 and Phase\_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync\_Seg, otherwise its distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame only resynchronization is possible.

- Hard Synchronization

After a hard synchronization, the bit time is restarted with the end of Sync\_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes resynchronization is positive, Phase\_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase\_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge which causes resynchronization is negative, Phase\_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase\_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop\_Seg + Phase\_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The "leading" transmitter does not necessarily win the arbitration, therefore the receivers have to synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator's tolerance range.

The examples in [Figure 26-15](#) show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

**Figure 26-15. Synchronization on Late and Early Edges**

In the first example, an edge from recessive to dominant occurs at the end of Prop\_Seg. The edge is "late" since it occurs after the Sync\_Seg. Reacting to the "late" edge, Phase\_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync\_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync\_Seg.

In the second example, an edge from recessive to dominant occurs during Phase\_Seg2. The edge is "early" since it occurs before a Sync\_Seg. Reacting to the "early" edge, Phase\_Seg2 is shortened and Sync\_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync\_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync\_Seg when synchronizing on an "early" edge because it cannot subsequently redefine that time quantum of Phase\_Seg2 where the edge occurs to be the Sync\_Seg.

The examples in [Figure 26-16](#) show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop\_Seg and has the length of (Prop\_Seg + Phase\_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 26-16. Filtering of Short Dominant Spikes**

#### 26.13.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with

$$(1 - df) \cdot f_{nom} \leq f_{osc} \leq (1 + df) \cdot f_{nom}$$

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both shall be met):

(11)

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\_time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time}$$

(12)

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8  $\mu$ s) with a bus length of 40 m.

### 26.13.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 26-17).

Figure 26-17. Structure of the CAN Core's CAN Protocol Controller

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, for example, SJW (functional range of [1...4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values)  $[TSEG1 + TSEG2 + 3] t_q$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$ .

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP.

The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is  $0 t_q$  for the CAN.

Generally, the IPT is CAN controller specific, but may not be longer than  $2 t_q$ . The IPT length is the lower limit of the programmed length of Phase\_Seg2. In case of a synchronization, Phase\_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

### 26.13.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

**NOTE:** 8 MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the Baud Rate Prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{CAN\_CLK}$ . Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop\_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is 1  $t_q$  long (fixed), leaving (bit time - Prop\_Seg - 1)  $t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, Phase\_Seg2 = Phase\_Seg1, else Phase\_Seg2 = Phase\_Seg1 + 1.

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0...2]  $t_q$ .

The length of the synchronization jump width is set to its maximum value, which is the minimum of 4 and Phase\_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Section 26.13.1.4](#).

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

(Phase\_Seg2-1)&(Phase\_Seg1+Prop\_Seg-1)&

(SynchronizationJumpWidth-1)&(Prescaler-1)

### 26.13.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN\_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

|                           |        |   |                                             |
|---------------------------|--------|---|---------------------------------------------|
| $t_q$                     | 100 ns | = | $t_{\text{CAN\_CLK}}$                       |
| delay of bus driver       | 90 ns  | = |                                             |
| delay of receiver circuit | 40 ns  | = |                                             |
| delay of bus line (40m)   | 220 ns | = |                                             |
| $t_{\text{Prop}}$         | 700 ns | = | $2 \cdot \text{delays} = 7 \cdot t_q$       |
| $t_{\text{SJW}}$          | 100 ns | = | $1 \cdot t_q$                               |
| $t_{\text{TSeg1}}$        | 800 ns | = | $t_{\text{Prop}} + t_{\text{SJW}}$          |
| $t_{\text{TSeg2}}$        | 100 ns | = | Information Processing Time + $1 \cdot t_q$ |
| $t_{\text{Sync-Seg}}$     | 100 ns | = | $1 \cdot t_q$                               |

|                       |         |   |                                                                                                   |
|-----------------------|---------|---|---------------------------------------------------------------------------------------------------|
| bit time              | 1000 ns | = | $t_{\text{Sync-Seg}} + t_{\text{Tseg1}} + t_{\text{Tseg2}}$                                       |
| tolerance for CAN_CLK | 0.35 %  | = | $\frac{\min(T_{\text{seg1}}, T_{\text{seg2}})}{2((13 \times \text{bit time}) - T_{\text{seg2}})}$ |
|                       |         | = | $\frac{0.1 \mu\text{s}}{2((13 \times 1 \mu\text{s}) - 0.1 \mu\text{s})}$                          |

In this example, the concatenated bit time parameters are  $(1-1)_3 \& (8-1)_4 \& (1-1)_2 \& (1-1)_6$ , so the Bit Timing Register is programmed to = 0x00000700.

### 26.13.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN\_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

|                           |                  |   |                                                                                                   |
|---------------------------|------------------|---|---------------------------------------------------------------------------------------------------|
| $t_q$                     | 1 $\mu\text{s}$  | = | $2 \cdot t_{\text{CAN\_CLK}}$                                                                     |
| delay of bus driver       | 200 ns           | = |                                                                                                   |
| delay of receiver circuit | 80 ns            | = |                                                                                                   |
| delay of bus line (40m)   | 220 ns           | = |                                                                                                   |
| $t_{\text{Prop}}$         | 1 $\mu\text{s}$  | = | $1 \cdot t_q$                                                                                     |
| $t_{\text{SJW}}$          | 4 $\mu\text{s}$  | = | $4 \cdot t_q$                                                                                     |
| $t_{\text{Tseg1}}$        | 5 $\mu\text{s}$  | = | $t_{\text{Prop}} + t_{\text{SJW}}$                                                                |
| $t_{\text{Tseg2}}$        | 4 $\mu\text{s}$  | = | Information Processing Time + $4 \cdot t_q$                                                       |
| $t_{\text{Sync-Seg}}$     | 1 $\mu\text{s}$  | = | $1 \cdot t_q$                                                                                     |
| bit time                  | 10 $\mu\text{s}$ | = | $t_{\text{Sync-Seg}} + t_{\text{Tseg1}} + t_{\text{Tseg2}}$                                       |
| tolerance for CAN_CLK     | 1.58 %           | = | $\frac{\min(T_{\text{seg1}}, T_{\text{seg2}})}{2((13 \times \text{bit time}) - T_{\text{seg2}})}$ |
|                           |                  | = | $\frac{4 \mu\text{s}}{2((13 \times 10 \mu\text{s}) - 4 \mu\text{s})}$                             |

In this example, the concatenated bit time parameters are  $(4-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$ , so the Bit Timing register is programmed to = 0x000034C1.

## 26.14 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modify-write cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see [Section 26.15.1](#)) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

That being said, there is one condition that can cause a write access to the message RAM to be lost. If `MsgVal = 1` for the message object which is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM may be lost. The reason for this is that it might happen that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when it is in the process of receiving a message for the same message object.

To avoid this issue with receive mail boxes, reset `MsgVal` before changing any of the following: `Id28-0`, `Xtd`, `Dir`, `DLC3-0`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`.

To avoid this issue with transmit mail boxes, reset `MsgVal` before changing any of the following: `Dir`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`. Other fields not listed above, like `Data`, may be changed without fear of losing a write to the message RAM.

### 26.14.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register will be overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register will be copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see [Figure 26-18](#) ).

**Figure 26-18. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### 26.14.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA will be requested. The DMA request stays active until the first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in the CAN Control register.

---

**NOTE:** The IF3 register set can not be used for transferring data into message objects.

---

## 26.15 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed via the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

### 26.15.1 Structure of Message Objects

Figure 26-19 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 26-19. Structure of a Message Object**

| Message Object |           |      |      |          |        |        |        |        |        |        |        |        |
|----------------|-----------|------|------|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| UMask          | Msk[28:0] | MXtd | MDir | EoB      | unused | NewDat | MsgLst | RxIE   | TxIE   | IntPnd | RmtEn  | TxRqst |
| MsgVal         | ID[28:0]  | Xtd  | Dir  | DLC[3:0] | Data 0 | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 | Data 7 |

**Table 26-5. Message Object Field Descriptions**

| Name      | Value                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 26-5. Message Object Field Descriptions (continued)**

| Name     | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DLC[3:0] | 0-8<br>9-15 | Data length code<br>Data frame has 0-8 data bytes.<br>Data frame has 8 data bytes.<br>Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.                                                  |
| Data 0   |             | 1st data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 1   |             | 2nd data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 2   |             | 3rd data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 3   |             | 4th data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 4   |             | 5th data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 5   |             | 6th data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 6   |             | 7th data byte of a CAN data frame                                                                                                                                                                                                                                                                                                                                                                                |
| Data 7   |             | 8th data byte of a CAN data frame<br>Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values. |

### 26.15.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) \* 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

**NOTE:** '0' is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

Message Object number 1 has the highest priority.

**Table 26-6. Message RAM Addressing in Debug Mode**

| Message Object Number      | Offset From Base Address | Word Number | Debug Mode <sup>(1)</sup> |
|----------------------------|--------------------------|-------------|---------------------------|
| last implemented (here:32) | 0x0000                   | 1           | Parity                    |
|                            | 0x0004                   | 2           | MXtd,MDir,Mask            |
|                            | 0x0008                   | 3           | Xtd,Dir,ID                |
|                            | 0x000C                   | 4           | Ctrl                      |
|                            | 0x0010                   | 5           | Data Bytes 3-0            |
|                            | 0x0014                   | 6           | Data Bytes 7-4            |
| 1                          | 0x0020                   | 1           | Parity                    |
|                            | 0x0024                   | 2           | MXtd,MDir,Mask            |
|                            | 0x0028                   | 3           | Xtd,Dir,ID                |
|                            | 0x002C                   | 4           | Ctrl                      |
|                            | 0x0030                   | 5           | Data Bytes 3-0            |
|                            | 0x0034                   | 6           | Data Bytes 7-4            |

<sup>(1)</sup> See [Section 26.15.3](#).

**Table 26-6. Message RAM Addressing in Debug Mode (continued)**

| Message Object Number | Offset From Base Address | Word Number | Debug Mode <sup>(1)</sup> |
|-----------------------|--------------------------|-------------|---------------------------|
| 2                     | 0x0040                   | 1           | Parity                    |
|                       | 0x0044                   | 2           | MXtd,MDir,Mask            |
|                       | 0x0048                   | 3           | Xtd,Dir,ID                |
|                       | 0x004C                   | 4           | Ctrl                      |

### 26.15.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

**NOTE:** During debug mode, the Message RAM cannot be accessed via the IFx register sets.

**Figure 26-20. Message RAM Representation in Debug Mode**

## 26.16 CAN Registers

This section describes the Controller Area Network registers.

### 26.16.1 CAN Base Addresses

**Table 26-7. CAN Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| CanaRegs         | CAN_REGS      | 0x0004_8000   | 0x0004_87FF |
| CanbRegs         | CAN_REGS      | 0x0004_A000   | 0x0004_A7FF |

## 26.16.2 CAN\_REGS Registers

Table 26-8 lists the CAN\_REGS registers. All register offset addresses not listed in Table 26-8 should be considered as reserved locations and the register contents should not be modified.

**Table 26-8. CAN\_REGS Registers**

| Offset | Acronym         | Register Name                          | Write Protection | Section            |
|--------|-----------------|----------------------------------------|------------------|--------------------|
| 0h     | CAN_CTL         | CAN Control Register                   |                  | <a href="#">Go</a> |

| i,j,k,l,m,n                     |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 26.16.2.1 CAN\_CTL Register (Offset = 0h) [reset = 1401h]

CAN\_CTL is shown in [Figure 26-21](#) and described in [Table 26-10](#).

Return to the [Summary Table](#).

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

**Figure 26-21. CAN\_CTL Register**

### 26.16.2.2 CAN\_ES Register (Offset = 4h) [reset = 7h]

CAN\_ES is shown in [Figure 26-22](#) and described in [Table 26-11](#).

Return to the [Summary Table](#).

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

| 2-0 | LEC   | R    | 7h    | <p>Last Error Code</p> <p>The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register.</p> <p>0 No Error</p> <p>1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node.</p> <p>4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'.</p> <p>Reset type: SYSRSn</p> |

### 26.16.2.3 CAN\_ERRC Register (Offset = 8h) [reset = 0h]

CAN\_ERRC is shown in [Figure 26-23](#) and described in [Table 26-12](#).

Return to the [Summary Table](#).

This register reflects the value of the Transmit and Receive error counters

**Figure 26-23. CAN\_ERRC Register**

### 26.16.2.4 CAN\_BTR Register (Offset = Ch) [reset = 2301h]

CAN\_BTR is shown in [Figure 26-24](#) and described in [Table 26-13](#).

Return to the [Summary Table](#).

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN\_CLK periods.

The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.</p> <p>Reset type: SYSRSn</p> |

### 26.16.2.6 CAN\_TEST Register (Offset = 14h) [reset = 0h]

CAN\_TEST is shown in [Figure 26-26](#) and described in [Table 26-15](#).

Return to the [Summary Table](#).

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

Note: Setting Tx[1:0] other than '00' will disturb message transfer.

Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

**Figure 26-26. CAN\_TEST Register**

### 26.16.2.7 CAN\_PERR Register (Offset = 1Ch) [reset = 100h]

CAN\_PERR is shown in [Figure 26-27](#) and described in [Table 26-16](#).

Return to the [Summary Table](#).

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism

it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

**Figure 26-27. CAN\_PERR Register**

### 26.16.2.8 CAN\_RAM\_INIT Register (Offset = 40h) [reset = 5h]

CAN\_RAM\_INIT is shown in [Figure 26-28](#) and described in [Table 26-17](#).

Return to the [Summary Table](#).

This register is used to initialize the Mailbox RAM. It clears the entire mailbox RAM, including the MsgVal bits.

**Figure 26-28. CAN\_RAM\_INIT Register**

### 26.16.2.12 CAN\_ABOTR Register (Offset = 80h) [reset = 0h]

CAN\_ABOTR is shown in [Figure 26-32](#) and described in [Table 26-21](#).

Return to the [Summary Table](#).

This register is used to introduce a variable delay before the Bus-off recovery sequence is started.

**Figure 26-32. CAN\_ABOTR Register**

| 31-0 | ABO_Time | R/W  | 0h    | <p>Auto-Bus-On Timer</p> <p>Number of clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. "Clock" refers to the input clock to the CAN module. This function has to be enabled by setting bit ABO in CAN Control Register.</p> <p>The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase.</p> <p>NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.</p> <p>NOTE: During Debug mode, running Auto-Bus-On timer will be paused.</p> <p>Reset type: SYSRSn</p> |

### 26.16.2.13 CAN\_TXRQ\_X Register (Offset = 84h) [reset = 0h]

CAN\_TXRQ\_X is shown in [Figure 26-33](#) and described in [Table 26-22](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN\_TXRQ\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

### 26.16.2.14 CAN\_TXRQ\_21 Register (Offset = 88h) [reset = 0h]

CAN\_TXRQ\_21 is shown in [Figure 26-34](#) and described in [Table 26-23](#).

Return to the [Summary Table](#).

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

### 26.16.2.15 CAN\_NDAT\_X Register (Offset = 98h) [reset = 0h]

CAN\_NDAT\_X is shown in [Figure 26-35](#) and described in [Table 26-24](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN New Data 21 Register (CAN\_NDAT\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the NewDat bits of these mailboxes are set, the corresponding bit in this register will be set.

**Figure 26-35. CAN\_NDAT\_X Register**

### 26.16.2.16 CAN\_NDAT\_21 Register (Offset = 9Ch) [reset = 0h]

CAN\_NDAT\_21 is shown in [Figure 26-36](#) and described in [Table 26-25](#).

Return to the [Summary Table](#).

This register holds the NewDat bits of all mailboxes. By reading out the NewDat bits, the CPU can check for which mailboxes the data portion was updated. The NewDat bit of a specific mailbox can be set/reset by the CPU via the IFx "Message Interface" Registers or by the Message Handler after reception of a Data Frame or after a successful transmission.

**Figure 26-36. CAN\_NDAT\_21 Register**

### 26.16.2.17 CAN\_IPEN\_X Register (Offset = ACh) [reset = 0h]

CAN\_IPEN\_X is shown in [Figure 26-37](#) and described in [Table 26-26](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Interrupt Pending 21 Register (CAN\_IPEN\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the IntPnd bits of these mailboxes are set, the corresponding bit in this register will be set.

### 26.16.2.18 CAN\_IPEN\_21 Register (Offset = B0h) [reset = 0h]

CAN\_IPEN\_21 is shown in [Figure 26-38](#) and described in [Table 26-27](#).

Return to the [Summary Table](#).

This register holds the IntPnd bits of the mailboxes. By reading out these bits, the CPU can check for pending interrupts in the mailboxes. The IntPnd bit of a specific mailbox can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

**Figure 26-38. CAN\_IPEN\_21 Register**

### 26.16.2.20 CAN\_MVAL\_21 Register (Offset = C4h) [reset = 0h]

CAN\_MVAL\_21 is shown in [Figure 26-40](#) and described in [Table 26-29](#).

Return to the [Summary Table](#).

This registers hold the MsgVal bits of all mailboxes. By reading out the MsgVal bits, the CPU can check which mailbox is valid. The MsgVal bit of a specific mailbox can be set/reset by the CPU via the IF1/2 "Message Interface" Registers.

**Figure 26-40. CAN\_MVAL\_21 Register**

### 26.16.2.21 CAN\_IP\_MUX21 Register (Offset = D8h) [reset = 0h]

CAN\_IP\_MUX21 is shown in [Figure 26-41](#) and described in [Table 26-30](#).

Return to the [Summary Table](#).

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

**Figure 26-41. CAN\_IP\_MUX21 Register**

### 26.16.2.22 CAN\_IF1CMD Register (Offset = 100h) [reset = 1h]

CAN\_IF1CMD is shown in [Figure 26-42](#) and described in [Table 26-31](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 26.16.2.23 CAN\_IF1MSK Register (Offset = 104h) [reset = FFFFFFFFh]

CAN\_IF1MSK is shown in [Figure 26-43](#) and described in [Table 26-32](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

**Figure 26-43. CAN\_IF1MSK Register**

### 26.16.2.24 CAN\_IF1ARB Register (Offset = 108h) [reset = 0h]

CAN\_IF1ARB is shown in [Figure 26-44](#) and described in [Table 26-33](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 26.16.2.25 CAN\_IF1MCTL Register (Offset = 10Ch) [reset = 0h]

CAN\_IF1MCTL is shown in [Figure 26-45](#) and described in [Table 26-34](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.

### 26.16.2.26 CAN\_IF1DATA Register (Offset = 110h) [reset = 0h]

CAN\_IF1DATA is shown in [Figure 26-46](#) and described in [Table 26-35](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 26.16.2.27 CAN\_IF1DATB Register (Offset = 114h) [reset = 0h]

CAN\_IF1DATB is shown in [Figure 26-47](#) and described in [Table 26-36](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

**Figure 26-47. CAN\_IF1DATB Register**

### 26.16.2.28 CAN\_IF2CMD Register (Offset = 120h) [reset = 1h]

CAN\_IF2CMD is shown in [Figure 26-48](#) and described in [Table 26-37](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 26.16.2.29 CAN\_IF2MSK Register (Offset = 124h) [reset = FFFFFFFFh]

CAN\_IF2MSK is shown in [Figure 26-49](#) and described in [Table 26-38](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

**Figure 26-49. CAN\_IF2MSK Register**

### 26.16.2.30 CAN\_IF2ARB Register (Offset = 128h) [reset = 0h]

CAN\_IF2ARB is shown in [Figure 26-50](#) and described in [Table 26-39](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 26.16.2.31 CAN\_IF2MCTL Register (Offset = 12Ch) [reset = 0h]

CAN\_IF2MCTL is shown in [Figure 26-51](#) and described in [Table 26-40](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.

**Figure 26-51. CAN\_IF2MCTL Register**

### 26.16.2.32 CAN\_IF2DATA Register (Offset = 130h) [reset = 0h]

CAN\_IF2DATA is shown in [Figure 26-52](#) and described in [Table 26-41](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 26.16.2.34 CAN\_IF3OBS Register (Offset = 140h) [reset = 0h]

CAN\_IF3OBS is shown in [Figure 26-54](#) and described in [Table 26-43](#).

Return to the [Summary Table](#).

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

### 26.16.2.36 CAN\_IF3ARB Register (Offset = 148h) [reset = 0h]

CAN\_IF3ARB is shown in [Figure 26-56](#) and described in [Table 26-45](#).

Return to the [Summary Table](#).

The bits of the IF3 Arbitration Register mirrors the arbitration bits of a message object.

**Figure 26-56. CAN\_IF3ARB Register**

### 26.16.2.37 CAN\_IF3MCTL Register (Offset = 14Ch) [reset = 0h]

CAN\_IF3MCTL is shown in [Figure 26-57](#) and described in [Table 26-46](#).

Return to the [Summary Table](#).

The bits of the IF3 Message Control Register mirrors the message control bits of a message object.

**Figure 26-57. CAN\_IF3MCTL Register**

### 26.16.2.38 CAN\_IF3DATA Register (Offset = 150h) [reset = 0h]

CAN\_IF3DATA is shown in [Figure 26-58](#) and described in [Table 26-47](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message.

**Figure 26-58. CAN\_IF3DATA Register**

### 26.16.2.40 CAN\_IF3UPD Register (Offset = 160h) [reset = 0h]

CAN\_IF3UPD is shown in [Figure 26-60](#) and described in [Table 26-49](#).

Return to the [Summary Table](#).

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. Note: IF3 Update enable should not be set for transmit objects.

**Figure 26-60. CAN\_IF3UPD Register**

## ***Local Interconnect Network (LIN)***

This chapter describes the local interconnect network (LIN) module. Since this module can also operate like a conventional serial communications interface (SCI) port, it is referred to as the SCI/LIN module in this document. In SCI compatibility mode, it is functionally compatible to the standalone SCI module. However, since the SCI/LIN module uses a different register/bit structure, code written for this module cannot be directly ported to the standalone SCI module and vice versa.

This module can be configured to operate in either SCI (UART) or LIN mode.

## 27.1 Introduction

The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*. The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The SCI's hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter (UART) that implements the standard non-return to zero format.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-master/multiple-slave with a message identification for multi-cast transmission between any network nodes.

Throughout the chapter, Compatibility Mode refers to SCI Mode functionality of the SCI/LIN Module. [Section 27.2](#) explains about the SCI functionality and [Section 27.3](#) explains about the LIN functionality. Though the registers are common for LIN and SCI, the register descriptions has notes to identify the register/bit usage in different modes.

### 27.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard non-return to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- At 100-MHz peripheral clock, 3.125 Mbits/s is the Max Baud Rate achievable
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Five error flags and Seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multi-buffered receive and transmit units

---

#### NOTE:

- The SCI/LIN module is functionally compatible with C2000 SCI modules, but not directly software compatible due to different register control structures.
  - The SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general purpose I/O pin.
  - The SCI/LIN module does not support isosynchronous mode as there is no SCICLK pin.
-

### 27.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3, 2.0, and 2.1 protocols
- Configurable Baud Rate up to 20 kbps
- Two external pins: LINRX and LINTX.
- Multi-buffered receive and transmit units
- Identification masks for message filtering
- Automatic master header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Slave automatic synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- $2^{31}$  programmable transmission rates with 7 fractional bits
- Wake up on LINRX dominant level from transceiver
- Automatic wake up support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 Interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

### 27.1.3 Block Diagram

The SCI/LIN module contains core SCI block with added sub-blocks to support LIN protocol.

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

**Transmitter (TX)** contains two major registers to perform the double- buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.

#### **Baud Clock Generator**

- A programmable baud generator produces a baud clock scaled from the input clock VCLK

**Receiver (RX)** contains two major registers to perform the double- buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. [Figure 27-1](#) shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multi-buffered receiver and transmitter. The SCI interface, the DMA control subblocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. [Figure 27-2](#) shows the SCI/LIN block diagram.

## 27.2 Serial Communications Interface Module

### 27.2.1 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

#### 27.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 27-3](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 27-3](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 27-3](#) use one stop bit per frame.

**Figure 27-3. Typical SCI Data Frame Formats**

### 27.2.1.2 SCI Timing Mode

The SCI can be configured to use asynchronous timing mode using TIMING MODE bit in SCIGCR1 register.

#### 27.2.1.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises.

Figure 27-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

**Figure 27-4. Asynchronous Communication Bit Timing**

#### 27.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK \text{ Frequency} = \frac{VCLK \text{ Frequency}}{P + 1 + \frac{M}{16}}$$

$$\text{Asynchronous baud value} = \frac{SCICLK \text{ Frequency}}{16}$$

For P = 0,

$$\text{Asynchronous baud value} = \frac{VCLK \text{ Frequency}}{32} \quad (13)$$

**Table 27-1. P and M values for standard bit-rates<sup>(1)</sup>**

| Desired bit rate | Actual bit-rate | Percentage error | P value | M value |
|------------------|-----------------|------------------|---------|---------|
| 115200           | 115207.4        | 0.0064           | 26      | 2       |
| 57600            | 57603.69        | 0.0064           | 53      | 4       |
| 38400            | 38402.46        | 0.0064           | 80      | 6       |
| 19200            | 19201.23        | 0.0064           | 161     | 12      |
| 9600             | 9600.61         | 0.0064           | 324     | 8       |
| 4800             | 4799.85         | 0.0032           | 650     | 1       |
| 2400             | 2400.04         | 0.0016           | 1301    | 1       |
| 1200             | 1199.99         | 0.0008           | 2603    | 1       |

<sup>(1)</sup> For a 100 MHz device, LIN module input clock = 50 MHz

### 27.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see Table 27-3). The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ . If the character length is more than 10, then the modulation table will be a rolled-over version of the original table (Table 27-2), as shown in Table 27-3.

The baud rate will vary over a data field to average according to the BRS[30:28] value by a “d” fraction of the peripheral internal clock:  $0 < d < 1$ . See Figure 27-5 for a simple Average “d” calculation based on “U” value (BRS[30:28]).

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (14)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (15)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

**Table 27-2. Superfractional Bit Modulation for SCI Mode (Normal Configuration) <sup>(1)</sup>**

| BRS[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |

<sup>(1)</sup> VCLK = 50 MHz

<sup>(2)</sup> Values are in decimal except for column 2.

#### 27.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

##### 27.2.1.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. [Figure 27-6](#) illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

**Figure 27-6. Idle-Line Multiprocessor Communication Format**

#### 27.2.1.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. [Figure 27-7](#) illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 27-7. Address-Bit Multiprocessor Communication Format**

### 27.2.1.5 SCI Multi Buffered Mode

To reduce CPU load when Receiving or Transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate receive and transmit buffers. Multi buffered mode is enabled by setting the MBUF MODE bit.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) could occur after transmitting a response.

Figure 27-8 and Figure 27-9 shows the receive and transmit multi-buffer functional block diagram.

Figure 27-8. Receive Buffers

Figure 27-9. Transmit Buffers

## 27.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 27-10](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers respectively.

Each interrupt also has a bit that can be set as interrupt level 0(INT0) or as interrupt level 1(INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 27-10. General Interrupt Scheme**

**Figure 27-11. Interrupt Generation for Given Flags**

### 27.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD before any interrupt gets generated. To transmit further data, data can be written to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 27.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, SET RX DMA must be cleared to select interrupt functionality.

### 27.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 27.2.2.4 Error Interrupts

The following error detection are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register.

There are 16 interrupt sources in the SCI/LIN module, In SCI mode 8 interrupts are supported, as seen in [Table 27-6](#).

**Table 27-6. SCI/LIN Interrupts**

| Offset <sup>(1)</sup> | Interrupt                                  | Applicable to SCI | Applicable to LIN |
|-----------------------|--------------------------------------------|-------------------|-------------------|
| 0                     | No interrupt                               |                   |                   |
| 1                     | Wakeup                                     | Yes               | Yes               |
| 2                     | Inconsistent-sync-field error              | No                | Yes               |
| 3                     | Parity error                               | Yes               | Yes               |
| 4                     | ID                                         | No                | Yes               |
| 5                     | Physical bus error                         | No                | Yes               |
| 6                     | Frame error                                | Yes               | Yes               |
| 7                     | Break detect                               | Yes               | No                |
| 8                     | Checksum error                             | No                | Yes               |
| 9                     | Overrun error                              | Yes               | Yes               |
| 10                    | Bit error                                  | Yes               | Yes               |
| 11                    | Receive                                    | Yes               | Yes               |
| 12                    | Transmit                                   | Yes               | Yes               |
| 13                    | No-response error                          | No                | Yes               |
| 14                    | Timeout after wakeup signal (150 ms)       | No                | Yes               |
| 15                    | Timeout after three wakeup signals (1.5 s) | No                | Yes               |
| 16                    | Timeout (Bus Idle, 4s)                     | No                | Yes               |

<sup>(1)</sup> Offset 1 is the highest priority. Offset 16 is the lowest priority.

**Table 27-7. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| CE       | SCIFLR   | 29  | 0                                |
| ISFE     | SCIFLR   | 28  | 0                                |
| NRE      | SCIFLR   | 27  | 0                                |
| FE       | SCIFLR   | 26  | 0                                |
| OE       | SCIFLR   | 25  | 0                                |
| PE       | SCIFLR   | 24  | 0                                |
| RXWAKE   | SCIFLR   | 12  | 0                                |
| RXRDY    | SCIFLR   | 9   | 0                                |
| BUSY     | SCIFLR   | 3   | 0                                |
| IDLE     | SCIFLR   | 2   | 1                                |
| WAKEUP   | SCIFLR   | 1   | 0                                |
| BRKDT    | SCIFLR   | 0   | 0                                |

<sup>(1)</sup> The flags are frozen with their reset value while SWnRST = 0.

**Table 27-8. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| BE       | SCIFLR   | 31  | 0                                |
| PBE      | SCIFLR   | 30  | 0                                |
| TXWAKE   | SCIFLR   | 10  | 0                                |
| TXEMPTY  | SCIFLR   | 11  | 1                                |
| TXRDY    | SCIFLR   | 8   | 1                                |

<sup>(1)</sup> The flags are frozen with their reset value while SWnRST = 0.

### 27.2.3 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA transfers depending on whether multi-buffer mode bit (MBUF MODE) is enabled or not enabled. See for more information.

#### 27.2.3.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

In Multi-Buffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RX DMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

#### 27.2.3.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

In Multi-Buffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

## 27.2.4 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 27.2.4.1](#) or [Section 27.2.4.2](#)).

### 27.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffer Mode

After a valid idle period is detected, data is automatically received as it arrives on the LINRX pin.

#### 27.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

#### 27.2.4.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, DMA, or interrupt method to read the data. The SCI clears the RXRDY bit after the new data in SCIRD has been read.

#### 27.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffered or Buffered SCI Mode

##### 27.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) or by disabling the transmitter (clear TXENA bit).

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

##### 27.2.4.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. SCI waits for data to be written to the SCITD register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

### 27.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

#### 27.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 27-7](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 27.3 Local Interconnect Network Module

### 27.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls, and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling LIN MODE bit in SCIGCR1 register.

---

**NOTE:** The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10. For the START bit, the first three samples are used.

---

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see [Section 27.6](#).

#### 27.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

- i. Support for LIN 2.0 checksum
- ii. Enhanced synchronizer FSM support for frame processing
- iii. Enhanced handling of extended frames
- iv. Enhanced baud rate generator
- v. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package Revision 1.3 and 2.0* by hardware.

The Master Mode of LIN module is compatible with LIN 2.1 standard.

### 27.3.1.2 Message Frame

The LIN protocol defines a message frame format, illustrated in Figure 27-12. Each frame includes one master header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces may be 0.

**Figure 27-12. LIN Protocol Message Frame Format: Master Header and Slave Response**

There is no arbitration in the definition of the LIN protocol; therefore, multiple slave nodes responding to a header might be detected as an error.

The LIN bus is a single channel wired-AND. The bus has a binary level: either dominant for a value of 0, or recessive for a value of 1.

#### 27.3.1.2.1 Message Header

The header of a message is initiated by a master (see Figure 27-13) and consists of a three field-sequence:

- The sync break field signaling the beginning of a message
- The sync field conveying bit rate information of the LIN bus
- The ID field denoting the content of a message

**Figure 27-13. Header 3 Fields: Sync Break, Sync, and ID**

### 27.3.1.2.2 Response

The format of the response is as illustrated in [Figure 27-14](#). There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

**Figure 27-14. Response Format of LIN Message Frame**

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames ([Section 27.3.1.6](#)). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see [Table 27-9](#), or by LENGTH value in SCIFORMAT[18:16] register; see [Table 27-10](#). The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

**Table 27-9. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than 1.3**

| ID5 | ID4 | Number of Data bytes |
|-----|-----|----------------------|
| 0   | 0   | 2                    |
| 0   | 1   | 2                    |
| 1   | 0   | 4                    |
| 1   | 1   | 8                    |

**Table 27-10. Response Length with SCIFORMAT[18:16] Programming**

| SCIFORMAT[18:16] | No. of Bytes |
|------------------|--------------|
| 000              | 1            |

### 27.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between master and slave nodes. It generates the master header data stream, it synchronizes to the LIN bus for responding, and it locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN\_speed value in the LIN description file.

The LIN synchronizer will perform the following functions: master header signal generation, slave detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

### 27.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time  $T_{bit}$ . The bit time is derived from the fields P and M in the baud rate selection register (BRSR). There is an additional 3-bit fractional divider value, field U in the BRSR register, which further fine-tunes the data field baud rate.

The ranges for the prescaler values in the BRSR register are:

$$P = 0, 1, 2, 3, \dots, 2^{24} - 1$$

$$M = 0, 1, 2, \dots, 15$$

$$U = 0, 1, 2, 3, 4, 5, 6, 7$$

The P, M, and U values in the BRSR register are user programmable. The P and M dividers could be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that " $a T_{VCLK}$ " (with  $a = 0,1$ ) is added to each  $T_{bit}$  as explained in [Section 27.3.1.4.2](#). If the ADAPT bit is set and the LIN slave is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as follows:

$$1\text{kHz} \leq F_{LINCLK} \leq 20\text{kHz}$$

All transmitted bits are shifted in and out at  $T_{bit}$  periods.

#### 27.3.1.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time,  $T_{bit}$  is expressed in terms of the VCLK period  $T_{VCLK}$  as follows:

For all P other than 0, and all M,

$$T_{bit} = 16 \left( P + 1 + \frac{M}{16} \right) T_{VCLK} \quad (16)$$

$$\text{For } P = 0 : T_{bit} = 32 T_{VCLK}$$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P + 1 + \frac{M}{16})} \quad \text{For all } P \text{ other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For } P = 0 \quad (17)$$

### 27.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN master mode (sync field + identifier field + response field + checksum field)
- LIN slave mode (response field + checksum field)

#### 27.3.1.4.2.1 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in [Table 27-11](#). The sync field (0x55), the identifier field and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ .

**Table 27-11. Superfractional Bit Modulation for LIN Master Mode and Slave Mode <sup>(1)</sup>**

| BRSR[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |
|-------------|-----------|------|------|------|------|------|------|------|------|----------|
| 0h          | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0        |
| 1h          | 1         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 0        |
| 2h          | 1         | 0    | 0    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 3h          | 1         | 0    | 1    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 4h          | 1         | 0    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 0        |
| 5h          | 1         | 1    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 1        |
| 6h          | 1         | 1    | 1    | 0    | 1    | 1    | 1    | 0    | 1    | 1        |
| 7h          | 1         | 1    | 1    | 1    | 1    | 1    | 1    | 0    | 1    | 1        |

(1)

1. In LIN master mode bit modulation applies to sync field + identifier field + response field
2. In LIN slave mode bit modulation applies to identifier field + response field

The baud rate will vary over a LIN data field to average according to the BRSR[30:28] value by a  $d$  fraction of the peripheral internal clock:  $0 < d < 1$ .

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (18)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (19)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

### 27.3.1.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA will trigger a message header generation and the LIN state machine will handle the generation itself. A master node initiates header generation on CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the master to initiate a LIN communication and consists of three fields: break field, synchronization field, and identification field, as seen in Figure 27-15.

**NOTE:** The LIN protocol uses the parity bits in the identifier. The control length bits are optional to the LIN protocol.

**Figure 27-15. Message Header in Terms of  $T_{bit}$**

- The break field consists of two components:
  - The synchronization break (SYNC BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The sync break length may be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The sync break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNC FIELD) consists of one start bit, byte 0x55, and a stop bit. It is used to convey  $T_{bit}$  information and resynchronize LIN bus nodes.
- The identifier field's ID byte may use six bits as an identifier, with optional length control (see *Note: Optional Control Length Bits*), and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITY\_ENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 27-16 for an illustration of the ID field.

**Figure 27-16. ID Field**

**NOTE: Optional Control Length Bits**

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

**NOTE:** If the LIN module, configured as Slave in multi-buffer mode, is in the process of transmitting data while a new header comes in, the module might end up in responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario the following procedure could be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Sync Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise TD0/TD1 might be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data will be transmitted by the node.

#### 27.3.1.5.1 Event Triggered Frame Handling

The LIN 2.0 protocol uses event-triggered frames that may occasionally cause collisions. Event-triggered frames have to be handled in software.

If no slave answers to an event triggered frame header, the master node will set the NRE flag, and a NRE interrupt will occur if enabled. If a collision occurs, a frame error and checksum error may arise before the NRE error. Those errors are flagged and the appropriate interrupts will occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding slaves. If the slaves are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The bus busy flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision the flag is cleared in the same cycle as the NRE flag is set.

Software could implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the bus busy flag to get set or NRE flag to get set.
- If bus busy flag is not set before NRE flag, then it is a true no response case (no data has been transmitted onto the bus).
- If bus busy flag gets set, then wait for NRE flag to get set or for successful reception. If NRE flag is set, then in this case a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

### 27.3.1.5.2 Header Reception and Adaptive Baud Rate

A slave node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a slave measures the baud rate during detection of the sync field. If ADAPT bit is set, then the measured baud rate is compared to the slave node's programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The LIN synchronizer determines two measurements: BRK\_count and BAUD\_count (Figure 27-17). These values are always calculated during the Header reception for sync field validation (Figure 27-18).

**Figure 27-17. Measurements for Synchronization**

By measuring the values BRK\_count and BAUD\_count, a valid sync break sequence can be detected as described in Figure 27-18. The four numbered events in Figure 27-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the sync break relative to the detecting node  $T_{bit}$ . For a slave node receiving the sync break, a threshold of  $11 T_{bit}$  is used as required by the LIN protocol. For detection of the dominant data stream of the sync break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the sync break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD\_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A slave node can calculate a single  $T_{bit}$  time by division of BAUD\_count by 8. In addition, for consistency between the detected edges the following is evaluated:

$$BAUD\_count + BAUD\_count \gg 2 + BAUD\_count \gg 3 \leq BRK\_count$$

The BAUD\_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a  $T_{bit}$  unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 27-18, if the measured BRK\_count value is less than  $11 T_{bit}$ , the sync break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK\_count and BAUD\_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

**NOTE:** In adaptive mode the MBRS divider should be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a sync break.

The break-threshold relative to the slave node is  $11 T_{bit}$ . The break is  $13 T_{bit}$  as specified in LIN version 1.3.

Figure 27-18. Synchronization Validation Process and Baud Rate Adjustment

If the sync field is not detected within the given tolerances, the inconsistent-sync-field-error (ISFE) flag will be set. An ISFE interrupt will be generated, if enabled by its respective bit in the SCISSETINT register. The ID byte should be received after the sync field validation was successful. Any time a valid break (larger than  $11 T_{bit}$ ) is detected, the receiver's state machine should reset to reception of this new frame. This reset condition is only valid during response state, not if an additional sync break occurs during header reception.

**NOTE:** When an inconsistent sync field (ISFE) error occurs, suggested action for the application is to Reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to their normal states

### 27.3.1.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier will be set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see [Figure 27-19](#). Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

**Figure 27-19. Optional Embedded Checksum in Response for Extended Frames**

An ID interrupt will be generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC will initiate an automatic send of the checksum byte. The last data field should always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see [Figure 27-20](#).

**NOTE:** The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

**Figure 27-20. Checksum Compare and Send for Extended Frames**

### 27.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a master node could flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

#### 27.3.1.7.1 No-Response Error (NRE)

The no-response error will occur when any node expecting a response waits for  $T_{\text{FRAME\_MAX}}$  time and the message frame is not fully completed within the maximum length allowed,  $T_{\text{FRAME\_MAX}}$ . After this time a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{\text{FRAME\_MIN}} = T_{\text{HEADER\_MIN}} + T_{\text{DATA\_FIELD}} + T_{\text{CHECKSUM\_FIELD}} = 44 + 10N$$

where  $N$  = number of data fields.

And the maximum time frame is given by:

$$T_{\text{FRAME\_MAX}} = T_{\text{FRAME\_MIN}} * 1.4 = (44 + 10N) * 1.4$$

The timeout value  $T_{\text{FRAME\_MAX}}$  is derived from the  $N$  number of data fields value. The  $N$  value is either embedded in the header's ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register, will indicate the value for  $N$ .

**NOTE:** The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE will not be handled by the LIN controller hardware.

**Table 27-12. Timeout Values in  $T_{\text{bit}}$  Units**

| N | $T_{\text{DATA\_FIELD}}$ | $T_{\text{FRAME\_MIN}}$ | $T_{\text{FRAME\_MAX}}$ |
|---|--------------------------|-------------------------|-------------------------|
| 1 | 10                       | 54                      | 76                      |
| 2 | 20                       | 64                      | 90                      |

**Table 27-12. Timeout Values in  $T_{\text{bit}}$  Units (continued)**

| N | $T_{\text{DATA\_FIELD}}$ | $T_{\text{FRAME\_MIN}}$ | $T_{\text{FRAME\_MAX}}$ |
|---|--------------------------|-------------------------|-------------------------|
| 3 | 30                       | 74                      | 104                     |
| 4 | 40                       | 84                      | 118                     |
| 5 | 50                       | 94                      | 132                     |
| 6 | 60                       | 104                     | 146                     |
| 7 | 70                       | 114                     | 160                     |
| 8 | 80                       | 124                     | 174                     |

### 27.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 s (this is 80,000  $F_{\text{LINCLK}}$  cycles with the fastest bus rate of 20 kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, then it can be assumed that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

---

**NOTE:** After the timeout was flagged, a SWnRESET should be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame was on the bus before the idle period.

---

### 27.3.1.7.3 Timeout after Wakeup Signal and Timeout after Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup should expect a header from the master within a defined amount of time: timeout after wakeup signal. See [Section 27.4.3](#) for more details.

### 27.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

### 27.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor ensures that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 27-21.

**NOTE:** If a bit occurs due to receiving a header during a slave response, NRE/TIMEOUT flag will not be set for the new frame.

Figure 27-21. TXRX Error Detector

### 27.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a master if no valid message can be generated on the bus (Bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Sync Break can be generated (for example, because of a bus shortage to VBAT) or if no sync break delimiter can be generated (for example, because of a bus shortage to GND). Once the Sync Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

### 27.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm.

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \text{ (even Parity)}$$

$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \text{ (odd Parity)}$$

(20)

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 27.3.1.9 for details.

#### 27.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end if the calculated modulo-256 sum over all received data bytes (including the ID byte if it is the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of its resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see [Figure 27-22](#)) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see [Figure 27-23](#)) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation should always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit will be overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

**Figure 27-22. Classic Checksum Generation at Transmitting Node**

**Figure 27-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node**

### 27.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes will participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in [Figure 27-24](#). During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in [Figure 27-16](#)) to determine whether they transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See [Figure 27-24](#). All nodes compare the received ID to the identifier stored in the ID-SlaveTask BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there will be an ID TX flag and an interrupt will be triggered if enabled in the SCSETINT register.

The masked bits become don't cares for the comparison. To build a mask for a set of identifiers, an XOR function could be used.

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most significant bits (MSBs) and filter 3 least significant bits (LSBs), the acceptance mask could be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07 \quad (21)$$

A mask of all zeros will compare all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF will always cause a match. A mask of all 1s will filter all bits of the received identifier, and thus there will be an ID match regardless of the content of the ID-SlaveTask BYTE field in the LINID register.

---

**NOTE:** When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. A mask of all 0s will compare all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s will filter all bits of the received identifier and there will be no match.

---

#### If HGEN CTRL = 1:

- Received ID is compared with the ID-Slave-Task byte, using the RXID mask and the TXID mask.
- A mask of all ones will always result in a match.
- A mask of all zeroes means all the bits must be the same to result in a match.
- If a mask has some bits which are ones, then those bits will not be used for the filtering criterion.

#### If HGEN CTRL = 0:

- Received ID is compared with the ID byte, using the RXID mask and the TXID mask.
- A mask of all ones will result in no match.
- A mask of all zeroes means all the bits must be the same to result in a match.
- If a mask has some bits which are ones, then those bits will not be used for the filtering criterion.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU may read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

---

**NOTE:** When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

---

In multi-buffer mode, the TXRDY flag will be set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multi-buffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multi-buffer mode, the TXEMPTY flag is set when both the transmit buffer(s) TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In nonmulti-buffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all slave receiving nodes will validate the identifier using all eight bits of the received ID byte. The SCI/LIN will flag a corrupted identifier if an ID-parity error is detected.

**Figure 27-24. ID Reception, Filtering and Validation**

### 27.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. [Figure 27-8](#) illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt will be generated if enabled in the SCISSETINT register.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multi-buffer mode is enabled, or to RD0 if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the ID BYTE field does not convey message length (see *Note: Optional Control Length Bits* in [Section 27.3.1.5](#)), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A receive interrupt, and a receive ready RXRDY flag as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte will be compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multi-buffer mode is enabled or not (MBUF MODE bit).

---

**NOTE:** In multi-buffer mode following are the scenarios associated with clearing the "RXRDY" flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
  2. For LENGTH less than or equal to 4, Read to RD0 register will clear the "RXRDY" flag.
  3. For LENGTH greater than 4, Read to RD1 register will clear the "RXRDY" flag.
- 

### 27.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TXy transmit buffers. Optionally, a DMA transfer could be done on a byte-per-byte basis when multi-buffer mode is not enabled (MBUF MODE bit). [Figure 27-9](#) illustrates the transmit buffers.

The multi-buffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multi-buffer mode is enabled, or from TD0 to SCITXSHF if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in [Section 27.3.1.5](#)), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A transmit interrupt (TX interrupt) and a transmit ready flag (TXRDY flag), as well as a DMA request (TXDMA) could occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multi-buffer mode is enabled or not (MBUF MODE bit).

The checksum byte will be automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multi-buffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

---

**NOTE:** The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLRINT register or by disabling the transmitter via the TXENA bit.

---

### 27.3.2 LIN Interrupts

LIN and SCI mode have a common Interrupt block as explained in [Section 27.2.2](#). There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in [Table 27-6](#).

A LIN message frame indicating the timing and sequence of the LIN interrupts that could occur is shown in [Figure 27-25](#).

**Figure 27-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence**

### 27.3.3 Servicing LIN interrupts

When servicing an interrupt, clear the corresponding flag in the flag register (SCIFLR) before clearing the global interrupt flag (LIN\_GLB\_INT\_CLR). The ISR should follow the guidelines below. This will prevent any spurious or duplicate interrupt from occurring.

- Clear the LIN interrupt flag in the SCIFLR register.
- Read the LIN interrupt status register to make sure the flag is cleared.
- Clear the global interrupt flag bit in LIN\_GLB\_INT\_CLR.

**NOTE:** The transmit interrupt is generated before the LIN transmitter is ready to accept new data. Inside of the LIN transmit ISR, the software should wait until the buffer is completely empty before loading the next data. This can be done by polling for the Bus Busy Flag (SCIFLR.BUSY) to be 0.

### 27.3.4 LIN DMA Interface

LIN DMA Interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multi-buffer mode is enabled or not via the multi-buffer enable control bit (MBUF MODE).

**NOTE:** Do not use the DMA to transmit data to multiple slave IDs. Writing to the LINID register will initiate a new transmission. The DMA will write to the LINID register before the LIN state machine is ready to accept the new ID. Doing so will cause the LIN to miss this transmission.

#### **27.3.4.1 LIN Receive DMA Requests**

In LIN mode, when the multi-buffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled and disabled using the SET RX DMA and CLR RX DMA bits, respectively.

#### **27.3.4.2 LIN Transmit DMA Requests**

In LIN mode with the multi-buffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled and disabled using the SET TX DMA and CLR TX DMA bits, respectively.

### 27.3.5 LIN Configurations

The following list details the configuration steps that software should perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit.
- Clear SWnRST to 0 before configuring the LIN.
- Enable the LINRX and LINTX pins by setting the RX FUNC and TX FUNC bits.
- Select LIN mode by programming LIN MODE bit.
- Select Master or Slave mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multi-buffer mode by programming MBUF MODE bit.
- Select the baud rate to be used for communication by programming BRSR.
- Set the maximum baud rate to be used for communication by programming MBRSR.
- Set the CONT bit to make LIN not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally if needed (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Select the RX ID MASK and the TX ID MASK fields in the LINMASK register.
- Set SWnRST to 1 after the LIN is configured.
- Perform Receive or Transmit data (see [Section 27.3.1.9](#), [Section 27.3.5.1](#), and [Section 27.3.5.2](#)).

---

**NOTE:** If TXENA is set and the SWnRST is released, the LIN will only generate a new DMA request. The LIN hardware will not generate a new Transmit interrupt request. If using interrupts, the first transmission must be started by software by writing the data to transmit followed by writing to LIN TX to initiate the transmission.

---

#### 27.3.5.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The ID RX FLAG is set after a valid LIN ID is received with RX Match. An ID interrupt is generated, if enabled.

##### 27.3.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when it transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit must be set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum will be compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit will be cleared once the checksum is received. A CE will immediately be flagged if there is a checksum error.

#### **27.3.5.1.2 Receiving Data in Multi-Buffer Mode**

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, DMA, or interrupt method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit will be cleared once the checksum is received and compared.

#### **27.3.5.2 Transmitting Data**

The LIN transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The ID TX flag is set after a valid LIN ID is received with TX Match. An ID interrupt is generated, if enabled.

#### **27.3.5.2.1 Transmitting Data in Single-Buffer Mode**

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte will be sent after the current byte transmission. The SC bit will be cleared after the checksum byte has been transmitted.

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

#### 27.3.5.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum will be sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit will be cleared after the checksum byte has been transmitted.

### 27.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The LIN module may enter low-power mode either when there was no activity on the LINRX pin for more than 4s (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal will terminate the sleep mode of the LIN bus.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wake-up interrupt to clear the powerdown bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

---

#### 27.4.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic master request frame with identifier 0x3C (60), with the first data field as 0x00. There should be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

## 27.4.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

**NOTE:** If the wakeup interrupt is disabled then the SCI/LIN enters low-power mode whenever it is requested to do so, but a low level on the receive RX pin does NOT cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal; see Figure 27-26. A slave node that detects the bus in sleep mode, and with a wakeup request pending, will send a wakeup signal. The wakeup signal is a dominant value on the LIN bus for  $T_{WUSIG}$ ; this is at least  $5 T_{bits}$  for the LIN bus baud rates. The wakeup signal is generated by sending an 0xF0 byte containing 5 dominant  $T_{bits}$  and 5 recessive  $T_{bits}$ .

Figure 27-26. Wakeup Signal Generation

$$0.25\text{ms} \leq T_{WUSIG} \leq 5\text{ms} \quad (22)$$

Assuming a perfect bus with no noise or loading effects, a write of 0xF0 to TD0 will load the transmitter to meet the wakeup signal timing requirement for  $T_{WUSIG}$ . Then, setting the GENWU bit will transmit the preloaded value in TD0 for a wakeup signal transmission.

**NOTE:** The GENWU bit can be set/reset only when SWnRST is set to '1' and the node is in power down mode. The bit will be cleared on a valid sync break detection. A master sending a wakeup request, will exit power down mode upon reception of the wakeup pulse. The bit will be cleared on a SWnRST. This can be used to stop a master from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, will translate it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, it will generate a wakeup interrupt if enabled in the SCISSETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150 ms will detect it as a wakeup request. The LIN controller's slave is ready to listen to the bus in less than 100 ms ( $T_{INITIALIZE} < 100\text{ms}$ ) after a dominant-to-recessive edge (end-of-wakeup signal).

### 27.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the master to send a header. If no sync field is detected before 150 ms (3,000 cycles at 20 kHz) after wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5 s (30,000 cycles at 20 kHz) period after three breaks.

---

**NOTE:** To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to assure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup should set the MBRS register accordingly to meet the targeted time as  $128 \text{ Tbits} \times \text{programmed prescaler}$ .

The LIN controller handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

---

## 27.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. When set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register will not have any effect on the flags in the SCIFLR register.

---

**NOTE:** When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

---

## 27.6 SCI/LIN Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in the following sections. Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

### 27.6.1 LIN Base Addresses

**Table 27-13. I2C Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| LinaRegs         | LIN_REGS      | 0000 6A00     | 0000 6AFF   |

## 27.6.2 LIN\_REGS Registers

Table 27-14 lists the LIN\_REGS registers. All register offset addresses not listed in Table 27-14 should be considered as reserved locations and the register contents should not be modified.

**Table 27-14. LIN\_REGS Registers**

| Offset | Acronym         | Register Name                        | Write Protection | Section            |
|--------|-----------------|--------------------------------------|------------------|--------------------|
| 0h     | SCIGCR0         | Global Control Register 0            |                  | <a href="#">Go</a> |
| 4h     | SCIGCR1         | Global Control Register 1            |                  | <a href="#">Go</a> |
| 8h     | SCIGCR2         | Global Control Register 2            |                  | <a href="#">Go</a> |
| Ch     | SCISSETINT      | Interrupt Enable Register            |                  | <a href="#">Go</a> |
| 10h    | SCICLEARINT     | Interrupt Disable Register           |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 27-15 shows the codes that are used for access types in this section.

**Table 27-15. LIN\_REGS Access Type Codes**

| Access Type                   | Code    | Description         |
|-------------------------------|---------|---------------------|
| <b>Read Type</b>              |         |                     |
| R                             | R       | Read                |
| <b>Write Type</b>             |         |                     |
| W                             | W       | Write               |
| W1C                           | W<br>1C | Write<br>1 to clear |
| W1S                           | W<br>1S | Write<br>1 to set   |
| <b>Reset or Default Value</b> |         |                     |

**Table 27-15. LIN\_REGS Access Type  
Codes (continued)**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 27.6.2.1 SCIGCR0 Register (Offset = 0h) [reset = 0h]

SCIGCR0 is shown in [Figure 27-27](#) and described in [Table 27-16](#).

Return to the [Summary Table](#).

The SCIGCR0 register defines the module reset.

**Figure 27-27. SCIGCR0 Register**

### 27.6.2.2 SCIGCR1 Register (Offset = 4h) [reset = 0h]

SCIGCR1 is shown in [Figure 27-28](#) and described in [Table 27-17](#).

Return to the [Summary Table](#).

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

**Figure 27-28. SCIGCR1 Register**

When the extended frame communication is stopped, this bit is cleared automatically.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No effect</p> <p>1h (R/W) = Extended frame communication will be stopped, once current frame transmission/reception is completed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 12  | HGENCTRL     | R/W  | 0h    | <p>HGEN control bit.</p> <p>This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ID filtering using ID-Byte.</p> <p>RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match.</p> <p>1h (R/W) = ID filtering using ID-SlaveTask byte (Recommended).</p> <p>RECEIVEDID and IDSLAVETASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match</p>                                                                                                                                                                                                                                                                                                   |
| 11  | CTYPE        | R/W  | 0h    | <p>Checksum type.</p> <p>This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Classic checksum is used.</p> <p>This checksum is compatible with LIN 1.3 slave nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must always use the classic checksum.</p> <p>1h (R/W) = Enhanced checksum is used.</p> <p>The enhanced checksum is compatible with LIN 2.0 and newer slave nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.</p>                                                                                                                                                                                                                                                   |
| 10  | MBUFMODE     | R/W  | 0h    | <p>Multibuffer mode.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The multi-buffer mode is disabled.</p> <p>1h (R/W) = The multi-buffer mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 9   | ADAPT        | R/W  | 0h    | <p>Adapt mode enable.</p> <p>This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN slave node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register.</p> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Automatic baudrate adjustment is disabled.</p> <p>1h (R/W) = Automatic baudrate adjustment is enabled.</p> |

**Table 27-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | SLEEP      | R/W  | 0h    | <p>SCI sleep.</p> <p>SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode is disabled.</p> <p>1h (R/W) = Sleep mode is enabled.</p> |
| 7   | SWnRST     | R/W  | 0h    | <p>Software reset (active low).</p> <p>This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0.</p> <p>Only the following configuration bits can be changed in runtime (i.e., while SWnRESET = 1):</p> <ul style="list-style-type: none"> <li>- STOP EXT Frame (SCIGCR1[13])</li> <li>- CC bit (SCIGCR2[17])</li> <li>- SC bit (SCIGCR2[16])</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The SCI/LIN is in its reset state no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>1h (R/W) = The SCI/LIN is in its ready state transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.</p>                                                   |
| 6   | LINMODE    | R/W  | 0h    | <p>LIN mode</p> <p>This bit controls the mode of operation of the module.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = LIN mode is disabled<br/>SCI compatibility mode is enabled.</p> <p>1h (R/W) = LIN mode is enabled<br/>SCI compatibility mode is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 5   | CLK_MASTER | R/W  | 0h    | <p>SCI internal clock enable or LIN Master/Slave configuration.</p> <p>In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a slave or master.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Reserved.<br/>LIN mode: The module is in slave mode.</p> <p>1h (R/W) = SCI-compatible mode: Enable clock to the SCI module.<br/>LIN mode: The node is in master mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 27-17. SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | STOP       | R/W  | 0h    | <p>SCI number of stop bits.</p> <p>This bit is effective in SCI-compatible mode only.</p> <p>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = One stop bit is used.</p> <p>1h (R/W) = Two stop bits are used.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| 3   | PARITY     | R/W  | 0h    | <p>SCI parity odd/even selection.</p> <p>This bit is effective in SCI-compatible mode only. If the PARITY ENA bit (SCIGCR1.2) is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</p> <p>1h (R/W) = Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</p> |
| 2   | PARITYENA  | R/W  | 0h    | <p>Parity enable.</p> <p>Enables or disables the parity function.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Parity disabled<br/>no parity bit is generated during transmission or is expected during reception.</p> <p>LIN mode: ID-parity verification is disabled.</p> <p>1h (R/W) = SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception.</p> <p>LIN mode: ID-parity verification is enabled.</p>                                                                                                                                                                                                                                                                                                                                        |
| 1   | TIMINGMODE | R/W  | 0h    | <p>SCI timing mode bit.</p> <p>This bit is effective in SCI-compatible mode only. It must be set to 1 when the SCI mode is used. This bit configures the SCI for asynchronous operation.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Reserved.</p> <p>1h (R/W) = Must be set to 1 when module is configured for SCI operation</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0   | COMMMODE   | R/W  | 0h    | <p>SCI/LIN communication mode bit.</p> <p>In compatibility mode, it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Idle-line mode is used.</p> <p>LIN mode: ID4 and ID5 are not used for length control.</p> <p>1h (R/W) = SCI-compatible mode: Address-bit mode is used.</p> <p>LIN mode: ID4 and ID5 are used for length control.</p>                                                                                                                                                                                                                                                                                                                                                         |

### 27.6.2.3 SCIGCR2 Register (Offset = 8h) [reset = 0h]

SCIGCR2 is shown in [Figure 27-29](#) and described in [Table 27-18](#).

Return to the [Summary Table](#).

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

| 0    | POWERDOWN | R/W  | 0h    | <p>Power down.</p> <p>This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection (more than 4 seconds, i.e. 80,000 cycles at 20kHz)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Normal operation</p> <p>1h (R/W) = Request local low-power mode</p>                                                                             |

#### 27.6.2.4 SCISSETINT Register (Offset = Ch) [reset = 0h]

SCISSETINT is shown in [Figure 27-30](#) and described in [Table 27-19](#).

Return to the [Summary Table](#).

The SCISSETINT register is used to enable the various interrupts available in the LIN module.

### 27.6.2.5 SCICLEARINT Register (Offset = 10h) [reset = 0h]

SCICLEARINT is shown in [Figure 27-31](#) and described in [Table 27-20](#).

Return to the [Summary Table](#).

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISSETINT register.

### 27.6.2.6 SCISSETINTLVL Register (Offset = 14h) [reset = 0h]

SCISSETINTLVL is shown in [Figure 27-32](#) and described in [Table 27-21](#).

Return to the [Summary Table](#).

The SCISSETINTLVL register is used to map individual interrupt sources to the INT1 interrupt line.

### 27.6.2.7 SCICLEARINTLVL Register (Offset = 18h) [reset = 0h]

SCICLEARINTLVL is shown in [Figure 27-33](#) and described in [Table 27-22](#).

Return to the [Summary Table](#).

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

**Figure 27-33. SCICLEARINTLVL Register**

### 27.6.2.8 SCIFLR Register (Offset = 1Ch) [reset = 904h]

SCIFLR is shown in [Figure 27-34](#) and described in [Table 27-23](#).

Return to the [Summary Table](#).

The SCIFLR register indicates the current status of the various interrupt sources of the LIN module.

**Figure 27-34. SCIFLR Register**

This is detected by the bit monitor in the internal bit monitor. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No bit error detected.</p> <p>1h (R/W) = Bit error detected.</p> |

**Table 27-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|-------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30  | PBE   | R/W1C | 0h    | <p>Physical Bus Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been a physical bus error. This is detected by the bit monitor in TED. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>Note: this PBE will only be flagged if no sync break can be generated. (because of a bus shortage to VBAT) or if no sync break delimiter can be generated (because of a bus shortage to GND).</p> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No physical bus error detected.<br/>1h (R/W) = Physical bus error detected.</p> |
| 29  | CE    | R/W1C | 0h    | <p>Checksum Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No Checksum error detected.<br/>1h (R/W) = Checksum error detected.</p>                                                                                                                                                                           |
| 28  | ISFE  | R/W1C | 0h    | <p>Inconsistent Sync Field Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the "Header Reception and Adaptive Baudrate" section for more information. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.<br/>Reset type: SYSRSn<br/>0h (R/W) = No Inconsistent Sync Field error detected.<br/>1h (R/W) = Inconsistent Sync Field error detected.</p>                                                                 |

**Table 27-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|-------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27  | NRE   | R/W1C | 0h    | <p>No-Response Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is no response to a master's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length (identifiers 0 to 61). This error is detected by the synchronizer of the module. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No No-Response error detected.</p> <p>1h (R/W) = No-Response error detected.</p>                                                                                                                                                                                         |
| 26  | FE    | R/W1C | 0h    | <p>Framing error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new character (SCI-compatible mode), or frame (LIN mode)</li> </ul> <p>In multibuffer mode the frame is defined in the SCIFORMAT register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No framing error detected.</p> <p>1h (R/W) = Framing error detected.</p> |
| 25  | OE    | R/W1C | 0h    | <p>Overrun error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun error detected.</p> <p>1h (R/W) = Overrun error detected.</p>                                                                                                                                                                                                                                                                                           |

**Table 27-23. SCIFLR Register Field Descriptions (continued)**

| Bit   | Field    | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|----------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24    | PE       | R/W1C | 0h    | <p>Parity error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In Idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the "SCI Global Control Register (SCIGCR1)" description. If the parity function is disabled (that is, SCIGCR1.2 = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Reception of a new character (SCI-compatible mode) or frame (LIN mode)</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn<br/> 0h (R/W) = No parity error or parity disabled.<br/> 1h (R/W) = Parity error detected.</p> |

| 13  | IDTXFLAG | R/W1C | 0h    | <p>Identifier On Transmit Flag.</p> <p>This bit is effective in LIN mode only. This flag is set once an identifier is received with a TX match and no ID-parity error. See the "Message Filtering and Validation" section for more details. When this flag is set it indicates that a new valid identifier has been received on a TX match. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting SWnRESET</li> <li>- System reset</li> <li>- Reading the LINID register</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No valid ID received.</p> <p>1h (R/W) = Valid ID received in LINID[23:16] on TX match.</p>                                                                                                                                                                                                                                        |
| 12  | RXWAKE   | R     | 0h    | <p>Receiver wakeup detect flag.</p> <p>This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset</li> <li>- Receipt of a data frame</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The data in SCIRD is not an address.</p> <p>1h (R/W) = The data in SCIRD is an address.</p> <p>See [1] Section 3.4.4, Sleep Mode for Multiprocessor Communication, on page 16 for more information on using the RXWAKE bit with sleep mode.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| 11  | TXEMPTY  | R     | 1h    | <p>Transmitter Empty flag.</p> <p>The value of this flag indicates the contents of the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF). In multibuffer mode, this flag indicates the value of the TDx registers and shift register (SCITXSHF). In non multibuffer mode, this flag indicates the value of LINTD0 (byte) and shift register (SCITXSHF). This bit is set by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset.</li> </ul> <p>Note: This bit does not cause an interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer or shift register (or both) are loaded with data. In LIN mode using multibuffer mode: Multibuffer or shift register (or all) are loaded with data.</p> <p>1h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer and shift registers are both empty. In LIN mode using multibuffer mode: Multibuffer and shift registers are all empty.</p> |

**Table 27-23. SCIFLR Register Field Descriptions (continued)**

| Bit | Field  | Type  | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|--------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | TXWAKE | R/W   | 0h    | <p>SCI transmitter wakeup method select.</p> <p>This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit (SCIGCR1.7).</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Address-bit mode: Frame to be transmitted will be data (address bit = 0).</p> <p>Idle-line mode: Frame to be transmitted will be data.</p> <p>1h (R/W) = Address-bit mode: Frame to be transmitted will be an address (address bit=1).</p> <p>Idle-line mode: Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>                                                                                                                                                                |
| 9   | RXRDY  | R/W1C | 0h    | <p>Receiver ready flag.</p> <p>In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set</p> <p>if the interrupt-enable bit is set (SCISETINT.9). RXRDY is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reading SCIRD in while in SCI compatibility mode</li> <li>- Reading last data byte RDy of the response in LIN mode</li> </ul> <p>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No new data in SCIRD/RDy.</p> <p>1h (R/W) = New data ready to be read from SCIRD.</p> |

| 2   | IDLE   | R     | 1h    | <p>SCI receiver in idle state.</p> <p>This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state:</p> <ul style="list-style-type: none"> <li>- After a system reset</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- After coming out of power down</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Idle period detected, the SCI is ready to receive.</p> <p>1h (R/W) = Idle period not detected, the SCI will not receive any data.</p>                                                                                                                                                                                  |
| 1   | WAKEUP | R/W1C | 0h    | <p>Wake-up flag.</p> <p>This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT.1) is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit.</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Do not wake up from power-down mode.</p> <p>1h (R/W) = Wake up from power-down mode.</p>                                                                                                                                                                                 |
| 0   | BRKDT  | R/W1C | 0h    | <p>SCI break-detect flag.</p> <p>This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- By writing a 1 to this bit.</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No break condition detected.</p> <p>1h (R/W) = Break condition detected.</p> |

### 27.6.2.9 SCIINTVECT0 Register (Offset = 20h) [reset = 0h]

SCIINTVECT0 is shown in [Figure 27-35](#) and described in [Table 27-24](#).

Return to the [Summary Table](#).

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

**Figure 27-35. SCIINTVECT0 Register**

| 2-0 | CHAR  | R/W  | 0h    | <p>Character length control bits.</p> <p>These bits are effective in SCI compatible mode only. These bits set the SCI character length from 1 to 8 bits.</p> <p>Note: In compatibility mode or buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified.</p> <p>Note: Data written to the SCITD should be right justified but does not need to be padded with leading zeros.</p> <p>These bits are writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The character is 1 bits long.<br/> 1h (R/W) = The character is 2 bits long.<br/> 2h (R/W) = The character is 3 bits long.<br/> 3h (R/W) = The character is 4 bits long.<br/> 4h (R/W) = The character is 5 bits long.<br/> 5h (R/W) = The character is 6 bits long.<br/> 6h (R/W) = The character is 7 bits long.<br/> 7h (R/W) = The character is 8 bits long.</p> |

### 27.6.2.12 BRSR Register (Offset = 2Ch) [reset = 0h]

BRSR is shown in [Figure 27-38](#) and described in [Table 27-27](#).

Return to the [Summary Table](#).

The BRSR register is used to configure the baud rate of the LIN module.

**Figure 27-38. BRSR Register**

### 27.6.2.13 SCIED Register (Offset = 30h) [reset = 0h]

SCIED is shown in [Figure 27-39](#) and described in [Table 27-28](#).

Return to the [Summary Table](#).

The SCIED register is a duplicate copy of SCIRD register that has no affect on the RXRDY flag for use with an emulator.

### 27.6.2.14 SCIRD Register (Offset = 34h) [reset = 0h]

SCIRD is shown in [Figure 27-40](#) and described in [Table 27-29](#).

Return to the [Summary Table](#).

The SCIRD register is where received data is stored and can be read from.

**Figure 27-40. SCIRD Register**

| 7-0  | RD       | R    | 0h    | <p>Received Data.</p> <p>This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA (SCISSETINT0.9) is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared.</p> <p>When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified.</p> <p>Reset type: SYSRSn</p> |

### 27.6.2.15 SCITD Register (Offset = 38h) [reset = 0h]

SCITD is shown in [Figure 27-41](#) and described in [Table 27-30](#).

Return to the [Summary Table](#).

The SCITD register is where data to be transmitted is written to by application software.

**Figure 27-41. SCITD Register**

### 27.6.2.18 LINCOMP Register (Offset = 60h) [reset = 0h]

LINCOMP is shown in [Figure 27-44](#) and described in [Table 27-33](#).

Return to the [Summary Table](#).

The LINCOMPARE register is used to configure the sync delimiter and sync break extension.

### 27.6.2.21 LINMASK Register (Offset = 6Ch) [reset = 0h]

LINMASK is shown in [Figure 27-47](#) and described in [Table 27-36](#).

Return to the [Summary Table](#).

The LINMASK register is used to configure the masks used for filtering incoming ID messages for receive and transmit frames.

**Figure 27-47. LINMASK Register**

### 27.6.2.22 LINID Register (Offset = 70h) [reset = 0h]

LINID is shown in [Figure 27-48](#) and described in [Table 27-37](#).

Return to the [Summary Table](#).

The LINID register contains the identification fields for LIN communication.

NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

**Figure 27-48. LINID Register**

### 27.6.2.25 MBRSR Register (Offset = 7Ch) [reset = DACH]

MBRSR is shown in [Figure 27-51](#) and described in [Table 27-40](#).

Return to the [Summary Table](#).

The MBRSR register is used to configure the expected maximum baud rate of the LIN network.

**Figure 27-51. MBRSR Register**

| 12-0  | MBR      | R/W  | DACH  | <p>Maximum Baud Rate Prescaler.</p> <p>This field is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see the "Header Reception and Adaptive Baudrate" section) of a slave module if the ADAPT bit is set. In this way, a SCI/LIN slave using an automatic or select bit rate modes detects any LIN bus legal rate automatically.</p> <p>The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a s 0x00 data byte could mistakenly be detected as sync break.</p> <p>The default value is for a 70MHz LINCLK (0xDAC).</p> <p>This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20kHz rate.</p> <p>Reset type: SYSRSn</p> |

### 27.6.2.26 IODFTCTRL Register (Offset = 90h) [reset = 500h]

IODFTCTRL is shown in [Figure 27-52](#) and described in [Table 27-41](#).

Return to the [Summary Table](#).

The IODFTCTRL register is used to emulate various error and test conditions.

### 27.6.2.27 LIN\_GLB\_INT\_EN Register (Offset = E0h) [reset = 0h]

LIN\_GLB\_INT\_EN is shown in [Figure 27-53](#) and described in [Table 27-42](#).

Return to the [Summary Table](#).

The LIN\_GLB\_INT\_EN register is used to enable the INT0 and INT1 interrupt lines to propagate to the PIE block.

**Figure 27-53. LIN\_GLB\_INT\_EN Register**

### 27.6.2.28 LIN\_GLB\_INT\_FLG Register (Offset = E4h) [reset = 0h]

LIN\_GLB\_INT\_FLG is shown in [Figure 27-54](#) and described in [Table 27-43](#).

Return to the [Summary Table](#).

The LIN\_GLB\_INT\_FLG register contains the current status of the INT0 and INT1 flags.

**Figure 27-54. LIN\_GLB\_INT\_FLG Register**

### 27.6.2.29 LIN\_GLB\_INT\_CLR Register (Offset = E8h) [reset = 0h]

LIN\_GLB\_INT\_CLR is shown in [Figure 27-55](#) and described in [Table 27-44](#).

Return to the [Summary Table](#).

The LIN\_GLB\_INT\_CLR register is used to clear the interrupt flags in LIN\_GLB\_INT\_FLG register.

**Figure 27-55. LIN\_GLB\_INT\_CLR Register**

## ***Fast Serial Interface (FSI)***

---

---

This chapter contains a general description of the Fast Serial Interface (FSI) module. The FSI is a serial peripheral capable of reliable high-speed communication across isolation barriers.

## 28.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, they can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to ensure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, please refer to the following source:

- <http://www.ti.com/lit/an/spracj9/spracj9.pdf>

## 28.2 Features

The FSI module includes the following features:

- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- DMA support
- CLA task triggering
- SPI compatibility mode (limited features available)

## 28.3 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features may require additional configuration of modules that are not within the scope of this chapter, the details of which can be found elsewhere in this document.

### 28.3.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.

**Figure 28-1. FSI Transmitter (FSITX) CPU Interface**

A The signals connected to the trigger muxes are described in [Section 28.3.6](#).

**Figure 28-2. FSI Receiver (FSIRX) CPU Interface**

**Figure 28-3. FSI Receiver (FSIRX) CPU Interface with CLB**

### 28.3.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core will communicate directly to a single FSI receiver core. Similarly, an FSI receiver core will receive data from a single FSI transmitter core.

Each FSI core has three signals associated with it: one clock and two data signals. Data is always transmitted or received with the most significant bit of each frame field being first. If multi-lane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and their GPIOs repurposed for other application needs. [Table 28-1](#) and [Table 28-2](#) describe the various signals that can be selected by the GPIO mux to be brought out to device pins.

**Table 28-1. FSI Transmitter Core Signals**

| Signal Name | Direction | Description                                                                                                                                                                                                                                                                                    | Inactive Level <sup>(1)</sup> |
|-------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| TXCLK       | Output    | This is the transmit clock. It is driven by the FSI transmit module.                                                                                                                                                                                                                           | Logic High                    |
|             |           | During a transmission, four clock edges will be transmitted before the start of frame phase (preamble) and four clock edges will follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock.                                                                 |                               |
|             |           | In SPI compatibility mode, the preamble and the post frame clock edges will not be transmitted. Data is transmitted only on one edge of the clock. The data is launched on the falling edge of the clock with the expectation that the receiving SPI will capture the data on the rising edge. |                               |
| TXD0        | Output    | This is the primary data output line for transmission. This signal is driven by the FSI transmit module.                                                                                                                                                                                       | Logic High                    |

<sup>(1)</sup> Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

**Table 28-1. FSI Transmitter Core Signals (continued)**

| Signal Name | Direction | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Inactive Level <sup>(1)</sup> |
|-------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
|             |           | When the FSI is configured for multi-lane transmission, TXD0 will contain all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame will be transmitted in full.                                                                                                                                                                                                                                                                              |                               |
| TXD1        | Output    | This is an additional data output line for transmission if the FSI is configured for multi-lane transmission. This signal is driven by the FSI transmit module.<br><br>During transmission, the data bits are split between TXD0 and TXD1. TXD1 will contain all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line will be identical to TXD0. | Logic High                    |

**Table 28-2. FSI Receiver Core Signals**

| Signal Name | Direction | Description                                                                                                                                                         | Inactive Level <sup>(1)</sup> |
|-------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| RXCLK       | Input     | This is the receive clock input signal for the FSI receive module.<br><br>This must should be connected to TXCLK of the transmitting FSI module.                    | Logic High                    |
| RXD0        | Input     | This is the primary data input line for reception. This should be connected to the TXD0 of the transmitting FSI module.                                             | Logic High                    |
| RXD1        | Input     | This is an additional data input line for reception. This signal should be connected to the TXD1 of the transmitting FSI module if multi-lane transmission is used. | Logic High                    |

<sup>(1)</sup> Inactive level refers to the state of the pin while the module is not actively receiving data.

### 28.3.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See *General Purpose Input-Output*, [Chapter 8](#), for more details on the GPIO mux and settings.

### 28.3.3 Interrupts

Each FSI module contains multiple interrupt sources which can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT\_STS, EVT\_FRC, and the EVT\_CLR registers, respectively.

**NOTE:** Because the transmitter and receiver cores have their own distinct register sets, the preceding 'TX\_' and 'RX\_' will be left off of the register names unless otherwise noted.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX\_INT\_CTRL register. The receiver events are assigned an interrupt vector using RX\_INT1\_CTRL and RX\_INT2\_CTRL registers. If an interrupt is not required, ensure the bit is not set in the respective INT\_CTRL register.

#### 28.3.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME\_DONE)**  
This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF\_UNDERRUN)**  
This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CLA, CPU, or DMA.
- **Buffer Overrun (BUF\_OVERRUN)**  
The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun may occur if a piece of data is overwritten before it has been transmitted.
- **Ping Frame Triggered (PING\_TRIGGERED)**  
The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit will be set when the ping counter has timed out or an external ping trigger event has occurred.

### 28.3.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events. These events are described below.

- **Ping Watchdog Timeout (PING\_WD\_TO)**  
This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX\_PING\_WD\_REF register.
- **Frame Watchdog Timeout (FRAME\_WD\_TO)**  
This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX\_FRAME\_WD\_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter will start counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog will time out and this event will be generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **CRC Error (CRC\_ERR)**  
This error indicates that a CRC error has occurred. A CRC error will be generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE\_ERR)**  
This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **End-of-Frame Error (EOF\_ERR)**  
This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **Receive Buffer Overrun (BUF\_OVERRUN)**  
This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF\_UNDERRUN)**  
This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads the buffer while it is empty.
- **Frame Done (FRAME\_DONE)**  
This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR\_FRAME)**  
This event indicates that an error frame has been received.
- **Ping Frame Received (PING\_FRAME)**  
This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME\_OVERRUN)**  
This event indicates that a new frame has been received while the FRAME\_DONE flag was still set.
- **Data Frame Received (DATA\_FRAME)**  
This event indicates that a data frame has been received.

### 28.3.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application should select the interrupt vector for each desired event using the TX\_INT\_CTRL register for the transmitter, and RX\_INT1\_CTRL and RX\_INT2\_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

---

**NOTE:** If an event is registered for both interrupt vectors, both interrupts will fire. There are no hardware checks for overlapping interrupt vector assignments.

---

### 28.3.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user should clear the event flag using the EVT\_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt will be generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This may cause the application to miss events that may be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine will be similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX\_EVT\_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events which require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX\_EVT\_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag may still be set at the end of the ISR. As soon as the ISR completes, a new interrupt will be generated and this flag will still be set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR may cause race conditions which will cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both are handled within the same interrupt line, the software may only respond to one of the events if they both occur close in time.

### 28.3.4 CLA Task Triggering

In addition to generating interrupt vectors to the PIE, both interrupt lines for each module TX\_INT1, TX\_INT2, RX\_INT1, and RX\_INT2 can be assigned to trigger CLA tasks. Refer to the Configuration options table for the list of all sources capable of CLA task triggering. The configuration and use of CLA tasks are described in the [Section 5.3.4](#). The CLA has access to the entire FSI register map. This allows the CLA to manage the FSI independently from the CPU, freeing it up for other tasks.

### 28.3.5 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. The transmitter must also set TX\_OPER\_CTRL.LO.START\_MODE to 0x2 to allow either a write to the TX\_FRAME\_CTRL.START bit or to the TX\_FRAME\_TAG\_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX\_DMA\_CTRL.DMA\_EVT\_EN to 1.

Refer to [Section 28.4.2](#) and [Section 28.4.3](#) for more DMA information specific to each FSI Module.

### 28.3.6 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and/or generic frames. These muxes are independently configured for each type of frame. The application may select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX\_PING\_CTRL.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_PING\_CTRL.EXT\_TRIG\_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX\_OPER\_CTRL\_HI.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x1 in order for a frame to be transmitted by an external trigger.

**Table 28-3. External Trigger Sources and Their Index**

| Index | External Trigger Source |
|-------|-------------------------|

## 28.4 FSI Operation

### 28.4.1 Introduction to Operation

The transmitter and receiver modules are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

### 28.4.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU, CLA, and the DMA.

The transmitter has the following features:

- Automated ping frame generation

- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- DMA support
- CLA task triggering

Figure 28-4 shows the high-level block diagram of the FSI transmitter. Figure 28-5 shows the block diagram of the transmitter core submodule.

**Figure 28-4. FSI Transmitter Block Diagram**

The block diagram of the transmitter core submodule is shown in Figure 28-5.

**Figure 28-5. FSI Transmitter Core Block Diagram**

The following sections describe the various aspects of the FSI transmitter in detail.

#### 28.4.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module should execute the following initialization sequence in order to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX\_CLK\_CTRL.CLK\_RST to 1 and subsequently clearing it.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX\_OPER\_CTRL\_LO.SEL\_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX\_CLK\_CTRL.PRESCALE\_VAL.
4. Enable the transmitter clock divider by setting TX\_CLK\_CTRL.CLK\_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX\_MASTER\_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX\_MASTER\_CTRL.

After initialization and configuration, the transmitter module should synchronize with receiver module before transmitting. The synchronization sequence is described in [Section 28.5.1](#).

#### CAUTION

Do not change TX\_CLK\_CTRL.PRESCALE\_VAL while the clock is enabled (TX\_CLK\_CTRL.CLK\_EN = 1). Doing so may cause undefined behavior.

#### 28.4.2.2 Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX\_CLK\_CTRL.PRESCALE\_VAL) then setting the clock divider enable bit (TX\_CLK\_CTRL.CLK\_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0x0 or 0x1) through 255 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

#### CAUTION

TXCLK should never be configured to be faster than SYSCLK.

### 28.4.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps may be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
  - Set the user data
  - Write to the data buffer
  - Set the word length if the frame is a software defined frame length
4. Set the start condition

**NOTE:** Note: There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior will be as follows:

- The transmitted frame structure will be exactly like an NWORD data frame. The size of the data frame will be determined by the value in the TX\_FRAME\_CTRL.N\_WORDS register.
- The frame type field of the transmitted data frame will be transmitted as programmed. If this is received by an FSI receiver, it will generate a Type error.

This mechanism can be used to force a Type error in a received frame for testing purposes.

The following sections describe the specific configuration for each frame type and start condition.

#### 28.4.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps should be executed. Steps 1-6 may be executed in any order before setting TX\_FRAME\_CTRL.START. Some fields may not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and will be re-transmitted in the subsequent frame unless they are modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX\_FRAME\_CTRL.FRAME\_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX\_FRAME\_CTRL.N\_WORDS to 1 less than the number of words to be transmitted if TX\_FRAME\_CTRL.FRAME\_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words will be transmitted, N = 16, set TX\_FRAME\_CTRL.N\_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware will calculate the CRC to be transmitted. If TX\_OPER\_CTRL.LO.SW\_CRC is 1, the application may calculate a custom CRC value and then set TX\_USER\_CRC to the result.

5. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired tag.
6. Set TX\_FRAME\_TAG\_UDATA.USER\_DATA to the desired user data.
7. Set TX\_FRAME\_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

#### 28.4.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See [Section 28.3.6](#) for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in [Section 28.4.2.3.1](#). The only difference is that in Step 7, the start condition will be automatically set when the external trigger condition is met rather than by software.

It is important to note that by externally triggering frames, the frame information to be sent will be pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX will take the data as is, and the application software should ensure that this data has been updated as necessary.

Using TX\_EVT\_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

#### 28.4.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

##### 28.4.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX\_PING\_CTRL.CNT\_RST.
2. Set the desired ping tag to TX\_PING\_TAG.TAG.
3. Set the ping timer reference value to TX\_PING\_TO\_REF.TO\_REF.
4. Enable the ping timer by writing 1 to TX\_PING\_CTRL.TIMER\_EN.

The ping timer is a free-running counter which will count up from 0. The current value of the ping timer counter is found in TX\_PING\_TO\_CNT. When the current value of TX\_PING\_TO\_CNT matches the reference value TX\_PING\_TO\_REF.TO\_REF, TX\_EVT\_STS.PING\_TRIGGERED will be set. TX\_PING\_TO\_CNT will reset to 0 and resume counting until the next match has occurred or the ping timer is halted by software (TX\_PING\_CTRL.TIMER\_EN is set to 0).

##### 28.4.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX\_FRAME\_CTRL.FRAME\_TYPE to 0000'b to denote that the frame being sent will be a Ping Frame.
2. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired value.
3. Write 1 to TX\_FRAME\_CTRL.START. This will start the transmission.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

##### 28.4.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers may be selected. See [Section 28.3.6](#) for the list of input sources.

### CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX\_PING\_CTRL.EXT\_TRIG\_EN is set to 1, it will take precedence and the ping timer will be ignored.

#### 28.4.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data which is continuously fed with the DMA. A DMA trigger will be generated every time a data frame transmission is completed. This is concurrent with the FRAME\_DONE signal that sets the TX\_EVT\_STS.FRAME\_DONE flag.

In order to transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. Next, TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX\_FRAME\_CTRL.START or TX\_FRAME\_TAG\_UDATA..

The DMA must also be configured properly for the FSI to send the data. One possible solution of using the DMA to continuously feed the transmit buffer is shown below:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps the after 16 words are copied.

**NOTE:** Because the frame tag and user data must be written in to in order to initiate the transmission of the frame, use two consecutive DMA channels. This ensures that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer should be the lower numbered channel and the tag/user data channel should be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

#### 28.4.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer from which it pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way in which the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, it means that the buffer went out of sync. This would not only affect the current transfer, but all future transfers also could not be guaranteed due to the ring buffer. Under such conditions, the underrun would need a soft reset to cleanly recover. Alternately, the software could manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and will guarantee a full reset of the control registers.

Due to the flexibility of the transmit buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields may be ignored without adversely affecting the transmitter capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX\_BUF\_PTR\_LOAD. This will force the transmitter to start picking the data from the indicated location in the buffer.

### 28.4.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX\_OPER\_CTRL\_LO.SW\_CRC appropriately.

If hardware CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial  $0x7 (x^8 + x^2 + x + 1)$ . The transmitter module will automatically compute the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC Submodule, refer to [Section 28.4.7](#).

If software CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 1), the CRC must be computed by software and placed in the TX\_USER\_CRC register. The next frame to be transmitted will use the value placed in the TX\_USER\_CRC register in place of the CRC value generated by the hardware.

As the TX\_USER\_CRC register is software-programmable, the application may use this field as an extra data field for application specific purposes. If TX\_USER\_CRC is used in this manner, the CRC detection on the receiver will not be valid and should be ignored.

### 28.4.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt may or may not require a soft reset in order to resume proper operation. This determination is up to the application software. Refer to [Section 28.4.2.4](#) for more information on the transmit buffer.

### 28.4.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state.

## 28.4.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after they pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU, CLA, and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- CLA task triggering
- SPI compatibility mode

[Figure 28-6](#) provides a high-level overview of the internal modules present in the FSI receiver. [Figure 28-7](#) shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

**Figure 28-6. FSI Receiver Block Diagram**

**Figure 28-7. FSI Receiver Core Block Diagram**

The following sections describe the various aspects of the FSI receiver module

### 28.4.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module should assert and release the receiver core reset bit (RX\_MASTER\_CTRL.CORE\_RST) prior to any other initialization. Once the receiver module is initialized, the following steps may be executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See [Section 28.4.3.4](#) for configuration details.
3. If required, configure the frame watchdog to ensure that each frame is received within a predetermined window. See [Section 28.4.3.5](#) for configuration details.
4. Initialize the receive buffer pointer by writing to the RX\_BUF\_PTR\_LOAD register. Received data will be placed into the buffer starting with the address loaded in this register.
5. Ensure all errors and flags have been cleared from the RX\_EVT\_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX\_EVT\_STS register for various conditions. For example, when the RX\_EVT\_STS.FRAME\_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application should configure the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in [Section 28.5.1](#).

### 28.4.3.2 Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

#### CAUTION

RXCLK should never be faster than SYSCLK.

### 28.4.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. It is important to note that there is no equivalent to a chip select signal to gate incoming data. Every valid clock edge will latch data into the receiver.

The header information of the received frame will be placed in their respective register fields.

- RX\_FRAME\_INFO.FRAME\_TYPE will contain the received frame type.
- RX\_FRAME\_TAG\_UDATA.FRAME\_TAG will contain the received frame tag.
- RX\_FRAME\_TAG\_UDATA.USER\_DATA will contain the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag will be set in the RX\_EVT\_STS register.

**NOTE:** If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The following errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

#### 28.4.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move it from the receiver buffer with the DMA. A DMA trigger will be generated every time a data frame has been received. This is concurrent with the FRAME\_DONE signal that sets the RX\_EVT\_STS.FRAME\_DONE flag. In order to receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set RX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This will allow the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One possible solution for using the receiver to continuously feed the DMA is show below:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel which is handling the data buffer, execute before the DMA channel handling the received tag and user data.

#### 28.4.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event will be triggered which can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter which is reset and restarted upon the successful reception of a ping frame. The watchdog counter will be incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting RX\_PING\_WD\_CTRL.PING\_WD\_RST to 1 and then subsequently clearing it to 0.
2. Set RX\_OPER\_CTRL.PING\_WD\_RST\_MODE to the desired watchdog reset event, either 0 for ping frames only, or 1 for any frame.
3. Set RX\_PING\_WD\_REF to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting RX\_PING\_WD\_CTRL.PING\_EN to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the RX\_PING\_WD\_CNT value reaches the value programmed in RX\_PING\_WD\_REF, the RX\_EVT\_STS.PING\_WD\_TO flag will be set. If configured, an interrupt can be generated on this event.

#### 28.4.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration that it takes for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog will be triggered which can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting RX\_FRAME\_WD\_CTRL.FRAME\_WD\_CNT\_RST to 1 and then subsequently clearing it to 0.
2. Set RX\_FRAME\_WD\_REF.FRAME\_WD\_REF to the maximum number of SYSCLK cycles expected to be in the longest frame that may be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting RX\_FRAME\_WD\_CTRL.FRAME\_WD\_CNT\_EN to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the RX\_FRAME\_WD\_CNT reaches the value programmed in RX\_FRAME\_WD\_REF, the RX\_EVT\_STS.FRAME\_WD\_TO flag will be set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

### 28.4.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX\_DLY\_LINE\_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values should only be adjusted while the FSIRX is held in soft reset, ensuring that there are no active transmissions during this process. Figure 28-8 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits will behave similarly.

**Figure 28-8. Delay Line Control Circuit**

For more information on skew compensation, please refer to <http://www.ti.com/lit/an/spracj9/spracj9.pdf>.

### 28.4.3.7 Buffer Management

The FSI receiver has a 16-word buffer into which the data is copied to when it has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no guaranteed receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer guarantee which values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields may be ignored without adversely affecting the receiver capability. Additionally, the CURR\_WORD\_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX\_BUF\_PTR\_LOAD. This will force the receiver to start storing the received data starting at the indicated location in the buffer.

#### 28.4.3.8 CRC Submodule

The receive module will automatically calculate the CRC on the incoming data. The received CRC value is placed into RX\_CRC\_INFO.RX\_CRC. The CRC value calculated by hardware on the received data is placed into RX\_CRC\_INFO.CALC\_CRC. These values are compared by hardware and will set RX\_EVT\_STS.CRC\_ERROR if there is a mismatch. The receiver can generate an interrupt based on RX\_EVT\_STS.CRC\_ERROR if enabled.

Since the CRC is only used in data frames, the values found in RX\_CRC\_INFO.RX\_CRC and RX\_CRC\_INFO.CALC\_CRC are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to [Section 28.4.7](#).

If the transmitting module is sending a software-defined CRC value (FSITX.TX\_OPER\_CTRL\_LO.SW\_CRC = 1) the receiver module will trigger a CRC Error event if the received value does not match the hardware-calculated value. As this is an application level decision, the FSIRX can safely disregard the CRC error event. Application software will need to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field may have also been used as an application-specific value, not a CRC, the application can use the RX\_CRC\_INFO.RX\_CRC as required. All CRC errors and flags can be ignored in this situation.

#### 28.4.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (RX\_FRAME\_TAG\_UDATA) register and receiver ping tag (RX\_PING\_TAG) register) have the Least Significant Bit is set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions which can be called depending on the tag value. A function pointer needs a 32-bit storage space and hence each successive pointer will be offset by 2. If the first pointer is at address x, then the second pointer will be at address x+2, the third at address x+4 and so on. By keeping the LSB 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

#### 28.4.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver will receive data on every clock edge. While there are specific patterns which determine the start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset in order to ensure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver may be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (RX\_VIS\_1.RX\_CORE\_STS) can be monitored to determine if it has entered into an error state requiring a soft reset in order to resume communication. Incorrect frame type and end of frame errors will always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout will always require a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. RX\_CORE\_STS can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also will not cause

RX\_CORE\_STS to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter may have gone offline and never sent a ping frame. Alternately, during idle time, a noise event may have occurred, thereby putting the receiver into a corrupt state. As the receiver will be able to detect this during the ping frame watchdog timeout interrupt handler, this type of event will not be lost and the application can act appropriately.

As the receiver is clocked by RXCLK, not SYSCLK, a noisy clock or data line may cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Ensure that the clock and data lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the data manual for this device. Failure to do so may cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application should check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun may warrant a soft reset in order to resynchronize with the local application software. Refer to [Section 28.4.3.8](#) for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device should stop transmitting and begin a new synchronization phase.

#### 28.4.3.11 Reset

The receiver module and its registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX\_MASTER\_CTRL.CORE\_RST.

A module reset will cause the registers to be reset to their default state. After a module reset, the receiver module must be re-initialized, and the data link re-established.

### 28.4.4 Frame Format

The FSI module transmits and receives information in frames. Each frame will contain multiple phases where different information can be found. The number of phases as well as the total length of the frame will vary depending on the frame type being transmitted. Frames may be as short as 16 bits long for a ping or error frame or 288 bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown below. Each phase of the frame (such as start-of-frame, frame type, and so on) will be transmitted with the most significant bit first. [Table 28-4](#) describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

**Table 28-4. Basic Frame Structure**

| Idle state | Preamble | Start of Frame | Frame Type | User Data | Data Words | CRC byte | Frame Tag | End of Frame | Postamble | Idle state |
|------------|----------|----------------|------------|-----------|------------|----------|-----------|--------------|-----------|------------|
|            | 1111     | 1001           | 4 bits     | 8 bits    | 1-16 words | 8 bits   | 4 bits    | 0110         | 1111      |            |

The FSI also supports a SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to [Section 28.4.9](#) for more information on how to configure and use the SPI compatibility mode.

**NOTE:** One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI .

#### 28.4.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail below:

- **Idle State**  
During the idle state, the clock and data lines will be driven high, the inactive state.
- **Preamble**  
The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare it for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame**  
The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type**  
The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in [Section 28.4.4.2](#). The transmitter must set the TX\_FRAME\_CTRL.FRAME\_TYPE field before transmitting a frame. The received frame type is stored in the RX\_FRAME\_INFO.FRAME\_TYPE.
- **User Data**  
The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX\_FRAME\_TAG\_UDATA.USER\_DATA. The received user data is stored in RX\_FRAME\_TAG\_UDATA.USER\_DATA.
- **Data**  
The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and will be placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames can be found in [Section 28.4.4.2.3](#).
- **CRC Byte**  
The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX\_OPER\_CTRL\_LO.SW\_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag**  
The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX\_FRAME\_TAG\_UDATA.FRAME\_TAG bits for data frames. Ping frames use the tag defined in TX\_PING\_TAG.TAG. The receiver can access the received frame tag in RX\_FRAME\_TAG\_UDATA.FRAME\_TAG.
- **End of Frame**  
The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble**  
The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines will be driven high, their inactive state. This phase is not present in SPI compatibility mode.

#### 28.4.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

[Table 28-5](#) provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

**Table 28-5. Frame Types and their 4-bit codes**

| Frame Type  | 4-bit Frame Code          | Description                                                                                                                                                                                               |
|-------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PING        | 0000                      | This is the ping frame which can be sent either by software or automatically by hardware.                                                                                                                 |
| ERROR       | 1111                      | This should be used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software is at liberty to use this for any purpose. |
| DATA_1_WORD | 0100                      | 1 word data packet (16 bits of data)                                                                                                                                                                      |
| DATA_2_WORD | 0101                      | 2 word data packet (32 bits of data)                                                                                                                                                                      |
| DATA_4_WORD | 0110                      | 4 word data packet (64 bits of data)                                                                                                                                                                      |
| DATA_6_WORD | 0111                      | 6 word data packet (96 bits of data)                                                                                                                                                                      |
| DATA_N_WORD | 0011                      | N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules should have the same value programmed.                |
| Reserved    | 0001, 0010, and 1000-1110 | Reserved                                                                                                                                                                                                  |

#### 28.4.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. [Table 28-6](#) shows the structure of the ping frames.

**Table 28-6. Ping Frame**

| Idle state | Preamble | SOF  | Frame Type | Frame Tag | EOF  | Postamble | Idle state |
|------------|----------|------|------------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 0000       | xxxx      | 0110 | 1111      |            |

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to ensure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See [Section 28.4.2.3.3](#) for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between it and the transmitter has been broken. See [Section 28.4.3.4](#) for information on how the receiver handles ping frames.

#### 28.4.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. [Table 28-7](#) shows the structure of an error frame.

**Table 28-7. Error Frame**

| Idle state | Preamble | SOF  | Frame Type | Frame Tag | EOF  | Postamble | Idle state |
|------------|----------|------|------------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 1111       | xxxx      | 0110 | 1111      |            |

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX\_FRAME\_TAG\_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX\_FRAME\_TAG\_UDATA register and act on up to 16 different conditions.

#### 28.4.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. [Table 28-8](#) shows the general structure of data frames.

**Table 28-8. Data Frame**

| Idle state | Preamble | SOF  | Frame Type | User Data | Data Words | CRC Byte  | Frame Tag | EOF  | Postamble | Idle state |
|------------|----------|------|------------|-----------|------------|-----------|-----------|------|-----------|------------|
|            | 1111     | 1001 | 0xxx       | xxxx xxxx | 1-16 words | xxxx xxxx | xxxx      | 0110 | 1111      |            |

The frame type field will reflect the 4-bit code of the frame type. A list of frame types can be seen in [Table 28-5](#). The number of the data words transmitted will be determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N\_WORDS field of the transmitter's TX\_FRAME\_CTRL register and receiver's RX\_OPER\_CTRL register.

#### 28.4.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits will be split between the data lines while the start of frame, frame type, frame tag, and end of frame fields will be identical and complete on each line. The user data, data, and CRC fields will be split between the data lines. Starting with the most significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the example below, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12...d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

**Table 28-9. Multi-Lane Frame Format**

| Idle state | Preamble | SOF  | Frame Type | User Data                                                   | Data Words                                        | CRC Byte                                                    | Frame Tag | EOF  | Postamble | Idle state |
|------------|----------|------|------------|-------------------------------------------------------------|---------------------------------------------------|-------------------------------------------------------------|-----------|------|-----------|------------|
| TXD0       | 1111     | 1001 | 0011       | u <sup>7</sup> u <sup>5</sup> u <sup>3</sup> u <sup>1</sup> | d <sup>15</sup> d <sup>13</sup> ...d <sup>1</sup> | c <sup>7</sup> c <sup>5</sup> c <sup>3</sup> c <sup>1</sup> | xxxx      | 0110 | 1111      |            |
| TXD1       | 1111     | 1001 | 0011       | u <sup>6</sup> u <sup>4</sup> u <sup>2</sup> u <sup>0</sup> | d <sup>14</sup> d <sup>12</sup> ...d <sup>0</sup> | c <sup>6</sup> c <sup>4</sup> c <sup>2</sup> c <sup>0</sup> | xxxx      | 0110 | 1111      |            |

#### 28.4.5 The Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before it can receive and decode frames. The receiver core has an asynchronous reset mechanism which will allow the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset will be released synchronous to the receive clock (RXCLK). Thus, the receiver will require five full clock pulses to be able to come out of reset. Sending the flush pattern will ensure that these clock edges are received and any subsequent frames sent to the receiver will be correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

Figure 28-9 shows a sample plot of the flush sequence.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI will have the same effect as a flush sequence.

### 28.4.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting `RX_MASTER_CTRL.INT_LOOPBACK` to 1. Internal loopback will route the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter.

Figure 28-10 shows the signal connections with internal loopback.

### 28.4.7 CRC Generation

The FSI uses CRC-8 with the polynomial 0x07 for the internal hardware CRC generation. This polynomial is also represented as  $x^8 + x^2 + x + 1$ .

For example, for a 2-word data packet the following calculation would occur:

Data-1 = 0x4433

Data-0 = 0x2211

User Data = 0xAA

The CRC would be computed with the bytes being taken in the following order (first to last)

0xAA – Byte 0, User Data

0x11 – Byte 1, Data-0, Least significant byte

0x22 – Byte 2, Data-0, Most significant byte

0x33 – Byte 3, Data-1, Least significant byte

0x44 – Byte 4, Data-1, Most significant byte

### 28.4.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX\_OPER\_CTRL\_HI.ECC\_SEL to 1.
2. Write the data to the TX\_ECC\_DATA register as well as the transmit buffer.
3. Read TX\_ECC\_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX\_ECC\_VAL to TX\_FRAME\_TAG\_UDATA.USER\_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX\_ECC\_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX\_FRAME\_TAG\_UDATA.USER\_DATA to the RX\_ECC\_VAL register.
3. Read the RX\_ECC\_LOG register. This contains the result of the ECC computation using the RX\_ECC\_DATA and RX\_ECC\_VAL registers.
  1. If no ECC errors were detected, RX\_ECC\_LOG will be 0. The correct data will be available in RX\_ECC\_SEC\_DATA.
  2. If a single bit error was detected, RX\_ECC\_LOG.SBE will be 1. The autocorrected data will be available in RX\_ECC\_SEC\_DATA.
  3. If multiple bit errors occurred, RX\_ECC\_LOG.MBE will be set to 1. The data in RX\_ECC\_SEC\_DATA is invalid and should not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame and allocate one of the data words to be the ECC value.

### 28.4.9 SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode follow:

- Data will transmit on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 will be driven like an active-low, chip-select signal. The signal will be low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks will be transmitted. All signals return to the IDLE state after the frame phase is finished.

- It is not possible to transmit in the SPI slave configuration because the FSI TXCLK cannot take an external clock source.

Table 28-10 lists the frame structure of the SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI slave, the standard SPI must encode the transmission to be sent.

**Table 28-10. SPI Compatibility Frame Structure**

| Idle state | Start of Frame | Frame Type | User Data | Data Words | CRC byte <sup>(1)</sup> | Frame Tag | End of Frame | Idle state |
|------------|----------------|------------|-----------|------------|-------------------------|-----------|--------------|------------|
|            | 1001           | 4 bits     | 8 bits    | 1-16 words | 8 bits                  | 4 bits    | 0110         |            |

<sup>(1)</sup> The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data would be arranged in the following manner. The example provided in Table 28-11 assumes a DATA\_2\_WORD frame has been sent.

**Table 28-11. Contents of Data Received by a Standard SPI**

| SPI Data   | Data Contents                    |
|------------|----------------------------------|
| SPI word 0 | 1001, 0100, 8-bit User Data      |
| SPI word 1 | Data word 1                      |
| SPI word 2 | Data word 2                      |
| SPI word 3 | 8-bit CRC, 4-bit Frame Tag, 0110 |

### 28.4.9.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with a SPI module.

#### 28.4.9.1.1 FSITX as SPI Master, Transmit Only

The FSITX can operate as an independent SPI Master module. In this condition, TXCLK will be connected to SPICLK, TXD0 will be connected to SPISIMO, and TXD1 will be connected to SPISTE, the chip select.

**Figure 28-11. FSITX as SPI Master, Transmit Only**

When the FSI is a SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver will require some software to act upon this information.

**Table 28-12. FSI as Master Transmitter, SPI as Slave Receiver**

| Capability                        | Availability | Comment                                             |
|-----------------------------------|--------------|-----------------------------------------------------|
| Framing checks on the data frames | Yes          | Can be implemented in software on the SPI receiver. |

**Table 28-12. FSI as Master Transmitter, SPI as Slave Receiver (continued)**

| Capability                                            | Availability | Comment                                                                                                                        |
|-------------------------------------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| Ability to detect line breaks                         | Yes          | Can be implemented in software on the SPI receiver but will require additional software overhead such as a timer, or watchdog. |
| CRC check                                             | Yes          | Can be implemented in software on the SPI receiver. For devices which have VCU, this will be more efficient.                   |
| ECC on data                                           | Yes          | Can be implemented in software in the SPI receiver                                                                             |
| Detection of abruptly terminated frames               | No           |                                                                                                                                |
| Double edge data rate                                 | No           |                                                                                                                                |
| Recovery from glitches on signal lines between frames | No           |                                                                                                                                |
| Skew adjustment on signal lines                       | No           |                                                                                                                                |

#### 28.4.9.1.1.1 Initialization

To configure the FSITX module to be a SPI master for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX\_OPER\_CTRL\_LO.SPI\_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

#### 28.4.9.1.1.2 Operation

The operation of the FSITX module in SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to [Section 28.4.2](#) for more information on each of these features.

#### 28.4.9.1.2 FSIRX as SPI Slave, Receive Only

The FSIRX can operate as an independent SPI slave module. In the usage, RXCLK will be connected to SPICLK, and RXD0 will be connected to SPISIMO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence will be required to resynchronize the FSIRX module with the Master.

**Figure 28-12. FSIRX as SPI Slave, Receive Only**

When the FSI is a SPI receiver communicating with a SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

**Table 28-13. SPI as master transmitter, FSI as slave receiver**

| Capability                                            | Availability | Comment                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Framing checks on the data frames                     | Yes          | Standard on FSI                                                                                                                                                                                                                                                                                                                           |
| Ability to detect line breaks                         | Yes          | Can be implemented in software in the SPI transmitter. But will have to use some timer or watchdog in the transmitting SPI device                                                                                                                                                                                                         |
| CRC check                                             | Yes          | Can be implemented in software in the SPI transmitter.                                                                                                                                                                                                                                                                                    |
| ECC on data                                           | Yes          | Can be implemented in software in the SPI transmitter.                                                                                                                                                                                                                                                                                    |
| Detection of abruptly terminated frames               | Yes          | This is accomplished with the FSI setting up the frame watchdog counter.                                                                                                                                                                                                                                                                  |
| Double edge data rate                                 | No           |                                                                                                                                                                                                                                                                                                                                           |
| Recovery from glitches on signal lines between frames | Yes          | Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame will discard the effects of these glitches and will cause the receiver to resynchronize when the real "start-of-frame" pattern is seen. So, the ability to reject glitches in between frames is hence very high. |
| Skew adjustment on signal lines                       | Yes          | The FSI receiver has the ability to add delays to the incoming signal lines.                                                                                                                                                                                                                                                              |

#### 28.4.9.1.2.1 Initialization

To configure the FSIRX module to be a SPI slave for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set RX\_OPER\_CTRL.SPI\_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

#### 28.4.9.1.2.2 Operation

The operation of the FSIRX module in SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to [Section 28.4.3](#) for more information on each of these features.

#### 28.4.9.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Master

In this configuration, the FSITX is the clock master. The FSITX module will drive TXCLK (SPICLK), TXD0 (SPISIMO), and TXD1 (SPISTE/chip select), to the SPI slave. The SPISOMI signal will be connected back to the RXD0 signal. RXCLK can be fed either internally using the internal SPI pairing feature or wired externally, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX could also be thought of as an additional SPI slave. Some software logic will be required in order for the FSI to emulate a SPI master fully.

**Figure 28-13. FSITX and FSIRX as SPI Master, Full Duplex**

#### 28.4.9.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI master operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set their respective SPI\_MODE bits. This will enable the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX\_MASTER\_CTRL.SPI\_PAIRING to 1. This will internally connect TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK may be reallocated to other application requirements.

If the application requires an external clock loopback, ensure that TXCLK is connected to RXCLK. This may be required if the SPI Slave is across an isolation barrier and there is latency between TXCLK being launched and SPISOMI data being received on RXD0.

#### 28.4.9.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI master module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

### 28.5 Programmer's Model

This section describes various operational sequences and features for the FSI.

#### 28.5.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules may exchange data. Since the receiver will accept data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example walks through a suggested approach for establishing a clean communication link on two separate devices that may power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to ensure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 28-14 shows the connection of the devices in this example. While there is no true concept of a master or a slave node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

**Figure 28-14. Point to Point Connection**

Device 1 is the master node; it will be the driver of the initialization sequence. Device 2 is the slave node; it will respond to the master's commands. In this example, as well as in a real world use-case, neither the master nor the slave may know precisely when the other is ready to receive communication.

Sample sequences for both the master device and slave device are provided below:

#### 28.5.1.1 Establishing the Communication Link From the Master

The following sequence is an example of how the master node can establish the communication link with the slave without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
  - Send the flush sequence.
  - Send a ping frame with the frame tag 0000.
  - Wait for some time. (determined by application)
  - If the FSIRX has received a valid ping frame, continue; else iterate the loop again.
  - If the received ping frame tag was 0001, continue; else iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point both the master transmit and receive channels have successfully received a frame from their slave counterparts. The link has been established and standard application communication may begin.

#### 28.5.1.2 Establishing the Communication Link from the Slave

The following sequence is an example of how the slave node can establish the communication link with the master without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else return to step 4.
6. If the received frame tag was 0000, continue; else discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else return to step 4.

11. If the received ping frame tag was 0001, continue; else if the received frame tag was 0000, return to step 9. This can happen if a second ping frame was already in transit before receiving the slave's response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from their master counterparts. The link has been established and regular communication may now proceed. The application may configure periodic ping frames from the transmitter, initialize the receiver's ping and frame watchdogs and begin the communication required by the application.

### 28.5.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a master register lock. These protections ensure that no spurious writes or unintentional modifications to these registers are accepted. Refer to the [Section 28.6](#) for the register and bit descriptions to find the list of registers with write protections available.

#### EALLOW Protection

EALLOW is a device-level register protection; refer to [Section 3.1](#) for more information on EALLOW. For those registers with EALLOW protection, the EALLOW bit should be set before modifying the register. The application should then clear the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

#### Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. In order to write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX\_MASTER\_CTRL.CORE\_RST must be set. To do this, write 0xA501 to TX\_MASTER\_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE\_RESET bit. Refer to the register descriptions for more information on which registers have write keys added.

#### Control Register Lock Protection

There also exists a master lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the register descriptions section. The control register lock will prevent any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX\_LOCK\_CTRL and TX\_LOCK\_CTRL for the receiver and transmitter respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV\_CFG\_REGS.SOFTPRESx) for the FSI module. Refer to [Section 28.4.2.7](#) for more information on SYSRSn.

### 28.5.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores will always be in free running mode. CPU halts will not have any effect on the operation of the FSI. However, reads of registers and data buffers by the debugger will not affect any flags, or status of the data buffers.

If the user wishes to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

## 28.6 FSI Registers

This section describes the Fast Serial Interface Registers. The FSI module contains two distinct sets of registers. One for the FSI receiver, and another for the FSI transmitter.

### 28.6.1 FSI Base Addresses

**Table 28-14. FSI Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|------------------|---------------|---------------|-------------|
| FsiTxaRegs       | FSI_TX_REGS   | 0x0000_6600   | 0x0000_667F |
| FsiRxaRegs       | FSI_RX_REGS   | 0x0000_6680   | 0x0000_66FF |

## 28.6.2 FSI\_RX\_REGS Registers

Table 28-15 lists the FSI\_RX\_REGS registers. All register offset addresses not listed in Table 28-15 should be considered as reserved locations and the register contents should not be modified.

**Table 28-15. FSI\_RX\_REGS Registers**

| Offset        | Acronym            | Register Name                                  | Write Protection | Section            |
|---------------|--------------------|------------------------------------------------|------------------|--------------------|
| 0h            | RX_MASTER_CTRL     | Receive master control register                | EALLOW           | <a href="#">Go</a> |
| 4h            | RX_OPER_CTRL       | Receive operation control register             | EALLOW and LOCK  | <a href="#">Go</a> |
| 6h            | RX_FRAME_INFO      | Receive frame control register                 |                  | <a href="#">Go</a> |
| 7h            | RX_FRAME_TAG_UDATA | Receive frame tag and user data register       |                  | <a href="#">Go</a> |
| 8h            | RX_DMA_CTRL        | Receive DMA event control register             | EALLOW and LOCK  | <a href="#">Go</a> |
| Ah            | RX_EVT_STS         | Receive event and error status flag register   |                  | <a href="#">Go</a> |
| Bh            | RX_CRC_INFO        | Receive CRC info of received and computed CRC  |                  | <a href="#">Go</a> |
| Ch            | RX_EVT_CLR         | Receive event and error clear register         | EALLOW           | <a href="#">Go</a> |
| Dh            | RX_EVT_FRC         | Receive event and error flag force register    | EALLOW           | <a href="#">Go</a> |
| Eh            | RX_BUF_PTR_LOAD    | Receive buffer pointer load register           | EALLOW           | <a href="#">Go</a> |
| Fh            | RX_BUF_PTR_STS     | Receive buffer pointer status register         |                  | <a href="#">Go</a> |
| 10h           | RX_FRAME_WD_CTRL   | Receive frame watchdog control register        | EALLOW and LOCK  | <a href="#">Go</a> |
| 12h           | RX_FRAME_WD_REF    | Receive frame watchdog counter reference       | EALLOW and LOCK  | <a href="#">Go</a> |
| 14h           | RX_FRAME_WD_CNT    | Receive frame watchdog current count           |                  | <a href="#">Go</a> |
| 16h           | RX_PING_WD_CTRL    | Receive ping watchdog control register         | EALLOW and LOCK  | <a href="#">Go</a> |
| 17h           | RX_PING_TAG        | Receive ping tag register                      |                  | <a href="#">Go</a> |
| 18h           | RX_PING_WD_REF     | Receive ping watchdog counter reference        | EALLOW and LOCK  | <a href="#">Go</a> |
| 1Ah           | RX_PING_WD_CNT     | Receive pingwatchdog current count             |                  | <a href="#">Go</a> |
| 1Ch           | RX_INT1_CTRL       | Receive interrupt control register for RX_INT1 | EALLOW and LOCK  | <a href="#">Go</a> |
| 1Dh           | RX_INT2_CTRL       | Receive interrupt control register for RX_INT2 | EALLOW and LOCK  | <a href="#">Go</a> |
| 1Eh           | RX_LOCK_CTRL       | Receive lock control register                  |                  | <a href="#">Go</a> |
| 20h           | RX_ECC_DATA        | Receive ECC data register                      |                  | <a href="#">Go</a> |

### 28.6.3 FSI\_TX\_REGS Registers

Table 28-45 lists the FSI\_TX\_REGS registers. All register offset addresses not listed in Table 28-45 should be considered as reserved locations and the register contents should not be modified.

**Table 28-45. FSI\_TX\_REGS Registers**

| Offset        | Acronym            | Register Name                                   | Write Protection | Section            |
|---------------|--------------------|-------------------------------------------------|------------------|--------------------|
| 0h            | TX_MASTER_CTRL     | Transmit master control register                | EALLOW           | <a href="#">Go</a> |
| 2h            | TX_CLK_CTRL        | Transmit clock control register                 | EALLOW and LOCK  | <a href="#">Go</a> |
| 4h            | TX_OPER_CTRL_LO    | Transmit operation control register low         | EALLOW and LOCK  | <a href="#">Go</a> |
| 5h            | TX_OPER_CTRL_HI    | Transmit operation control register high        | EALLOW and LOCK  | <a href="#">Go</a> |
| 6h            | TX_FRAME_CTRL      | Transmit frame control register                 |                  | <a href="#">Go</a> |
| 7h            | TX_FRAME_TAG_UDATA | Transmit frame tag and user data register       |                  | <a href="#">Go</a> |
| 8h            | TX_BUF_PTR_LOAD    | Transmit buffer pointer control load register   | EALLOW           | <a href="#">Go</a> |
| 9h            | TX_BUF_PTR_STS     | Transmit buffer pointer control status register |                  | <a href="#">Go</a> |
| Ah            | TX_PING_CTRL       | Transmit ping control register                  | EALLOW and LOCK  | <a href="#">Go</a> |
| Bh            | TX_PING_TAG        | Transmit ping tag register                      |                  | <a href="#">Go</a> |
| Ch            | TX_PING_TO_REF     | Transmit ping timeout counter reference         | YES              | <a href="#">Go</a> |
| Eh            | TX_PING_TO_CNT     | Transmit ping timeout current count             |                  | <a href="#">Go</a> |
| 10h           | TX_INT_CTRL        | Transmit interrupt event control register       | EALLOW and LOCK  | <a href="#">Go</a> |
| 11h           | TX_DMA_CTRL        | Transmit DMA event control register             | EALLOW and LOCK  | <a href="#">Go</a> |
| 12h           | TX_LOCK_CTRL       | Transmit lock control register                  | EALLOW and LOCK  | <a href="#">Go</a> |
| 14h           | TX_EVT_STS         | Transmit event and error status flag register   |                  | <a href="#">Go</a> |
| 16h           | TX_EVT_CLR         | Transmit event and error clear register         | EALLOW           | <a href="#">Go</a> |
| 17h           | TX_EVT_FRC         | Transmit event and error flag force register    | EALLOW           | <a href="#">Go</a> |
| 18h           | TX_USER_CRC        | Transmit user-defined CRC register              |                  | <a href="#">Go</a> |
| 20h           | TX_ECC_DATA        | Transmit ECC data register                      |                  | <a href="#">Go</a> |
| 22h           | TX_ECC_VAL         | Transmit ECC value register                     |                  | <a href="#">Go</a> |
| 40h + formula | TX_BUF_BASE_y      | Base address for transmit buffer                |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 28-46 shows the codes that are used for access types in this section.

**Table 28-46. FSI\_TX\_REGS Access Type Codes**

| Access Type                     | Code | Description                            |
|---------------------------------|------|----------------------------------------|

**Table 28-46. FSI\_TX\_REGS Access Type  
Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 28.6.3.1 TX\_MASTER\_CTRL Register (Offset = 0h) [reset = 0h]

TX\_MASTER\_CTRL is shown in [Figure 28-43](#) and described in [Table 28-47](#).

Return to the [Summary Table](#).

## ***Configurable Logic Block (CLB)***

---

---

This chapter describes the features and operation of the C2000 configurable logic block (CLB) which is a collection of configurable blocks that may be inter-connected using software to implement custom digital logic functions.

## 29.1 Introduction

The C2000 configurable logic block (CLB) is a collection of configurable blocks that can be interconnected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provides a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB Tool. For more information on the CLB tool, available examples, application reports and user guide, please refer to the following location in your C2000WARE package (C2000Ware\_2\_00\_00\_03 and higher):

**C2000WARE\_INSTALL\_LOCATION\utilities\clb\_tool\clb\_syscfg\doc**

## 29.2 Features

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices may contain more or fewer tiles. Tiles are numbered 1 to 'N', where 'N' is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. The figure below shows the structure of the CLB subsystem in the device.

**Figure 29-1. Block Diagram of the CLB Subsystem in the Device**

The tile contains the core logic providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. The figure below shows the connections between the tile, the CPU interface, and the device.

**Figure 29-2. Block Diagram of a CLB Tile and CPU Interface**

## 29.3 CLB Input/Output Connection

### 29.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance sees a common set 72 input signals referred to as global input signals. Additionally, each CLB instance has a specific set of 25 input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

### 29.3.2 CLB Input Selection

Each CLB module has eight inputs that feed into the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

A set of 72 signals is common to all the CLB instances. These are referred to as global inputs in the figure below. A separate set of 25 signals is unique to each instance of the CLB. These are referred to as local inputs in the figure below.

Registers **CLB\_LCL\_MUX\_SEL\_1** and **CLB\_LCL\_MUX\_SEL\_2** control the local mux selection for each of the eight inputs. The mux control registers **CLB\_GLBL\_MUX\_SEL\_1** and **CLB\_GLBL\_MUX\_SEL\_2** control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting **CLB\_LCL\_MUX\_SEL\_IN\_0 = 0** and **CLB\_GLBL\_MUX\_SEL\_IN\_0 = 8** causes the global mux input number 8 to be connected to CLB Input 0.

**Figure 29-3. CLB Input Mux and Filter**

The global and local input mux settings are shown in [Table 29-1](#) and [Table 29-2](#).

**Table 29-1. Global Signals and Mux Selection**

| Global Input Mux Bit Position | Signal Name             | Instance Name |
|-------------------------------|-------------------------|---------------|
| 0                             | ePWMxA                  | EPWM1         |

(1) PWMA[OE] and PWMB[OE] refer to trip outputs from the respective PWM module.

(2) PWMA[AQ] and PWMB[AQ] refer to the output of the AQ submodule in the respective PWM module.

(3) PWMA[DB] and PWMB[DB] refer to the output of the DB submodule in the respective PWM module.

**Table 29-2. Local Signals and Mux Selection**

| Bit Position | Signal Name      | Instance Name (for CLB1) | Instance Name (for CLB2) | Instance Name (for CLB3) | Instance Name (for CLB4) |
|--------------|------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| 0            | Global Mux input | Global Mux input         | Global Mux input         | Global Mux input         | Global Mux input         |
| 1            | DCAEVT1          | EPWM1                    | EPWM2                    | EPWM3                    | EPWM4                    |

In order to use GPIOs as inputs to the CLB, the user must utilize the Input X-BAR and the CLB X-BAR. The figure below shows how GPIOs can be used as inputs to the CLB tiles.

**Figure 29-4. GPIO to CLB Tile Connections**

### 29.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 16 output signals. Each of these 16 outputs has a separate enable bit defined in the CLB output enable register, CLB\_OUT\_EN\_REG. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB.

**Figure 29-5. CLB Outputs**

### 29.3.4 Peripheral Signal Multiplexer

Each CLB output signal passes through an external multiplexer which intersects a specific peripheral signal. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by a bit in the CLB output enable register CLB\_OEN.

The table below shows the allocation of peripheral signals and the CLB outputs with which they are multiplexed.

**Table 29-3. Peripheral Signal Multiplexer Table**

| CLB Instance | CLB Output Signal | Peripheral Signal | Peripheral Name |
|--------------|-------------------|-------------------|-----------------|
| CLB1         | CLB1_OUT0_0       | PWMA              | EPWM1           |
| CLB1         | CLB1_OUT1_0       | PWMA_OE           | EPWM1           |
| CLB1         | CLB1_OUT2_0       | PWMB              | EPWM1           |

## 29.4 The CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter**

The counter submodule can be configured either as an adder, a counter, or a shifter. When functioning as an adder, it can either add or subtract. When functioning as a counter, it can count up or count down. When functioning as a shifter, it can shift left or shift right. The counter event inputs, as well as the reset input, may be freely connected to any of the other submodules in the same tile. There are three counters in each tile.

- **LUT4**

The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.

- **FSM**

The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combinational output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.

- **Output LUT**

The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.

- **High Level Controller**

The High Level Controller (HLC) submodule is an event-driven block which can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) which can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.

- **Configurable Switch Block**

The configurable switch block provides dynamic connectivity between all of the blocks listed above. submodules can be connected by the user, with the sole restriction that they must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 29-7.

**Figure 29-7. The CLB Tile Submodules**

The functionality of the LUT sub-modules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at its output. The register field would therefore be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM sub-module.

### 29.4.1 Static Switch Block

The Static switch Block provides the configurable connectivity between the sub-modules in the CLB tile. The outputs of all the sub-modules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value which allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) which are tied off in the design to prevent creation of accidental combinatorial loops.

**Table 29-4. Output Table**

| Bit position | Signal connection | Comment                                                |
|--------------|-------------------|--------------------------------------------------------|
| 0            | Always '0'        | This select value will be used to tie an input to '0'. |
| 1            | COUNTER_0 MATCH2  |                                                        |
| 2            | COUNTER_0 ZERO    |                                                        |
| 3            | COUNTER_0 MATCH1  |                                                        |
| 4            | FSM_0 STATE_BIT_0 |                                                        |
| 5            | FSM_0 STATE_BIT_1 |                                                        |
| 6            | FSM_0 LUT output  |                                                        |
| 7            | LUT4_0 output     |                                                        |
| 8            | Always '1'        | This select value will be used to tie an input to '1'. |
| 9            | COUNTER_1 MATCH2  |                                                        |
| 10           | COUNTER_1 ZERO    |                                                        |
| 11           | COUNTER_1 MATCH1  |                                                        |
| 12           | FSM_1 STATE_BIT_0 |                                                        |
| 13           | FSM_1 STATE_BIT_1 |                                                        |
| 14           | FSM_1 LUT output  |                                                        |
| 15           | LUT4_1 output     |                                                        |
| 16           | Always '0'        |                                                        |
| 17           | COUNTER_2 MATCH2  |                                                        |
| 18           | COUNTER_2 ZERO    |                                                        |
| 19           | COUNTER_2 MATCH1  |                                                        |

**Table 29-4. Output Table (continued)**

|    |                   |  |
|----|-------------------|--|

| 28 | External Input 4  |  |
| 29 | External Input 5  |  |
| 30 | External Input 6  |  |
| 31 | External Input 7  |  |

**Table 29-5. Input Table**

| Module name   | Port name     | Description                                                                                                                |
|---------------|---------------|----------------------------------------------------------------------------------------------------------------------------|
| Counter Block | RESET         | Acts as an active high reset when used as a counter                                                                        |
|               | MODE_0        | Acts as a enable when used as a counter. The counter will count only when this input is '1'.                               |
|               | MODE_1        | Acts as a direction control when used as a counter. If this input is '1', then the counter counts up else, it counts down. |
| LUT           | IN0           | Input 0 of the 4-input LUT.                                                                                                |
|               | IN1           | Input 1 of the 4-input LUT.                                                                                                |
|               | IN2           | Input 2 of the 4-input LUT.                                                                                                |
|               | IN3           | Input 3 of the 4-input LUT.                                                                                                |
| FSM           | EXT_IN0       | Input 0 of the FSM block.                                                                                                  |
|               | EXT_IN1       | Input 1 of the FSM block.                                                                                                  |
|               | EXTRA_EXT_IN0 | Extra external Input 0 of the FSM block. This input matters only if it is configured in the LUT mode.                      |
|               | EXTRA_EXT_IN1 | Extra external Input 1 of the FSM block. This input matters only if it is configured in the LUT mode.                      |

The static switch block allows the user to define the input connection of any sub-module to come from any of the outputs in the output table, above. It is therefore easy to create a combinatorial loop. In order to prevent this, certain paths are broken in the input path of each sub-module. These port positions are tied to '0', as shown in the table below.

**Table 29-6. Ports Tied Off to Prevent Combinatorial Loops**

| Module name | Ports of input MUX tied off to '0' to prevent combinational loops |
|-------------|-------------------------------------------------------------------|
| LUT_0       | LUT_0 , LUT_1 and LUT_2 output, FSM_0, FSM_1 and FSM_2 output.    |
| FSM_0       | LUT_1 and LUT_2 output, FSM_0, FSM_1 and FSM_2 output.            |
| LUT_1       | LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.                   |
| FSM_1       | LUT_2 output, FSM_1 and FSM_2 output.                             |
| LUT_2       | LUT_2 output, FSM_2 output.                                       |
| FSM_2       | FSM_2 output.                                                     |

## 29.4.2 Counter Block

### 29.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter sub are shown in the figure below.

**Figure 29-8. Counter Block**

### 29.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the configurable switch block.

The counter inputs are as follows.

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as it remains high, the counter will reset to 0 on the next clock cycle.
- **MODE\_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE\_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE\_1:** This input is the direction control for the counter. If this input is high, then the counter will increment on every clock cycle where it sees MODE\_0 to be high. If this input is low, then the counter decrements for every clock cycle it sees MODE\_0 high. The counter wraps around to 0x00000000 after 0xFFFFFFFF when counting up. The counter wraps around to 0xFFFFFFFF after 0x00000000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event itself can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned

operations and there is no saturation.

Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation will continue based on the MODE\_0, MODE\_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see [Table 29-12](#).

The three logic outputs of the counter block are as follows:

- **ZERO:** This output goes high whenever the counter register is zero.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG\_MISC\_CTRL register. The following three bits of this register are relevant for each counter. The “x” below refers to the counter instance; 0, 1, or 2. For more information, see the CLB\_MISC\_CONTROL register description located in [Section 29.6](#).

- COUNT\_EVENT\_CTRL\_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter will just load the static value; 1 means and add/shift operation will be performed.
- COUNT\_ADD\_SHIFT\_x. 1 means add, 0 means shift.
- COUNT\_DIR\_x. 1 means left shift or add. 0 means right shift or subtract.

The table below shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are as follows:

Load: CNTVAL = EVENT\_LOAD\_VAL

Shift right: CNTVAL = CNTVAL >> EVENT\_LOAD\_VAL

Shift left: CNTVAL = CNTVAL << EVENT\_LOAD\_VAL

Subtract: CNTVAL = CNTVAL - EVENT\_LOAD\_VAL

Add: CNTVAL = CNTVAL + EVENT\_LOAD\_VAL

**Table 29-7. Counter Block Operating Modes**

| EVENT | MODE_0 | MODE_1 | COUNT_EVENT_CTRL_x | COUNT_ADD_SHIFT_x | COUNT_DIR_x | Action on CNTVAL |
|-------|--------|--------|--------------------|-------------------|-------------|------------------|
| 0     | 0      | 0      | X                  | X                 | X           | None             |
| 0     | 0      | 1      | X                  | X                 | X           | None             |
| 0     | 1      | 0      | X                  | X                 | X           | Count down       |
| 0     | 1      | 1      | X                  | X                 | X           | Count up         |
| 1     | X      | X      | 0                  | X                 | X           | Load             |
| 1     | X      | X      | 1                  | 0                 | 0           | Shift right      |
| 1     | X      | X      | 1                  | 0                 | 1           | Shift left       |
| 1     | X      | X      | 1                  | 1                 | 0           | Subtract         |
| 1     | X      | X      | 1                  | 1                 | 1           | Add              |

### 29.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. It has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machines. For additional flexibility, there are two auxiliary inputs (EXTRA\_EXT\_IN0 and EXTRA\_EXT\_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in the figure below.

**Figure 29-9. FSM Block**

The signals and functionality of the FSM block are described below:

- **EXT\_IN0 and EXT\_IN1:** These are the two external inputs that can be used to control the output FSM\_LUT\_OUT or either of the states S0 and S1.
- **S0 and S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM\_LUT\_OUT. An additional level of configurability is provided such that FSM\_LUT\_OUT can use extra inputs in case the states S0 and S1 are unused.

One extra bit is used to select EXTRA\_EXT\_IN0 instead of S0. One extra bit is used to select EXTRA\_EXT\_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM\_LUT\_OUT by giving up one or two state bits, respectively.

The CFG\_MISC\_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM\_EXTRA\_EXT\_INx. '0' means use the state bit, and '1' means use the FSM\_EXTRA\_EXT\_IN0 / FSM\_EXTRA\_EXT\_IN1 signal.

Figure 29-10. FSM LUT Block

#### 29.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3. Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in [Section 29.6](#).

Figure 29-11. LUT4 Block

#### 29.4.5 Output LUT Block

The output LUT block is very similar in functionality to the LUT4 block, except that it has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence they cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in [Section 29.6](#).

Figure 29-12. Output LUT Block

### 29.4.6 High Level Controller (HLC)

The high level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. It performs two main functions:

- Provides a means of communication and data exchange with the rest of the device.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 29-14. It is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

Figure 29-13. High Level Controller Block

Figure 29-14.

#### 29.4.6.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Event 0 is the highest priority and Event 3 is the lowest priority. Events are selected from the set of signals shown in Table 29-8. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

**Table 29-8. HLC Event List**

| Index | HLC Event Mux     |
|-------|-------------------|
| 0     | Always '0'        |
| 1     | COUNTER_0 MATCH2  |
| 2     | COUNTER_0 ZERO    |
| 3     | COUNTER_0 MATCH1  |
| 4     | FSM_0 STATE_BIT_0 |
| 5     | FSM_0 STATE_BIT_1 |
| 6     | FSM_0 LUT output  |
| 7     | LUT4_0 output     |
| 8     | Always '1'        |
| 9     | COUNTER_1 MATCH2  |
| 10    | COUNTER_1 ZERO    |
| 11    | COUNTER_1 MATCH1  |
| 12    | FSM_1 STATE_BIT_0 |
| 13    | FSM_1 STATE_BIT_1 |
| 14    | FSM_1 LUT output  |
| 15    | LUT4_1 output     |
| 16    | Always '0'        |
| 17    | COUNTER_2 MATCH2  |
| 18    | COUNTER_2 ZERO    |
| 19    | COUNTER_2 MATCH1  |
| 20    | FSM_2 STATE_BIT_0 |
| 21    | FSM_2 STATE_BIT_1 |
| 22    | FSM_2 LUT output  |
| 23    | LUT4_2 output     |
| 24    | External Input 0  |
| 25    | External Input 1  |
| 26    | External Input 2  |
| 27    | External Input 3  |
| 28    | External Input 4  |
| 29    | External Input 5  |
| 30    | External Input 6  |
| 31    | External Input 7  |

### 29.4.6.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in [Table 29-9](#). An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences will each be executed sequentially in priority order.

**Table 29-9. HLC Instruction Address Ranges**

| Address        | Instructions for |
|----------------|------------------|
| 00000 to 00111 | Event 0          |
| 01000 to 01111 | Event 1          |
| 10000 to 10111 | Event 2          |
| 11000 to 11111 | Event 3          |

The instruction format is shown in [Table 29-10](#).

**Table 29-10. Instruction Format**

| Last Instruction Bit                                                | 5-Bit Opcode                                                                                                  | 3-Bit Source                             | 3-Bit Destination                                                                                                          |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| This bit set to 1 will stop execution after the current instruction | MOV 00000<br>T1_MOV 00001<br>T2_MOV 00010<br>PUSH 00011<br>PULL 00100<br>ADD 00101<br>SUB 00110<br>INTR 00111 | Source can be R0, R1, R2, R3, C0, C1, C2 | Destination can be R0, R1, R2, R3, C0, C1, C2<br>Note that for ADD/SUB instructions, only R0 to R3 can be the destination. |

R0, R1, R2, and R3 are four 32-bit general purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination.

- **MOV <Src> <Dest>**  
This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2.
- **MOV\_T1 <Src> <Dest>**  
This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are:
  - This instruction moves the count value in C1 into register R0.  
MOV\_T1 C1 R0
  - This instruction moves the value in R2 into the Match1 register of counter C0.  
MOV\_T1 R2 C0
- **MOV\_T2 <Src> <Dest>**  
This instruction is similar to “MOV\_T1”, above. It moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.
- **ADD <Src> <Dest>**  
This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. Both <Src> and <Dest> can be R0, R1, R2, R3, C0, C1, or C2.
- **SUB <Src> <Dest>**  
This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src> Both <Src> and <Dest> can be R0, R1, R2, R3, C0, C1, or C2.
- **PUSH <Src>**  
This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.
- **PULL <Dest>**  
This instruction transfers data from to the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.
- **INTR <6-bit constant>**  
This instruction will flag an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB\_INTR\_TAG\_REG.

### 29.4.6.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in [Section 29.6](#).

**Table 29-11. HLC Register Encoding**

| Register | Bits |
|----------|------|
| R0       | 000  |
| R1       | 001  |
| R2       | 010  |
| R3       | 011  |
| C0       | 100  |
| C1       | 101  |
| C2       | 110  |

#### 29.4.6.4 Operation of the PUSH and PULL Instructions (overflow and underflow detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations will write to successive locations in a linearly mapped memory buffer. The PUSH buffer is mapped at address offset 0x200 and the PULL buffer is mapped at address offset 0x300.

The CPU can read from and write to the PUSH and PULL buffers respectively, in order to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC will be written by the CPU to the PULL buffer and will be read by the HLC using the PULL instruction.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine their value. They are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

## 29.5 CPU Interface

### 29.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses will be different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- Logic configuration registers (0x000 – 0x0FF)

These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.

- Top level control registers (0x100 – 0x1FF)

These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.

- Data exchange registers (0x200 – 0x3FF)

These registers are used to exchange data between the CLB and the rest of the device. They are accessible by normal memory mapped access and no EALLOW or LOCK protection exists.

**NOTE:** EALLOW protection means that the write access to the register will be enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see [Section 29.6](#).

## 29.5.2 Non-Memory Mapped Registers

The memory mapped CLB registers are described later in this document, however many of the CLB resources including counters, the instruction memory of the High Level controller, and the HLC general purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory mapped. These registers are accessible through the two memory mapped registers CLB\_LOAD\_DATA and CLB\_LOAD\_ADDR.

The user loads the data to be written into the CLB\_LOAD\_DATA register, then loads the appropriate address into CLB\_LOAD\_ADDR to determine where this data is written. Writing a '1' to bit position 0 in the CLB\_LOAD\_EN register then causes an internal write operation to be triggered. The address allocation for the CLB\_LOAD\_ADDR register is shown in [Table 29-12](#).

**Table 29-12. Non-Memory Mapped Register Addresses**

| Address (Binary) | Resource                          |
|------------------|-----------------------------------|
| 000000 to 000010 | Counter 0 to 2 load value         |
| 000100 to 000110 | Counter 0 to 2 Match1 value       |
| 001000 to 001010 | Counter 0 to 2 Match2 value       |
| 001100 to 001111 | R0 to R3 of High Level controller |
| 100000 to 100111 | Instructions for Event 0          |
| 101000 to 101111 | Instructions for Event 1          |
| 110000 to 110111 | Instructions for Event 2          |
| 111000 to 111111 | Instructions for Event 3          |

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB\_LOAD\_DATA.
2. Write 0xc to CLB\_LOAD\_ADDR.
3. Write 0x1 to CLB\_LOAD\_EN.

## 29.6 CLB Registers

This section describes the Configurable Logic Block Registers.

### 29.6.1 CLB Base Addresses

This is the Configurable Logic Block Base Address Table.

**Table 29-13. CLB Base Address Table (C28)**

| Bit Field Name    |                        | DriverLib Name      | Base Address |
|-------------------|------------------------|---------------------|--------------|
| Instance          | Structure              |                     |              |
| Clb1LogicCfgRegs  | CLB_LOGIC_CONFIG_REGS  | CLB1_LOGICCFG_BASE  | 0x0000_3000  |
| Clb1LogicCtrlRegs | CLB_LOGIC_CONTROL_REGS | CLB1_LOGICCTRL_BASE | 0x0000_3100  |
| Clb1DataExchRegs  | CLB_DATA_EXCHANGE_REGS | CLB1_DATAEXCH_BASE  | 0x0000_3200  |
| Clb2LogicCfgRegs  | CLB_LOGIC_CONFIG_REGS  | CLB2_LOGICCFG_BASE  | 0x0000_3400  |
| Clb2LogicCtrlRegs | CLB_LOGIC_CONTROL_REGS | CLB2_LOGICCTRL_BASE | 0x0000_3500  |
| Clb2DataExchRegs  | CLB_DATA_EXCHANGE_REGS | CLB2_DATAEXCH_BASE  | 0x0000_3600  |
| Clb3LogicCfgRegs  | CLB_LOGIC_CONFIG_REGS  | CLB3_LOGICCFG_BASE  | 0x0000_3800  |
| Clb3LogicCtrlRegs | CLB_LOGIC_CONTROL_REGS | CLB3_LOGICCTRL_BASE | 0x0000_3900  |
| Clb3DataExchRegs  | CLB_DATA_EXCHANGE_REGS | CLB3_DATAEXCH_BASE  | 0x0000_3A00  |
| Clb4LogicCfgRegs  | CLB_LOGIC_CONFIG_REGS  | CLB4_LOGICCFG_BASE  | 0x0000_3C00  |
| Clb4LogicCtrlRegs | CLB_LOGIC_CONTROL_REGS | CLB4_LOGICCTRL_BASE | 0x0000_3D00  |
| Clb4DataExchRegs  | CLB_DATA_EXCHANGE_REGS | CLB4_DATAEXCH_BASE  | 0x0000_3E00  |

## 29.6.2 CLB\_LOGIC\_CONFIG\_REGS Registers

Table 29-14 lists the CLB\_LOGIC\_CONFIG\_REGS registers. All register offset addresses not listed in Table 29-14 should be considered as reserved locations and the register contents should not be modified.

**Table 29-14. CLB\_LOGIC\_CONFIG\_REGS Registers**

| Offset | Acronym              | Register Name                                         | Write Protection | Section            |
|--------|----------------------|-------------------------------------------------------|------------------|--------------------|
| 2h     | CLB_COUNT_RESET      | Counter Block RESET                                   | EALLOW, LOCK     | <a href="#">Go</a> |
| 4h     | CLB_COUNT_MODE_1     | Counter Block MODE_1                                  | EALLOW, LOCK     | <a href="#">Go</a> |
| 6h     | CLB_COUNT_MODE_0     | Counter Block MODE_0                                  | EALLOW, LOCK     | <a href="#">Go</a> |
| 8h     | CLB_COUNT_EVENT      | Counter Block EVENT                                   | EALLOW, LOCK     | <a href="#">Go</a> |
| Ah     | CLB_FSM_EXTRA_IN0    | FSM Extra EXT_IN0                                     | EALLOW, LOCK     | <a href="#">Go</a> |
| Ch     | CLB_FSM_EXTERNAL_IN0 | FSM EXT_IN0                                           | EALLOW, LOCK     | <a href="#">Go</a> |
| Eh     | CLB_FSM_EXTERNAL_IN1 | FSM_EXT_IN1                                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 10h    | CLB_FSM_EXTRA_IN1    | FSM Extra_EXT_IN1                                     | EALLOW, LOCK     | <a href="#">Go</a> |
| 12h    | CLB_LUT4_IN0         | LUT4_0/1/2 IN0 input source                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 14h    | CLB_LUT4_IN1         | LUT4_0/1/2 IN1 input source                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 16h    | CLB_LUT4_IN2         | LUT4_0/1/2 IN2 input source                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 18h    | CLB_LUT4_IN3         | LUT4_0/1/2 IN3 input source                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 1Ch    | CLB_FSM_LUT_FN1_0    | LUT function for FSM Unit 1 and Unit 0                | EALLOW, LOCK     | <a href="#">Go</a> |
| 1Eh    | CLB_FSM_LUT_FN2      | LUT function for FSM Unit 2                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 20h    | CLB_LUT4_FN1_0       | LUT function for LUT4 block of Unit 1 and 0           | EALLOW, LOCK     | <a href="#">Go</a> |
| 22h    | CLB_LUT4_FN2         | LUT function for LUT4 block of Unit 2                 | EALLOW, LOCK     | <a href="#">Go</a> |
| 24h    | CLB_FSM_NEXT_STATE_0 | FSM Next state equations for Unit 0                   | EALLOW, LOCK     | <a href="#">Go</a> |
| 26h    | CLB_FSM_NEXT_STATE_1 | FSM Next state equations for Unit 1                   | EALLOW, LOCK     | <a href="#">Go</a> |
| 28h    | CLB_FSM_NEXT_STATE_2 | FSM Next state equations for Unit 2                   | EALLOW, LOCK     | <a href="#">Go</a> |
| 2Ah    | CLB_MISC_CONTROL     | Static controls for Ctr,FSM                           | EALLOW, LOCK     | <a href="#">Go</a> |
| 2Ch    | CLB_OUTPUT_LUT_0     | Inp Sel, LUT fns for Out0                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 2Eh    | CLB_OUTPUT_LUT_1     | Inp Sel, LUT fns for Out1                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 30h    | CLB_OUTPUT_LUT_2     | Inp Sel, LUT fns for Out2                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 32h    | CLB_OUTPUT_LUT_3     | Inp Sel, LUT fns for Out3                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 34h    | CLB_OUTPUT_LUT_4     | Inp Sel, LUT fns for Out4                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 36h    | CLB_OUTPUT_LUT_5     | Inp Sel, LUT fns for Out5                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 38h    | CLB_OUTPUT_LUT_6     | Inp Sel, LUT fns for Out6                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 3Ah    | CLB_OUTPUT_LUT_7     | Inp Sel, LUT fns for Out7                             | EALLOW, LOCK     | <a href="#">Go</a> |
| 3Ch    | CLB_HLC_EVENT_SEL    | Event Selector register for the High Level controller | EALLOW, LOCK     | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 29-15 shows the codes that are used for access types in this section.

**Table 29-15. CLB\_LOGIC\_CONFIG\_REGS Access Type Codes**

| Access Type       | Code | Description      |
|-------------------|------|------------------|
| <b>Read Type</b>  |      |                  |
| R                 | R    | Read             |
| R-0               | R-0  | Read Returns 0s  |
| <b>Write Type</b> |      |                  |
| W                 | W    | Write            |
| W1C               | W1C  | Write 1 to clear |

**Table 29-15. CLB\_LOGIC\_CONFIG\_REGS Access Type Codes (continued)**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Reset or Default Value</b>   |      |                                                                                                                                                                                                                                                                                      |
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 29.6.2.1 CLB\_COUNT\_RESET Register (Offset = 2h) [reset = 0h]

CLB\_COUNT\_RESET is shown in [Figure 29-15](#) and described in [Table 29-16](#).

Return to the [Summary Table](#).

Counter Block RESET

Complex bit access types are encoded to fit into small table cells. Table 29-46 shows the codes that are used for access types in this section.

**Table 29-46. CLB\_LOGIC\_CONTROL\_REGS Access Type Codes**

| Access Type                     | Code | Description                            |
|---------------------------------|------|----------------------------------------|
| <b>Read Type</b>                |      |                                        |
| R                               | R    | Read                                   |
| R-0                             | R-0  | Read Returns 0s                        |
| R-1                             | R-1  | Read Returns 1s                        |
| <b>Write Type</b>               |      |                                        |
| W                               | W    | Write                                  |
| <b>Reset or Default Value</b>   |      |                                        |
| -n                              |      | Value after reset or the default value |
| <b>Register Array Variables</b> |      |                                        |

**Table 29-46. CLB\_LOGIC\_CONTROL\_REGS Access  
Type Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 29.6.3.1 CLB\_LOAD\_EN Register (Offset = 0h) [reset = 0h]

CLB\_LOAD\_EN is shown in [Figure 29-44](#) and described in [Table 29-47](#).

Return to the [Summary Table](#).

Global enable & indirect load enable control

## 29.6.4 CLB\_DATA\_EXCHANGE\_REGS Registers

Table 29-69 lists the CLB\_DATA\_EXCHANGE\_REGS registers. All register offset addresses not listed in Table 29-69 should be considered as reserved locations and the register contents should not be modified.

**Table 29-69. CLB\_DATA\_EXCHANGE\_REGS Registers**

| Offset         | Acronym    | Register Name                      | Write Protection | Section            |
|----------------|------------|------------------------------------|------------------|--------------------|
| 0h + formula   | CLB_PUSH_y | CLB_PUSH FIFO Registers (from HLC) |                  | <a href="#">Go</a> |
| 100h + formula | CLB_PULL_y | CLB_PULL FIFO Registers (TO HLC)   |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 29-70 shows the codes that are used for access types in this section.

**Table 29-70. CLB\_DATA\_EXCHANGE\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |      |                                                                                                                                                                                                                                                                                      |
| R                               | R    | Read                                                                                                                                                                                                                                                                                 |
| <b>Write Type</b>               |      |                                                                                                                                                                                                                                                                                      |
| W                               | W    | Write                                                                                                                                                                                                                                                                                |
| <b>Reset or Default Value</b>   |      |                                                                                                                                                                                                                                                                                      |
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 29.6.4.1 CLB\_PUSH\_y Register (Offset = 0h + formula) [reset = 0h]

CLB\_PUSH\_y is shown in [Figure 29-66](#) and described in [Table 29-71](#).

Return to the [Summary Table](#).

CLB\_PUSH FIFO Registers (from HLC)

Offset = 0h + (y \* 2h); where y = 0h to 3h

**Figure 29-66. CLB\_PUSH\_y Register**

## Revision History

| Changes from January 17, 2019 to August 10, 2019                                                                           | Page |
|----------------------------------------------------------------------------------------------------------------------------|------|
| • <a href="#">Section 3.3</a> : Revised this section with an itemized list. ....                                           | 89   |
| • <a href="#">Table 4-2</a> : Revised text in Step 4.....                                                                  | 609  |
| • <a href="#">Table 4-4</a> : Removed rRw 8 and the accompanying reference. ....                                           | 610  |
| • <a href="#">Table 4-14</a> : Removed the last row referencing the PLC. ....                                              | 618  |
| • <a href="#">Table 4-16</a> : Removed rows containing the text "PLC.".....                                                | 619  |
| • <a href="#">Table 4-17</a> : Removed rows containing "PLC." .....                                                        | 619  |
| • <a href="#">Table 4-40</a> : Deleted row containing "PLC boot has started." .....                                        | 639  |
| • <a href="#">Figure 10-3</a> : Revised the diagram. ....                                                                  | 1367 |
| • <a href="#">Section 13.4.2</a> : Revised the text in this section for better clarity. ....                               | 1479 |
| • <a href="#">Section 15.2.3</a> : Added the EPWMSYNCPER Signal section. ....                                              | 1677 |
| • <a href="#">Section 16.7.1</a> EPWMSYNCO updated to EPWMSYNCPER. ....                                                    | 1695 |
| • <a href="#">Section 16.7.2</a> : Added the Synchronizer, Digital Filter, and Latch Delays section. ....                  | 1695 |
| • <a href="#">Section 16.7.3</a> : Added the Calibrating the CMPSS section. ....                                           | 1696 |
| • <a href="#">Section 18.1</a> : Added a Note to the end of the Introduction. ....                                         | 1811 |
| • <a href="#">Section 18.1.1</a> : Added EPWMSYNCPER description to the PWMxSYNCl and EPWMxSYNCO bulleted llist item. .... | 1813 |
| • <a href="#">Table 18-2</a> : Added EPWMxSYNCPER .....                                                                    | 1821 |
| • <a href="#">Section 18.4.3.3</a> : Added snippet about SYNCPER.....                                                      | 1824 |
| • <a href="#">Figure 19-8</a> : Revised the graphic. ....                                                                  | 1825 |
| • <a href="#">Figure 18-54</a> : Revised the Event Filtering figure.....                                                   | 1877 |
| • <a href="#">Section 21.8</a> : Modified the text in the first paragraph. ....                                            | 2160 |
| • <a href="#">Section 27.1</a> : Removed K-Line comment. ....                                                              | 2473 |
| • <a href="#">Chapter 29</a> : Added the Configurable Logic Block chapter.....                                             | 2684 |
