

# **TMS320F28004x Microcontrollers**

## **Technical Reference Manual**

Literature Number: SPRUI33C  
November 2015—Revised August 2019

|                                                       |           |
|-------------------------------------------------------|-----------|
| <b>Preface</b>                                        | <b>80</b> |
| <b>1 C2000 Software Support</b>                       | <b>81</b> |
| 1.1 Introduction                                      | 82        |
| 1.2 C2000Ware Structure                               | 82        |
| 1.3 Documentation                                     | 82        |
| 1.4 Devices                                           | 82        |
| 1.5 Libraries                                         | 82        |
| 1.6 Code Composer Studio                              | 82        |
| 1.7 PinMUX Tool                                       | 83        |
| <b>2 C28x Processor</b>                               | <b>84</b> |
| 2.1 Introduction                                      | 85        |
| 2.2 Features                                          | 85        |
| 2.3 Floating-Point Unit                               | 85        |
| 2.4 Trigonometric Math Unit                           | 85        |
| 2.5 Viterbi, Complex Math and CRC Unit (VCU)          | 86        |
| <b>3 TMS320F28004x System Control</b>                 | <b>87</b> |
| 3.1 Introduction                                      | 88        |
| 3.2 Power Management                                  | 88        |
| 3.2.1 Internal 1.2-V Switching Regulator (DC-DC)      | 88        |
| 3.3 Device Identification and Configuration Registers | 89        |
| 3.4 Resets                                            | 89        |
| 3.4.1 Reset Sources                                   | 89        |
| 3.4.2 External Reset (XRS)                            | 90        |
| 3.4.3 Power-On Reset (POR)                            | 90        |
| 3.4.4 Debugger Reset (SYSRS)                          | 90        |
| 3.4.5 Watchdog Reset (WDRS)                           | 90        |
| 3.4.6 NMI Watchdog Reset (NMIWDRS)                    | 90        |
| 3.4.7 DCSM Safe Code Copy Reset (SCCRESET)            | 90        |
| 3.5 Peripheral Interrupts                             | 91        |
| 3.5.1 Interrupt Concepts                              | 91        |
| 3.5.2 Interrupt Architecture                          | 91        |
| 3.5.3 Interrupt Entry Sequence                        | 92        |
| 3.5.4 Configuring and Using Interrupts                | 93        |
| 3.5.5 PIE Channel Mapping                             | 95        |
| 3.5.6 Vector Tables                                   | 96        |
| 3.6 Exceptions and Non-Maskable Interrupts            | 102       |
| 3.6.1 Configuring and Using NMIs                      | 102       |
| 3.6.2 Emulation Considerations                        | 102       |
| 3.6.3 NMI Sources                                     | 102       |
| 3.6.4 Illegal Instruction Trap (ITRAP)                | 103       |
| 3.6.5 Error Pin                                       | 103       |
| 3.7 Clocking                                          | 104       |
| 3.7.1 Clock Sources                                   | 104       |
| 3.7.2 Derived Clocks                                  | 107       |
| 3.7.3 Device Clock Domains                            | 107       |

|         |                                                                      |     |
|---------|----------------------------------------------------------------------|-----|
| 3.7.4   | XCLKOUT.....                                                         | 108 |
| 3.7.5   | Clock Connectivity .....                                             | 108 |
| 3.7.6   | Clock Source and PLL Setup .....                                     | 110 |
| 3.7.7   | Using an External Crystal or Resonator .....                         | 110 |
| 3.7.8   | Using an External Oscillator .....                                   | 111 |
| 3.7.9   | Choosing PLL Settings.....                                           | 111 |
| 3.7.10  | System Clock Setup.....                                              | 111 |
| 3.7.11  | Clock Configuration Examples .....                                   | 112 |
| 3.7.12  | Missing Clock Detection .....                                        | 112 |
| 3.8     | 32-Bit CPU Timers 0/1/2 .....                                        | 114 |
| 3.9     | Watchdog Timer .....                                                 | 115 |
| 3.9.1   | Servicing the Watchdog Timer .....                                   | 115 |
| 3.9.2   | Minimum Window Check .....                                           | 116 |
| 3.9.3   | Watchdog Reset or Watchdog Interrupt Mode.....                       | 116 |
| 3.9.4   | Watchdog Operation in Low Power Modes .....                          | 117 |
| 3.9.5   | Emulation Considerations .....                                       | 117 |
| 3.10    | Low Power Modes .....                                                | 118 |
| 3.10.1  | IDLE .....                                                           | 118 |
| 3.10.2  | Guidelines on Software Emulation of STANDBY Mode .....               | 118 |
| 3.10.3  | HALT .....                                                           | 119 |
| 3.10.4  | Flash Power-down Considerations .....                                | 119 |
| 3.11    | Memory Controller Module .....                                       | 121 |
| 3.11.1  | Functional Description .....                                         | 121 |
| 3.12    | Flash and OTP Memory .....                                           | 128 |
| 3.12.1  | Features.....                                                        | 128 |
| 3.12.2  | Flash Tools .....                                                    | 128 |
| 3.12.3  | Default Flash Configuration .....                                    | 129 |
| 3.12.4  | Flash Bank, OTP and Pump .....                                       | 129 |
| 3.12.5  | Flash Module Controller (FMC) .....                                  | 129 |
| 3.12.6  | Flash and OTP and Wakeup Power-Down Modes.....                       | 130 |
| 3.12.7  | Flash and OTP Performance.....                                       | 131 |
| 3.12.8  | Flash Access Interface .....                                         | 131 |
| 3.12.9  | Erase/Program Flash.....                                             | 134 |
| 3.12.10 | Error Correction Code (ECC) Protection .....                         | 135 |
| 3.12.11 | Reserved Locations Within Flash and OTP .....                        | 138 |
| 3.12.12 | Procedure to Change the Flash Control Registers .....                | 138 |
| 3.13    | Dual Code Security Module (DCSM).....                                | 139 |
| 3.13.1  | Functional Description .....                                         | 139 |
| 3.13.2  | C Code Example to get Zone Select Block Addr for Zone1 in BANK0..... | 147 |
| 3.13.3  | Flash and OTP Erase/Program .....                                    | 147 |
| 3.13.4  | Safe Copy Code .....                                                 | 147 |
| 3.13.5  | SafeCRC.....                                                         | 148 |
| 3.13.6  | CSM Impact on Other On-Chip Resources .....                          | 148 |
| 3.13.7  | Incorporating Code Security in User Applications.....                | 150 |
| 3.14    | F28004x System Control Registers .....                               | 155 |
| 3.14.1  | System Control Base Addresses .....                                  | 155 |
| 3.14.2  | ACCESS_PROTECTION_REGS Registers.....                                | 156 |
| 3.14.3  | CLK_CFG_REGS Registers .....                                         | 179 |
| 3.14.4  | CPU_SYS_REGS Registers .....                                         | 195 |
| 3.14.5  | CPUTIMER_REGS Registers.....                                         | 236 |
| 3.14.6  | DCSM_BANK0_Z1_REGS Registers.....                                    | 243 |
| 3.14.7  | DCSM_BANK0_Z2_REGS Registers.....                                    | 268 |
| 3.14.8  | DCSM_BANK1_Z1_REGS Registers.....                                    | 289 |

|          |                                                  |            |
|----------|--------------------------------------------------|------------|
| 3.14.9   | DCSM_BANK1_Z2_REGS Registers .....               | 300        |
| 3.14.10  | DCSM_COMMON_REGS Registers .....                 | 311        |
| 3.14.11  | DEV_CFG_REGS Registers.....                      | 324        |
| 3.14.12  | DMA_CLA_SRC_SEL_REGS Registers.....              | 352        |
| 3.14.13  | FLASH_CTRL_REGS Registers .....                  | 359        |
| 3.14.14  | FLASH_ECC_REGS Registers .....                   | 369        |
| 3.14.15  | MEM_CFG_REGS Registers .....                     | 392        |
| 3.14.16  | MEMORY_ERROR_REGS Registers .....                | 438        |
| 3.14.17  | NMI_INTERRUPT_REGS Registers .....               | 455        |
| 3.14.18  | PERIPH_AC_REGS Registers .....                   | 464        |
| 3.14.19  | PIE_CTRL_REGS Registers .....                    | 518        |
| 3.14.20  | ROM_PREFETCH_REGS Registers .....                | 570        |
| 3.14.21  | ROM_WAIT_STATE_REGS Registers.....               | 571        |
| 3.14.22  | UID_REGS Registers.....                          | 572        |
| 3.14.23  | WD_REGS Registers .....                          | 581        |
| 3.14.24  | XINT_REGS Registers .....                        | 588        |
| 3.14.25  | Register to Driverlib Function Mapping.....      | 597        |
| <b>4</b> | <b>ROM Code and Peripheral Booting .....</b>     | <b>608</b> |
| 4.1      | Introduction .....                               | 609        |
| 4.2      | Device Boot Philosophy.....                      | 609        |
| 4.3      | Device Boot Modes.....                           | 609        |
| 4.3.1    | Configuring Alternate Boot Mode Pins .....       | 610        |
| 4.3.2    | Configuring Alternate Boot Mode Options.....     | 611        |
| 4.3.3    | Boot Mode Example Use Cases.....                 | 612        |
| 4.4      | Device Boot Flow Diagrams .....                  | 614        |
| 4.4.1    | Emulation Boot Flow Diagram .....                | 615        |
| 4.4.2    | Standalone Boot Flow Diagram.....                | 616        |
| 4.5      | Device Reset and Exception Handling.....         | 617        |
| 4.5.1    | Reset Causes and Handling.....                   | 617        |
| 4.5.2    | Exceptions and Interrupts Handling .....         | 617        |
| 4.6      | Boot ROM Description .....                       | 618        |
| 4.6.1    | Boot ROM Registers .....                         | 618        |
| 4.6.2    | Boot ROM User OTP .....                          | 618        |
| 4.6.3    | Entry Points.....                                | 618        |
| 4.6.4    | Wait Points.....                                 | 619        |
| 4.6.5    | Memory Maps .....                                | 619        |
| 4.6.6    | ROM Tables .....                                 | 621        |
| 4.6.7    | Boot Modes.....                                  | 622        |
| 4.6.8    | Boot Data Stream Structure .....                 | 634        |
| 4.6.9    | GPIO Assignments .....                           | 636        |
| 4.6.10   | DCSM Usage.....                                  | 637        |
| 4.6.11   | Clock Initialization.....                        | 638        |
| 4.6.12   | Boot Status Information.....                     | 638        |
| 4.6.13   | ROM Version .....                                | 639        |
| 4.7      | Application Notes for Using the Bootloaders..... | 640        |

| 12-8. VMONCTL Register.....                                                             | 1465 |
| 12-9. DCDCCTL Register .....                                                            | 1466 |
| 12-10. DCDCSTS Register .....                                                           | 1467 |
| 12-11. CMPHPMXSEL Register .....                                                        | 1468 |
| 12-12. CMPLPMXSEL Register .....                                                        | 1470 |
| 12-13. CMPHNMXSEL Register .....                                                        | 1472 |
| 12-14. CMPLNMXSEL Register .....                                                        | 1473 |
| 12-15. LOCK Register.....                                                               | 1474 |
| 13-1. ADC Module Block Diagram .....                                                    | 1478 |
| 13-2. SOC Block Diagram.....                                                            | 1481 |
| 13-3. Single-Ended Input Model.....                                                     | 1482 |
| 13-4. Round Robin Priority Example .....                                                | 1487 |
| 13-5. High Priority Example.....                                                        | 1488 |
| 13-6. Burst Priority Example .....                                                      | 1490 |
| 13-7. ADC EOC Interrupts .....                                                          | 1491 |
| 13-8. ADC PPB Block Diagram .....                                                       | 1493 |
| 13-9. ADC PPB Interrupt Event .....                                                     | 1495 |
| 13-10. Opens/Shorts Detection Circuit.....                                              | 1496 |
| 13-11. Input Circuit Equivalent with OSDETECT Enabled .....                             | 1497 |
| 13-12. ADC Timings for 12-bit Mode in Early Interrupt Mode .....                        | 1500 |
| 13-13. ADC Timings for 12-bit Mode in Late Interrupt Mode .....                         | 1501 |
| 13-14. Example: Basic Synchronous Operation .....                                       | 1502 |
| 13-15. Example: Synchronous Operation with Multiple Trigger Sources.....                | 1503 |
| 13-16. Example: Synchronous Operation with Uneven SOC Numbers .....                     | 1504 |
| 13-17. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow.....  | 1504 |
| 13-18. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions ..... | 1505 |
| 13-19. ADC Shared Reference System.....                                                 | 1507 |
| 13-20. ADC Shared Reference .....                                                       | 1508 |
| 13-21. ADCCTL1 Register.....                                                            | 1513 |
| 13-22. ADCCTL2 Register.....                                                            | 1515 |
| 13-23. ADCBURSTCTL Register .....                                                       | 1516 |
| 13-24. ADCINTFLG Register.....                                                          | 1518 |
| 13-25. ADCINTFLGCLR Register .....                                                      | 1520 |
| 13-26. ADCINTOVF Register .....                                                         | 1522 |
| 13-27. ADCINTOVFCLR Register .....                                                      | 1524 |
| 13-28. ADCINTSEL1N2 Register .....                                                      | 1525 |
| 13-29. ADCINTSEL3N4 Register .....                                                      | 1527 |
| 13-30. ADCSOCPRICTL Register .....                                                      | 1529 |
| 13-31. ADCINTSOCSEL1 Register .....                                                     | 1532 |

|                                     |      |

| 18-50. DCAEVT1 Event Triggering.....                                                                | 1876 |
| 18-51. DCAEVT2 Event Triggering.....                                                                | 1876 |
| 18-52. DCBEVT1 Event Triggering.....                                                                | 1877 |
| 18-53. DCBEVT2 Event Triggering.....                                                                | 1877 |
| 18-54. Event Filtering .....                                                                        | 1878 |
| 18-55. Blanking Window Timing Diagram .....                                                         | 1879 |
| 18-56. Valley Switching .....                                                                       | 1880 |
| 18-57. ePWM X-BAR .....                                                                             | 1881 |
| 18-58. ePWM XBAR Architecture - Single Output .....                                                 | 1882 |
| 18-59. Simplified ePWM Module.....                                                                  | 1884 |
| 18-60. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave .....                      | 1885 |
| 18-61. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$ ..... | 1886 |
| 18-62. Buck Waveforms for (Note: Only three bucks shown here) .....                                 | 1887 |
| 18-63. Control of Four Buck Stages. (Note: $F_{PWM2} = N \times F_{PWM1}$ ).....                    | 1888 |
| 18-64. Buck Waveforms for (Note: $F_{PWM2} = F_{PWM1}$ ).....                                       | 1889 |
| 18-65. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ ).....                  | 1890 |
| 18-66. Half-H Bridge Waveforms for (Note: Here $F_{PWM2} = F_{PWM1}$ ).....                         | 1891 |
| 18-67. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control .....           | 1892 |
| 18-68. 3-Phase Inverter Waveforms for (Only One Inverter Shown) .....                               | 1893 |
| 18-69. Configuring Two PWM Modules for Phase Control.....                                           | 1894 |
| 18-70. Timing Waveforms Associated With Phase Control Between Two Modules .....                     | 1895 |
| 18-71. Control of a 3-Phase Interleaved DC/DC Converter .....                                       | 1896 |
| 18-72. 3-Phase Interleaved DC/DC Converter Waveforms for .....                                      | 1897 |
| 18-73. Controlling a Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ ) .....                            | 1898 |
| 18-74. ZVS Full-H Bridge Waveforms .....                                                            | 1899 |
| 18-75. Peak Current Mode Control of a Buck Converter .....                                          | 1900 |
| 18-76. Peak Current Mode Control Waveforms for .....                                                | 1900 |
| 18-77. Control of Two Resonant Converter Stages .....                                               | 1901 |
| 18-78. H-Bridge LLC Resonant Converter PWM Waveforms.....                                           | 1901 |
| 18-79. Resolution Calculations for Conventionally Generated PWM .....                               | 1903 |
| 18-80. Operating Logic Using MEP .....                                                              | 1905 |
| 18-81. HRPWM Extension Registers and Memory Configuration.....                                      | 1906 |
| 18-82. HRPWM System Interface .....                                                                 | 1907 |
| 18-83. HRPWM Block Diagram .....                                                                    | 1908 |
| 18-84. HRPWM and HRCAL Source Clock .....                                                           | 1908 |
| 18-85. Required PWM Waveform for a Requested Duty = 40.5% .....                                     | 1911 |
| 18-86. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0) .....                           | 1914 |
| 18-87. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0) .....                          | 1916 |
| 18-88. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1) .....                          | 1916 |
| 18-89. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE]=1).....                      | 1917 |
| 18-90. Simple Buck Controlled Converter Using a Single PWM .....                                    | 1922 |
| 18-91. PWM Waveform Generated for Simple Buck Controlled Converter .....                            | 1922 |
| 18-92. Simple Reconstruction Filter for a PWM-based DAC .....                                       | 1924 |
| 18-93. PWM Waveform Generated for the PWM DAC Function .....                                        | 1924 |
| 18-94. TBCTL Register .....                                                                         | 1934 |
| 18-95. TBCTL2 Register .....                                                                        | 1937 |

| 19-23. ECCTL0 Register .....                                                                       | 2108 |
| 19-24. ECCTL1 Register .....                                                                       | 2109 |
| 19-25. ECCTL2 Register .....                                                                       | 2111 |
| 19-26. ECEINT Register .....                                                                       | 2114 |
| 19-27. ECFLG Register .....                                                                        | 2116 |
| 19-28. ECCLR Register .....                                                                        | 2118 |
| 19-29. ECFRC Register .....                                                                        | 2119 |
| 20-1. HRCAP Operations Block Diagram .....                                                         | 2124 |
| 20-2. HRCAP Calibration .....                                                                      | 2126 |
| 20-3. HRCTL Register .....                                                                         | 2130 |
| 20-4. HRINTEN Register .....                                                                       | 2132 |
| 20-5. HRFLG Register .....                                                                         | 2133 |
| 20-6. HRCLR Register .....                                                                         | 2134 |
| 20-7. HRFRC Register .....                                                                         | 2135 |
| 20-8. HRCALPRD Register .....                                                                      | 2136 |
| 20-9. HRSYSCLKCTR Register .....                                                                   | 2137 |
| 20-10. HRSYSCLKCAP Register .....                                                                  | 2138 |
| 20-11. HRCLKCTR Register .....                                                                     | 2139 |
| 20-12. HRCLKCAP Register .....                                                                     | 2140 |
| 21-1. Optical Encoder Disk .....                                                                   | 2142 |
| 21-2. QEP Encoder Output Signal for Forward/Reverse Movement .....                                 | 2142 |
| 21-3. Index Pulse Example .....                                                                    | 2143 |
| 21-4. Functional Block Diagram of the eQEP Peripheral .....                                        | 2145 |
| 21-5. Functional Block Diagram of Decoder Unit .....                                               | 2147 |
| 21-6. Quadrature Decoder State Machine .....                                                       | 2148 |
| 21-7. Quadrature-clock and Direction Decoding .....                                                | 2149 |
| 21-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or 0xF9F) ..... | 2151 |
| 21-9. Position Counter Underflow/Overflow (QPOS MAX = 4) .....                                     | 2152 |
| 21-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1) .....                         | 2153 |
| 21-11. Strobe Event Latch (QEPCTL[SEL] = 1) .....                                                  | 2154 |
| 21-12. eQEP Position-compare Unit .....                                                            | 2155 |
| 21-13. eQEP Position-compare Event Generation Points .....                                         | 2156 |
| 21-14. eQEP Position-compare Sync Output Pulse Stretcher .....                                     | 2156 |
| 21-15. eQEP Edge Capture Unit .....                                                                | 2158 |
| 21-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010) .....                  | 2158 |
| 21-17. eQEP Edge Capture Unit - Timing Details .....                                               | 2159 |
| 21-18. eQEP Watchdog Timer .....                                                                   | 2160 |
| 21-19. eQEP Unit Time Base .....                                                                   | 2161 |
| 21-20. QMA Module Block Diagram .....                                                              | 2162 |
| 21-21. QMA Mode-1 .....                                                                            | 2163 |
| 21-22. QMA Mode-2 .....                                                                            | 2164 |
| 21-23. QMA Mode-3 .....                                                                            | 2165 |
| 21-24. EQEP Interrupt Generation .....                                                             | 2166 |

|                                                                                                   |      |
|---------------------------------------------------------------------------------------------------|------|
| 21-25. QPOSCNT Register .....                                                                     | 2170 |
| 21-26. QPOSINIT Register .....                                                                    | 2171 |
| 21-27. QPOSMAX Register .....                                                                     | 2172 |
| 21-28. QPOSCMP Register .....                                                                     | 2173 |
| 21-29. QPOSILAT Register .....                                                                    | 2174 |
| 21-30. QPOSSLAT Register .....                                                                    | 2175 |
| 21-31. QPOSLAT Register .....                                                                     | 2176 |
| 21-32. QUTMR Register .....                                                                       | 2177 |
| 21-33. QUPRD Register .....                                                                       | 2178 |
| 21-34. QWDTMR Register .....                                                                      | 2179 |
| 21-35. QWDPRD Register .....                                                                      | 2180 |
| 21-36. QDECCTL Register .....                                                                     | 2181 |
| 21-37. QEPCTL Register .....                                                                      | 2183 |
| 21-38. QCAPCTL Register .....                                                                     | 2186 |
| 21-39. QPOSCTL Register .....                                                                     | 2187 |
| 21-40. QEINT Register .....                                                                       | 2188 |
| 21-41. QFLG Register .....                                                                        | 2190 |
| 21-42. QCLR Register .....                                                                        | 2192 |
| 21-43. QFRC Register .....                                                                        | 2194 |
| 21-44. QEPSTS Register .....                                                                      | 2196 |
| 21-45. QCTMR Register .....                                                                       | 2198 |
| 21-46. QCPRD Register .....                                                                       | 2199 |
| 21-47. QCTMRLAT Register .....                                                                    | 2200 |
| 21-48. QCPRDLAT Register .....                                                                    | 2201 |
| 21-49. REV Register .....                                                                         | 2202 |
| 21-50. QEPSTROBESEL Register .....                                                                | 2203 |
| 21-51. QMACTRL Register .....                                                                     | 2204 |
| 22-1. SPI CPU Interface .....                                                                     | 2209 |
| 22-2. SPI Interrupt Flags and Enable Logic Generation .....                                       | 2211 |
| 22-3. SPI DMA Trigger Diagram .....                                                               | 2212 |
| 22-4. SPI Master/Slave Connection .....                                                           | 2213 |
| 22-5. SPI Module Master Configuration .....                                                       | 2214 |
| 22-6. SPI Module Slave Configuration .....                                                        | 2215 |
| 22-7. SPICLK Signal Options .....                                                                 | 2218 |
| 22-8. SPI: SPICLK-LSPCLK Characteristic When (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1 ..... | 2218 |
| 22-9. SPI 3-wire Master Mode .....                                                                | 2221 |
| 22-10. SPI 3-wire Slave Mode .....                                                                | 2221 |
| 22-11. Five Bits per Character .....                                                              | 2224 |
| 22-12. SPI Digital Audio Receiver Configuration Using Two SPIs .....                              | 2226 |
| 22-13. Standard Right-Justified Digital Audio Data Format .....                                   | 2226 |
| 22-14. SPICCR Register .....                                                                      | 2229 |
| 22-15. SPICTL Register .....                                                                      | 2231 |
| 22-16. SPISTS Register .....                                                                      | 2233 |
| 22-17. SPIBRR Register .....                                                                      | 2235 |
| 22-18. SPIRXEMU Register .....                                                                    | 2236 |
| 22-19. SPIRXBUF Register .....                                                                    | 2237 |
| 22-20. SPITXBUF Register .....                                                                    | 2238 |
| 22-21. SPIDAT Register .....                                                                      | 2239 |
| 22-22. SPIFFTX Register .....                                                                     | 2240 |

|                                                                                             |      |
|---------------------------------------------------------------------------------------------|------|

| 22-24. SPIFFCT Register.....                                                                | 2244 |
| 22-25. SPIPRI Register .....                                                                | 2245 |
| 23-1. SCI CPU Interface .....                                                               | 2250 |
| 23-2. Serial Communications Interface (SCI) Module Block Diagram .....                      | 2251 |
| 23-3. Typical SCI Data Frame Formats .....                                                  | 2253 |
| 23-4. Idle-Line Multiprocessor Communication Format .....                                   | 2255 |
| 23-5. Double-Buffered WUT and TXSHF .....                                                   | 2256 |
| 23-6. Address-Bit Multiprocessor Communication Format.....                                  | 2257 |
| 23-7. SCI Asynchronous Communications Format .....                                          | 2258 |
| 23-8. SCI RX Signals in Communication Modes.....                                            | 2258 |
| 23-9. SCI TX Signals in Communications Mode .....                                           | 2259 |
| 23-10. SCI FIFO Interrupt Flags and Enable Logic .....                                      | 2261 |
| 23-11. SCICCR Register.....                                                                 | 2265 |
| 23-12. SCICTL1 Register .....                                                               | 2267 |
| 23-13. SCIHBAUD Register .....                                                              | 2269 |
| 23-14. SCILBAUD Register .....                                                              | 2270 |
| 23-15. SCICTL2 Register .....                                                               | 2271 |
| 23-16. SCIRXST Register .....                                                               | 2273 |
| 23-17. SCIRXEMU Register.....                                                               | 2275 |
| 23-18. SCIRXBUF Register .....                                                              | 2276 |
| 23-19. SCITXBUF Register.....                                                               | 2277 |
| 23-20. SCIFFTX Register.....                                                                | 2278 |
| 23-21. SCIFFRX Register .....                                                               | 2280 |
| 23-22. SCIFFCT Register.....                                                                | 2282 |
| 23-23. SCIPRI Register .....                                                                | 2283 |
| 24-1. Multiple I2C Modules Connected.....                                                   | 2287 |
| 24-2. I2C Module Conceptual Block Diagram .....                                             | 2289 |
| 24-3. Clocking Diagram for the I2C Module .....                                             | 2289 |
| 24-4. The Roles of the Clock Divide-Down Values (ICCL and ICCH).....                        | 2290 |
| 24-5. Bit Transfer on the I2C bus .....                                                     | 2291 |
| 24-6. I2C Module START and STOP Conditions .....                                            | 2293 |
| 24-7. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown) ..... | 2294 |
| 24-8. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR) .....                  | 2294 |
| 24-9. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR) .....                 | 2294 |
| 24-10. I2C Module Free Data Format (FDF = 1 in I2CMDR) .....                                | 2295 |
| 24-11. Repeated START Condition (in This Case, 7-Bit Addressing Format).....                | 2295 |
| 24-12. Synchronization of Two I2C Clock Generators During Arbitration .....                 | 2296 |
| 24-13. Arbitration Procedure Between Two Master-Transmitters .....                          | 2297 |
| 24-14. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit .....         | 2298 |
| 24-15. Enable Paths of the I2C Interrupt Requests .....                                     | 2299 |
| 24-16. Backwards Compatibility Mode Bit, Slave Transmitter .....                            | 2300 |
| 24-17. I2C_FIFO_interrupt.....                                                              | 2301 |
| 24-18. I2COAR Register .....                                                                | 2304 |
| 24-19. I2CIER Register .....                                                                | 2305 |
| 24-20. I2CSTR Register .....                                                                | 2306 |
| 24-21. I2CCLKL Register .....                                                               | 2310 |
| 24-22. I2CCLKH Register.....                                                                | 2311 |
| 24-23. I2CCNT Register .....                                                                | 2312 |

|                                                                                       |      |
|---------------------------------------------------------------------------------------|------|
| 24-24. I2CDRR Register .....                                                          | 2313 |
| 24-25. I2CSAR Register .....                                                          | 2314 |
| 24-26. I2CDXR Register .....                                                          | 2315 |
| 24-27. I2CMDR Register .....                                                          | 2316 |
| 24-28. I2CISRC Register .....                                                         | 2320 |
| 24-29. I2CEMDR Register .....                                                         | 2321 |
| 24-30. I2CPSC Register .....                                                          | 2322 |
| 24-31. I2CFFTX Register .....                                                         | 2323 |
| 24-32. I2CFFRX Register .....                                                         | 2325 |
| 25-1. PMBus Module Conceptual Block Diagram .....                                     | 2331 |
| 25-2. Quick Command Message .....                                                     | 2332 |
| 25-3. Send Byte Message with and without PEC .....                                    | 2333 |
| 25-4. Receive Byte Message with and without PEC .....                                 | 2333 |
| 25-5. Write Byte and Write Word Messages with and without PEC .....                   | 2334 |
| 25-6. Read Byte and Read Word Messages with and without PEC .....                     | 2335 |
| 25-7. Process Call Message with and without PEC .....                                 | 2336 |
| 25-8. Block Write Message with and without PEC .....                                  | 2336 |
| 25-9. Block Read Message with and without PEC .....                                   | 2337 |
| 25-10. Block Write-Block Read Process Call Message with and without PEC .....         | 2338 |
| 25-11. Alert Response Message .....                                                   | 2338 |
| 25-12. Extended Command Write Byte and Write Word Messages with and without PEC ..... | 2339 |
| 25-13. Extended Command Write Byte and Write Word Messages with and without PEC ..... | 2339 |
| 25-14. Group Command Message with and without PEC .....                               | 2340 |
| 25-15. Quick Command Message .....                                                    | 2341 |
| 25-16. Send Byte Message with and without PEC .....                                   | 2341 |
| 25-17. Receive Byte Message with and without PEC .....                                | 2342 |
| 25-18. Write Byte and Write Word Messages with and without PEC .....                  | 2342 |
| 25-19. Read Byte and Read Word Messages with and without PEC .....                    | 2343 |
| 25-20. Process Call Message with and without PEC .....                                | 2344 |
| 25-21. Block Write Message with and without PEC .....                                 | 2344 |
| 25-22. Block Read Message with and without PEC .....                                  | 2345 |
| 25-23. Block Write-Block Read Process Call Message with and without PEC .....         | 2346 |
| 25-24. Alert Response Message .....                                                   | 2346 |
| 25-25. Extended Command Write Message with and without PEC .....                      | 2347 |
| 25-26. Extended Command Read Message with and without PEC .....                       | 2347 |
| 25-27. Group Command Message with and without PEC .....                               | 2348 |

## About This Manual

---

---

---

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

### Trademarks

C2000, Code Composer Studio are trademarks of Texas Instruments.

### Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers may be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

### Glossary

*TI Glossary* — This glossary lists and explains terms, acronyms, and definitions.

### Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at <http://www.ti.com>. Additionally, the *TMS320C28x CPU and Instruction Set Reference Guide* (SPRU430) and *TMS320C28x Floating Point Unit and Instruction Set Reference Guide* (SPRUE02) must be used in conjunction with this TRM.

## ***C2000 Software Support***

## 1.1 Introduction

C2000Ware for C2000™ Microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

## 1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure:

**Table 1-1. C2000Ware Root Directories**

| Directory Name | Description                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------|
| boards         | Contains the hardware design schematics, BOM, gerber files, and documentation for C2000 controlCARDS. |
| device_support | Contains all device-specific support files, bit field headers and device development user's guides.   |
| docs           | Contains the C2000Ware package user's guides and the HTML index page of all package documentation.    |
| driverlib      | Contains the device-specific driver library and driver-based peripheral examples.                     |
| libraries      | Contains the device-specific and core libraries.                                                      |

## 1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

## 1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000 microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000 microcontrollers, visit [www.ti.com/c2000](http://www.ti.com/c2000).

## 1.5 Libraries

The libraries included in C2000Ware range from fixed point and floating point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the flash API files and boot ROM source code are located in the "libraries" directory.

## 1.6 Code Composer Studio

Code Composer Studio is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. Code Composer Studio comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio can be obtained at the following link:

<http://www.ti.com/ccstudio>

All projects and examples in C2000Ware are built for and tested with TI's Code Composer Studio. Although Code Composer Studio is not included with the C2000Ware installer, it is easily obtainable in a variety of versions.

## 1.7 PinMUX Tool

The Pin MUX Utility is a software tool which provides a Graphical User Interface for configuring pin multiplexing settings, resolving conflicts and specifying I/O cell characteristics for TI MPUs. Results are output as C header/code files that can be imported into software development kits (SDKs) or used to configure customer's custom software.

The latest version of the PinMux Tool can be obtained at the following link:<http://dev.ti.com/>

## C28x Processor

This chapter contains a short description of the C28x Processor and extended instruction sets.

Further information about this device can be found in the following document(s):

[TMS320C28x CPU and Instruction Set Reference Guide](#)

[TMS320C28x Extended Instruction Sets Technical Reference Manual](#)

[Accelerators: Enhancing the Capabilities of the C2000 MCU Family Technical Brief](#)

| <b>2.5 Viterbi, Complex Math and CRC Unit (VCU) .....</b> | <b>86</b> |

## 2.1 Introduction

The C28x CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing, reduced instruction set computing (RISC), microcontroller architectures, firmware, and tool sets.

For more information on CPU architecture and instruction set, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

## 2.2 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

## 2.3 Floating-Point Unit

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.4 Trigonometric Math Unit

The TMU extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 2-1](#).

**Table 2-1. TMU Supported Instructions**

| INSTRUCTIONS            | C EQUIVALENT OPERATION                     | PIPELINE CYCLES |
|-------------------------|--------------------------------------------|-----------------|
| MPY2PIF32 RaH,RbH       | $a = b * 2\pi$                             | 2/3             |
| DIV2PIF32 RaH,RbH       | $a = b / 2\pi$                             | 2/3             |
| DIVF32 RaH,RbH,RcH      | $a = b/c$                                  | 5               |
| SQRTF32 RaH,RbH         | $a = \sqrt{b}$                             | 5               |
| SINPUF32 RaH,RbH        | $a = \sin(b*2\pi)$                         | 4               |
| COSPUF32 RaH,RbH        | $a = \cos(b*2\pi)$                         | 4               |
| ATANPUF32 RaH,RbH       | $a = \tan(b)/2\pi$                         | 4               |
| QUADF32 RaH,RbH,RcH,RdH | Operation to assist in calculating ATANPU2 | 5               |

No changes have been made to existing instructions, pipeline or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out their operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.5 Viterbi, Complex Math and CRC Unit (VCU)

The C28x with VCU (C28x+VCU) processor extends the capabilities of the C28x fixed-point or floating-point CPU by adding registers and instructions to support the following algorithm types:

- **Viterbi decoding**

Viterbi decoding is commonly used in baseband communications applications. The viterbi decode algorithm consists of three main parts: branch metric calculations, compare-select (viterbi butterfly), and a traceback operation. [Table 2-2](#) shows a summary of the VCU performance for each of these operations.

**Table 2-2. Viterbi Decode Performance**

| Viterbi Operation                           | VCU Cycles       |
|---------------------------------------------|------------------|
| Branch Metric Calculation (code rate = 1/2) | 1                |
| Branch Metric Calculation (code rate = 1/3) | 2p               |
| Viterbi Butterfly (add-compare-select)      | 2 <sup>(1)</sup> |
| Traceback per Stage                         | 3 <sup>(2)</sup> |

<sup>(1)</sup> C28x CPU takes 15 cycles per butterfly.

<sup>(2)</sup> C28x CPU takes 22 cycles per stage.

- **Cyclic redundancy check (CRC)**

CRC algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCU can perform 8-, 16-, and 32-bit CRCs. For example, the VCU can compute the CRC for a block length of 10 bytes in 10 cycles. A CRC result register contains the current CRC which is updated whenever a CRC instruction is executed.

- **Complex math**

Complex math is used in many applications; a few of which are:

- Fast fourier transform (FFT)

The complex FFT is used in spread spectrum communications, as well as many signal processing algorithms.

- Complex filters

Complex filters improve data reliability, transmission distance, and power efficiency. The C28x+VCU can perform a complex I and Q multiply with coefficients (four multiplies) in a single cycle. In addition, the C28x+VCU can read/write the real and imaginary parts of 16-bit complex data to memory in a single cycle.

[Table 2-3](#) shows a summary of a few complex math operations enabled by the VCU.

**Table 2-3. Complex Math Performance**

| Complex Math Operation      | VCU Cycles | Notes                                               |
|-----------------------------|------------|-----------------------------------------------------|
| Add Or Subtract             | 1          | 32 +/- 32 = 32-bit (Useful for filters)             |
| Add or Subtract             | 1          | 16 +/- 32 = 15-bit (Useful for FFT)                 |
| Multiply                    | 2p         | 16 x 16 = 32-bit                                    |
| Multiply & Accumulate (MAC) | 2p         | 32 + 32 = 32-bit, 16 x 16 = 32-bit                  |
| RPT MAC                     | 2p+N       | Repeat MAC. Single cycle after the first operation. |

Throughout this document the following notations are used:

- C28x refers to the C28x fixed-point CPU.
- C28x plus Floating-Point and C28x+FPU both refer to the C28x CPU with enhancements to support IEEE single-precision floating-point operations.
- C28x plus VCU and C28x+VCU both refer to the C28x CPU with enhancements to support viterbi decode, complex math and CRC.
- Some devices have both the FPU and the VCU. These are referred to as C28x+FPU+VCU.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## TMS320F28004x System Control

The system-level functionality of this microcontroller configures the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

Further information about this device can be found in the following document(s):

- [A Technical Introduction to the TMS320F28004x Microcontroller](#)
- [The TMS320F28004x MCU: A Comparison to the TMS320F2806x and TMS320F2803x MCUs](#)

| <b>3.14 F28004x System Control Registers .....</b>                 | <b>155</b> |

## 3.1 Introduction

System-level configuration is controlled by a group of submodules which are collectively referred to as the system control module. The system control module provides the following capabilities:

- System-level resets, including power-on and brownout resets
- Clock source selection and PLL configuration
- Missing clock detection
- Clock-gating low-power modes
- Peripheral interrupt handling
- Non-maskable interrupts for certain fault conditions
- Three 32-bit timers
- Windowed watchdog timer, which can generate an interrupt or a reset
- RAM initialization, write protection, and mastership control
- Flash memory ECC, wait state, and cache configuration
- Dual-zone code security module

Some registers in the system are protected from spurious CPU writes by the EALLOW protection mechanism. This uses the special CPU instructions EALLOW and EDIS to enable and disable access to protected registers. The current protection state is given by the EALLOW bit in the CPU's ST1 register.

**Table 3-1. Access to EALLOW-Protected Registers**

| EALLOW Bit | CPU Writes | CPU Reads | JTAG Writes            | JTAG Reads |
|------------|------------|-----------|------------------------|------------|
| 0          | Ignored    | Allowed   | Allowed <sup>(1)</sup> | Allowed    |
| 1          | Allowed    | Allowed   | Allowed                | Allowed    |

<sup>(1)</sup> The EALLOW bit is overridden via the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio interface.

Register protection is enabled by default at startup. While protected, all writes to protected registers by the CPU are ignored. Only CPU reads, JTAG reads, and JTAG writes are allowed. If protection is disabled by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, they can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

Writes to the clock configuration and peripheral clock enable registers may be disabled until the next reset by writing to special lock registers.

## 3.2 Power Management

### 3.2.1 Internal 1.2-V Switching Regulator (DC-DC)

The internal DC-DC regulator is disabled by default. To use this supply, the TMS320F28004x MCU core must power up initially with the internal LDO (VREG) and then transition to the internal DC-DC regulator via application software. Follow the procedure below to enable the internal DC-DC regulator:

1. Set EALLOW bit.
2. Set the DCDCTL.DCDCEN bit.
3. Wait for DCDSTS.SWSEQDON to equal 0x1.
  - If this bit does not get set then the transition from VREG to DC-DC was not successful (check the hardware connections on the application board). Consult the F28004x Data Manual for schematic details.
4. Wait for DCDSTS.INNDETECT to equal 0x1.
  - If this bit does not get set then the inductor was not detected on the VSW pin.
  - Note that steps 3 and 4 can be combined.
5. Delay 80us for the DC-DC regulator output to settle (delay function based on 10MHz CPU clock).

## 6. EDIS

The procedure to enable the internal DC-DC regulator must be completed prior to all other initialization functions and application code.

### 3.3 Device Identification and Configuration Registers

The device identification registers and configuration registers provide information on the part number, product family, revision, pin count, qualification status, and feature availability of the device.

All of the device information is part of the DEV\_CFG\_REGS space. The identification registers are PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID\_REGS. The 256 bits are separated into these registers:

- UID\_PSRAND0-5: 192 bits of pseudo-random data
- UID\_UNIQUE: 32-bit unique data, the value in this register will be unique across all devices with the same PARTIDH
- UID\_CHECKSUM: 32-bit fletcher checksum of UID\_PSRAND0-5 and UID\_UNIQUE and calculated as either little- or big-endian during factory testing

### 3.4 Resets

This section explains the types and effects of the different resets on this device.

#### 3.4.1 Reset Sources

Table 3-2 summarizes the various reset signals and their effect on the device.

**Table 3-2. Reset Signals**

| Reset Source                               | CPU Core Reset<br>(C28x, FPU,<br>VCU) | Peripherals<br>Reset | JTAG / Debug<br>Logic Reset | IOs  | $\overline{\text{XRS}}$ Output |
|--------------------------------------------|---------------------------------------|----------------------|-----------------------------|------|--------------------------------|
| POR                                        | Yes                                   | Yes                  | Yes                         | Hi-Z | Yes                            |
| $\overline{\text{XRS}}$ Pin                | Yes                                   | Yes                  | No                          | Hi-Z | -                              |
| $\overline{\text{WDRS}}$                   | Yes                                   | Yes                  | No                          | Hi-Z | Yes                            |
| $\overline{\text{NMIWDRS}}$                | Yes                                   | Yes                  | No                          | Hi-Z | Yes                            |
| $\overline{\text{SYSRS}}$ (Debugger Reset) | Yes                                   | Yes                  | No                          | Hi-Z | No                             |
| $\overline{\text{SCCRESET}}$               | Yes                                   | Yes                  | No                          | Hi-Z | No                             |

The resets can be divided into two groups:

- Chip-level resets ( $\overline{\text{XRS}}$ , POR, BOR,  $\overline{\text{WDRS}}$ , and  $\overline{\text{NMIWDRS}}$ ), which reset all or almost all of the device.
- System resets ( $\overline{\text{SYSRS}}$  and  $\overline{\text{SCCRESET}}$ ), which reset a large subset of the device but maintain some system-level configuration.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. They can only be cleared by a power-on reset (POR) or by writing ones to the RESCCLR register. Some are cleared by the boot ROM as part of its start-up routines.

Many peripheral modules have individual resets accessible through the SOFTPRESx registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After any reset, the CPU begins execution from address 0x3FFFC0 (the reset vector), which is in the boot ROM. After running the boot ROM code, the CPU will typically branch to the start of the flash memory at address 0x80000. For more information on controlling the boot process, see the ROM Code and Peripheral Booting chapter.

---

**NOTE:** After a POR, the boot ROMs will clear the M0/M1, LSx, GSx, and message RAMs to ensure that they contain valid ECC or parity.

---

### 3.4.2 External Reset ( $\overline{XRS}$ )

The external reset ( $\overline{XRS}$ ) is the main chip-level reset for the device. It resets the CPU, all peripherals and I/O pin configurations, and most of the system control registers. There is a dedicated open-drain pin for  $\overline{XRS}$ . This pin may be used to drive reset pins for other ICs in the application, and may itself be driven by an external source. The  $\overline{XRS}$  is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register will be set whenever  $\overline{XRS}$  is driven low for any reason. This bit is then cleared by the boot ROM.

### 3.4.3 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The  $\overline{XRS}$  pin is held low for the duration of the POR. In most applications,  $\overline{XRS}$  is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, the  $\overline{XRS}$  pin can be driven low externally to provide the correct reset duration. A POR resets everything that  $\overline{XRS}$  does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), and the X1 clock counter register (X1CNT). A POR also resets the debug logic used by the JTAG port.

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

### 3.4.4 Debugger Reset ( $\overline{SYSRS}$ )

During development, it is sometimes necessary to reset the CPU and its peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, the CPU has its own subsystem reset, which can be triggered by a debugger using Code Composer Studio. This reset ( $\overline{SYSRS}$ ) resets the CPU, its peripherals, many system control registers (including its clock gating and LPM configuration), and all I/O pin configurations.

The  $\overline{SYSRS}$  does not reset the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.4.3](#)).

### 3.4.5 Watchdog Reset ( $\overline{WDRS}$ )

The device has a watchdog timer that can optionally trigger a reset if it is not serviced by the CPU within a user-specified amount of time. This watchdog reset ( $\overline{WDRS}$ ) produces an  $\overline{XRS}$  that lasts for 512 INTOSC1 cycles.

After a watchdog reset, the WDRSn bit in RESC is set.

### 3.4.6 NMI Watchdog Reset ( $\overline{NMIWDRS}$ )

The device has a non-maskable interrupt (NMI) module that detects hardware errors in the system. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This NMI watchdog reset ( $\overline{NMIWDRS}$ ) produces an  $\overline{XRS}$  that lasts for 512 INTOSC1 cycles.

After an NMI watchdog reset, the NMIWDRSn bit in RESC is set.

### 3.4.7 DCSM Safe Code Copy Reset ( $\overline{SCCRESET}$ )

The device has a dual-zone code security module (DCSM) that blocks read access to certain areas of the flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. This security reset ( $\overline{SCCRESET}$ ) is similar to a  $\overline{SYSRS}$ . However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

### 3.5 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.6](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

#### 3.5.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

#### 3.5.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line. It also expands the vector table to allow each interrupt to have its own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has its own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

**Figure 3-1. Device Interrupt Architecture**

##### 3.5.2.1 Peripheral Stage

Each peripheral has its own unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral might use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt will be generated.

### 3.5.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, it fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition will not happen unless software changes the state of the PIE while an interrupt is propagating. [Section 3.5.4](#) contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

### 3.5.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of its interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC and CLRC instructions. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is set, the next instruction in the pipeline will run with interrupts disabled. No software delays are needed.

## 3.5.3 Interrupt Entry Sequence

[Figure 3-2](#) shows how peripheral interrupts propagate to the CPU.

**Figure 3-2. Interrupt Propagation Path**

When a peripheral generates an interrupt (on PIE group x, channel y), it triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.

7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves its context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories will add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

### 3.5.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

#### 3.5.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in [Table 3-3](#). Note that the vector table is EALLOW-protected.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be found in [Table 3-3](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

#### 3.5.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU will not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

#### 3.5.4.3 Disabling Interrupts

To disable all interrupts, set the CPU's global interrupt mask via DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction will execute with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, it may reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation may cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR will only contain a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to its original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

#### 3.5.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts via software control of the IER and PIEIERx registers. Documentation and example code can be found in C2000Ware and on the TI Processors wiki: [http://processors.wiki.ti.com/index.php/Interrupt\\_Nesting\\_on\\_C28x](http://processors.wiki.ti.com/index.php/Interrupt_Nesting_on_C28x)

#### 3.5.4.5 Vector Address Validity Check

There are two copies of the ePIE vector table. The primary vector table is located at addresses 0xD00 - 0xEFF. The redundant vector table is located at addresses 0x0100D00 - 0x0100EFF. A write to a primary vector address writes to both tables, while a write to a redundant vector address only writes to the redundant table. Both tables are read independently.

During a vector fetch, the ePIE performs a hardware comparison of both vector table outputs. If there is a mismatch between the two vector tables, the CPU branches to the address in the PIEVERRADDR register and the ePIE sends trip signals to the PWMs. If the PIEVERRADDR register value has not been set, the default boot ROM handler at address 0x003FFFBE is used.

### 3.5.5 PIE Channel Mapping

**Table 3-3** shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel is the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

**Table 3-3. PIE Channel Mapping**

|         | INTx.1       | INTx.2        | INTx.3       | INTx.4       | INTx.5       | INTx.6       | INTx.7           | INTx.8                | INTx.9   | INTx.10                       | INTx.11                         | INTx.12                      | INTx.13          | INTx.14         | INTx.15          | INTx.16              |
|---------|--------------|---------------|--------------|--------------|--------------|--------------|------------------|-----------------------|----------|-------------------------------|---------------------------------|------------------------------|------------------|-----------------|------------------|----------------------|
| INT1.y  | ADCA1        | ADCB1         | ADCC1        | XINT1        | XINT2        | -            | TIMER0           | WAKE<br>/WDOG         | -        | -                             | -                               | -                            | -                | -               | -                | -                    |
| INT2.y  | EPWM1_<br>TZ | EPWM2_<br>TZ  | EPWM3_<br>TZ | EPWM4_<br>TZ | EPWM5_<br>TZ | EPWM6_<br>TZ | EPWM7_<br>TZ     | EPWM8_<br>TZ          | -        | -                             | -                               | -                            | -                | -               | -                | -                    |
| INT3.y  | EPWM1        | EPWM2         | EPWM3        | EPWM4        | EPWM5        | EPWM6        | EPWM7            | EPWM8                 | -        | -                             | -                               | -                            | -                | -               | -                | -                    |
| INT4.y  | ECAP1        | ECAP2         | ECAP3        | ECAP4        | ECAP5        | ECAP6        | ECAP7            | -                     | -        | -                             | -                               | -                            | -                | ECAP6_<br>HRCAL | ECAP7_<br>HRCAL  | -                    |
| INT5.y  | EQEP1        | EQEP2         | -            | -            | CLB1         | CLB2         | CLB3             | CLB4                  | SDFM1    | -                             | -                               | -                            | SDFM1DR1         | SDFM1DR2        | SDFM1DR3         | SDFM1DR4             |

### 3.5.6 Vector Tables

Table 3-4 shows the CPU interrupt vector table. The vectors for INT1 – INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table. All vectors are EALLOW-protected.

**Table 3-4. CPU Interrupt Vectors**

| Name    | Vector ID | Address     | Size (x16) | Description                                                   | Core priority | ePIE group Priority |
|---------|-----------|-------------|------------|---------------------------------------------------------------|---------------|---------------------|
| Reset   | 0         | 0x0000 0D00 | 2          | Reset is always fetched from location 0x003F_FFC0 in Boot ROM | 1 (Highest)   | -                   |
| INT1    | 1         | 0x0000 0D02 | 2          | Not used. See PIE Group 1                                     | 5             | -                   |
| INT2    | 2         | 0x0000 0D04 | 2          | Not used. See PIE Group 2                                     | 6             | -                   |
| INT3    | 3         | 0x0000 0D06 | 2          | Not used. See PIE Group 3                                     | 7             | -                   |
| INT4    | 4         | 0x0000 0D08 | 2          | Not used. See PIE Group 4                                     | 8             | -                   |
| INT5    | 5         | 0x0000 0D0A | 2          | Not used. See PIE Group 5                                     | 9             | -                   |
| INT6    | 6         | 0x0000 0D0C | 2          | Not used. See PIE Group 6                                     | 10            | -                   |
| INT7    | 7         | 0x0000 0D0E | 2          | Not used. See PIE Group 7                                     | 11            | -                   |

**Table 3-5. PIE Interrupt Vectors (continued)**

| Name     | Vector ID | Address     | Size (x16) | Description             | Core priority | ePIE group Priority |
|----------|-----------|-------------|------------|-------------------------|---------------|---------------------|
| INT12.15 | 222       | 0x0000 0EBC | 2          | CLA overflow interrupt  | 16            | 15                  |
| INT12.16 | 223       | 0x0000 0EBE | 2          | CLA underflow interrupt | 16            | 16 (Lowest)         |

## 3.6 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

### 3.6.1 Configuring and Using NMIs

An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value in the NMIWDPRD register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register may also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

### 3.6.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

|                            |                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU Suspended              | When the CPU is suspended, the NMI watchdog counter will be suspended.                                                                                     |
| Run-Free Mode              | When the CPU is placed in run-free mode, the NMI watchdog counter will resume operation as normal.                                                         |
| Real-Time Single-Step Mode | When the CPU is in real-time single-step mode, the NMI watchdog counter will be suspended. The counter remains suspended even within real-time interrupts. |
| Real-Time Run-Free Mode    | When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.                                                                   |

### 3.6.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

#### 3.6.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and an NMI is fired to the CPU. For more information on missing clock detection, see [Section 3.7.12](#).

#### 3.6.3.2 RAM Uncorrectable ECC Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read will trigger an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.11.1.7](#).

### 3.6.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a flash read will trigger an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on flash error detection, see .

### 3.6.3.4 Software-Forced Error

There is a special NMI source that can only be triggered by writing to the SWERR bit in the NMIFLGFR register. Since the SWERR flag is never set by a real hardware fail, it can be used to implement a self-test mode for the NMI subsystem.

## 3.6.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, it generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has its own vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

---

**NOTE:** A RAM fetch access violation will trigger an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU will handle the ITRAP first.

---

## 3.6.5 Error Pin

A signal called ERRORSTS can be output to GPIO24, GPIO28, or GPIO29. This signal goes low when any bit is set in the NMI shadow flag register (NMISHDFLG). It can be used to alert an external system to a problem in the microcontroller. Since the state of ERRORSTS is based on the shadow flags, ERRORSTS will remain low until the flags are cleared by the CPU or a power-on reset occurs.

All GPIO pins are inputs on power-up. If the state of the chosen ERRORSTS pin during power-up is important, an external pull-up should be connected to the pin.

### 3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. [Figure 3-3](#) and [Figure 3-4](#) provide an overview of the device's clocking system.

**Figure 3-3. Clocking System**

**Figure 3-4. System PLL**

#### 3.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

### 3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10 MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source, and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application. Note that INTOSC2's frequency tolerance is too loose to meet the timing requirements for CAN. Use of the CAN modules requires an external oscillator. When INTOSC2 is used as the system clock source, GPIO18 (X2) is available for use as a GPIO. A 1k pull-down resistor must be connected to X1. GPIO18 has different electrical characteristics from the other GPIOs due to interaction with the oscillator circuit. For more information, see the device datasheet.

**Figure 3-5. Using GPIO18 when INTOSC2 is the SYSCLK source**

### 3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system clock source for debug purposes.

### 3.7.1.3 External Oscillator (XTAL)

The device supports an external clock source (XTAL), which can be used as the main system and CAN bit clock source. Frequency limits and timing requirements can be found in the device datasheet. External clock sources use the X1 and X2/GPIO18 pins. After power-up, the X1 and X2 pin functionality can be enabled by following the procedure in [Section 3.7.6](#).

Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal should be connected to X1, as shown in [Figure 3-6](#). X2/GPIO18 is not available as a GPIO.

**Figure 3-6. Single-ended 3.3V External Clock**

- An external crystal. The crystal should be connected across X1 and X2 with its load capacitors connected to VSS as shown in [Figure 3-7](#).

**Figure 3-7. External Crystal**

- An external resonator. The resonator should be connected across X1 and X2 with its ground connected to VSS as shown in [Figure 3-8](#).

**Figure 3-8. External Resonator**

### 3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (via PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

#### 3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

#### 3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at its maximum rated operating frequency, and in most applications will generate the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier. PLLRAWCLK is the output of the PLL's voltage-controlled oscillator (VCO). For configuration instructions, see [Section 3.7.6](#).

### 3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

#### 3.7.3.1 System Clock (PLLSYSCLK)

The NMI watchdog timer has its own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK may be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured via the SYCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

#### 3.7.3.2 CPU Clock (CPUCLK)

The CPU has its own clock (CPUCLK) which is used to clock the CPU, its coprocessors, its private RAMs (M0 and M1), and the boot ROM and flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or HALT mode.

### 3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

The CPU provides a clock (SYSCLK) to the CLA, DMA, and most peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters HALT mode.

Each peripheral clock has its own independent clock gating which is controlled by the PCLKCRx registers.

### 3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI and SPI modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed via the LOSPCP register. Each SCI and SPI module's clock (PERx.LSPCLK) can be gated independently via the PCLKCRx registers.

### 3.7.3.5 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to XTAL via the CLKSRCCTL2 register. There is an independent selection for each CAN module.

To guarantee correct operation, the frequency of the CAN bit clock must be less than or equal to the SYSCLK frequency.

### 3.7.3.6 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but may also be connected to INTOSC1, INTOSC2, or XTAL via the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a non-SYSCLK source is used, it must be divided down to no more than half the SYSCLK frequency.

The main reason to use a non-SYSCLK source would be for internal frequency measurement. In most applications, timer 2 will run off of SYSCLK.

## 3.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, which can be GPIO16 or GPIO18. The available clock sources are PLLSYSCLK, PLLRAWCLK, SYSCLK, INTOSC1, INTOSC2, and XTAL.

To use XCLKOUT, first select the clock source via the CLKSRCCTL3 register. Next, select the desired output divider via the XCLKOUTDIVSEL register. Finally, connect GPIO16 or GPIO18 to mux channel 11 using the GPIO configuration registers.

## 3.7.5 Clock Connectivity

The tables below provide details on the clock connections of every module present in the device.

**Table 3-6. Clock Connections Sorted by Clock Domain**

| Clock Domain | Module Name  |
|--------------|--------------|
| CPUCLK       | CPU          |
|              | FPU          |
|              | TMU          |
|              | VCU          |
|              | Flash        |
|              | M0 - M1 RAMs |
|              | Boot ROM     |
| SYSCLK       | ePIE         |

**Table 3-6. Clock Connections Sorted by Clock Domain (continued)**

| Clock Domain    | Module Name                                                                                                                                              |

### 3.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but they should provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. What types of external oscillators or clock sources are available?

If CAN is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, it may be possible to use only INTOSC2 and avoid the need for more external components.

### 3.7.7 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO19 and GPIO18. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Clear the X1 counter by writing a 1 to X1CNT.CLR.
3. Wait for the X1 counter value in the X1CNT register to reach 1023 (0x3ff).
4. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
5. Check the MCLKSTS bit in the MCDPCR register. If it's set, the oscillator has not finished powering up, and more time is required:
  - a. Clear the missing clock status by writing a 1 to MCDPCR.MCLKCLR.
  - b. Repeat steps 2-5. Do not reset the device. Doing so will power down the oscillator, which requires the procedure to be restarted from step 1.
  - c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
6. If MCDPCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

### 3.7.8 Using an External Oscillator

The procedure for using an external oscillator connected to the X1 pin is similar to the procedure for using a crystal or resonator:

1. Clear the XTALCR.OSCOFF bit.
2. Set the XTALCR.SE bit to enable single-ended mode.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR.
4. Wait for the X1 counter value in the X1CNT register to reach 1023 (0x3ff).
5. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
6. Check the MCLKSTS bit in the MCDPCR register. If it's set, either the external oscillator or the device has failed.
7. If MCLKSTS is clear, the switch to the external clock is a success. The system clock is now derived from XTAL.

### 3.7.9 Choosing PLL Settings

There are two settings to configure for the PLL – a multiplier and a divider. They obey the formula:

$$f_{\text{PLLSYSCLK}} = f_{\text{OSCCLK}} * (\text{SYSPLLMULT.IMULT} + \text{SYSPLLMULT.FMULT}) / (\text{SYSPLLMULT.ODIV} * \text{SYSCLKDIVSEL.PLLSYSCLKDIV})$$

where  $f_{\text{OSCCLK}}$  is the system oscillator clock frequency, IMULT and FMULT are the integral and fractional parts of the multipliers, ODIV is the PLL output divider, and PLLSYSCLKDIV is the system clock divider. For the permissible values of the multipliers and dividers, see the documentation for their respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the datasheet's  $f_{\text{(VCO)}}$  parameter. The VCO frequency divided by the output divider (known as the PLL output frequency) must be in the range specified by the datasheet's  $f_{\text{(PLLRAWCLK)}}$  parameter. The examples below will use 120 - 200 MHz for this parameter.

---

**NOTE:** The system clock frequency (PLLSYSCLK) may not exceed the limits specified in the data sheet's  $f_{\text{(SYSCLK)}}$  parameter. These limits do not allow for oscillator tolerance.

---

### 3.7.10 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

1. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. To enable XTAL, follow the instructions in the previous sections.

2. Set up the system PLL if desired. TI recommends using the C2000Ware SysCtl:setClock() function for proper configuration of the PLL clock.
3. Select the LSPCLK divider by writing to LOSPCP.
4. If an alternate CAN bit clock is needed, select it by writing to CLKSRCCTL2.CANABCLKSEL and CLKSRCCTL2.CANBBCLKSEL.
5. Enable the desired peripheral clocks by writing to the PCLKCRx registers.

The system clock configuration can be changed at run time. Changing the OSCCLK source will automatically bypass the PLL and set the multiplier to zero. Changing the multiplier from one non-zero value to another will temporarily bypass the PLL until it re-locks.

### 3.7.11 Clock Configuration Examples

**Example 1:** Using INTOSC2 (10 MHz) as a reference, generate a CPU frequency of 100 MHz - 3%:

```
CLKSRCCTL1.OSCCLKSRCSEL = 0x0
SYSPLLMULT = 0x00113
SYSCLKDIVSEL.PLLSYSCLKDIV = 2 (0x1)
SYSPLLCTL1.PLLCLKEN = 1
IMULT = 19 (0x13), FMULT = 0.25 (0x1), ODIV = 1 (0x0)
```

This gives a PLLRAWCLK of 192.5 MHz, which is within the acceptable range of 150 - 200 MHz. The CPU frequency is 96.25 MHz with a 3% tolerance due to variation in the internal oscillator.

**Example 2:** Using a crystal (20 MHz) as a reference, generate a CPU frequency of 85 MHz:

```
XTALCR.OSCOFF = 0
XTALCR.X1CNT.CLR = 1
(wait for X1CNT to reach 0x3ff)
CLKSRCCTL1.OSCCLKSRCSEL = 0x1
(check MCDCCR.MCLKSTS and repeat the above if necessary)
SYSPLLMULT = 0x00208
SYSCLKDIVSEL.PLLSYSCLKDIV = 2 (0x1)
SYSPLLCTL1.PLLCLKEN = 1
IMULT = 8 (0x08), FMULT = .50 (0x2), ODIV = 1 (0x0)
```

This gives a PLLRAWCLK of 170 MHz, which is in the acceptable range. The CPU frequency is exactly 85 MHz.

---

#### NOTE:

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
  2. At least 60 CPU clock cycles delay is needed after bypassing PLL i.e. SYSPLLCTL1.PLLCLKEN=0.
  3. At least 60 CPU clock cycles delay is needed after PLL is powered down i.e. SYSPLLCTL1.PLEN=0.
  4. At least 60 CPU clock cycles delay is needed after OSSCLK source is changed.
- 

### 3.7.12 Missing Clock Detection

The missing clock detection (MCD) subsystem detects OSCCLK failure using INTOSC1 as a reference clock. This subsystem only detects complete loss of OSCCLK. Frequency drift is not detected.

OSCCLK is connected to a 7-bit counter (MCDPCNT). INTOSC1 is connected to a 13-bit counter (MCDSCNT). When MCDPCNT overflows, MCDSCNT is reset. Thus, if OSCCLK is present and its frequency is greater than 1/64 of INTOSC1's frequency, MCDSCNT will never overflow. If OSCCLK stops for any reason, MCDSCNT will overflow and a missing clock condition will be detected.

When the MCD subsystem detects that OSCCLK is missing, the following occurs:

- The PLL is bypassed and OSCCLK is connected to INTOSC1 (after the PLLSYSCLK divider). PLLMULT is zeroed out automatically.
- The MDCR.MCDSTS flag is set. While this flag is set, the OSCCLKSRCSEL bits have no effect.
- The CLOCKFAIL signal goes high, which generates trip events to the PWM modules and triggers an NMI.
- The MCDSCNT counter is frozen to prevent further missing clock detection.

To clear a missing clock condition, write a 1 to the MDCR.MCLKCLR bit. This will restore the functionality of the OSCCLKSRCSEL bits and reset the MCD counters. To lock the PLL during a missing clock condition, switch the OSCCLK source to INTOSC1 using the OSCCLKSRCSEL bits, clear the missing clock condition, then write to the PLL registers.

Missing clock detection is enabled at startup.

### 3.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU timers (TIMER0/1/2) shown in [Figure 3-9](#).

Timer0 and Timer1 can be used in user applications. Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then Timer2 can be used in the application. timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in [Figure 3-10](#).

**Figure 3-10. CPU Timer Interrupt Signals and Output Signal**

- A The timer registers are connected to the memory bus of the C28x processor.
- B The CPU Timers are synchronized to SYSCLKOUT.

The general operation of a CPU timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every (TPR[TDDR:TDDBR]+1) SYSCLK cycles, where TDDR:TDDBR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in [Section 3.14](#) are used to configure the timers.

## 3.9 Watchdog Timer

The watchdog module consists of an 8-bit counter fed by a prescaled clock (WDCLK, which is connected to INTOSC1). When the counter reaches its maximum value, the module generates an output pulse 512 WDCLKs wide. This pulse can generate an interrupt or a reset. The CPU must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled.

The counter's clock is divided down from WDCLK by two dividers. The prescaler is adjustable from /1 to /64 in powers of two. The pre-divider defaults to /512 for backwards compatibility, but is adjustable from /2 to /4096 in powers of two. This allows a wide range of timeout values for safety-critical applications.

Figure 3-11 shows the various functional blocks within the watchdog module.

**Figure 3-11. Watchdog Timer Module**

### 3.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

**Table 3-8. Example Watchdog Key Sequences**

| Step | Value Written to WDKEY | Result                                                                                            |
|------|------------------------|---------------------------------------------------------------------------------------------------|
| 1    | 0xAA                   | No action                                                                                         |
| 2    | 0xAA                   | No action                                                                                         |
| 3    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 4    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 5    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 6    | 0xAA                   | WDCNTR is reset.                                                                                  |
| 7    | 0xAA                   | No action                                                                                         |
| 8    | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 9    | 0xAA                   | WDCNTR is reset.                                                                                  |
| 10   | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 11   | 0x32                   | Improper value written to WDKEY.<br>No action, WDCNTR no longer enabled to be reset by next 0xAA. |
| 12   | 0xAA                   | No action due to previous invalid value.                                                          |
| 13   | 0x55                   | WDCNTR is enabled to be reset if next value is 0xAA.                                              |
| 14   | 0xAA                   | WDCNTR is reset.                                                                                  |

The first action that enables the WDCNTR to be reset is shown in Step 3 in [Table 3-8](#). The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits will reset the device and set the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program should clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

### 3.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value will take effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR will trigger a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

### 3.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ( $\overline{\text{WDRST}}$ ) or assert an interrupt ( $\overline{\text{WDINT}}$ ) if the watchdog counter reaches its maximum value. The behavior of each condition is described below:

- **Reset mode:**

If the watchdog is configured to reset the device, then the  $\overline{\text{WDRST}}$  signal will pull the device reset ( $\overline{\text{XRS}}$ ) pin low for 512 OSCCLK cycles when the watchdog counter reaches its maximum value.

- **Interrupt mode:**

When the watchdog counter expires, it will assert an interrupt by driving the  $\overline{\text{WDINT}}$  signal low for 512 OSCCLK cycles. The falling edge of  $\overline{\text{WDINT}}$  triggers a WAKEINT interrupt in the PIE if it is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while  $\overline{\text{WDINT}}$  is active will not produce a duplicate interrupt.

To avoid unexpected behavior, software should not change the configuration of the watchdog while  $\overline{\text{WDINT}}$  is active. For example, changing from interrupt mode to reset mode while  $\overline{\text{WDINT}}$  is active will immediately reset the device. Disabling the watchdog while  $\overline{\text{WDINT}}$  is active will cause a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while  $\overline{\text{WDINT}}$  is active, the reset cause register (RESC) will show a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of  $\overline{\text{WDINT}}$ .

### 3.9.4 Watchdog Operation in Low Power Modes

In IDLE mode, the watchdog interrupt ( $\overline{\text{WDINT}}$ ) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt will trigger a WAKE interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

**Note:** If the watchdog interrupt is used to wake-up from an IDLE low power mode condition, software must make sure that the  $\overline{\text{WDINT}}$  signal goes back high before attempting to reenter the IDLE mode. The  $\overline{\text{WDINT}}$  signal will be held low for 512 OSCCLK cycles when the watchdog interrupt is generated. The current state of  $\overline{\text{WDINT}}$  can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of  $\overline{\text{WDINT}}$  by two SYSCLKOUT cycles.

In HALT mode, the internal oscillators and watchdog timer are kept active if the user sets CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

### 3.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

|                             |                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU Suspended:              | When the CPU is suspended, the watchdog clock (WDCLK) is suspended                                                                                       |
| Run-Free Mode:              | When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.                                                           |
| Real-Time Single-Step Mode: | When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts. |
| Real-Time Run-Free Mode:    | When the CPU is in real-time run-free mode, the watchdog operates as normal.                                                                             |

### 3.10 Low Power Modes

All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes should not be entered into while a flash program or erase operation is ongoing. Entering HALT will stop all CPU and peripheral activities. This includes active transmissions and control algorithms. When preparing to enter HALT mode, the application should ensure that the system is prepared to enter a period of inactivity.

Before entering HALT mode check the value of the GPIODAT register of the pin selected for HALT wake-up (GPIOLPMSEL0/1) prior to entering the low-power mode to ensure that the wake event has not already been asserted.

#### 3.10.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events.

Any enabled interrupt will wake the CPU up from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

The CPU will resume normal operations upon any enabled interrupt event.

#### 3.10.2 Guidelines on Software Emulation of STANDBY Mode

STANDBY is not supported on this device, but can be emulated using the steps below in order to conserve power:

1. Switch SYSCLK source from PLLCLK to OSCCLK by configuring SYSPLLCTL1.PLLCLKEN=0
2. Disable peripheral clocks through PCLKCRx registers
3. Enter IDLE mode using the instructions defined in [Section 3.10.1](#).

Here are the key differences between Software Emulated STANDBY vs STANDBY mode.

**Table 3-9. Software Emulated STANDBY vs STANDBY Mode**

| Software Emulated STANDBY                                                                                                                                           | STANDBY (Not Supported)                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peripheral clocks needs to be disabled prior to entering IDLE mode.                                                                                                 | Peripheral clocks are automatically disabled.                                                                                                              |
| Wakeup source is XINT or WDINT.                                                                                                                                     | Wakeup source is WAKEINT or WDINT.                                                                                                                         |
| Peripheral Interrupts should be disabled prior to entering IDLE mode, since any interrupt going into the PIE will wake up the system.                               | System can only wake up externally through WAKENIT (dedicated LPM Interrupt).                                                                              |
| Any GPIO can be routed through INPUT XBAR to XINT as a wake up source. Qualification of the GPIO is through GPxQSEL.                                                | GPIO has to be configured as LPM interrupt through GPIOLPMSELx to trigger WAKEINT. Qualification of the GPIO is through dedicated Low Power Mode register. |
| On wakeup, the CPU enters XINT ISR.                                                                                                                                 | On wakeup, the CPU enters WAKEINT ISR.                                                                                                                     |
| Any peripheral clocks and Interrupts disabled prior to entering IDLE mode should be re-enabled by software on Wakeup.                                               | System resumes normal operation on wake up. No extra steps needed.                                                                                         |
| If SYSCLK is switched from PLLCLK to OSCCLK prior to entering IDLE mode, it has to be switched back by configuring SYSPLLCTL1.PLLCLKEN=1 to resume normal operation | System resumes normal operation on wake up. No extra steps needed.                                                                                         |

### 3.10.3 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks.

Unlike on other C2000 devices, HALT mode will not automatically power down the XTAL upon HALT entry. Additionally, if the XTAL is not powered on, waking up from HALT mode will not automatically power on the XTAL. The XTALCR.OSCOFF bit has been added to power on and off the XTAL circuitry when not needed through application software.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

GPIO0-63 can be configured to wake up the system from HALT. No other wakeup option is available. However, the watchdog timer may still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, the CPU receives a WAKEINT interrupt.

#### To enter HALT mode:

1. Enable the WAKEINT interrupt in the PIE .
2. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
3. Set CLKSRCCTL1.WDHALTI to 1 to keep the watchdog timer active and INTOSC1 and INTOSC2 powered up in HALT.
4. Set CLKSRCCTL1.WDHALTI to 0 to disable the watchdog timer and power down INTOSC1 and INTOSC2 in HALT.
5. Execute the IDLE instruction to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system will begin executing the WAKEINT ISR. After HALT wakeup, ISR execution will resume where it left off.

**NOTE:** Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), it must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device will never wake up.

#### To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5us. This will activate the WAKEINT PIE interrupt.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL
3. Wait 16us plus 1024 OSCCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

### 3.10.4 Flash Power-down Considerations

The Flash module on this device can be powered down at any time during an application. There are some considerations that must be made when powering down the Flash.

When the application software powers down the Flash, it must ensure that the function that puts the Flash to sleep is executed from RAM. Note that there should not be any access to Flash after the Flash is put to sleep to realize the power savings. If there is an access to Flash, Flash wakeup process (wakeup time depends on PSLEEP and RWAIT as mentioned in [Flash/OTP and Pump Power Modes and Wakeup](#) gets initialized and the application will not realize Flash power savings. For example, if the application has to execute any code after putting the Flash to sleep and before putting the device in to low power mode, the application should execute that code from RAM and not from Flash.

As mentioned in [Flash/OTP and Pump Power Modes and Wakeup](#), PSLEEP and RWAIT can be optimized to reduce the Flash wakeup time for a given SYSCLK frequency. BootROM configures the best possible PSLEEP value for the 100MHz operation. However, the application software can decrease the PSLEEP value to reduce the Flash wakeup time if the application SYSCLK is less than 100MHz. This is applicable in the context of an application entering the Halt mode since PLL must be disabled before entering the Halt mode. In this case, the PSLEEP value can be decreased to get a faster Flash wakeup upon exit from LPM.

If the Wake ISR is in Flash, it is suggested to optimize the PSLEEP and RWAIT values before entering the LPM, and after the Flash is in sleep, since application does not get a chance to modify these before Flash is awake after exiting from LPM. However, after the LPM exit and once the Flash is awake, application should branch to RAM to restore RWAIT and PSLEEP (as per the application SYSCLK to which PLL will be locked for) and then proceed with Flash execution to lock the PLL.

If the Wake ISR is in RAM, application can optimize the PSLEEP and RWAIT values in the Wake ISR and then do a dummy Flash access to initiate the Flash wakeup process. While the Flash is waking up, application can initialize the PLL lock process. Once the Flash is awake, application can put the PLL in clock path. If the user does not want to lock the PLL from RAM, PLL can be locked from Flash (this means Flash wakeup and PLL lock are not done in parallel), but in any case make sure to restore the RWAIT and PSLEEP (as per the application SYSCLK to which PLL will be locked for) in Wake ISR before proceeding to Flash execution.

Unlike F28M3x, F2837x, and F2807x devices, the Flash fallback mode is not configured as active mode automatically upon Flash wakeup in F28004x and instead stays as it is configured before entering the Flash low power mode. Hence, the BootROM code and the Flash initialization routine in C2000Ware configure the Flash fallback mode to active mode to avoid Flash falling back to low power mode after the grace period expiration. Similarly, in the context of the device LPM, the application software must change the Flash Fallback mode to the Active state in the Wake ISR if required. If not, Flash will enter the configured fallback power mode when the grace period expires as mentioned in [Flash/OTP and Pump Power Modes and Wakeup](#). This applies to all low power modes on this device.

### 3.11 Memory Controller Module

For these devices, the RAMs have different characteristics. Some are:

- dedicated to the CPU (M0, and M1),
- shared between the CPU and CLA (LSx RAM),
- shared between the CPU and DMA (GSx RAM), and
- used to send and receive messages between processors (MSGRAM).

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. All dedicated RAMs are enabled with the ECC feature (both data and address) and shared RAMs, are enabled with the parity (both data and address) feature. Some of the dedicated memories are secure memory as well. Refer to [Section 3.13](#) for more details. Each RAM has its own controller which takes care of the access protection/security related checks and ECC/Parity features for that RAM.

[Figure 3-12](#) shows the configuration of these RAMs.

**Figure 3-12. Memory Architecture**

**NOTE:** All RAMs on these devices are SRAMs.

#### 3.11.1 Functional Description

This section further defines and discusses the dedicated RAMs, shared RAMs, and MSG RAMs on this device.

##### 3.11.1.1 Dedicated RAM (Mx RAM)

This device has two dedicated RAM blocks: M0 and M1. M0 and M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (including DMA) have any access to these memories.

All dedicated RAMs have the ECC feature.

##### 3.11.1.2 Local Shared RAM (LSx RAM)

RAM blocks which are accessible to the CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the parity feature. By default, these memories are dedicated to the CPU only, and the user could choose to share these memories with the CLA by appropriately configuring the MSEL\_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user could choose to use these memories as CLA program memory by configuring the CLAPGM\_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks which are programmed as CLA program memory are blocked.

All these RAMs have the access protection (CPU write/CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers. [Table 3-10](#) shows the LSx RAM features.

**Table 3-10. Local Shared RAM**

| MSEL_LSx | CLAPGM_LSx | CPUx Allowed Access               | CPUx.CLA1 Allowed Access                                               | Comment                                       |
|----------|------------|-----------------------------------|------------------------------------------------------------------------|-----------------------------------------------|
| 00       | X          | All                               | -                                                                      | LSx memory is configured as CPU dedicated RAM |
| 01       | 0          | All                               | Data Read<br>Data Write<br>Emulation Data Read<br>Emulation Data Write | LSx memory is shared between CPU and CLA1     |
| 01       | 1          | Emulation Read<br>Emulation Write | Fetch Only<br>Emulation Program Read<br>Emulation Program Write        | LSx memory is CLA1 program memory             |

### 3.11.1.3 Global Shared RAM (GSx RAM)

RAM blocks which are accessible from the CPU and DMA are called global shared RAMs (GSx RAMs). [Table 3-11](#) shows the features of the GSx RAM.

**Table 3-11. Global Shared RAM**

| CPU (Fetch) | CPU (Read) | CPU (Write) | CPU.DMA (Read) | CPU.DMA (Write) |
|-------------|------------|-------------|----------------|-----------------|
| Yes         | Yes        | Yes         | Yes            | Yes             |

Like other shared RAM, these RAMs also have different levels of access protection which can be enabled or disabled by configuring specific bits in the GSxACCPROT registers.

Master select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once a configuration is committed for a particular GSx RAM block, it can not be changed further until CPU.SYSRS is issued.

### 3.11.1.4 Message RAM (CLA MSGRAM)

These RAM blocks are used to share data between the CPU and CLA. The CLA has read and write access to the CLA to CPU MSGRAM. The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

### 3.11.1.5 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

[Figure 3-13](#) represents the arbitration scheme on global shared memories:

**Figure 3-13. Arbitration Scheme on Global Shared Memories**

Figure 3-14 represents arbitration scheme on local shared memories.

**Figure 3-14. Arbitration Scheme on Local Shared Memories**

### 3.11.1.6 Access Protection

All RAM blocks except for M0/M1 have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses, hence reads are always allowed from all the masters which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

---

**NOTE:** For debug accesses, all the protections are disabled.

---

#### 3.11.1.6.1 CPU Fetch Protection

Fetch accesses from the CPU can be protected by setting the FETCHPROTx bit of the specific register to '1.' If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

If a fetch protection violation occurs, it results in an ITRAP for CPU. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU fetch access violation address register.

#### **3.11.1.6.2 CPU Write Protection**

Write accesses from the CPU can be protected by setting the CPUWRPROTx bit of the specific register to '1.' If write access is done by a CPU to memory where it is protected, a write protection violation occurs.

If a write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

#### **3.11.1.6.3 CPU Read Protection**

For local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the accesses from the CPU, including a read, will be blocked and the violation will be considered a non-master access violation.

If a read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

#### **3.11.1.6.4 CLA Fetch Protection**

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, it results in a MSTOP. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

#### **3.11.1.6.5 CLA Write Protection**

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the CPU if enabled in the interrupt enable register.

#### **3.11.1.6.6 CLA Read Protection**

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

#### **3.11.1.6.7 DMA Write Protection**

Write accesses from the DMA can be protected by setting the DMAWRPROTx bit of a specific register to '1.' If a write access is done by the DMA to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master DMA, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to '1' for that memory, it is called a master DMA write protection violation.

A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

- Note 1:** All access protections are ignored during debug accesses. Write access to a protected memory will go through when it is done via the debugger, irrespective of the write protection configuration for that memory.
- Note 2:** Access protection is not implemented for M0 and M1 memories.
- Note 3:** In the case of local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the accesses from the CPU (including read) and data accesses from the CLA will be blocked, and the violation will be considered a non-master access violation. If the memory is configured as dedicated to the CPU, all accesses from the CLA will be blocked and the violation will be considered a non-master access violation.

### 3.11.1.7 Memory Error Detection, Correction and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs support error correction code (ECC) protection and the shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit of data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

#### 3.11.1.7.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent a double-bit error due to another single-bit error at the same memory address.

#### 3.11.1.7.2 Error Handling

For each correctable error, the count in the correctable error count register will increment by one. When the value in this count register becomes equal to the value configured in the correctable error threshold register, an interrupt is generated to the CPU, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into a register and a flag also gets set in a status register.

If there are uncorrectable errors, an NMI gets generated for the CPU. In this case also, the address for which the error occurred gets latched into a register, and a flag gets set in a status register.

Table 3-12 summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

**Table 3-12. Error Handling in Different Scenarios**

| Access Type | Error Found In        | Error Type                                                                                       | Status Indication                                                                                                                 | Error Notification                                                                           |
|-------------|-----------------------|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Reads       | Data read from memory | Uncorrectable Error<br>(Single-bit error for Parity RAMs<br>OR<br>Double bit Error for ECC RAMs) | Yes - CPU/CPU.DMA/CPU.CLA1<br>CPU/DMA/CLA Read Error Address<br>Register Data returned to<br>CPU/CPU.DMA/CPU.CLA1 is<br>incorrect | NMI for CPU access<br>NMI for CPU.DMA access<br>NMI to CPU for CPU.CLA1 access               |
| Reads       | Data read from memory | Single-bit error for ECC RAMs                                                                    | Yes - CPU/CPU.DMA CPU/DMA<br>Read Error Address Register<br>Increment single error counter                                        | Interrupt when error counter reaches<br>the user programmable threshold for<br>single errors |
| Reads       | Address               | Address error                                                                                    | Yes - CPU/CPU.DMA/CPU.CLA1<br>CPU/DMA/CLA Read Address Error<br>Register Data returned to<br>CPU/CPU.DMA/CPU.CLA1 is<br>incorrect | NMI to CPU for CPU access<br>NMI to CPU for CPU.DMA access<br>NMI to CPU for CPU.CLA1 access |

**NOTE:** In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

### 3.11.1.8 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error could be injected into data.

**NOTE:** The memory map for ECC/Parity bits and data bits are the same. The user must choose a different test mode to access ECC/Parity bits. In test mode, all access to memories (data as well as ECC/Parity) should be done as 32-bit access only.

The following table shows the bit mapping for the ECC/Parity bits when they are read in RAMTEST mode using their respective addresses.

**Table 3-13. Mapping of ECC Bits in Read Data from ECC/Parity Address Map**

| Data Bits Location in Read Data | Content (ECC Memory)               |
|---------------------------------|------------------------------------|
| 6:0                             | ECC Code for lower 16 bits of data |
| 7                               | Not Used                           |
| 14:8                            | ECC Code for upper 16 bits of data |
| 15                              | Not Used                           |
| 22:16                           | ECC Code for address               |
| 31:23                           | Not Used                           |

**Table 3-14. Mapping of Parity Bits in Read Data from ECC/Parity Address Map**

| Data Bits Location in Read Data | Content (Parity Memory)          |
|---------------------------------|----------------------------------|
| 0                               | Parity for lower 16 bits of data |
| 7:1                             | Not Used                         |
| 8                               | Parity for upper 16 bits of data |
| 15:9                            | Not Used                         |
| 16                              | Parity for address               |
| 31:17                           | Not Used                         |

### 3.11.1.9 RAM Initialization

To ensure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM\_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to '1' for the specific RAM block in INIT registers. To check the status of RAM initialization, SW should poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access should be made to that RAM memory block.

---

**NOTE:** None of the masters should access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization will not happen correctly.

---

## 3.12 Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of flash. It also includes information on flash and OTP power modes, how to improve flash performance by enabling the flash prefetch/cache mode, and the SECEDED safety feature.

### 3.12.1 Features

Features of flash memory include:

- Up to two flash banks (Bank0 and Bank1) (refer to the device data manual for the number and size of the flash banks)
- One FMC controlling up to two flash banks
- 128 bits (bank width) can be programmed at a time along with ECC
- Multiple sectors providing the option of leaving some sectors programmed and only erasing specific sectors
- User-programmable OTP locations (in user-configurable DCSM OTP, also called USER OTP) for configuring security, OTP boot-mode and boot-mode select pins (if the user is unable to use the factory-default boot-mode select pins)
- Flash pump shared by the two banks
- Enhanced performance using the code-prefetch mechanism and data cache in FMC
- Configurable wait states to give the best performance for a given execution speed
- Safety Features
  - SECEDED-single error correction and double error detection is supported in the FMC
  - Address bits are included in ECC
  - Test mode to check the health of ECC logic
- Supports low-power modes for flash bank and pump for power savings
- Built-in power mode control logic
- Integrated flash program/erase state machine (FSM) in the FMC
  - Simple flash API algorithms
  - Fast erase and program times (refer to the device data manual for details)
- Dual Code Security Module (DCSM) to prevent access to the flash by unauthorized persons (refer to [DCSM](#) for details)

### 3.12.2 Flash Tools

Texas Instruments provides the following tools for flash:

- Code Composer Studio (CCS) - the development environment with integrated flash plugin
- F021 Flash API Library - a set of software peripheral functions to erase/program flash. Please refer to the [TMS320F28004x Flash API Reference Guide](#) for more information.
- UniFlash - standalone tool to erase/program/verify the flash content through JTAG. No CCS is required.
- Linker ECC generation - to generate the Flash ECC from the Flash data and to introduce errors in Flash/ECC space. Please refer to the [\(TMS320C28x Assembly Language Tools User's Guide\)](#) for more information.
- CCS On-Chip Flash Plugin and UniFlash tools are developed for a fully Flash-embedded application, which should be a standalone program that has all the initialized sections linked to flash. Any code that needs to be executed from RAM should be copied from Flash at run time.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

### 3.12.3 Default Flash Configuration

The following are flash module configuration settings at power-up:

- Flash banks are in sleep power mode (BNKPWR bit field in the FBFALLBAC register)
- Shared pump is in sleep power mode (PMPPWR bit field in the FPAC1 register)
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled in the FMC
- Bank and pump active grace periods are set to 0x0 (refer to the BAGP field in the FBAC register and PAGP bit field in the FPAC2 register)

Note that boot ROM changes the BNKPWR and PMPPWR bit fields to active mode.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD\_INTF\_CTRL register, to achieve optimum system performance. Software that configures flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from flash memory.

---

**NOTE:** Before initializing wait-states, turn off the pre-fetch and data caching in the FRD\_INTF\_CTRL register.

---

### 3.12.4 Flash Bank, OTP and Pump

There are two flash banks, Bank0 and Bank1 (refer to the device data manual for the number of banks available). Also, there is a one-time programmable (OTP) memory called USER OTP, which the user can program only once and cannot erase. Flash and OTP are uniformly mapped in both program and data memory space.

There is also a TI-OTP which contains manufacturing information like settings used by the flash state machine for erase and program operations, and so on. Users may read TI-OTP but it cannot be programmed or erased. For memory map and size information of the banks, TI-OTP, USER OTP, and corresponding ECC locations, please refer to the device data manual.

Bank0 and Bank1 share a common flash pump; therefore, only one bank can be programmed or erased at a time. Execution or reads from one bank, while erase or program is in progress on the other bank, is supported.

Figure 3-19 depicts the user-programmable OTP locations in USER-OTP . For more information on the functionality of these fields, please refer to [DCSM](#) and the *ROM Code and Peripheral Booting* chapter.

### 3.12.5 Flash Module Controller (FMC)

A single FMC controls both Bank0 and Bank1. The CPU interfaces with the FMC, which in turn interfaces with Bank0 and Bank1 and the shared pump, to perform erase or program operations, to read data, and execute code from these flash banks.

**Figure 3-15. FMC Interface with Core, Bank and Pump**

There is a state machine in FMC which generates the erase/program sequences in hardware. This simplifies the Flash API software which configures control registers in the FMC to perform flash erase and program operations. Please refer to the [TMS320F28004x Flash API Reference Guide](#) for more information for details on Flash API.

[Section 3.12.6](#) through [Section 3.12.10](#) describe FMC in detail.

### 3.12.6 Flash and OTP and Wakeup Power-Down Modes

The flash banks and pump consume a significant amount of power when active. The flash module provides a mechanism to power-down flash banks and pump. Special timers automatically sequence the power-up and power-down of Bank0 and Bank1 independently of each other. The shared charge pump module has its own independent power-up and power-down timers as well.

#### 3.12.6.1 Flash/OTP and Pump Power Modes and Wakeup

The flash banks and OTP operate in three power modes: Sleep (lowest power), Standby, and Active (highest power)

- **Sleep State**  
This is the state after a device reset. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the standby state and then to the active state. During this transition time to the active state, the CPU will automatically be stalled.
- **Standby State**  
This state uses more power than the sleep state, but takes a shorter time to transition to the active or read state. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the active state. During this transition time to the active state, the CPU will automatically be stalled. Once the flash/OTP has reached the active state, the CPU access will complete as normal.
- **Active State**  
In this state, the bank and pump are in active power mode state (highest power)

The charge pump operates in two power modes:

- Sleep (lowest power)
- Active (highest power)

Any access to any flash bank/OTP causes the charge pump to go into active mode, if it is in sleep mode. Also, any erase or program command causes the charge pump and bank to become active. If any bank is active or in standby mode, the charge pump will be in active mode, independent of the charge pump power mode control configuration (refer to the PMPPWR bit field in the FPAC1 register). While the pump is in sleep state, a charge pump sleep down counter holds a user-configurable value (PSLEEP bit field in the FPAC1 register) and when the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles (prescaled clock is SYSCLK/2) before putting the charge pump into active power mode. Note that the configured PPSLEEP value should yield at least a delay of 20  $\mu$ s for the pump to go to active mode. Refer to the register descriptions, [Registers](#), for detailed information.

Below are the number of cycles it will take for the bank and pump to wake up from low power modes.

1. Pump sleep to active = PSLEEP \* (SYSCLK/2) cycles
2. Bank sleep to standby = 254 Flash clock cycles
3. Bank standby to active = 55 Flash clock cycles

Where in Flash clock = SYSCLK/(RWAIT+1)

#### 3.12.6.2 Active Grace Period

The active grace period (AGP) can be used to optimize the flash module power consumption versus access time. Faster access times are associated with higher-power modes of operation. At one extreme, the power control logic could attempt to reduce power consumption by putting the bank and charge pump into a low-power mode immediately at the end of every flash access. However, if accesses are only a few cycles apart, this can actually increase power consumption versus leaving the flash powered, because the bank and charge pump consume more power during flash startup and access.

The active grace periods (supported for Bank0 and Bank1 together, in addition to the charge pump module) allow the banks and/or charge pump to be maintained in active mode for a specified period following an access. This is done in anticipation of another read within the AGP time, to allow the subsequent read to have a faster access and spend less time dissipating power, than if the bank went into one of the low power modes immediately. If the next access does not occur within the AGP time, the power control logic can automatically put the bank and/or charge pump into a low-power mode to reduce power consumption during long periods of inactivity.

The AGP value is programmed by a set of programmable counters (FBAC and FPAC2) which keep the flash bank or charge pump in active mode until the counter expires, at which time the bank or charge pump reverts to its fallback power mode as defined in the FBFALLBACK and FPAC1 (refer to PMPPWR bit-field) registers. The application software can configure the fallback power mode to reduce power consumption, or configure it to be active mode to keep the bank active regardless of counter settings (default is SLEEP). The charge pump AGP counter remains in its initialized state when the bank is active, including the AGP counter of the bank. The charge pump AGP counter begins counting when the bank has become inactive.

The application software can check the current power mode of flash bank and charge pump by reading the FBPRDY register. Refer to the register descriptions, [Registers](#), for detailed information.

### 3.12.7 Flash and OTP Performance

Once the flash bank and pump are in the active power state, a read or fetch access can be classified as a flash access (access to an address location in flash) or an OTP access (access to an address location in OTP). Once the CPU throws an access to a flash memory address, data is returned after RWAIT+1 number of SYSCLK cycles. For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait-states and is configurable using the RWAIT bit-field in the FRDCNTL register. At reset, the RWAIT bit-field defaults to a worst-case wait-state count (15), and therefore needs to be initialized for the appropriate number of wait states to improve performance, based on the CPU clock rate and the access time of the flash.

For a given system clock frequency, RWAIT has to be configured using below formula:

$$\text{RWAIT} = \text{ceiling}[(\text{SYSCLK}/\text{FCLK})-1]$$

where SYSCLK is the system operating frequency

FCLK is flash clock frequency. FCLK should be  $\leq \text{FCLK}_{\text{max}}$ , allowed maximum flash clock frequency at RWAIT=0.

If RWAIT results in a fractional value when calculated using the above formula, RWAIT has to be rounded up to the nearest integer. Please see the device data manual for the RWAIT configuration details.

### 3.12.8 Flash Access Interface

This section provides details about the modes to access flash/OTP and the configuration registers which control the read interface. In addition to a standard read mode, the FMC has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

#### 3.12.8.1 Standard Access Mode

Standard access mode is defined as the access mode in effect when the code prefetch-mechanism and data cache are disabled. It is also the default mode after reset. During this mode, each access to flash is decoded by the flash wrapper to read/fetch the data/code from the addressed location and the data/code is returned after the RWAIT+1 number of cycles.

The prefetch buffer associated with the prefetch mechanism and data cache is bypassed in standard access mode; therefore, every access to the flash/OTP is used by the CPU immediately, and every access creates a unique flash bank access.

Standard access mode is the recommended mode for lower system frequency operation in which RWAIT can be set to zero to provide single-cycle access operation. The FMC can operate at higher frequencies using standard access mode at the expense of adding wait states. At higher system frequencies, it is recommended to enable cache and prefetch mechanisms to improve performance. Refer to the device-specific data manual to determine the maximum flash frequency allowed in standard access mode (that is, maximum flash clock frequency with RWAIT=0,  $FCLK_{max}$ ).

### 3.12.8.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from sequential memory addresses, except when a discontinuity occurs. Usually the portion of the code that resides in sequential addresses makes up the majority of the application code and is referred to as linear code. To improve the performance of linear code execution, a flash prefetch-mechanism has been implemented in the FMC. Figure 3-16 illustrates how this mode functions.

**Figure 3-16. Flash Prefetch Mode**

This prefetch mechanism does a look-ahead prefetch on linear address increments starting from the address of the last instruction fetch. The flash prefetch mechanism is disabled by default. Setting the PREFETCH\_EN bit in the FRD\_INTF\_CTRL register enables this prefetch mode.

An instruction fetch from the flash or OTP reads out 128 bits per access. The starting address of the access from flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. With the flash prefetch mode enabled, the 128 bits read from the instruction buffer are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the flash bank, it is likely that there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time it takes to process these instructions, the flash prefetch mechanism automatically initiates another access to the flash bank to prefetch the next 128 bits. In this manner, the flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from flash or OTP is improved significantly.

---

**NOTE:** If the prefetch mechanism is enabled, then the last two rows (16 16-bit words i.e. 256 bits) of the bank which does not have valid address beyond its boundary should not be used, because the prefetch logic which does a look-ahead prefetch, will try to fetch from outside the bank and would result in an ECC error.

---

The flash prefetch is aborted only on a PC discontinuity caused by executing an instruction such as a branch, BANC, call, or loop. When this occurs, the prefetch mechanism is aborted and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the flash and OTP, the prefetch is aborted and begins again only when a branch is made back into the flash or OTP. The flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch buffer capability and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When this read happens, the prefetch buffer is bypassed but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read will be stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

### 3.12.8.3 Data Cache

Along with the prefetch mechanism, a data cache of 128 bits wide is also implemented to improve data-space read and program-space read performance. This data cache will not be filled by the prefetch mechanism. When any kind of data-space read or program-space read is made by the CPU from an address in the bank, and if the data corresponding to the requested address is not in the data cache, then 128 bits of data will be read from the bank and loaded in the data cache. This data is eventually sent to the CPU for processing. The starting address of the access from flash is automatically aligned to a 128-bit boundary such that the requested address location is within the 128 bits to be read from the bank. By default, this data cache is disabled and can be enabled by setting DATA\_CACHE\_EN bit in the FRD\_INTF\_CTRL register. Note that the data cache gets bypassed when RWAIT is configured as zero.

Some other points to keep in mind when working with flash/ OTP:

- Reads of the USER OTP locations are hardwired for 10 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to the flash or OTP memory map areas are ignored. They complete in a single cycle.
- If a security zone is in the locked state and the respective password lock bits are not all 1s, then,
  - Data reads to Zx-CSMPSWD will return 0
  - Program space reads to Zx-CSMPSWD will return 0
  - Program fetches to Zx-CSMPSWD will return 0
- When the Dual Code Security Module (DCSM) is secured, reads to the flash/OTP memory map area from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns a zero.
- The arbitration scheme in FMC prioritizes CPU accesses in the fixed priority order of data read (highest priority), program space read and program fetches/program prefetches (lowest priority).
- When FSM interface is active for erase/program operations, data in the prefetch buffers and data cache in FMC will be flushed.

When the data cache is enabled, the debugger memory window open to Flash/OTP space will invoke data caching. Therefore, the debugger memory window should not be left open for Flash/OTP space when benchmarking the code for performance.

### 3.12.9 Erase/Program Flash

Flash memory may be programmed either by using the CCS Flash plugin or by using Uniflash. If these methods are not feasible in an application, the API may be used. The Flash memory should be programmed, erased, and verified only by using the F021 Flash API library. These functions are written, compiled and validated by Texas Instruments. The flash module contains a flash state machine (FSM) to perform program and erase operations. This section only provides a high-level description for these operations; therefore, please refer to the [TMS320F28004x Flash API Reference Guide](#) for more information.

Note that Flash API execution is interruptible. However, there should not be any read/fetch access from the Flash bank on which an erase/program operation is in progress. In single-bank devices, Flash API must be executed from RAM. In dual-bank devices Flash API can execute from one bank to perform erase/program operations on another bank. If prefetch is enabled, note that the last 128 bits of Bank0 should not be accessed when erasing/programming Bank1 since accessing them will cause a prefetch access to Bank1.

A typical flow to program flash is:

Erase → Program → Verify

Always refer to the device-specific support folder in C2000Ware for the latest Flash API library.

#### 3.12.9.1 Erase

When the target flash is erased, it reads as all 1's. This state is called 'blank.' The erase function must be executed before programming. The user should NOT skip erase on sectors that read as 'blank' because these sectors may require additional erasing due to marginally erased bits columns. The FSM provides an "Erase Sector" command to erase the target sector. The erase function erases the data and the ECC together. This command is implemented by the following Flash API function:

```
Fapi_issueAsyncCommandWithAddress();
```

The Flash API provides the following function to determine if the flash bank is 'blank':

```
Fapi_doBlankCheck();
```

#### 3.12.9.2 Program

The FSM provides a command to program the USER OTP and Flash. This command is also used to program ECC check bits.

This command is implemented by the following Flash API function:

```
Fapi_issueProgrammingCommand();
```

The Program function provides the options to program data without ECC, data with user-provided ECC data with ECC calculated by API software, and to program ECC only.

---

**NOTE:** The main array flash programming must be aligned to 64-bit address boundaries and each 64-bit word may only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128 bit address boundaries and each 128 bit word may only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP should be programmed together, and may be programmed 1 bit at a time as required by the DCSM operation.
  - The DCSM Zx-LINKPOINTER3 values in the DCSM OTP may be programmed 1 bit at a time on a 64-bit boundary to separate it from Zx-PSWDLOCK, which must only be programmed once.
- 

#### 3.12.9.3 Verify

After programming, the user can verify the programmed contents using API function `Fapi_doVerify()`. This function verifies the flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default) catches single-bit errors, double-bit errors, and address errors whenever the CPU reads or fetches from a Flash address.

### 3.12.10 Error Correction Code (ECC) Protection

FMC contains an embedded single error correction and double error detection (SECDED) module. SECDED, when enabled, provides the capability to screen out memory faults. SECDED can detect and correct single-bit data errors and detect address errors/double-bit data errors. For every 64 bits of flash/OTP data (aligned on a 64-bit memory boundary) that is programmed, eight ECC check bits have to be calculated and programmed in ECC memory space. Refer to the device data manual for the Flash/OTP ECC memory map. ECC memory space in Flash should not be used to program code or data; it is used only for error correction and detection. SECDED works with a total of eight user-calculated error correction code (ECC) check bits associated with each 64-bit wide data word and its corresponding 128-bit memory-aligned address. Users must program ECC check bits along with flash. TI recommends using the AutoEccGeneration option available in Plugin/API to program ECC. Users can use the F021 Flash API to calculate and program ECC data along with flash data. Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with Code Composer Studio, uses Flash API to generate and program ECC data. Alternatively users can use the linker-supported ECC generation option to generate and place ECC in separate sections through the linker command file. Please refer to TMS320C28x Assembly Language Tools User's Guide for more information on using the linker-supported ECC generation method.

Figure 3-17 illustrates the ECC logic inputs and outputs.

**Figure 3-17. ECC Logic Inputs and Outputs**

During an instruction fetch or a data read operation, the 19 most significant address bits (three least significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of flash banks/ECC memory map area, pass through the SECDED logic and the eight checkbits are produced in FMC. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the SECDED module to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- An uncorrectable error (double-bit data error or address error) occurred

If the SECDED logic finds a single-bit error in the address field, then it is considered to be an uncorrectable error.

---

**NOTE:** Since ECC is calculated for an entire 64-bit data, a non 64-bit read such as a byte read or a half-word read will still force the entire 64-bit data to be read and calculated, but only the byte or half-word will be actually used by the CPU.

---

This ECC (SECDED) feature is enabled at reset. The ECC\_ENABLE register can be used to configure (enable/disable) the ECC feature. The ECC for the application code must be programmed. There are two SECDED modules in each FMC. Out of the 128-bit data (aligned on a 128-bit memory boundary) read from the bank/OTP address, the lower 64-bits of data and corresponding 8 ECC bits (read from user programmable ECC memory area) are fed as inputs to one SECDED module along with 128-bit aligned 19-bit address from where data has been read. The upper 64-bits of data and corresponding 8 ECC bits are fed as inputs to another SECDED module in parallel, along with 128-bit aligned 19-bit address. Each of the SECDED modules evaluate their inputs and determine if there is any single-bit data error or double-bit data error/address error.

ECC logic will be bypassed when the 64 data bits and the associated ECC bits fetched from the bank are either all ones or zeros.

### 3.12.10.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in flash data or in ECC data, then it is considered as a single-bit data error. The SECDED module detects and corrects single-bit errors, if any, in the 64-bit flash data or eight ECC check bits read from the flash/ECC memory map before the read data is provided to the CPU.

When SECDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the single-bit error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the SINGLE\_ERR\_ADDR\_LOW register. If the single-bit error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the SINGLE\_ERR\_ADDR\_HIGH register.
- Whether the error occurred in data bits or ECC bits – the ERR\_TYPE\_L and ERR\_TYPE\_H bit fields in the ERR\_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64-bits, or the upper 64-bits respectively, of a 128-bit memory-aligned data.
- Bit position at which error occurred – the ERR\_POS\_L and ERR\_POS\_H bit fields in the ERR\_POS register indicate the bit position of the error in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned data.
- Whether the corrected value is 0 (FAIL\_0\_L, FAIL\_0\_H flags in ERR\_STATUS register)
- Whether the corrected value is 1 (FAIL\_1\_L, FAIL\_1\_H flags in ERR\_STATUS register)
- A single bit error counter that increments on every single bit error occurrence (ERR\_CNT register) until a user-configurable threshold (see ERR\_THRESHOLD) is met
- A flag that gets set when one or more single-bit errors occurs after ERR\_CNT equals ERR\_THRESHOLD (SINGLE\_ERR\_INT\_FLG flag in the ERR\_INTFLG register)

When the ERR\_CNT value equals THRESHOLD+1 value and a single bit error occurs, the SINGLE\_ERR\_INT flag is set, and an interrupt (FLASH\_CORRECTABLE\_ERR on C28x PIE has to be enabled for interrupt, if needed) is fired. The SINGLE\_ERR interrupt will not be fired again until the SINGLE\_ERR\_INTFLG is cleared. If the single error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, the error interrupt will not come again, as this is an edge-based interrupt.

When multiple single-bit errors get caught by ECC logic, the Flash ECC error registers will hold the information related to the latest ECC error. Although ECC is calculated on a 64-bit basis, a read of any address location within a 128-bit aligned flash memory will cause the single-bit error flag to get set when there is a single-bit error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 3.12.10.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data/ECC. When SECEDED finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the uncorrectable error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_LOW register. If the uncorrectable error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the UNC\_ERR\_ADDR\_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC\_ERR\_L and UNC\_ERR\_H flags in the ERR\_STATUS register indicate the uncorrectable error occurrence in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned data.
- A flag is set indicating that an uncorrectable error interrupt is fired (UNC\_ERR\_INTFLG in ERR\_INTFLG register)

When an uncorrectable error occurs, the UNC\_ERR\_INTFLG bit is set and an uncorrectable error interrupt is fired. This uncorrectable error interrupt generates an NMI, if enabled. If an uncorrectable error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR\_INTCLR register, an error interrupt will not come again, as this is an edge based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the uncorrectable error flag to get set when there is a uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data. NMI will occur on the CPU for a read of any address location within a 128-bit aligned Flash memory, when there is an uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

### 3.12.10.3 SECEDED Logic Correctness Check

Since error detection and correction logic are part of safety-critical logic, safety applications may need to ensure that the SECEDED logic is always working properly. For these safety concerns, in order to ensure the correctness of the SECEDED logic, an ECC test mode is provided to test the correctness of ECC logic periodically. In ECC test mode, Data/ECC and address inputs to the ECC logic are controlled by the ECC test mode registers FDATAH\_TEST, FDATAL\_TEST, FECC\_TEST, and FADDR\_TEST, respectively. Using this test mode, users can introduce single-bit errors, double-bit errors, or address errors and check whether or not SECEDED logic is catching those errors. Users can also check if SECEDED logic is reporting any false errors when no errors are introduced.

This ECC test mode can be enabled by setting the ECC\_TEST\_EN bit in the FECC\_CTRL register. When ECC test mode is enabled, the CPU cannot read the data from flash and instead the CPU gets data from the ECC test mode registers (FDATAH\_TEST/FDATAL\_TEST). This is because ECC test mode registers (FDATAH\_TEST, FDATAL\_TEST, FECC\_TEST) are multiplexed with data from the flash. Hence, the CPU should not read/fetch from Flash when ECC test mode is enabled. For this reason, ECC test mode code should be executed from RAM and not from flash.

Only one of the SECEDED modules (out of the two SECEDED modules that work on lower 64 bits and upper 64 bits of a read 128-bit data) at a time can be tested. The ECC\_SELECT bit in the FECC\_CTRL register can be configured by users to select one of the SECEDED modules for test.

To test the ECC logic using ECC test mode, users can follow the steps below:

1. Obtain the ECC for a given Flash address (128-bit aligned) and 64-bit data by using Auto ECC generation option provided in Flash API or by using the linker ECC generation method.
2. Develop an application to test ECC logic using the above data. In this application
  - Write the 128-bit aligned 19-bit Flash address in FADDR\_TEST

- Write 64-bit data in FDATAH\_TEST (upper 32 bits) and FDATA\_L\_TEST (lower 32 bits) registers
- Write the corresponding 8-bit ECC in the FECC\_TEST register
- In any of the above three steps, users can insert errors (single-bit data error or double-bit data error or address error or single-bit ECC error or double-bit ECC error) so that they can check whether or not ECC logic is able to catch the errors
- Select the ECC logic block (lower 64-bits or upper 64-bits) which needs to be tested using the ECC\_SELECT bit in the FECC\_CTRL register
- Enable ECC test mode using the ECC\_TEST\_EN bit in FECC\_CTRL register
- Write a value of 1 in the DO\_ECC\_CALC bit in FECC\_CTRL register to enable ECC test logic for a single cycle to evaluate the address, data, ECC in FADDR\_TEST, FDATAx\_TEST and FECC\_TEST registers for ECC errors

Once the above ECC test mode registers are written by the user:

- The FECC\_OUTH register holds the data output bits 63:32 from the SECDED block under test
- The FECC\_OUTL register holds the data output bits 31:0 from the SECDED block under test
- The FECC\_STATUS register holds the status of single-bit error occurrence, uncorrectable error occurrence, and error position of single-bit error in data/check bits

#### 3.12.10.4 Reading ECC Memory From a Higher Address Space

In these devices, ECC memory for Flash and OTP is allocated at a higher address space (address width more than 22 bits). C2000 Codegen tools (6.2 and onwards) are updated to include the below intrinsics to read ECC space.

For 16-bit read:

```
unsigned int variable = __addr32_read_uint16(unsigned long address);
```

For 32-bit read:

```
unsigned long variable = __addr32_read_uint32(unsigned long address);
```

#### 3.12.11 Reserved Locations Within Flash and OTP

When allocating code and data to flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, please refer to [Section 3.13](#), and the *ROM Code and Peripheral Booting* chapter.
- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in flash for real-time operating system usage and a boot-to-flash entry point. A boot-to-flash entry point is reserved for an entry-into-flash branch instruction. When the boot-to-flash boot option is used, the boot ROM will jump to this address in flash. If the user programs a branch instruction here, that will then redirect code execution to the entry point of the application.

#### 3.12.12 Procedure to Change the Flash Control Registers

During flash configuration, no accesses to the flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, you should follow the procedure shown below for any code that modifies the flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the flash configuration code (that writes to flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the flash configuration cannot execute from the Flash or OTP. It must reside in RAM.
3. Execute the flash configuration code (should be located in RAM) that writes to flash control registers like FRDCNTL, FRD\_INTF\_CTRL, and so on.
4. At the end of the flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function which might reside in RAM or Flash/OTP and continue execution.

### 3.13 Dual Code Security Module (DCSM)

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) to unauthorized persons. It also prevents duplication and reverse engineering of proprietary code. The term “secure” implies that access to on-chip secure memories and resources are blocked. The term “unsecure” implies that access is allowed (the contents of the memory could be read by any means); for example, through a debugging tool such as Code Composer Studio™.

The CSM has dual-zone security; zone1 and zone2.

#### 3.13.1 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone 1 (Z1) and Zone 2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF). This device has two Flash banks (Bank0 and Bank1) and each bank has its own USER OTP. Both banks' USER OTP are secure and partitioned between Zone1 and Zone2.
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM location in the Bank0 USER OTP.
- **Flash Sectors:** Flash sectors of both the banks (Bank0 and Bank1) can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT location in the respective bank's USER OTP.
- **Secure ROM:** This device also has secure ROM which is EXEONLY-protected. This ROM contains specific function for the user, provided by TI.

Table 3-15 shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

**Table 3-15. RAM/Flash Status**

| Zone 1<br>GRAMRAMx/GRABSECTx Bits | Zone 2<br>GRAMRAMx/GRABSECT | Ownership and Accessibility             |
|-----------------------------------|-----------------------------|-----------------------------------------|
| 01                                | 10                          | RAM block/Flash Sector belongs to Zone1 |
| 01                                | 11 <sup>(1)</sup>           | RAM block/Flash Sector belongs to Zone1 |
| 10                                | 01                          | RAM block/Flash Sector belongs to Zone2 |
| 11 <sup>(2)</sup>                 | 01                          | RAM block/Flash Sector belongs to Zone2 |
| 10                                | 10                          | RAM block/Flash Sector is unsecure      |
| 11 <sup>(2)</sup>                 | 11 <sup>(1)</sup>           | RAM block/Flash Sector is unsecure      |

<sup>(1)</sup> Zone2 is unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user hence Zone2 will always be unsecure.

<sup>(2)</sup> Zone1 is unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user hence Zone1 will always be unsecure.

**NOTE:** The user should never program any other values in these fields. Failing any these conditions for a RAM block/Flash sector will make that RAM block/Flash sector inaccessible.

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in Bank0 USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 3.13.7.4](#).

There are three types of accesses: data/program reads, JTAG access, and instruction fetches (calls, jumps, code executions, ISRs). Instruction fetches are never blocked. JTAG accesses are always blocked when a memory is secure. Data reads to a secure memory are always blocked unless the program is executing from a memory which belongs to the same zone. Data reads to unsecure memory are always allowed. [Table 3-16](#) shows the levels of security.

**Table 3-16. Security Levels**

| PMF Executed With Correct Password? | Operating Mode of the Zone | Program Fetch Location | Security Description                                                                                                            |
|-------------------------------------|----------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| No                                  | Secure                     | Outside secure memory  | Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.     |
| No                                  | Secure                     | Inside secure memory   | CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents. |
| Yes                                 | Unsecure                   | Anywhere               | Full access for CPU and JTAG port to secure memory of that zone.                                                                |

### 3.13.1.1 CSM Passwords

Unlike earlier C2000 devices, on this device ALL\_1 value (0xFFFFFFFF,0xFFFFFFFF,0xFFFFFFFF,0xFFFFFFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL\_1 from USER OTP, the device will be in BLOCKED state. Due to this reason TI will program a few bits in the second 32-bit password value (ZxOTP\_CSMPSWD1) in every zone select block of each zone with value '0'. The default value for this password location is chosen in a manner that the respective ECC value remains ALL\_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. Please see [Table 3-17](#) for ZxOTP\_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user will be able to change this value by flipping the bits which are '1' to '0' but leaving the ones which are already programmed by TI as '0'. BOOTROM code will write the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL\_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers which means the zone cannot be unlocked using PMF, the password match flow described in [Section 3.13.7.4](#). Therefore, the user should never use ALL\_0 as password. A password of ALL\_0 will prevent debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Default value of other fields in USER OTP are also not ALL\_1. While programming these setting in USER OTP, user must keep already programmed bits '0' only else programming operation will not work.

Default value for all the LINKPOINTER location in USER OTP is 0x1ffffff.

**Table 3-17. Default Value of ZxOTP\_CSMPSWD1 and other fields (programmed by TI)**

| Zone Select Block  | Zone1      |            | Zone2      |            |
|--------------------|------------|------------|------------|------------|
|                    | Address    | Value      | Address    | Value      |
| PSWDLOCK (LSW)     | 0x00078010 | 0xfb7ffff  | 0x00078210 | 0xbf7ffff  |
| PSWDLOCK (MSW)     | 0x00078012 | 0x7ffffff  | 0x00078212 | 0x77ffffff |
| CRCLOCK (LSW)      | 0x00078014 | 0x4bffffff | 0x00078214 | 0x0ffffff  |
| CRCLOCK (MSW)      | 0x00078016 | 0x3ffffff  | 0x00078216 | 0x37ffffff |
| Zone_Select_Block0 | 0x0007802a | 0x47ffffff | 0x0007822a | 0xe3ffffff |
| Zone_Select_Block1 | 0x0007803a | 0xdb7ffff  | 0x0007823a | 0x977ffff  |
| Zone_Select_Block2 | 0x0007804a | 0x4bffffff | 0x0007824a | 0xf1ffffff |

**Table 3-17. Default Value of ZxOTP\_CSMPSWD1 and other fields (programmed by TI) (continued)**

| Zone Select Block   | Zone1      |            | Zone2      |            |
|---------------------|------------|------------|------------|------------|
| Zone_Select_Block3  | 0x0007805a | 0x3f7fffff | 0x0007825a | 0x9b7fffff |
| Zone_Select_Block4  | 0x0007806a | 0xcfbfffff | 0x0007826a | 0x5b7fffff |
| Zone_Select_Block5  | 0x0007807a | 0x8bfffff  | 0x0007827a | 0x2fffff   |
| Zone_Select_Block6  | 0x0007808a | 0x53fffff  | 0x0007828a | 0x1fffff   |
| Zone_Select_Block7  | 0x0007809a | 0xcf7fffff | 0x0007829a | 0x6b7fffff |
| Zone_Select_Block8  | 0x000780aa | 0xe77fffff | 0x000782aa | 0xab7fffff |
| Zone_Select_Block9  | 0x000780ba | 0x93fffff  | 0x000782ba | 0x37fffff  |
| Zone_Select_Block10 | 0x000780ca | 0xeb7fffff | 0x000782ca | 0x4f7fffff |
| Zone_Select_Block11 | 0x000780da | 0x69fffff  | 0x000782da | 0x3bfffff  |
| Zone_Select_Block12 | 0x000780ea | 0xa9fffff  | 0x000782ea | 0xe5fffff  |
| Zone_Select_Block13 | 0x000780fa | 0xdd7fffff | 0x000782fa | 0x8f7fffff |
| Zone_Select_Block14 | 0x0007810a | 0x8bfffff  | 0x0007830a | 0x2fffff   |
| Zone_Select_Block15 | 0x0007811a | 0xcfbfffff | 0x0007831a | 0x5b7fffff |
| Zone_Select_Block16 | 0x0007812a | 0x3f7fffff | 0x0007832a | 0x9b7fffff |
| Zone_Select_Block17 | 0x0007813a | 0x4bfffff  | 0x0007833a | 0xf1fffff  |
| Zone_Select_Block18 | 0x0007814a | 0xdb7fffff | 0x0007834a | 0x977fffff |
| Zone_Select_Block19 | 0x0007815a | 0x47fffff  | 0x0007835a | 0xe3fffff  |
| Zone_Select_Block20 | 0x0007816a | 0x87fffff  | 0x0007836a | 0xcbfffff  |
| Zone_Select_Block21 | 0x0007817a | 0xf37fffff | 0x0007837a | 0x577fffff |
| Zone_Select_Block22 | 0x0007818a | 0xdd7fffff | 0x0007838a | 0x8f7fffff |
| Zone_Select_Block23 | 0x0007819a | 0xa9fffff  | 0x0007839a | 0xe5fffff  |
| Zone_Select_Block24 | 0x000781aa | 0x69fffff  | 0x000783aa | 0x3bfffff  |
| Zone_Select_Block25 | 0x000781ba | 0xeb7fffff | 0x000783ba | 0x4f7fffff |
| Zone_Select_Block26 | 0x000781ca | 0x93fffff  | 0x000783ca | 0x37fffff  |
| Zone_Select_Block27 | 0x000781da | 0xe77fffff | 0x000783da | 0xab7fffff |
| Zone_Select_Block28 | 0x000781ea | 0xcf7fffff | 0x000783ea | 0x6b7fffff |
| Zone_Select_Block29 | 0x000781fa | 0x53fffff  | 0x000783fa | 0x1fffff   |

### 3.13.1.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected will trip the ECSL and break the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, the user must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This will disable the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU will start running and may execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL will trip and cause the emulator connection to be broken.

The solution to this problem is:

- Use the Wait Boot Mode boot option. In this mode, the CPU will be in a loop and hence will not jump to the user application code. Using this BOOTMODE, the user can connect to CCS and debug the code.

### 3.13.1.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

### 3.13.1.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

### 3.13.1.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone's PSWDLOCK field with any value other than "1111" (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations will not be secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a fresh device the value for password lock fields for all zones at the PSWDLOCK location in OTP will be "1111" which means the password for all zones will be unlocked.

---

**NOTE:** Password unlock only makes password locations non-secure. All other secure memories and other locations of Flash sectors, which contain a password, remains secure as per security settings. But since passwords are non-secure, anyone can read the password and make the zone non-secure by running through PMF.

---

### 3.13.1.6 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists in both the banks which holds the configuration related to the zone's security. The following are the available programmed configurations:

#### **BANK0 USER OTP**

- B0\_ZxOTP\_LINKPOINTER1
- B0\_ZxOTP\_LINKPOINTER2
- B0\_ZxOTP\_LINKPOINTER3
- ZxOTP\_GPREG1
- ZxOTP\_GPREG2
- ZxOTP\_PSWDLOCK
- ZxOTP\_CRCLOCK
- ZxOTP\_BOOTCTRL
- ZxOTP\_GPREG3
- ZxOTP\_EXEONLYRAM
- B0\_ZxOTP\_EXEONLYSECT
- ZxOTP\_GRABRAM
- B0\_ZxOTP\_GRABSECT
- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1

- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3

#### **BANK1 USER OTP**

- B1\_ZxOTP\_LINKPOINTER1
- B1\_ZxOTP\_LINKPOINTER2
- B1\_ZxOTP\_LINKPOINTER3
- B1\_ZxOTP\_EXEONLYSECT
- B1\_ZxOTP\_GRABSECT

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks.

- ZxOTP\_EXEONLYRAM
- B0\_ZxOTP\_EXEONLYSECT
- ZxOTP\_GRABRAM
- B0\_ZxOTP\_GRABSECT
- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1
- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3
- B1\_ZxOTP\_EXEONLYSECT
- B1\_ZxOTP\_GRABSECT

The location of the zone select block in OTP is decided based on the value of three 29-bit link pointers (Bx-Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointer locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware when a dummy read is done to all the link pointers by comparing all the three values (bit-wise voting logic). Since in OTP, a '1' can be flipped by the user to '0' but '0' can't be flipped to '1' (no erase operation for OTP), the most significant bit position in the resolved link pointer which is '0', defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in [Figure 3-18](#), the final link pointer value becomes All\_1 (0xFFFF\_FFFF) which selects the Zone-Select-Block1 (also known as the default zone select block).

**Figure 3-18. Storage of Zone-Select Bits in OTP**

| Zx-LINKPOINTER                                        | Addr Offset Of Zone-Select Block |
|-------------------------------------------------------|----------------------------------|
| 32'b00011111111111111111111111111111                  | 0x20                             |
| 32'b00011111111111111111111111111111 0                | 0x30                             |
| 32'b00011111111111111111111111111111 0x               | 0x40                             |

| 32'b00011111111111111111111111111111 0xxxxxxxxxxxxxxx | 0x1c0                            |
| 32'b00011111111111111111111111111111 0xxxxxxxxxxxxxxx | 0x1d0                            |
| 32'b00011111111111111111111111111111 0xxxxxxxxxxxxxxx | 0x1e0                            |
| 32'b00011111111111111111111111111111 0xxxxxxxxxxxxxxx | 0x1f0                            |

  

| Zone Select Block |                   |
|-------------------|-------------------|
| Addr Offset       | 32-Bit Content    |
| 0x0               | Zx-EXEONLYRAM     |
| 0x2               | Bx-Zx EXEONLYSECT |
| 0x4               | Zx-GRABRAM        |
| 0x6               | Bx-Zx GRABSECT    |
| 0x8               | Zx-CSMPSWD0       |
| 0xa               | Zx-CSMPSWD1       |
| 0xc               | Zx-CSMPSWD2       |
| 0xe               | Zx-CSMPSWD3       |

**NOTE:** Address locations for other security settings (PSWDLOCK/CRCLOCK) that are not part of Zone Select blocks) can be programmed only once; therefore, the user should program them towards end of the development cycle.

**NOTE:** Zone select blocks in BANK1 only have Zx-EXEONLYSECT and Zx-GRABSECT as valid configurations. Other locations in zone select block of BANK1 are reserved.

**Figure 3-19. Location of Zone-Select Block Based on Link-Pointer for Bank0**

**Figure 3-20. Location of Zone-Select Block Based on Link-Pointer for Bank1**

**NOTE:** USER OTP is ECC protected. The user must program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value may cause the device to be blocked permanently and the user will have to replace the device.

### 3.13.2 C Code Example to get Zone Select Block Addr for Zone1 in BANK0

```

unsigned long LinkPointer;
unsigned long *Zone1SelBlockPtr;
int Bitpos = 28;
int ZeroFound = 0;

// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;

// Bits 31 30 and 29 as most-significant 0 are reserved LinkPointer options

LinkPointer = LinkPointer << 3;

while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        Zone1SelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 3)*16));
    } else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    Zone1SelBlockPtr = (unsigned long *)0x78020;
}

```

### 3.13.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has its own dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECT location in OTP of both the banks. Each zone has its own CSM passwords; read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Zone 2 and vice versa. Before programming any secure Flash sector, the user must either unlock the zone to which that particular sector belongs, using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

The flash wrapper registers through which any flash or OTP program/erase operations are performed are common resources shared by the two security zones. A semaphore mechanism is provided to avoid the conflict between Zone1 and Zone2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

### 3.13.4 Safe Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific "Safe Copy Code" library functions for each zone to enable the user to copy content from EXEONLY secure flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure flash sector belong to the same zone.
- Both the secure RAM block and the secure flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

### 3.13.5 SafeCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC for content in EXEONLY memories using the VCU. But in some safety-critical applications, the user may have to calculate the CRC on these memories as well. To enable this without compromising on security, TI provides specific "SafeCRC" library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length\_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

---

**NOTE:** The user must disable all the interrupts before calling the safe copy code and the safeCRC function. If there is a vector fetch during copy code operation, the CPU gets reset immediately.

---

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

### 3.13.6 CSM Impact on Other On-Chip Resources

On this device, M0/M1 and GSx memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP ) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT\_ROM and OTP is accessible to the user.

The following steps are required after reset (any type of reset) to initialize the security on each CPU subsystem.

#### Security Initialization

- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER1 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER2 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z1OTP\_LINKPOINTER3 in Z1 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER1 in Z2 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER2 in Z2 OTP of Bank0
- Dummy Read to address location of B0\_Z2OTP\_LINKPOINTER3 in Z2 OTP of Bank0
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER1 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER2 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z1OTP\_LINKPOINTER3 in Z1 OTP of Bank1
- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER1 in Z2 OTP of Bank1
- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER2 in Z2 OTP of Bank1

- Dummy Read to address location of B1\_Z2OTP\_LINKPOINTER3 in Z2 OTP of Bank1
- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP\_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_CRCLOCK in Z1 OTP
- Dummy Read to address location 0x78018 in Z1 OTP
- Dummy Read to address location of Z1OTP\_GPREG1, Z1OTP\_GPREG2, Z1OTP\_GPREG3 in Z1 OTP of Bank0
- Dummy Read to address location of Z1OTP\_BOOTCTRL in Z1 OTP
- Dummy Read to address location of Z2OTP\_PSWDLOCK in Z2 OTP of Bank0
- Dummy Read to address location of Z2OTP\_CRCLOCK in Z2 OTP of Bank0
- Dummy Read to address location 0x78218 in Z2 OTP of Bank0
- Dummy Read to address location of Z2OTP\_GPREG1, Z2OTP\_GPREG2, Z2OTP\_GPREG3 in Z2 OTP of Bank0
- Dummy Read to address location of Z2OTP\_BOOTCTRL in Z2 OTP of Bank0
- Read to memory map register of B0\_Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP\_EXEONLYRAM in Z1 OTP of Bank0
- Dummy read to address location of B0\_Z1OTP\_EXEONLYSECT in Z1 OTP of Bank0
- Dummy read to address location of Z1OTP\_GRABRAM in Z1 OTP of Bank0
- Dummy read to address location of B0\_Z1OTP\_GRABSECT in Z1 OTP of Bank0
- Read to memory map register of B0\_Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP\_EXEONLYRAM in Z2 OTP of Bank0
- Dummy read to address location of B0\_Z2OTP\_EXEONLYSECT in Z2 OTP of Bank0
- Dummy read to address location of Z2OTP\_GRABRAM in Z2 OTP of Bank0
- Dummy read to address location of B0\_Z2OTP\_GRABSECT in Z2 OTP of Bank0
- Read to memory map register of B1\_Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of B1\_Z1OTP\_EXEONLYSECT in Z1 OTP of Bank1
- Dummy read to address location of B1\_Z1OTP\_GRABSECT in Z1 OTP of Bank1
- Read to memory map register of B1\_Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of B1\_Z2OTP\_EXEONLYSECT in Z2 OTP of Bank1
- Dummy read to address location of B1\_Z2OTP\_GRABSECT in Z2 OTP of Bank1

---

**NOTE:** Security Initialization is done by BOOTROM code on all the resets (as part of device initialization). This will not be part of user application code

---

---

**NOTE:** The order of initialization matters hence if a memory watch window with the USER OTP address is opened in the debugger (CCS) the security initialization could occur in an incorrect order, locking the device down. To avoid this, user should not keep a memory window with USER OTP address opened in the debugger(CCS) when performing a reset.

---

### 3.13.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password should be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx\_CR.15) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (via JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

#### 3.13.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring can be required:

- Code development using debuggers (such as Code Composer Studio). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the flash utilities disable the security logic before attempting to program the Flash. The flash utilities can disable the code security logic in new devices without any authorization, since new devices come with an erased Flash. However, reprogramming devices that already contain a custom password require the password to be supplied to the flash utilities in order to unlock the device to enable programming. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application  
In addition to the above, access to secure memory contents can be required in situations such as:
  - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
  - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 3-21](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

### 3.13.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 3-21](#) shows how PMF helps to initialize the security logic registers and disable security logic.

**Figure 3-21. CSM Password Match Flow (PMF)**

### 3.13.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)0x5F000; //CSM register file
volatile long int *CSMPWL = (volatile long int *)0x78028; //CSM Password location (assuming
default Zone select block)

volatile int tmp;

int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// If the password locations (CSMPWL) are all = ones (0xFFFF),
// then the zone will now be unsecure. If the password
// is not all ones (0xFFFF), then the code below is required
// to unsecure the CSM.
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F014
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F016
```

### 3.13.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

### 3.13.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and may halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections will get disconnected, which can be inconvenient for the user. Note that unlocking ECSL doesn't enable access to secure code but only avoids disconnection of CCS (JTAG).

### 3.13.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. [Figure 3-22](#) shows how the PMF helps to initialize the security logic registers and disable security logic.

**Figure 3-22. ECSL Password Match Flow (PMF)**

### 3.13.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

### 3.13.7.7.1 C Code Example to Disable ECSL for C28x-Zone1

```
volatile long int *ECSL = (volatile int *)0x5F000; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)

volatile int tmp;

int I;
// Read the 64-bits of the password locations (PWL)
.
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// If the ECSL password locations (ECSLPWL) are all = ones (0xFFFF),
// then the ECSL will now be disable. If the password
// is not all ones (0xFFFF), then the code below is required
// to disable the ECSL.
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
```

### 3.13.7.8 Device Unique ID

Bank 0 OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x703C0. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

## 3.14 F28004x System Control Registers

### 3.14.1 System Control Base Addresses

**Table 3-18. System Control Base Address Table**

| Device Registers     | Register Name          | Start Address | End Address |
|----------------------|------------------------|---------------|-------------|
| CpuTimer0Regs        | CPUTIMER_REGS          | 0x0000_0C00   | 0x0000_0C07 |
| CpuTimer1Regs        | CPUTIMER_REGS          | 0x0000_0C08   | 0x0000_0C0F |

### 3.14.2 ACCESS\_PROTECTION\_REGS Registers

Table 3-19 lists the ACCESS\_PROTECTION\_REGS registers. All register offset addresses not listed in Table 3-19 should be considered as reserved locations and the register contents should not be modified.

**Table 3-19. ACCESS\_PROTECTION\_REGS Registers**

| Offset | Acronym        | Register Name                                         | Write Protection | Section            |
|--------|----------------|-------------------------------------------------------|------------------|--------------------|
| 0h     | NMAVFLG        | Non-Master Access Violation Flag Register             |                  | <a href="#">Go</a> |
| 2h     | NMAVSET        | Non-Master Access Violation Flag Set Register         | EALLOW           | <a href="#">Go</a> |
| 4h     | NMAVCLR        | Non-Master Access Violation Flag Clear Register       | EALLOW           | <a href="#">Go</a> |
| 6h     | NMAVINTEN      | Non-Master Access Violation Interrupt Enable Register | EALLOW           | <a href="#">Go</a> |
| 8h     | NMCPURDAVADDR  | Non-Master CPU Read Access Violation Address          |                  | <a href="#">Go</a> |
| Ah     | NMCPUWRAVADDR  | Non-Master CPU Write Access Violation Address         |                  | <a href="#">Go</a> |
| Ch     | NMCPUFAVADDR   | Non-Master CPU Fetch Access Violation Address         |                  | <a href="#">Go</a> |
| Eh     | NMDMAWRAVADDR  | Non-Master DMA Write Access Violation Address         |                  | <a href="#">Go</a> |
| 10h    | NMCLA1RDAVADDR | Non-Master CLA1 Read Access Violation Address         |                  | <a href="#">Go</a> |
| 12h    | NMCLA1WRAVADDR | Non-Master CLA1 Write Access Violation Address        |                  | <a href="#">Go</a> |
| 14h    | NMCLA1FAVADDR  | Non-Master CLA1 Fetch Access Violation Address        |                  | <a href="#">Go</a> |
| 20h    | MAVFLG         | Master Access Violation Flag Register                 |                  | <a href="#">Go</a> |
| 22h    | MAVSET         | Master Access Violation Flag Set Register             | EALLOW           | <a href="#">Go</a> |
| 24h    | MAVCLR         | Master Access Violation Flag Clear Register           | EALLOW           | <a href="#">Go</a> |
| 26h    | MAVINTEN       | Master Access Violation Interrupt Enable Register     | EALLOW           | <a href="#">Go</a> |
| 28h    | MCPUFAVADDR    | Master CPU Fetch Access Violation Address             |                  | <a href="#">Go</a> |
| 2Ah    | MCPUWRAVADDR   | Master CPU Write Access Violation Address             |                  | <a href="#">Go</a> |
| 2Ch    | MDMAWRAVADDR   | Master DMA Write Access Violation Address             |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-20 shows the codes that are used for access types in this section.

**Table 3-20. ACCESS\_PROTECTION\_REGS Access Type Codes**

| Access Type                     | Code | Description                            |
|---------------------------------|------|----------------------------------------|
| <b>Read Type</b>                |      |                                        |
| R                               | R    | Read                                   |
| R-0                             | R-0  | Read Returns 0s                        |
| <b>Write Type</b>               |      |                                        |
| W                               | W    | Write                                  |
| W1S                             | W1S  | Write 1 to set                         |
| <b>Reset or Default Value</b>   |      |                                        |
| -n                              |      | Value after reset or the default value |
| <b>Register Array Variables</b> |      |                                        |

**Table 3-20. ACCESS\_PROTECTION\_REGS Access  
Type Codes (continued)**

| Access Type | Code | Description                                                                                                                                                                                                                                                                          |
|-------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i,j,k,l,m,n |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y           |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.2.1 NMAVFLG Register (Offset = 0h) [reset = 0h]

NMAVFLG is shown in [Figure 3-23](#) and described in [Table 3-21](#).

Return to the [Summary Table](#).

Non-Master Access Violation Flag Register

| R-0h        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 3-38. MDMAWRVADDR Register Field Descriptions**

| Bit  | Field       | Type | Reset | Description                                                                                                             |
|------|-------------|------|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MDMAWRVADDR | R    | 0h    | This register captures the address location for which master DMA write access violation occurred.<br>Reset type: SYSRSn |

### 3.14.3 CLK\_CFG\_REGS Registers

Table 3-39 lists the CLK\_CFG\_REGS registers. All register offset addresses not listed in Table 3-39 should be considered as reserved locations and the register contents should not be modified.

**Table 3-39. CLK\_CFG\_REGS Registers**

| Offset | Acronym       | Register Name                         | Write Protection | Section            |
|--------|---------------|---------------------------------------|------------------|--------------------|
| 2h     | CLKCFGLOCK1   | Lock bit for CLKCFG registers         | EALLOW           | <a href="#">Go</a> |
| 8h     | CLKSRCCTL1    | Clock Source Control register-1       | EALLOW           | <a href="#">Go</a> |
| Ah     | CLKSRCCTL2    | Clock Source Control register-2       | EALLOW           | <a href="#">Go</a> |
| Ch     | CLKSRCCTL3    | Clock Source Control register-3       | EALLOW           | <a href="#">Go</a> |
| Eh     | SYSPLLCTL1    | SYSPLL Control register-1             | EALLOW           | <a href="#">Go</a> |
| 14h    | SYSPLLMULT    | SYSPLL Multiplier register            | EALLOW           | <a href="#">Go</a> |
| 16h    | SYSPLLSTS     | SYSPLL Status register                |                  | <a href="#">Go</a> |
| 22h    | SYSCLKDIVSEL  | System Clock Divider Select register  | EALLOW           | <a href="#">Go</a> |
| 28h    | XCLKOUTDIVSEL | XCLKOUT Divider Select register       | EALLOW           | <a href="#">Go</a> |
| 2Ch    | LOSPCP        | Low Speed Clock Source Prescaler      | EALLOW           | <a href="#">Go</a> |
| 2Eh    | MCDCR         | Missing Clock Detect Control Register | EALLOW           | <a href="#">Go</a> |
| 30h    | X1CNT         | 10-bit Counter on X1 Clock            |                  | <a href="#">Go</a> |
| 32h    | XTALCR        | XTAL Control Register                 | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-40 shows the codes that are used for access types in this section.

**Table 3-40. CLK\_CFG\_REGS Access Type Codes**

| Access Type                     | Code   | Description                                                                                                                                                                                                                                                                          |

| <b>Register Array Variables</b> |        |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |        | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |        | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.3.1 CLKCFGLOCK1 Register (Offset = 2h) [reset = 0h]

CLKCFGLOCK1 is shown in [Figure 3-41](#) and described in [Table 3-41](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

|-----|--------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-0 | OSCCLKSRCSEL | R/W  | 0h    | <p>Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK.</p> <p>00 = INTOSC2 (default on reset)</p> <p>01 = External Oscillator (XTAL)</p> <p>10 = INTOSC1</p> <p>11 = reserved (default to INTOSC1)</p> <p>At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier.</p> <p>The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete..</p> <p>Notes:</p> <p>[1] Reserved selection defaults to 00 configuration</p> <p>[2] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL.</p> <p>Reset type: XRSn</p> |

### 3.14.3.3 CLKSRCCTL2 Register (Offset = Ah) [reset = 0h]

CLKSRCCTL2 is shown in [Figure 3-43](#) and described in [Table 3-43](#).

Return to the [Summary Table](#).

| 1    | SE       | R/W  | 0h    | Configures XTAL oscillator in single-ended or Crystal mode when XTAL oscillator is powered up(i.e. OSCOFF = 0)<br><br>0 XTAL oscillator in Crystal mode<br>1 XTAL oscilator in single-ended mode (through X1)<br>Reset type: XRSn                                                                                 |
| 0    | OSCOFF   | R/W  | 1h    | This bit if '1', powers-down the XTAL oscillator macro and hence doesn't let X2 to be driven by the XTAL oscillator. If a crystal is connected to X1/X2, user needs to first clear this bit, wait for the oscillator to power up (using X1CNT) and then only switch the clock source to X1/X2<br>Reset type: XRSn |

### 3.14.4 CPU\_SYS\_REGS Registers

Table 3-54 lists the CPU\_SYS\_REGS registers. All register offset addresses not listed in Table 3-54 should be considered as reserved locations and the register contents should not be modified.

**Table 3-54. CPU\_SYS\_REGS Registers**

| Offset | Acronym     | Register Name                                           | Write Protection | Section            |
|--------|-------------|---------------------------------------------------------|------------------|--------------------|

Complex bit access types are encoded to fit into small table cells. Table 3-55 shows the codes that are used for access types in this section.

**Table 3-55. CPU\_SYS\_REGS Access Type Codes**

| Access Type                   | Code   | Description     |
|-------------------------------|--------|-----------------|
| <b>Read Type</b>              |        |                 |
| R                             | R      | Read            |
| R-0                           | R-0    | Read Returns 0s |
| <b>Write Type</b>             |        |                 |
| W                             | W      | Write           |
| W1S                           | W1S    | Write 1 to set  |
| WSonce                        | WSonce | Write Set once  |
| <b>Reset or Default Value</b> |        |                 |

**Table 3-55. CPU\_SYS\_REGS Access Type  
Codes (continued)**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.4.1 CPUSYSLOCK1 Register (Offset = 0h) [reset = 0h]

CPUSYSLOCK1 is shown in [Figure 3-54](#) and described in [Table 3-56](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

**Figure 3-54. CPUSYSLOCK1 Register**

### 3.14.4.23 GPIO\_LPMSEL1 Register (Offset = 7Ah) [reset = 0h]

GPIO\_LPMSEL1 is shown in [Figure 3-76](#) and described in [Table 3-78](#).

Return to the [Summary Table](#).

GPIO LPM Wakeup select registers

Connects the selected pin to the LPM circuit. Refer to LPM section of the TRM for the wakeup capabilities of the selected pin.

### 3.14.5 CPUTIMER\_REGS Registers

Table 3-82 lists the CPUTIMER\_REGS registers. All register offset addresses not listed in Table 3-82 should be considered as reserved locations and the register contents should not be modified.

**Table 3-82. CPUTIMER\_REGS Registers**

| Offset | Acronym | Register Name                     | Write Protection | Section            |
|--------|---------|-----------------------------------|------------------|--------------------|
| 0h     | TIM     | CPU-Timer, Counter Register       |                  | <a href="#">Go</a> |
| 2h     | PRD     | CPU-Timer, Period Register        |                  | <a href="#">Go</a> |
| 4h     | TCR     | CPU-Timer, Control Register       |                  | <a href="#">Go</a> |
| 6h     | TPR     | CPU-Timer, Prescale Register      |                  | <a href="#">Go</a> |
| 7h     | TPRH    | CPU-Timer, Prescale Register High |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-83 shows the codes that are used for access types in this section.

**Table 3-83. CPUTIMER\_REGS Access Type Codes**

| Access Type                     | Code    | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |         |                                                                                                                                                                                                                                                                                      |
| R                               | R       | Read                                                                                                                                                                                                                                                                                 |
| <b>Write Type</b>               |         |                                                                                                                                                                                                                                                                                      |

| W1C                             | W<br>1C | Write<br>1 to clear                                                                                                                                                                                                                                                                  |
| <b>Reset or Default Value</b>   |         |                                                                                                                                                                                                                                                                                      |
| -n                              |         | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |         |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |         | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |         | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.5.1 TIM Register (Offset = 0h) [reset = FFFFh]

TIM is shown in [Figure 3-80](#) and described in [Table 3-84](#).

Return to the [Summary Table](#).

CPU-Timer, Counter Register

|------|-------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-8 | PSC   | R    | 0h    | <p>CPU-Timer Prescale Counter.</p> <p>These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0.</p> <p>Reset type: SYSRSn</p> |
| 7-0  | TDDR  | R/W  | 0h    | <p>CPU-Timer Divide-Down.</p> <p>Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software.</p> <p>Reset type: SYSRSn</p>                                                                                                                             |

### 3.14.5.5 TPRH Register (Offset = 7h) [reset = 0h]

TPRH is shown in [Figure 3-84](#) and described in [Table 3-88](#).

### 3.14.7 DCSM\_BANK0\_Z2\_REGS Registers

Table 3-107 lists the DCSM\_BANK0\_Z2\_REGS registers. All register offset addresses not listed in Table 3-107 should be considered as reserved locations and the register contents should not be modified.

**Table 3-107. DCSM\_BANK0\_Z2\_REGS Registers**

| Offset | Acronym              | Register Name                                   | Write Protection | Section            |
|--------|----------------------|-------------------------------------------------|------------------|--------------------|
| 0h     | B0_Z2_LINKPOINTER    | Zone 2 Link Pointer for flash BANK0             |                  | <a href="#">Go</a> |
| 2h     | Z2_OTPSECLOCK        | Zone 2 OTP Secure JTAG lock                     |                  | <a href="#">Go</a> |
| 6h     | B0_Z2_LINKPOINTERERR | Link Pointer Error for flash BANK0              |                  | <a href="#">Go</a> |
| 10h    | Z2_CSMKEY0           | Zone 2 CSM Key 0                                |                  | <a href="#">Go</a> |
| 12h    | Z2_CSMKEY1           | Zone 2 CSM Key 1                                |                  | <a href="#">Go</a> |
| 14h    | Z2_CSMKEY2           | Zone 2 CSM Key 2                                |                  | <a href="#">Go</a> |
| 16h    | Z2_CSMKEY3           | Zone 2 CSM Key 3                                |                  | <a href="#">Go</a> |
| 19h    | Z2_CR                | Zone 2 CSM Control Register                     |                  | <a href="#">Go</a> |
| 1Ah    | B0_Z2_GRABSECTR      | Zone 2 Grab Flash BANK0 Sectors Register        |                  | <a href="#">Go</a> |
| 1Ch    | Z2_GRABRAMR          | Zone 2 Grab RAM Blocks Register                 |                  | <a href="#">Go</a> |
| 1Eh    | B0_Z2_EXEONLYSECTR   | Zone 2 Flash BANK0 Execute_Only Sector Register |                  | <a href="#">Go</a> |
| 20h    | Z2_EXEONLYRAMR       | Zone 2 RAM Execute_Only Block Register          |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-108 shows the codes that are used for access types in this section.

**Table 3-108. DCSM\_BANK0\_Z2\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

### 3.14.8 DCSM\_BANK1\_Z1\_REGS Registers

Table 3-121 lists the DCSM\_BANK1\_Z1\_REGS registers. All register offset addresses not listed in Table 3-121 should be considered as reserved locations and the register contents should not be modified.

**Table 3-121. DCSM\_BANK1\_Z1\_REGS Registers**

| Offset | Acronym              | Register Name                                   | Write Protection | Section            |
|--------|----------------------|-------------------------------------------------|------------------|--------------------|
| 0h     | B1_Z1_LINKPOINTER    | Zone 1 Link Pointer for flash BANK1             |                  | <a href="#">Go</a> |
| 6h     | B1_Z1_LINKPOINTERERR | Link Pointer Error for flash BANK1              |                  | <a href="#">Go</a> |
| 1Ah    | B1_Z1_GRABSECTR      | Zone 1 Grab Flash BANK1 Sectors Register        |                  | <a href="#">Go</a> |
| 1Eh    | B1_Z1_EXEONLYSECTR   | Zone 1 Flash BANK1 Execute_Only Sector Register |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-122 shows the codes that are used for access types in this section.

**Table 3-122. DCSM\_BANK1\_Z1\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

| R                               | R    | Read                                                                                                                                                                                                                                                                                 |
| R-0                             | R-0  | Read Returns 0s                                                                                                                                                                                                                                                                      |
| <b>Reset or Default Value</b>   |      |                                                                                                                                                                                                                                                                                      |
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.8.1 B1\_Z1\_LINKPOINTER Register (Offset = 0h) [reset = E0000000h]

B1\_Z1\_LINKPOINTER is shown in [Figure 3-113](#) and described in [Table 3-123](#).

Return to the [Summary Table](#).

### 3.14.9 DCSM\_BANK1\_Z2\_REGS Registers

Table 3-127 lists the DCSM\_BANK1\_Z2\_REGS registers. All register offset addresses not listed in Table 3-127 should be considered as reserved locations and the register contents should not be modified.

**Table 3-127. DCSM\_BANK1\_Z2\_REGS Registers**

| Offset | Acronym              | Register Name                                   | Write Protection | Section            |
|--------|----------------------|-------------------------------------------------|------------------|--------------------|
| 0h     | B1_Z2_LINKPOINTER    | Zone 2 Link Pointer for flash BANK1             |                  | <a href="#">Go</a> |
| 6h     | B1_Z2_LINKPOINTERERR | Link Pointer Error for flash BANK1              |                  | <a href="#">Go</a> |
| 1Ah    | B1_Z2_GRABSECTR      | Zone 2 Grab Flash BANK1 Sectors Register        |                  | <a href="#">Go</a> |
| 1Eh    | B1_Z2_EXEONLYSECTR   | Zone 2 Flash BANK1 Execute_Only Sector Register |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-128 shows the codes that are used for access types in this section.

**Table 3-128. DCSM\_BANK1\_Z2\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 3.14.10 DCSM\_COMMON\_REGS Registers

Table 3-133 lists the DCSM\_COMMON\_REGS registers. All register offset addresses not listed in Table 3-133 should be considered as reserved locations and the register contents should not be modified.

**Table 3-133. DCSM\_COMMON\_REGS Registers**

| Offset | Acronym     | Register Name                       | Write Protection | Section            |
|--------|-------------|-------------------------------------|------------------|--------------------|
| 0h     | FLSEM       | Flash Wrapper Semaphore Register    | EALLOW           | <a href="#">Go</a> |
| 2h     | B0_SECTSTAT | Flash BANK0 Sectors Status Register |                  | <a href="#">Go</a> |
| 4h     | RAMSTAT     | RAM Status Register                 |                  | <a href="#">Go</a> |
| 8h     | B1_SECTSTAT | Flash BANK1 Sectors Status Register |                  | <a href="#">Go</a> |
| Ah     | SECERRSTAT  | Security Error Status Register      |                  | <a href="#">Go</a> |
| Ch     | SECERRCLR   | Security Error Clear Register       |                  | <a href="#">Go</a> |
| Eh     | SECERRFRC   | Security Error Force Register       |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-134 shows the codes that are used for access types in this section.

**Table 3-134. DCSM\_COMMON\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Reset or Default Value</b>   |      |                                                                                                                                                                                                                                                                                      |
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.10.1 FLSEM Register (Offset = 0h) [reset = 0h]

FLSEM is shown in [Figure 3-121](#) and described in [Table 3-135](#).

Return to the [Summary Table](#).

Flash Wrapper Semaphore Register

Complex bit access types are encoded to fit into small table cells. Table 3-143 shows the codes that are used for access types in this section.

**Table 3-143. DEV\_CFG\_REGS Access Type Codes**

| Access Type                   | Code   | Description      |
|-------------------------------|--------|------------------|
| <b>Read Type</b>              |        |                  |
| R                             | R      | Read             |
| R-0                           | R-0    | Read Returns 0s  |
| <b>Write Type</b>             |        |                  |
| W                             | W      | Write            |
| W1S                           | W1S    | Write 1 to set   |
| WOnce                         | WOnce  | Write Write once |
| WSonce                        | WSonce | Write Set once   |
| <b>Reset or Default Value</b> |        |                  |

**Table 3-143. DEV\_CFG\_REGS Access Type  
Codes (continued)**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n                              |      | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |      |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |      | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |      | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.11.22 SOFTPRES20 Register (Offset = AAh) [reset = 0h]

SOFTPRES20 is shown in [Figure 3-149](#) and described in [Table 3-165](#).

Return to the [Summary Table](#).

Peripheral Software Reset register

When bits in this register are set, the respective peripheral is in reset. All data is lost and the peripheral registers are returned to their reset states. Bits must be manually cleared after being set.

### 3.14.12 DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 3-168 lists the DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 3-168 should be considered as reserved locations and the register contents should not be modified.

**Table 3-168. DMA\_CLA\_SRC\_SEL\_REGS Registers**

| Offset | Acronym            | Register Name                                   | Write Protection | Section            |
|--------|--------------------|-------------------------------------------------|------------------|--------------------|
| 0h     | CLA1TASKSRCSELLOCK | CLA1 Task Trigger Source Select Lock Register   | EALLOW           | <a href="#">Go</a> |
| 4h     | DMACHSRCSELLOCK    | DMA Channel Trigger Source Select Lock Register | EALLOW           | <a href="#">Go</a> |
| 6h     | CLA1TASKSRCSEL1    | CLA1 Task Trigger Source Select Register-1      | EALLOW           | <a href="#">Go</a> |
| 8h     | CLA1TASKSRCSEL2    | CLA1 Task Trigger Source Select Register-2      | EALLOW           | <a href="#">Go</a> |
| 16h    | DMACHSRCSEL1       | DMA Channel Trigger Source Select Register-1    | EALLOW           | <a href="#">Go</a> |
| 18h    | DMACHSRCSEL2       | DMA Channel Trigger Source Select Register-2    | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-169 shows the codes that are used for access types in this section.

**Table 3-169. DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

| Access Type                     | Code  | Description                                                                                                                                                                                                                                                                          |

### 3.14.13 FLASH\_CTRL\_REGS Registers

Table 3-176 lists the FLASH\_CTRL\_REGS registers. All register offset addresses not listed in Table 3-176 should be considered as reserved locations and the register contents should not be modified.

**Table 3-176. FLASH\_CTRL\_REGS Registers**

| Offset | Acronym       | Register Name                         | Write Protection | Section            |
|--------|---------------|---------------------------------------|------------------|--------------------|
| 0h     | FRDCNTL       | Flash Read Control Register           | EALLOW           | <a href="#">Go</a> |
| 1Eh    | FBAC          | Flash Bank Access Control Register    | EALLOW           | <a href="#">Go</a> |
| 20h    | FBFALLBACK    | Flash Bank Fallback Power Register    | EALLOW           | <a href="#">Go</a> |
| 22h    | FBPRDY        | Flash Bank Pump Ready Register        | EALLOW           | <a href="#">Go</a> |
| 24h    | FPAC1         | Flash Pump Access Control Register 1  | EALLOW           | <a href="#">Go</a> |
| 26h    | FPAC2         | Flash Pump Access Control Register 2  | EALLOW           | <a href="#">Go</a> |
| 2Ah    | FMSTAT        | Flash Module Status Register          | EALLOW           | <a href="#">Go</a> |
| 180h   | FRD_INTF_CTRL | Flash Read Interface Control Register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-177 shows the codes that are used for access types in this section.

**Table 3-177. FLASH\_CTRL\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

| 31-16 | RESERVED | R    | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 15-8  | BAGP     | R/W  | 0h    | Bank Active Grace Period. These bits contain the starting count value for the BAGP down counter. Any access to a given bank causes its BAGP counter to reload the BAGP value for that bank. After the last access to this flash bank, the down counter delays from 0 to 255 prescaled SYSCLK clock cycles before putting the bank into one of the fallback power modes as determined by the FBFALLBACK register. This value must be greater than 1 when the fallback mode is not ACTIVE.<br><br>Note: The prescaled clock used for the BAGP down counter is a clock divided by 16 from input SYSCLK.<br>Reset type: SYSRSn |

| 27-16 | PSLEEP   | R/W  | A0h   | <p>Pump sleep. These bits contain the starting count value for the charge pump sleep down counter. While the charge pump is in sleep mode, the power mode management logic holds the charge pump sleep counter at this value. When the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles before putting the charge pump into active power mode.</p> <p>Note: The pump sleep down counter uses the same prescaled clock as Bank sleep down counter which is divided by 2 of input SYSCLK.</p> <p>Note: BootROM configures the PSLEEP value as 0x3E8 for 100 MHz operation. Users can modify the PSLEEP value based on their application requirements if needed.</p> <p>Reset type: SYSRSn</p> |

| 15-0  | PAGP     | R/W  | 0h    | <p>Pump Active Grace Period. This register contains the starting count value for the PAGP mode down counter. Any access to flash memory causes the counter to reload with the PAGP value. After the last access to flash memory, the down counter delays from 0 to 65535 prescaled SYSCLK clock cycles before entering one of the charge pump fallback power modes as determined by PUMPPWR in the FPAC1 register.</p> <p>Note: The PAGP down counter is clocked by the same prescaled clock as the BAGP down counter which is divided by 16 of input SYSCLK.</p> <p>Reset type: SYSRSn</p> |

### 3.14.13.7 FMSTAT Register (Offset = 2Ah) [reset = 0h]

FMSTAT is shown in [Figure 3-164](#) and described in [Table 3-184](#).

### 3.14.14 FLASH\_ECC\_REGS Registers

Table 3-186 lists the FLASH\_ECC\_REGS registers. All register offset addresses not listed in Table 3-186 should be considered as reserved locations and the register contents should not be modified.

**Table 3-186. FLASH\_ECC\_REGS Registers**

| Offset | Acronym              | Register Name                    | Write Protection | Section            |
|--------|----------------------|----------------------------------|------------------|--------------------|
| 0h     | ECC_ENABLE           | ECC Enable                       | EALLOW           | <a href="#">Go</a> |
| 2h     | SINGLE_ERR_ADDR_LOW  | Single Error Address Low         | EALLOW           | <a href="#">Go</a> |
| 4h     | SINGLE_ERR_ADDR_HIGH | Single Error Address High        | EALLOW           | <a href="#">Go</a> |
| 6h     | UNC_ERR_ADDR_LOW     | Uncorrectable Error Address Low  | EALLOW           | <a href="#">Go</a> |
| 8h     | UNC_ERR_ADDR_HIGH    | Uncorrectable Error Address High | EALLOW           | <a href="#">Go</a> |
| Ah     | ERR_STATUS           | Error Status                     | EALLOW           | <a href="#">Go</a> |

| 70h    | MSGxTEST     | Message RAM TEST Register                     | EALLOW           | <a href="#">Go</a> |
| 72h    | MSGxINIT     | Message RAM Init Register                     | EALLOW           | <a href="#">Go</a> |
| 74h    | MSGxINITDONE | Message RAM InitDone Status Register          |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-209 shows the codes that are used for access types in this section.

**Table 3-209. MEM\_CFG\_REGS Access Type Codes**

| Access Type       | Code | Description     |
|-------------------|------|-----------------|
| <b>Read Type</b>  |      |                 |
| R                 | R    | Read            |
| R-0               | R-0  | Read Returns 0s |
| <b>Write Type</b> |      |                 |
| W                 | W    | Write           |
| W1S               | W1S  | Write 1 to set  |

**Table 3-209. MEM\_CFG\_REGS Access Type  
Codes (continued)**

| Access Type                     | Code       | Description                                                                                                                                                                                                                                                                                                  |

### 3.14.16 MEMORY\_ERROR\_REGS Registers

Table 3-239 lists the MEMORY\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-239 should be considered as reserved locations and the register contents should not be modified.

**Table 3-239. MEMORY\_ERROR\_REGS Registers**

| Offset | Acronym      | Register Name                                    | Write Protection | Section            |
|--------|--------------|--------------------------------------------------|------------------|--------------------|
| 0h     | UCERRFLG     | Uncorrectable Error Flag Register                |                  | <a href="#">Go</a> |
| 2h     | UCERRSET     | Uncorrectable Error Flag Set Register            | EALLOW           | <a href="#">Go</a> |
| 4h     | UCERRCLR     | Uncorrectable Error Flag Clear Register          | EALLOW           | <a href="#">Go</a> |
| 6h     | UCCPUREADDR  | Uncorrectable CPU Read Error Address             |                  | <a href="#">Go</a> |
| 8h     | UCDMAREADDR  | Uncorrectable DMA Read Error Address             |                  | <a href="#">Go</a> |
| Ah     | UCCLA1READDR | Uncorrectable CLA1 Read Error Address            |                  | <a href="#">Go</a> |
| 20h    | CERRFLG      | Correctable Error Flag Register                  |                  | <a href="#">Go</a> |
| 22h    | CERRSET      | Correctable Error Flag Set Register              | EALLOW           | <a href="#">Go</a> |
| 24h    | CERRCLR      | Correctable Error Flag Clear Register            | EALLOW           | <a href="#">Go</a> |
| 26h    | CCPUREADDR   | Correctable CPU Read Error Address               |                  | <a href="#">Go</a> |
| 2Eh    | CERRCNT      | Correctable Error Count Register                 |                  | <a href="#">Go</a> |
| 30h    | CERRTHRES    | Correctable Error Threshold Value Register       | EALLOW           | <a href="#">Go</a> |
| 32h    | CEINTFLG     | Correctable Error Interrupt Flag Status Register |                  | <a href="#">Go</a> |
| 34h    | CEINTCLR     | Correctable Error Interrupt Flag Clear Register  | EALLOW           | <a href="#">Go</a> |
| 36h    | CEINTSET     | Correctable Error Interrupt Flag Set Register    | EALLOW           | <a href="#">Go</a> |
| 38h    | CEINTEN      | Correctable Error Interrupt Enable Register      | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-240 shows the codes that are used for access types in this section.

**Table 3-240. MEMORY\_ERROR\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

### 3.14.17 NMI\_INTRUPT\_REGS Registers

Table 3-257 lists the NMI\_INTRUPT\_REGS registers. All register offset addresses not listed in Table 3-257 should be considered as reserved locations and the register contents should not be modified.

**Table 3-257. NMI\_INTRUPT\_REGS Registers**

| Offset | Acronym   | Register Name                    | Write Protection | Section            |
|--------|-----------|----------------------------------|------------------|--------------------|
| 0h     | NMICFG    | NMI Configuration Register       | EALLOW           | <a href="#">Go</a> |
| 1h     | NMIFLG    | NMI Flag Register (SYSRsn Clear) |                  | <a href="#">Go</a> |
| 2h     | NMIFLGCLR | NMI Flag Clear Register          | EALLOW           | <a href="#">Go</a> |
| 3h     | NMIFLGFRC | NMI Flag Force Register          | EALLOW           | <a href="#">Go</a> |
| 4h     | NMIWDCNT  | NMI Watchdog Counter Register    |                  | <a href="#">Go</a> |
| 5h     | NMIWDPRD  | NMI Watchdog Period Register     | EALLOW           | <a href="#">Go</a> |
| 6h     | NMISHDFLG | NMI Shadow Flag Register         |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-258 shows the codes that are used for access types in this section.

**Table 3-258. NMI\_INTRUPT\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

### 3.14.17.3 NMIFLGCLR Register (Offset = 2h) [reset = 0h]

NMIFLGCLR is shown in [Figure 3-233](#) and described in [Table 3-261](#).

Return to the [Summary Table](#).

Writing a 1 to one of these bits clears the corresponding bit in the NMIFLG register. Writes of 0 are ignored, and these bits always read 0. If an NMI arrives on the same cycle that this register is written, the NMI is latched. All other NMI flags must be cleared before the NMIINT flag is cleared, otherwise NMIINT will be set again.

### 3.14.17.4 NMIFLGFR Register (Offset = 3h) [reset = 0h]

NMIFLGFR is shown in [Figure 3-234](#) and described in [Table 3-262](#).

Return to the [Summary Table](#).

Writing a 1 to one of these bits sets the corresponding bit in the NMIFLG register. Writes of 0 are ignored, and these bits always read 0. This register can be used to test the NMI functionality.

**Figure 3-234. NMIFLGFR Register**

| Bit  | Field    | Type | Reset | Description                                                                                                                                                                                                                                           |
|------|----------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | NMIWDPRD | R/W  | FFFFh | <p>NMI Watchdog Period</p> <p>These bits specify the period of the NMI watchdog timer in SYSCLK cycles. Writing a period value that is smaller than the current counter value will immediately force a reset (NMIWDRS).</p> <p>Reset type: SYSRSn</p> |

### 3.14.17.7 NMISHDFLG Register (Offset = 6h) [reset = 0h]

NMISHDFLG is shown in [Figure 3-237](#) and described in [Table 3-265](#).

Return to the [Summary Table](#).

These shadow flag bits are set whenever the corresponding bits in the NMIFLG register are set. The shadow flags are only reset by a power-on reset (POR), but any system or external reset will reset the normal flags. The shadow flags allow NMIs to be tracked across resets.

### 3.14.18 PERIPH\_AC\_REGS Registers

Table 3-266 lists the PERIPH\_AC\_REGS registers. All register offset addresses not listed in Table 3-266 should be considered as reserved locations and the register contents should not be modified.

**Table 3-266. PERIPH\_AC\_REGS Registers**

| Offset | Acronym        | Register Name                              | Write Protection | Section            |
|--------|----------------|--------------------------------------------|------------------|--------------------|
| 0h     | ADCA_AC        | ADCA Master Access Control Register        | EALLOW           | <a href="#">Go</a> |

| -n                              |       | Value after reset or the default value                                                                                                                                                                                                                                               |
| <b>Register Array Variables</b> |       |                                                                                                                                                                                                                                                                                      |
| i,j,k,l,m,n                     |       | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y                               |       | When this variable is used in a register name, an offset, or an address it refers to the value of a register array.                                                                                                                                                                  |

### 3.14.18.1 ADCA\_AC Register (Offset = 0h) [reset = 3Fh]

ADCA\_AC is shown in [Figure 3-238](#) and described in [Table 3-268](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-238. ADCA\_AC Register**

### 3.14.18.5 CMPSS2\_AC Register (Offset = 12h) [reset = 3Fh]

CMPSS2\_AC is shown in [Figure 3-242](#) and described in [Table 3-272](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-242. CMPSS2\_AC Register**

### 3.14.18.10 CMPSS7\_AC Register (Offset = 1Ch) [reset = 3Fh]

CMPSS7\_AC is shown in [Figure 3-247](#) and described in [Table 3-277](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-247. CMPSS7\_AC Register**

### 3.14.18.14 PGA2\_AC Register (Offset = 3Ah) [reset = 3Fh]

PGA2\_AC is shown in [Figure 3-251](#) and described in [Table 3-281](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-251. PGA2\_AC Register**

### 3.14.18.19 PGA7\_AC Register (Offset = 44h) [reset = 3Fh]

PGA7\_AC is shown in [Figure 3-256](#) and described in [Table 3-286](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-256. PGA7\_AC Register**

### 3.14.18.23 EPWM4\_AC Register (Offset = 4Eh) [reset = 3Fh]

EPWM4\_AC is shown in [Figure 3-260](#) and described in [Table 3-290](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-260. EPWM4\_AC Register**

### 3.14.18.28 EQEP1\_AC Register (Offset = 70h) [reset = 3Fh]

EQEP1\_AC is shown in [Figure 3-265](#) and described in [Table 3-295](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.14.18.32 ECAP3\_AC Register (Offset = 84h) [reset = 3Fh]

ECAP3\_AC is shown in [Figure 3-269](#) and described in [Table 3-299](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-269. ECAP3\_AC Register**

### 3.14.18.37 SDFM1\_AC Register (Offset = A8h) [reset = 3Fh]

SDFM1\_AC is shown in [Figure 3-274](#) and described in [Table 3-304](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.14.18.41 CLB4\_AC Register (Offset = B6h) [reset = 3Fh]

CLB4\_AC is shown in [Figure 3-278](#) and described in [Table 3-308](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

### 3.14.18.45 PMBUS\_A\_AC Register (Offset = 130h) [reset = 3Fh]

PMBUS\_A\_AC is shown in [Figure 3-282](#) and described in [Table 3-312](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-282. PMBUS\_A\_AC Register**

### 3.14.18.49 FSIATX\_AC Register (Offset = 158h) [reset = 3Fh]

FSIATX\_AC is shown in [Figure 3-286](#) and described in [Table 3-316](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

**Figure 3-286. FSIATX\_AC Register**

The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch.</p> <p>Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts.</p> <p>Reset type: SYSRSn</p> |
| 0    | ENPIE   | R/W  | 0h    | <p>Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled.</p> <p>Reset type: SYSRSn</p>                                                                                                                                                                                                                 |

### 3.14.19.2 PIEACK Register (Offset = 1h) [reset = 0h]

PIEACK is shown in [Figure 3-291](#) and described in [Table 3-323](#).

Return to the [Summary Table](#).

#### Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt. Writes of 0 are ignored.

**Figure 3-291. PIEACK Register**

### 3.14.19.3 PIEIER1 Register (Offset = 2h) [reset = 0h]

PIEIER1 is shown in [Figure 3-292](#) and described in [Table 3-324](#).

Return to the [Summary Table](#).

Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-292. PIEIER1 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.4 PIEIFR1 Register (Offset = 3h) [reset = 0h]

PIEIFR1 is shown in [Figure 3-293](#) and described in [Table 3-325](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-293. PIEIFR1 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.6 PIEIFR2 Register (Offset = 5h) [reset = 0h]

PIEIFR2 is shown in [Figure 3-295](#) and described in [Table 3-327](#).

Return to the [Summary Table](#).

Interrupt Group 2 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-295. PIEIFR2 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.7 PIEIER3 Register (Offset = 6h) [reset = 0h]

PIEIER3 is shown in [Figure 3-296](#) and described in [Table 3-328](#).

Return to the [Summary Table](#).

Interrupt Group 3 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-296. PIEIER3 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.11 PIEIER5 Register (Offset = Ah) [reset = 0h]

PIEIER5 is shown in [Figure 3-300](#) and described in [Table 3-332](#).

Return to the [Summary Table](#).

Interrupt Group 5 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-300. PIEIER5 Register**

### 3.14.19.12 PIEIFR5 Register (Offset = Bh) [reset = 0h]

PIEIFR5 is shown in [Figure 3-301](#) and described in [Table 3-333](#).

Return to the [Summary Table](#).

#### Interrupt Group 5 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-301. PIEIFR5 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.17 PIEIER8 Register (Offset = 10h) [reset = 0h]

PIEIER8 is shown in [Figure 3-306](#) and described in [Table 3-338](#).

Return to the [Summary Table](#).

Interrupt Group 8 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-306. PIEIER8 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.18 PIEIFR8 Register (Offset = 11h) [reset = 0h]

PIEIFR8 is shown in [Figure 3-307](#) and described in [Table 3-339](#).

Return to the [Summary Table](#).

Interrupt Group 8 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-307. PIEIFR8 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.23 PIEIER11 Register (Offset = 16h) [reset = 0h]

PIEIER11 is shown in [Figure 3-312](#) and described in [Table 3-344](#).

Return to the [Summary Table](#).

Interrupt Group 11 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

**Figure 3-312. PIEIER11 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.19.24 PIEIFR11 Register (Offset = 17h) [reset = 0h]

PIEIFR11 is shown in [Figure 3-313](#) and described in [Table 3-345](#).

Return to the [Summary Table](#).

#### Interrupt Group 11 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-313. PIEIFR11 Register**

| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      |

### 3.14.20 ROM\_PREFETCH\_REGS Registers

Table 3-348 lists the ROM\_PREFETCH\_REGS registers. All register offset addresses not listed in Table 3-348 should be considered as reserved locations and the register contents should not be modified.

**Table 3-348. ROM\_PREFETCH\_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|--------|---------|---------------|------------------|---------|
|--------|---------|---------------|------------------|---------|

Complex bit access types are encoded to fit into small table cells. Table 3-349 shows the codes that are used for access types in this section.

**Table 3-349. ROM\_PREFETCH\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

### 3.14.21 ROM\_WAIT\_STATE\_REGS Registers

Table 3-350 lists the ROM\_WAIT\_STATE\_REGS registers. All register offset addresses not listed in Table 3-350 should be considered as reserved locations and the register contents should not be modified.

**Table 3-350. ROM\_WAIT\_STATE\_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|--------|---------|---------------|------------------|---------|
|--------|---------|---------------|------------------|---------|

Complex bit access types are encoded to fit into small table cells. Table 3-351 shows the codes that are used for access types in this section.

**Table 3-351. ROM\_WAIT\_STATE\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

| Checksum |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| R-X      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 3-361. UID\_CHECKSUM Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                        |
|------|----------|------|-------|--------------------------------------------------------------------|
| 31-0 | Checksum | R    | X     | Fletcher checksum of UID_PSRANDx and UID_UNIQUE<br>Reset type: N/A |

### 3.14.23 WD\_REGS Registers

Table 3-362 lists the WD\_REGS registers. All register offset addresses not listed in Table 3-362 should be considered as reserved locations and the register contents should not be modified.

**Table 3-362. WD\_REGS Registers**

| Offset | Acronym | Register Name                      | Write Protection | Section            |
|--------|---------|------------------------------------|------------------|--------------------|
| 22h    | SCSR    | System Control & Status Register   | EALLOW           | <a href="#">Go</a> |
| 23h    | WDCNTR  | Watchdog Counter Register          | EALLOW           | <a href="#">Go</a> |
| 25h    | WDKEY   | Watchdog Reset Key Register        | EALLOW           | <a href="#">Go</a> |
| 29h    | WDCR    | Watchdog Control Register          | EALLOW           | <a href="#">Go</a> |
| 2Ah    | WDWCR   | Watchdog Windowed Control Register | EALLOW           | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-363 shows the codes that are used for access types in this section.

**Table 3-363. WD\_REGS Access Type Codes**

| Access Type                     | Code    | Description                                                                                                                                                                                                                                                                          |
|---------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Read Type</b>                |         |                                                                                                                                                                                                                                                                                      |
| R                               | R       | Read                                                                                                                                                                                                                                                                                 |

| 7-0  | MIN      | R/W  | 0h    | <p>Watchdog Window Threshold</p> <p>These bits specify the lower limit of the watchdog counter reset window. If the counter is reset via the WDKEY register before the counter value reaches the value in this register, the watchdog immediately triggers a reset or interrupt.</p> <p>Reset type: IORSn</p> |

### 3.14.24 XINT\_REGS Registers

Table 3-369 lists the XINT\_REGS registers. All register offset addresses not listed in Table 3-369 should be considered as reserved locations and the register contents should not be modified.

**Table 3-369. XINT\_REGS Registers**

| Offset | Acronym  | Register Name                | Write Protection | Section            |
|--------|----------|------------------------------|------------------|--------------------|
| 0h     | XINT1CR  | XINT1 configuration register |                  | <a href="#">Go</a> |
| 1h     | XINT2CR  | XINT2 configuration register |                  | <a href="#">Go</a> |
| 2h     | XINT3CR  | XINT3 configuration register |                  | <a href="#">Go</a> |
| 3h     | XINT4CR  | XINT4 configuration register |                  | <a href="#">Go</a> |
| 4h     | XINT5CR  | XINT5 configuration register |                  | <a href="#">Go</a> |
| 8h     | XINT1CTR | XINT1 counter register       |                  | <a href="#">Go</a> |
| 9h     | XINT2CTR | XINT2 counter register       |                  | <a href="#">Go</a> |
| Ah     | XINT3CTR | XINT3 counter register       |                  | <a href="#">Go</a> |

Complex bit access types are encoded to fit into small table cells. Table 3-370 shows the codes that are used for access types in this section.

**Table 3-370. XINT\_REGS Access Type Codes**

| Access Type                     | Code | Description                                                                                                                                                                                                                                                                          |

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|--------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | INTCTR | R    | 0h    | <p>This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset.</p> <p>Reset type: SYSRSn</p> |

### 3.14.25 Register to Driverlib Function Mapping

## ***ROM Code and Peripheral Booting***

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

Further information about this device can be found in the following document(s):

- [TMS320F28004x Boot Features and Configurations](#)

## 4.1 Introduction

The purpose of this chapter is to explain the boot ROM code functionality including the boot procedure when executed, the functions and features of the boot ROM code, and to detail the ROM memory map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence will initialize the device to run application code. The boot ROM also contains peripheral bootloaders which can be used to load an application into RAM.

**Table 4-1. ROM Memory**

| ROM               | SIZE   |
|-------------------|--------|
| Unsecure boot ROM | 128 KB |
| Secure ROM        | 64 KB  |
| CLA Data ROM      | 8 KB   |

## 4.2 Device Boot Philosophy

The boot philosophy describes the general boot ROM procedure each time the CPU core is reset. During booting, the boot ROM code updates a boot status location in RAM that details the actions taken during this process.

Refer to [Boot Status Information](#) for more details on the boot status information.

**Table 4-2. Boot ROM Philosophy**

| Step | Action                                                                                                                                                                                                                                                   |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | After reset, the FUSE error register is checked for any errors and are handled accordingly.                                                                                                                                                              |
| 2    | Clock and Flash configuration.                                                                                                                                                                                                                           |
| 3    | Device configuration registers are programmed from OTP.                                                                                                                                                                                                  |
| 4    | On power-on reset (POR), all CPU RAMs are initialized. RAM initialization includes the following RAMs: <ul style="list-style-type: none"> <li>• M0,M1</li> <li>• LS0 to LS7</li> <li>• GS0 to GS3</li> <li>• CLA1TOCPUMSGRAM, CPUTOCLA1MSGRAM</li> </ul> |
| 5    | Any pending NMI is handled by the code.                                                                                                                                                                                                                  |
| 6    | DCSM and OTPJTAGLOCK sequences are executed. (Refer to <a href="#">DCSM Usage</a> for details on how boot ROM interprets the OTP data after initialization)                                                                                              |
| 7    | Device calibration is performed, trimming the specified peripherals with set OTP values.                                                                                                                                                                 |
| 8    | The boot mode GPIO pins are polled to determine whether to boot from SRAM, flash, or peripherals.                                                                                                                                                        |
| 9    | Based on the boot mode and options, the appropriate boot sequence is executed. Refer to <a href="#">Device Boot Flow Diagram</a> for a flow diagram of the device boot sequence and the emulation and standalone boot modes.                             |

## 4.3 Device Boot Modes

This section explains the boot modes supported on this device. The boot ROM uses the boot control GPIO pins to determine the boot mode configuration. The device can be configured to boot to RAM, boot to flash, execute a bootloader, or hold in a wait mode.

[Table 4-3](#) shows the default boot mode options. Users have the option to customize the boot modes supported as well as the boot mode select pins.

**Table 4-3. Device Default Boot Modes**

| Boot Mode       | GPIO24<br>(Default boot mode select pin 1) | GPIO32<br>(Default boot mode select pin 0) |
|-----------------|--------------------------------------------|--------------------------------------------|
| Parallel IO     | 0                                          | 0                                          |
| SCI / Wait boot | 0                                          | 1                                          |
| CAN             | 1                                          | 0                                          |
| Flash           | 1                                          | 1                                          |

**Table 4-4. All Available Boot Modes**

| Boot Mode Number | Boot Mode       |
|------------------|-----------------|
| 0                | Parallel IO     |
| 1                | SCI / Wait boot |
| 2                | CAN             |
| 3                | Flash           |
| 4                | Wait            |
| 5                | RAM             |
| 6                | SPI Master      |
| 7                | I2C Master      |

**NOTE:** All the peripheral boot modes supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, it is actually referring to the first module instance, meaning SCI boot on the SCIA port. The same applies to the other peripheral boots.

### 4.3.1 Configuring Alternate Boot Mode Pins

This section explains how the boot mode select pins can be customized by the user, by programming the BOOTPIN\_CONFIG location in user-configurable DCSM OTP. The location in user DCSM OTP is Z1-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use 0, 1, 2, or 3 boot mode select pins as needed.

**Table 4-5. BOOTPIN\_CONFIG Bit Fields**

| Bit   | Name                           | Description                                                                                                                                                                                                                                                                                                        |
|-------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Key                            | Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid                                                                                                                                                                                                                      |
| 23-16 | Boot Mode Select Pin 2 (BMSP2) | Refer to BMSP0 description except for BMSP2                                                                                                                                                                                                                                                                        |
| 15-8  | Boot Mode Select Pin 1 (BMSP1) | Refer to BMSP0 description except for BMSP1                                                                                                                                                                                                                                                                        |
| 7-0   | Boot Mode Select Pin 0 (BMSP0) | Set to the GPIO pin to be used during boot (up to 255).<br>0x0 = GPIO0; 0x01 = GPIO1 and so on<br>0xFF is invalid and selects the factory default chosen BMSP0, if all other BMSPs are also set to 0xFF.<br>If any other BMSPs are not set to 0xFF, then setting a BMSP to 0xFF will disable that particular BMSP. |

**NOTE:** The following GPIOs **cannot** be used as a BMSP. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIO (the factory default for BMSP2 is 0xFF, which disables the BMSP).

- GPIO 20 to 23
- GPIO 36
- GPIO 38
- GPIO 60 to 223

**Table 4-6. Standalone Boot Mode Select Pin Decoding**

| BOOTPIN_CONFIG Key | BMSP0      | BMSP1      | BMSP2      | Realized Boot Mode                                                     |
|--------------------|------------|------------|------------|------------------------------------------------------------------------|
| != 0x5A            | Don't Care | Don't Care | Don't Care | Boot as defined by the factory default BMSPs (GPIO24, GPIO32)          |
| = 0x5A             | 0xFF       | 0xFF       | 0xFF       | Boot as defined in the boot table for boot mode 0 (All BMSPs disabled) |
|                    | Valid GPIO | 0xFF       | 0xFF       | Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)       |
|                    | 0xFF       | Valid GPIO | 0xFF       | Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)       |
|                    | 0xFF       | 0xFF       | Valid GPIO | Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)       |
|                    | Valid GPIO | Valid GPIO | 0xFF       | Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)      |
|                    | Valid GPIO | 0xFF       | Valid GPIO | Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)      |
|                    | 0xFF       | Valid GPIO | Valid GPIO | Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)      |
|                    | Valid GPIO | Valid GPIO | Valid GPIO | Boot as defined by the values of BMSP0, BMSP1, and BMSP2               |

### 4.3.2 Configuring Alternate Boot Mode Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options. The 64-bit location is located in user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins are being used. Refer to [Boot Mode Example Use Cases](#) for examples on how to use the BOOTPIN\_CONFIG and BOOTDEF values.

**Table 4-7. BOOTDEF Bit Fields**

| BOOTDEF Name | Byte Position | Name                   | Description                                                                                                                                                                                                                                                                                 |
|--------------|---------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BOOT_DEF0    | 7-0           | BOOT_DEF0 Mode/Options | Set the boot mode and boot mode options. This can include changing the GPIOs for a particular boot peripheral or specifying a different flash entry point. Any unsupported boot mode will cause the device to reset.<br>Refer to <a href="#">GPIO Assignments</a> for valid BOOTDEF values. |
| BOOT_DEF1    | 15-8          | BOOT_DEF1 Mode/Options | Refer to BOOT_DEF0 descriptions                                                                                                                                                                                                                                                             |
| BOOT_DEF2    | 23-16         | BOOT_DEF2 Mode/Options |                                                                                                                                                                                                                                                                                             |
| BOOT_DEF3    | 31-24         | BOOT_DEF3 Mode/Options |                                                                                                                                                                                                                                                                                             |
| BOOT_DEF4    | 39-32         | BOOT_DEF4 Mode/Options |                                                                                                                                                                                                                                                                                             |
| BOOT_DEF5    | 47-40         | BOOT_DEF5 Mode/Options |                                                                                                                                                                                                                                                                                             |
| BOOT_DEF6    | 55-48         | BOOT_DEF6 Mode/Options |                                                                                                                                                                                                                                                                                             |
| BOOT_DEF7    | 63-56         | BOOT_DEF7 Mode/Options |                                                                                                                                                                                                                                                                                             |

### 4.3.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins.

#### 4.3.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to flash.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table.
  - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to flash with a boot mode value of 0
  - Optionally: Set BOOTDEF.BOOT\_DEF0\_ALT\_OPTIONS to a different value to switch to one of the available flash entry point alternatives.

**Table 4-8. Zero Boot Pin Boot Table Result**

| Boot Mode Number | Boot Mode         |
|------------------|-------------------|
| 0                | Flash Boot (0x03) |

Refer to [Entry Points](#) for the available alternative entry point addresses.

#### 4.3.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to flash or using CAN boot.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0

- Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table.
- Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting with a boot mode value of 0
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to flash with a boot mode value of 1
  - Optionally: Set BOOTDEF.BOOT\_DEF1\_ALT\_OPTIONS to a different value to switch to one of the available flash entry point alternatives.

**Table 4-9. One Boot Pin Boot Table Result**

| Boot Mode Number | Boot Mode         |
|------------------|-------------------|
| 0                | CAN Boot (0x02)   |
| 1                | Flash Boot (0x03) |

Refer to [Entry Points](#) for the available alternative entry point addresses.

## 4.4 Device Boot Flow Diagrams

Figure 4-1 shows the device boot flow detailing the actions executed by boot ROM after a reset.

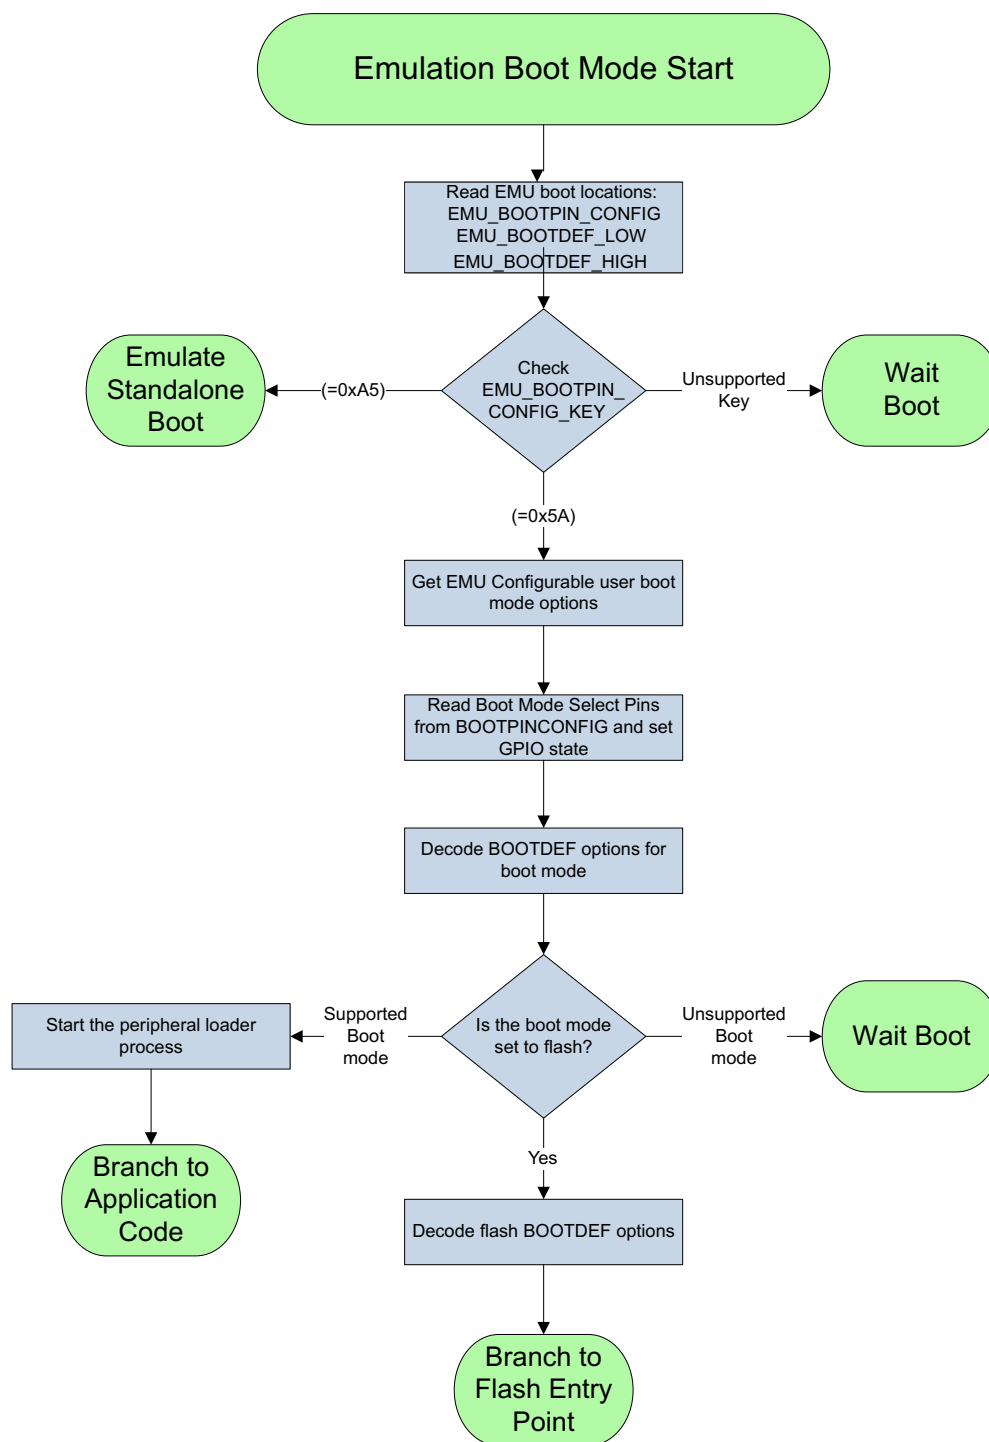

**Figure 4-1. Device Boot Flow**

#### 4.4.1 Emulation Boot Flow Diagram

Figure 4-2 shows the device boot flow when running the device in emulation mode.

Figure 4-2. Emulation Boot Flow

#### 4.4.2 Standalone Boot Flow Diagram

Figure 4-3 shows the device boot flow when running the device in standalone boot mode.

**Figure 4-3. Standalone Boot Flow**

## 4.5 Device Reset and Exception Handling

### 4.5.1 Reset Causes and Handling

This section explains the actions boot ROM performs upon reset after checking the reset cause.

**Table 4-10. Boot ROM Reset Causes and Actions**

| Reset Source   | Boot ROM Actions                                                                                                                                                                       |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POR            | <ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. RAM initialization</li> <li>4. Continue default boot flow</li> </ol> |
| XRS            | <ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>   |
| WDRS           | <ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>   |
| NMIWDRS        | <ol style="list-style-type: none"> <li>1. Adjust clock divider to /1</li> <li>2. Device configuration</li> <li>3. Clear boot stack</li> <li>4. Continue default boot flow</li> </ol>   |
| SCCRESET       | <ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>                                                                           |
| Debugger Reset | <ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>                                                                           |

### 4.5.2 Exceptions and Interrupts Handling

This section explains the actions boot ROM performs if any exceptions that can occur during boot.

**Table 4-11. Boot ROM Exceptions and Actions**

| Exception Event Source        | Boot ROM Action                          | Event Logged |
|-------------------------------|------------------------------------------|--------------|
| Single-bit error in FUSEERR   | Ignore and continue to boot              | No           |
| Multi-bit error in FUSEERR    | Reset the device                         | No           |
| Clock fail condition detected | Clear NMI, log, and continue to boot     | Yes          |
| Double-bit ECC error from RAM | Reset the device                         | Yes          |
| Double-bit error from Flash   | Reset the device                         | Yes          |
| Software NMI error            | Let the device reset                     | Yes          |
| ITRAP Exception               | Give the ROM location where it will loop | Yes          |

**NOTE:** The above NMI errors are logged into a RAM variable for an application to read it when it starts. Refer to [Boot Status Information](#) for more details on the boot status information.

## 4.6 Boot ROM Description

This section explains the details regarding the device boot ROM.

### 4.6.1 Boot ROM Registers

The boot ROM code accesses several memory addresses and registers during execution. There are two sets of addresses, one for emulation and one for standalone boot flow. The emulation locations emulate OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and thus can only be written once. [Table 4-12](#) details these locations.

**Table 4-12. Boot ROM Registers**

| Boot Flow  | DCSM Name   | Boot ROM Name         | Address     |
|------------|-------------|-----------------------|-------------|
| Emulation  | Z1-GPREG1   | EMU-BOOTPIN-CONFIG    | 0x0000 0D00 |
|            | Z1-GPREG3   | EMU-BOOTDEF-LOW       | 0x0000 0D04 |
|            | Z1-BOOTCTRL | EMU-BOOTDEF-HIGH      | 0x0000 0D06 |
| Standalone | Z1-GPREG1   | Z1-OTP-BOOTPIN-CONFIG | 0x0005 F008 |
|            | Z1-GPREG2   | Z1-OTP-BOOT-GPREG2    | 0x0005 F00A |
|            | Z1-GPREG3   | Z1-OTP-BOOTDEF-LOW    | 0x0005 F00C |
|            | Z1-BOOTCTRL | Z1-OTP-BOOTDEF-HIGH   | 0x0005 F004 |

### 4.6.2 Boot ROM User OTP

The boot ROM user configurable DCSM OTP field descriptions and memory addresses are detailed in [Table 4-13](#).

**Table 4-13. User-Configurable DCSM OTP Fields**

| Field name      | Description            | Bank 0           |
|-----------------|------------------------|------------------|
|                 |                        | USER OTP Address |
| GPREG1[0:15]    | BOOTPIN_CONFIG [0:15]  | 0x7800C          |
| GPREG1[16:31]   | BOOTPIN_CONFIG [16:31] | 0x7800D          |
| GPREG2[0:15]    | GPREG2[0:15]           | 0x7800E          |

### 4.6.3 Entry Points

This section gives details about the entry point addresses for various boot modes. These entry points tell the boot ROM where to branch to at the end of booting as per the selected boot mode.

**Table 4-14. Entry Point Addresses**

| Entry Point                     | Address     |
|---------------------------------|-------------|
| RAM                             | 0x0000 0000 |
| Flash (Option 1 – Default)      | 0x0008 0000 |
| Flash (Option 2)                | 0x0008 EFF0 |
| Flash (Option 3) <sup>(1)</sup> | 0x0009 0000 |
| Flash (Option 4) <sup>(1)</sup> | 0x0009 EFF0 |

<sup>(1)</sup> This option is not supported on device part numbers that do not have flash bank 1. Please check the device data sheet for the part numbers.

#### 4.6.4 Wait Points

During boot ROM execution, there are situations where the CPU may enter a wait loop in the code. This state can occur for a variety of reasons. [Table 4-15](#) details the address ranges that the CPU PC register value will fall between if it has entered one of these instances.

**Table 4-15. Wait Point Addresses**

| Address Range           | Description    |
|-------------------------|----------------|
| 0x003FAD74 – 0x003FB0CD | In Wait Boot   |
| 0x000706DC – 0x000706DF | In SCI Boot    |
| 0x003FBCD1 – 0x003FBD67 | In NMI Handler |
| 0x003FBD67 – 0x003FBDD5 | In ITRAP ISR   |

#### 4.6.5 Memory Maps

This section details the ROM memory maps.

##### 4.6.5.1 Boot ROM Memory Map

**Table 4-16. Boot ROM Memory Map (Silicon revision 0,A)**

| Memory                          | Start Address | End Address | Length |
|---------------------------------|---------------|-------------|--------|
| ROM Signature                   | 0x003F 0000   | 0x003F 0001 | 0x0002 |
| TI-RTOS (ROM)                   | 0x003F 7200   | 0x003F 91FF | 0x2000 |
| FPU32 Table                     | 0x003F 9200   | 0x003F A9FF | 0x1800 |
| Boot                            | 0x003F AA00   | 0x003F E9CF | 0x3FD0 |
| Unsecure ROM Checksum           | 0x003F E9D0   | 0x003F EA11 | 0x0042 |
| CPU Spintac Data <sup>(1)</sup> | 0x003F EA12   | 0x003F EA21 | 0x0010 |
| CPU Fast Data <sup>(1)</sup>    | 0x003F EA22   | 0x003F EB21 | 0x1000 |
| PIE Mismatch Handler            | 0x003F FF22   | 0x003F FF71 | 0x0050 |
| CRC Table                       | 0x003F FF72   | 0x003F FF79 | 0x0008 |
| Version                         | 0x003F FF7A   | 0x003F FF7B | 0x0002 |
| Vectors                         | 0x003F FFBE   | 0x003F FFFF | 0x0042 |
| TI-RTOS (Flash)                 | 0x0008 1010   | 0x0008 13EE | 0x3FDF |

<sup>(1)</sup> Check the data manual to determine if these are available for your device part number. If not available, treat these sections as reserved.

**Table 4-17. Boot ROM Memory Map (Silicon revision B)**

| Memory                          | Start Address | End Address | Length |
|---------------------------------|---------------|-------------|--------|
| ROM Signature                   | 0x003F 0000   | 0x003F 0001 | 0x0002 |
| TI-RTOS (ROM)                   | 0x003F 7200   | 0x003F 91FF | 0x2000 |
| FPU32 Tables (1024pt CFFT/RFFT) | 0x003F 9200   | 0x003F 9FF7 | 0x0DF8 |

#### 4.6.5.2 CLA Data ROM Memory Map

**Table 4-18. CLA Data ROM Memory Map**

| Memory            | Start Address | End Address | Length |
|-------------------|---------------|-------------|--------|
| FFT Tables (Load) | 0x0100 1070   | 0x0100 186F | 0x0800 |
| Data (Load)       | 0x0100 1870   | 0x0100 1FF9 | 0x078A |
| Version (Load)    | 0x0100 1FFA   | 0x0100 1FFF | 0x0006 |
| FFT Tables (Run)  | 0x0000 F070   | 0x0000 F86F | 0x0800 |
| Data (Run)        | 0x0000 F870   | 0x0000 FFF9 | 0x078A |
| Version (Run)     | 0x0000 FFFA   | 0x0000 FFFF | 0x0006 |

#### 4.6.5.3 Reserved RAM and Flash Memory Map

This section details memory usage in RAM and Flash that is reserved for boot ROM to use. These memory sections should be reserved in the user application.

**Table 4-19. Reserved RAM and Flash Memory Map (Silicon revision A)**

| Memory | Description               | Start Address | End Address | Length |
|--------|---------------------------|---------------|-------------|--------|
| RAM    | Boot ROM                  | 0x0000 0002   | 0x0000 00F3 | 0x00F1 |
|        | TI-RTOS <sup>(1)</sup>    | 0x0000 0780   | 0x0000 07FF | 0x0080 |
| Flash  | TI-RTOS <sup>(1)(2)</sup> | 0x0008 1010   | 0x0008 13EE | 0x03DF |

<sup>(1)</sup> If the user is not planning on using TI-RTOS in ROM, then these memory locations are free to be used by the application.

<sup>(2)</sup> For using the TI-RTOS in flash sector A, TI recommends that this sector be made unsecure, or at minimum, the sector should be verified that there is no secure zone claiming this sector.

**Table 4-20. Reserved RAM and Flash Memory Map (Silicon revision B)**

| Memory | Description                      | Start Address | End Address | Length |
|--------|----------------------------------|---------------|-------------|--------|
| RAM    | Boot ROM                         | 0x0000 0002   | 0x0000 00F3 | 0x00F1 |
|        | Flash API Library <sup>(1)</sup> | 0x0000 0760   | 0x0000 077F | 0x0020 |
|        | TI-RTOS <sup>(1)</sup>           | 0x0000 0780   | 0x0000 07FF | 0x0080 |
| Flash  | TI-RTOS <sup>(2)</sup>           | 0x0008 1010   | 0x0008 13EE | 0x03DF |

<sup>(1)</sup> If the user is not planning on using Flash API or TI-RTOS in ROM, then these memory locations are free to be used by the application.

<sup>(2)</sup> For using the TI-RTOS in flash sector A, TI recommends that this sector be made unsecure, or at minimum, the sector should be verified that there is no secure zone claiming this sector.

## 4.6.6 ROM Tables

This section details the boot ROM and CLA ROM symbol tables.

### 4.6.6.1 Boot ROM Tables

The boot ROM and flash API symbols and their addresses can be located in the .map file included with the released boot ROM source and header code. Within the .map file, locate the Global Symbols category to get a list of the boot ROM symbols and addresses present.

### 4.6.6.2 CLA ROM Tables

This section has the symbol tables included in ROM for the CLA and their addresses.

**Table 4-21. CLA ROM Tables**

| Table                              | Address     |
|------------------------------------|-------------|
| _cla_twiddleFactors                | 0x0000 f070 |
| _cla_bitReversalTable              | 0x0000 f470 |
| _CLAatan2HalfPITable               | 0x0000 f870 |
| _CLAINV2PI                         | 0x0000 f874 |

## 4.6.7 Boot Modes

The available boot modes supported on this device are detailed in this section. Each boot mode allows for various options, providing configurations with different IOs to be used depending on the application.

### 4.6.7.1 Wait Boot Mode

The wait boot mode puts the CPU in a loop and does not branch to the user application code. The device can enter wait boot mode either manually or because an error occurred during boot up. TI recommends using wait boot when using a debugger to avoid any JTAG complications.

Actions resulting in entering wait boot mode:

- Wait boot is set by the user as the boot mode
- The boot mode is unrecognized and a debugger is connected to the device
- The emulation BOOTPIN\_CONFIG key is not equal to 0xA5 or 0x5A
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode

### 4.6.7.2 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as outlined in [Example 4-1](#).

**Figure 4-4. Overview of SCI Bootloader Operation**

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader will echo back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable auto-baud detection at higher baud rates (typically beyond 100kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host may then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

**Figure 4-5. Overview of SCI Boot Function**

#### 4.6.7.3 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial flash device to be present on the SPI-A pins as indicated in [Figure 4-6](#). The SPI bootloader supports an 8-bit data stream. It does not support a 16-bit data stream.

**Figure 4-6. SPI Loader**

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be setup to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI\_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, you could specify a change in baud rate or low speed peripheral clock.

**Table 4-22. SPI 8-Bit Data Stream**

| Byte | Contents                                                                                                   |
|------|------------------------------------------------------------------------------------------------------------|
| 1    | LSB: AA (KeyValue for memory width = 8-bits)                                                               |
| 2    | MSB: 08h (KeyValue for memory width = 8-bits)                                                              |
| 3    | LSB: LOSPCP                                                                                                |

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

- Step 1. The SPI-A port is initialized
- Step 2. The SPISTE pin is used as a chip-select for the serial SPI EEPROM or flash

- Step 3. The SPI-A outputs a read command for the serial SPI EEPROM or flash
- Step 4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or flash must have the downloadable packet starting at address 0x0000 in the EEPROM or flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
- Step 5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to flash.
- Step 6. The next 2 bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next 7 words are reserved for future enhancements. The SPI bootloader reads these 7 words and discards them.
- Step 7. The next two words makeup the 32-bit entry point address where execution will continue after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
- Step 8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

**Figure 4-7. Data Transfer From EEPROM Flow**

#### 4.6.7.4 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as indicated in [Figure 4-8](#). The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

**Figure 4-8. EEPROM Device at Address 0x50**

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

Figure 4-9. Overview of I2C Boot Function

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100-kHz bit rate (standard I2C mode) when the system clock is 10 MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400-kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that it is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C\_Get Word). If a non acknowledgment is received during the data read messages, the I2C bus will hang. [Table 18-1](#) shows the 8-bit data stream used by the I2C.

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 4-10](#) and [Figure 4-11](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA) from it, is shown in [Figure 4-10](#). All subsequent reads are shown in [Figure 4-11](#) and are read two bytes at a time.

**Figure 4-10. Random Read**

**Figure 4-11. Sequential Read**

#### 4.6.7.5 Parallel Boot Mode

The parallel general purpose I/O (GPIO) boot mode asynchronously transfers code from GPIO0 to GPIO7 internal memory. Each value is 8 bits long and follows the same data flow as outlined in [Figure 4-12](#).

**Figure 4-12. Overview of Parallel GPIO Bootloader Operation**

The control subsystem communicates with the external host device by polling/driving the GPIO16 and GPIO11 lines. The handshake protocol shown in [Figure 4-13](#) must be used to successfully transfer each word via GPIO [0-7]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The most significant byte (MSB) is read first followed by the least significant byte (LSB). In this case, data is read from GPIO[0-7].

The 8-bit data stream is shown in [Table 4-24](#).

**Table 4-24. Parallel GPIO Boot 8-Bit Data Stream**

| n+2 n+3 | 00                          | 00                          | Block size of 0000h - indicates end of the source program                             |

The device first signals the host that it is ready to begin data transfer by pulling the GPIO16 pin low. The host load then initiates the data transfer by pulling the GPIO11 pin low. The complete protocol is shown in Figure 4-13:

**Figure 4-13. Parallel GPIO Bootloader Handshake Protocol**

1. The device indicates it is ready to start receiving data by pulling the GPIO16 pin low.
2. The bootloader waits until the host puts data on GPIO [0-7]. The host signals to the device that data is ready by pulling the GPIO11 pin low.
3. The device reads the data and signals the host that the read is complete by pulling GPIO16 high.
4. The bootloader waits until the host acknowledges the device by pulling GPIO11 high.
5. The device again indicates it is ready for more data by pulling the GPIO16 pin low.

This process is repeated for each data value to be sent.

Figure 4-14 shows an overview of the Parallel GPIO bootloader flow.

**Figure 4-14. Parallel GPIO Mode Overview**

Figure 4-15 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host will wait for the device and the device will in turn wait for the host. In this manner the protocol will work with both a host running faster and a host running slower than the device.

**Figure 4-15. Parallel GPIO Mode - Host Transfer Flow**

Figure 4-16 shows the flow used to read a single word of data from the parallel port.

- **8-bit data stream**

The 8-bit routine, shown in Figure 4-16, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with GPIO7 in bit position 7 and GPIO6 in bit position 6 as the the least significant byte (LSB) of the word to be fetched. The routine will then perform a second read to fetch the most significant byte (MSB). It then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

**Figure 4-16. 8-Bit Parallel GetWord Function**

#### 4.6.7.6 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

**Figure 4-17. Overview of CAN-A Bootloader Operation**

The bit timing registers are programmed in such a way that a 100 kbps bit rate is achieved with a 20 MHz external oscillator, as shown in [Table 4-25](#).

**Table 4-25. Bit-Rate Value for Internal Oscillators**

| OSCCLK | SYSCCLK | Bit Rate |
|--------|---------|----------|
| 20 MHz | 10 MHz  | 100 kbps |

The SYSCCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host should transmit only 2 bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 4-26](#):

**Table 4-26. CAN 8-Bit Data Stream**

| Bytes | Byte 1 of 2 | Byte 2 of 2 | Description                                                       |
|-------|-------------|-------------|-------------------------------------------------------------------|
| 1 2   | AA          | 08          | 0x08AA (KeyValue for memory width = 16 bits)                      |

## 4.6.8 Boot Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on the C2000 devices.

### 4.6.8.1 Bootloader Data Stream Structure

The following two tables and associated examples show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex.

The first 16-bit word in the data stream is known as the key value. The key value is used to tell the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders will accept both 8 and 16-bit streams. Please refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream it is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to it. If a bootloader does not use these values then they are reserved for future use and the bootloader simply reads the value and then discards it. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size would be 0x000A to indicate 10 16-bit words.

The next two words tell the loader the destination address of the block of data. Following the size and address will be the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point the loader will return the entry point address to the calling routine which in turn will cleanup and exit. Execution will then continue at the entry point address as determined by the input data stream contents.

**Table 4-27. LSB/MSB Loading Sequence in 8-Bit Data Stream**

| Byte |     | Contents                                                                                                                                                                                                                                          |                                                        |
|------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
|      |     | LSB (First Byte of 2)                                                                                                                                                                                                                             | MSB (Second Byte of 2)                                 |
| 1    | 2   | LSB: AA (KeyValue for memory width = 8 bits)                                                                                                                                                                                                      | MSB: 08h (KeyValue for memory width = 8 bits)          |
| 3    | 4   | LSB: Register initialization value or reserved                                                                                                                                                                                                    | MSB: Register initialization value or reserved         |
| 5    | 6   | LSB: Register initialization value or reserved                                                                                                                                                                                                    | MSB: Register initialization value or reserved         |
| 7    | 8   | LSB: Register initialization value or reserved                                                                                                                                                                                                    | MSB: Register initialization value or reserved         |
| ...  | ... | ...                                                                                                                                                                                                                                               | ...                                                    |
| ...  | ... | ...                                                                                                                                                                                                                                               | ...                                                    |
| 17   | 18  | LSB: Register initialization value or reserved                                                                                                                                                                                                    | MSB: Register initialization value or reserved         |
| 19   | 20  | LSB: Upper half of Entry point PC[23:16]                                                                                                                                                                                                          | MSB: Upper half of entry point PC[31:24] (Always 0x00) |
| 21   | 22  | LSB: Lower half of Entry point PC[7:0]                                                                                                                                                                                                            | MSB: Lower half of Entry point PC[15:8]                |
| 23   | 24  | LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program. Otherwise another block follows. For example, a block size of 0x000A would indicate 10 words or 20 bytes in the block. | MSB: block size                                        |
| 25   | 26  | LSB: MSW destination address, first block Addr[23:16]                                                                                                                                                                                             | MSB: MSW destination address, first block Addr[31:24]  |

**Example 4-1. Data Stream Structure 8-bit**

```

AA 08          ; 0x08AA 8-bit key value
00 00 00 00    ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80    ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00          ; 0x0005 - First block consists of 5 16-bit words
3F 00 10 90    ; 0x003F9010 - First block will be loaded starting at 0x3F9010
01 00          ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00          ; 0x0002 - 2nd block consists of 2 16-bit words

```

**Example 4-1. Data Stream Structure 8-bit (continued)**

```

3F 00 00 80 ; 0x003F8000 - 2nd block will be loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 - Size of 0 indicates end of data stream

```

After load has completed the following memory values will have been initialized as follows:

| Location | Value  |
|----------|--------|
| 0x3F9010 | 0x0001 |
| 0x3F9011 | 0x0002 |
| 0x3F9012 | 0x0003 |
| 0x3F9013 | 0x0004 |
| 0x3F9014 | 0x0005 |
| 0x3F8000 | 0x7700 |
| 0x3F8001 | 0x7625 |

PC Begins execution at 0x3F8000

### 4.6.9 GPIO Assignments

This section details the GPIOs and boot options used for each boot mode set in BOOT\_DEFx located at Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH. Refer to [Configuring Alternate Boot Mode Pins](#) on how to manipulate BOOT\_DEFx. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

**Table 4-28. SCI Boot Options**

| Option      | BOOTDEFx Value | SCIATX GPIO | SCIARX GPIO |
|-------------|----------------|-------------|-------------|
| 0 (default) | 0x01           | GPIO29      | GPIO28      |
| 1           | 0x21           | GPIO16      | GPIO17      |
| 2           | 0x41           | GPIO8       | GPIO9       |
| 3           | 0x61           | GPIO48      | GPIO49      |
| 4           | 0x81           | GPIO24      | GPIO25      |

**NOTE:** Pull-ups are enabled on the SCIATX and SCIARX pins.

**Table 4-29. CAN Boot Options**

| Option      | BOOTDEFx Value | CANTXA GPIO | CANRXA GPIO |
|-------------|----------------|-------------|-------------|
| 0 (default) | 0x02           | GPIO32      | GPIO33      |
| 1           | 0x22           | GPIO4       | GPIO5       |
| 2           | 0x42           | GPIO31      | GPIO30      |
| 3           | 0x62           | GPIO37      | GPIO35      |

**NOTE:** Pull-ups are enabled on the CANTXA and SCIARX pins.

**Table 4-30. Flash Boot Options**

| Option      | BOOTDEFx Value | Flash Entry Point (Address)              | Flash Bank,Sector |
|-------------|----------------|------------------------------------------|-------------------|
| 0 (default) | 0x03           | Flash – Default Option 1<br>(0x00080000) | Bank 0, Sector 0  |
| 1           | 0x23           | Flash – Option 2<br>(0x0008EFF0)         | Bank 0, Sector 14 |
| 2           | 0x43           | Flash – Option 3<br>(0x00090000)         | Bank 1, Sector 0  |

**Table 4-30. Flash Boot Options (continued)**

| Option | BOOTDEFx Value | Flash Entry Point (Address)      | Flash Bank, Sector |
|--------|----------------|----------------------------------|--------------------|
| 3      | 0x63           | Flash – Option 4<br>(0x0009EFF0) | Bank 1, Sector 14  |

**Table 4-31. Wait Boot Options**

| Option | BOOTDEFx Value | Watchdog Status |
|--------|----------------|-----------------|
| 0      | 0x04           | Enabled         |
| 1      | 0x24           | Disabled        |

**Table 4-32. SPI Boot Options**

| Option | BOOTDEFx Value | SPIA_SIMO | SPIA_SOMI | SPIA_CLK | SPIA_STE |
|--------|----------------|-----------|-----------|----------|----------|
| 1      | 0x26           | GPIO8     | GPIO10    | GPIO9    | GPIO11   |
| 2      | 0x46           | GPIO54    | GPIO55    | GPIO56   | GPIO57   |
| 3      | 0x66           | GPIO16    | GPIO17    | GPIO56   | GPIO57   |
| 4      | 0x86           | GPIO8     | GPIO17    | GPIO9    | GPIO11   |

**NOTE:** Pull-ups are enabled on the SPIA\_SIMO, SPIA\_SOMI, SPIA\_CLK, and SPIA\_STE pins.

**Table 4-33. I2C Boot Options**

| Option | BOOTDEFx Value | SDAA GPIO | SCLA GPIO |
|--------|----------------|-----------|-----------|
| 0      | 0x07           | GPIO32    | GPIO33    |
| 1      | 0x47           | GPIO26    | GPIO27    |
| 2      | 0x67           | GPIO42    | GPIO43    |

**NOTE:** Pull-ups are enabled on the SDAA and SCLA pins.

**Table 4-34. Parallel Boot Options**

| Option      | BOOTDEFx Value | D0-D7 GPIO  | DSP Control GPIO | Host Control GPIO |
|-------------|----------------|-------------|------------------|-------------------|
| 0 (default) | 0x00           | GPIO0-GPIO7 | GPIO16           | GPIO11            |

**NOTE:** Pull-ups are enabled on GPIO0 to GPIO7.

**Table 4-35. RAM Boot Options**

| Option | BOOTDEFx Value | RAM Entry Point (Address) |
|--------|----------------|---------------------------|
| 0      | 0x05           | 0x00000000                |

#### 4.6.10 DCSM Usage

This section explains how the bit field values from the user-configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2, are decoded by the boot ROM after DCSM initialization is complete.

**Table 4-36. DCSM Z1-OTP-BOOT-GPREG2 Bit Fields**

| Bit   | Name             | Description                                                                                                                       | Boot ROM Action                                                                                                                          |
|-------|------------------|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Key              | Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.                                    | If user set to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores the values in this register. |
| 23-8  | Reserved         | Reserved                                                                                                                          | No action                                                                                                                                |
| 7-6   | Reserved         | Reserved                                                                                                                          | No action                                                                                                                                |
| 5-4   | Error Status Pin | Sets the GPIO pin to be used as the ERRORSTS<br>0x0 – GPIO24<br>0x1 – GPIO28<br>0x2 – GPIO29<br>0x3 – ERRORSTS disabled (Default) | Boot ROM configures the appropriate mux for the selected GPIO pin.                                                                       |
| 3-0   | Reserved         |                                                                                                                                   |                                                                                                                                          |

**NOTE:** Users should program user DCSM OTP locations Z1-OTP-BOOT-GPREG2 and Z1-OTP-BOOTPIN-CONFIG at the same time, because they share ECC.

#### 4.6.11 Clock Initialization

During boot up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR or XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

**Table 4-37. Boot Clock Sources**

| Source  | Frequency | Description                                                                              |
|---------|-----------|------------------------------------------------------------------------------------------|
| INTOSC2 | 10 MHz    | Default clock source                                                                     |
| INTOSC1 | 10 MHz    | Set as clock source if missing clock is detected at power up or right after device reset |

**Table 4-38. Clock State after Boot ROM**

| Reset Source     | Clock State                                                                   |
|------------------|-------------------------------------------------------------------------------|
| POR/XRS          | Bypassed PLL.<br>PLL multiplier is set to 0x0.<br>Clock divider is set to /1. |
| All other Resets | Maintain clocks setup before device reset.                                    |

**NOTE:** When the PLL is used by the bootloader, it is bypassed by the boot ROM code before branching to the user application.

#### 4.6.12 Boot Status Information

Boot ROM keeps a record of the different events that can occur during boot ROM execution. This is because NMI and other exceptions are enabled by default in the device, and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can look at this boot status and take the necessary actions per the application's needs to handle these events.

#### 4.6.12.1 Booting Status

This section details the boot status RAM location and its bit field definitions. When the specific bit field is set, the described event or action has occurred.

**Table 4-39. Boot Status Address**

| Description | Address     |
|-------------|-------------|
| BROM_STATUS | 0x0000 0002 |

**Table 4-40. Boot Status Bit Fields**

| Bit | Description                             |
|-----|-----------------------------------------|
| 22  | Boot ROM detected a missing clock NMI   |
| 21  | Boot ROM detected a RAM bit error NMI   |
| 20  | Boot ROM detected a Flash bit error NMI |
| 17  | Boot ROM detected a PIE mismatch        |
| 16  | Boot ROM detected an ITRAP              |
| 15  | Boot ROM has completed running          |
| 13  | Boot ROM handled POR                    |
| 12  | Boot ROM handled XRS                    |
| 11  | Boot ROM handled all the resets         |
| 10  | POR memory test has completed           |
| 9   | DCSM initialization has completed       |
| 7   | CAN boot has started                    |
| 6   | I2C boot has started                    |
| 5   | SPI boot has started                    |
| 4   | SCI boot has started                    |
| 3   | RAM boot has started                    |
| 2   | Parallel boot has started               |
| 1   | Flash boot has started                  |
| 0   | Boot ROM has started running            |

#### 4.6.12.2 Flash Single Bit Error Status

After DCSM is initialized during a reset by the boot ROM, the flash single bit error status is stored at the high and low RAM location detailed in this section. Both the high and low status are 32 bits wide.

**Table 4-41. Flash Single Bit Error Status Addresses**

| Description                   | Address     |
|-------------------------------|-------------|
| Flash Single Bit Error (Low)  | 0x0000 0004 |
| Flash Single Bit Error (High) | 0x0000 0006 |

#### 4.6.12.3 PBIST Status

When PBIST is enabled to run, the status of the test is set within a status variable in boot ROM. This variable is reset on every run of boot ROM. If the user application requires the preservation of this status, the PBIST status must be copied to the application's RAM

#### 4.6.13 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in this section.

**Table 4-42. Boot ROM Version Information**

| Start Address | End Address | Contents        |
|---------------|-------------|-----------------|
| 0x003F FF7A   | 0x003F FF7A | Revision Number |
| 0x003F FF7B   | 0x003F FF7B | Revision Date   |

Interpreting the contents:

- Reading a revision number value of “0x100” represents version “1.0”.
- Reading a revision date value of “0x0715” represents “07/15” or “July 2015”.

## 4.7 Application Notes for Using the Bootloaders

### 4.7.1 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in [Bootloader Data Stream Structure](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 4-2](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, etc.) will differ from one specific application to another and some additional conversion may be required.

To build the boot table, follow these steps:

#### 1. Assemble or compile the code.

This creates the object files that will then be used by the linker to create a single output file.

#### 2. Link the file.

The linker combines all of the object files into a single output file in common object file format (COFF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the COFF file. Uninitialized sections are not converted by the hex conversion utility. The following options may be useful:

The linker -m option can be used to generate a map file. This map file will show all of the sections that were created, their location in memory and their length. It can be useful to check this file to make sure that the initialized sections are where you expect them to be.

The linker -w option configures the linker to show if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called ramfuncs.

#### 3. Run the hex conversion utility.

Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the COFF file produced by the linker to a boot table.

See the *TMS320C28x Assembly Language Tools User's Guide* ([SPRU513](#)) and the *TMS320C28x Optimizing C/C++ Compiler User's Guide* ([SPRU514](#)) for more information on the compiling and linking process.

[Table 4-43](#) summarizes the hex conversion utility options available for the bootloader. See the *TMS320C28x Assembly Language Tools User's Guide* ([SPRU513](#)) for a detailed description of the hex2000 operations used to generate a boot table. Updates will be made to support the I2C boot. See the Codegen release notes for the latest information.

**Table 4-43. Boot Loader Options**

| Option | Description                                                                   |
|--------|-------------------------------------------------------------------------------|
| -boot  | Convert all sections into bootable form (use instead of a SECTIONS directive) |
| -sci8  | Specify the source of the bootloader table as the SCI-A port, 8-bit mode      |

**Table 4-43. Boot Loader Options (continued)**

| Option         | Description                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -spi8          | Specify the source of the bootloader table as the SPI-A port, 8-bit mode                                                                                                                                                                                                                                                                                                       |
| -gpio8         | Specify the source of the bootloader table as the GPIO port, 8-bit mode                                                                                                                                                                                                                                                                                                        |
| -bootorg value | Specify the source address of the bootloader table                                                                                                                                                                                                                                                                                                                             |
| -lospcp value  | Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.                                                                                                                                                                |
| -spibrr value  | Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.                                                                                                                                                                |
| -e value       | Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally _c_int00 unless defined otherwise by the -e linker option. |
| -i2c8          | Specify the source of the bootloader table as the I2C-A port, 8-bit                                                                                                                                                                                                                                                                                                            |
| -i2cpsc value  | Specify the value for the I2CPSC register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM. This value will be truncated to the least significant eight bits and should be set to maintain an I2C module clock of 7-12 MHz.                                                                                  |
| -i2cclkh value | Specify the value for the I2CCLKH register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM.                                                                                                                                                                                                                 |
| -i2cclkl value | Specify the value for the I2CCLKL register. This value will be loaded and take effect after all I2C options are loaded, prior to reading data from the EEPROM.                                                                                                                                                                                                                 |

**Example 4-2. HEX2000.exe Command Syntax**

```
C: HEX2000 GPIO34T0G.OUT -boot -gpio8 -a
```

Where:

- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN uses the same data format as the GPIO in 8-bit mode.
- a Select ASCII-Hex as the output format.

## Control Law Accelerator (CLA)

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows it to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

## 5.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

## 5.2 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines, or 7 tasks and a main background task.
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until its completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.
  - The Type-2 CLA can have a main task that runs continuously in the background, while other high priority events trigger a foreground task.
- Task trigger mechanisms:
  - C28x CPU via the IACK instruction
  - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
  - Task8 can be set to be the background task, while Tasks 1 through 7 take peripheral triggers.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - Two dedicated message RAMs for communication between the CLA and the DMA.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

**Figure 5-1. CLA (Type 2) Block Diagram**

## 5.3 CLA Interface

This chapter describes how the C28x main CPU can interface to the CLA and vice versa.

### 5.3.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in detail below. The CLA RAMs are protected by the DCSM module. Refer to the *DCSM* section of this manual for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by Code Composer Studio™.

Once the memory is initialized with CLA code, the CPU maps it to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in [Section 3.11](#).

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps it to the CLA data space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT<sub>x</sub> registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in [Section 3.11](#).

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM**

The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.

- **CPU to CLA Message RAM**

The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

### 5.3.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA will begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and will be described in the device-specific data manual.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and will automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus will automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

### 5.3.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CPU, CLA, and DMA can share access to some peripherals. There is a 3-way arbitration among the different master's that is described in [Section 5.4](#). Each peripheral has an access control register with two bit fields, CPUAnAC, CLAnAC, and DMAAnAC (n being the instance) that determine what kind of access is given to that particular master.

**Note:** The CLA read access time to the bus is 2-wait states while write access is 0-wait.

Refer to the device data manual for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise the MEDIS CLA instruction will disable write access. This way the CLA can enable/disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, the user may use the intervening cycles, until the completion of the conversion, to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 5.6](#).

### 5.3.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, Task 8, as a background task that, once triggered, runs continuously until the user either terminates it or resets the CLA or the device. The remaining tasks, 1 through 7, maintain their priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives its interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 5-1](#).

**Table 5-1. Configuration Options**

| Select Value (8-bit) | CLA Trigger Source |
|----------------------|--------------------|
| 0                    | Software Trigger   |
| 1                    | ADCA1_INT          |
| 2                    | ADCA2_INT          |
| 3                    | ADCA3_INT          |
| 4                    | ADCA4_INT          |
| 5                    | ADCA_EVT_INT       |
| 6                    | ADCB1_INT          |
| 7                    | ADCB2_INT          |
| 8                    | ADCB3_INT          |
| 9                    | ADCB4_INT          |
| 10                   | ADCB_EVT_INT       |
| 11                   | ADCC1_INT          |
| 12                   | ADCC2_INT          |
| 13                   | ADCC3_INT          |
| 14                   | ADCC4_INT          |
| 15                   | ADCC_EVT_INT       |
| 28:16                | Reserved           |
| 29                   | XINT1              |
| 30                   | XINT2              |
| 31                   | XINT3              |
| 32                   | XINT4              |
| 33                   | XINT5              |
| 35:34                | Reserved           |
| 36                   | EPWM1INT           |
| 37                   | EPWM2INT           |
| 38                   | EPWM3INT           |
| 39                   | EPWM4INT           |
| 40                   | EPWM5INT           |
| 41                   | EPWM6INT           |

**Table 5-1. Configuration Options (continued)**

| Select Value (8-bit) | CLA Trigger Source |
|----------------------|--------------------|
| 42                   | EPWM7INT           |
| 43                   | EPWM8INT           |

| 120:119              | Reserved           |
| 121                  | CLA1PROMCRC        |
| 122                  | Reserved           |
| 123                  | FSITX_INT1         |
| 124                  | FSITX_INT2         |
| 125                  | FSIRX_INT1         |
| 126                  | FSIRX_INT2         |
| 127                  | CLB1INT            |

**Table 5-1. Configuration Options (continued)**

| Select Value (8-bit) | CLA Trigger Source |
|----------------------|--------------------|
| 128                  | CLB2INT            |
| 129                  | CLB3INT            |
| 130                  | CLB4INT            |
| 255:131              | Reserved           |

For example, Task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.bit.TASK1. To disable the triggering of a task by a peripheral, the user must set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. It should be noted that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because it does not require you to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example IACK #0x0001 will set bit 0 in the MIFR register to start task 1. Likewise IACK #0x0003 will set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the user to use Task 8 as a background task that runs continuously until the user disables it or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and its operation controlled by the MCTLBGRND register; it is enabled by setting the BGEN bit to 1. The user can then kick off the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default the background task is interruptible; the highest priority pending task will be executed first. When a task completes, and there aren't any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. The user may choose to make sections of the background task un-interruptible; it is possible to do this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task; if it is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while it has already started the overflow (BGOVF) bit is set.

The CLA has its own fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled, and running, it is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags will remain set until they are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) will start. The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has

completed.

6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

### 5.3.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. Please see [Section 5.8](#) for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt will not be issued to the C28x when that task completes.

## 5.4 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA, DMA, or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure will occur. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

They are covered in detail in the [Section 3.11](#).

### 5.4.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation will not be generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM but the write will be ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories described in the [Section 3.11](#).

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:  
The following accesses are allowed:
  - CPU reads
  - CLA data reads and writes
  - CPU debug reads and writes

The following accesses are ignored:

  - CPU writes
- CPU to CLA Message RAM:  
The following accesses are allowed:
  - CPU reads and writes
  - CLA reads
  - CPU debug reads and writes

The following accesses are ignored:

- CLA writes

## 5.5 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

### 5.5.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 5.7](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in its own assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This would typically be done in C or C++ but can also include C28x assembly code. The main CPU will also copy the CLA code to the program memory and, if needed, initialize the CLA data RAM(s). Once system initialization is complete and the application begins, the CLA will service its interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

The CLA Type 2 requires Codegen VXX.X.X or later with the compiler switch: `--cla_support=cla2`.

### 5.5.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

#### 1. Copy CLA code into the CLA program RAM

The source for the CLA code can initially reside in the flash or a data stream from a communications peripheral or anywhere the main CPU can access it. The debugger can also be used to load code directly to the CLA program RAM during development.

#### 2. Initialize CLA data RAM, if necessary

Populate the CLA data RAM with any required data coefficients or constants.

#### 3. Configure the CLA registers

Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):

- **Enable the CLA peripheral clock using the assigned PCLKCRn register**  
The peripheral clock control (PCLKCRn) registers are defined in the *System Control* chapter.
- **Populate the CLA task interrupt vectors**
  - MVECT1 to MVECT8  
Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.
  - MVECT1 to MVECT7, and MVECTBGRND  
When using the background task, its vector (MVECTBGRND) must be loaded with the start address of the task in lower 64K of memory. Note that Task 8 is ignored when the background task is enabled
- **Select the task interrupt sources**  
For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt. Since the background task takes the place of Task 8, it will use the same peripheral trigger source as task 8.
- **Enable IACK to start a task from software, if desired**  
To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit. If the background task is enabled, the IACK bit for task 8 is ignored; the user must, instead, write to the BGSTART bit of the MCTLBGRND register to start the background task (TRIGEN should be 0 to avoid a peripheral trigger from causing an overflow, for example, MSTSBGRND.BGOVF is set to 1).
- **Map CLA data RAM to CLA space, if necessary**  
Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit, and then specifying

the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_Lx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT<sub>x</sub> registers.

- **Map CLA program RAM to CLA space**

Map the CLA program RAM to CLA space by first assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_Lx] bit, and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_Lx] bit. When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles in which the CLA is not fetching a new instruction.

#### 4. Initialize the PIE vector table and registers

When a CLA task completes, the associated interrupt in the PIE will be flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.

#### 5. Enable CLA tasks/interrupts

Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts.

#### 6. Initialize other peripherals

Initialize any peripherals (such as ePWM, ADC, and others) that will generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

### 5.5.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

#### 5.5.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction will flush all the instructions that have already been fetched; on a single-step or run-free command, the CLA will re-fetch the same instruction which it replaced. [Table 5-2](#) illustrates the pipeline behavior.

**Table 5-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction**

| Cycles | F1          | F2             | D1             | D2             | R1 | R2 | E  | W  | Comments   |
|--------|-------------|----------------|----------------|----------------|----|----|----|----|------------|
| 1      | i1          |                |                |                |    |    |    |    |            |
| 2      | i2          | i1             |                |                |    |    |    |    |            |
| 3      | i3          | i2             | i1             |                |    |    |    |    |            |
| 4      | i4          | i3             | i2             | i1             |    |    |    |    |            |
| 5      | MDEBUGSTOP1 | i4             | i3             | i2             | i1 |    |    |    |            |
| 6      | i6          | MDEBUGSTOP1    | i4             | i3             | i2 | i1 |    |    |            |
| 7      | i7          | i6             | MDEBUGSTOP1    | i4             | i3 | i2 | i1 |    |            |
| 9      | i8          | Flushed (MNOP) | Flushed (MNOP) | Flushed (MNOP) | i4 | i3 | i2 | i1 | CLA halted |

**Table 5-2. Pipeline Behavior of the MDEBUSTOP1 Instruction (continued)**

| Cycles | F1                  | F2                  | D1                  | D2                  | R1                | R2                | E                 | W                 | Comments        |
|--------|---------------------|---------------------|---------------------|---------------------|-------------------|-------------------|-------------------|-------------------|-----------------|
| 10     | i5(MDEBU<br>GSTOP1) | Flushed<br>(MNOP)   | Flushed<br>(MNOP)   | Flushed<br>(MNOP)   | Flushed<br>(MNOP) | i4                | i3                | i2                | CLA<br>step/run |
| 11     | i6                  | i5(MDEBU<br>GSTOP1) | Flushed<br>(MNOP)   | Flushed<br>(MNOP)   | Flushed<br>(MNOP) | Flushed<br>(MNOP) | i4                | i3                | CLA<br>step/run |
| 12     | i7                  | i6                  | i5(MDEBU<br>GSTOP1) | Flushed<br>(MNOP)   | Flushed<br>(MNOP) | Flushed<br>(MNOP) | Flushed<br>(MNOP) | i4                | CLA<br>step/run |
| 13     | i8                  | i7                  | i6                  | i5(MDEBU<br>GSTOP1) | Flushed<br>(MNOP) | Flushed<br>(MNOP) | Flushed<br>(MNOP) | Flushed<br>(MNOP) | CLA<br>step/run |

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUSTOP1. It takes 3 cycles for the MDEBUSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

### 5.5.3.2 Legacy Breakpoint Support (MDEBUSTOP)

#### 1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUSTOP instruction) into the code where you want the CLA to halt, then rebuild and reload the code. Because the CLA does not flush its pipeline when you single-step, the MDEBUSTOP instruction must be inserted as part of the code. The debugger cannot insert it as needed.

If CLA breakpoints are not enabled, then the MDEBUSTOP will be ignored and is treated as a MNOP. The MDEBUSTOP instruction can be placed anywhere in the CLA code as long as it is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler will ensure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

#### 2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In Code Composer Studio, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

#### 3. Start the task

There are three ways to start the task:

1. The peripheral can assert an interrupt,
2. The main CPU can execute an IACK instruction, or
3. The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA will execute instructions until the MDEBUSTOP is in the D2 phase of the pipeline. At this point, the CLA will halt and the pipeline will be frozen. The MPC register will reflect the address of the MDEBUSTOP instruction.

#### 4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the 28x CPU, the pipeline is flushed for each single-step.

You can also run to the next MDEBUSTOP or to the end of the task. If another task is pending, it will automatically start when you run to the end of the task.

**NOTE:** A CLA fetch has higher priority than CPU debug reads. For this reason, it is possible for the CLA to permanently block CPU debug accesses if the CLA is executing in a loop. This might occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory will return all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, you can use a soft or hard reset to exit the condition. A debugger reset will also exit the condition.

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" will start if you continue to step through the MSTOP instruction. Basically if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, it will be flagged in the MIFR register but it may or may not start if you continue to single-step through the MSTOP instruction of "task A."

It depends on exactly when the new task comes in. To reliably start "task B" perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

## 5. Disable CLA breakpoints, if desired

In Code Composer Studio you can disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA will be halted and no other tasks will start.

### 5.5.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, it will behave as follows:

- The CLA will halt with the illegal opcode in the D2 phase of the pipeline as if it were a breakpoint. This will occur whether CLA breakpoints are enabled or not.
- The CLA will issue the task-specific interrupt to the PIE.
- The MIRUN bit for the task will remain set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 5.5.5](#).

### 5.5.5 Resetting the CLA

There may be times when you need to reset the CLA. For example, during code debug the CLA may enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset**

Writing a 1 to the MCTL[HARDRESET] bit will perform a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (via  $\overline{\text{XRS}}$  or the debugger). In this case all CLA configuration and execution registers will be set to their default state and CLA execution will halt.

- **Soft Reset**

Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing it will halt and the associated MIRUN bit will be cleared. All bits within the interrupt enable (MIER) register

will also be cleared so that no new tasks start. In addition, the background task's start bit (MCTLBGRN.BGSTART) and Trigger Enable bit (MCTLBGRND.TRIGEN) are reset. The MVECTBGRNACTIVE is set to the value of MVECTBGRND, and the status register (MSTSBGRND) is also reset.

## 5.6 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

### 5.6.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1)**  
During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2)**  
During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1)**  
During D1 the instruction is decoded.
4. **Decode 2 (D2)**  
Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1)**  
Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage will be stalled.
6. **Read 2 (R2)**  
Read the data value using the CLA data read data bus.
7. **Execute (EXE)**  
Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W)**  
Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage will be stalled.

### 5.6.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

In both the C28x and the CLA pipeline the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read will complete first as shown in [Table 5-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location the code must wait for the write to complete before issuing the read as shown in [Table 5-4](#).

This behavior is different for the 28x CPU. For the 28x CPU any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write will complete before the read. In addition some peripheral frames are protected such that a 28x CPU write to one location within the frame will always complete before a read to the frame. The CLA does not have this protection mechanism. Instead the code must wait to perform the read.

**Table 5-3. Write Followed by Read - Read Occurs First**

| Instruction          | F1 | F2 | D1 | D2 | R1 | R2 | E  | W  |
|----------------------|----|----|----|----|----|----|----|----|
| I1 MMOV16 @Reg1, MR3 | I1 |    |    |    |    |    |    |    |
| I2 MMOV16 MR2, @Reg2 | I2 | I1 |    |    |    |    |    |    |
|                      |    | I2 | I1 |    |    |    |    |    |
|                      |    |    | I2 | I1 |    |    |    |    |
|                      |    |    |    | I2 | I1 |    |    |    |
|                      |    |    |    |    | I2 | I1 |    |    |
|                      |    |    |    |    |    | I2 | I1 |    |
|                      |    |    |    |    |    |    | I2 | I1 |

**Table 5-4. Write Followed by Read - Write Occurs First**

| Instruction          | F1 | F2 | D1 | D2 | R1 | R2 | E  | W  |
|----------------------|----|----|----|----|----|----|----|----|
| I1 MMOV16 @Reg1, MR3 | I1 |    |    |    |    |    |    |    |
| I2                   | I2 | I1 |    |    |    |    |    |    |
| I3                   | I3 | I2 | I1 |    |    |    |    |    |
| I4                   | I4 | I3 | I2 | I1 |    |    |    |    |
| I5 MMOV16 MR2, @Reg2 | I5 | I4 | I3 | I2 | I1 |    |    |    |
|                      |    | I5 | I4 | I3 | I2 | I1 |    |    |
|                      |    |    | I5 | I4 | I3 | I2 | I1 |    |
|                      |    |    |    | I5 | I4 | I3 | I2 | I1 |
|                      |    |    |    |    | I5 | I4 | I3 |    |
|                      |    |    |    |    |    | I5 | I4 |    |
|                      |    |    |    |    |    |    | I5 |    |

- Delayed Conditional instructions: MBCNDD, MCCNDD and MRCNDD**

Referring to [Example 5-1](#), the following applies to delayed conditional instructions:

- I1**

I1 is the last instruction that can effect the CNDF flags for the branch, call or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#) is in the D2 phase.

- I2, I3 and I4**

The three instructions preceding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the branch, call or return instruction. These three instructions must not be a [MSTOP](#), [MDEBUGSTOP](#), [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#).

- I5, I6 and I7**

The three instructions following a branch, call or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

For a more detailed description refer to the functional description for [MBCNDD](#), [MCCNDD](#) and [MRCNDD](#).

**Example 5-1. Code Fragment For MBCNDD, MCCNDD or MRCNDD**

```

<Instruction 1> ; I1 Last instruction that can affect flags for
                ; the branch, call or return operation

<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return

<branch/call/ret> ; MBCNDD, MCCNDD or MRCNDD

                ; I5-I7: Three instructions after are always
                ; executed whether the branch/call or return is
                ; taken or not

<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return

<Instruction 8> ; I8
<Instruction 9> ; I9
....

```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The [MSTOP](#) and [MDEBUGSTOP](#) instructions cannot be placed three instructions before or after a conditional branch, call or return instruction ([MBCNDD](#), [MCCNDD](#) or [MRCNDD](#)). Refer to [Example 5-1](#). To single-step through a branch/call or return, insert the [MDEBUGSTOP](#) at least four instructions back and step from there.

- **Loading MAR0 or MAR1**

A load of auxiliary register MAR0 or MAR1 will occur in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing will occur in the D2 phase of the pipeline. Referring to [Example 5-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following the load instruction will use the value in MAR0 or MAR1 before the update occurs.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there will be a conflict. In the case of a conflict, the update due to address-mode post increment will win and the auxiliary register will not be updated with #\_X.

- **I4**

Starting with the 4th instruction MAR0 or MAR1 will have the new value.

- **Background Task Interrupted Close to a Branch**

When the background task is running, if another task request happens (and MSTSBGRND.BGINTM is not set), then the following sequence of operations happen.

- A check is made to determine if the following instructions are not in the pipeline (D2 – R2).
  - MBCNDD
  - MCCNDD
  - MRCNDD

If any of the above instructions are present in the pipeline, the back ground task continues to execute until such time when the condition is satisfied. Once it is satisfied, the following actions are performed:

- The MPC value of the D1 phase instruction is saved to the MVECTBGRNDACTIVE register.
- The run status bit of the background task (MSTSBGRND.RUNSTS) is cleared.
- An MSTOP instruction is forced into the D2 phase of the pipeline; it will cause the background task

to terminate.

When the background task terminates, the CLA picks the next highest pending task and begins execution. It is important to note that while the background task is pending it has the lowest priority and will, therefore, yield to any other pending task. Once all pending non-background tasks have completed execution the CLA will restore the program counter (MPC), that is, load the address from the MVECTBGRNDACTIVE register to the MPC, set the background status to RUN (MSTSBGRND.RUN = 1), and continue execution from that point.

- **MSTOP in the Background Task**

If an MSTOP instruction occurs in the D1 phase while the background task is running, the following sequence of operations happens:

- The RUN bit (MSTSBGRND.RUN) is cleared.
- The address stored in MVECTBGRND is copied over to MVECTBGRNDACTIVE.
- An interrupt, signaling the background task has completed execution, is generated. This interrupt signal is ANDed with the interrupt from Task 8 and fed to the PIE. It should be noted that if an illegal instruction occurs inside the background task, the interrupt for task 8 is fired.
- When the background task terminates, the CLA resumes arbitration among the pending tasks.

### Example 5-2. Code Fragment for Loading MAR0 or MAR1

```
; Assume MAR0 is 50 and #_X is 20

MMOV16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1> ; I1 Will use the old value of MAR0 (50)
<Instruction 2> ; I2 Will use the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Will use the new value of MAR0 (20)
<Instruction 5> ; I5 Will use the new value of MAR0 (20)
....
```

#### 5.6.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA will be able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user will have to account for the conversion time in SYSCLK cycles.

For example, if using the 12-bit ADC with ADCCLK at SYSCLK / 4, it would take  $10.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 42 \text{ SYSCLK}$  cycles to complete a conversion.

From a CLA perspective, the pipeline activity is shown in [Table 5-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction will arrive in the R2 phase just in time to read the result register. While the prior instructions will enter the R2 phase of the pipeline too soon to read the conversion, they can be efficiently used for pre-processing calculations needed by the task.

**Table 5-5. ADC to CLA Early Interrupt Response**

| ADC Activity                    | CLA Activity       | F1 | F2 | D1 | D2 | R1 | R2 | E | W |
|---------------------------------|--------------------|----|----|----|----|----|----|---|---|
| Sample                          |                    |    |    |    |    |    |    |   |   |
| Sample                          |                    |    |    |    |    |    |    |   |   |
| ...                             |                    |    |    |    |    |    |    |   |   |
| Sample                          |                    |    |    |    |    |    |    |   |   |
| Conversion <sub>(Cycle 1)</sub> | Interrupt Received |    |    |    |    |    |    |   |   |
| Conversion <sub>(Cycle 2)</sub> | Task Startup       |    |    |    |    |    |    |   |   |
| Conversion <sub>(Cycle 3)</sub> | Task Startup       |    |    |    |    |    |    |   |   |

**Table 5-5. ADC to CLA Early Interrupt Response (continued)**

| ADC Activity                      | CLA Activity             | F1                       | F2                       | D1                       | D2                       | R1                        | R2                        | E | W |

### 5.6.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

#### Example 5-3. Math Operation with Parallel Load

```
; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
    MADDF32    MR0, MR1, #2      ; MR0 = MR1 + 2,
    || MMOV32  MR1, @Val         ; MR1 gets the contents of Val
                                ; <-- MMOV32 completes here (MR1 is valid)
                                ; <-- DDF32 completes here (MR0 is valid)
    MMPYF32 MR0, MR0, MR1        ; Any instruction, can use MR1 and/or MR0
```

#### Example 5-4. Multiply with Parallel Add

```
; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
    MMPYF32 MR0, MR1, MR3        ; MR0 = MR1 * MR3
    || MADDF32 MR1, MR2, MR0     ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
                                ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
    MMPYF32 MR1, MR1, MR0        ; Any instruction, can use MR1 and/or MR0
```

## 5.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

### 5.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction may present the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you will find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x; the source operand(s) are always on the right and the destination operand(s) are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the C28x CLA are given in [Table 5-6](#).

**Table 5-6. Operand Nomenclature**

| Symbol    | Description                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| #16FHi    | 16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero. |
| #16FHiHex | 16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.            |
| #16FLoHex | A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value                                                                 |
| #32Fhex   | 32-bit immediate value that represents an IEEE 32-bit floating-point value                                                                                            |
| #32F      | Immediate float value represented in floating-point representation                                                                                                    |
| #0.0      | Immediate zero                                                                                                                                                        |
| #SHIFT    | Immediate value of 1 to 32 used for arithmetic and logical shifts.                                                                                                    |
| addr      | Opcode field indicating the addressing mode                                                                                                                           |
| CNDF      | Condition to test the flags in the MSTF register                                                                                                                      |
| FLAG      | Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change                                                              |
| MAR0      | auxiliary register 0                                                                                                                                                  |
| MAR1      | auxiliary register 1                                                                                                                                                  |
| MARx      | Either MAR0 or MAR1                                                                                                                                                   |
| mem16     | 16-bit memory location accessed using direct, indirect, or offset addressing modes                                                                                    |
| mem32     | 32-bit memory location accessed using direct, indirect, or offset addressing modes                                                                                    |
| MRa       | MR0 to MR3 registers                                                                                                                                                  |
| MRb       | MR0 to MR3 registers                                                                                                                                                  |
| MRc       | MR0 to MR3 registers                                                                                                                                                  |
| MRd       | MR0 to MR3 registers                                                                                                                                                  |
| MRe       | MR0 to MR3 registers                                                                                                                                                  |
| MRf       | MR0 to MR3 registers                                                                                                                                                  |
| MSTF      | CLA Floating-point Status Register                                                                                                                                    |
| shift     | Opcode field indicating the number of bits to shift.                                                                                                                  |
| VALUE     | Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1                                                                              |

Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

**Table 5-7. INSTRUCTION dest, source1, source2 Short Description**

|              | Description                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dest1        | Description for the 1st operand for the instruction                                                                                                                                                                                                                                  |
| source1      | Description for the 2nd operand for the instruction                                                                                                                                                                                                                                  |
| source2      | Description for the 3rd operand for the instruction                                                                                                                                                                                                                                  |
| Opcode       | This section shows the opcode for the instruction                                                                                                                                                                                                                                    |
| Description  | Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.                                                                                                                             |
| Restrictions | Any constraints on the operands or use of the instruction imposed by the processor are discussed.                                                                                                                                                                                    |
| Pipeline     | This section describes the instruction in terms of pipeline cycles as described in <a href="#">Section 5.6</a>                                                                                                                                                                       |
| Example      | Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed it data. |
| Operands     | Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).                                                                                               |

## 5.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA will access it using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 5-8](#).

**Table 5-8. Addressing Modes**

| Addressing Mode | 'addr' Opcode Field Encode <sup>(1)</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| @dir            | 0000                                      | <b>Direct Addressing Mode</b><br>Example 1: MMOV32 MR1, @_VarA<br>Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all<br>In this case the 'mmmm mmmm mmmm mmmm' opcode field will be populated with the 16-bit address of the variable. This is the low 16-bits of the address that you would use to access the variable using the main CPU.<br>For example @_VarA will populate the address of the variable VarA. and @_EPwm1Regs.CMPA.all will populate the address of the CMPA register.                                                                                                                                                     |

Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.                                                                                                                   |
| *MAR1+[#imm16]  | 0110                                      | <b>MAR1 Offset Addressing with 16-bit Immediate Offset</b><br>addr = MAR0 Add the offset #imm16<br>(or MAR1) + #imm16to address stored in MAR0(MAR1) to access the desired memory<br>the base location<br>Example 1: MMOV32 MR0, *MAR0+[2]<br>Example 1: MMOV32 MR1, *MAR1+[-2]<br>The 'mmmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.                                                                                                                   |

<sup>(1)</sup> Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in [Table 5-9](#).

**Table 5-9. Shift Field Encoding**

| Shift Value | 'shift' Opcode Field Encode |
|-------------|-----------------------------|
| 1           | 0000                        |
| 2           | 0001                        |
| 3           | 0010                        |
| ....        | ....                        |
| 32          | 1111                        |

Table 5-11 shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

For instructions that use MR<sub>x</sub> (where x could be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example,

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to Table 5-10.

**Table 5-10. Operand Encoding**

| Two-Bit Field | Working Register |
|---------------|------------------|
| b'00          | MR0              |
| b'01          | MR1              |
| b'10          | MR2              |
| b'11          | MR3              |

**Table 5-11. Condition Field Encoding**

| Encode <sup>(1)</sup> | CNDF                | Description                          | MSTF Flags Tested   |
|-----------------------|---------------------|--------------------------------------|---------------------|
| 0000                  | NEQ                 | Not equal to zero                    | ZF == 0             |
| 0001                  | EQ                  | Equal to zero                        | ZF == 1             |
| 0010                  | GT                  | Greater than zero                    | ZF == 0 AND NF == 0 |
| 0011                  | GEQ                 | Greater than or equal to zero        | NF == 0             |
| 0100                  | LT                  | Less than zero                       | NF == 1             |
| 0101                  | LEQ                 | Less than or equal to zero           | ZF == 1 OR NF == 1  |
| 1010                  | TF                  | Test flag set                        | TF == 1             |
| 1011                  | NTF                 | Test flag not set                    | TF == 0             |
| 1100                  | LU                  | Latched underflow                    | LUF == 1            |
| 1101                  | LV                  | Latched overflow                     | LVF == 1            |
| 1110                  | UNC                 | Unconditional                        | None                |
| 1111                  | UNCF <sup>(2)</sup> | Unconditional with flag modification | None                |

<sup>(1)</sup> Values not shown are reserved.

<sup>(2)</sup> This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

### 5.7.3 Instructions

The instructions are listed alphabetically, preceded by a summary.

**Table 5-12. General Instructions**

| Title                                                                                                                               | Page |
|-------------------------------------------------------------------------------------------------------------------------------------|------|
| <b>MMABSF32 MRa, MRb</b> — 32-Bit Floating-Point Absolute Value .....                                                               | 669  |
| <b>MADD32 MRa, MRb, MRc</b> — 32-Bit Integer Add .....                                                                              | 670  |
| <b>MADDF32 MRa, #16FHi, MRb</b> — 32-Bit Floating-Point Addition .....                                                              | 671  |
| <b>MADDF32 MRa, MRb, #16FHi</b> — 32-Bit Floating-Point Addition .....                                                              | 672  |
| <b>MADDF32 MRa, MRb, MRc</b> — 32-Bit Floating-Point Addition .....                                                                 | 674  |
| <b>MADDF32 MRd, MRe, MRf   MMOV32 mem32, MRa</b> — 32-Bit Floating-Point Addition with Parallel Move .....                          | 675  |
| <b>MADDF32 MRd, MRe, MRf   MMOV32 MRa, mem32</b> — 32-Bit Floating-Point Addition with Parallel Move .....                          | 676  |
| <b>MAND32 MRa, MRb, MRc</b> — Bitwise AND .....                                                                                     | 678  |
| <b>MASR32 MRa, #SHIFT</b> — Arithmetic Shift Right .....                                                                            | 679  |
| <b>MBCNDD 16BitDest {, CNDF}</b> — Branch Conditional Delayed .....                                                                 | 680  |
| <b>MCCNDD 16BitDest {, CNDF}</b> — Call Conditional Delayed .....                                                                   | 685  |
| <b>MCLRC BGINTM</b> — Clear Background Task Interrupt Mask .....                                                                    | 689  |
| <b>MCMP32 MRa, MRb</b> — 32-Bit Integer Compare for Equal, Less Than or Greater Than .....                                          | 690  |
| <b>MCMPF32 MRa, MRb</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than .....                                  | 691  |
| <b>MCMPF32 MRa, #16FHi</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than .....                               | 692  |
| <b>MDEBUGSTOP</b> — Debug Stop Task .....                                                                                           | 694  |
| <b>MDEBUGSTOP1</b> — Software Breakpoint .....                                                                                      | 695  |
| <b>MEALLOW</b> — Enable CLA Write Access to EALLOW Protected Registers .....                                                        | 696  |
| <b>MEDIS</b> — Disable CLA Write Access to EALLOW Protected Registers .....                                                         | 697  |
| <b>MEINVF32 MRa, MRb</b> — 32-Bit Floating-Point Reciprocal Approximation .....                                                     | 698  |
| <b>MEISQRTF32 MRa, MRb</b> — 32-Bit Floating-Point Square-Root Reciprocal Approximation .....                                       | 699  |
| <b>MF32TOI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer .....                                             | 700  |
| <b>MF32TOI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round .....                                  | 701  |
| <b>MF32TOI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Integer .....                                             | 702  |
| <b>MF32TOUI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer .....                                   | 703  |
| <b>MF32TOUI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round .....                        | 704  |
| <b>MF32TOUI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer .....                                   | 705  |
| <b>MFRACF32 MRa, MRb</b> — Fractional Portion of a 32-Bit Floating-Point Value .....                                                | 706  |
| <b>MI16TOF32 MRa, MRb</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....                                             | 707  |
| <b>MI16TOF32 MRa, mem16</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....                                           | 708  |

## MMABSF32 MRa, MRb 32-Bit Floating-Point Absolute Value

### Operands

|     |                                                      |
|-----|------------------------------------------------------|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3)      |

### Opcode

LSW: 0000 0000 0000 bbaa  
MSW: 0111 1110 0010 0000

### Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MMABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

### Pipeline

This is a single-cycle instruction.

### Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MMABSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
```

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMABSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
```

```
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MMABSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

## MADD32 MRa, MRb, MRc 32-Bit Integer Add

### Operands

|     |                                                      |
|-----|------------------------------------------------------|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point destination register (MR0 to MR3) |
| MRC | CLA floating-point destination register (MR0 to MR3) |

### Opcode

LSW: 0000 0000 000cc bbaa  
MSW: 0111 1110 1100 0000

### Description

32-bit integer addition of MRb and MRc.

$MRa(31:0) = MRb(31:0) + MRc(31:0);$

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

### Pipeline

This is a single-cycle instruction.

### Example

```
; Given A = (int32)1
;      B = (int32)2
;      C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFF9FC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

## MADDF32 MRa, #16FHi, MRb 32-Bit Floating-Point Addition

### Operands

|        |                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MRa    | CLA floating-point destination register (MR0 to MR3)                                                                                                        |
| #16FHi | A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. |
| MRb    | CLA floating-point source register (MR0 to MR3)                                                                                                             |

### Opcode

LSW: I I I I I I I I I I I I I I I I  
MSW: 0111 0111 1100 bbaa

### Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb + #16FHi:0;

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

### Pipeline

This is a single-cycle instruction.

### Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1    ; MR0 = 2.0 + MR1

; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3   ; MR2 = -2.5 + MR3

; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

## MADDF32 MRa, MRb, #16FHi 32-Bit Floating-Point Addition

### Operands

|        |                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MRa    | CLA floating-point destination register (MR0 to MR3)                                                                                                        |
| MRb    | CLA floating-point source register (MR0 to MR3)                                                                                                             |
| #16FHi | A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. |

### Opcode

LSW: I I I I I I I I I I I I I I I I  
MSW: 0111 0111 1100 bbaa

### Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb + #16FHi:0;

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

### Pipeline

This is a single-cycle instruction.

### Example 1

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store it in Result
;
_Cla1Task1:
    MMOV16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len       ; Length of the array
    MNOP
    MNOP      ; delay for MAR1 load
    MNOP      ; delay for MAR1 load
    MMOV32    MR1, *MAR1[2]++    ; MR1 = X0
LOOP
    MMOV32    MR2, *MAR1[2]++    ; MR2 = next element
    MMAXF32   MR1, MR2           ; MR1 = MAX(MR1, MR2)
    MADDF32   MR0, MR0, #-1.0    ; Decrement the counter
    MCMPF32   MR0 #0.0           ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD    LOOP, NEQ          ; Branch if not equal to zero
    MMOV32    @_Result, MR1      ; Always executed
    MNOP      ; Always executed
    MNOP      ; Always executed
    MSTOP
```

**Example 2**

```
; Show the basic operation of MADDF32
;
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
    MADDF32 MR0, MR1, #2.0    ; MR0 = MR1 + 2.0

; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
    MADDF32 MR2, MR3, #-2.5   ; MR2 = MR3 + (-2.5)

; Add to MR0 the value 0x3FC00000 (1.5)
; Store the result in MR0
    MADDF32 MR0, MR0, #0x3FC0 ; MR0 = MR0 + 1.5
```

## MADDF32 MRa, MRb, MRc 32-Bit Floating-Point Addition

### Operands

|     |                                                      |
|-----|------------------------------------------------------|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3)      |
| MRc | CLA floating-point source register (MR0 to MR3)      |

### Opcode

LSW: 000 0000 00cc bbaa  
MSW: 0111 1100 0010 0000

### Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

MRa = MRb + MRc;

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

### Pipeline

This is a single-cycle instruction.

### Example

```
; Given M1, X1 and B1 are 32-bit floating point numbers
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
    MOV32 MR0,@M1      ; Load MR0 with M1
    MOV32 MR1,@X1      ; Load MR1 with X1
    MPYF32 MR1,MR1,MR0 ; Multiply M1*X1
|| MOV32 MR0,@B1      ; and in parallel load MR0 with B1
    MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
    MOV32 @Y1,MR1      ; Store the result
    MSTOP              ; end of task
```

## MADDF32 MRd, MRe, MRf||MMOV32 mem32, MRa 32-Bit Floating-Point Addition with Parallel Move

### Operands

|       |                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------|
| MRd   | CLA floating-point destination register for the MADDF32 (MR0 to MR3)                                                     |
| MRe   | CLA floating-point source register for the MADDF32 (MR0 to MR3)                                                          |
| MRf   | CLA floating-point source register for the MADDF32 (MR0 to MR3)                                                          |
| mem32 | 32-bit memory location accessed using one of the available addressing modes. This will be the destination of the MMOV32. |
| MRa   | CLA floating-point source register for the MMOV32 (MR0 to MR3)                                                           |

### Opcode

LSW: mmmm mmmm mmmm mmmm  
MSW: 0101 ffee ddaa addr

### Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

MRd = MRe + MRf;  
[mem32] = MRa;

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

### Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

### Example

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_Cla1Task2:
    MMOV32  MR0, @_A      ; Load MR0 with A
    MMOV32  MR1, @_B      ; Load MR1 with B
    MPMYF32 MR1, MR1, MR0 ; Multiply A*B
|| MMOV32   MR0, @_C      ; and in parallel load MR0 with C
    MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
|| MMOV32   @_Y2, MR1     ; and in parallel store A*B
    MMOV32  @_Y3, MR1     ; Store the A*B + C
    MSTOP
```

## MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 32-Bit Floating-Point Addition with Parallel Move

### Operands

|       |                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------|
| MRd   | CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.   |
| MRe   | CLA floating-point source register for the MADDF32 (MR0 to MR3)                                                 |
| MRf   | CLA floating-point source register for the MADDF32 (MR0 to MR3)                                                 |
| MRa   | CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.    |
| mem32 | 32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32. |

### Opcode

LSW: mmmm mmmm mmmm mmmm  
MSW: 0001 ffee ddaa addr

### Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

MRd = MRe + MRf;  
MRa = [mem32];

### Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | Yes | Yes |

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction will set the NF and ZF flags as follows:

NF = MRa(31);  
ZF = 0;  
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };

### Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

### Example 1

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y1 = A + 4B
;           Y2 = A + C
;
;_Cla1Task1:
;  MMOV32 MR0, @A           ; Load MR0 with A
;  MMOV32 MR1, @B           ; Load MR1 with B
;  MMPYF32 MR1, MR1, #4.0   ; Multiply 4 * B
||  MMOV32 MR2, @C           ; and in parallel load C
;  MADDF32 MR3, MR0, MR1    ; Add A + 4B
;  MADDF32 MR3, MR0, MR2    ; Add A + C
||  MMOV32 @Y1, MR3          ; and in parallel store A+4B
;  MMOV32 @Y2, MR3          ; store A + C MSTOP
;                             ; end of task
```

**Example 2**

```

; Given A, B and C are 32-bit floating-point numbers
; Calculate Y3 = (A + B)
;           Y4 = (A + B) * C
;
_Cla1Task2:
    MMOV32 MR0, @A      ; Load MR0 with A
    MMOV32 MR1, @B      ; Load MR1 with B
    MADDF32 MR1, MR1, MR0 ; Add A+B
||  MMOV32 MR0, @C      ; and in parallel load MR0 with C
    MMPYF32 MR1, MR1, MR0 ; Multiply (A+B) by C
||  MMOV32 @Y3, MR1      ; and in parallel store A+B
    MMOV32 @Y4, MR1      ; Store the (A+B) * C
    MSTOP                ; end of task

```

## MAND32 MRa, MRb, MRc Bitwise AND

### Operands

|     |                                                      |
|-----|------------------------------------------------------|
| MRa | CLA floating-point destination register (MR0 to MR3) |
| MRb | CLA floating-point source register (MR0 to MR3)      |
| MRC | CLA floating-point source register (MR0 to MR3)      |

### Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

### Description

Bitwise AND of MRb with MRc.

$MRa(31:0) = MRb(31:0) \text{ AND } MRc(31:0);$

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified based on the integer results of the operation.

$NF = MRa(31);$

$ZF = 0;$

$\text{if}(MRa(31:0) == 0) \{ ZF = 1; \}$

### Pipeline

This is a single-cycle instruction.

### Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
```

```
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
```

```
; 0101 AND 0101 = 0101 (5)
; 0101 AND 0100 = 0100 (4)
; 0101 AND 0011 = 0001 (1)
; 0101 AND 0010 = 0000 (0)
; 1010 AND 1111 = 1010 (A)
; 1010 AND 1110 = 1010 (A)
; 1010 AND 1101 = 1000 (8)
; 1010 AND 1100 = 1000 (8)
```

```
MAND32 MR2, MR1, MR0 ; MR3 = 0x5410AA88
```

## MASR32 MRa, #SHIFT *Arithmetic Shift Right*

### Operands

|        |                                                             |
|--------|-------------------------------------------------------------|
| MRa    | CLA floating-point source/destination register (MR0 to MR3) |
| #SHIFT | Number of bits to shift (1 to 32)                           |

### Opcode

LSW: 0000 0000 0shi ftaa  
MSW: 0111 1011 0100 0000

### Description

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);

### Flags

This instruction modifies the following flags in the MSTF register:

| Flag     | TF | ZF  | NF  | LUF | LVF |
|----------|----|-----|-----|-----|-----|
| Modified | No | Yes | Yes | No  | No  |

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

### Pipeline

This is a single-cycle instruction.

### Example

```
; Given m2 = (int32)32
;          x2 = (int32)64
;          b2 = (int32)-128
;
; Calculate
;          m2 = m2/2
;          x2 = x2/4
;          b2 = b2/8
;
_Cla1Task2:
    MOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
    MOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
    MOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
    MASR32 MR0, #1 ; MR0 = 16 (0x00000010)
    MASR32 MR1, #2 ; MR1 = 16 (0x00000010)
    MASR32 MR2, #3 ; MR2 = -16 (0xFFFFF0)
    MOV32 @_m2, MR0 ; store results
    MOV32 @_x2, MR1
    MOV32 @_b2, MR2
    MSTOP ; end of task
```

## MBCNDD 16BitDest {, CNDF} *Branch Conditional Delayed*

### Operands

|           |                                         |
|-----------|-----------------------------------------|
| 16BitDest | 16-bit destination if condition is true |
| CNDF      | Optional condition tested               |

### Opcode

LSW: dest dest dest dest  
MSW: 0111 1001 1000 cndf

### Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, it wraps around. Therefore a value of "0xFFFF" will put the MPC back to the MBCNDD instruction.

Please refer to the pipeline section for important information regarding this instruction.

if (CNDF == TRUE) MPC += 16BitDest;

CNDF is one of the following conditions:

| Encode <sup>(1)</sup> | CNDF                | Description                          | MSTF Flags Tested   |
|-----------------------|---------------------|--------------------------------------|---------------------|
| 0000                  | NEQ                 | Not equal to zero                    | ZF == 0             |
| 0001                  | EQ                  | Equal to zero                        | ZF == 1             |
| 0010                  | GT                  | Greater than zero                    | ZF == 0 AND NF == 0 |
| 0011                  | GEQ                 | Greater than or equal to zero        | NF == 0             |
| 0100                  | LT                  | Less than zero                       | NF == 1             |
| 0101                  | LEQ                 | Less than or equal to zero           | ZF == 1 OR NF == 1  |
| 1010                  | TF                  | Test flag set                        | TF == 1             |
| 1011                  | NTF                 | Test flag not set                    | TF == 0             |
| 1100                  | LU                  | Latched underflow                    | LUF == 1            |
| 1101                  | LV                  | Latched overflow                     | LVF == 1            |
| 1110                  | UNC                 | Unconditional                        | None                |
| 1111                  | UNCF <sup>(2)</sup> | Unconditional with flag modification | None                |

<sup>(1)</sup> Values not shown are reserved.

<sup>(2)</sup> This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

### Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD or MRCNDD instruction. Refer to the pipeline section for more information.

### Flags

This instruction does not modify flags in the MSTF register.

| Flag     | TF | ZF | NF | LUF | LVF |
|----------|----|----|----|-----|-----|
| Modified | No | No | No | No  | No  |

### Pipeline

The MBCNDD instruction by itself is a single-cycle instruction. As shown in [Table 5-13](#) for each branch 6 instruction slots are executed; three before the branch instruction (I2-I4) and three after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken may not be the same as for a branch not taken.

Referring to [Table 5-13](#) and [Table 5-14](#), the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3 and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **I5, I6 and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

```

<Instruction 1> ; I1 Last instruction that can affect flags for
                ; the MBCNDD operation
