

TPS25924x 12-V eFuse with Over Voltage Protection and Blocking FET Control

1 Features

- $V_{\text{OPERATING}} = 4.5 \text{ V to } 13.8 \text{ V}$, $V_{\text{ABSMAX}} = 20 \text{ V}$
- Integrated 28-m Ω Pass MOSFET
- Fixed 15-V Over Voltage Clamp
- 1-A to 5-A Adjustable I_{LIMIT}
- $\pm 8\%$ I_{LIMIT} Accuracy at 3.7 A
- Reverse Current Blocking Support
- Programmable OUT Slew Rate, UVLO
- Built-in Thermal Shutdown
- UL 2367 Recognized – File No. E339631*
 - *RILIM $\leq 130 \text{ k}\Omega$ (5 A maximum)
- Safe During Single Point Failure Test (UL60950)
- Small Foot Print – 10L (3 mm x 3 mm) VSON

2 Applications

- Adapter Powered Devices
- HDD and SSD Drives
- Set Top Boxes
- Servers / AUX Supplies
- Fan Control
- PCI/PCIe Cards

3 Description

The TPS25924x family of eFuses is a highly integrated circuit protection and power management solution in a tiny package. The devices use few external components and provide multiple protection modes. They are a robust defense against overloads, shorts circuits, voltage surges, excessive inrush current, and reverse current.

Current limit level can be set with a single external resistor. Over voltage events are limited by internal clamping circuits to a safe fixed maximum, with no external components required.

Applications with particular voltage ramp requirements can set dV/dT with a single capacitor to ensure proper output ramp rates. Many systems, such as SSDs, must not allow holdup capacitance energy to dump back through the FET body diode onto a drooping or shorted input bus. The BFET pin is for such systems. An external NFET can be connected “Back to Back (B2B)” with the TPS25924x output and the gate driven by BFET to prevent current flow from load to source (see [Figure 43](#)).

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TPS259241	VSON (10)	3.00 mm x 3.00 mm
TPS259240		

(1) For all available packages, see the orderable addendum at the end of the data sheet.

6 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
BFET	9	O	Connect this pin to the gate of a blocking NFET. See the Feature Description section. This pin can be left floating if it is not used
dV/dT	1	O	Tie a capacitor from this pin to GND to control the ramp rate of OUT at device turnon
EN/UVLO	2	I	This is a dual function control pin. When used as an ENABLE pin and pulled down, it shuts off the internal pass MOSFET and pulls BFET to GND. When pulled high, it enables the device and BFET. As an UVLO pin, it can be used to program different UVLO trip point via external resistor divider
GND	Thermal Pad	—	GND
ILIM	10	O	A resistor from this pin to GND sets the overload and short circuit limit
OUT	6-8	O	Output of the device
VIN	3-5	I	Input supply voltage

7 Specifications

7.1 Absolute Maximum Ratings

over operating temperature range (unless otherwise noted) ⁽¹⁾ ⁽²⁾

		MIN	MAX	UNIT
VIN	Supply voltage ⁽¹⁾	−0.3	20	V
VIN (10-ms transient)			22	
OUT	Output voltage	−0.3	VIN + 0.3	V
OUT (transient < 1 μs)			−1.2	V
ILIM	Voltage	−0.3	7	V
EN/UVLO		−0.3	7	
dV/dT		−0.3	7	
BFET		−0.3	30	
T _{stg}	Storage temperature	−65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values, except differential voltages, are with respect to network ground terminal.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	TYP	MAX	UNIT
VIN	Input voltage	4.5	12	13.8	V
BFET		0		VIN+6	
dV/dT, EN/UVLO		0		6	
ILIM		0		3	
I _{OUT}	Continuous output current	0		5	A
ILIM	Resistance	10	100	162	kΩ
OUT	External capacitance	0.1	1	1000	μF
dV/dT			1	1000	nF
T _J	Operating junction temperature	−40	25	125	°C
T _A	Operating Ambient temperature	−40	25	85	°C

7.4 Thermal Information

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

THERMAL METRIC		TPS25924x	UNIT

8 Detailed Description

8.1 Overview

The TPS25924x is an e-fuse with integrated power switch that is used to manage current, voltage and start-up voltage ramp to a connected load. The device starts its operation by monitoring the VIN bus. When VIN exceeds the undervoltage-lockout threshold (V_{UVLO}), the device samples the EN/UVLO pin. A high level on this pin enables the internal MOSFET. As VIN rises, the internal MOSFET of the device starts conducting and allow current to flow from VIN to OUT. When EN/UVLO is held low (below V_{ENF}), internal MOSFET is turned off. User also has the ability to modify the output voltage ramp time by connecting a capacitor between dV/dT pin and GND.

After a successful start-up sequence, the device now actively monitors its load current and input voltage, ensuring that the adjustable overload current limit I_{OL} is not exceeded and input voltage spikes are safely clamped to V_{OVC} level at the output. This keeps the output device safe from harmful voltage and current transients. The device also has built-in thermal sensor. In the event device temperature (T_J) exceeds T_{SHDN} , typically 150°C , the thermal shutdown circuitry shuts down the internal MOSFET thereby disconnecting the load from the supply. In TPS259240, the output remains disconnected (MOSFET open) until power to device is recycled or EN/UVLO is toggled (pulled low and then high). The TPS259241 device remains off during a cooling period until device temperature falls below $T_{SHDN} - 10^{\circ}\text{C}$, after which it attempts to restart. This ON and OFF cycle continues until fault is cleared.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 GND

This is the most negative voltage in the circuit and is used as a reference for all voltage measurements unless otherwise specified.

Feature Description (continued)

8.3.2 VIN

Input voltage to the TPS25924x. A ceramic bypass capacitor close to the device from VIN to GND is recommended to alleviate bus transients. The recommended operating voltage range is 4.5 V to 13.8 V for TPS25924x. The device can continuously sustain a voltage of 20 V on VIN pin. However, above the recommended maximum bus voltage, the device will be in over-voltage protection (OVP) mode, limiting the output voltage to V_{OVC} . The power dissipation in OVP mode is $P_{D_OVP} = (V_{VIN} - V_{OVC}) \times I_{OUT}$, which can potentially heat up the device and cause thermal shutdown.

8.3.3 dV/dT

Connect a capacitor from this pin to GND to control the slew rate of the output voltage at power-on. This pin can be left floating to obtain a predetermined slew rate (minimum T_{dVdT}) on the output. Equation governing slew rate at start-up is shown in [Equation 1](#):

$$\frac{dV_{OUT}}{dt} = \frac{I_{dVdT} \times GAIN_{dVdT}}{C_{dVdT} + C_{INT}}$$

where

- $I_{dVdT} = 220 \text{ nA}$ (Typical)
- $C_{INT} = 70 \text{ pF}$ (Typical)
- $GAIN_{dVdT} = 4.85$

$$\frac{dV_{OUT}}{dT} = \text{Desired output slew rate} \tag{1}$$

The total ramp time (T_{dVdT}) for 0 to VIN can be calculated using [Equation 2](#):

$$T_{dVdT} = 10^6 \times V_{IN} \times (C_{dVdT} + 70 \text{ pF}) \tag{2}$$

For details on how to select an appropriate charging time/rate, refer to the applications section [Setting Output Voltage Ramp Time \(\$T_{dVdT}\$ \)](#).

8.3.4 BFET

Connect this pin to an external NFET that can be used to disconnect input supply from rest of the system in the event of power failure at VIN. The BFET pin is controlled by either input UVLO (V_{UVR}) event or EN/UVLO (see [Table 1](#)). BFET can source charging current of 2 μA (TYP) and sink (discharge) current from the gate of the external FET via a 26- Ω internal discharge resistor to initiate fast turnoff, typically <1 μs . Due to 2 μA charging current, it is recommended to use >10 M Ω impedance when probing the BFET node.

Table 1. BFET

EN/UVLO > V_{ENR}	VIN > V_{UVR}	BFET MODE
H	H	Charge
X	L	Discharge
L	X	Discharge

8.3.5 EN/UVLO

As an input pin, it controls both the ON and OFF state of the internal MOSFET and that of the external blocking FET. In its high state, the internal MOSFET is enabled and charging begins for the gate of external FET. A low on this pin turns off the internal MOSFET and pull the gate of the external FET to GND via the built-in discharge resistor. High and Low levels are specified in the parametric table of the datasheet. The EN/UVLO pin is also used to clear a thermal shutdown latch in the TPS259240 by toggling this pin (H→L).

The internal de-glitch delay on EN/UVLO falling edge is intentionally kept low (1 μs typical) for quick detection of power failure. When used with a resistor divider from supply to EN/UVLO to GND, power-fail detection on EN/UVLO helps in quick turnoff of the BFET driver, thereby stopping the flow of reverse current (see typical application diagram, [Figure 43](#)). For applications where a higher de-glitch delay on EN/UVLO is desired, or when the supply is particularly noisy, it is recommended to use an external bypass capacitor from EN/UVLO to GND.

8.3.6 ILIM

The device continuously monitors the load current and keeps it limited to the value programmed by R_{ILIM} . After start-up event and during normal operation, current limit is set to I_{OL} (over-load current limit) as shown in Equation 3.

$$I_{OL} = (0.7 + 3 \times 10^{-5} \times R_{ILIM}) \quad (3)$$

When power dissipation in the internal MOSFET [$P_D = (V_{VIN} - V_{OUT}) \times I_{OUT}$] exceeds 10 W, there is a 2% – 12% thermal foldback in the current limit value so that I_{OL} drops to I_{SC} . In each of the two modes, MOSFET gate voltage is regulated to throttle short-circuit and overload current flowing to the load. Eventually, the device shuts down due to over temperature. See Figure 36.

Figure 36. Thermal Foldback in Current Limit

During a transient short circuit event, the current through the device increases very rapidly. The current-limit amplifier cannot respond very quickly to this event due to its limited bandwidth. Therefore, the TPS25924x incorporates a fast-trip comparator, which shuts down the pass device very quickly when $I_{OUT} > I_{FASTTRIP}$, and terminates the rapid short-circuit peak current. The trip threshold is set to 60% higher than the programmed over-load current limit ($I_{FASTTRIP} = 1.6 \times I_{OL}$). After the transient short-circuit peak current has been terminated by the fast-trip comparator, the current limit amplifier smoothly regulates the output current to I_{OL} (see Figure 37 and Figure 38).

8.4 Device Functional Modes

The TPS25924x is a hot-swap controller with integrated power switch that is used to manage current/voltage/start-up voltage ramp to a connected load. The device starts its operation by monitoring the VIN bus. When V_{VIN} exceeds the undervoltage-lockout threshold (V_{UVLO}), the device samples the EN/UVLO pin. A high level on this pin enables the internal MOSFET and also start charging the gate of external blocking FET (if connected) via the BFET pin. As VIN rises, the internal MOSFET of the device and external FET (if connected) starts conducting and allow current to flow from VIN to OUT. When EN/UVLO is held low (that is, below V_{ENF}), the internal MOSFET is turned off and BFET pin is discharged, thereby, blocking the flow of current from VIN to OUT. User also has the ability to modify the output voltage ramp time by connecting a capacitor between dV/dT pin and GND.

Having successfully completed its start-up sequence, the device now actively monitors its load current and input voltage, ensuring that the adjustable overload current limit I_{OL} is not exceeded and input voltage spikes are safely clamped to V_{OVC} level at the output. This keeps the output device safe from harmful voltage and current transients. The device also has built-in thermal sensor. In the event device temperature (T_J) exceeds T_{SHDN} , typically 150°C , the thermal shutdown circuitry shuts down the internal MOSFET thereby disconnecting the load from the supply. In the TPS259240, the output remains disconnected (MOSFET open) until power to device is recycled or EN/UVLO is toggled (pulled low and then high). The TPS259241 device remains off during a cooling period until device temperature falls below $T_{SHDN} - 10^{\circ}\text{C}$, after which it attempts to restart. This ON and OFF cycle continues until fault is cleared.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The TPS25924x is a smart eFuse. It is typically used for Hot-Swap and Power rail protection applications. It operates from 4.5 V to 18 V with programmable current limit and undervoltage protection. The device aids in controlling the in-rush current and provides precise current limiting during overload conditions for systems such as Set-Top-Box, DTVs, Gaming Consoles, SSDs/HDDs and Smart Meters. The device also provides robust protection for multiple faults on the sub-system rail.

The following design procedure can be used to select component values for the device. Alternatively, the WEBENCH® software may be used to generate a complete design. The WEBENCH® software uses an iterative design procedure and accesses a comprehensive database of components when generating a design. Additionally, a spreadsheet design tool *TPS2592xx Design Calculator* (SLUC570) is available on web folder. This section presents a simplified discussion of the design process.

9.2 Typical Applications

9.2.1 Simple 3.7-A eFuse Protection for Set Top Boxes

Figure 39. Typical Application Schematic: Simple 3.7-A e-Fuse for STBs

9.2.1.1 Design Requirements

Table 2 shows the design parameters for this application.

Table 2. Design Parameters

DESIGN PARAMETER		EXAMPLE VALUE
V _{IN}	Input voltage	12 V
V _(UV)	Undervoltage lockout set point	Default: V _{UVR} = 4.3 V
V _(OV)	Overvoltage protection set point	Default: V _{OVC} = 15 V
R _{L(SU)}	Load at start-up	4 Ω
I _{OL} = I _{ILIM}	Current limit	3.7 A
C _{OUT}	Load capacitance	1 μF
T _A	Maximum ambient temperature	85°C

9.2.1.2 Detailed Design Procedure

The following design procedure can be used to select component values for the TPS25924x.

9.2.1.2.1 Step by Step Design Procedure

This design procedure below seeks to control the junction temperature of device under both static and transient conditions by proper selection of output ramp-up time and associated support components. The designer can adjust this procedure to fit the application and design criteria.

9.2.1.2.2 Programming the Current-Limit Threshold: R_{ILIM} Selection

The R_{ILIM} resistor at the ILIM pin sets the over load current limit, this can be set using [Equation 4](#).

$$R_{ILIM} = \frac{I_{ILIM} - 0.7}{3 \times 10^{-5}} \quad (4)$$

For $I_{OL} = I_{ILIM} = 3.7$ A, from [Equation 4](#), $R_{ILIM} = 100$ k Ω , choose closest standard value resistor with 1% tolerance.

9.2.1.2.3 Undervoltage Lockout Set Point

The undervoltage lockout (UVLO) trip point is adjusted using the external voltage divider network of R_1 and R_2 as connected between IN, EN/UVLO and GND pins of the device. The values required for setting the undervoltage are calculated solving [Equation 5](#).

$$V_{(UV)} = \frac{R_1 + R_2}{R_2} \times V_{ENR} \quad (5)$$

Where $V_{ENR} = 1.4$ V is enable voltage rising threshold.

Since R_1 and R_2 leak the current from input supply (V_{IN}), these resistors must be selected based on the acceptable leakage current from input power supply (V_{IN}). The current drawn by R_1 and R_2 from the power supply $\{I_{R12} = V_{IN}/(R_1 + R_2)\}$.

However, leakage currents due to external active components connected to the resistor string can add error to these calculations. So, the resistor string current, I_{R12} must be chosen to be 20x greater than the leakage current expected.

For default UVLO of $V_{UVR} = 4.3$ V, select $R_2 = \text{OPEN}$, and $R_1 = 1$ M Ω . Since EN/UVLO pin is rated only to 7 V, it cannot be connected directly to $V_{IN} = 12$ V. It has to be connected through $R_1 = 1$ M Ω only, so that the pull-up current for EN/UVLO pin is limited to < 20 μ A.

The power failure threshold is detected on the falling edge of supply. This threshold voltage is 4% lower than the rising threshold, V_{UVR} . This is calculated using [Equation 6](#).

$$V_{(PFAIL)} = 0.96 \times V_{UVR} \quad (6)$$

Where V_{UVR} is 4.3 V, Power fail threshold set is 4.1 V.

9.2.1.2.4 Setting Output Voltage Ramp Time (T_{dVdT})

For a successful design, the junction temperature of device must be kept below the absolute-maximum rating during both dynamic (start-up) and steady state conditions. Dynamic power stresses often are an order of magnitude greater than the static stresses, so it is important to determine the right start-up time and in-rush current limit required with system capacitance to avoid thermal shutdown during start-up with and without load.

The ramp-up capacitor C_{dVdT} needed is calculated considering the two possible cases:

9.2.1.2.4.1 Case 1: Start-Up without Load: Only Output Capacitance C_{OUT} Draws Current During Start-Up

During start-up, as the output capacitor charges, the voltage difference as well as the power dissipated across the internal FET decreases. The average power dissipated in the device during start-up is calculated using [Equation 8](#).

For TPS25924x, the inrush current is determined as shown in [Equation 7](#):

$$I_{(INRUSH)} = C_{(OUT)} \times \frac{V_{(IN)}}{T_{dVdT}} \quad (7)$$

Power dissipation during start-up is given by [Equation 8](#):

$$P_{D(INRUSH)} = 0.5 \times V_{(IN)} \times I_{(INRUSH)} \quad (8)$$

[Equation 8](#) assumes that load does not draw any current until the output voltage has reached its final value.

9.2.1.2.4.2 Case 2: Start-Up with Load: Output Capacitance C_{OUT} and Load Draws Current During Start-Up

When load draws current during the turnon sequence, there is additional power dissipated. Considering a resistive load during start-up ($R_{L(SU)}$), load current ramps up proportionally with increase in output voltage during T_{dVdT} time. The average power dissipation in the internal FET during charging time due to resistive load is given by [Equation 9](#):

$$P_{D(LOAD)} = \left(\frac{1}{6} \right) \times \frac{V_{(IN)}^2}{R_{L(SU)}} \quad (9)$$

Total power dissipated in the device during startup is given by [Equation 10](#):

$$P_{D(STARTUP)} = P_{D(INRUSH)} + P_{D(LOAD)} \quad (10)$$

Total current during startup is given by [Equation 11](#):

$$I_{(STARTUP)} = I_{(INRUSH)} + I_L(t) \quad (11)$$

If $I_{(STARTUP)} > I_{OL}$, the device limits the current to I_{OL} and the current limited charging time is determined by [Equation 12](#):

$$T_{dVdT(Current-Limited)} = C_{OUT} \times R_{L(SU)} \times \left[\frac{I_{OL}}{I_{(INRUSH)}} - 1 + \ln \left(\frac{I_{(INRUSH)}}{I_{OL} - \frac{V_{(IN)}}{R_{L(SU)}}} \right) \right] \quad (12)$$

The power dissipation, with and without load, for selected start-up time must not exceed the shutdown limits as shown in [Figure 40](#):

Figure 40. Thermal Shutdown Limit Plot

For the design example under discussion, select ramp-up capacitor $C_{dVdT} = \text{OPEN}$. Then, using [Equation 2](#), we get [Equation 13](#):

$$T_{dVdT} = 10^6 \times 12 \times (0 + 70 \text{ pF}) = 840 \text{ } \mu\text{s} \quad (13)$$

The inrush current drawn by the load capacitance (C_{OUT}) during ramp-up using [Equation 7](#) is given by [Equation 14](#):

$$I_{(INRUSH)} = 1 \text{ } \mu\text{F} \times \frac{12}{840 \text{ } \mu\text{s}} = 15 \text{ mA} \quad (14)$$

The inrush Power dissipation is calculated, using [Equation 8](#) as shown in [Equation 15](#):

TPS259240, TPS259241

SLVSCU9B –AUGUST 2015–REVISED SEPTEMBER 2016

www.ti.com

$$P_{D(INRUSH)} = 0.5 \times 12 \times 15 \text{ m} = 90 \text{ mW} \quad (15)$$

For 90 mW of power loss, the thermal shut down time of the device must not be less than the ramp-up time T_{dVdT} to avoid the false trip at maximum operating temperature. From thermal shutdown limit graph [Figure 40](#) at $T_A = 85^\circ\text{C}$, for 90 mW of power, the shutdown time is infinite. So it is safe to use 0.79 ms as start-up time without any load on output.

Considering the start-up with load 4Ω , the additional power dissipation, when load is present during start up is calculated by [Equation 16](#), using [Equation 9](#):

$$P_{D(LOAD)} = \frac{12 \times 12}{6 \times 4} = 6 \text{ W} \quad (16)$$

The total device power dissipation during start up, using [Equation 10](#) is given by [Equation 17](#):

$$P_{D(STARTUP)} = 6 + 90 \text{ m} = 6.09 \text{ W} \quad (17)$$

From thermal shutdown limit graph at $T_A = 85^\circ\text{C}$, the thermal shutdown time for 6.09 W is more than 10 ms. So it is well within acceptable limits to not use an external capacitor (C_{dVdT}) with start-up load of 4Ω .

If, due to large C_{OUT} , there is a need to decrease the power loss during start-up, it can be done with increase of C_{dVdT} capacitor.

9.2.1.2.5 Support Component Selection— C_{VIN}

C_{VIN} is a bypass capacitor to help control transient voltages, unit emissions, and local supply noise. Where acceptable, a value in the range of $0.001 \mu\text{F}$ to $0.1 \mu\text{F}$ is recommended for C_{VIN} .

9.2.1.3 Application Curves

Figure 41. Output Ramp without Load on Output

Figure 42. Output Ramp with 4-Ω Load at Start Up

9.2.2 Inrush and Reverse Current Protection for Hold-Up Capacitor Application (for example, SSD)

Figure 43. Inrush and Reverse Current Protection for Hold-Up Capacitor Application (for example, SSD) (TPS25924x UVLO is used as power fail comparator)

9.2.2.1 Design Requirements

The design parameters for this design example are shown in [Table 3](#).

Table 3. Design Parameters

DESIGN PARAMETER		EXAMPLE VALUE
V _{IN}	Input voltage	12 V
V _(UV)	Undervoltage lockout set point	10.8 V
V _(OV)	Overvoltage protection set point	Default: V _{OV} = 15 V
R _{L(SU)}	Load at start-up	1000 Ω
I _{OL} = I _{ILIM}	Current limit	3 A
C _{OUT}	Load capacitance	4700 μF
T _A	Maximum ambient temperature	85°C

9.2.2.2 Detailed Design Procedure

9.2.2.2.1 Programming the Current-Limit Threshold: R_{ILIM} Selection

The R_{ILIM} resistor at the ILIM pin sets the over load current limit, this can be set using [Equation 4](#).

For I_{OL} = I_{ILIM} = 3 A, from [Equation 4](#), R_{ILIM} = 76.8 kΩ. Choose closest standard value resistor with 1% tolerance.

9.2.2.2.2 Undervoltage Lockout Set Point

The undervoltage lockout (UVLO) trip point is adjusted using the external voltage divider network of R₁ and R₂ as connected between IN, EN/UVLO and GND pins of the device. The values required for setting the undervoltage are calculated solving [Equation 5](#).

For UVLO of V_(UV) = 10.8 V, select R₂ = 150 kΩ, and R₁ = 1 MΩ.

The power failure threshold is detected on the falling edge of supply. This threshold voltage is 4% lower than the rising threshold, V_(UV). This is calculated using [Equation 6](#).

Where V_(UV) = 10.73 V, Power fail threshold set is V_(PFAIL) = 10.35 V.

9.2.2.2.3 Setting Output Voltage Ramp Time (T_{dVdT})

For a successful design, the junction temperature of device must be kept below the absolute-maximum rating during both dynamic (start-up) and steady state conditions. Dynamic power stresses often are an order of magnitude greater than the static stresses, so it is important to determine the right start-up time and in-rush current limit required with system capacitance to avoid thermal shutdown during start-up with and without load.

For the design example under discussion, select ramp-up capacitor C_{dVdT} = 22 nF. Then, using [Equation 2](#) we get [Equation 18](#):

$$T_{dVdT} = 10^6 \times 12 \times (22 \text{ nF} + 70 \text{ pF}) = 265 \text{ ms} \quad (18)$$

The inrush current drawn by the load capacitance (C_{OUT}) during ramp-up using [Equation 7](#) is given by [Equation 19](#):

$$I_{(INRUSH)} = 4700 \text{ μF} \times \frac{12}{265 \text{ ms}} = 213 \text{ mA} \quad (19)$$

The inrush Power dissipation is calculated, using [Equation 8](#) is given by [Equation 20](#):

$$P_{D(INRUSH)} = 0.5 \times 12 \times 213 \text{ m} = 1278 \text{ mW} \quad (20)$$

Considering the start-up with load 1000 Ω, the additional power dissipation, when load is present during start up is calculated, using [Equation 9](#) is given by [Equation 21](#):

$$P_{D(LOAD)} = \frac{12 \times 12}{6 \times 1000} = 24 \text{ mW} \quad (21)$$

The total device power dissipation during start up is given by [Equation 22](#):

$$P_{D(STARTUP)} = 1278 + 24 = 1302 \text{ mW} \quad (22)$$

From thermal shutdown limit graph at $T_A = 85^{\circ}\text{C}$, the thermal shutdown time for 1.3 W is more than 300 ms. So the device starts safely.

If $C_{dVdT} = 4.7 \text{ nF}$ was used, the device must have tried to charge the $4700\text{-}\mu\text{F}$ output cap with inrush current of 986 mA in 57.24 ms , dissipating power of 5.94 W . This is outside the safe starting condition of the device, and must have led the device to enter thermal shutdown during start-up.

9.2.2.3 Application Curves

Figure 44. Output Ramp Up

Figure 45. Hold-up Power When VIN Fails

9.2.3 Controlled Power Down using TPS25924x

When the device is disabled, the output voltage is left floating and power down profile is entirely dictated by the load. In some applications, this can lead to undesired activity as the load is not powered down to a defined state. Controlled output discharge can ensure the load is turned off completely and not in an undefined operational state. The BFET pin in TPS25924x family of eFuses facilitates Quick Output Discharge (QOD) function as illustrated in [Figure 46](#). When the device is/get disabled, the BFET pin pulls low which enables the external P-MOSFET Q1 for discharge feature to function. The output voltage discharge rate is dictated by the output capacitor C_{OUT} , the discharge resistance R_{DCHG} and the load.

Figure 46. Circuit Implementation with Quick Output Discharge Function

10 Power Supply Recommendations

The device is designed for supply voltage range of $4.5\text{ V} \leq V_{\text{IN}} \leq 18\text{ V}$. If the input supply is located more than a few inches from the device an input ceramic bypass capacitor higher than $0.1\text{ }\mu\text{F}$ is recommended. Power supply must be rated higher than the current limit set to avoid voltage droops during over current and short-circuit conditions.

10.1 Transient Protection

In case of short circuit and over load current limit, when the device interrupts current flow, input inductance generates a positive voltage spike on the input and output inductance generates a negative voltage spike on the output. The peak amplitude of voltage spikes (transients) is dependent on value of inductance in series to the input or output of the device. Such transients can exceed the [Absolute Maximum Ratings](#) of the device if steps are not taken to address the issue.

Typical methods for addressing transients include:

- Minimizing lead length and inductance into and out of the device
- Using large PCB GND plane
- Schottky diode across the output to absorb negative spikes
- A low value ceramic capacitor ($C_{\text{IN}} = 0.001\text{ }\mu\text{F}$ to $0.1\text{ }\mu\text{F}$) to absorb the energy and dampen the transients. The approximate value of input capacitance can be estimated with [Equation 23](#):

$$V_{\text{SPIKE(Absolute)}} = V_{\text{(IN)}} + I_{\text{(LOAD)}} \times \sqrt{\frac{L_{\text{(IN)}}}{C_{\text{(IN)}}}}$$

where

- $V_{\text{(IN)}}$ is the nominal supply voltage
- $I_{\text{(LOAD)}}$ is the load current
- $L_{\text{(IN)}}$ equals the effective inductance seen looking into the source
- $C_{\text{(IN)}}$ is the capacitance present at the input

(23)

Some applications may require the addition of a Transient Voltage Suppressor (TVS) to prevent transients from exceeding the [Absolute Maximum Ratings](#) of the device.

The circuit implementation with optional protection components (a ceramic capacitor, TVS and schottky diode) is shown in [Figure 47](#).

Figure 47. Circuit Implementation with Optional Protection Components

10.2 Output Short-Circuit Measurements

It is difficult to obtain repeatable and similar short-circuit testing results. Source bypassing, input leads, circuit layout and component selection, output shorting method, relative location of the short, and instrumentation all contribute to variation in results. The actual short itself exhibits a certain degree of randomness as it microscopically bounces and arcs. Care in configuration and methods must be used to obtain realistic results. Do not expect to see waveforms exactly like those in the data sheet; every setup differs.

11 Layout

11.1 Layout Guidelines

- For all applications, a 0.01- μ F or greater ceramic decoupling capacitor is recommended between IN terminal and GND. For hot-plug applications, where input power path inductance is negligible, this capacitor can be eliminated/minimized.
- The optimum placement of decoupling capacitor is closest to the IN and GND terminals of the device. Care must be taken to minimize the loop area formed by the bypass-capacitor connection, the IN terminal, and the GND terminal of the IC. See Figure 48 for a PCB layout example.
- High current carrying power path connections must be as short as possible and must be sized to carry at least twice the full-load current.
- The GND terminal must be tied to the PCB ground plane at the terminal of the IC. The PCB ground must be a copper plane or island on the board.
- Locate all support components: R_{ILIM} , C_{dVdT} and resistors for EN/UVLO, close to their connection pin. Connect the other end of the component to the GND pin of the device with shortest trace length. The trace routing for the R_{ILIM} and C_{dVdT} components to the device must be as short as possible to reduce parasitic effects on the current limit and soft start timing. These traces must not have any coupling to switching signals on the board.
- Protection devices such as TVS, snubbers, capacitors, or diodes must be placed physically close to the device they are intended to protect, and routed with short traces to reduce inductance. For example, a protection Schottky diode is recommended to address negative transients due to switching of inductive loads, and it must be physically close to the OUT pins.
- Obtaining acceptable performance with alternate layout schemes is possible; however this layout has been shown to produce good results and is intended as a guideline.

11.2 Layout Example

12.7 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

LAND PATTERN EXAMPLE
EXPOSED METAL SHOWN
SCALE:20X

SOLDER MASK DETAILS

4218878/B 07/2018

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/sluea271).
5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

DRC0010J

VSON - 1 mm max height

PLASTIC SMALL OUTLINE - NO LEAD

SOLDER PASTE EXAMPLE BASED ON 0.125 mm THICK STENCIL

EXPOSED PAD 11:
80% PRINTED SOLDER COVERAGE BY AREA
SCALE:25X

4218878/B 07/2018

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, or other requirements. These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.
