LM34922

TEXAS INSTRUMENTS

28V, 2A Constant On-Time Switching Regulator with Adjustable Current Limit

General Description

The LM34922 Constant On-time Step-Down Switching Regulator features all the functions needed to implement a low cost, efficient, buck bias regulator capable of supplying up to 2A of load current. This voltage regulator contains an N-Channel Buck switch, a startup regulator, current limit detection, and internal ripple control. The constant on-time regulation principle requires no loop compensation, results in fast load transient response, and simplifies circuit implementation. The operating frequency remains constant with line and load. The adjustable valley current limit detection results in a smooth transition from constant voltage to constant current mode when current limit is reached, without the use of current limit foldback. The PGD output indicates the output voltage has increased to within 5% of the expected regulation value. Additional features include: Low output ripple, VIN under-voltage lock-out, adjustable soft-start timing, thermal shutdown, gate drive pre-charge, gate drive under-voltage lock-out, and maximum duty cycle limit.
Features

- Input operating voltage range: 6V to 28V
- Absolute maximum input rating: 30V
- Integrated 2A N-Channel Buck Switch
- Adjustable current limit allows for smaller inductor
- Adjustable output voltage from 2.51V
- Minimum ripple voltage at V_{OUT}
- Power Good output
- Switching frequency adjustable to 1MHz
- COT topology features:
  -Switching frequency remains nearly constant with load current and input voltage variations
  -Ultra-fast transient response
  -No loop compensation required
  -Stable operation with ceramic output capacitors
  -Allows for smaller output capacitor and current sense resistor
- Adjustable Soft-Start timing
- Thermal shutdown
- Precision 2% feedback reference

Package

Ordering Information

Order Number	Package Type	NSC Package Drawing	Supplied As
LM34922MY	MSOP-10EP	MUC10A	1000 Units on Tape and Reel
LM34922MYX	MSOP-10EP	MUC10A	3500 Units on Tape and Reel

Pin Descriptions

Pin No.	Name	Description	Application Information
1	VIN	Input supply voltage	Operating input range is 6V to 28V. Transient capability is 30V. A low ESR capacitor must be placed as close as possible to the VIN and SGND pins.
2	RT	On-time Control	An external resistor from VIN to this pin sets the buck switch on-time, and the switching frequency.
3	PGD	Power Good	Logic output indicates when the voltage at the FB pin has increased to above 95% of the internal reference voltage. Hysteresis is provided. An external pull-up resistor to a voltage less than 7V is required.
4	SS	Soft-Start	An internal current source charges an external capacitor to provide the soft-start function.
5	SGND	Signal Ground	Ground for all internal circuitry other than the current limit sense circuit.
6	FB	Feedback	Internally connected to the regulation comparator. The regulation level is 2.51V.
7	CSG	Current Sense Ground	Ground connection for the current limit sensing circuit. Connect to ground and to the current sense resistor.
8	CS	Current sense	Connect to the current sense resistor and the anode of the free-wheeling diode.
9	SW	Switching Node	Internally connected to the buck switch source. Connect to the external inductor, cathode of the free-wheeling diode, and bootstrap capacitor.
10	BST	Bootstrap capacitor connection of the buck switch gate driver.	Connect a 0.1μF capacitor from SW to this pin. The capacitor is charged during the buck switch off-time via an internal diode.

Absolute Maximum Ratings (*Note 1*)

If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/ Distributors for availability and specifications.

VIN to SGND (T_J = 25°C)	30V
BST to SGND	37V
SW to SGND (Steady State)	-1.5V to 30V
BST to SW	-0.3V to 7V
CS to CSG	-0.3V to 0.3V
CSG to SGND	-0.3V to 0.3V
PGD to SGND	-0.3V to 7V
SS to SGND	-0.3V to 3V
RT to SGND	-0.3V to 1V
FB to SGND	-0.3V to 7V
ESD Rating (*Note 2*)	
Human Body Model	2kV
Storage Temperature Range	-65°C to +150°C

Junction Temperature	150°C

Operating Ratings (*Note 1*)

VIN Voltage	6.0V to 28V
Junction Temperature	−40°C to +125°C

Electrical Charateristics

Specifications with standard type are for T_J = 25°C only; limits in **boldface type** apply over the full Operating Junction Temperature (T_J) range. Minimum and Maximum limits are guaranteed through test, design, or statistical correlation. Typical values represent the most likely parametric norm at T_J = 25°C, and are provided for reference purposes only. Unless otherwise stated the following conditions apply: V_{IN} = 12V, R_T = 50kΩ.

FIGURE 1. Startup Sequence

Functional Description

The LM34922 Constant On-time Step-down Switching Regulator features all the functions needed to implement a low cost, efficient buck bias power converter capable of supplying up to 2.0A to the load. This high voltage regulator contains an N-Channel buck switch, is easy to implement, and is available in a 10-pin MSOP power enhanced package. The regulator's operation is based on a constant on-time control principle with the on-time inversely proportional to the input voltage. This feature results in the operating frequency remaining relatively constant with load and input voltage variations. The constant on-time feedback control principle requires no loop compensation resulting in very fast load transient response. The adjustable valley current limit detection results in a smooth transition from constant voltage to constant current when current limit is reached. To aid in controlling excessive switch current due to a possible saturating inductor the on-time is reduced by ≅40% when current limit is detected. The Power Good output (PGD pin) indicates when the output voltage is within 5% of the expected regulation voltage.

The LM34922 can be implemented to efficiently step-down higher voltages in non-isolated applications. Additional features include: Low output ripple, VIN under-voltage lock-out, adjustable soft-start timing, thermal shutdown, gate drive pre-charge, gate drive under-voltage lock-out, and maximum duty cycle limit.

Control Circuit Overview

The LM34922 buck regulator employs a control principle based on a comparator and a one-shot on-timer, with the output voltage feedback (FB) compared to an internal reference (2.51V). If the FB voltage is below the reference the internal buck switch is switched on for the one-shot timer period, which is a function of the input voltage and the programming resistor (R_T). Following the on-time the switch remains off until the FB voltage falls below the reference, but never less than the minimum off-time forced by the off-time one-shot timer. When the FB pin voltage falls below the reference and the off-time one-shot period expires, the buck switch is then turned on for another on-time one-shot period.

When in regulation, the LM34922 operates in continuous conduction mode at heavy load currents and discontinuous conduction mode at light load currents. In continuous conduction mode the inductor's current is always greater than zero, and the operating frequency remains relatively constant with load and line variations. The minimum load current for continuous conduction mode is one-half the inductor's ripple current am-

plitude. The approximate operating frequency is calculated as follows:

$$F_S = \frac{V_{OUT}}{(4.1 \times 10^{-11} \times (R_T + 0.5k)) + (V_{IN} \times 15 \text{ ns})} \quad (1)$$

The buck switch duty cycle is approximately equal to:

$$DC = \frac{t_{ON}}{t_{ON} + t_{OFF}} = t_{ON} \times F_S = \frac{V_{OUT}}{V_{IN}} \quad (2)$$

When the load current is less than one half the inductor's ripple current amplitude the circuit operates in discontinuous conduction mode. The off-time is longer than in continuous conduction mode while the inductor current is zero, causing the switching frequency to reduce as the load current is reduced. Conversion efficiency is maintained at light loads since the switching losses are reduced with the reduction in load and frequency. The approximate discontinuous operating frequency can be calculated as follows:

$$F_S = \frac{V_{OUT}^2 \times L1 \times 1.19 \times 10^{21}}{R_L \times R_T^2} \quad (3)$$

where R_L = the load resistance, and L1 is the circuit's inductor. The output voltage is set by the two feedback resistors (R_{FB1}, R_{FB2} in the Block Diagram). The regulated output voltage is calculated as follows:

$$V_{OUT} = 2.51V \times (R_{FB1} + R_{FB2}) / R_{FB1} \quad (4)$$

Ripple voltage, which is required at the input of the regulation comparator for proper output regulation, is generated internally in the LM34922. In the LM34922 the ERM (Emulated Ripple Mode) control circuit generates the required internal ripple voltage from the ripple waveform at the CS pin.

On-Time Timer

The on-time for the LM34922 is determined by the R_T resistor and the input voltage (V_{IN}), calculated from:

$$t_{ON} = \frac{4.1 \times 10^{-11} \times (R_T + 500\Omega)}{(V_{IN})} + 15 \text{ ns} \quad (5)$$

The inverse relationship with V_{IN} results in a nearly constant frequency as V_{IN} is varied. To set a specific continuous conduction mode switching frequency (F_S), the R_T resistor is determined from the following:

$$R_T = \frac{V_{OUT} - (V_{IN} \times F_S \times 15 \text{ ns})}{F_S \times 4.1 \times 10^{-11}} - 500\Omega \quad (6)$$

The on-time must be chosen greater than 90ns for proper operation. Equations 1, 5 and 6 are valid only during normal operation - i.e., the circuit is not in current limit. When the LM34922 operates in current limit, the on-time is reduced by ≅40%. This feature reduces the peak inductor current which may be excessively high if the load current and the input voltage are simultaneously high. This feature operates on a cycle-by-cycle basis until the load current is reduced and the output voltage resumes its normal regulated value. The maximum continuous current into the RT pin must be less than 2mA. For high frequency applications, the maximum switching frequency is limited at the maximum input voltage by the minimum on-time one-shot period (90ns). At minimum input voltage the maximum switching frequency is limited by the minimum off-time one-shot period, which, if reached, prevents achievement of the proper duty cycle.

Current Limit

Current limit detection occurs during the off-time by monitoring the voltage across the external current sense resistor R_S. Referring to the Block Diagram, during the off-time the recirculating current flows through the inductor, through the load, through the sense resistor, and through D1 to the inductor. If the voltage across the sense resistor exceeds the threshold (V_{ILIM}) the current limit comparator output switches to delay the start of the next on-time period. The next on-time starts when the recirculating current decreases such that the voltage across R_S reduces to the threshold and the voltage at FB is below 2.51V. The operating frequency is typically lower due to longer-than-normal off-times. When current limit is detected, the on-time is reduced by ≅40% if the voltage at the FB pin is below its threshold when the voltage across R_S reduces to its threshold (V_{OUT} is low due to current limiting).

Figure 2 illustrates the inductor current waveform during normal operation and in current limit. During the first "Normal Operation" the load current is I_{01}, the average of the inductor current waveform. As the load resistance is reduced, the inductor current increases until the lower peak of the inductor ripple current exceeds the threshold. During the "Current Limited" portion of Figure 2, each on-time is reduced by ≅40%, resulting in lower ripple amplitude for the inductor's current. During this time the LM34922 is in a constant current mode with an average load current equal to the current limit threshold plus half the ripple amplitude (I_{OCL}), and the output voltage is below the normal regulated value. Normal operation resumes when the load current is reduced (to I_{O2}), allowing V_{OUT} and the on-time to return to their normal values. Note that in the second period of "Normal Operation", even though the inductor's peak current exceeds the current limit threshold during part of each cycle, the circuit is not in current limit since the inductor current falls below the current limit threshold during each off time. The peak current allowed through the buck switch is 3.5A, and the maximum allowed average current is 2.0A.
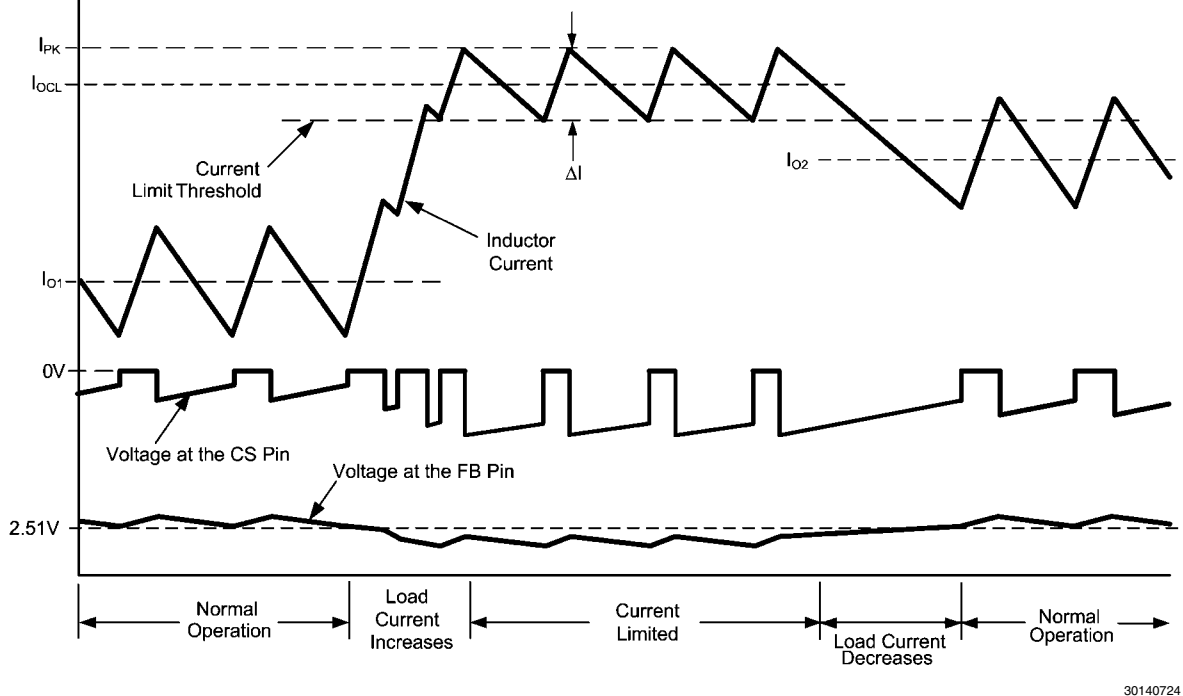

FIGURE 2. Normal and Current Limit Operation

Ripple Requirements

The LM34922 requires a minimum of 15mVp-p ripple voltage at the CS pin. That ripple voltage is generated by the decreasing recirculating current (the inductor's ripple current) through R_S during the off-time. See Figure 3a.

(3a)

CS Pin Waveform

30140725

FIGURE 3.

The ripple voltage is equal to:

$$V_{RIPPLE} = \Delta I \times R_S$$

where ΔI is the inductor current ripple amplitude, and R_S is the current sense resistor at the CS pin.

N-Channel Buck Switch and Driver

The LM34922 integrates an N-Channel buck switch and associated floating high voltage gate driver. The gate driver circuit works in conjunction with an external bootstrap capacitor (C_{BST}) and an internal high voltage diode. A 0.1µF capac-

itor connected between BST and SW provides the supply voltage for the driver during the on-time. During each off-time, the SW pin is at approximately -1V, and C_{BST} is recharged from the internal 5V regulator for the next on-time. The minimum off-time ensures a sufficient time each cycle to recharge the bootstrap capacitor.

Soft-Start

The soft-start feature allows the converter to gradually reach a steady state operating point, thereby reducing startup stresses and current surges. Upon turn-on, when V_{IN} reaches its under-voltage lock-out threshold an internal 10µA current source charges the external capacitor at the SS pin to 2.51V (t1 in Figure 1). The ramping voltage at SS ramps the non-inverting input of the regulation comparator, and the output voltage, in a controlled manner. For proper operation, the soft-start capacitor should be no smaller than 1000pF.

The LM34922 can be employed as a tracking regulator by applying the controlling voltage to the SS pin. The regulator's output voltage tracks the applied voltage, gained up by the ratio of the feedback resistors. The applied voltage at the SS pin must be within the range of 0.5V to 2.6V. The absolute maximum rating for the SS pin is 3.0V. If the tracking function causes the voltage at the FB pin to go below the thresholds for the PGD pin, the PGD pin will switch low (see the Power Good Output section). An internal switch grounds the SS pin if the input voltage at VIN is below its under-voltage lock-out threshold or if the Thermal Shutdown activates. If the tracking function (described above) is used, the tracking voltage applied to the SS pin must be current limited to a maximum of 1mA.

Shutdown Function

The SS pin can be used to shutdown the LM34922 by grounding the SS pin as shown in Figure 4. Releasing the pin allows normal operation to resume.

FIGURE 4. Shutdown Implemetation

Power Good Output (PGD)

The Power Good output (PGD) indicates when the voltage at the FB pin is close to the internal 2.51V reference voltage. The rising threshold at the FB pin for the PGD output to switch high is 95% of the internal reference. The falling threshold for the PGD output to switch low is approximately 3.3% below the rising threshold.

The PGD pin is internally connected to the drain of an N-channel MOSFET switch. An external pull-up resistor (R_{PGD}), connected to an appropriate voltage not exceeding 7V, is required at PGD to indicate the LM34922's status to other circuitry. When PGD is low, the pin's voltage is deter-mined by the current into the pin. See the graph "PGD Low Voltage vs. Sink Current".

Upon powering up the LM34922, the PGD pin is high until the voltage at V_{IN} reaches 2V, at which time PGD switches low. As V_{IN} is increased PGD stays low until the output voltage takes the voltage at the FB pin above 95% of the internal reference voltage, at which time PGD switches high. As V_{IN} is decreased (during shutdown) PGD remains high until either the voltage at the FB pin falls below ≅92% of the internal reference, or when V_{IN} falls below its lower UVLO threshold, whichever occurs first. PGD then switches low, and remains low until V_{IN} falls below 2V, at which time PGD switches high. If the LM34922 is used as a tracking regulator (see the Soft-start section), the PGD output is high as long as the voltage at the FB pin is above the thresholds mentioned above.

Thermal Shutdown

The LM34922 should be operated so the junction temperature does not exceed 125°C. If the junction temperature increases above that, an internal Thermal Shutdown circuit activates (typically) at 155°C, taking the controller to a low power reset state by disabling the buck switch and taking the SS pin to ground. This feature helps prevent catastrophic failures from accidental device overheating. When the junction temperature reduces below 135°C (typical hysteresis = 20°C) normal operation resumes.
