

FLASH MEMORY

CMOS

32 M (4 M × 8/2 M × 16) BIT Dual Operation

MBM29DL32XTE/BE_{80/90}

DESCRIPTION

The MBM29DL32XTE/BE are a 32 M-bit, 3.0 V-only Flash memory organized as 4 Mbytes of 8 bits each or 2 Mwords of 16 bits each. These devices are designed to be programmed in-system with the standard system 3.0 V V_{CC} supply. 12.0 V V_{PP} and 5.0 V V_{CC} are not required for write or erase operations. The devices can also be reprogrammed in standard EPROM programmers.

MBM29DL32XTE/BE are organized into two banks, Bank 1 and Bank 2, which are considered to be two separate memory arrays for operations. It is the Fujitsu's standard 3 V only Flash memories, with the additional capability of allowing a normal non-delayed read access from a non-busy bank of the array while an embedded write (either a program or an erase) operation is simultaneously taking place on the other bank.

PRODUCT LINE UP

Part No.	MBM29DL32XTE/BE	
	80	90
Power Supply Voltage V_{CC} (V)	3.3 $^{+0.3}_{-0.3}$	3.0 $^{+0.6}_{-0.3}$
Max Address Access Time (ns)	80	90
Max $\overline{CE}$ Access Time (ns)	80	90
Max $\overline{OE}$ Access Time (ns)	30	35

PACKAGES

(Continued)

In the MBM29DL32XTE/BE, a new design concept is implemented, so called "Sliding Bank Architecture". Under this concept, the MBM29DL32XTE/BE can be produced a series of devices with different Bank 1/Bank 2 size combinations; 4 Mb/28 Mb, 8 Mb/24 Mb, 16 Mb/16 Mb.

To eliminate bus contention the devices have separate chip enable ($\overline{CE}$), write enable ($\overline{WE}$), and output enable ($\overline{OE}$) controls.

The MBM29DL32XTE/BE are pin and command set compatible with JEDEC standard E²PROMs. Commands are written to the command register using standard microprocessor write timings. Register contents serve as input to an internal state-machine which controls the erase and programming circuitry. Write cycles also internally latch addresses and data needed for the programming and erase operations.

Typically, each sector can be programmed and verified in about 0.5 seconds.

A sector is typically erased and verified in 1.0 second. (If already completely preprogrammed.)

The devices also feature a sector erase architecture. The sector mode allows each sector to be erased and reprogrammed without affecting other sectors. The MBM29DL32XTE/BE are erased when shipped from the factory.

Internally generated and regulated voltages are provided for the program and erase operations. A low V_{CC} detector automatically inhibits write operations on the loss of power. The end of program or erase is detected by Data Polling of DQ₇, by the Toggle Bit feature on DQ₆, or the RY/ $\overline{BY}$ output pin. Once the end of a program or erase cycle has been completed, the devices internally reset to the read mode.

The MBM29DL32XTE/BE memories electrically erase the entire chip or all bits within a sector simultaneously via Fowler-Nordhiem tunneling. The bytes/words are programmed one byte/word at a time using the EPROM programming mechanism of hot electron injection.

■ FEATURES

- **0.23 μ m Process Technology**
- **Simultaneous Read/Write operations (dual bank)**
Multiple devices available with different bank sizes (Refer to “MBM29DL32XTE/BE Device Bank Divisions” in “■ FEATURES”)
Host system can program or erase in one bank, then immediately and simultaneously read from the other bank
Zero latency between read and write operations
Read-while-erase
Read-while-program
- **Single 3.0 V read, program, and erase**
Minimizes system level power requirements
- **Compatible with JEDEC-standard commands**
Uses same software commands as E²PROMs
- **Compatible with JEDEC-standard world-wide pinouts**
48-pin TSOP (1) (Package suffix : TN – Normal Bend Type, TR – Reversed Bend Type)
63-ball FBGA (Package suffix : PBT)
- **Minimum 100,000 program/erase cycles**
- **High performance**
80 ns maximum access time
- **Sector erase architecture**
Eight 4 Kword and sixty-three 32 Kword sectors in word mode
Eight 8 Kbyte and sixty-three 64 Kbyte sectors in byte mode
Any combination of sectors can be concurrently erased. Also supports full chip erase.
- **Boot Code Sector Architecture**
T = Top sector
B = Bottom sector
- **HiddenROM region**
64 Kbyte of HiddenROM, accessible through a new “HiddenROM Enable” command sequence
Factory serialized and protected to provide a secure electronic serial number (ESN)
- **WP/ACC input pin**
At V_{IL} , allows protection of boot sectors, regardless of sector group protection/unprotection status
At V_{ACC} , increases program performance
- **Embedded Erase™ Algorithms**
Automatically pre-programs and erases the chip or any sector
- **Embedded Program™ Algorithms**
Automatically writes and verifies data at specified address
- **Data Polling and Toggle Bit feature for detection of program or erase cycle completion**
- **Ready/Busy output (RY/BY)**
Hardware method for detection of program or erase cycle completion
- **Automatic sleep mode**
When addresses remain stable, automatically switch themselves to low power mode.
- **Low V_{CC} write inhibit ≤ 2.5 V**
- **Erase Suspend/Resume**
Suspends the erase operation to allow a read data and/or program in another sector within the same device
- **Sector group protection**
Hardware method disables any combination of sector groups from program or erase operations

Embedded Erase™ and Embedded Program™ are trademarks of Advanced Micro Devices, Inc.

MBM29DL32XTE/BE_{80/90}

(Continued)

- **Sector Group Protection Set function by Extended sector group protection command**
- **Fast Programming Function by Extended Command**
- **Temporary sector group unprotection**
Temporary sector group unprotection via the $\overline{\text{RESET}}$ pin.
- **In accordance with CFI (Common Flash Memory Interface)**

MBM29DL32XTE/BE Device Bank Divisions

Device Part Number	Organiza- tion	Bank 1		Bank 2	
		Mega- bits	Sector sizes	Mega- bits	Sector sizes
MBM29DL322TE/BE	× 8/× 16	4 Mbit	Eight 8 Kbyte/4 Kword, seven 64 Kbyte/32 Kword	28 Mbit	Fifty-six 64 Kbyte/32 Kword
MBM29DL323TE/BE		8 Mbit	Eight 8 Kbyte/4 Kword, fifteen 64 Kbyte/32 Kword	24 Mbit	Forty-eight 64 Kbyte/32 Kword
MBM29DL324TE/BE		16 Mbit	Eight 8 Kbyte/4 Kword, thirty-one 64 Kbyte/ 32 Kword	16 Mbit	Thirty-two 64 Kbyte/32 Kword

PIN ASSIGNMENTS

(Continued)

* : Peripheral Balls on each corner are shorted together via substrate but not connected to the die.

■ PIN DESCRIPTIONS

MBM29DL32XTE/BE Pin Configuration

Pin Name	Function
A ₂₀ to A ₀ , A ₋₁	Address Input
DQ ₁₅ to DQ ₀	Data Input/Output
$\overline{\text{CE}}$	Chip Enable
$\overline{\text{OE}}$	Output Enable
$\overline{\text{WE}}$	Write Enable
RY/ $\overline{\text{BY}}$	Ready/Busy Output
$\overline{\text{RESET}}$	Hardware Reset Pin/Temporary Sector Group Unprotection
$\overline{\text{BYTE}}$	Selects 8-bit or 16-bit mode
$\overline{\text{WP/ACC}}$	Hardware Write Protection/Program Acceleration
N.C.	No Internal Connection
V _{SS}	Device Ground
V _{CC}	Device Power Supply

	Byte		AAAh		555h		(HRBA) AAAh							

*1 : Both of these reset commands are equivalent.

*2 : This command is valid during Fast Mode.

*3 : This command is valid while $\overline{\text{RESET}} = V_{\text{ID}}$ (except during HiddenROM MODE).

*4 : The valid address are A_6 to A_0 .

*5 : This command is valid during HiddenROM mode.

*6 : The data "00h" is also acceptable.

*7 : The fourth bus cycle is only for read.

Notes : • Address bits A_{20} to $A_{11} = X = "H"$ or $"L"$ for all address commands except or Program Address (PA) , Sector Address (SA) , Bank Address (BA) and Sector Group Address (SPA) .

• Bus operations are defined in "MBM29DL32XTE/BE User Bus Operations ($\overline{\text{BYTE}} = V_{\text{IH}}$) " and "MBM29DL32XTE/BE User Bus Operations ($\overline{\text{BYTE}} = V_{\text{IL}}$) " .

• RA = Address of the memory location to be read

IA = Autoselect read address sets both the bank address specified at ($A_{19}, A_{18}, A_{17}, A_{16}, A_{15}$) and all the other $A_6, A_1, A_0, (A_{-1})$.

PA = Address of the memory location to be programmed

Addresses are latched on the falling edge of the write pulse.

SA = Address of the sector to be erased. The combination of $A_{20}, A_{19}, A_{18}, A_{17}, A_{16}, A_{15}, A_{14}, A_{13}$, and A_{12} will uniquely select any sector.

BA = Bank Address (A_{20} to A_{15})

• RD = Data read from location RA during read operation.

ID = Device code/manufacture code for the address located by IA.

PD = Data to be programmed at location PA. Data is latched on the rising edge of write pulse.

• SPA = Sector group address to be protected. Set sector group address and (A_6, A_1, A_0) = (0, 1, 0) .

SD = Sector group protection verify data. Output 01h at protected sector group addresses and output 00h at unprotected sector group addresses.

• HRA = Address of the HiddenROM area

29DL32XTE (Top Boot Type) Word Mode : 1F8000h to 1FFFFFFh

Byte Mode : 3F0000h to 3FFFFFFh

29DL32XBE (Bottom Boot Type) Word Mode : 000000h to 007FFFh

Byte Mode : 000000h to 00FFFFh

• HRBA = Bank Address of the HiddenROM area

29DL32XTE (Top Boot Type) : $A_{20} = A_{19} = A_{18} = A_{17} = A_{16} = A_{15} = V_{\text{IH}}$

29DL32XBE (Bottom Boot Type) : $A_{20} = A_{19} = A_{18} = A_{17} = A_{16} = A_{15} = V_{\text{IL}}$

• The system should generate the following address patterns :

Word Mode : 555h or 2AAh to addresses A_{10} to A_0

Byte Mode : AAAh or 555h to addresses A_{10} to A_0 , and A_{-1}

- Both Read/Reset commands are functionally equivalent, resetting the device to the read mode.
- The command combinations not described in "MBM29DL32XTE/BE Command Definitions" are illegal.

In case of applying V_{ID} on A₉, since both Bank 1 and Bank 2 enters Autoselect mode, the simultaneous operation can not be executed.

MBM29DL322TE/BE Sector Group Protection Verify Autoselect Codes

Type			A ₂₀ to A ₁₂	A ₆	A ₁	A ₀	A ₋₁ ^{*1}	Code (HEX)
Manufacture's Code			BA* ³	V _{IL}	V _{IL}	V _{IL}	V _{IL}	04h

		Word					X	2255h
	MBM29DL322BE	Byte	BA* ³	V _{IL}	V _{IL}	V _{IH}	V _{IL}	56h
		Word					X	2256h
Sector Group Protection			Sector group addresses	V _{IL}	V _{IH}	V _{IL}	V _{IL}	01h* ²

*1 : A₋₁ is for Byte mode. At Byte mode, DQ₈ to DQ₁₄ are High-Z and DQ₁₅ is A₋₁, the lowest address.

*2 : Outputs 01h at protected sector group addresses and outputs 00h at unprotected sector group addresses.

*3 : When V_{ID} is applied to A₉, both Bank 1 and Bank 2 are put into Autoselect mode, which makes simultaneous operation unable to be executed. Consequently, specifying the bank address is not required. However, the bank address needs to be indicated when Autoselect mode is read out at command mode, because then it enables to activate simultaneous operation.

■ FUNCTIONAL DESCRIPTION

• Simultaneous Operation

MBM29DL32XTE/BE have feature, which is capability of reading data from one bank of memory while a program or erase operation is in progress in the other bank of memory (simultaneous operation) , in addition to the conventional features (read, program, erase, erase-suspend read, and erase-suspend program) . The bank selection can be selected by bank address (A_{20} to A_{15}) with zero latency.

The MBM29DL322TE/BE have two banks which contain

Bank 1 (8 KB × eight sectors, 64 KB × seven sectors) and Bank 2 (64 KB × fifty-six sectors) .

The MBM29DL323TE/BE have two banks which contain

Bank 1 (8 KB × eight sectors, 64 KB × fifteen sectors) and Bank 2 (64 KB × forty-eight sectors) .

The MBM29DL324TE/BE have two banks which contain

Bank 1 (8 KB × eight sectors, 64 KB × thirty-one sectors) and Bank 2 (64 KB × thirty-two sectors) .

The simultaneous operation can not execute multi-function mode in the same bank. “Simultaneous Operation” in “■ FUNCTIONAL DESCRIPTION” shows combination to be possible for simultaneous operation. (Refer to the “Bank-to-bank Read/Write Timing Diagram” in “■ TIMING DIAGRAM”.)

Simultaneous Operation

Case	Bank 1 status	Bank 2 status
1	Read Mode	Read Mode
2	Read Mode	Autoselect Mode
3	Read Mode	Program Mode
4	Read Mode	Erase Mode *
5	Autoselect Mode	Read Mode
6	Program Mode	Read Mode
7	Erase Mode *	Read Mode

* : By writing erase suspend command on the bank address of sector being erased, the erase operation gets suspended so that it enables reading from or programming the remaining sectors.

• Read Mode

The MBM29DL32XTE/BE have two control functions which must be satisfied in order to obtain data at the outputs. $\overline{CE}$ is the power control and should be used for a device selection. $\overline{OE}$ is the output control and should be used to gate data to the output pins if a device is selected.

Address access time (t_{ACC}) is equal to the delay from stable addresses to valid output data. The chip enable access time (t_{CE}) is the delay from stable addresses and stable $\overline{CE}$ to valid data at the output pins. The output enable access time is the delay from the falling edge of $\overline{OE}$ to valid data at the output pins (Assuming the addresses have been stable for at least $t_{ACC-tOE}$ time) . When reading out a data without changing addresses after power-up, it is necessary to input hardware reset or to change $\overline{CE}$ pin from “H” or “L”

• Standby Mode

There are two ways to implement the standby mode on the MBM29DL32XTE/BE devices, one using both the $\overline{CE}$ and $\overline{RESET}$ pins; the other via the $\overline{RESET}$ pin only.

When using both pins, a CMOS standby mode is achieved with $\overline{CE}$ and $\overline{RESET}$ inputs both held at $V_{CC} \pm 0.3 V$. Under this condition the current consumed is less than 5 μA Max During Embedded Algorithm operation, V_{CC}

active current (I_{CC2}) is required even $\overline{CE} = "H"$. The device can be read with standard access time (t_{CE}) from either of these standby modes.

When using the $\overline{RESET}$ pin only, a CMOS standby mode is achieved with $\overline{RESET}$ input held at $V_{SS} \pm 0.3 V$ ($\overline{CE} = "H"$ or $"L"$). Under this condition the current consumed is less than 5 μA Max. Once the $\overline{RESET}$ pin is taken high, the device requires t_{RH} of wake up time before outputs are valid for read access.

In the standby mode the outputs are in the high impedance state, independent of the $\overline{OE}$ input.

• Automatic Sleep Mode

There is a function called automatic sleep mode to restrain power consumption during read-out of MBM29DL32XTE/BE data. This mode can be used effectively with an application requested low power consumption such as handy terminals.

To activate this mode, MBM29DL32XTE/BE automatically switch themselves to low power mode when MBM29DL32XTE/BE addresses remain stably during access time of 150 ns. It is not necessary to control $\overline{CE}$, $\overline{WE}$, and $\overline{OE}$ on the mode. Under the mode, the current consumed is typically 1 μA (CMOS Level).

During simultaneous operation, V_{CC} active current (I_{CC2}) is required.

Since the data are latched during this mode, the data are read-out continuously. If the addresses are changed, the mode is canceled automatically and MBM29DL32XTE/BE read-out the data for changed addresses.

• Output Disable

With the $\overline{OE}$ input at a logic high level (V_{IH}), output from the devices are disabled. This will cause the output pins to be in a high impedance state.

• Autoselect

The autoselect mode allows the reading out of a binary code from the devices and will identify its manufacturer and type. This mode is intended for use by programming equipment for the purpose of automatically matching the devices to be programmed with its corresponding programming algorithm. This mode is functional over the entire temperature range of the devices.

To activate this mode, the programming equipment must force V_{ID} (11.5 V to 12.5 V) on address pin A_9 . Two identifier bytes may then be sequenced from the devices outputs by toggling address A_0 from V_{IL} to V_{IH} . All addresses are DON'T CARES except A_0 , A_1 , and A_6 (A_{-1}). (See "MBM29DL32XTE/BE User Bus Operations ($\overline{BYTE} = V_{IH}$)" and "MBM29DL32XTE/BE User Bus Operations ($\overline{BYTE} = V_{IL}$)" in "■ DEVICE BUS OPERATION".)

The manufacturer and device codes may also be read via the command register, for instances when the MBM29DL32XTE/BE are erased or programmed in a system without access to high voltage on the A_9 pin. The command sequence is illustrated in "MBM29DL32XTE/BE Command Definitions" in "■ DEVICES BUS OPERATION". (Refer to Autoselect Command section.)

Byte 0 ($A_0 = V_{IL}$) represents the manufacturer's code (Fujitsu = 04h) and word 1 ($A_0 = V_{IH}$) represents the device identifier code (MBM29DL322TE = 55h and MBM29DL322BE = 56h for $\times 8$ mode; MBM29DL322TE = 2255h and MBM29DL322BE = 2256h for $\times 16$ mode). (MBM29DL323TE = 50h and MBM29DL323BE = 53h for $\times 8$ mode; MBM29DL323TE = 2250h and MBM29DL323BE = 2253h for $\times 16$ mode). (MBM29DL324TE = 5Ch and MBM29DL324BE = 5Fh for $\times 8$ mode; MBM29DL324TE = 225Ch and MBM29DL324BE = 225Fh for $\times 16$ mode). These two bytes/words are given in "MBM29DL322/323/324TE/BE Sector Group Protection Verify Autoselect Codes Tables", "Extended Autoselect Code Tables" in "■ DEVICE BUS OPERATION". All identifiers for manufactures and device will exhibit odd parity with DQ_7 defined as the parity bit. In order to read the proper device codes when executing the autoselect, A_1 must be V_{IL} . (See "MBM29DL322/323/324TE/BE Sector Group Protection Verify Autoselect Codes Tables", "Extended Autoselect Code Tables" in "■ DEVICE BUS OPERATION".)

• Write

Device erasure and programming are accomplished via the command register. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device.

The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The command register is written by bringing $\overline{WE}$ to V_{IL} , while $\overline{CE}$ is at V_{IL} and $\overline{OE}$ is at V_{IH} . Addresses are latched on the falling edge of $\overline{WE}$ or $\overline{CE}$, whichever happens later; while data is latched on the rising edge of $\overline{WE}$ or $\overline{CE}$, whichever happens first. Standard microprocessor write timings are used.

Refer to AC Write Characteristics and the Erase/Programming Waveforms for specific timing parameters.

• Sector Group Protection

The MBM29DL32XTE/BE feature hardware sector group protection. This feature will disable both program and erase operations in any combination of twenty five sector groups of memory. (See "Sector Group Addresses (MBM29DL32XTE) (Top Boot Block)" and "Sector Group Addresses (MBM29DL32XBE) (Bottom Boot Block)" in "■ FLEXIBLE SECTOR-ERASE ARCHITECTURE"). The sector group protection feature is enabled using programming equipment at the user's site. The device is shipped with all sector groups unprotected.

To activate this mode, the programming equipment must force V_{ID} on address pin A_9 and control pin $\overline{OE}$, (suggest $V_{ID} = 11.5\text{ V}$), $\overline{CE} = V_{IL}$ and $A_6 = A_0 = V_{IL}$, $A_1 = V_{IH}$. The sector group addresses (A_{20} , A_{19} , A_{18} , A_{17} , A_{16} , A_{15} , A_{14} , A_{13} , and A_{12}) should be set to the sector to be protected. "Sector Address Table (MBM29DL322TE)", "Sector Address Table (MBM29DL322BE)", "Sector Address Table (MBM29DL323TE)", "Sector Address Table (MBM29DL323BE)", "Sector Address Table (MBM29DL324TE)" and "Sector Address Table (MBM29DL324BE)" in "■ FLEXIBLE SECTOR-ERASE ARCHITECTURE" define the sector address for each of the seventy one (71) individual sectors, and "Sector Group Addresses (MBM29DL32XTE) (Top Boot Block)" and "Sector Group Addresses (MBM29DL32XBE) (Bottom Boot Block)" in "■ FLEXIBLE SECTOR-ERASE ARCHITECTURE" define the sector group address for each of the twenty five (25) individual group sectors. Programming of the protection circuitry begins on the falling edge of the $\overline{WE}$ pulse and is terminated with the rising edge of the same. Sector group addresses must be held constant during the $\overline{WE}$ pulse. See "Sector Group Protection Timing Diagram" in "■ TIMING DIAGRAM" and "Sector Group Protection Algorithm" in "■ FLOW CHART" for sector group protection waveforms and algorithm.

To verify programming of the protection circuitry, the programming equipment must force V_{ID} on address pin A_9 with $\overline{CE}$ and $\overline{OE}$ at V_{IL} and $\overline{WE}$ at V_{IH} . Scanning the sector group addresses (A_{20} , A_{19} , A_{18} , A_{17} , A_{16} , A_{15} , A_{14} , A_{13} , and A_{12}) while (A_6 , A_1 , A_0) = (0, 1, 0) will produce a logical "1" code at device output DQ_0 for a protected sector. Otherwise the device will produce "0" for unprotected sector. In this mode, the lower order addresses, except for A_0 , A_1 , and A_6 are DON'T CARES. Address locations with $A_1 = V_{IL}$ are reserved for Autoselect manufacturer and device codes. A_{-1} requires to apply to V_{IL} on byte mode.

It is also possible to determine if a sector group is protected in the system by writing an Autoselect command. Performing a read operation at the address location XX02h, where the higher order addresses (A_{20} , A_{19} , A_{18} , A_{17} , A_{16} , A_{15} , A_{14} , A_{13} , and A_{12}) are the desired sector group address will produce a logical "1" at DQ_0 for a protected sector group. See "MBM29DL322/323/324TE/BE Sector Group Protection Verify Autoselect Codes Tables", "Extended Autoselect Code Tables" in "■ DEVICE BUS OPERATION" for Autoselect codes.

• Temporary Sector Group Unprotection

This feature allows temporary unprotection of previously protected sector groups of the MBM29DL32XTE/BE devices in order to change data. The Sector Group Unprotection mode is activated by setting the $\overline{RESET}$ pin to high voltage (V_{ID}). During this mode, formerly protected sector groups can be programmed or erased by selecting the sector group addresses. Once the V_{ID} is taken away from the $\overline{RESET}$ pin, all the previously protected sector groups will be protected again. Refer to "Temporary Sector Group Unprotection Timing Diagram" in "■ TIMING DIAGRAM" and "Temporary Sector Group Unprotection Algorithm" in "■ FLOW CHART".

- **RESET**

Hardware Reset

The MBM29DL32XTE/BE devices may be reset by driving the $\overline{\text{RESET}}$ pin to V_{IL} . The $\overline{\text{RESET}}$ pin has a pulse requirement and has to be kept low (V_{IL}) for at least “ t_{RP} ” in order to properly reset the internal state machine. Any operation in the process of being executed will be terminated and the internal state machine will be reset to the read mode “ t_{READY} ” after the $\overline{\text{RESET}}$ pin is driven low. Furthermore, once the $\overline{\text{RESET}}$ pin goes high, the devices require an additional “ t_{RH} ” before it will allow read access. When the $\overline{\text{RESET}}$ pin is low, the devices will be in the standby mode for the duration of the pulse and all the data output pins will be tri-stated. If a hardware reset occurs during a program or erase operation, the data at that particular location will be corrupted. Please note that the RY/BY output signal should be ignored during the $\overline{\text{RESET}}$ pulse. See “RESET, RY/BY Timing Diagram” in “■ TIMING DIAGRAM” for the timing diagram. Refer to Temporary Sector Group Unprotection for additional functionality.

- **Byte/Word Configuration**

The $\overline{\text{BYTE}}$ pin selects the byte (8-bit) mode or word (16-bit) mode for the MBM29DL32XTE/BE devices. When this pin is driven high, the devices operate in the word (16-bit) mode. The data is read and programmed at DQ₀ to DQ₁₅. When this pin is driven low, the devices operate in byte (8-bit) mode. Under this mode, the DQ_{15/A-1} pin becomes the lowest address bit and DQ₈ to DQ₁₄ bits are tri-stated. However, the command bus cycle is always an 8-bit operation and hence commands are written at DQ₀ to DQ₇ and the DQ₈ to DQ₁₅ bits are ignored. Refer to “Timing Diagram for Word Mode Configuration”, “Timing Diagram for Byte Mode Configuration” and “ $\overline{\text{BYTE}}$ Timing Diagram for Write Operations” in “■ TIMING DIAGRAM” for the timing diagram.

- **Boot Block Sector Protection**

The Write Protection function provides a hardware method of protecting certain boot sectors without using V_{ID} . This function is one of two provided by the $\overline{\text{WP/ACC}}$ pin.

If the system asserts V_{IL} on the $\overline{\text{WP/ACC}}$ pin, the device disables program and erase functions in the two “outermost” 8 Kbyte boot sectors (MBM29DL32XTE : SA69 and SA70, MBM29DL32XBE : SA0 and SA1) independently of whether those sectors were protected or unprotected using the method described in “Sector Group Protection”. The two outermost 8 Kbyte boot sectors are the two sectors containing the lowest addresses in a bottom-boot-configured device, or the two sectors containing the highest addresses in a top-boot-configured device.

If the system asserts V_{IH} on the $\overline{\text{WP/ACC}}$ pin, the device reverts to whether the two outermost 8 Kbyte boot sectors were last set to be protected or unprotected. That is, sector group protection or unprotection for these two sectors depends on whether they were last protected or unprotected using the method described in “Sector Group Protection”.

- **Accelerated Program Operation**

MBM29DL32XTE/BE offers accelerated program operation which enables the programming in high speed.

If the system asserts V_{ACC} to the $\overline{\text{WP/ACC}}$ pin, the device automatically enters the acceleration mode and the time required for program operation will reduce to about 60%. This function is primarily intended to allow high speed program, so caution is needed as the sector group will temporarily be unprotected.

The system would use a fast program command sequence when programming during acceleration mode. Set command to fast mode and reset command from fast mode are not necessary. When the device enters the acceleration mode, the device automatically set to fast mode. Therefore, the present sequence could be used for programming and detection of completion during acceleration mode.

Removing V_{ACC} from the $\overline{\text{WP/ACC}}$ pin returns the device to normal operation. Do not remove V_{ACC} from $\overline{\text{WP/ACC}}$ pin while programming. See “Accelerated Program Timing Diagram” in “■ TIMING DIAGRAM”. Erase operation during Accelerated Program Operation is strictly prohibited.

■ COMMAND DEFINITIONS

Device operations are selected by writing specific address and data sequences into the command register. Some commands are required Bank Address (BA) input. When command sequences are inputted to bank being read, the commands have priority than reading. “MBM29DL32XTE/BE Command Definitions” in “■ DEVICEBUS OPERATION” defines the valid register command sequences. Note that the Erase Suspend (B0h) and Erase Resume (30h) commands are valid only while the Sector Erase operation is in progress. Also the Program Suspend (B0h) and Program Resume (30h) commands are valid only while the Program operation is in progress. Moreover both Read/Reset commands are functionally equivalent, resetting the device to the read mode. Please note that commands are always written at DQ₀ to DQ₇ and DQ₈ to DQ₁₅ bits are ignored.

• Read/Reset Command

In order to return from Autoselect mode or Exceeded Timing Limits (DQ₅ = 1) to Read/Reset mode, the Read/Reset operation is initiated by writing the Read/Reset command sequence into the command register. Microprocessor read cycles retrieve array data from the memory. The devices remain enabled for reads until the command register contents are altered.

The devices will automatically power-up in the Read/Reset state. In this case, a command sequence is not required to read data. Standard microprocessor read cycles will retrieve array data. This default value ensures that no spurious alteration of the memory content occurs during the power transition. Refer to the AC Read Characteristics and Waveforms for the specific timing parameters.

• Autoselect Command

Flash memories are intended for use in applications where the local CPU alters memory contents. As such, manufacture and device codes must be accessible while the devices reside in the target system. PROM programmers typically access the signature codes by raising A₉ to a high voltage. However, multiplexing high voltage onto the address lines is not generally desired system design practice.

The device contains an Autoselect command operation to supplement traditional PROM programming methodology. The operation is initiated by writing the Autoselect command sequence into the command register.

The Autoselect command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle that contains the bank address (BA) and the Autoselect command. Then the manufacture and device codes can be read from the bank, and an actual data of memory cell can be read from the another bank.

Following the command write, a read cycle from address (BA) 00h retrieves the manufacture code of 04h. A read cycle from address (BA) 01h for ×16 ((BA) 02h for ×8) returns the device code (MBM29DL322TE = 55h and MBM29DL322BE = 56h for ×8 mode; MBM29DL322TE = 2255h and MBM29DL322BE = 2256h for ×16 mode) . (MBM29DL323TE = 50h and MBM29DL323BE = 53h for ×8 mode; MBM29DL323TE = 2250h and MBM29DL323BE = 2253h for ×16 mode) . (MBM29DL324TE = 5Ch and MBM29DL324BE = 5Fh for ×8 mode; MBM29DL324TE = 225Ch and MBM29DL324BE = 225Fh for ×16 mode) . (See “MBM29DL322/323/324TE/BE Sector Group Protection Verify Autoselect Codes Tables”, “Extended Autoselect Code Tables” in “■ DEVICE BUS OPERATION”.)

All manufacturer and device codes will exhibit odd parity with DQ₇ defined as the parity bit. Sector state (protection or unprotection) will be informed by address (BA) 02h for ×16 ((BA) 04h for ×8) . Scanning the sector group addresses (A₂₀, A₁₉, A₁₈, A₁₇, A₁₆, A₁₅, A₁₄, A₁₃, and A₁₂) while (A₆, A₁, A₀) = (0, 1, 0) will produce a logical “1” at device output DQ₀ for a protected sector group. The programming verification should be performed by verify sector group protection on the protected sector. (See “Sector Address Table (MBM29DL324TE)”, “Sector Address Table (MBM29DL324BE)”, “Sector Group Addresses (MBM29DL32XTE) (Top Boot Block)” and “Sector Group Addresses (MBM29DL32XBE) (Bottom Boot Block)” in “■ FLEXIBLE SECTOR-ERASE ARCHITECTURE”).

The manufacture and device codes can be allowed reading from selected bank. To read the manufacture and device codes and sector group protection status from non-selected bank, it is necessary to write Read/Reset command sequence into the register and then Autoselect command should be written into the bank to be read.

If the software (program code) for Autoselect command is stored into the Flash memory, the device and manufacture codes should be read from the other bank where is not contain the software.

To terminate the operation, it is necessary to write the Read/Reset command sequence into the register, and also to write the Autoselect command during the operation, execute it after writing Read/Reset command sequence.

• Byte/Word Programming

The devices are programmed on a byte-by-byte (or word-by-word) basis. Programming is a four bus cycle operation. There are two “unlock” write cycles. These are followed by the program set-up command and data write cycles. Addresses are latched on the falling edge of $\overline{CE}$ or $\overline{WE}$, whichever happens later and the data is latched on the rising edge of $\overline{CE}$ or $\overline{WE}$, whichever happens first. The rising edge of $\overline{CE}$ or $\overline{WE}$ (whichever happens first) begins programming. Upon executing the Embedded Program Algorithm command sequence, the system is not required to provide further controls or timings. The device will automatically provide adequate internally generated program pulses and verify the programmed cell margin.

The system can determine the status of the program operation by using DQ_7 ($\overline{Data}$ Polling) , DQ_6 (Toggle Bit) , or $RY/\overline{BY}$. The $\overline{Data}$ Polling and Toggle Bit must be performed at the memory location which is being programmed.

The automatic programming operation is completed when the data on DQ_7 is equivalent to data written to this bit at which time the devices return to the read mode and addresses are no longer latched. (See “Hardware Sequence Flags” in “■ COMMAND DEFINITIONS”, Hardware Sequence Flags.) Therefore, the devices require that a valid address to the devices be supplied by the system at this particular instance of time. Hence, $\overline{Data}$ Polling must be performed at the memory location which is being programmed.

If hardware reset occurs during the programming operation, it is impossible to guarantee the data are being written.

Programming is allowed in any sequence and across sector boundaries. Beware that a data “0” cannot be programmed back to a “1”. Attempting to do so may either hang up the device or result in an apparent success according to the data polling algorithm but a read from Read/Reset mode will show that the data is still “0”. Only erase operations can convert “0”s to “1”s.

“Embedded Program™ Algorithm” in “■ FLOW CHART” illustrates the Embedded Program™ Algorithm using typical command strings and bus operations.

• Program Suspend/Resume

The Program Suspend command allows the system to interrupt a program operation so that data can be read from any address. Writing the Program Suspend command (B0h) during the Embedded Program operation immediately suspends the programming. The Program Suspend command may also be issued during a programming operation while an erase is suspended. The bank addresses of sector being programmed should be set when writing the Program Suspend command.

When the Program Suspend command is written during a process, the device halts the program operation within 1 μ s and updates the state bits.

After the program operation has been suspended, the system can read data from any address. The data at program-suspended address is not valid. Normal read timing and command definitions apply.

After Program Resume command (30h) is written, the device reverts to programming. The bank address of sectors being suspended should be set when writing the Program Resume command. The system can determine the program operation status using the DQ_7 or DQ_6 status bits, just as in the standard program operation. See “Write Operation Status” for more information.

The system may also write Autoselect command sequence when the device in the Program Suspend mode. The device allows reading Autoselect codes at the addresses within programming sectors, since the codes are not stored in the memory. When the device exits form the Autoselect mode, the device reverts to the Program

Suspend mode, and is ready for another valid operation. See “Autoselect Command Sequence” for more information.

The system must write the Program Resume command (address bits are “Bank Address”) to exit from the Program Suspend mode and continue programming operation. Further writes of the Resume command are ignored. Another Program Suspend command can be written after the device resumes programming.

• Chip Erase

Chip erase is a six bus cycle operation. There are two “unlock” write cycles. These are followed by writing the “set-up” command. Two more “unlock” write cycles are then followed by the chip erase command.

Chip erase does not require the user to program the device prior to erase. Upon executing the Embedded Erase Algorithm command sequence the devices will automatically program and verify the entire memory for an all zero data pattern prior to electrical erase (Preprogram function) . The system is not required to provide any controls or timings during these operations.

The system can determine the status of the erase operation by using $\overline{DQ_7}$ (Data Polling) , $\overline{DQ_6}$ (Toggle Bit) , or $\overline{RY/BY}$. The chip erase begins on the rising edge of the last $\overline{CE}$ or $\overline{WE}$, whichever happens first in the command sequence and terminates when the data on $\overline{DQ_7}$ is “1” (See Write Operation Status section.) at which time the device returns to read the mode.

Chip Erase Time; Sector Erase Time × All sectors + Chip Program Time (Preprogramming)

“Embedded Erase™ Algorithm” in “■ FLOW CHART” illustrates the Embedded Erase™ Algorithm using typical command strings and bus operations.

• Sector Erase

Sector erase is a six bus cycle operation. There are two “unlock” write cycles. These are followed by writing the “set-up” command. Two more “unlock” write cycles are then followed by the Sector Erase command. The sector address (any address location within the desired sector) is latched on the falling edge of $\overline{CE}$ or $\overline{WE}$ whichever happens later, while the command (Data = 30h) is latched on the rising edge of $\overline{CE}$ or $\overline{WE}$ which happens first. After time-out of “ t_{TOW} ” from the rising edge of the last sector erase command, the sector erase operation will begin.

Multiple sectors may be erased concurrently by writing the six bus cycle operations on “MBM29DL32XTE/BE Command Definitions” in “■ DEVICEBUS OPERATION”. This sequence is followed with writes of the Sector Erase command to addresses in other sectors desired to be concurrently erased. The time between writes must be less than “ t_{TOW} ” otherwise that command will not be accepted and erasure will start. It is recommended that processor interrupts be disabled during this time to guarantee this condition. The interrupts can be re-enabled after the last Sector Erase command is written. A time-out of “ t_{TOW} ” from the rising edge of last $\overline{CE}$ or $\overline{WE}$ whichever happens first will initiate the execution of the Sector Erase command (s) . If another falling edge of $\overline{CE}$ or $\overline{WE}$, whichever happens first occurs within the “ t_{TOW} ” time-out window the timer is reset. (Monitor $\overline{DQ_3}$ to determine if the sector erase timer window is still open, see section $\overline{DQ_3}$, Sector Erase Timer.) Resetting the devices once execution has begun will corrupt the data in the sector. In that case, restart the erase on those sectors and allow them to complete. (Refer to the Write Operation Status section for Sector Erase Timer operation.) Loading the sector erase buffer may be done in any sequence and with any number of sectors (0 to 38) .

Sector erase does not require the user to program the devices prior to erase. The devices automatically program all memory locations in the sector (s) to be erased prior to electrical erase (Preprogram function) . When erasing a sector or sectors the remaining unselected sectors are not affected. The system is not required to provide any controls or timings during these operations.

The system can determine the status of the erase operation by using $\overline{DQ_7}$ (Data Polling) , $\overline{DQ_6}$ (Toggle Bit) , or $\overline{RY/BY}$.

The sector erase begins after the “ t_{TOW} ” time out from the rising edge of $\overline{CE}$ or $\overline{WE}$ whichever happens first for the last sector erase command pulse and terminates when the data on $\overline{DQ_7}$ is “1” (See Write Operation Status

section.) at which time the devices return to the read mode. $\overline{\text{Data}}$ polling and Toggle Bit must be performed at an address within any of the sectors being erased.

Multiple Sector Erase Time; [Sector Erase Time + Sector Program Time (Preprogramming)] $\times$ Number of Sector Erase

In case of multiple sector erase across bank boundaries, a read from bank (read-while-erase) can not perform.

“Embedded Erase™ Algorithm” in “■ FLOW CHART” illustrates the Embedded Erase™ Algorithm using typical command strings and bus operations.

• Erase Suspend/Resume

The Erase Suspend command allows the user to interrupt a Sector Erase operation and then perform data reads from or programs to a sector not being erased. This command is applicable ONLY during the Sector Erase operation which includes the time-out period for sector erase. Writing the Erase Suspend command (B0h) during the Sector Erase time-out results in immediate termination of the time-out period and suspension of the erase operation.

Writing the Erase Resume command (30h) resumes the erase operation. The bank addresses of sector being erasing or suspending should be set when writing the Erase Suspend or Erase Resume command.

When the Erase Suspend command is written during the Sector Erase operation, the device will take a maximum of “ t_{SPD} ” to suspend the erase operation. When the devices have entered the erase-suspended mode, the $\text{RY}/\overline{\text{BY}}$ output pin will be at high impedance state and the DQ_7 bit will be at logic “1”, and DQ_6 will stop toggling. The user must use the address of the erasing sector for reading DQ_6 and DQ_7 to determine if the erase operation has been suspended. Further writes of the Erase Suspend command are ignored.

When the erase operation has been suspended, the devices default to the erase-suspend-read mode. Reading data in this mode is the same as reading from the standard read mode except that the data must be read from sectors that have not been erase-suspended. Successively reading from the erase-suspended sector while the device is in the erase-suspend-read mode will cause DQ_2 to toggle. (See the section on DQ_2 .)

After entering the erase-suspend-read mode, the user can program the device by writing the appropriate command sequence for Program. This program mode is known as the erase-suspend-program mode. Again, programming in this mode is the same as programming in the regular Program mode except that the data must be programmed to sectors that are not erase-suspended. Successively reading from the erase-suspended sector while the devices are in the erase-suspend-program mode will cause DQ_2 to toggle. The end of the erase-suspended Program operation is detected by the $\text{RY}/\overline{\text{BY}}$ output pin, $\overline{\text{Data}}$ polling of DQ_7 or by the Toggle Bit I (DQ_6) which is the same as the regular Program operation. Note that DQ_7 must be read from the Program address while DQ_6 can be read from any address within bank being erase-suspended.

To resume the operation of Sector Erase, the Resume command (30h) should be written to the bank being erase suspended. Any further writes of the Resume command at this point will be ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

• Extended Command

(1) Fast Mode

MBM29DL32XTE/BE has Fast Mode function. This mode dispenses with the initial two unlock cycles required in the standard program command sequence by writing Fast Mode command into the command register. In this mode, the required bus cycle for programming is two cycles instead of four bus cycles in standard program command. (Do not write erase command in this mode.) The read operation is also executed after exiting this mode. To exit this mode, it is necessary to write Fast Mode Reset command into the command register. The first cycle must contain the bank address. (Refer to the “Extended Sector Group Protection Algorithm” in “■ FLOW CHART”.) The V_{CC} active current is required even $\overline{\text{CE}} = V_{IH}$ during Fast Mode.

(2) Fast Programming

During Fast Mode, the programming can be executed with two bus cycles operation. The Embedded Program Algorithm is executed by writing program set-up command (A0h) and data write cycles (PA/PD) . (Refer to the “Extended Sector Group Protection Algorithm” in “■ FLOW CHART”).)

(3) Extended Sector Group Protection

In addition to normal sector group protection, the MBM29DL32XTE/BE has Extended Sector Group Protection as extended function. This function enable to protect sector group by forcing V_{ID} on $\overline{RESET}$ pin and write a command sequence. Unlike conventional procedure, it is not necessary to force V_{ID} and control timing for control pins. The only $\overline{RESET}$ pin requires V_{ID} for sector group protection in this mode. The extended sector group protection requires V_{ID} on $\overline{RESET}$ pin. With this condition, the operation is initiated by writing the set-up command (60h) into the command register. Then, the sector group addresses pins ($A_{20}, A_{19}, A_{18}, A_{17}, A_{16}, A_{15}, A_{14}, A_{13}$ and A_{12}) and (A_6, A_1, A_0) = (0, 1, 0) should be set to the sector group to be protected (recommend to set V_{IL} for the other addresses pins) , and write extended sector group protection command (60h) . A sector group is typically protected in 250 μ s. To verify programming of the protection circuitry, the sector group addresses pins ($A_{20}, A_{19}, A_{18}, A_{17}, A_{16}, A_{15}, A_{14}, A_{13}$ and A_{12}) and (A_6, A_1, A_0) = (0, 1, 0) should be set and write a command (40h) . Following the command write, a logical “1” at device output DQ_0 will produce for protected sector in the read operation. If the output data is logical “0”, please repeat to write extended sector group protection command (60h) again. To terminate the operation, it is necessary to set $\overline{RESET}$ pin to V_{IH} . (Refer to the “Extended Sector Group Protection Timing Diagram” in “■ TIMING DIAGRAM” and “Extended Sector Group Protection Algorithm” in “■ FLOW CHART”).)

(4) CFI (Common Flash Memory Interface)

The CFI (Common Flash Memory Interface) specification outlines device and host system software interrogation handshake which allows specific vendor-specified software algorithms to be used for entire families of devices. This allows device-independent, JEDEC ID-independent, and forward-and backward-compatible software support for the specified flash device families. Refer to CFI specification in detail.

The operation is initiated by writing the query command (98h) into the command register. The bank address should be set when writing this command. Then the device information can be read from the bank, and an actual data of memory cell be read from the another bank. Following the command write, a read cycle from specific address retrieves device information. Please note that output data of upper byte (DQ_{15} to DQ_8) is “0” in word mode (16 bit) read. Refer to the CFI code table. To terminate operation, it is necessary to write the read/reset command sequence into the register. (See “Common Flash Memory Interface Code” in “■ FLEXIBLE SECTOR-ERASE ARCHITECTURE”).)

• HiddenROM Region

The HiddenROM feature provides a Flash memory region that the system may access through a new command sequence. This is primarily intended for customers who wish to use an Electronic Serial Number (ESN) in the device with the ESN protected against modification. Once the HiddenROM region is protected, any further modification of that region is impossible. This ensures the security of the ESN once the product is shipped to the field.

The HiddenROM region is 64 Kbytes in length and is stored at the same address of the 8 KB $\times$ 8 sectors. The MBM29DL32XTE occupies the address of the byte mode 3F0000h to 3FFFFFFh (word mode 1F8000h to 1FFFFFFh) and the MBM29DL32XBE type occupies the address of the byte mode 000000h to 00FFFFFFh (word mode 000000h to 007FFFFh) . After the system has written the Enter HiddenROM command sequence, the system may read the HiddenROM region by using the addresses normally occupied by the boot sectors. That is, the device sends all commands that would normally be sent to the boot sectors to the HiddenROM region. This mode of operation continues until the system issues the Exit HiddenROM command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to the boot sectors.

When reading the HiddenROM region, either change addresses or change $\overline{CE}$ pin from “H” to “L”. The same procedure should be taken (changing addresses or $\overline{CE}$ pin from “H” to “L”) after the system issues the Exit HiddenROM command sequence to read actual data of memory cell.

• HiddenROM Entry Command

MBM29DL32XTE/BE has a HiddenROM area with One Time Protect function. This area is to enter the security code and to enable the change of the code once set. Program/erase is possible in this area until it is protected. However, once it is protected, it is impossible to unprotect, so please use this with caution.

HiddenROM area is 64 KByte and in the same address area of 8 KB sector. The address of top boot is 3F0000h to 3FFFFFFh at byte mode (1F8000h to 1FFFFFFh at word mode) and the bottom boot is 000000h to 00FFFFh at byte mode (000000h to 007FFFh at word mode) . These areas are normally the boot block area (8 KB ×8 sector) . Therefore, write the HiddenROM entry command sequence to enter the HiddenROM area. It is called as HiddenROM mode when the HiddenROM area appears.

Sector other than the boot block area could be read during HiddenROM mode. Read/program/erase of the HiddenROM area is possible during HiddenROM mode. Write the HiddenROM reset command sequence to exit the HiddenROM mode. The bank address of the HiddenROM should be set on the third cycle of this reset command sequence.

• HiddenROM Program Command

To program the data to the HiddenROM area, write the HiddenROM program command sequence during HiddenROM mode. This command is same as the program command in the past except to write the command during HiddenROM mode. Therefore the detection of completion method is the same as in the past, using the DQ₇ data poling, DQ₆ toggle bit and RY/ $\overline{BY}$ pin. Need to pay attention to the address to be programmed. If the address other than the HiddenROM area is selected to program, the data of the address will be changed.

• HiddenROM Erase Command

To erase the HiddenROM area, write the HiddenROM erase command sequence during HiddenROM mode. This command is same as the sector erase command in the past except to write the command during HiddenROM mode. Therefore the detection of completion method is the same as in the past, using the DQ₇ data poling, DQ₆ toggle bit and RY/ $\overline{BY}$ pin. Need to pay attention to the sector address to be erased. If the sector address other than the HiddenROM area is selected, the data of the sector will be changed.

• HiddenROM Protect Command

There are two methods to protect the HiddenROM area. One is to write the sector group protect setup command (60h) , set the sector address in the HiddenROM area and (A_6, A_1, A_0) = (0, 1, 0) , and write the sector group protect command (60h) during the HiddenROM mode. The same command sequence could be used because except that it is in the HiddenROM mode and that it does not apply high voltage to $\overline{RESET}$ pin, it is the same as the extension sector group protect in the past. Please refer to “Function Explanation **Extended Command** (3) Extended Sector Group Protection” for details of extension sector group protect setting.

The other is to apply high voltage (V_{ID}) to A_9 and $\overline{OE}$, set the sector address in the HiddenROM area and (A_6, A_1, A_0) = (0, 1, 0) , and apply the write pulse during the HiddenROM mode. To verify the protect circuit, apply high voltage (V_{ID}) to A_9 , specify (A_6, A_1, A_0) = (0, 1, 0) and the sector address in the HiddenROM area, and read. When “1” appears to DQ₀, the protect setting is completed. “0” will appear to DQ₀ if it is not protected. Please apply write pulse again. The same command sequence could be used for the above method because other than the HiddenROM mode, it is the same as the sector group protect in the past. Please refer to “Function Explanation **Sector Group Protection**” for details of sector group protect setting

Other sector group will be effected if the address other than the HiddenROM area is selected for the sector group address, so please be careful. Once it is protected, protection can not be cancelled, so please pay closest attention.

• Write Operation Status

Detailed in “Hardware Sequence Flags” in “■ COMMAND DEFINITIONS” are all the status flags that can determine the status of the bank for the current mode operation. The read operation from the bank where is not operate Embedded Algorithm returns a data of memory cell. These bits offer a method for determining whether a Embedded Algorithm is completed properly. The information on DQ₂ is address sensitive. This means that if an address from an erasing sector is consecutively read, then the DQ₂ bit will toggle. However, DQ₂ will not toggle if an address from a non-erasing sector is consecutively read. This allows the user to determine which sectors are erasing and which are not.

The status flag is not output from bank (non-busy bank) not executing Embedded Algorithm. For example, there is bank (busy bank) which is now executing Embedded Algorithm. When the read sequence is [1] < busy bank > , [2] < non-busy bank > , [3] < busy bank > , the DQ₆ is toggling in the case of [1] and [3]. In case of [2], the data of memory cell is outputted. In the erase-suspend read mode with the same read sequence, DQ₆ will not be toggled in the [1] and [3].

In the erase suspend read mode, DQ₂ is toggled in the [1] and [3]. In case of [2], the data of memory cell is outputted.

Hardware Sequence Flags

Status			DQ ₇	DQ ₆	DQ ₅	DQ ₃	DQ ₂
In Progress	Embedded Program Algorithm		$\overline{DQ_7}$	Toggle	0	0	1
	Embedded Erase Algorithm		0	Toggle	0	1	Toggle* ¹
	Erase Suspended Mode	Erase Suspend Read (Erase Suspended Sector)	1	1	0	0	Toggle
		Erase Suspend Read (Non-Erase Suspended Sector)	Data	Data	Data	Data	Data
		Erase Suspend Program (Non-Erase Suspended Sector)	$\overline{DQ_7}$	Toggle	0	0	1* ²
	Program Suspended Mode	Program Suspend Read (Program Suspended Sector)	Data	Data	Data	Data	Data
		Program Suspend Read (Non-Program Suspended Sector)	Data	Data	Data	Data	Data
Exceeded Time Limits	Embedded Program Algorithm		$\overline{DQ_7}$	Toggle	1	0	1
	Embedded Erase Algorithm		0	Toggle	1	1	N/A
	Erase Suspended Mode	Erase Suspend Program (Non-Erase Suspended Sector)	$\overline{DQ_7}$	Toggle	1	0	N/A

*1 : Successive reads from the erasing or erase-suspend sector causes DQ₂ to toggle.

*2 : Reading from non-erase suspend sector address will indicate logic “1” at the DQ₂ bit.

• DQ₇

Data Polling

The MBM29DL32XTE/BE devices feature Data Polling as a method to indicate to the host that the Embedded Algorithms are in progress or completed. During the Embedded Program Algorithm an attempt to read the devices will produce the complement of the data last written to DQ₇. Upon completion of the Embedded Program Algorithm, an attempt to read the device will produce the true data last written to DQ₇. During the Embedded Erase Algorithm, an attempt to read the device will produce a “0” at the DQ₇ output. Upon completion of the

Embedded Erase Algorithm an attempt to read the device will produce a “1” at the DQ₇ output. The flowchart for Data Polling (DQ₇) is shown in “Data Polling Algorithm” in “■ FLOW CHART”.

For programming, the $\overline{\text{Data}}$ Polling is valid after the rising edge of fourth write pulse in the four write pulse sequence.

For chip erase and sector erase, the $\overline{\text{Data}}$ Polling is valid after the rising edge of the sixth write pulse in the six write pulse sequence. Data Polling also works as a flag to indicate whether the device is in erase-suspended mode. DQ₇ goes from “0” to “1” during erase-suspended mode. Notice that to determine DQ₇ entering erase-suspended mode, indicate the sector address of sector being erased. $\overline{\text{Data}}$ Polling must be performed at sector address within any of the sectors being erased and not a protected sector. Otherwise, the status may not be valid.

If a program address falls within a protected sector, $\overline{\text{Data}}$ Polling on DQ₇ is active for approximately 1 μs , then that bank returns to the read mode. After an erase command sequence is written, if all sectors selected for erasing are protected, $\overline{\text{Data}}$ Polling on DQ₇ is active for approximately 400 μs , then the bank returns to read mode.

Once the Embedded Algorithm operation is close to being completed, the MBM29DL32XTE/BE data pins (DQ₇) may change asynchronously while the output enable ($\overline{\text{OE}}$) is asserted low. This means that the devices are driving status information on DQ₇ at one instant of time and then that byte's valid data at the next instant of time. Depending on when the system samples the DQ₇ output, it may read the status or valid data. Even if the device has completed the Embedded Algorithm operation and DQ₇ has a valid data, the data outputs on DQ₀ to DQ₆ may be still invalid. The valid data on DQ₀ to DQ₇ will be read on the successive read attempts.

The Data Polling feature is only active during the Embedded Programming Algorithm, Embedded Erase Algorithm or sector erase time-out. (See “Hardware Sequence Flags” in “■ COMMAND DEFINITIONS”).

See “Data Polling during Embedded Algorithm Operation Timing Diagram” in “■ TIMING DIAGRAM” for the Data Polling timing specifications and diagrams.

• DQ₆

Toggle Bit I

The MBM29DL32XTE/BE also feature the “Toggle Bit I” as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During an Embedded Program or Erase Algorithm cycle, successive attempts to read ($\overline{\text{OE}}$ toggling) data from the devices will result in DQ₆ toggling between one and zero. Once the Embedded Program or Erase Algorithm cycle is completed, DQ₆ will stop toggling and valid data will be read on the next successive attempts. During programming, the Toggle Bit I is valid after the rising edge of the fourth write pulse in the four write pulse sequence. For chip erase and sector erase, the Toggle Bit I is valid after the rising edge of the sixth write pulse in the six write pulse sequence. The Toggle Bit I is active during the sector time out.

In programming, if the sector being written to is protected, the toggle bit will toggle for about 1 μs and then stop toggling without the data having changed. In erase, the devices will erase all the selected sectors except for the ones that are protected. If all selected sectors are protected, the chip will toggle the toggle bit for about 400 μs and then drop back into read mode, having changed none of the data.

Either $\overline{\text{CE}}$ or $\overline{\text{OE}}$ toggling will cause the DQ₆ to toggle. In addition, an Erase Suspend/Resume command will cause the DQ₆ to toggle.

The system can use DQ₆ to determine whether a sector is actively erasing or is erase-suspended. When a bank is actively erasing (that is, the Embedded Erase Algorithm is in progress), DQ₆ toggles. When a bank enters the Erase Suspend mode, DQ₆ stops toggling. Successive read cycles during the erase-suspend-program cause DQ₆ to toggle.

To operate toggle bit function properly, $\overline{\text{CE}}$ or $\overline{\text{OE}}$ must be high when bank address is changed.

See “Toggle Bit I during Embedded Algorithm Operation Timing Diagram” in “■ TIMING DIAGRAM” for the Toggle Bit I timing specifications and diagrams.

- DQ₅

Exceeded Timing Limits

DQ₅ will indicate if the program or erase time has exceeded the specified limits (internal pulse count) . Under these conditions DQ₅ will produce a “1”. This is a failure condition which indicates that the program or erase cycle was not successfully completed. $\overline{\text{Data}}$ Polling is the only operating function of the devices under this condition. The $\overline{\text{CE}}$ circuit will partially power down the device under these conditions (to approximately 2 mA) . The $\overline{\text{OE}}$ and $\overline{\text{WE}}$ pins will control the output disable functions as described in “MBM29DL32XTE/BE User Bus Operations ($\overline{\text{BYTE}} = V_{IH}$) ” and “MBM29DL32XTE/BE User Bus Operations ($\overline{\text{BYTE}} = V_{IL}$) ” in “■ DEVICE BUS OPERATION”.

The DQ₅ failure condition may also appear if a user tries to program a non blank location without erasing. In this case the devices lock out and never complete the Embedded Algorithm operation. Hence, the system never reads a valid data on DQ₇ bit and DQ₆ never stops toggling. Once the devices have exceeded timing limits, the DQ₅ bit will indicate a “1.” Please note that this is not a device failure condition since the devices were incorrectly used. If this occurs, reset the device with command sequence.

- DQ₃

Sector Erase Timer

After the completion of the initial sector erase command sequence the sector erase time-out will begin. DQ₃ will remain low until the time-out is complete. $\overline{\text{Data}}$ Polling and Toggle Bit are valid after the initial sector erase command sequence.

If $\overline{\text{Data}}$ Polling or the Toggle Bit I indicates the device has been written with a valid erase command, DQ₃ may be used to determine if the sector erase timer window is still open. If DQ₃ is high (“1”) the internally controlled erase cycle has begun. If DQ₃ is low (“0”) the device will accept additional sector erase commands. To insure the command has been accepted, the system software should check the status of DQ₃ prior to and following each subsequent Sector Erase command. If DQ₃ were high on the second status check, the command may not have been accepted.

See “Hardware Sequence Flags” in “■ COMMAND DEFINITIONS” : Hardware Sequence Flags.

- DQ₂

Toggle Bit II

This toggle bit II, along with DQ₆, can be used to determine whether the devices are in the Embedded Erase Algorithm or in Erase Suspend.

Successive reads from the erasing sector will cause DQ₂ to toggle during the Embedded Erase Algorithm. If the devices are in the erase-suspended-read mode, successive reads from the erase-suspended sector will cause DQ₂ to toggle. When the devices are in the erase-suspended-program mode, successive reads from the byte address of the non-erase suspended sector will indicate a logic “1” at the DQ₂ bit.

DQ₆ is different from DQ₂ in that DQ₆ toggles only when the standard program or Erase, or Erase Suspend Program operation is in progress. The behavior of these two status bits, along with that of DQ₇, is summarized as follows :

For example, DQ₂ and DQ₆ can be used together to determine if the erase-suspend-read mode is in progress. (DQ₂ toggles while DQ₆ does not.) See also “Toggle Bit Status” in “■ COMMAND DEFINITIONS” and “DQ₂ vs. DQ₆” in “■ TIMING DIAGRAM”.

Furthermore, DQ₂ can also be used to determine which sector is being erased. When the device is in the erase mode, DQ₂ toggles if this bit is read from an erasing sector.

To operate toggle bit function properly, $\overline{\text{CE}}$ or $\overline{\text{OE}}$ must be high when bank address is changed.

Reading Toggle Bits DQ₆/DQ₂

Whenever the system initially begins reading toggle bit status, it must read DQ₇ to DQ₀ at least twice in a row to determine whether a toggle bit is toggling. Typically a system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device has completed the program or erase operation. The system can read array data on DQ₇ to DQ₀ on the following read cycle.

However, if, after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ₅ is high (see the section on DQ₅). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ₅ went high. If the toggle bit is no longer toggling, the device has successfully completed the program or erase operation. If it is still toggling, the device did not complete the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ₅ has not gone high. The system may continue to monitor the toggle bit and DQ₅ through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation. (Refer to “Toggle Bit Algorithm” in “■ FLOW CHART”.)

Toggle Bit Status

Mode	DQ ₇	DQ ₆	DQ ₂
Program	$\overline{\text{DQ}}_7$	Toggle	1
Erase	0	Toggle	Toggle ^{*1}
Erase-Suspend Read (Erase-Suspended Sector)	1	1	Toggle
Erase-Suspend Program	$\overline{\text{DQ}}_7$	Toggle	1 ^{*2}

*1 : Successive reads from the erasing or erase-suspend sector will cause DQ₂ to toggle.

*2 : Reading from the non-erase suspend sector address will indicate logic “1” at the DQ₂ bit.

• RY/ $\overline{\text{BY}}$

Ready/Busy

The MBM29DL32XTE/BE provide a RY/ $\overline{\text{BY}}$ open-drain output pin as a way to indicate to the host system that the Embedded Algorithms are either in progress or has been completed. If the output is low, the devices are busy with either a program or erase operation. If the output is high, the devices are ready to accept any read/write or erase operation. If the MBM29DL32XTE/BE are placed in an Erase Suspend mode, the RY/ $\overline{\text{BY}}$ output will be high.

During programming, the RY/ $\overline{\text{BY}}$ pin is driven low after the rising edge of the fourth write pulse. During an erase operation, the RY/ $\overline{\text{BY}}$ pin is driven low after the rising edge of the sixth write pulse. The RY/ $\overline{\text{BY}}$ pin will indicate a busy condition during the $\overline{\text{RESET}}$ pulse. Refer to “RY/ $\overline{\text{BY}}$ Timing Diagram during Program/Erase Operations” and “ $\overline{\text{RESET}}$, RY/ $\overline{\text{BY}}$ Timing Diagram” for a detailed timing diagram. The RY/ $\overline{\text{BY}}$ pin is pulled high in standby mode.

Since this is an open-drain output, the pull-up resistor needs to be connected to V_{CC}; multiples of devices may be connected to the host system via more than one RY/ $\overline{\text{BY}}$ pin in parallel.

- **Data Protection**

The MBM29DL32XTE/BE are designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transitions. During power up the devices automatically reset the internal state machine in the Read mode. Also, with its control register architecture, alteration of the memory contents only occurs after successful completion of specific multi-bus cycle command sequences.

The devices also incorporate several features to prevent inadvertent write cycles resulting from V_{CC} power-up and power-down transitions or system noise.

- **Low V_{CC} Write Inhibit**

To avoid initiation of a write cycle during V_{CC} power-up and power-down, a write cycle is locked out for V_{CC} less than V_{LKO} (Min) . If $V_{CC} < V_{LKO}$, the command register is disabled and all internal program/erase circuits are disabled. Under this condition the device will reset to the read mode. Subsequent writes will be ignored until the V_{CC} level is greater than V_{LKO} . It is the users responsibility to ensure that the control pins are logically correct to prevent unintentional writes when V_{CC} is above V_{LKO} (Min) .

If Embedded Erase Algorithm is interrupted, there is possibility that the erasing sector (s) cannot be used.

- **Write Pulse “Glitch” Protection**

Noise pulses of less than 3 ns (typical) on $\overline{OE}$, $\overline{CE}$, or $\overline{WE}$ will not initiate a write cycle.

- **Logical Inhibit**

Writing is inhibited by holding any one of $\overline{OE} = V_{IL}$, $\overline{CE} = V_{IH}$, or $\overline{WE} = V_{IH}$. To initiate a write cycle $\overline{CE}$ and $\overline{WE}$ must be a logical zero while $\overline{OE}$ is a logical one.

- **Power-Up Write Inhibit**

Power-up of the devices with $\overline{WE} = \overline{CE} = V_{IL}$ and $\overline{OE} = V_{IH}$ will not accept commands on the rising edge of $\overline{WE}$. The internal state machine is automatically reset to the read mode on power-up.

- **Sector Group Protection**

Device user is able to protect each sector group individually to store and protect data. Protection circuit voids both write and erase commands that are addressed to protected sectors.

Any commands to write or erase addressed to protected sector are ignored (see “■ FUNCTIONAL DESCRIPTION Sector Group Protection”)

■ ABSOLUTE MAXIMUM RATINGS (See WARNING)

Parameter	Symbol	Rating		Unit
		Min	Max	
Storage Temperature	T _{stg}	−55	+125	°C
Ambient Temperature with Power Applied	T _A	−40	+85	°C
Voltage with Respect to Ground All pins except A ₉ , $\overline{\text{OE}}$, $\overline{\text{RESET}}$ *1, *2	V _{IN} , V _{OUT}	−0.5	V _{CC} + 0.5	V
Power Supply Voltage *1	V _{CC}	−0.5	+4.0	V
A ₉ , $\overline{\text{OE}}$, and $\overline{\text{RESET}}$ *1, *3	V _{IN}	−0.5	+13.0	V
$\overline{\text{WP/ACC}}$ *1, *4	V _{ACC}	−0.5	+10.5	V

*1 : Voltage is defined on the basis of V_{SS} = GND = 0 V.

*2 : Minimum DC voltage on input or I/O pins is −0.5 V. During voltage transitions, input or I/O pins may undershoot V_{SS} to −2.0 V for periods of up to 20 ns. Maximum DC voltage on input or I/O pins is V_{CC} + 0.5 V. During voltage transitions, input or I/O pins may overshoot to V_{CC} + 2.0 V for periods of up to 20 ns.

*3 : Minimum DC input voltage on A₉, $\overline{\text{OE}}$ and $\overline{\text{RESET}}$ pins is −0.5 V. During voltage transitions, A₉, $\overline{\text{OE}}$ and $\overline{\text{RESET}}$ pins may undershoot V_{SS} to −2.0 V for periods of up to 20 ns. Voltage difference between input and supply voltage (V_{IN} − V_{CC}) does not exceed +9.0 V. Maximum DC input voltage on A₉, $\overline{\text{OE}}$ and $\overline{\text{RESET}}$ pins is +13.0 V which may overshoot to +14.0 V for periods of up to 20 ns.

*4 : Minimum DC input voltage on $\overline{\text{WP/ACC}}$ pin is −0.5 V. During voltage transitions, $\overline{\text{WP/ACC}}$ pin may undershoot V_{SS} to −2.0 V for periods of up to 20 ns. Maximum DC input voltage on $\overline{\text{WP/ACC}}$ pin is +10.5 V which may overshoot to +12.0 V for periods of up to 20 ns when V_{CC} is applied.

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

■ RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Conditions	Value		Unit
			Min	Max	
Ambient Temperature	T _A	MBM29DL32XTE/BE80/90	−40	+85	°C
Power Supply Voltage*	V _{CC}	MBM29DL32XTE/BE80	+3.0	+3.6	V
		MBM29DL32XTE/BE90	+2.7	+3.6	V

* : Voltage is defined on the basis of V_{SS} = GND = 0 V.

Note : Operating ranges define those limits between which the functionality of the devices are guaranteed.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

Address to Output Delay	t _{AVQV}	t _{ACC}	$\overline{CE} = V_{IL}$ $\overline{OE} = V_{IL}$	—	80	—	90	ns
Chip Enable to Output Delay	t _{ELQV}	t _{CE}	$\overline{OE} = V_{IL}$	—	80	—	90	ns
Output Enable to Output Delay	t _{GLQV}	t _{OE}	—	—	30	—	35	ns
Chip Enable to Output High-Z	t _{EHQZ}	t _{DF}	—	—	25	—	30	ns
Output Enable to Output High-Z	t _{GHQZ}	t _{DF}	—	—	25	—	30	ns
Output Hold Time from Addresses, $\overline{CE}$ or $\overline{OE}$, Whichever Occurs First	t _{AXQX}	t _{OH}	—	0	—	0	—	ns
$\overline{RESET}$ Pin Low to Read Mode	—	t _{READY}	—	—	20	—	20	μs
$\overline{CE}$ to $\overline{BYTE}$ Switching Low or High	—	t _{ELFL} t _{ELFH}	—	—	5	—	5	ns

Note : Test Conditions :

Output Load : 1 TTL gate and 30 pF (MBM29DL32XTE/BE80)

1 TTL gate and 100 pF (MBM29DL32XTE/BE90)

Input rise and fall times : 5 ns

Input pulse levels : 0.0 V or 3.0 V

Timing measurement reference level

Input : 1.5 V

Output : 1.5 V

- Notes :
- $C_L = 30$ pF including jig capacitance (MB29DL32XTE/BE80)
 - $C_L = 100$ pF including jig capacitance (MB29DL32XTE/BE90)

Test Conditions

• Write/Erase/Program Operations

Parameter		Symbol		Value						Unit
				80			90			
		JEDEC	Standard	Min	Typ	Max	Min	Typ	Max	
Write Cycle Time		t _{AVAV}	t _{WC}	80	—	—	90	—	—	ns

*1 : This does not include preprogramming time.

*2 : This timing is for Sector Group Protection operation.

*3 : This timing is limited for Accelerated Program Operation only.

■ ERASE AND PROGRAMMING PERFORMANCE

Parameter	Limit			Unit	Comments
	Min	Typ	Max		
Sector Erase Time	—	1	10	s	Excludes programming time prior to erasure
Word Programming Time	—	16	360	μs	Excludes system-level overhead
Byte Programming Time	—	8	300	μs	
Chip Programming Time	—	—	100	s	Excludes system-level overhead
Program/Erase Cycle	100,000	—	—	cycle	—

■ PIN CAPACITANCE

Parameter	Symbol	Test setup	Typ	Max	Unit
Input Capacitance	C _{IN}	V _{IN} = 0	6.0	7.5	pF
Output Capacitance	C _{OUT}	V _{OUT} = 0	8.5	12.0	pF
Control Pin Capacitance	C _{IN2}	V _{IN} = 0	8.0	11.0	pF
WP/ACC Pin Capacitance	C _{IN3}	V _{IN} = 0	21.5	22.5	pF

Notes : • Test conditions T_A = +25 °C, f = 1.0 MHz
 • DQ_{15/A-1} pin capacitance is stipulated by output capacitance.

■ FBGA PIN CAPACITANCE

Parameter	Symbol	Condition	Typ	Max	Unit
Input Capacitance	C _{IN}	V _{IN} = 0	7.0	9.0	pF
Output Capacitance	C _{OUT}	V _{OUT} = 0	9.5	13.0	pF
Control Pin Capacitance	C _{IN2}	V _{IN} = 0	9.0	12.0	pF
WP/ACC Pin Capacitance	C _{IN3}	V _{IN} = 0	21.5	22.5	pF

Notes : • Test conditions T_A = +25 °C, f = 1.0 MHz
 • DQ_{15/A-1} pin capacitance is stipulated by output capacitance.

■ TIMING DIAGRAM

• Key to Switching Waveforms

WAVEFORM	INPUTS	OUTPUTS
	Must Be Steady	Will Be Steady
	May Change from H to L	Will Change from H to L
	May Change from L to H	Will Change from L to H
	"H" or "L" Any Change Permitted	Changing State Unknown
	Does Not Apply	Center Line is High-Impedance "Off" State

Read Operation Timing Diagram

- Notes :
- PA is address of the memory location to be programmed.
 - PD is data to be programmed at byte address.
 - $\overline{\text{DQ}}_7$ is the output of the complement of the data written to the device.
 - DOUT is the output of the data written to the device.
 - Figure indicates last two bus cycles out of four bus cycle sequence.
 - These waveforms are for the $\times 16$ mode. (The addresses differ from $\times 8$ mode.)

Alternate $\overline{\text{WE}}$ Controlled Program Operation Timing Diagram

- Notes :
- PA is address of the memory location to be programmed.
 - PD is data to be programmed at byte address.
 - $\overline{DQ_7}$ is the output of the complement of the data written to the device.
 - D_{OUT} is the output of the data written to the device.
 - Figure indicates last two bus cycles out of four bus cycle sequence.
 - These waveforms are for the $\times 16$ mode. (The addresses differ from $\times 8$ mode.)

Alternate $\overline{CE}$ Controlled Program Operation Timing Diagram

* : SA is the sector address for Sector Erase. Addresses = 555h (Word) , AAh (Byte) for Chip Erase.

Note : These waveforms are for the $\times 16$ mode. (The addresses differ from $\times 8$ mode.)

Chip/Sector Erase Operation Timing Diagram

* : DQ_7 = Valid Data (The device has completed the Embedded operation) .

Data Polling during Embedded Algorithm Operation Timing Diagram

* : DQ₆ stops toggling (The device has completed the Embedded operation) .

Toggle Bit I during Embedded Algorithm Operation Timing Diagram

Note : This is example of Read for Bank 1 and Embedded Algorithm (program) for Bank 2.

BA1 : Address corresponding to Bank 1

BA2 : Address corresponding to Bank 2

Bank-to-bank Read/Write Timing Diagram

* : DQ₂ is read from the erase-suspended sector.

DQ₂ vs. DQ₆

■ FLOW CHART

EMBEDDED ALGORITHM

Program Command Sequence (Address/Command):

- Notes :
- The sequence is applied for $\times 16$ mode.
 - The addresses differ from $\times 8$ mode.

Embedded Program™ Algorithm

EMBEDDED ALGORITHM

Chip Erase Command Sequence
(Address/Command):

Individual Sector/Multiple Sector
Erase Command Sequence
(Address/Command):

- Notes :
- The sequence is applied for ×16 mode.
 - The addresses differ from ×8 mode.

Embedded Erase™ Algorithm

VA = Address for programming
 = Any of the sector addresses within the sector being erased during sector erase or multiple sector erases operation.
 = Any of the sector addresses within the sector not being protected during chip erase operation.

* : DQ₇ is rechecked even if DQ₅ = "1" because DQ₇ may change simultaneously with DQ₅.

Data Polling Algorithm

VA = Bank address being executed
Embedded Algorithm.

*1 : Read toggle bit twice to determine whether it is toggling.

*2 : Recheck toggle bit because it may stop toggling as DQ₅ changes to "1".

Toggle Bit Algorithm

* : A₋₁ is V_{IL} on byte mode.

Sector Group Protection Algorithm

*1 : All protected sector groups are unprotected.

*2 : All previously protected sector groups are protected once again.

Temporary Sector Group Unprotection Algorithm

Extended Sector Group Protection Algorithm

FAST MODE ALGORITHM

Note : The sequence is applied for $\times 16$ mode.
The addresses differ from $\times 8$ mode.

Embedded Programming Algorithm for Fast Mode

The contents of this document are subject to change without notice. Customers are advised to consult with FUJITSU sales representatives before ordering.

The information, such as descriptions of function and application circuit examples, in this document are presented solely for the purpose of reference to show examples of operations and uses of Fujitsu semiconductor device; Fujitsu does not warrant proper operation of the device with respect to use based on such information. When you develop equipment incorporating the device based on such information, you must assume any responsibility arising out of such use of the information. Fujitsu assumes no liability for any damages whatsoever arising out of the use of the information.

Any information in this document, including descriptions of function and schematic diagrams, shall not be construed as license of the use or exercise of any intellectual property right, such as patent right or copyright, or any other right of Fujitsu or any third party or does Fujitsu warrant non-infringement of any third-party's intellectual property right or other right by using such information. Fujitsu assumes no liability for any infringement of the intellectual property rights or other rights of third parties which would result from the use of information contained herein.

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for use accompanying fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for use requiring extremely high reliability (i.e., submersible repeater and artificial satellite).

Please note that Fujitsu will not be liable against you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products.

Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the prior authorization by Japanese government will be required for export of those products from Japan.
