Very Low Power CMOS SRAM
64K X 16 bit

Pb-Free and Green package materials are compliant to RoHS

BS616LV1010

n FEATURES

- Wide V_{CC} operation voltage : 2.4V ~ 5.5V
- Very low power consumption :
  - V_{CC} = 3.0V Operation current : 25mA (Max.) at 55ns
    2mA (Max.) at 1MHz
    Standby current : 0.02uA (Typ.) at 25 ^{O}C
  - V_{CC} = 5.0V Operation current : 45mA (Max.) at 55ns
    5mA (Max.) at 1MHz
    Standby current : 0.4uA (Typ.) at 25^{O}C
- High speed access time :
  - -55 55ns(Max.) at V_{CC}=2.7~5.5V
  - -70 70ns(Max.) at V_{CC}=2.4~5.5V
- Automatic power down when chip is deselected
- Easy expansion with $\overline{CE}$ and $\overline{OE}$ options
- I/O Configuration x8/x16 selectable by $\overline{LB}$ and $\overline{UB}$ pin.
- Three state outputs and TTL compatible
- Fully static operation
- Data retention supply voltage as low as 1.5V

n DESCRIPTION

The BS616LV1010 is a high performance, very low power CMOS Static Random Access Memory organized as 65,536 by 16 bits and operates form a wide range of 2.4V to 5.5V supply voltage.

Advanced CMOS technology and circuit techniques provide both high speed and low power features with typical CMOS standby current of 0.02uA at 3.0V/25^{O}C and maximum access time of 55ns at 2.7V/85^{O}C.

Easy memory expansion is provided by an active LOW chip enable ($\overline{CE}$) and active LOW output enable ($\overline{OE}$) and three-state output drivers.

The BS616LV1010 has an automatic power down feature, reducing the power consumption significantly when chip is deselected.

The BS616LV1010 is available in DICE form, JEDEC standard 44-pin TSOP II and 48-ball BGA package.

n PIN DESCRIPTIONS

Name	Function
A0-A15 Address Input	These 16 address inputs select one of the 65,536 x 16-bit in the RAM
$\overline{CE}$ Chip Enable Input	$\overline{CE}$ is active LOW. Chip enable must be active when data read form or write to the device. If chip enable is not active, the device is deselected and is in standby power mode. The DQ pins will be in the high impedance state when the device is deselected.
$\overline{WE}$ Write Enable Input	The write enable input is active LOW and controls read and write operations. With the chip selected, when $\overline{WE}$ is HIGH and $\overline{OE}$ is LOW, output data will be present on the DQ pins; when $\overline{WE}$ is LOW, the data present on the DQ pins will be written into the selected memory location.
$\overline{OE}$ Output Enable Input	The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impendence state when $\overline{OE}$ is inactive.
$\overline{LB}$ and $\overline{UB}$ Data Byte Control Input	Lower byte and upper byte data input/output control pins.
DQ0-DQ15 Data Input/Output Ports	There 16 bi-directional ports are used to read data from or write data into the RAM.
V_{CC}	Power Supply
V_{SS}	Ground

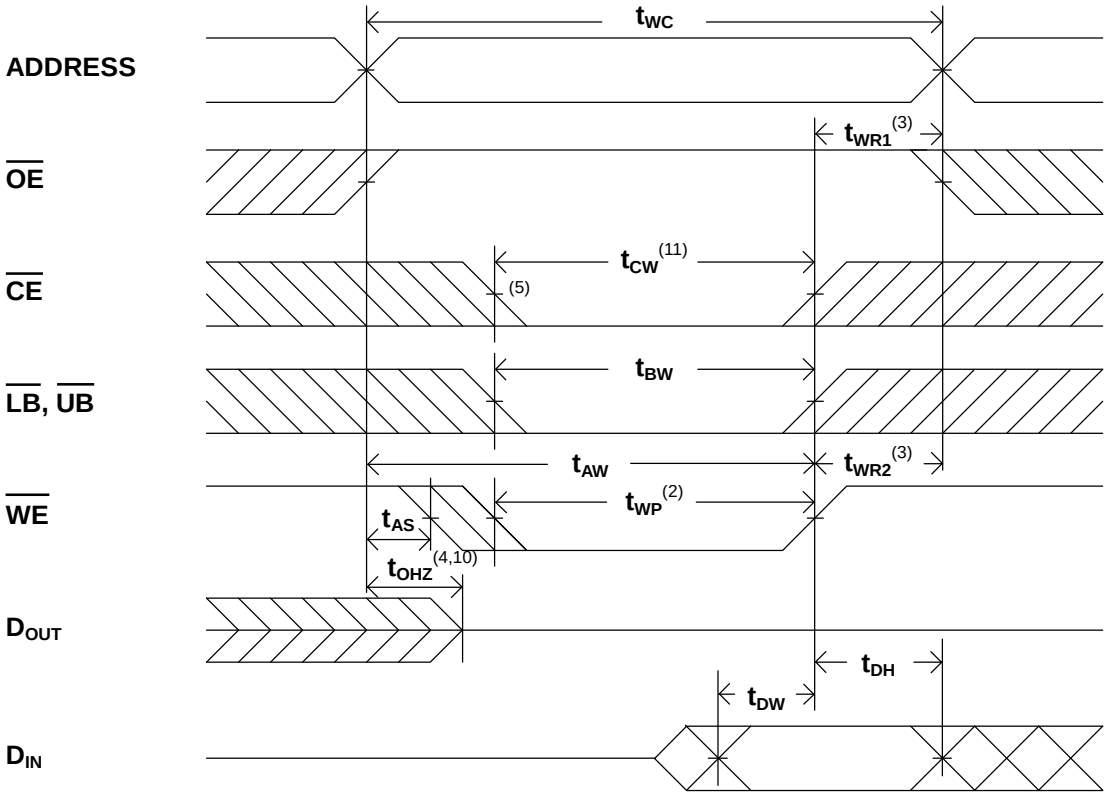
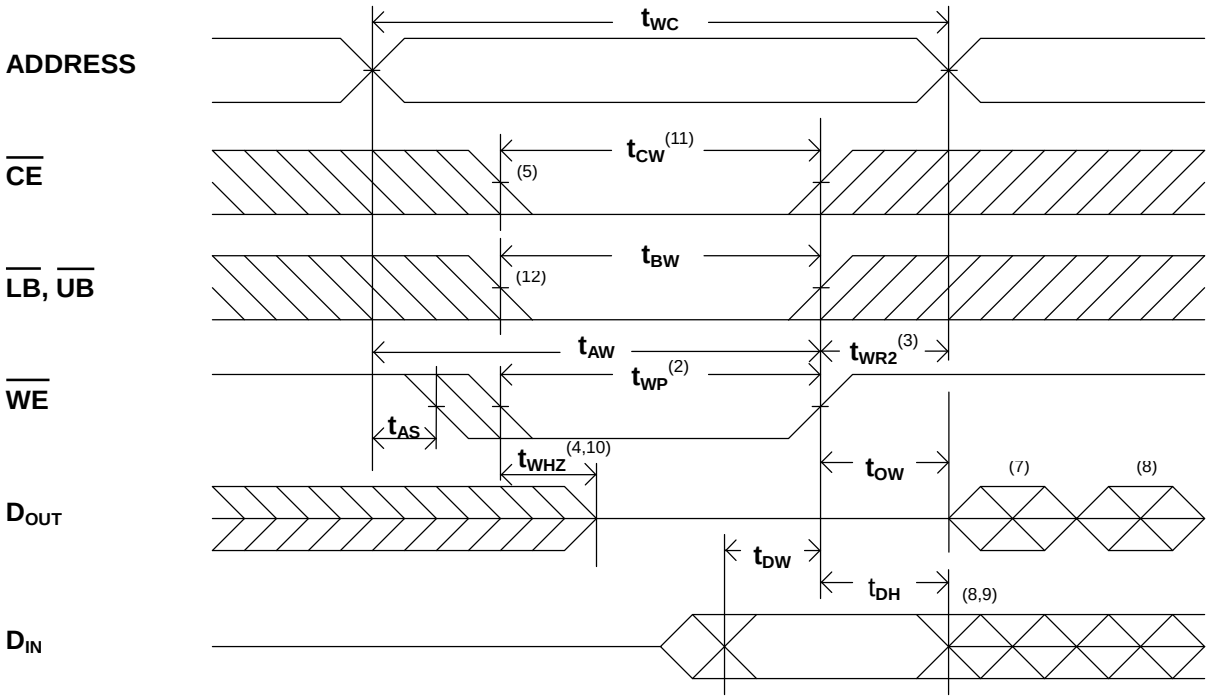
n SWITCHING WAVEFORMS (WRITE CYCLE)

WRITE CYCLE 1 (1)



WRITE CYCLE 2 (1,6)



NOTES:

1. $\overline{WE}$ must be high during address transitions.
2. The internal write time of the memory is defined by the overlap of $\overline{CE}$ and $\overline{WE}$ low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
3. t_{WR} is measured from the earlier of $\overline{CE}$ or $\overline{WE}$ going high at the end of write cycle.
4. During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
5. If the $\overline{CE}$ low transition occurs simultaneously with the $\overline{WE}$ low transitions or after the $\overline{WE}$ transition, output remain in a high impedance state.
6. $\overline{OE}$ is continuously low ($\overline{OE} = V_{IL}$).
7. D_{OUT} is the same phase of write data of this write cycle.
8. D_{OUT} is the read data of next address.
9. If $\overline{CE}$ is low during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
10. Transition is measured ± 500mV from steady state with C_L = 5pF. The parameter is guaranteed but not 100% tested.
11. t_{CW} is measured from the later of $\overline{CE}$ going low to the end of write.
12. The change of Read/Write cycle must accompany with $\overline{CE}$ or address toggled.
