

Normally – OFF Silicon Carbide Junction Transistor

V_{DS}	=	1700 V
$R_{DS(ON)}$	=	20 mΩ
I_D ($T_C = 25^\circ\text{C}$)	=	100 A
I_D ($T_C > 125^\circ\text{C}$)	=	50 A
h_{FE} ($T_C = 25^\circ\text{C}$)	=	100

Features

- 175 °C Maximum Operating Temperature
- Gate Oxide Free SiC Switch
- Exceptional Safe Operating Area
- Excellent Gain Linearity
- Temperature Independent Switching Performance
- Low Output Capacitance
- Positive Temperature Coefficient of $R_{DS,ON}$
- Suitable for Connecting an Anti-parallel Diode

Package

TO-247

Advantages

- Compatible with Si MOSFET/IGBT Gate Drive ICs
- > 20 μs Short-Circuit Withstand Capability
- Lowest-in-class Conduction Losses
- High Circuit Efficiency
- Minimal Input Signal Distortion
- High Amplifier Bandwidth

Applications

- Down Hole Oil Drilling, Geothermal Instrumentation
- Hybrid Electric Vehicles (HEV)
- Solar Inverters
- Switched-Mode Power Supply (SMPS)
- Power Factor Correction (PFC)
- Induction Heating
- Uninterruptible Power Supply (UPS)
- Motor Drives

Section V: Driving the GA50JT17-247

Drive Topology	Gate Drive Power Consumption	Switching Frequency	Application Emphasis	Availability
TTL Logic	High	Low	Wide Temperature Range	Coming Soon
Constant Current	Medium	Medium	Wide Temperature Range	Coming Soon
High Speed – Boost Capacitor	Medium	High	Fast Switching	Production
High Speed – Boost Inductor	Low	High	Ultra Fast Switching	Coming Soon
Proportional	Lowest	High	Wide Drain Current Range	Coming Soon
Pulsed Power	Medium	N/A	Pulse Power	Coming Soon

A: Static TTL Logic Driving

The GA50JT17-247 may be driven using direct (5 V) TTL logic after current amplification. The (amplified) current level of the supply must meet or exceed the steady state gate current ($I_{G,steady}$) required to operate the GA50JT17-247. The power level of the supply can be estimated from the target duty cycle of the particular application. $I_{G,steady}$ is dependent on the anticipated drain current I_D through the SJT and the DC current gain h_{FE} , it may be calculated from the following equation. An accurate value of the h_{FE} may be read from Figure 6.

$$I_{G,steady} \approx \frac{I_D}{h_{FE}(T, I_D)} * 1.5$$

Figure 22: TTL Gate Drive Schematic

B: High Speed Driving

The SJT is a current controlled transistor which requires a positive gate current for turn-on as well as to remain in on-state. An ideal gate current waveform for ultra-fast switching of the SJT, while maintaining low gate drive losses, is shown in Figure 23 which features a positive current peak during turn-on, a negative current peak during turn-off, and continuous gate current to remain on.

Figure 23: An idealized gate current waveform for fast switching of an SJT.

An SJT is rapidly switched from its blocking state to on-state, when the necessary gate charge, Q_G , for turn-on is supplied by a burst of high gate current, $I_{G,on}$, until the gate-source capacitance, C_{GS} , and gate-drain capacitance, C_{GD} , are fully charged.

$$Q_{on} = I_{G,on} * t_1$$

$$Q_{on} \geq Q_{gs} + Q_{gd}$$

Ideally, $I_{G,pon}$ should terminate when the drain voltage falls to its on-state value in order to avoid unnecessary drive losses during the steady on-state. In practice, the rise time of the $I_{G,on}$ pulse is affected by the parasitic inductances, L_{par} in the device package and drive circuit. A voltage developed across the parasitic inductance in the source path, L_s , can de-bias the gate-source junction, when high drain currents begin to flow through the device. The voltage applied to the gate pin should be maintained high enough, above the $V_{GS,sat}$ (see Figure 7) level to counter these effects.

A high negative peak current, $-I_{G,off}$ is recommended at the start of the turn-off transition, in order to rapidly sweep out the injected carriers from the gate, and achieve rapid turn-off. While satisfactory turn off can be achieved with $V_{GS} = 0$ V, a negative gate voltage V_{GS} may be used in order to speed up the turn-off transition.

Two high-speed drive topologies for the SiC SJTs are presented below.

B:1: High Speed, Low Loss Drive with Boost Capacitor, GA03IDDJT30-FR4

The GA50JT17-247 may be driven using a High Speed, Low Loss Drive with Boost Capacitor topology in which multiple voltage levels, a gate resistor, and a gate capacitor are used to provide fast switching current peaks at turn-on and turn-off and a continuous gate current while in on-state. A 3 kV isolated evaluation gate drive board (GA03IDDJT30-FR4) utilizing this topology is commercially available for high and low-side driving, its datasheet provides additional details about this drive topology.

Figure 24: Topology of the GA03IDDJT30-FR4 Two Voltage Source gate driver.

The GA03IDDJT30-FR4 evaluation board comes equipped with two on board gate drive resistors (RG1, RG2) pre-installed for an effective gate resistance³ of $R_G = 3.75 \Omega$. It may be necessary for the user to reduce RG1 and RG2 under high drain current conditions for safe operation of the GA50JT17-247. The steady state current supplied to the gate pin of the GA50JT17-247 with on-board $R_G = 3.75 \Omega$, is shown in Figure 25. The maximum allowable safe value of R_G for the user's required drain current can be read from Figure 26.

For the GA50JT17-247, R_G must be reduced for $I_D \geq \sim 14$ A for safe operation with the GA03IDDJT30-FR4.

For operation at $I_D \geq \sim 14$ A, R_G may be calculated from the following equation, which contains the DC current gain h_{FE} (Figure 6) and the gate-source saturation voltage $V_{GS,sat}$ (Figure 7).

$$R_{G,max} = \frac{(4.7V - V_{GS,sat}) * h_{FE}(T, I_D)}{I_D * 1.5} - 0.6 \Omega$$

Figure 25: Typical steady state gate current supplied by the GA03IDDJT30-FR4 board for the GA50JT17-247 with the on board resistance of 3.75 Ω

Figure 26: Maximum gate resistance for safe operation of the GA50JT17-247 at different drain currents using the GA03IDDJT30-FR4 board.

B:2: High Speed, Low Loss Drive with Boost Inductor

A High Speed, Low-Loss Driver with Boost Inductor is also capable of driving the GA50JT17-247 at high-speed. It utilizes a gate drive inductor instead of a capacitor to provide the high-current gate current pulses $I_{G,on}$ and $I_{G,off}$. During operation, inductor L is charged to a specified $I_{G,on}$ current value then made to discharge I_L into the SiC SGT gate pin using logic control of S_1 , S_2 , S_3 , and S_4 , as shown in Figure 27. After turn on, while the device remains on the necessary steady state gate current $I_{G,steady}$ is supplied from source V_{CC} through R_G . Please refer to the article "A current-source concept for fast and efficient driving of silicon carbide transistors" by Dr. Jacek Rąbkowski for additional information on this driving topology.⁴

Figure 27: Simplified Inductive Pulsed Drive Topology

³ – $R_G = (1/R_{G1} + 1/R_{G2})^{-1}$. Driver is pre-installed with $R_{G1} = R_{G2} = 7.5 \Omega$

C: Proportional Gate Current Driving

For applications in which the GA50JT17-247 will operate over a wide range of drain current conditions, it may be beneficial to drive the device using a proportional gate drive topology to optimize gate drive power consumption. A proportional gate driver relies on instantaneous drain current I_D feedback to vary the steady state gate current $I_{G,steady}$ supplied to the GA50JT17-247

C:1: Voltage Controlled Proportional Driver

The voltage controlled proportional driver relies on a gate drive IC to detect the GA50JT17-247 drain-source voltage V_{DS} during on-state to sense I_D . The gate drive IC will then increase or decrease $I_{G,steady}$ in response to I_D . This allows $I_{G,steady}$, and thus the gate drive power consumption, to be reduced while I_D is relatively low or for $I_{G,steady}$ to increase when I_D is higher. A high voltage diode connected between the drain and sense protects the IC from high-voltage when the driver and GA50JT17-247 are in off-state. A simplified version of this topology is shown in Figure 29, additional information will be available in the future at <http://www.genesicsemi.com/commercial-sic/sic-junction-transistors/>

Figure 28: Simplified Voltage Controlled Proportional Driver

C:2: Current Controlled Proportional Driver

The current controlled proportional driver relies on a low-loss transformer in the drain or source path to provide feedback I_D of the GA50JT17-247 during on-state to supply $I_{G,steady}$ into the device gate. $I_{G,steady}$ will then increase or decrease in response to I_D at a fixed forced current gain which is set by the turns ratio of the transformer, $h_{force} = I_D / I_G = N_2 / N_1$. GA50JT17-247 is initially tuned-on using a gate current pulse supplied into an RC drive circuit to allow I_D current to begin flowing. This topology allows $I_{G,steady}$, and thus the gate drive power consumption, to be reduced while I_D is relatively low or for $I_{G,steady}$ to increase when I_D is higher. A simplified version of this topology is shown in Figure 29, additional information will be available in the future at <http://www.genesicsemi.com/commercial-sic/sic-junction-transistors/>.
