## Features

- **Operating Range from 5 V to 18 V**
- **Baud Rate up to 20 Kbaud**
- **Improved Slew Rate Control According to LIN Specification 2.0**
- **Fully Compatible with 3.3 V and 5 V Devices**
- **Dominant Time-out Function at Transmit Data (TXD)**
- **Normal and Sleep Mode**
- **Wake-up Capability via LIN Bus (90 µs Dominant)**
- **External Wake-up via WAKE Pin (130 µs Low Level)**
- **Control of External Voltage Regulator via INH Pin**
- **Very Low Standby Current During Sleep Mode (10 µA)**
- **60 V Load Dump Protection at LIN Pin (42-V Power Net)**
- **Wake-up Source Recognition**
- **Bus Pin Short-circuit Protected versus GND and Battery**
- **LIN Input Current <3 µA if V$_{BAT}$ Is Disconnected**
- **Overtemperature Protection**
- **High EMC Level**
- **Interference and Damage Protection According to ISO/CD 7637**
- **ESD HBM 6 kV at LIN Bus Pin and Supply VS Pin**

LIN Transceiver

ATA6661

Description

The ATA6661 is a fully integrated LIN transceiver according to the LIN specification 2.0. It interfaces the LIN protocol handler and the physical layer. The device is designed to handle the low-speed data communication in vehicles, e.g., in convenience electronics. Improved slope control at the LIN bus ensures secure data communication up to 20 kBaud with an RC-oscillator for protocol handling. In order to comply with the 42-V power net requirements, the bus output is capable of withstanding high voltages. Sleep mode guarantees minimal current consumption.

Pin Description

Pin	Symbol	Function
1	RXD	Receive data output (open drain)
2	EN	Enables normal mode, when the input is open or low, the device is in sleep mode
3	WAKE	High voltage input for local wake-up request
4	TXD	Transmit data input; active low output (strong pull-down) after a local wake-up request
5	GND	Ground
6	LIN	LIN bus line input/output
7	VS	Battery supply
8	INH	Battery related inhibit output for controlling an external voltage regulator; active high after a wake-up request

Functional Description

Supply Pin (V_S)

Undervoltage detection is implemented to disable transmission if V_S is falling to a value below 5 V to avoid false bus messages. After switching on V_S the IC switches to pre-normal mode and INHIBIT is switched on. The supply current in sleep mode is typically 10 µA.

Ground Pin (GND)

The ATA6661 is neutral on the LIN pin in case of a GND disconnection. It is able to handle a ground shift up to 3 V for V_S > 9 V.

Bus Pin (LIN)

A low-side driver with internal current limitation and thermal shutdown as well as an internal pull-up resistor according to LIN specification 2.0 are implemented. The voltage range is from -27 V to +60 V. This pin exhibits no reverse current from the LIN bus to V_S, even in case of a GND shift or V_{Batt} disconnection. The LIN receiver thresholds are compatible to the LIN protocol specification.The fall time (from recessive to dominant) and the rise time (from dominant to recessive) are slope controlled. The output has a short circuit limitation. This is a self adapting current limitation; i.e., during current limitation as the chip temperature increases so the current reduces.

Input Pin (TXD)

This pin is the microcontroller interface to control the state of the LIN output. TXD is low to bring LIN low. If TXD is high, the LIN output transistor is turned off. In this case, the bus is in recessive mode via the internal pull-up resistor. The TXD pin is compatible to a 3.3 V and 5 V supply.

TXD Dominant Time-out Function

The TXD input has an internal pull-down resistor. An internal timer prevents the bus line from being driven permanently in dominant state. If TXD is forced low longer than $t_{dom} > 4$ ms, the pin LIN will be switched off to recessive mode. To reset this mode switch TXD to high (>10 µs) before switching LIN to dominant again.

Output Pin (RXD)

This pin reports to the microcontroller the state of the LIN bus. LIN high (recessive) is reported by a high level at RXD, LIN low (dominant) is reported by a low voltage at RXD. The output is an open drain, therefore, it is compatible to a 3.3 V or 5 V power supply. The AC characteristics are defined with a pull-up resistor of 5 kΩ to 5 V and a load capacitor of 20 pF. The output is short-current protected. In unpowered mode ($V_S = 0$ V), RXD is switched off. For ESD protection a Zener diode is implemented with $V_Z = 6.1$ V.

Enable Input Pin (EN)

This pin controls the operation mode of the interface. If EN = 1, the interface is in normal mode, with the transmission path from TXD to LIN and from LIN to Rx both active. If EN = 0, the device is switched to sleep mode and no transmission is possible. In sleep mode, the LIN bus pin is connected to V_S with a weak pull-up current source. The device can transmit only after being woken up (see "Inhibit Output Pin (INH)" on page 3).

During sleep mode the device is still supplied from the battery voltage. The supply current is typically 10 µA. The pin EN provides a pull-down resistor in order to force the transceiver into sleep mode in case the pin is disconnected.

Inhibit Output Pin (INH)

This pin is used to control an external switchable voltage regulator having a wake-up input. The inhibit pin provides an internal switch towards pin V_S. If the device is in normal mode, the inhibit high-side switch is turned on and the external voltage regulator is activated. When the device is in sleep mode, the inhibit switch is turned off and disables the voltage regulator.

A wake-up event on the LIN bus or at pin WAKE will switch the INH pin to the V_S level. After a system power-up (V_S rises from zero), the pin INH switches automatically to the V_S level. The R_{DSon} of the highside output is <1 kΩ

Wake-up Input Pin (WAKE)

This pin is a high-voltage input used to wake-up the device from sleep mode. It is usually connected to an external switch in the application to generate a local wake-up. If you do not need a local wake-up in your application, connect pin WAKE directly to pin VS. A pull-up current source with typically -10 µA is implemented. The voltage threshold for a wake-up signal is 3 V below the VS voltage with an output current of typival -3 µA.

Wake-up events from sleep mode:
- LIN bus
- EN pin
- WAKE pin

Figure 3 on page 5, Figure 4 on page 6 and Figure 5 on page 6 show details of wake-up operations.

Mode of Operation

1. Normal mode
   This is the normal transmitting and receiving mode. All features are available.

2. Sleep mode
   In this mode the transmission path is disabled and the device is in low power mode. Supply current from V_{Batt} is typically 10 µA. A wake-up signal from the LIN bus or via pin WAKE will be detected and switches the device to pre-normal mode. If EN, then switches to high, normal mode is activated. Input debounce timers at pin WAKE (T_{WAKE}), LIN (T_{BUS}) and EN (T_{sleep}, T_{nom}) prevent unwanted wake-up events due to automotive transients or EMI. In sleep mode the INH pin is floating. The internal termination between pin LIN and pin V_S is disabled to minimize the power dissipation in case pin LIN is short-circuited to GND. Only a weak pull-up current (typical 10 µA) between pin LIN and pin V_S is present.

3. Pre-normal mode
   At system power-up, the device automatically switches to pre-normal mode. It switches the INH pin to a high state, to the V_S level. The microcontroller of the application will then confirm the normal mode by setting the EN pin to high.

Remote Wake-up via Dominant Bus State

A falling edge at pin LIN, followed by a dominant bus level maintained for a certain time period (T_{BUS}), results in a remote wake-up request. The device switches to pre-normal mode. Pin INH is activated (switches to V_S) and the internal termination resistor is switched on. The remote wake-up request is indicated by a low level at pin RXD to interrupt the microcontroller (see Figure 4 on page 6). The voltage threshold for a wake-up signal is 3 V below the VS voltage with an output current of typival -3 µA.

Local Wake-up via Pin WAKE

A falling edge at pin WAKE, followed by a low level maintained for a certain time period (T_{WAKE}), results in a local wake-up request. The extra long wake-up time (T_{WAKE}) ensures that no transient, according to ISO7637, creates a wake-up. The device switches to pre-normal mode. Pin INH is activated (switches to V_S) and the internal termination resistor is switched on. The local wake-up request is indicated by a low level at pin RXD to interrupt the microcontroller and a strong pull-down at pin TXD (see Figure 5 on page 6).

Wake-up Source Recognition

The device can distinguish between a local wake-up request (pin WAKE) and a remote wake-up request (dominant LIN bus). The wake-up source can be read on pin TXD in pre-normal mode. If an external pull-up resistor (typically 5 kΩ) on pin TXD to the power supply of the microcontroller has been added, a high level indicates a remote wake-up request (weak pull-down at pin TXD) and a low level indicates a local wake-up request (strong pull-down at pin TXD).

The wake-up request flag (signalled on pin RXD) as well as the wake-up source flag (signalled on pin TXD) are reset immediately, if the microcontroller sets pin EN to high (see Figure 4 on page 6 and Figure 5 on page 6).

Figure 3. Mode of Operation

a: $V_S > 5$ V
b: $V_S < 5$ V
c: Bus wake-up event
d: Wake-up from Wake switch
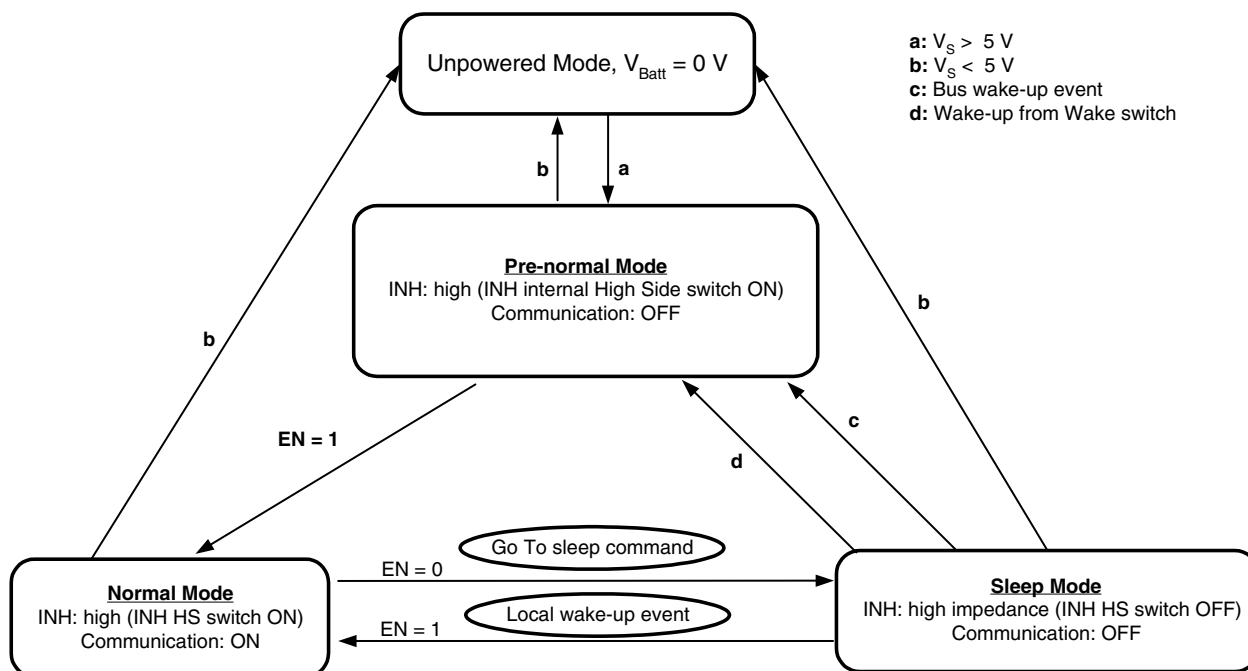

Fail-safe Features

- There are now reverse currents <3 µA at pin LIN during loss of V_{BAT} or GND. Optimal behavior for bus systems where some slave modes supplied from battery or ignition.
- Pin EN provides pull-down resistor to force the transceiver into sleep mode if EN is disconnected.
- Pin RXD is set floating if V_{BAT} is disconnected.
- Pin TXD provides a pull-down resistor to provide a static low if TXD is disconnected.
- The LIN output driver has a current limitation and if the junction temperature T_j exceeds the thermal shut-down temperature T_{off} the output driver switches off.
- The implemented hysteresis T_{hys} enables the LIN output again after the temperature has been decreased.

Absolute Maximum Ratings

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
