### Description

The TLE7273-2 is a monolithic voltage regulator with integrated window watchdog and reset dedicated for microcontroller supplies under harsh automotive environment conditions.

Due to its ultra low quiescent current, the TLE7273-2 is perfectly suited for applications that are permanently connected to battery. In addition, the regulator can be shut down via the Enable input causing the current consumption to drop below  $3 \mu\text{A}$ . The TLE7273-2 is equipped with an output current limitation and an overtemperature shutdown, protecting the device against overload, short circuit and over-temperature. It operates in the wide junction temperature range from  $-40 \text{ }^\circ\text{C}$  to  $150 \text{ }^\circ\text{C}$ .

## 5 Block Description and Electrical Characteristics

### 5.1 Description

#### 5.1.1 Power On Reset and Reset Output

For an output voltage level of  $V_Q \geq 1\text{ V}$ , the reset output is held low. When the level of  $V_Q$  reaches the reset threshold  $V_{RT}$ , the signal at RO remains low for the power-up reset delay time  $t_{RD}$ . The reset function and timing is illustrated in **Figure 4**. The reset reaction time  $t_{RR}$  avoids wrong triggering caused by short “glitches” on the  $V_Q$ -line. In case of  $V_Q$  power down ( $V_Q < V_{RT}$  for  $t > t_{RR}$ ) a logic low signal is generated at the pin RO to reset an external microcontroller.

The TLE7273-2GV50 and TLE7273-2EV50 feature an integrated pull-up resistor on the reset output while the TLE7273-2GV33 and TLE7273-2GV26 have an open drain output requiring an external pull-up resistor. When connected to a voltage level of 5 V, a recommended value for this external resistor is  $\geq 5.6\text{ k}\Omega$ .

But it's also possible calculating its value by using the following formula, based on the reset sink current (Example: external pull-up resistor connected to  $V_{ext} = 5\text{ V}$ ):

$$R_{\text{extmin}} = \Delta V / I_{RO} = (V_{\text{ext}} - V_{RO\text{min}}) / I_{RO} = (5\text{ V} - 0.25\text{ V}) / 1.0\text{ mA} = 4.75\text{ k}\Omega$$

At low output voltage levels  $V_Q < 1\text{ V}$  the integrated pull-up resistor of the TLE7273-2GV50 is switched off setting the reset output high ohmic.

**Figure 4** Reset Function and Timing Diagram

#### 5.1.2 Watchdog Operation

The watchdog uses a fraction of the charge pump oscillator's clock signal as timebase. The watchdog timebase can be adjusted using the pins WM1 and WM2 (see **Figure 5**). The watchdog can be turned off setting WM1 and WM2 to high level. The timing values refer to typ. values with WM1 and WM2 connected to GND (fast watchdog and reset timing).

**Figure 5** shows the state diagram of the window watchdog (WWD) and the watchdog and reset mode selection. After power-on, the reset output signal at the RO pin (microcontroller reset) is kept LOW for the reset delay time  $t_{RD}$  of typ. 16 ms. With the LOW to HIGH transition of the signal at RO the device starts the ignore window time  $t_{CW}$  (32 ms). During this window the signal at the WDI pin is ignored. Next the WWD starts the open window which

**Block Description and Electrical Characteristics**

is in the very first turn after power up a long open window with  $t_{max} = 4 * t_{OW}$ . In the following turns, the timing corresponds to the standard timing setting as described in the specification.

When a valid trigger signal is detected during the open window a closed window is initialized immediately. A trigger signal within the closed window is interpreted as a pretrigger failure and results in a reset. After the closed window the open window with the duration  $t_{OW}$  is started again. The open window lasts at minimum until the trigger process has occurred, at maximum  $t_{OW}$  is 32 ms (typ. value with fast timing).

A HIGH to LOW transition of the watchdog trigger signal at pin WDI is considered as a valid trigger pulse.

See **Figure 7**: To avoid wrong triggering due to parasitic glitches two HIGH samples followed by two LOW samples (sample period  $t_{sam}$  typ. 0.5 ms) are decoded as a valid trigger .

A reset is generated (RO goes LOW) if there is no trigger pulse during the open window or if a pretrigger occurs during the closed window. The triggering is correct also, if the first three samples (two HIGH one LOW) of the trigger pulse at pin WDI are inside the closed window and only the fourth sample (the second LOW sample) is taken in the open window.

After turning OFF the Watchdog by output current reduction, RO remains high. (see also the signal diagram in **Figure 6**). After turning ON the WWD again by exceeding the current threshold, the logic cycle starts again with the Ignore Window and goes then into the "1st. long open window". This 1st long OW is maximum  $4 * t_{OW}$  long and allows the re-synchronisation between the micro controller and the WWD timing. The 1st. long OW is closed by the first valid trigger on WDI from the micro controller. This trigger ensures the synchronisation. As soon as this trigger is done, the micro controller timing must be stable and correspondent to  $t_{WD}$ .
