

11-13.2Vin, 54.2V/4.44A Single Output, High Efficiency SIP Converter

Typical unit

FEATURES

- 240 Watts total output power
- 94% Ultra-high efficiency @ full load, 100LFM
- 12V Input (11-13.2V range)
- 54.2V/4.44A Output for PoE+ (Power-over-Ethernet)
- Input Over/Under Voltage Shutdown
- 320kHz fixed switching frequency
- Fully isolated, 2250V (BASIC)
- Low 500mVp-p ripple/noise max value.
- PGOOD signal
- Stable no-load operation
- Thermal shutdown
- Fully I/O protected
- UL 1950/IEC/EN60950 certification
- Output over voltage latch

ORDERING GUIDE SUMMARY					
Model	Vout Range	Iout Range	Vin Range	Ripple/Noise	Efficiency
SPC-54/4.4-L12PG-C	54.2V	0-4.44A	11-13.2V	500mVp-p (max)	94%
INPUT CHARACTERISTICS					
Parameter	Typ. @ 25°C, full load		Notes		
Voltage Range	11-13.2 Volts		12V nominal		
Current, full power	24.5 Amps		Vin = 11V		
Turn On/Start-up Threshold	10.3-11 Volts		Vin increasing		
Undervoltage Shutdown	9-9.9 Volts		Vin decreasing		
No Load Current	300mA		Vin = 12V		
OUTPUT CHARACTERISTICS					
Parameter	Typ. @ 25°C, full load		Notes		
Voltage	54.2 Volts		±1%		
Current	0 to 4.44 Amps		No minimum load		
Power Output	240 Watts				
Ripple & Noise	500mVp-p		20MHz bandwidth, 100µF output capacitance		
Line and Load Regulation	±1%/±1%				
Overcurrent Protection	5.33 Amps		With hiccup auto-restart		
Overtemperature Protection	130 °C				
Efficiency (minimum)	92.8%		80% load, Vin nom.		
Efficiency (typical)	94%

Notes

- ① Typical at TA = +25°C under nominal line voltage and nominal-load conditions, unless noted.
- ② Devices have no minimum-load requirements and will regulate under no-load conditions.
- ③ External capacitance could be all ceramic or a mix of electrolytic and ceramic.
- ④ a) Period between Vin connection and Vout rising to 10% of final value when Enable signal is existing, or b) Period between Enable signal connection and Vout rising to 10% of final value when Vin is existing.
- ⑤ The output rise time measured from 10% of Vnom to the lower limit of the regulation band with 0% to 100% load and external cap.
- ⑥ The Power supply will start up normally and without any damage under a pre-bias output voltage.
- ⑦ Tested under all loading conditions.
- ⑧ Tested under all loading conditions.
- ⑨ Pgood is referenced to Vin(-). An external pull-up resistor is connected between PGOOD pin and a bias voltage. A high signal shown in the pin represents the good status of the output voltage.
- ⑩ Tested under full operating temperature and input voltage ranges.

Technical Notes

I/O Filtering and Noise Reduction

The SPC is tested and specified with external output capacitors. These capacitors are necessary to accommodate our test equipment and may not be required to achieve desired performance in your application. The SPC is designed with high-quality, high-performance *internal* I/O caps, and will operate within spec in most applications with *no additional external components*.

In particular, the SPC input capacitors are specified for low ESR and are fully rated to handle the units' input ripple currents. Similarly, the internal output capacitors are specified for low ESR and full-range frequency response.

In critical applications, input/output ripple/noise may be further reduced using filtering techniques, the simplest being the installation of external I/O caps.

External input capacitors serve primarily as energy-storage devices. They minimize high-frequency variations in input voltage (usually caused by IR drops in conductors leading to the DC/DC) as the switching converter draws pulses of current. Input capacitors should be selected for bulk capacitance (at appropriate frequencies), low ESR, and high rms-ripple-current ratings. The switching nature of modern DC/DC's requires that the dc input voltage source have low ac impedance at the frequencies of interest. Highly inductive source impedances can greatly affect system stability. Your specific system configuration may necessitate additional considerations.

Input Fusing

Most applications and or safety agencies require the installation of fuses at the inputs of power conversion components. The SPC Series may have an optional input fuse. Therefore, if input fusing is mandatory, either a normal-blow or a fast-blow fuse with a value no greater than twice the maximum input current should be installed within the ungrounded input path to the converter.

Input Overvoltage and Reverse-Polarity Protection

The SPC does not incorporate input reverse-polarity protection. Input voltages in excess of the specified absolute maximum ratings and input polarity reversals of longer than "instantaneous" duration can cause permanent damage to these devices.

Start-Up Time

The V_{IN} to V_{OUT} Start-Up Time is the interval between the time at which a rising input voltage crosses the lower limit of the specified input voltage range

and the fully loaded output voltage enters and remains within its specified regulation band. Actual measured times will vary with input source impedance, external input capacitance, and the slew rate and final value of the input voltage as it appears to the converter.

The On/Off to V_{OUT} Start-Up Time assumes the converter is turned off via the On/Off Control with the nominal input voltage already applied to the converter. The specification defines the interval between the time at which the converter is turned on and the fully loaded output voltage enters and remains within its specified regulation band.

Thermal Considerations and Thermal Protection

The typical output-current thermal-derating curves shown below enable designers to determine how much current they can reliably derive from each model of the SPC under known ambient-temperature and air-flow conditions. Similarly, the curves indicate how much air flow is required to reliably deliver a specific output current at known temperatures.

The highest temperatures in SPC's occur at their output inductor, whose heat is generated primarily by I^2R losses. The derating curves were developed using thermocouples to monitor the inductor temperature and varying the load to keep that temperature below +110°C under the assorted conditions of air flow and air temperature. Once the temperature exceeds +125°C (approx.), the thermal protection will disable the converter using the hiccup shutdown mode.

Undervoltage Shutdown

When the input voltage falls below the undervoltage threshold, the converter will terminate its output. However, this is not a latching shutdown mode. As soon as the input voltage rises above the Start-Up Threshold, the converter will restore normal operation. This small amount of hysteresis prevents most uncommanded power cycling. Since some input sources with higher output impedance will increase their output voltage greater than this hysteresis as soon as the load is removed, it is possible for this undervoltage shutdown to cycle indefinitely. To prevent this, be sure that the input supply always has adequate voltage at full load.

Thermal Shutdown

Extended operation at excessive temperature will initiate overtemperature shutdown triggered by a temperature sensor inside the PWM controller. This operates similarly to overcurrent and short circuit mode. The inception point of the overtemperature condition depends on the average power delivered, the ambient temperature and the extent of forced cooling airflow.

Remote On/Off Control

The SPC may be turned off or on using the external remote on/off control. This terminal consists of a digital input to the internal PWM controller through a protective resistor and diode.

The on/off input circuit should be CMOS logic referred to the -Input power terminal however TTL or TTL-LS logic will also work or a switch to ground. If preferred, you can even run this using a bipolar transistor in "open collector" configuration or an "open drain" FET transistor.

Figure 1. Measuring Input Ripple Current

Power Good

The power supply shall provide an open-drain/open-collector type circuit representing that the output voltage is within the required voltage band. An external pull-up resistor will be placed between the PGOOD pin and a bias voltage. The signal is referenced to the Vin(-). The signal shall go to the high state when output voltage reaches a typical value, and returns to the low state when the output voltage falls below 50V.

Figure 2. External circuit configuration for PGOOD signal

Hottest Component Temperature Indicating Signal

The following schematic shall be implemented close to the hottest component. A signal type NPN transistor such as MMBT3904LT1, or a compatible part is recommended: The base-emitter voltage will change with a negative thermal coefficient over the temperature. The circuit connected to this device is referenced to the Vin(-).

Figure 3. Temperature sensing circuit

Soldering Guidelines

Murata Power Solutions recommends the specifications below when installing these converters. These specifications vary depending on the solder type. Exceeding these specifications may cause damage to the product. Be cautious when there is high atmospheric humidity. We strongly recommend a mild pre-bake (100° C. for 30 minutes). Your production environment may differ; therefore please thoroughly review these guidelines with your process engineers.

Wave Solder Operations for through-hole mounted products (THMT)			
For Sn/Ag/Cu based solders:		For Sn/Pb based solders:	
Maximum Preheat Temperature	115° C.	Maximum Preheat Temperature	105° C.
Maximum Pot Temperature	270° C.	Maximum Pot Temperature	250° C.
Maximum Solder Dwell Time	7 seconds	Maximum Solder Dwell Time	6 seconds

Emissions Performance

Murata Power Solutions measures its products for conducted emissions against the EN 55022 and CISPR 22 standards. Passive resistance loads are employed and the output is set to the maximum voltage. If you set up your own emissions testing, make sure the output load is rated at continuous power while doing the tests.

The recommended external input and output capacitors (if required) are included. Please refer to the fundamental switching frequency. All of this information is listed in the Product Specifications. An external discrete filter is installed and the circuit diagram is shown below.

[3] Conducted Emissions Test Results

Graph 1. Conducted emissions performance, CISPR 22, Class B, full load

[4] Layout Recommendations

Most applications can use the filtering which is already installed inside the converter or with the addition of the recommended external capacitors. For greater emissions suppression, consider additional filter components and/or shielding. Emissions performance will depend on the user's PC board layout, the chassis shielding environment and choice of external components. Please refer to Application Note GEAN-02 for further discussion.

Since many factors affect both the amplitude and spectra of emissions, we recommend using an engineer who is experienced at emissions suppression.

Figure 4. Vertical Wind Tunnel

Vertical Wind Tunnel

Murata Power Solutions employs a custom-designed enclosed vertical wind tunnel, infrared video camera system and test instrumentation for accurate airflow and heat dissipation analysis of power products. The system includes a precision low flow-rate anemometer, variable speed fan, power supply input and load controls, temperature gauges and adjustable heating element.

The IR camera can watch thermal characteristics of the Unit Under Test (UUT) with both dynamic loads and static steady-state conditions. A special optical port is used which is transparent to infrared wavelengths. The computer files from the IR camera can be studied for later analysis.

Both through-hole and surface mount converters are soldered down to a host carrier board for realistic heat absorption and spreading. Both longitudinal and transverse airflow studies are possible by rotation of this carrier board since there are often significant differences in the heat dissipation in the two airflow directions. The combination of both adjustable airflow, adjustable ambient heat and adjustable Input/Output currents and voltages mean that a very wide range of measurement conditions can be studied.

The airflow collimator mixes the heat from the heating element to make uniform temperature distribution. The collimator also reduces the amount of turbulence adjacent to the UUT by restoring laminar airflow. Such turbulence can change the effective heat transfer characteristics and give false readings. Excess turbulence removes more heat from some surfaces and less heat from others, possibly causing uneven overheating.

Both sides of the UUT are studied since there are different thermal gradients on each side. The adjustable heating element and fan, built-in temperature gauges and no-contact IR camera mean that power supplies are tested in real-world conditions.
