

Features

- 80C52 Compatible
 - 8051 Pin and Instruction Compatible
 - Four 8-bit I/O ports + 2 I/O 2-wire Interface (TWI) Pins
 - Three 16-bit Timer/Counters
 - 256 bytes Scratch Pad RAM
 - 10 Interrupt Sources with 4 Priority Levels
 - Dual Data Pointer
- Variable Length MOVX for Slow RAM/Peripherals
- ISP (In-System-Programming) Using Standard V_{cc} Power Supply
- Boot ROM Contains Low Level Flash Programming Routines and a Default Serial Loader
- High-speed Architecture
 - In Standard Mode:
 - 40 MHz (V_{cc} 2.7V to 5.5V, both Internal and external code execution)
 - 60 MHz (V_{cc} 4.5V to 5.5V and Internal Code execution only)
 - In X2 mode (6 Clocks/machine cycle)
 - 20 MHz (V_{cc} 2.7V to 5.5V, both Internal and external code execution)
 - 30 MHz (V_{cc} 4.5V to 5.5V and Internal Code execution only)
 - 32K Bytes On-chip Flash Program/Data Memory
 - Byte and Page (128 Bytes) Erase and Write
 - 100K Write Cycles
- On-chip 1024 Bytes Expanded RAM (XRAM)
 - Software Selectable Size (0, 256, 512, 768, 1024 Bytes)
 - 256 Bytes Selected at Reset for TS87C51RB2/RC2 Compatibility
- Keyboard Interrupt Interface on Port P1
- 400-Kbits/s Multimaster 2-wire Interface
- SPI Interface (Master/Slave Mode)
- Sub-clock 32 kHz Crystal Oscillator
- 8-bit clock Prescaler
- Improved X2 Mode With Independant Selection for CPU and Each Peripheral
- Programmable Counter Array 5 Channels with:
 - High Speed Output
 - Compare/Capture
 - Pulse Width Modulator
 - Watchdog Timer Capabilities
- Asynchronous Port Reset
- Full-duplex Enhanced UART
- Dedicated Baud Rate Generator for UART
- Low EMI (Inhibit ALE)
- Hardware Watchdog Timer (One-time enabled with Reset-Out)
- Power Control Modes:
 - Idle Mode
 - Power-down Mode
 - Power-Off Flag
- Power Supply:
 - 2.7 to 3.6 (3V Version)
 - 2.7 to 5.5V (5V Version)
- Temperature Ranges: Commercial (0 to +70°C) and Industrial (-40°C to +85°C)
- Packages: PLC44, VQFP44

8-bit Flash Microcontroller with 2-wire Interface

AT89C51IC2

Rev. 4301D-8051-02/08

Description

AT89C51IC2 is a high performance Flash version of the 80C51 8-bit microcontrollers. It contains a 32K bytes Flash memory block for program and data.

The 32K bytes Flash memory can be programmed either in parallel mode or in serial mode with the ISP capability or with software. The programming voltage is internally generated from the standard V_{CC} pin.

The AT89C51IC2 retains all features of the 80C52 with 256 bytes of internal RAM, a 10-source 4-level interrupt controller and three timer/counters.

In addition, the AT89C51IC2 has a 32 kHz Subsidiary clock Oscillator, a Programmable Counter Array, an XRAM of 1024 byte, a Hardware Watchdog Timer, a Keyboard Interface, a 2-wire interface, an SPI Interface, a more versatile serial channel that facilitates multiprocessor communication (EUART) and a speed improvement mechanism (X2 mode).

The fully static design of the AT89C51IC2 allows to reduce system power consumption by bringing the clock frequency down to any value, even DC, without loss of data.

The AT89C51IC2 has 2 software-selectable modes of reduced activity and 8-bit clock prescaler for further reduction in power consumption. In the Idle mode the CPU is frozen while the peripherals and the interrupt system are still operating. In the power-down mode the RAM is saved and all other functions are inoperative.

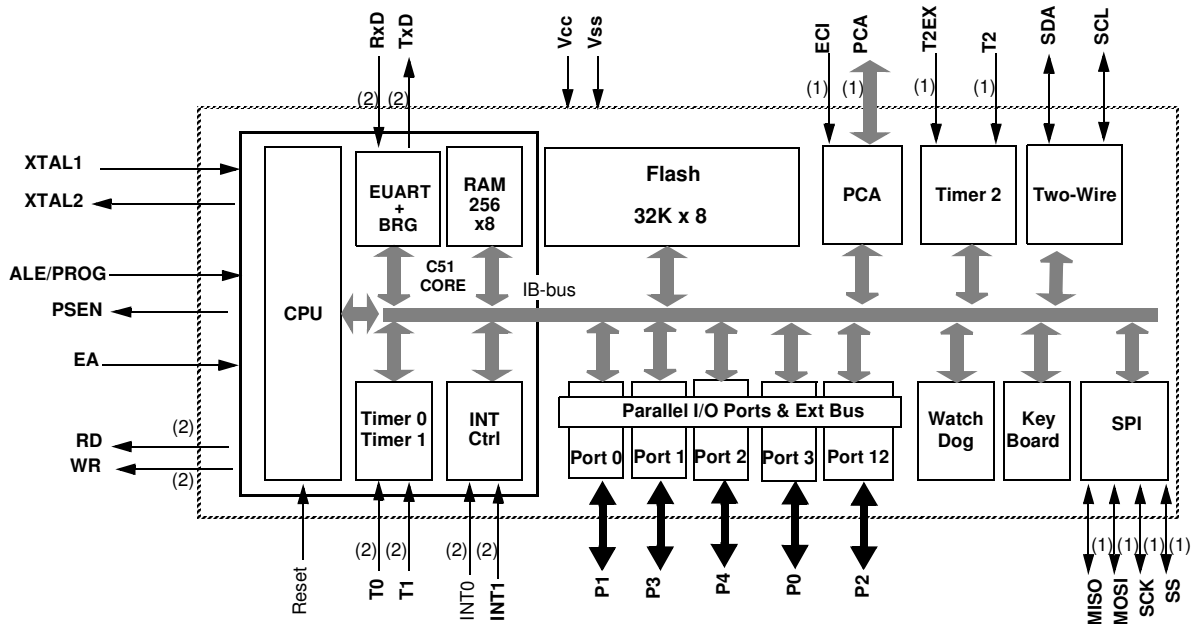

The added features of the AT89C51IC2 make it more powerful for applications that need pulse width modulation, high speed I/O and counting capabilities such as alarms, motor control, corded phones, smart card readers.

SFR Mapping

The Special Function Registers (SFRs) of the AT89C51IC2 fall into the following categories:

- C51 core registers: ACC, B, DPH, DPL, PSW, SP
- I/O port registers: P0, P1, P2, P3, P12
- Timer registers: T2CON, T2MOD, TCON, TH0, TH1, TH2, TMOD, TL0, TL1, TL2, RCAP2L, RCAP2H
- Serial I/O port registers: SADDR, SADEN, SBUF, SCON
- PCA (Programmable Counter Array) registers: CCON, CCAPMx, CL, CH, CCAPxH, CCAPxL (x: 0 to 4)
- Power and clock control registers: PCON
- Hardware Watchdog Timer registers: WDTRST, WDTPRG
- Interrupt system registers: IEN0, IPL0, IPH0, IEN1, IPL1, IPH1
- Keyboard Interface registers: KBE, KBF, KBL5
- SPI registers: SPCON, SPSTR, SPDAT
- 2-wire Interface registers: SSCR, SSCR, SSDAT, SSADR
- BRG (Baud Rate Generator) registers: BRL, BDRCON
- Flash register: FCON
- Clock Prescaler register: CKRL
- 32 kHz Sub Clock Oscillator registers: CKSEL, OSSCON

Pin Configurations

Figure 2. Pin Configurations

Table 13. Pin Description for 40/44 Pin Packages

Mnemonic	Pin Number		Type	Name and Function
	PLCC44	VQFP44 1.4		
V _{SS}	22	16	I	Ground: 0V reference
V _{CC}	44	38	I	Power Supply: This is the power supply voltage for normal, idle and power-down operation
P0.0 - P0.7	43 - 36	37 - 30	I/O	Port 0: Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high impedance inputs. Port 0 must be polarized to V _{CC} or V _{SS} in order to prevent any parasitic current consumption. Port 0 is also the multiplexed low-order address and data bus during access to external program and data memory. In this application, it uses strong internal pull-up when emitting 1s. Port 0 also inputs the code bytes during EPROM programming. External pull-ups are required during program verification during which P0 outputs the code bytes.
P1.0 - P1.7	2 - 9	40 - 44 1 - 3	I/O	Port 1: Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 1 pins that are externally pulled low will source current because of the internal pull-ups. Port 1 also receives the low-order address byte during memory programming and verification. Alternate functions for AT89C51IC2 Port 1 include:
			I/O	P1.0: Input/Output
	3	41	I/O	T2 (P1.0): Timer/Counter 2 external count input/Clockout
			I	XTALB1 (P1.0): Sub Clock input to the inverting oscillator amplifier
	4	42	I/O	P1.1: Input/Output
			I	T2EX: Timer/Counter 2 Reload/Capture/Direction Control
	5	43	I	SS: SPI Slave Select
			I/O	P1.2: Input/Output
	6	44	I	ECl: External Clock for the PCA
			I/O	P1.3: Input/Output
	7	1	I/O	CEX0: Capture/Compare External I/O for PCA module 0
			I/O	P1.4: Input/Output
	8	2	I/O	CEX1: Capture/Compare External I/O for PCA module 1
			I/O	P1.5: Input/Output
			I/O	CEX2: Capture/Compare External I/O for PCA module 2
			I/O	MISO: SPI Master Input Slave Output line When SPI is in master mode, MISO receives data from the slave peripheral. When SPI is in slave mode, MISO outputs data to the master controller.
		I/O	P1.6: Input/Output	
		I/O	CEX3: Capture/Compare External I/O for PCA module 3	
		I/O	SCK: SPI Serial Clock SCK outputs clock to the slave peripheral	

Table 13. Pin Description for 40/44 Pin Packages (Continued)

Mnemonic	Pin Number		Type	Name and Function
	PLCC44	VQFP44 1.4		
	9	3	I/O	P1.7: Input/Output:
			I/O I/O	CEX4: Capture/Compare External I/O for PCA module 4 MOSI: SPI Master Output Slave Input line When SPI is in master mode, MOSI outputs data to the slave peripheral. When SPI is in slave mode, MOSI receives data from the master controller.
XTALA1	21	15	I	Crystal A 1: Input to the inverting oscillator amplifier and input to the internal clock generator circuits.
XTALA2	20	14	O	Crystal A 2: Output from the inverting oscillator amplifier
XTALB1	2	40	I	Crystal B 1: (Sub Clock) Input to the inverting oscillator amplifier and input to the internal clock generator circuits.
XTALB2	1	39	O	Crystal B 2: (Sub Clock) Output from the inverting oscillator amplifier
P2.0 - P2.7	24 - 31	18 - 25	I/O	Port 2: Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 2 pins that are externally pulled low will source current because of the internal pull-ups. Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups emitting 1s. During accesses to external data memory that use 8-bit addresses (MOVX @Ri), port 2 emits the contents of the P2 SFR. Some Port 2 pins receive the high order address bits during EPROM programming and verification.
P3.0 - P3.7	11, 13 - 19	5, 7 - 13	I/O	Port 3: Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 3 pins that are externally pulled low will source current because of the internal pull-ups. Port 3 also serves the special features of the 80C51 family, as listed below.
	11	5	I	RXD (P3.0): Serial input port
	13	7	O	TXD (P3.1): Serial output port
	14	8	I	INT0 (P3.2): External interrupt 0
	15	9	I	INT1 (P3.3): External interrupt 1
	16	10	I	T0 (P3.4): Timer 0 external input
	17	11	I	T1 (P3.5): Timer 1 external input
	18	12	O	WR (P3.6): External data memory write strobe
	19	13	O	RD (P3.7): External data memory read strobe
PI2.0 - PI2.1	34, 12	28, 6		Port I2: Port I2 is an open drain. It can be used as inputs (must be polarized to Vcc with external resistor to prevent any parasitic current consumption).
	34	28	I/O	SCL (PI2.0): 2-wire Serial Clock SCL output the serial clock to slave peripherals SCL input the serial clock from master
	12	6	I/O	SDA (PI2.1): 2-wire Serial Data

Table 13. Pin Description for 40/44 Pin Packages (Continued)

Mnemonic	Pin Number		Type	Name and Function
	PLCC44	VQFP44 1.4		
				SDA is the bidirectional 2-wire data line
RST	10	4	I/O	Reset: A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V_{SS} permits a power-on reset using only an external capacitor to V_{CC} . This pin is an output when the hardware watchdog forces a system reset.
ALE/ $\overline{\text{PROG}}$	33	27	O (I)	Address Latch Enable/Program Pulse: Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 (1/3 in X2 mode) the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input ($\overline{\text{PROG}}$) during Flash programming. ALE can be disabled by setting SFR's AUXR.0 bit. With this bit set, ALE will be inactive during internal fetches.
PSEN	32	26	O	Program Strobe ENable: The read strobe to external program memory. When executing code from the external program memory, $\overline{\text{PSEN}}$ is activated twice each machine cycle, except that two $\overline{\text{PSEN}}$ activations are skipped during each access to external data memory. $\overline{\text{PSEN}}$ is not activated during fetches from internal program memory.
EA	35	29	I	External Access Enable: $\overline{\text{EA}}$ must be externally held low to enable the device to fetch code from external program memory locations 0000H to FFFFH (RD). If security level 1 is programmed, $\overline{\text{EA}}$ will be internally latched on Reset.

Oscillators

Overview

Two oscillators are available for CPU:

- OSCA used for high frequency: Up to 48 MHz @5V +/- 10%
- OSCB used for low frequency: 32.768 kHz

Several operating modes are available and programmable by software:

- to switch OSCA to OSCB and vice-versa
- to stop OSCA or OSCB to reduce consumption

In order to optimize the power consumption and the execution time needed for a specific task, an internal prescaler feature has been implemented between the selected oscillator and the CPU.

Functional Block Diagram

Figure 3. Functional Oscillator Block Diagram

Operating Modes

Reset

A hardware RESET puts the Clock generator in the following state:

The selected oscillator depends on OSC bit in Hardware Security Byte (HSB) (see HSB Table 84)

HSB.OSC = 1 (Oscillator A selected)

- OscAEn = 1 & OscBEn = 0: OscA is running, OscB is stopped.
- CKS = 1: OscA is selected for CPU.

HSB.OSC = 0 (Oscillator B selected)

- OscAEn = 0 & OscBEn = 1: OscB is running, OscA is stopped.
- CKS = 0: OscB is selected for CPU.

Functional Modes

Normal Modes

- CPU and Peripherals clock depend on the software selection using CKCON0, CKCON1 and CKRL registers
- CKS bit in CKSEL register selects either OscA or OscB
- CKRL register determines the frequency of the OscA clock.

- It is always possible to switch dynamically by software from OscA to OscB, and vice versa by changing CKS bit.

Idle Modes

- IDLE modes are achieved by using any instruction that writes into PCON.0 bit (IDL)
- IDLE modes A and B depend on previous software sequence, prior to writing into PCON.0 bit:
- IDLE MODE A: OscA is running (OscAEn = 1) and selected (CKS = 1)
- IDLE MODE B: OscB is running (OscBEn = 1) and selected (CKS = 0)
- The unused oscillator OscA or OscB can be stopped by software by clearing OscAEn or OscBEn respectively.
- IDLE mode can be canceled either by Reset, or by activation of any enabled interruption
- In both cases, PCON.0 bit (IDL) is cleared by hardware
- Exit from IDLE modes will leave Oscillators control bits (OscEnA, OscEnB, CKS) unchanged.

Power Down Modes

- POWER DOWN modes are achieved by using any instruction that writes into PCON.1 bit (PD)
- POWER DOWN modes A and B depend on previous software sequence, prior to writing into PCON.1 bit:
- Both OscA and OscB will be stopped.
- POWER DOWN mode can be cancelled either by a hardware Reset, an external interruption, or the keyboard interrupt.
- By Reset signal: The CPU will restart according to OSC bit in Hardware Security Bit (HSB) register.
- By INT0 or INT1 interruption, if enabled: (standard behavioral), request on Pads must be driven low enough to ensure correct restart of the oscillator which was selected when entering in Power down.
- By keyboard Interrupt if enabled: a hardware clear of the PCON.1 flag ensure the restart of the oscillator which was selected when entering in Power down.

Table 18. Overview

PCON.1	PCON.0	OscBEn	OscAEn	CKS	Selected Mode	Comment
0	0	0	1	1	NORMAL MODE A, OscB stopped	Default mode after power-up or Warm Reset
0	0	1	1	1	NORMAL MODE A, OscB running	Default mode after power-up or Warm Reset + OscB running
0	0	1	0	0	NORMAL MODE B, OscA stopped	OscB running and selected
0	0	1	1	0	NORMAL MODE B, OscA running	OscB running and selected + OscA running
X	X	0	0	X	INVALID	OscA & OscB cannot be stopped at the same time
X	X	X	0	1	INVALID	OscA must not be stopped, as used for CPU and peripherals
X	X	0	X	0	INVALID	OscB must not be stopped as used for CPU and peripherals

Table 18. Overview (Continued)

PCON.1	PCON.0	OscBEn	OscAEn	CKS	Selected Mode	Comment
0	1	X	1	1	IDLE MODE A	The CPU is off, OscA supplies the peripherals, OscB can be disabled (OscBEn = 0)
0	1	1	X	0	IDLE MODE B	The CPU is off, OscB supplies the peripherals, OscA can be disabled (OscAEn = 0)
1	X	X	1	X	POWER DOWN MODE	The CPU and peripherals are off, OscA and OscB are stopped

Design Considerations

Oscillators Control

- PwdOscA and PwdOscB signals are generated in the Clock generator and used to control the hard blocks of oscillators A and B.
- PwdOscA = '1' stops OscA
- PwdOscB = '1' stops OscB
- The following tables summarize the Operating modes:

PCON.1	OscAEn	PwdOscA	Comments
0	1	0	OscA running
1	X	1	OscA stopped by Power-down mode
0	0	1	OscA stopped by clearing OscAEn

PCON.1	OscBEn	PwdOscB	Comments
0	1	0	OscB running
1	X	1	OscB stopped by Power-down mode
0	0	1	OscB stopped by clearing OscBEn

Prescaler Divider

- A hardware RESET puts the prescaler divider in the following state:
 - CKRL = FFh: $F_{CLK CPU} = F_{CLK PERIPH} = F_{OSCA}/2$ (Standard C51 feature)
- CKS signal selects OSCA or OSCB: $F_{CLK OUT} = F_{OSCA}$ or F_{OSCB}
- Any value between FFh down to 00h can be written by software into CKRL register in order to divide frequency of the selected oscillator:
 - CKRL = 00h: minimum frequency
 $F_{CLK CPU} = F_{CLK PERIPH} = F_{OSCA}/1020$ (Standard Mode)
 $F_{CLK CPU} = F_{CLK PERIPH} = F_{OSCA}/510$ (X2 Mode)
 - CKRL = FFh: maximum frequency
 $F_{CLK CPU} = F_{CLK PERIPH} = F_{OSCA}/2$ (Standard Mode)
 $F_{CLK CPU} = F_{CLK PERIPH} = F_{OSCA}$ (X2 Mode)

- $F_{CLK\ CPU}$ and $F_{CLK\ PERIPH}$, for $CKRL \neq 0xFF$
In X2 Mode:

$$F_{CPU} = F_{CLK\ PERIPH} = \frac{F_{OSCA}}{2 \times (255 - CKRL)}$$

In X1 Mode:

$$F_{CPU} = F_{CLK\ PERIPH} = \frac{F_{OSCA}}{4 \times (255 - CKRL)}$$

Timer 0: Clock Inputs

Figure 4. Timer 0: Clock Inputs

Note: The SCLKT0 bit in OSCCON register allows to select Timer 0 Subsidiary clock.

SCLKT0 = 0: Timer 0 uses the standard T0 pin as clock input (Standard mode)

SCLKT0 = 1: Timer 0 uses the special Sub Clock as clock input, this feature can be use as periodic interrupt for time clock.

Enhanced Features

In comparison to the original 80C52, the AT89C51IC2 implements some new features, which are:

- The X2 option
- The Dual Data Pointer
- The extended RAM
- The Programmable Counter Array (PCA)
- The Hardware Watchdog
- The SPI interface
- The 2-wire interface
- The 4 level interrupt priority system
- The power-off flag
- The Power On Reset
- The ONCE mode
- The ALE disabling
- Some enhanced features are also located in the UART and the timer 2

X2 Feature and OSCA Clock Generation

The AT89C51IC2 core needs only 6 clock periods per machine cycle. This feature called "X2" provides the following advantages:

- Divide frequency crystals by 2 (cheaper crystals) while keeping same CPU power.
- Save power consumption while keeping same CPU power (oscillator power saving).
- Save power consumption by dividing dynamically the operating frequency by 2 in operating and idle modes.
- Increase CPU power by 2 while keeping same crystal frequency.

In order to keep the original C51 compatibility, a divider by 2 is inserted between the XTALA1 signal and the main clock input of the core (phase generator). This divider may be disabled by software.

Description

The clock for the whole circuit and peripherals is first divided by two before being used by the CPU core and the peripherals.

This allows any cyclic ratio to be accepted on XTALA1 input. In X2 mode, as this divider is bypassed, the signals on XTALA1 must have a cyclic ratio between 40 to 60%.

Figure 5. shows the clock generation block diagram. x2 bit is validated on the rising edge of the $XTALA1 \div 2$ to avoid glitches when switching from X2 to STD mode. Figure 6. shows the switching mode waveforms.

Figure 5. Clock Generation Diagram

Figure 6. Mode Switching Waveforms

The X2 bit in the CKCON0 register (see Table 19) allow to switch from 12 clock periods per instruction to 6 clock periods and vice versa. At reset, the speed is setting according to X2 bit of Hardware Security Byte (HSB). By default, Standard mode is activated. Setting the X2 bit activates the X2 feature (X2 mode).

The T0X2, T1X2, T2X2, UartX2, PcaX2, WdX2 and I2CX2 bits in the CKCON0 register (See Table 19.) and SPIX2 bit in the CKCON1 register (see Table 20) allow to switch from standard peripheral speed (12 clock periods per peripheral clock cycle) to fast peripheral speed (6 clock periods per peripheral clock cycle). These bits are active only in X2 mode.

More information about the X2 mode can be found in the application note "How to take advantage of the X2 features in TS80C51 microcontroller?"

Dual Data Pointer Register

The additional data pointer can be used to speed up code execution and reduce code size.

The dual DPTR structure is a way by which the chip will specify the address of an external data memory location. There are two 16-bit DPTR registers that address the external memory, and a single bit called DPS = AUXR1.0 (see Table 21) that allows the program code to switch between them (Refer to Figure 7).

Figure 7. Use of Dual Pointer

Table 21. AUXR1 register

AUXR1- Auxiliary Register 1(0A2h)

7	6	5	4	3	2	1	0
-	-	ENBOOT	-	GF3	0	-	DPS

0	DPS	Data Pointer Selection Cleared to select DPTR0. Set to select DPTR1.					

Reset Value: XXXX XX0X0b

Not bit addressable

Note: *Bit 2 stuck at 0; this allows to use INC AUXR1 to toggle DPS without changing GF3.

ASSEMBLY LANGUAGE

```
; Block move using dual data pointers
; Modifies DPTR0, DPTR1, A and PSW
; note: DPS exits opposite of entry state
; unless an extra INC AUXR1 is added
;
00A2  AUXR1 EQU 0A2H
;
0000 909000MOV DPTR,#SOURCE ; address of SOURCE
0003 05A2 INC AUXR1 ; switch data pointers
0005 90A000 MOV DPTR,#DEST ; address of DEST
0008 LOOP:
0008 05A2 INC AUXR1 ; switch data pointers
000A E0 MOVX A,@DPTR ; get a byte from SOURCE
000B A3 INC DPTR ; increment SOURCE address
000C 05A2 INC AUXR1 ; switch data pointers
000E F0 MOVX @DPTR,A ; write the byte to DEST
000F A3 INC DPTR ; increment DEST address
0010 70F6JNZ LOOP ; check for 0 terminator
0012 05A2 INC AUXR1 ; (optional) restore DPS
```

INC is a short (2 bytes) and fast (12 clocks) way to manipulate the DPS bit in the AUXR1 SFR. However, note that the INC instruction does not directly force the DPS bit to a particular state, but simply toggles it. In simple routines, such as the block move example, only the fact that DPS is toggled in the proper sequence matters, not its actual value. In other words, the block move routine works the same whether DPS is '0' or '1' on entry. Observe that without the last instruction (INC AUXR1), the routine will exit with DPS in the opposite state.

Expanded RAM (XRAM)

The AT89C51IC2 provides additional Bytes of random access memory (RAM) space for increased data parameter handling and high level language usage.

AT89C51IC2 devices have expanded RAM in external data space; maximum size and location are described in Table 22.

Table 22. Expanded RAM

	XRAM size	Address	
		Start	End
AT89C51IC2	1024	00h	3FFh

The AT89C51IC2 has internal data memory that is mapped into four separate segments.

The four segments are:

1. The Lower 128 bytes of RAM (addresses 00h to 7Fh) are directly and indirectly addressable.
2. The Upper 128 bytes of RAM (addresses 80h to FFh) are indirectly addressable only.
3. The Special Function Registers, SFRs, (addresses 80h to FFh) are directly addressable only.
4. The expanded RAM bytes are indirectly accessed by MOVX instructions, and with the EXTRAM bit cleared in the AUXR register (see Table 22)

The lower 128 bytes can be accessed by either direct or indirect addressing. The Upper 128 bytes can be accessed by indirect addressing only. The Upper 128 bytes occupy the same address space as the SFR. That means they have the same address, but are physically separate from SFR space.

Figure 8. Internal and External Data Memory Address

When an instruction accesses an internal location above address 7Fh, the CPU knows whether the access is to the upper 128 bytes of data RAM or to SFR space by the addressing mode used in the instruction.

- Instructions that use direct addressing access SFR space. For example: MOV 0A0H, # data, accesses the SFR at location 0A0h (which is P2).

- Instructions that use indirect addressing access the Upper 128 bytes of data RAM. For example: `MOV @R0, # data` where R0 contains 0A0h, accesses the data byte at address 0A0h, rather than P2 (whose address is 0A0h).
- The XRAM bytes can be accessed by indirect addressing, with EXTRAM bit cleared and MOVX instructions. This part of memory which is physically located on-chip, logically occupies the first bytes of external data memory. The bits XRS0 and XRS1 are used to hide a part of the available XRAM as explained in Table 22. This can be useful if external peripherals are mapped at addresses already used by the internal XRAM.
- With EXTRAM = 0, the XRAM is indirectly addressed, using the MOVX instruction in combination with any of the registers R0, R1 of the selected bank or DPTR. An access to XRAM will not affect ports P0, P2, P3.6 (WR) and P3.7 (RD). For example, with EXTRAM = 0, `MOVX @R0, # data` where R0 contains 0A0H, accesses the XRAM at address 0A0H rather than external memory. An access to external data memory locations higher than the accessible size of the XRAM will be performed with the MOVX DPTR instructions in the same way as in the standard 80C51, with P0 and P2 as data/address busses, and P3.6 and P3.7 as write and read timing signals. Accesses to XRAM above 0FFH can only be done by the use of DPTR.
- With EXTRAM = 1, `MOVX @Ri` and `MOVX @DPTR` will be similar to the standard 80C51. `MOVX @ Ri` will provide an eight-bit address multiplexed with data on Port0 and any output port pins can be used to output higher order address bits. This is to provide the external paging capability. `MOVX @DPTR` will generate a sixteen-bit address. Port2 outputs the high-order eight address bits (the contents of DPH) while Port0 multiplexes the low-order eight address bits (DPL) with data. `MOVX @ Ri` and `MOVX @DPTR` will generate either read or write signals on P3.6 (\overline{WR}) and P3.7 (\overline{RD}).

The stack pointer (SP) may be located anywhere in the 256 bytes RAM (lower and upper RAM) internal data memory. The stack may not be located in the XRAM.

The M0 bit allows to stretch the XRAM timings; if M0 is set, the read and write pulses are extended from 6 to 30 clock periods. This is useful to access external slow peripherals.

1	EXTRAM	EXTRAM bit Cleared to access internal XRAM using movx @ Ri/ @ DPTR. Set to access external memory. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), default setting, XRAM selected.															
0	AO	ALE Output bit Cleared, ALE is emitted at a constant rate of 1/6 the oscillator frequency (or 1/3 if X2 mode is used) (default) Set, ALE is active only during a MOVX or MOVC instruction is used.															

Reset Value = XX0X 00'HSB.XRAM'0b

Not bit addressable

Timer 2

The Timer 2 in the AT89C51IC2 is the standard C52 the Timer 2.

It is a 16-bit timer/counter: the count is maintained by two eight-bit timer registers, TH2 and TL2 are cascaded. It is controlled by T2CON (Table 24) and T2MOD (Table 25) registers. Timer 2 operation is similar to Timer 0 and Timer 1. C/T2 selects $F_{OSC}/12$ (timer operation) or external pin T2 (counter operation) as the timer clock input. Setting TR2 allows TL2 to be incremented by the selected input.

Timer 2 has 3 operating modes: capture, autoreload and Baud Rate Generator. These modes are selected by the combination of RCLK, TCLK and CP/RL2 (T2CON).

Refer to the Atmel 8-bit Microcontroller Hardware description for the description of Capture and Baud Rate Generator Modes.

Timer 2 includes the following enhancements:

- Auto-reload mode with up or down counter
- Programmable clock-output

Auto-Reload Mode

The auto-reload mode configures timer 2 as a 16-bit timer or event counter with automatic reload. If DCEN bit in T2MOD is cleared, timer 2 behaves as in 80C52 (refer to the Atmel 8-bit Microcontroller Hardware description). If DCEN bit is set, timer 2 acts as an Up/down timer/counter as shown in Figure 9. In this mode the T2EX pin controls the direction of count.

When T2EX is high, timer 2 counts up. Timer overflow occurs at FFFFh which sets the TF2 flag and generates an interrupt request. The overflow also causes the 16-bit value in RCAP2H and RCAP2L registers to be loaded into the timer registers TH2 and TL2.

When T2EX is low, timer 2 counts down. Timer underflow occurs when the count in the timer registers TH2 and TL2 equals the value stored in RCAP2H and RCAP2L registers. The underflow sets TF2 flag and reloads FFFFh into the timer registers.

The EXF2 bit toggles when timer 2 overflows or underflows according to the direction of the count. EXF2 does not generate any interrupt. This bit can be used to provide 17-bit resolution.

Figure 9. Auto-Reload Mode Up/Down Counter (DCEN = 1)

Programmable Clock-Output

In the clock-out mode, timer 2 operates as a 50%-duty-cycle, programmable clock generator (See Figure 10). The input clock increments TL2 at frequency $F_{CLK PERIPH}/2$. The timer repeatedly counts to overflow from a loaded value. At overflow, the contents of RCAP2H and RCAP2L registers are loaded into TH2 and TL2. In this mode, timer 2 overflows do not generate interrupts. The formula gives the clock-out frequency as a function of the system oscillator frequency and the value in the RCAP2H and RCAP2L registers:

$$Clock - OutFrequency = \frac{F_{CLKPERIPH}}{4 \times (65536 - RCAP2H/RCAP2L)}$$

For a 16 MHz system clock, timer 2 has a programmable frequency range of 61 Hz ($F_{CLK PERIPH}/2^{16}$) to 4 MHz ($F_{CLK PERIPH}/4$). The generated clock signal is brought out to T2 pin (P1.0).

Timer 2 is programmed for the clock-out mode as follows:

- Set T2OE bit in T2MOD register.
- Clear $C/\overline{T2}$ bit in T2CON register.
- Determine the 16-bit reload value from the formula and enter it in RCAP2H/RCAP2L registers.
- Enter a 16-bit initial value in timer registers TH2/TL2. It can be the same as the reload value or a different one depending on the application.
- To start the timer, set TR2 run control bit in T2CON register.

It is possible to use timer 2 as a baud rate generator and a clock generator simultaneously. For this configuration, the baud rates and clock frequencies are not independent since both functions use the values in the RCAP2H and RCAP2L registers.

Figure 10. Clock-Out Mode $C/\overline{T2} = 0$

Table 24. T2CON Register

T2CON - Timer 2 Control Register (C8h)

7	6	5	4	3	2	1	0
TF2	EXF2	RCLK	TCLK	EXEN2	TR2	C/T2#	CP/RL2#
Bit Number	Bit Mnemonic	Description					
7	TF2	Timer 2 overflow Flag Must be cleared by software. Set by hardware on timer 2 overflow, if RCLK = 0 and TCLK = 0.					
6	EXF2	Timer 2 External Flag Set when a capture or a reload is caused by a negative transition on T2EX pin if EXEN2=1. When set, causes the CPU to vector to timer 2 interrupt routine when timer 2 interrupt is enabled. Must be cleared by software. EXF2 doesn't cause an interrupt in Up/down counter mode (DCEN = 1)					
5	RCLK	Receive Clock bit Cleared to use timer 1 overflow as receive clock for serial port in mode 1 or 3. Set to use timer 2 overflow as receive clock for serial port in mode 1 or 3.					
4	TCLK	Transmit Clock bit Cleared to use timer 1 overflow as transmit clock for serial port in mode 1 or 3. Set to use timer 2 overflow as transmit clock for serial port in mode 1 or 3.					
3	EXEN2	Timer 2 External Enable bit Cleared to ignore events on T2EX pin for timer 2 operation. Set to cause a capture or reload when a negative transition on T2EX pin is detected, if timer 2 is not used to clock the serial port.					
2	TR2	Timer 2 Run control bit Cleared to turn off timer 2. Set to turn on timer 2.					
1	C/T2#	Timer/Counter 2 select bit Cleared for timer operation (input from internal clock system: F _{CLK PERIPH}). Set for counter operation (input from T2 input pin, falling edge trigger). Must be 0 for clock out mode.					
0	CP/RL2#	Timer 2 Capture/Reload bit If RCLK=1 or TCLK=1, CP/RL2# is ignored and timer is forced to auto-reload on timer 2 overflow. Cleared to auto-reload on timer 2 overflows or negative transitions on T2EX pin if EXEN2=1. Set to capture on negative transitions on T2EX pin if EXEN2=1.

Programmable Counter Array PCA

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of five compare/capture modules. Its clock input can be programmed to count any one of the following signals:

- Peripheral clock frequency ($F_{CLK\ PERIPH} \div 6$)
- Peripheral clock frequency ($F_{CLK\ PERIPH} \div 2$)
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture modules can be programmed in any one of the following modes:

- rising and/or falling edge capture
- software timer
- high-speed output
- pulse width modulator

Module 4 can also be programmed as a watchdog timer (See Section "PCA Watchdog Timer", page 46).

When the compare/capture modules are programmed in the capture mode, software timer, or high speed output mode, an interrupt can be generated when the module executes its function. All five modules plus the PCA timer overflow share one interrupt vector.

The PCA timer/counter and compare/capture modules share Port 1 for external I/O. These pins are listed below. If the port is not used for the PCA, it can still be used for standard I/O.

PCA component	External I/O Pin
16-bit Counter	P1.2 / ECI
16-bit Module 0	P1.3 / CEX0
16-bit Module 1	P1.4 / CEX1
16-bit Module 2	P1.5 / CEX2
16-bit Module 3	P1.6 / CEX3

The PCA timer is a common time base for all five modules (See Figure 11). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD register (Table 26) and can be programmed to run at:

- 1/6 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- 1/2 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- The Timer 0 overflow
- The input on the ECI pin (P1.2)

Reset Value = 00XX X000b

Not bit addressable

The CMOD register includes three additional bits associated with the PCA (See Figure 11 and Table 26).

- The CIDL bit which allows the PCA to stop during idle mode.
- The WDTE bit which enables or disables the watchdog function on module 4.
- The ECF bit which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows.

The CCON register contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (Refer to Table 27).

- Bit CR (CCON.6) must be set by software to run the PCA. The PCA is shut off by clearing this bit.
- Bit CF: The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software.
- Bits 0 through 4 are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software.

Table 27. CCON Register

0	CCF0	PCA Module 0 interrupt flag Must be cleared by software. Set by hardware when a match or capture occurs.					

Reset Value = 00X0 0000b

Not bit addressable

The watchdog timer function is implemented in module 4 (See Figure 14).

The PCA interrupt system is shown in Figure 12.

Figure 12. PCA Interrupt System

PCA Modules: each one of the five compare/capture modules has six possible functions. It can perform:

- 16-bit Capture, positive-edge triggered
- 16-bit Capture, negative-edge triggered
- 16-bit Capture, both positive and negative-edge triggered
- 16-bit Software Timer
- 16-bit High Speed Output
- 8-bit Pulse Width Modulator

In addition, module 4 can be used as a Watchdog Timer.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (See Table 28). The registers contain the bits that control the mode that each module will operate in.

- The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or 4 depending on the module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated module.
- PWM (CCAPMn.1) enables the pulse width modulation mode.
- The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register.
- The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.
- The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition.
- The last bit in the register ECOM (CCAPMn.6) when set enables the comparator function.

Table 28 shows the CCAPMn settings for the various PCA functions.

PCA Capture Mode

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated (Refer to Figure 13).

Figure 13. PCA Capture Mode

16-bit Software Timer/ Compare Mode

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (See Figure 14).

Figure 14. PCA Compare Mode and PCA Watchdog Timer

Before enabling ECOM bit, CCAPnL and CCAPnH should be set with a non zero value, otherwise an unwanted match could happen. Writing to CCAPnH will set the ECOM bit.

Once ECOM set, writing CCAPnL will clear ECOM so that an unwanted match doesn't occur while modifying the compare value. Writing to CCAPnH will set ECOM. For this reason, user software should write CCAPnL first, and then CCAPnH. Of course, the ECOM bit can still be controlled by accessing to CCAPMn register.

High Speed Output Mode In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (See Figure 15).

A prior write must be done to CCAPnL and CCAPnH before writing the ECOMn bit.

Figure 15. PCA High Speed Output Mode

Before enabling ECOM bit, CCAPnL and CCAPnH should be set with a non zero value, otherwise an unwanted match could happen.

Once ECOM set, writing CCAPnL will clear ECOM so that an unwanted match doesn't occur while modifying the compare value. Writing to CCAPnH will set ECOM. For this reason, user software should write CCAPnL first, and then CCAPnH. Of course, the ECOM bit can still be controlled by accessing to CCAPMn register.

Pulse Width Modulator Mode

All of the PCA modules can be used as PWM outputs. Figure 16 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPL_n. When the value of the PCA CL SFR is less than the value in the module's CCAPL_n SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPL_n is reloaded with the value in CCAPH_n. This allows updating the PWM without glitches. The PWM and ECOM bits in the module's CCAPM_n register must be set to enable the PWM mode.

Figure 16. PCA PWM Mode

PCA Watchdog Timer

An on-board watchdog timer is available with the PCA to improve the reliability of the system without increasing chip count. Watchdog timers are useful for systems that are susceptible to noise, power glitches, or electrostatic discharge. Module 4 is the only PCA module that can be programmed as a watchdog. However, this module can still be used for other modes if the watchdog is not needed. Figure 14 shows a diagram of how the watchdog works. The user pre-loads a 16-bit value in the compare registers. Just like the other compare modes, this 16-bit value is compared to the PCA timer value. If a match is allowed to occur, an internal reset will be generated. This will not cause the RST pin to be driven high.

In order to hold off the reset, the user has three options:

1. periodically change the compare value so it will never match the PCA timer,
2. periodically change the PCA timer value so it will never match the compare values, or
3. disable the watchdog by clearing the WDTE bit before a match occurs and then re-enable it.

The first two options are more reliable because the watchdog timer is never disabled as in option #3. If the program counter ever goes astray, a match will eventually occur and cause an internal reset. The second option is also not recommended if other PCA modules are being used. Remember, the PCA timer is the time base for all modules; changing the time base for other modules would not be a good idea. Thus, in most applications the first solution is the best option.

This watchdog timer won't generate a reset out on the reset pin.

Serial I/O Port

The serial I/O port in the AT89C51IC2 is compatible with the serial I/O port in the 80C52. It provides both synchronous and asynchronous communication modes. It operates as a Universal Asynchronous Receiver and Transmitter (UART) in three full-duplex modes (Modes 1, 2 and 3). Asynchronous transmission and reception can occur simultaneously and at different baud rates

Serial I/O port includes the following enhancements:

- Framing error detection
- Automatic address recognition

Framing Error Detection

Framing bit error detection is provided for the three asynchronous modes (modes 1, 2 and 3). To enable the framing bit error detection feature, set SMOD0 bit in PCON register (See Figure 17).

Figure 17. Framing Error Block Diagram

When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two CPUs. If a valid stop bit is not found, the Framing Error bit (FE) in SCON register (See Table 37.) bit is set.

Software may examine FE bit after each reception to check for data errors. Once set, only software or a reset can clear FE bit. Subsequently received frames with valid stop bits cannot clear FE bit. When FE feature is enabled, RI rises on stop bit instead of the last data bit (See Figure 18. and Figure 19.).

Figure 18. UART Timings in Mode 1

Figure 19. UART Timings in Modes 2 and 3

Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address, the receiver sets RI bit in SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.

If desired, you may enable the automatic address recognition feature in mode 1. In this configuration, the stop bit takes the place of the ninth data bit. Bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.

Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i.e. setting SM2 bit in SCON register in mode 0 has no effect).

Given Address

Each device has an individual address that is specified in SADDR register; the SADEN register is a mask byte that contains don't-care bits (defined by zeros) to form the device's given address. The don't-care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed.

To address a device by its individual address, the SADEN mask byte must be 1111 1111b.

For example:

```
SADDR0101 0110b
SADEN1111 1100b
Given0101 01XXb
```

The following is an example of how to use given addresses to address different slaves:

```
Slave A:SADDR1111 0001b
SADEN1111 1010b
Given1111 0X0Xb
```

```
Slave B:SADDR1111 0011b
SADEN1111 1001b
Given1111 0XX1b
```

```
Slave C:SADDR1111 0010b
SADEN1111 1101b
Given1111 00X1b
```

The SADEN byte is selected so that each slave may be addressed separately. For slave A, bit 0 (the LSB) is a don't-care bit; for slaves B and C, bit 0 is a 1. To communicate with slave A only, the master must send an address where bit 0 is clear (e.g. 1111 0000b).

For slave A, bit 1 is a 1; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves B and C, but not slave A, the master must send an address with bits 0 and 1 both set (e.g. 1111 0011b).

To communicate with slaves A, B and C, the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e.g. 1111 0001b).

Broadcast Address

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't-care bits, e.g.:

```
SADDR 0101 0110b
SADEN 1111 1100b
Broadcast =SADDR OR SADEN1111 111Xb
```

The use of don't-care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

```
Slave A:SADDR1111 0001b
SADEN1111 1010b
Broadcast1111 1X11b,
```

```
Slave B:SADDR1111 0011b
SADEN1111 1001b
Broadcast1111 1X11b,
```

```
Slave C:SADDR=1111 0010b
SADEN1111 1101b
Broadcast1111 1111b
```

For slaves A and B, bit 2 is a don't care bit; for slave C, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send an address FBh.

Reset Addresses

On reset, the SADDR and SADEN registers are initialized to 00h, i.e. the given and broadcast addresses are XXXX XXXXb (all don't-care bits). This ensures that the serial port will reply to any address, and so, that it is backwards compatible with the 80C51 microcontrollers that do not support automatic address recognition.

Baud Rate Selection for UART for mode 1 and 3

The Baud Rate Generator for transmit and receive clocks can be selected separately via the T2CON and BDRCON registers.

Figure 20. Baud Rate selection

Table 36. Baud Rate Selection Table UART

TCLK (T2CON)	RCLK (T2CON)	TBCK (BDRCON)	RBCK (BDRCON)	Clock Source UART Tx	Clock Source UART Rx
0	0	0	0	Timer 1	Timer 1
1	0	0	0	Timer 2	Timer 1
0	1	0	0	Timer 1	Timer 2
1	1	0	0	Timer 2	Timer 2
X	0	1	0	INT_BRG	Timer 1
X	1	1	0	INT_BRG	Timer 2
0	X	0	1	Timer 1	INT_BRG
1	X	0	1	Timer 2	INT_BRG
X	X	1	1	INT_BRG	INT_BRG

Internal Baud Rate Generator (BRG) When the internal Baud Rate Generator is used, the Baud Rates are determined by the BRG overflow depending on the BRL reload value, the value of SPD bit (Speed Mode) in BDRCON register and the value of the SMOD1 bit in PCON register.

Figure 21. Internal Baud Rate

- The baud rate for UART is taken by formula:

$$BaudRate = \frac{2^{SMOD} \times F_{CLKPERIPH}}{2 \times 2 \times 6 (1 - SPD) \times 16 \times [256 - (BRL)]}$$

$$(BRL) = 256 - \frac{2^{SMOD1} \times F_{CLKPERIPH}}{2 \times 2 \times 6 (1 - SPD) \times 16 \times BaudRate}$$

Interrupt System

The AT89C51IC2 has a total of 10 interrupt vectors: two external interrupts ($\overline{INT0}$ and $\overline{INT1}$), three timer interrupts (timers 0, 1 and 2), the serial port interrupt, SPI interrupt, Two Wire Interface (I2C) interrupt, Keyboard interrupt and the PCA global interrupt. These interrupts are shown in Figure 22.

Figure 22. Interrupt Control System

Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable register (Table 51 and Table 49). This register also contains a global disable bit, which must be cleared to disable all interrupts at once.

Each interrupt source can also be individually programmed to one out of four priority levels by setting or clearing a bit in the Interrupt Priority register (Table 52) and in the Interrupt Priority High register (Table 50 and Table 51) shows the bit values and priority levels associated with each combination.

Registers

The PCA interrupt vector is located at address 0033H, the SPI interrupt vector is located at address 0043H, the I2C interrupt vector at 0043H and Keyboard interrupt vector is located at address 003BH. All other vectors addresses are the same as standard C52 devices.

Table 47. Priority Level Bit Values

IPH.x	IPL.x	Interrupt Level Priority
0	0	0 (Lowest)
0	1	1
1	0	2
1	1	3 (Highest)

A low-priority interrupt can be interrupted by a high priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence.

Power Management

Two power reduction modes are implemented in the AT89C51C2: the Idle mode and the Power-down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 mode detailed in Section “Enhanced Features”.

Reset

In order to start-up (cold reset) or to restart (warm reset) properly the microcontroller, an high level has to be applied on the RST pin. A bad level leads to a wrong initialization of the internal registers like SFRs, Program Counter... and to unpredictable behavior of the microcontroller. A proper device reset initializes the AT89C51C2 and vectors the CPU to address 0000h. RST input has a pull-down resistor allowing power-on reset by simply connecting an external capacitor to V_{DD} as shown in Figure 23. A warm reset can be applied either directly on the RST pin or indirectly by an internal reset source such as the watchdog timer. Resistor value and input characteristics are discussed in the Section “DC Characteristics” of the AT89C51C2 datasheet.

Figure 23. Reset Circuitry and Power-On Reset

Cold Reset

2 conditions are required before enabling a CPU start-up:

- V_{DD} must reach the specified V_{DD} range
- The level on X1 input pin must be outside the specification (V_{IH} , V_{IL})

If one of these 2 conditions are not met, the microcontroller does not start correctly and can execute an instruction fetch from anywhere in the program space. An active level applied on the RST pin must be maintained till both of the above conditions are met. A reset is active when the level V_{IH1} is reached and when the pulse width covers the period of time where V_{DD} and the oscillator are not stabilized. 2 parameters have to be taken into account to determine the reset pulse width:

- V_{DD} rise time,
- Oscillator startup time.

To determine the capacitor value to implement, the highest value of these 2 parameters has to be chosen. Table 1 gives some capacitor values examples for a minimum R_{RST} of 50 K Ω and different oscillator startup and V_{DD} rise times.

Table 1. Minimum Reset Capacitor Value for a 50 kΩ Pull-down Resistor⁽¹⁾

Oscillator Start-Up Time	VDD Rise Time		
	1 ms	10 ms	100 ms
5 ms	820 nF	1.2 μF	12 μF
20 ms	2.7 μF	3.9 μF	12 μF

Note: These values assume V_{DD} starts from 0V to the nominal value. If the time between 2 on/off sequences is too fast, the power-supply de-coupling capacitors may not be fully discharged, leading to a bad reset sequence.

Warm Reset

To achieve a valid reset, the reset signal must be maintained for at least 2 machine cycles (24 oscillator clock periods) while the oscillator is running. The number of clock periods is mode independent (X2 or X1).

Watchdog Reset

As detailed in Section “Hardware Watchdog Timer”, page 102, the WDT generates a 96-clock period pulse on the RST pin. In order to properly propagate this pulse to the rest of the application in case of external capacitor or power-supply supervisor circuit, a 1 kΩ resistor must be added as shown Figure 24.

Figure 24. Reset Circuitry for WDT Reset-out Usage

Reset Recommendation to Prevent Flash Corruption

An example of bad initialization situation may occur in an instance where the bit ENBOOT in AUXR1 register is initialized from the hardware bit BLJB upon reset. Since this bit allows mapping of the bootloader in the code area, a reset failure can be critical.

If one wants the ENBOOT cleared in order to unmap the boot from the code area (yet due to a bad reset) the bit ENBOOT in SFRs may be set. If the value of Program Counter is accidentally in the range of the boot memory addresses then a Flash access (write or erase) may corrupt the Flash on-chip memory.

It is recommended to use an external reset circuitry featuring power supply monitoring to prevent system malfunction during periods of insufficient power supply voltage (power supply failure, power supply switched off).

Idle Mode

An instruction that sets PCON.0 indicates that it is the last instruction to be executed before going into Idle mode. In Idle mode, the internal clock signal is gated off to the CPU, but not to the interrupt, Timer, and Serial Port functions. The CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator and all other registers maintain their data during idle. The port pins hold the logical states they had at the time Idle was activated. ALE and PSEN hold at logic high level.

There are two ways to terminate the Idle mode. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating the Idle mode. The interrupt will be serviced, and following RETI the next instruction to be executed will be the one following the instruction that put the device into idle.

The flag bits GF0 and GF1 can be used to give an indication if an interrupt occurred during normal operation or during idle. For example, an instruction that activates idle can also set one or both flag bits. When idle is terminated by an interrupt, the interrupt service routine can examine the flag bits.

The other way of terminating the Idle mode is with a hardware reset. Since the clock oscillator is still running, the hardware reset needs to be held active for only two machine cycles (24 oscillator periods) to complete the reset.

Power-down Mode

To save maximum power, a Power-down mode can be invoked by software (see PCON register).

In Power-down mode, the oscillator is stopped and the instruction that invoked Power-down mode is the last instruction executed. The internal RAM and SFRs retain their value until the Power-down mode is terminated. V_{CC} can be lowered to save further power. Either a hardware reset or an external interrupt can cause an exit from Power-down. To properly terminate Power-down, the reset or external interrupt should not be executed before V_{CC} is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize.

Only external interrupts $\overline{INT0}$, $\overline{INT1}$ and Keyboard Interrupts are useful to exit from Power-down. For that, interrupt must be enabled and configured as level or edge sensitive interrupt input. When Keyboard Interrupt occurs after a power down mode, 1024 clocks are necessary to exit to power down mode and enter in operating mode.

Holding the pin low restarts the oscillator but bringing the pin high completes the exit as detailed in Figure 25. When both interrupts are enabled, the oscillator restarts as soon as one of the two inputs is held low and power down exit will be completed when the first input will be released. In this case, the higher priority interrupt service routine is executed. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that puts the AT89C51IC2 into Power-down mode.

Figure 25. Power-down Exit Waveform

Exit from Power-down by reset redefines all the SFRs, exit from Power-down by external interrupt does not affect the SFRs.

Exit from Power-down by either reset or external interrupt does not affect the internal RAM content.

Note: If idle mode is activated with Power-down mode (IDL and PD bits set), the exit sequence is unchanged, when execution is vectored to interrupt, PD and IDL bits are cleared and idle mode is not entered.

Table 55 shows the state of ports during idle and power-down modes.

Table 55. State of Ports

Mode	Program Memory	ALE	PSEN	PORT0	PORT1	PORT2	PORT3
Idle	Internal	1	1	Port Data ⁽¹⁾	Port Data	Port Data	Port Data
Idle	External	1	1	Floating	Port Data	Address	Port Data
Power Down	Internal	0	0	Port Data ⁽¹⁾	Port Data	Port Data	Port Data
Power Down	External	0	0	Floating	Port Data	Port Data	Port Data

Port 0 can force a 0 level. A "one" will leave port floating.

Serial Port Interface (SPI)

The Serial Peripheral Interface Module (SPI) allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs.

Features

Features of the SPI Module include the following:

- Full-duplex, three-wire synchronous transfers
- Master or Slave operation
- Eight programmable Master clock rates
- Serial clock with programmable polarity and phase
- Master Mode fault error flag with MCU interrupt capability
- Write collision flag protection

Signal Description

Figure 26 shows a typical SPI bus configuration using one Master controller and many Slave peripherals. The bus is made of three wires connecting all the devices.

Figure 26. SPI Master/Slaves Interconnection

The Master device selects the individual Slave devices by using four pins of a parallel port to control the four \overline{SS} pins of the Slave devices.

Master Output Slave Input (MOSI)

This 1-bit signal is directly connected between the Master Device and a Slave Device. The MOSI line is used to transfer data in series from the Master to the Slave. Therefore, it is an output signal from the Master, and an input signal to a Slave. A Byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

Master Input Slave Output (MISO)

This 1-bit signal is directly connected between the Slave Device and a Master Device. The MISO line is used to transfer data in series from the Slave to the Master. Therefore, it is an output signal from the Slave, and an input signal to the Master. A Byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

SPI Serial Clock (SCK)

This signal is used to synchronize the data movement both in and out of the devices through their MOSI and MISO lines. It is driven by the Master for eight clock cycles which allows to exchange one Byte on the serial lines.

Slave Select (\overline{SS})

Each Slave peripheral is selected by one Slave Select pin (\overline{SS}). This signal must stay low for any message for a Slave. It is obvious that only one Master (\overline{SS} high level) can

drive the network. The Master may select each Slave device by software through port pins (Figure 27). To prevent bus conflicts on the MISO line, only one slave should be selected at a time by the Master for a transmission.

In a Master configuration, the \overline{SS} line can be used in conjunction with the MODF flag in the SPI Status register (SPSTA) to prevent multiple masters from driving MOSI and SCK (see Error conditions).

A high level on the \overline{SS} pin puts the MISO line of a Slave SPI in a high-impedance state.

The \overline{SS} pin could be used as a general-purpose if the following conditions are met:

- The device is configured as a Master and the SSDIS control bit in SPCON is set. This kind of configuration can be found when only one Master is driving the network and there is no way that the \overline{SS} pin could be pulled low. Therefore, the MODF flag in the SPSTA will never be set⁽¹⁾.
- The Device is configured as a Slave with CPHA and SSDIS control bits set⁽²⁾. This kind of configuration can happen when the system comprises one Master and one Slave only. Therefore, the \overline{SS} pin should always be selected and there is no reason that the Master uses the \overline{SS} pin to select the communicating Slave device.

Note: 1. Clearing SSDIS control bit does not clear MODF.
 2. Special care should be taken not to set SSDIS control bit when CPHA = '0' because in this mode, the \overline{SS} is used to start the transmission.

Baud Rate

In Master mode, the baud rate can be selected from a baud rate generator which is controlled by three bits in the SPCON register: SPR2, SPR1 and SPR0. The Master clock is selected from one of seven clock rates resulting from the division of the internal clock by 2, 4, 8, 16, 32, 64 or 128.

Table 56 gives the different clock rates selected by SPR2:SPR1:SPR0.

Table 56. SPI Master Baud Rate Selection

SPR2	SPR1	SPR0	Clock Rate	Baud Rate Divisor (BD)
0	0	0	$F_{CLK PERIPH} / 2$	2
0	0	1	$F_{CLK PERIPH} / 4$	4
0	1	0	$F_{CLK PERIPH} / 8$	8
0	1	1	$F_{CLK PERIPH} / 16$	16
1	0	0	$F_{CLK PERIPH} / 32$	32
1	0	1	$F_{CLK PERIPH} / 64$	64
1	1	0	$F_{CLK PERIPH} / 128$	128

Functional Description

Figure 27 shows a detailed structure of the SPI Module.

Figure 27. SPI Module Block Diagram

Operating Modes

The Serial Peripheral Interface can be configured in one of the two modes: Master mode or Slave mode. The configuration and initialization of the SPI Module is made through one register:

- The Serial Peripheral Control register (SPCON)

Once the SPI is configured, the data exchange is made using:

- SPCON
- The Serial Peripheral STATUS register (SPSTA)
- The Serial Peripheral DATA register (SPDAT)

During an SPI transmission, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line (SCK) synchronizes shifting and sampling on the two serial data lines (MOSI and MISO). A Slave Select line (SS) allows individual selection of a Slave SPI device; Slave devices that are not selected do not interfere with SPI bus activities.

When the Master device transmits data to the Slave device via the MOSI line, the Slave device responds by sending data to the Master device via the MISO line. This implies full-duplex transmission with both data out and data in synchronized with the same clock (Figure 28).

Figure 28. Full-Duplex Master-Slave Interconnection

Master Mode

The SPI operates in Master mode when the Master bit, MSTR⁽¹⁾, in the SPCON register is set. Only one Master SPI device can initiate transmissions. Software begins the transmission from a Master SPI Module by writing to the Serial Peripheral Data Register (SPDAT). If the shift register is empty, the Byte is immediately transferred to the shift register. The Byte begins shifting out on MOSI pin under the control of the serial clock, SCK. Simultaneously, another Byte shifts in from the Slave on the Master's MISO pin. The transmission ends when the Serial Peripheral transfer data flag, SPIF, in SPSTA becomes set. At the same time that SPIF becomes set, the received Byte from the Slave is transferred to the receive data register in SPDAT. Software clears SPIF by reading the Serial Peripheral Status register (SPSTA) with the SPIF bit set, and then reading the SPDAT.

Slave Mode

The SPI operates in Slave mode when the Master bit, MSTR⁽²⁾, in the SPCON register is cleared. Before a data transmission occurs, the Slave Select pin, \overline{SS} , of the Slave device must be set to '0'. \overline{SS} must remain low until the transmission is complete.

In a Slave SPI Module, data enters the shift register under the control of the SCK from the Master SPI Module. After a Byte enters the shift register, it is immediately transferred to the receive data register in SPDAT, and the SPIF bit is set. To prevent an overflow condition, Slave software must then read the SPDAT before another Byte enters the shift register⁽³⁾. A Slave SPI must complete the write to the SPDAT (shift register) at least one bus cycle before the Master SPI starts a transmission. If the write to the data register is late, the SPI transmits the data already in the shift register from the previous transmission. The maximum SCK frequency allowed in slave mode is $F_{CLK PERIPH} / 4$.

Transmission Formats

Software can select any of four combinations of serial clock (SCK) phase and polarity using two bits in the SPCON: the Clock Polarity (CPOL⁽⁴⁾) and the Clock Phase (CPHA⁴). CPOL defines the default SCK line level in idle state. It has no significant effect on the transmission format. CPHA defines the edges on which the input data are sampled and the edges on which the output data are shifted (Figure 29 and Figure 30). The clock phase and polarity should be identical for the Master SPI device and the communicating Slave device.

1. The SPI Module should be configured as a Master before it is enabled (SPEN set). Also, the Master SPI should be configured before the Slave SPI.
2. The SPI Module should be configured as a Slave before it is enabled (SPEN set).
3. The maximum frequency of the SCK for an SPI configured as a Slave is the bus clock speed.
4. Before writing to the CPOL and CPHA bits, the SPI should be disabled (SPEN = '0').

Figure 29. Data Transmission Format (CPHA = 0)

Figure 30. Data Transmission Format (CPHA = 1)

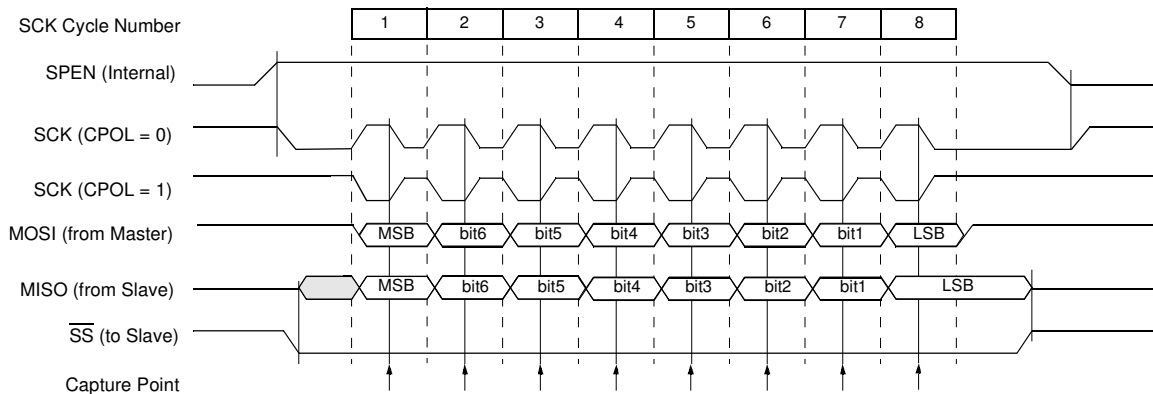

Figure 31. CPHA/SS Timing

As shown in Figure 29, the first SCK edge is the MSB capture strobe. Therefore, the Slave must begin driving its data before the first SCK edge, and a falling edge on the \overline{SS} pin is used to start the transmission. The \overline{SS} pin must be toggled high and then low between each Byte transmitted (Figure 31).

Figure 30 shows an SPI transmission in which CPHA is '1'. In this case, the Master begins driving its MOSI pin on the first SCK edge. Therefore, the Slave uses the first SCK edge as a start transmission signal. The \overline{SS} pin can remain low between transmissions (Figure 31). This format may be preferred in systems having only one Master and only one Slave driving the MISO data line.

Error Conditions

Mode Fault (MODF)

The following flags in the SPSTA signal SPI error conditions:

Mode Fault error in Master mode SPI indicates that the level on the Slave Select (\overline{SS}) pin is inconsistent with the actual mode of the device. MODF is set to warn that there may be a multi-master conflict for system control. In this case, the SPI system is affected in the following ways:

- An SPI receiver/error CPU interrupt request is generated
- The SPEN bit in SPCON is cleared. This disables the SPI
- The MSTR bit in SPCON is cleared

When \overline{SS} Disable (SSDIS) bit in the SPCON register is cleared, the MODF flag is set when the \overline{SS} signal becomes '0'.

However, as stated before, for a system with one Master, if the \overline{SS} pin of the Master device is pulled low, there is no way that another Master attempts to drive the network. In this case, to prevent the MODF flag from being set, software can set the SSDIS bit in the SPCON register and therefore making the \overline{SS} pin as a general-purpose I/O pin.

Clearing the MODF bit is accomplished by a read of SPSTA register with MODF bit set, followed by a write to the SPCON register. SPEN Control bit may be restored to its original set state after the MODF bit has been cleared.

Write Collision (WCOL)

A Write Collision (WCOL) flag in the SPSTA is set when a write to the SPDAT register is done during a transmit sequence.

WCOL does not cause an interruption, and the transfer continues uninterrupted.

Clearing the WCOL bit is done through a software sequence of an access to SPSTA and an access to SPDAT.

Overrun Condition

An overrun condition occurs when the Master device tries to send several data Bytes and the Slave device has not cleared the SPIF bit issuing from the previous data Byte transmitted. In this case, the receiver buffer contains the Byte sent after the SPIF bit was last cleared. A read of the SPDAT returns this Byte. All other Bytes are lost.

This condition is not detected by the SPI peripheral.

SS Error Flag (SSERR)

A Synchronous Serial Slave Error occurs when \overline{SS} goes high before the end of a received data in slave mode. SSERR does not cause an interruption, this bit is cleared by writing 0 to SPEN bit (reset of the SPI state machine).

Interrupts

Two SPI status flags can generate a CPU interrupt requests:

Table 57. SPI Interrupts

Flag	Request
SPIF (SP data transfer)	SPI Transmitter Interrupt request
MODF (Mode Fault)	SPI Receiver/Error Interrupt Request (if SSDIS = '0')

Serial Peripheral data transfer flag, SPIF: This bit is set by hardware when a transfer has been completed. SPIF bit generates transmitter CPU interrupt requests.

Mode Fault flag, MODF: This bit becomes set to indicate that the level on the \overline{SS} is inconsistent with the mode of the SPI. MODF with SSDIS reset, generates receiver/error CPU interrupt requests. When SSDIS is set, no MODF interrupt request is generated.

Figure 32 gives a logical view of the above statements.

Figure 32. SPI Interrupt Requests Generation

Registers

There are three registers in the Module that provide control, status and data storage functions. These registers are describes in the following paragraphs.

Serial Peripheral Control Register (SPCON)

- The Serial Peripheral Control Register does the following:
- Selects one of the Master clock rates
- Configure the SPI Module as Master or Slave
- Selects serial clock polarity and phase
- Enables the SPI Module
- Frees the SS pin for a general-purpose

Table 58 describes this register and explains the use of each bit

Table 58. SPCON Register

SPCON - Serial Peripheral Control Register (0C3H)

7	6	5	4	3	2	1	0
SPR2	SPEN	SSDIS	MSTR	CPOL	CPHA	SPR1	SPR0
Bit Number	Bit Mnemonic	Description					
7	SPR2	Serial Peripheral Rate 2 Bit with SPR1 and SPR0 define the clock rate.					
6	SPEN	Serial Peripheral Enable Cleared to disable the SPI interface. Set to enable the SPI interface.					
5	SSDIS	SS Disable Cleared to enable \overline{SS} in both Master and Slave modes. Set to disable \overline{SS} in both Master and Slave modes. In Slave mode, this bit has no effect if CPHA = '0'. When SSDIS is set, no MODF interrupt request is generated.					
4	MSTR	Serial Peripheral Master Cleared to configure the SPI as a Slave. Set to configure the SPI as a Master.					
3	CPOL	Clock Polarity Cleared to have the SCK set to '0' in idle state. Set to have the SCK set to '1' in idle low.					
2	CPHA	Clock Phase Cleared to have the data sampled when the SCK leaves the idle state (see CPOL). Set to have the data sampled when the SCK returns to idle state (see CPOL).					

Bit Number	Bit Mnemonic	Description
1	SPR1	SPR2 SPR1 SPR0 Serial Peripheral Rate 0 0 0 $F_{CLK PERIPH} / 2$
		0 0 1 $F_{CLK PERIPH} / 4$
		0 1 0 $F_{CLK PERIPH} / 8$
0	SPR0	0 1 1 $F_{CLK PERIPH} / 16$
		1 0 0 $F_{CLK PERIPH} / 32$
		1 0 1 $F_{CLK PERIPH} / 64$
		1 1 0 $F_{CLK PERIPH} / 128$
		1 1 1 Invalid

Reset Value = 0001 0100b

Not bit addressable

Serial Peripheral Status Register (SPSTA)

The Serial Peripheral Status Register contains flags to signal the following conditions:

- Data transfer complete
- Write collision
- Inconsistent logic level on \overline{SS} pin (mode fault error)

Table 59 describes the SPSTA register and explains the use of every bit in the register.

Table 59. SPSTA Register

SPSTA - Serial Peripheral Status and Control register (0C4H)

7	6	5	4	3	2	1	0
SPIF	WCOL	SSERR	MODF	-	-	-	-
Bit Number	Bit Mnemonic	Description					
7	SPIF	Serial Peripheral Data Transfer Flag Cleared by hardware to indicate data transfer is in progress or has been approved by a clearing sequence. Set by hardware to indicate that the data transfer has been completed.					
6	WCOL	Write Collision Flag Cleared by hardware to indicate that no collision has occurred or has been approved by a clearing sequence. Set by hardware to indicate that a collision has been detected.					
5	SSERR	Synchronous Serial Slave Error Flag Set by hardware when \overline{SS} is deasserted before the end of a received data. Cleared by disabling the SPI (clearing SPEN bit in SPCON).					
4	MODF	Mode Fault Cleared by hardware to indicate that the \overline{SS} pin is at appropriate logic level, or has been approved by a clearing sequence. Set by hardware to indicate that the \overline{SS} pin is at inappropriate logic level.					
3	-	Reserved The value read from this bit is indeterminate. Do not set this bit					
2	-	Reserved The value read from this bit is indeterminate. Do not set this bit.					

Bit Number	Bit Mnemonic	Description
1	-	Reserved The value read from this bit is indeterminate. Do not set this bit.
0	-	Reserved The value read from this bit is indeterminate. Do not set this bit.

Reset Value = 00X0 XXXXb

Not Bit addressable

Serial Peripheral DATa Register (SPDAT)

The Serial Peripheral Data Register (Table 60) is a read/write buffer for the receive data register. A write to SPDAT places data directly into the shift register. No transmit buffer is available in this model.

A Read of the SPDAT returns the value located in the receive buffer and not the content of the shift register.

Table 60. SPDAT Register

SPDAT - Serial Peripheral Data Register (0C5H)

7	6	5	4	3	2	1	0
R7	R6	R5	R4	R3	R2	R1	R0

Reset Value = Indeterminate

R7:R0: Receive data bits

SPCON, SPSTA and SPDAT registers may be read and written at any time while there is no on-going exchange. However, special care should be taken when writing to them while a transmission is on-going:

- Do not change SPR2, SPR1 and SPR0
- Do not change CPHA and CPOL
- Do not change MSTR
- Clearing SPEN would immediately disable the peripheral
- Writing to the SPDAT will cause an overflow.

Keyboard Interface

The AT89C51IC2 implements a keyboard interface allowing the connection of a 8 x n matrix keyboard. It is based on 8 inputs with programmable interrupt capability on both high or low level. These inputs are available as alternate function of P1 and allow to exit from idle and power down modes.

The keyboard interface interfaces with the C51 core through 3 special function registers: KBL5, the Keyboard Level Selection register (Table 63), KBE, The Keyboard interrupt Enable register (Table 62), and KBF, the Keyboard Flag register (Table 61).

Interrupt

The keyboard inputs are considered as 8 independent interrupt sources sharing the same interrupt vector. An interrupt enable bit (KBD in IEN1) allows global enable or disable of the keyboard interrupt (see Figure 33). As detailed in Figure 34 each keyboard input has the capability to detect a programmable level according to KBL5.x bit value. Level detection is then reported in interrupt flags KBF.x that can be masked by software using KBE.x bits.

This structure allow keyboard arrangement from 1 by n to 8 by n matrix and allow usage of P1 inputs for other purpose.

Figure 33. Keyboard Interface Block Diagram

Figure 34. Keyboard Input Circuitry

Power Reduction Mode

P1 inputs allow exit from idle and power down modes as detailed in Section “Power Management”, page 67.

2-wire Interface (TWI)

This section describes the 2-wire interface. In the rest of the section SSLC means Two-wire. The 2-wire bus is a bi-directional 2-wire serial communication standard. It is designed primarily for simple but efficient integrated circuit (IC) control. The system is comprised of two lines, SCL (Serial Clock) and SDA (Serial Data) that carry information between the ICs connected to them. The serial data transfer is limited to 400Kbit/s in standard mode. Various communication configuration can be designed using this bus. Figure 35 shows a typical 2-wire bus configuration. All the devices connected to the bus can be master and slave.

Figure 35. 2-wire Bus Configuration

Figure 36. Block Diagram

Description

The CPU interfaces to the 2-wire logic via the following four 8-bit special function registers: the Synchronous Serial Control register (SSCON; Table 73), the Synchronous Serial Data register (SSDAT; Table 74), the Synchronous Serial Control and Status register (SSCS; Table 75) and the Synchronous Serial Address register (SSADR Table 78).

SSCON is used to enable SSLC, to program the bit rate (see Table 66), to enable slave modes, to acknowledge or not a received data, to send a START or a STOP condition on the 2-wire bus, and to acknowledge a serial interrupt. A hardware reset disables SSLC.

In write mode, SSCS is used to select the 2-wire interface and to select the bit rate source. In read mode, SSCS contains a status code which reflects the status of the 2-wire logic and the 2-wire bus. The three least significant bits are always zero. The five most significant bits contains the status code. There are 26 possible status codes. When SSCS contains F8h, no relevant state information is available and no serial interrupt is requested. A valid status code is available in SSCS one machine cycle after SI is set by hardware and is still present one machine cycle after SI has been reset by software. Table 68.to Table 72. give the status for the master modes and miscellaneous states.

SSDAT contains a byte of serial data to be transmitted or a byte which has just been received. It is addressable while it is not in process of shifting a byte. This occurs when 2-wire logic is in a defined state and the serial interrupt flag is set. Data in SSDAT remains stable as long as SI is set. While data is being shifted out, data on the bus is simultaneously shifted in; SSDAT always contains the last byte present on the bus.

SSADR may be loaded with the 7-bit slave address (7 most significant bits) to which SSLC will respond when programmed as a slave transmitter or receiver. The LSB is used to enable general call address (00h) recognition.

Figure 37 shows how a data transfer is accomplished on the 2-wire bus.

Figure 37. Complete data transfer on 2-wire bus

The four operating modes are:

- Master Transmitter
- Master Receiver
- Slave transmitter
- Slave receiver

Data transfer in each mode of operation is shown in Table 68 to Table 72 and Figure 38. to Figure 41.. These figures contain the following abbreviations:

S : START condition

R : Read bit (high level at SDA)

W: Write bit (low level at SDA)

A: Acknowledge bit (low level at SDA)

\bar{A} : Not acknowledge bit (high level at SDA)

Data: 8-bit data byte

P : STOP condition

In Figure 38 to Figure 41, circles are used to indicate when the serial interrupt flag is set. The numbers in the circles show the status code held in SSCS. At these points, a service routine must be executed to continue or complete the serial transfer. These service routines are not critical since the serial transfer is suspended until the serial interrupt flag is cleared by software.

When the serial interrupt routine is entered, the status code in SSCS is used to branch to the appropriate service routine. For each status code, the required software action and details of the following serial transfer are given in Table 68 to Table 72.

Master Transmitter Mode

In the master transmitter mode, a number of data bytes are transmitted to a slave receiver (Figure 38). Before the master transmitter mode can be entered, SSSCON must be initialised as follows:

Table 64. SSSCON Initialization

CR2	SSIE	STA	STO	SI	AA	CR1	CR0
bit rate	1	0	0	0	X	bit rate	bit rate

CR0, CR1 and CR2 define the internal serial bit rate if external bit rate generator is not used. SSIE must be set to enable SSLC. STA, STO and SI must be cleared.

The master transmitter mode may now be entered by setting the STA bit. The 2-wire logic will now test the 2-wire bus and generate a START condition as soon as the bus becomes free. When a START condition is transmitted, the serial interrupt flag (SI bit in SSSCON) is set, and the status code in SSSCS will be 08h. This status must be used to vector to an interrupt routine that loads SSDAT with the slave address and the data direction bit (SLA+W).

When the slave address and the direction bit have been transmitted and an acknowledgement bit has been received, SI is set again and a number of status code in SSSCS are possible. There are 18h, 20h or 38h for the master mode and also 68h, 78h or B0h if the slave mode was enabled (AA=logiC 1). The appropriate action to be taken for each of these status code is detailed in Table 68. This scheme is repeated until a STOP condition is transmitted.

SSIE, CR2, CR1 and CR0 are not affected by the serial transfer and are referred to Table 7 to Table 11. After a repeated START condition (state 10h) SSLC may switch to the master receiver mode by loading SSDAT with SLA+R.

Master Receiver Mode

In the master receiver mode, a number of data bytes are received from a slave transmitter (Figure 39). The transfer is initialized as in the master transmitter mode. When the START condition has been transmitted, the interrupt routine must load SSDAT with the 7-bit slave address and the data direction bit (SLA+R). The serial interrupt flag SI must then be cleared before the serial transfer can continue.

When the slave address and the direction bit have been transmitted and an acknowledgement bit has been received, the serial interrupt flag is set again and a number of status code in SSCS are possible. There are 40h, 48h or 38h for the master mode and also 68h, 78h or B0h if the slave mode was enabled (AA=logic 1). The appropriate action to be taken for each of these status code is detailed in Table 69. This scheme is repeated until a STOP condition is transmitted.

SSIE, CR2, CR1 and CR0 are not affected by the serial transfer and are referred to Table 7 to Table 11. After a repeated START condition (state 10h) SSLC may switch to the master transmitter mode by loading SSDAT with SLA+W.

Slave Receiver Mode

In the slave receiver mode, a number of data bytes are received from a master transmitter (Figure 40). To initiate the slave receiver mode, SSADR and SSSCON must be loaded as follows:

Table 65. SSADR: slave receiver mode initialization

A6	A5	A4	A3	A2	A1	A0	GC
own slave address							

The upper 7 bits are the address to which SSLC will respond when addressed by a master. If the LSB (GC) is set SSLC will respond to the general call address (00h); otherwise it ignores the general call address.

Table 66. SSSCON: slave receiver mode initialization

CR2	SSIE	STA	STO	SI	AA	CR1	CR0
bit rate	1	0	0	0	1	bit rate	bit rate

CR0, CR1 and CR2 have no effect in the slave mode. SSIE must be set to enable SSLC. The AA bit must be set to enable the own slave address or the general call address acknowledgement. STA, STO and SI must be cleared.

When SSADR and SSSCON have been initialised, SSLC waits until it is addressed by its own slave address followed by the data direction bit which must be at logic 0 (W) for SSLC to operate in the slave receiver mode. After its own slave address and the W bit have been received, the serial interrupt flag is set and a valid status code can be read from SSSCS. This status code is used to vector to an interrupt service routine. The appropriate action to be taken for each of these status code is detailed in Table 70. The slave receiver mode may also be entered if arbitration is lost while SSLC is in the master mode (states 68h and 78h).

If the AA bit is reset during a transfer, SSLC will return a not acknowledge (logic 1) to SDA after the next received data byte. While AA is reset, SSLC does not respond to its own slave address. However, the 2-wire bus is still monitored and address recognition may be resume at any time by setting AA. This means that the AA bit may be used to temporarily isolate SSLC from the 2-wire bus.

Slave Transmitter Mode

In the slave transmitter mode, a number of data bytes are transmitted to a master receiver (Figure 41). Data transfer is initialized as in the slave receiver mode. When SSADR and SSSCON have been initialized, SSLC waits until it is addressed by its own

slave address followed by the data direction bit which must be at logic 1 (R) for SSLC to operate in the slave transmitter mode. After its own slave address and the R bit have been received, the serial interrupt flag is set and a valid status code can be read from SSCS. This status code is used to vector to an interrupt service routine. The appropriate action to be taken for each of these status code is detailed in Table 71. The slave transmitter mode may also be entered if arbitration is lost while SSLC is in the master mode.

If the AA bit is reset during a transfer, SSLC will transmit the last byte of the transfer and enter state C0h or C8h. SSLC is switched to the not addressed slave mode and will ignore the master receiver if it continues the transfer. Thus the master receiver receives all 1's as serial data. While AA is reset, SSLC does not respond to its own slave address. However, the 2-wire bus is still monitored and address recognition may be resume at any time by setting AA. This means that the AA bit may be used to temporarily isolate SSLC from the 2-wire bus.

Miscellaneous States

There are two SSCS codes that do not correspond to a define SSLC hardware state (Table 72). These codes are discuss hereafter.

Status F8h indicates that no relevant information is available because the serial interrupt flag is not set yet. This occurs between other states and when SSLC is not involved in a serial transfer.

Status 00h indicates that a bus error has occurred during an SSLC serial transfer. A bus error is caused when a START or a STOP condition occurs at an illegal position in the format frame. Examples of such illegal positions happen during the serial transfer of an address byte, a data byte, or an acknowledge bit. When a bus error occurs, SI is set. To recover from a bus error, the STO flag must be set and SI must be cleared. This causes SSLC to enter the not addressed slave mode and to clear the STO flag (no other bits in SSCON are affected). The SDA and SCL lines are released and no STOP condition is transmitted.

Notes

SSLC interfaces to the external 2-wire bus via two port pins: SCL (serial clock line) and SDA (serial data line). To avoid low level asserting on these lines when SSLC is enabled, the output latches of SDA and SLC must be set to logic 1.

Table 67. Bit frequency configuration

CR2	CR1	CR0	Bit Frequency (kHz)		F _{OSCA} divided by

Hardware Watchdog Timer

The WDT is intended as a recovery method in situations where the CPU may be subjected to software upset. The WDT consists of a 14-bit counter and the WatchDog Timer ReSeT (WDTRST) SFR. The WDT is by default disabled from exiting reset. To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will drive an output RESET HIGH pulse at the RST-pin.

Using the WDT

To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, the user needs to service it by writing to 01EH and 0E1H to WDTRST to avoid WDT overflow. The 14-bit counter overflows when it reaches 16383 (3FFFH) and this will reset the device. When WDT is enabled, it will increment every machine cycle while the oscillator is running. This means the user must reset the WDT at least every 16383 machine cycle. To reset the WDT the user must write 01EH and 0E1H to WDTRST. WDTRST is a write only register. The WDT counter cannot be read or written. When WDT overflows, it will generate an output RESET pulse at the RST-pin. The RESET pulse duration is $96 \times T_{CLK\ PERIPH}$, where $T_{CLK\ PERIPH} = 1/F_{CLK\ PERIPH}$. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset.

To have a more powerful WDT, a 2^7 counter has been added to extend the Time-out capability, ranking from 16ms to 2s @ $F_{OSCA} = 12\text{MHz}$. To manage this feature, refer to WDTPRG register description, Table 79.

Reset value XXXX X000

WDT During Power Down and Idle

In Power Down mode the oscillator stops, which means the WDT also stops. While in Power Down mode the user does not need to service the WDT. There are 2 methods of exiting Power Down mode: by a hardware reset or via a level activated external interrupt which is enabled prior to entering Power Down mode. When Power Down is exited with hardware reset, servicing the WDT should occur as it normally should whenever the AT89C51IC2 is reset. Exiting Power Down with an interrupt is significantly different. The interrupt is held low long enough for the oscillator to stabilize. When the interrupt is brought high, the interrupt is serviced. To prevent the WDT from resetting the device while the interrupt pin is held low, the WDT is not started until the interrupt is pulled high. It is suggested that the WDT be reset during the interrupt service routine.

To ensure that the WDT does not overflow within a few states of exiting of powerdown, it is better to reset the WDT just before entering powerdown.

In the Idle mode, the oscillator continues to run. To prevent the WDT from resetting the AT89C51IC2 while in Idle mode, the user should always set up a timer that will periodically exit Idle, service the WDT, and re-enter Idle mode.

Power-off Flag

The power-off flag allows the user to distinguish between a “cold start” reset and a “warm start” reset.

A cold start reset is the one induced by V_{CC} switch-on. A warm start reset occurs while V_{CC} is still applied to the device and could be generated for example by an exit from power-down.

The power-off flag (POF) is located in PCON register (Table 81). POF is set by hardware when V_{CC} rises from 0 to its nominal voltage. The POF can be set or cleared by software allowing the user to determine the type of reset.

Table 81. PCON Register

PCON - Power Control Register (87h)

7	6	5	4	3	2	1	0
SMOD1	SMOD0	-	POF	GF1	GF0	PD	IDL
Bit Number	Bit Mnemonic	Description					
7	SMOD1	Serial port Mode bit 1 Set to select double baud rate in mode 1, 2 or 3.					
6	SMOD0	Serial port Mode bit 0 Cleared to select SM0 bit in SCON register. Set to select FE bit in SCON register.					
5	-	Reserved The value read from this bit is indeterminate. Do not set this bit.					
4	POF	Power-Off Flag Cleared to recognize next reset type. Set by hardware when V_{CC} rises from 0 to its nominal voltage. Can also be set by software.					
3	GF1	General purpose Flag Cleared by user for general purpose usage. Set by user for general purpose usage.					
2	GF0	General purpose Flag Cleared by user for general purpose usage. Set by user for general purpose usage.					
1	PD	Power-Down mode bit Cleared by hardware when reset occurs. Set to enter power-down mode.					
0	IDL	Idle mode bit Cleared by hardware when interrupt or reset occurs. Set to enter idle mode.					

Reset Value = 00X1 0000b

Not bit addressable

ONCE[™] Mode (ON Chip Emulation)

The ONCE mode facilitates testing and debugging of systems using AT89C51IC2 without removing the circuit from the board. The ONCE mode is invoked by driving certain pins of the AT89C51IC2; the following sequence must be exercised:

- Pull ALE low while the device is in reset (RST high) and $\overline{\text{PSEN}}$ is high.
- Hold ALE low as RST is deactivated.

While the AT89C51IC2 is in ONCE mode, an emulator or test CPU can be used to drive the circuit. Table 82 shows the status of the port pins during ONCE mode.

Normal operation is restored when normal reset is applied.

Table 82. External Pin Status during ONCE Mode

ALE	PSEN	Port 0	Port 1	Port 2	Port 3	Port I2	XTALA1/2	XTALB1/2
Weak pull-up	Weak pull-up	Float	Weak pull-up	Weak pull-up	Weak pull-up	Float	Active	Active

(a) "Once" is a registered trademark of Intel Corporation.

Reduced EMI Mode

The ALE signal is used to demultiplex address and data buses on port 0 when used with external program or data memory. Nevertheless, during internal code execution, ALE signal is still generated. In order to reduce EMI, ALE signal can be disabled by setting AO bit.

The AO bit is located in AUXR register at bit location 0. As soon as AO is set, ALE is no longer output but remains active during MOVX and MOVC instructions and external fetches. During ALE disabling, ALE pin is weakly pulled high.

Table 83. AUXR Register

AUXR - Auxiliary Register (8Eh)

7	6	5	4	3	2	1	0
-	-	M0	-	XRS1	XRS0	EXTRAM	AO

7	-	Reserved The value read from this bit is indeterminate. Do not set this bit					
6	-	Reserved The value read from this bit is indeterminate. Do not set this bit					
5	M0	Pulse length Cleared to stretch MOVX control: the RD/ and the WR/ pulse length is 6 clock periods (default). Set to stretch MOVX control: the RD/ and the WR/ pulse length is 30 clock periods.					
4	-	Reserved The value read from this bit is indeterminate. Do not set this bit					
3	XRS1	XRAM Size <u>XRS1XRS0XRAM size</u> 0 0256 bytes (default) 0 1512 bytes 1 0768 bytes 1 11024 bytes					
2	XRS0						
1	EXTRAM	EXTRAM bit Cleared to access internal XRAM using movx @ Ri/ @ DPTR. Set to access external memory. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), default setting, XRAM selected.					
0	AO	ALE Output bit Cleared, ALE is emitted at a constant rate of 1/6 the oscillator frequency (or 1/3 if X2 mode is used).(default) Set, ALE is active only during a MOVX or MOVC instructione is used.					

Flash EEPROM Memory

The Flash memory increases EPROM and ROM functionality with in-circuit electrical erasure and programming. It contains 32K Bytes of program memory organized in 128 or 256 pages of 128 Bytes. This memory is both parallel and serial In-system Programmable (ISP). ISP allows devices to alter their own program memory in the actual end product under software control. A default serial loader (bootloader) program allows ISP of the Flash.

The programming does not require external dedicated programming voltage. The necessary high programming voltage is generated on-chip using the standard V_{CC} pins of the microcontroller.

Features

- Flash EEPROM internal program memory.
- Boot vector allows user provided Flash loader code to reside anywhere in the Flash memory space. This configuration provides flexibility to the user.
- Default loader in Boot ROM allows programming via the serial port without the need of a user-provided loader.
- Up to 64K Byte external program memory if the internal program memory is disabled ($EA = 0$).
- Programming and erase voltage with standard 5V or 3V V_{CC} supply.
- Read/Programming/Erase:
 - Byte-wise read without wait state
 - Byte or page erase and programming (10 ms)
- Typical programming time (32K Bytes) in 10 s
- Parallel programming with 87C51 compatible hardware interface to programmer
- Programmable security for the code in the Flash
- 10K write cycles
- 10 years data retention

Flash Programming and Erasure

The 32K Bytes Flash is programmed by Bytes or by pages of 128 Bytes. It is not necessary to erase a Byte or a page before programming. The programming of a Byte or a page includes a self erase before programming.

There are three methods of programming the Flash memory:

- First, the on-chip ISP bootloader may be invoked which will use low level routines to program the pages. The interface used for serial downloading of Flash is the UART.
- Second, the Flash may be programmed or erased in the end-user application by calling low-level routines through a common entry point in the Boot ROM.
- Third, the Flash may be programmed using the parallel method by using a conventional EPROM programmer. The parallel programming method used by these devices is similar to that used by EPROM 87C51 but it is not identical and the commercially available programmers need to have support for the AT89C51IC2. The bootloader and the Application Programming Interface (API) routines are located in the BOOT ROM.

Flash Registers and Memory Map

The AT89C51IC2 Flash memory uses several registers for its management:

- Hardware registers can only be accessed through the parallel programming modes which are handled by the parallel programmer.
- Software registers are in a special page of the Flash memory which can be accessed through the API or with the parallel programming modes. This page, called "Extra Flash Memory", is not in the internal Flash program memory addressing space.

Hardware Register

The only hardware register of the AT89C51IC2 is called Hardware Security Byte (HSB).

Table 84. Hardware Security Byte (HSB)

Bit Number	Bit Mnemonic	Description					
7	X2	X2 Mode Programmed ('0' value) to force X2 mode (6 clocks per instruction) after reset. Unprogrammed ('1' Value) to force X1 mode, Standard Mode, after reset (Default).					
6	BLJB	Boot Loader Jump Bit Unprogrammed ('1' value) to start the user's application on next reset at address 0000h. Programmed ('0' value) to start the boot loader at address F800h on next reset (Default).					
5	OSC	Oscillator Bit Programmed to allow oscillator B at startup Unprogrammed this bit to allow oscillator A at startup (Default).					
4	-	Reserved					
3	XRAM	XRAM config bit (only programmable by programmer tools) Programmed to inhibit XRAM Unprogrammed, this bit to valid XRAM (Default)					
2-0	LB2-0	User Memory Lock Bits (only programmable by programmer tools) See Table 85					

Boot Loader Jump Bit (BLJB)

One bit of the HSB, the BLJB bit, is used to force the boot address:

- When this bit is programmed ('1' value) the boot address is 0000h.
- When this bit is unprogrammed ('1' value) the boot address is F800h. By default, this bit is unprogrammed and the ISP is enabled.

Flash Memory Lock Bits

The three lock bits provide different levels of protection for the on-chip code and data, when programmed as shown in Table 85.

Table 85. Program Lock Bits

Program Lock Bits				Protection Description
Security Level	LB0	LB1	LB2	
1	U	U	U	No program lock features enabled.
2	P	U	U	MOVC instruction executed from external program memory is disabled from fetching code Bytes from internal memory, \overline{EA} is sampled and latched on reset, and further parallel programming of the Flash is disabled. ISP and software programming with API are still allowed.
3	X	P	U	Same as 2, also verify through parallel programming interface is disabled.
4	X	X	P	Same as 3, also external execution is disabled. (Default)

Note: U: unprogrammed or "one" level.
 P: programmed or "zero" level.
 X: don't care
WARNING: Security level '2' and '3' should only be programmed after Flash and code verification.

These security bits protect the code access through the parallel programming interface. They are set by default to level 4. The code access through the ISP is still possible and is controlled by the "software security bits" which are stored in the extra Flash memory accessed by the ISP firmware.

To load a new application with the parallel programmer, a chip erase must first be done. This will set the HSB in its inactive state and will erase the Flash memory. The part reference can always be read using Flash parallel programming modes.

Default Values

The default value of the HSB provides parts ready to be programmed with ISP:

- BLJB: Programmed force ISP operation.
- X2: Unprogrammed to force X1 mode (Standard Mode).
- XRAM: Unprogrammed to valid XRAM
- LB2-0: Security level four to protect the code from a parallel access with maximum security.

Software Registers

Several registers are used, in factory and by parallel programmers, to make copies of hardware registers contents. These values are used by Atmel ISP.

These registers are in the "Extra Flash Memory" part of the Flash memory. This block is also called "XAF" or eXtra Array Flash. They are accessed in the following ways:

- Commands issued by the parallel memory programmer.
- Commands issued by the ISP software.
- Calls of API issued by the application software.

Several software registers are described in Table 86.

Table 86. Default Values

Mnemonic	Definition	Default value	Description
SBV	Software Boot Vector	FCh	
HSB	Hardware security Byte	101x 1011b	
BSB	Boot Status Byte	0FFh	
SSB	Software Security Byte	FFh	
	Copy of the Manufacturer Code	58h	ATMEL
	Copy of the Device ID #1: Family Code	D7h	C51 X2, Electrically Erasable
	Copy of the Device ID #2: memories	F7h	AT89C51IC2 32KB
	Copy of the Device ID #3: name and revision	EFh	AT89C51IC2 32KB, Revision 0

After programming the part by ISP, the BSB must be cleared (00h) in order to allow the application to boot at 0000h.

The content of the Software Security Byte (SSB) is described in Table 86 and Table 88.

To assure code protection from a parallel access, the HSB must also be at the required level.

Table 87. Software Security Byte

7	6	5	4	3	2	1	0
-	-	-	-	-	-	LB1	LB0
Bit Number	Bit Mnemonic	Description					
7	-	Reserved Do not clear this bit.					
6	-	Reserved Do not clear this bit.					
5	-	Reserved Do not clear this bit.					
4	-	Reserved Do not clear this bit.					
3	-	Reserved Do not clear this bit.					
2	-	Reserved Do not clear this bit.					
1-0	LB1-0	User Memory Lock Bits see Table 88					

The two lock bits provide different levels of protection for the on-chip code and data, when programmed as shown in Table 88.

Table 88. Program Lock Bits of the SSB

Program Lock Bits			Protection Description
Security level	LB0	LB1	
1	U	U	No program lock features enabled.
2	P	U	ISP programming of the Flash is disabled.
3	X	P	Same as 2, also verify through ISP programming interface is disabled.

Note: U: unprogrammed or "one" level.
 P: programmed or "zero" level.
 X: don't care
 WARNING: Security level 2 and 3 should only be programmed after Flash and code verification.

Flash Memory Status

AT89C51C2 parts are delivered in standard with the ISP boot in the Flash memory. After ISP or parallel programming, the possible contents of the Flash memory are summarized on Figure 42.

Figure 42. Flash Memory Possible Contents

Memory Organization

In the AT89C51C2, the lowest 32K of the 64 KB program memory address space is filled by internal Flash.

When the \overline{EA} pin is high, the processor fetches instructions from internal program Flash. Bus expansion for accessing program memory from 32K upward automatic since external instruction fetches occur automatically when the program counter exceeds 7FFFh (32K). If the \overline{EA} pin is tied low, all program memory fetches are from external memory.

Bootloader Architecture

Introduction

The bootloader manages a communication according to a specific defined protocol to provide the whole access and service on Flash memory. Furthermore, all accesses and routines can be called from the user application.

Figure 43. Diagram Context Description

Acronyms

ISP: In-system Programming

SBV: Software Boot Vector

BSB: Boot Status Byte

SSB: Software Security Bit

HW : Hardware Byte

Functional Description

Figure 44. Bootloader Functional Description

On the above diagram, the on-chip bootloader processes are:

- ISP Communication Management

The purpose of this process is to manage the communication and its protocol between the on-chip bootloader and an external device. The on-chip ROM implements a serial protocol (see section Bootloader Protocol). This process translates serial communication frames (UART) into Flash memory access (read, write, erase ...).

- User Call Management

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface (API calls), included in the ROM bootloader. The programming functions are selected by setting up the microcontroller's registers before making a call to a common entry point (0xFFFF). Results are returned in the registers. The purpose of this process is to translate the registers' values into internal Flash Memory Management.

- Flash Memory Management

This process manages low-level access to Flash memory (performs read and write access).

Bootloader Functionality

Introduction

The bootloader can be activated by two means: Hardware conditions or regular boot process.

The Hardware conditions (EA = 1, PSEN = 0) during the Reset# falling edge force the on-chip bootloader execution. This allows an application to be built that will normally execute the end user's code but can be manually forced into default ISP operation.

As PSEN is an output port in normal operating mode (running user application or bootloader code) after reset, it is recommended to release PSEN after falling edge of reset signal. The hardware conditions are sampled at reset signal falling edge, thus they can be released at any time when reset input is low.

To ensure correct microcontroller startup, the PSEN pin should not be tied to ground during power-on (See Figure 45).

Figure 45. Hardware conditions typical sequence during power-on.

The on-chip bootloader boot process is shown in Figure 46.

	Purpose
Hardware Conditions	The Hardware Conditions force the bootloader execution whatever BLJB, BSB and SBV values.
BLJB	<p>The Boot Loader Jump Bit forces the application execution. BLJB = 0 => Boot loader execution. BLJB = 1 => Application execution.</p> <p>The BLJB is a fuse bit in the Hardware Byte. That can be modified by hardware (programmer) or by software (API).</p> <p>Note: The BLJB test is perform by hardware to prevent any program execution.</p>
SBV	<p>The Software Boot Vector contains the high address of customer bootloader stored in the application. SBV = FCh (default value) if no customer bootloader in user Flash.</p> <p>Note: The costumer bootloader is called by JMP [SBV]00h instruction.</p>

Boot Process

Figure 46. Bootloader process

ISP Protocol Description

Physical Layer

The UART used to transmit information has the following configuration:

- Character: 8-bit data
- Parity: none
- Stop: 1 bit
- Flow control: none
- Baud rate: autobaud is performed by the bootloader to compute the baud rate chosen by the host.

Frame Description

The Serial Protocol is based on the Intel Hex-type records.

Intel Hex records consist of ASCII characters used to represent hexadecimal values and are summarized below.

Table 89. Intel Hex Type Frame

Record Mark ':'	Reclen	Load Offset	Record Type	Data or Info	Checksum
1 byte	1 byte	2 bytes	1 bytes	n byte	1 byte

- Record Mark:
 - Record Mark is the start of frame. This field must contain ':'.
- Reclen:
 - Reclen specifies the number of Bytes of information or data which follows the Record Type field of the record.
- Load Offset:
 - Load Offset specifies the 16-bit starting load offset of the data Bytes, therefore this field is used only for
 - Data Program Record (see Section "ISP Commands Summary").
- Record Type:
 - Record Type specifies the command type. This field is used to interpret the remaining information within the frame. The encoding for all the current record types is described in Section "ISP Commands Summary".
- Data/Info:
 - Data/Info is a variable length field. It consists of zero or more Bytes encoded as pairs of hexadecimal digits. The meaning of data depends on the Record Type.
- Checksum:
 - The two's complement of the 8-bit Bytes that result from converting each pair of ASCII hexadecimal digits to one Byte of binary, and including the Reclen field to and including the last Byte of the Data/Info field. Therefore, the sum of all the ASCII pairs in a record after converting to binary, from the Reclen field to and including the Checksum field, is zero.

Functional Description

Software Security Bits (SSB)

The SSB protects any Flash access from ISP command.
The command "Program Software Security bit" can only write a higher priority level.

There are three levels of security:

- level 0: **NO_SECURITY** (FFh)

This is the default level.

From level 0, one can write level 1 or level 2.

- level 1: **WRITE_SECURITY** (FEh)

For this level it is impossible to write in the Flash memory, BSB and SBV.

The Bootloader returns 'P' on write access.

From level 1, one can write only level 2.

- level 2: **RD_WR_SECURITY** (FCh)

The level 2 forbids all read and write accesses to/from the Flash/EEPROM memory.

The Bootloader returns 'L' on read or write access.

Only a full chip erase in parallel mode (using a programmer) or ISP command can reset the software security bits.

From level 2, one cannot read and write anything.

Table 90. Software Security Byte Behavior

	Level 0	Level 1	Level 2
Flash/EEPROM	Any access allowed	Read only access allowed	Any access not allowed
Fuse Bit	Any access allowed	Read only access allowed	Any access not allowed
BSB & SBV	Any access allowed	Read only access allowed	Any access not allowed
SSB	Any access allowed	Write level 2 allowed	Read only access allowed
Manufacturer Info	Read only access allowed	Read only access allowed	Read only access allowed
Bootloader Info	Read only access allowed	Read only access allowed	Read only access allowed
Erase Block	Allowed	Not allowed	Not allowed
Full-chip Erase	Allowed	Allowed	Allowed
Blank Check	Allowed	Allowed	Allowed

Full Chip Erase

The ISP command "Full Chip Erase" erases all User Flash memory (fills with FFh) and sets some Bytes used by the bootloader at their default values:

- BSB = FFh
- SBV = FCh
- SSB = FFh and finally erase the Software Security Bits

The Full Chip Erase does not affect the bootloader.

Checksum Error

When a checksum error is detected send 'X' followed with CR&LF.

Flow Description

Overview

An initialization step must be performed after each Reset. After microcontroller reset, the bootloader waits for an autobaud sequence (see section 'autobaud performance').

When the communication is initialized the protocol depends on the record type requested by the host.

FLIP, a software utility to implement ISP programming with a PC, is available from the Atmel the web site.

Communication Initialization

The host initializes the communication by sending a 'U' character to help the bootloader to compute the baudrate (autobaud).

Figure 47. Initialization

Autobaud Performances

The ISP feature allows a wide range of baud rates in the user application. It is also adaptable to a wide range of oscillator frequencies. This is accomplished by measuring the bit-time of a single bit in a received character. This information is then used to program the baud rate in terms of timer counts based on the oscillator frequency. The ISP feature requires that an initial character (an uppercase U) be sent to the AT89C51C2 to establish the baud rate. Table 91 shows the autobaud capability.

Table 91. Autobaud Performances

Frequency (MHz) Baudrate (bit/s)	1.8432	2	2.4576	3	3.6864	4	5	6	7.3728	8
2400	OK	OK	OK	OK	OK	OK	OK	OK	OK	OK
4800	OK	-	OK	OK	OK	OK	OK	OK	OK	OK

115200	-	OK	-	OK	OK	-	-	-	-	

Command Data Stream Protocol

All commands are sent using the same flow. Each frame sent by the host is echoed by the bootloader.

Figure 48. Command Flow

Write/Program Commands

This flow is common to the following frames:

- Flash/EEPROM Programming Data Frame
- EOF or Atmel Frame (only Programming Atmel Frame)
- Config Byte Programming Data Frame
- Baud Rate Frame

Description

Figure 49. Write/Program Flow

Example

Programming Data (write 55h at address 0010h in the Flash)

HOST : 01 0010 00 55 9A
BOOTLOADER : 01 0010 00 55 9A . CR LF

Programming Atmel function (write SSB to level 2)

HOST : 02 0000 03 05 01 F5
BOOTLOADER : 02 0000 03 05 01 F5 . CR LF

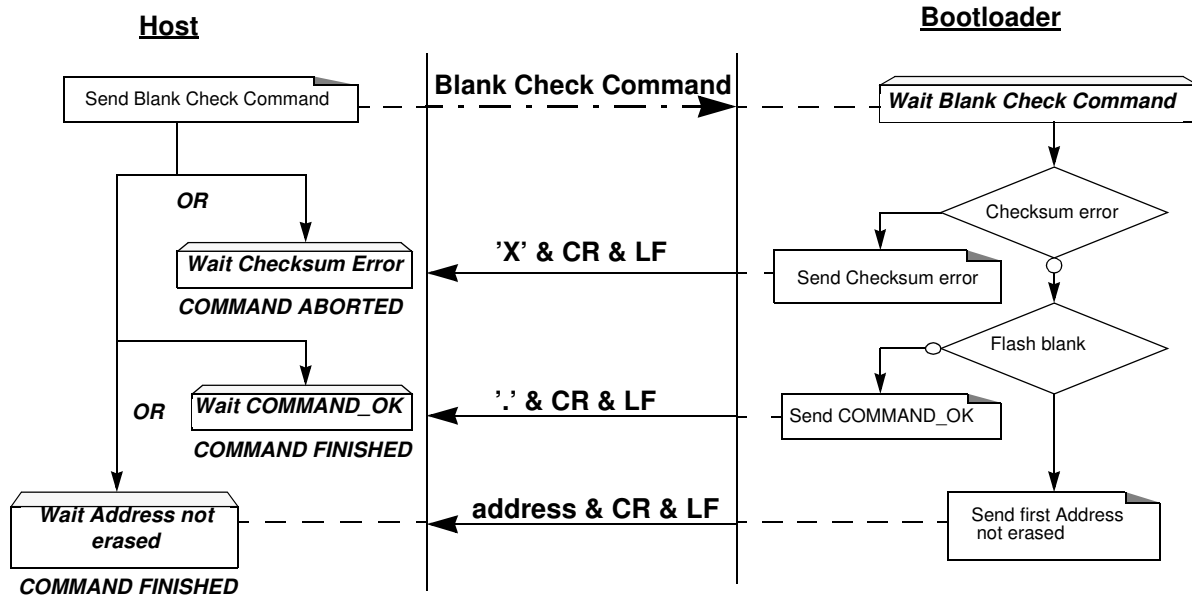

Writing Frame (write BSB to 55h)

HOST : 03 0000 03 06 00 55 9F
BOOTLOADER : 03 0000 03 06 00 55 9F . CR LF

Blank Check Command

Description

Figure 50. Blank Check Flow

Example

Blank Check ok

```

HOST      : 05 0000 04 0000 7FFF 01 78
BOOTLOADER : 05 0000 04 0000 7FFF 01 78 . CR LF
    
```

Blank Check ko at address xxxx

```

HOST      : 05 0000 04 0000 7FFF 01 78
BOOTLOADER : 05 0000 04 0000 7FFF 01 78 xxxx CR LF
    
```

Blank Check with checksum error

```

HOST      : 05 0000 04 0000 7FFF 01 70
BOOTLOADER : 05 0000 04 0000 7FFF 01 70 X CR LF CR LF
    
```

Display Data

Description

Figure 51. Display Flow

Note: The maximum size of block is 400h. To read more than 400h Bytes, the Host must send a new command.

Example

Display data from address 0000h to 0020h

```

HOST      : 05 0000 04 0000 0020 00 D7
BOOTLOADER : 05 0000 04 0000 0020 00 D7
BOOTLOADER 0000=-----data----- CR LF (16 data)
BOOTLOADER 0010=-----data----- CR LF (16 data)
BOOTLOADER 0020=data CR LF ( 1 data)
    
```

Read Function

This flow is similar for the following frames:

- Reading Frame
- EOF Frame/Atmel Frame (only reading Atmel Frame)

Description

Figure 52. Read Flow

Example

Read function (read SBV)

```

HOST      : 02 0000 05 07 02 F0
BOOTLOADER : 02 0000 05 07 02 F0 Value . CR LF
    
```

Atmel Read function (read Bootloader version)

```

HOST      : 02 0000 01 02 00 FB
BOOTLOADER : 02 0000 01 02 00 FB Value . CR LF
    
```

ISP Commands Summary

Table 92. ISP Commands Summary

Command	Command Name	Data[0]	Data[1]	Command Effect
00h	Program Data			Program Nb Data Byte. Bootloader will accept up to 128 (80h) data Bytes. The data Bytes should be 128 Byte page Flash boundary.
03h	Write Function	01h	00h	Erase block0 (0000h-1FFFh)
			20h	Erase block1 (2000h-3FFFh)
			40h	Erase block2 (4000h-7FFFh)
			80h	Erase block3 (8000h- BFFFh)
			C0h	Erase block4 (C000h- FFFFh)
		03h	00h	Hardware Reset
		04h	00h	Erase SBV & BSB
		05h	00h	Program SSB level 1
			01h	Program SSB level 2
		06h	00h	Program BSB (value to write in data[2])
			01h	Program SBV (value to write in data[2])
		07h	-	Full Chip Erase (This command needs about 6 sec to be executed)
		0Ah	02h	Program Osc fuse (value to write in data[2])
			04h	Program BLJB fuse (value to write in data[2])
			08h	Program X2 fuse (value to write in data[2])
04h	Display Function	Data[0:1] = start address Data [2:3] = end address Data[4] = 00h -> Display data Data[4] = 01h -> Blank check	Display Data Note: The maximum number of data that can be read with a single command frame (difference between start and end address) is 1kbyte.	
05h	Read Function	00h	00h	Manufacturer ID
			01h	Device ID #1
			02h	Device ID #2
			03h	Device ID #3
		07h	00h	Read SSB
			01h	Read BSB
			02h	Read SBV
			06h	Read Extra Byte
		0Bh	00h	Read Hardware Byte
		0Eh	00h	Read Device Boot ID1
			01h	Read Device Boot ID2
		0Fh	00h	Read Bootloader Version

API Call Description

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface, PGM_MTP. The programming functions are selected by setting up the microcontroller's registers before making a call to PGM_MTP at FFF0h. Results are returned in the registers.

When several Bytes have to be programmed, it is highly recommended to use the Atmel API "PROGRAM DATA PAGE" call. Indeed, this API call writes up to 128 Bytes in a single command.

All routines for software access are provided in the C Flash driver available at Atmel's web site.

The API calls description and arguments are shown in Table 93.

Table 93. API Call Summary

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
READ MANUF ID	00h	XXh	0000h	XXh	ACC = Manufacturer Id	Read Manufacturer identifier
READ DEVICE ID1	00h	XXh	0001h	XXh	ACC = Device Id 1	Read Device identifier 1
READ DEVICE ID2	00h	XXh	0002h	XXh	ACC = Device Id 2	Read Device identifier 2
READ DEVICE ID3	00h	XXh	0003h	XXh	ACC = Device Id 3	Read Device identifier 3
ERASE BLOCK	01h	XXh	DPH = 00h	00h	ACC = DPH	Erase block 0
			DPH = 20h			Erase block 1
			DPH = 40h			Erase block 2
			Address of byte to program			Program one Data Byte in user Flash
			XXh			Erase Software boot vector and boot status byte. (SBV = FCh and BSB = FFh)
PROGRAM SSB	05h	XXh	DPH = 00h DPL = 00h	00h	ACC = SSB value	Set SSB level 1
			DPH = 00h DPL = 01h			Set SSB level 2
			DPH = 00h DPL = 10h			Set SSB level 0
			DPH = 00h DPL = 11h			Set SSB level 1
PROGRAM BSB	06h	New BSB value	0000h	XXh	none	Program boot status byte
PROGRAM SBV	06h	New SBV value	0001h	XXh	none	Program software boot vector
READ SSB	07h	XXh	0000h	XXh	ACC = SSB	Read Software Security Byte
READ BSB	07h	XXh	0001h	XXh	ACC = BSB	Read Boot Status Byte
READ SBV	07h	XXh	0002h	XXh	ACC = SBV	Read Software Boot Vector

Table 93. API Call Summary (Continued)

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
PROGRAM DATA PAGE	09h	Number of byte to program	Address of the first byte to program in the Flash memory	Address in XRAM of the first data to program	ACC = 0: DONE	Program up to 128 bytes in user Flash. Remark: number of bytes to program is limited such as the Flash write remains in a single 128 bytes page. Hence, when ACC is 128, valid values of DPL are 00h, or, 80h.
PROGRAM X2 FUSE	0Ah	Fuse value 00h or 01h	0008h	XXh	none	Program X2 fuse bit with ACC
PROGRAM BLJB FUSE	0Ah	Fuse value 00h or 01h	0004h	XXh	none	Program BLJB fuse bit with ACC
READ HSB	0Bh	XXh	XXXXh	XXh	ACC = HSB	Read Hardware Byte
READ BOOT ID1	0Eh	XXh	DPL = 00h	XXh	ACC = ID1	Read boot ID1
READ BOOT ID2	0Eh	XXh	DPL = 01h	XXh	ACC = ID2	Read boot ID2
READ BOOT VERSION	0Fh	XXh	XXXXh	XXh	ACC = Boot_Version	Read bootloader version

R_{RST}	RST Pulldown Resistor	50	200 ⁽⁵⁾	250	k Ω	
I_{IL}	Logical 0 Input Current ports 1, 2, 3, 4 and 5			-50	μA	$V_{IN} = 0.45\text{V}$
I_{LI}	Input Leakage Current for P0 only			± 10	μA	$0.45\text{V} < V_{IN} < V_{CC}$
I_{TL}	Logical 1 to 0 Transition Current, ports 1, 2, 3, 4			-650	μA	$V_{IN} = 2.0\text{V}$
C_{IO}	Capacitance of I/O Buffer			10	pF	$F_C = 3\ \text{MHz}$ $T_A = 25^{\circ}\text{C}$
I_{PD}	Power Down Current		100	150	μA	$4.5\text{V} < V_{CC} < 5.5\text{V}^{(3)}$
I_{CCOP}	Power Supply Current on normal mode			$0.4 \times \text{Frequency (MHz)} + 5$	mA	$V_{CC} = 5.5\text{V}^{(1)}$
I_{CCIDLE}	Power Supply Current on idle mode			$0.3 \times \text{Frequency (MHz)} + 5$	mA	$V_{CC} = 5.5\text{V}^{(1)}$
I_{CCProg}	Power Supply Current during flash Write / Erase		$0.4 \times \text{Frequency (MHz)} + 20$		mA	$V_{CC} = 5.5\text{V}^{(8)}$

- Notes:
- Operating I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH} , $T_{CHCL} = 5\ \text{ns}$ (see Figure 56.), $V_{IL} = V_{SS} + 0.5\text{V}$, $V_{IH} = V_{CC} - 0.5\text{V}$; XTAL2 N.C.; $\overline{\text{EA}} = \text{RST} = \text{Port 0} = V_{CC}$. I_{CC} would be slightly higher if a crystal oscillator used (see Figure 53).
 - Idle I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH} , $T_{CHCL} = 5\ \text{ns}$, $V_{IL} = V_{SS} + 0.5\text{V}$, $V_{IH} = V_{CC} - 0.5\text{V}$; XTAL2 N.C.; Port 0 = V_{CC} ; $\overline{\text{EA}} = \text{RST} = V_{SS}$ (see Figure 54).
 - Power Down I_{CC} is measured with all output pins disconnected; $\overline{\text{EA}} = V_{SS}$, PORT 0 = V_{CC} ; XTAL2 NC.; RST = V_{SS} (see Figure 55).
 - Capacitance loading on Ports 0 and 2 may cause spurious noise pulses to be superimposed on the V_{OL} s of ALE and Ports 1 and 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make 1 to 0 transitions during bus operation. In the worst cases (capacitive loading 100pF), the noise pulse on the ALE line may exceed 0.45V with maxi V_{OL} peak 0.6V. A Schmitt Trigger use is not necessary.
 - Typical are based on a limited number of samples and are not guaranteed. The values listed are at room temperature and 5V.
 - Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
 Maximum I_{OL} per port pin: 10 mA
 Maximum I_{OL} per 8-bit port:
 Port 0: 26 mA
 Ports 1, 2 and 3: 15 mA
 Maximum total I_{OL} for all output pins: 71 mA
 If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
 - For other values, please contact your sales office.
 - I_{CC} Flash Write operation current while an on-chip flash page write is on going.
 - Flash Retention is guaranteed with the same formula for V_{CC} Min down to 0.

DC Parameters for Low Voltage

$T_A = 0^\circ\text{C}$ to $+70^\circ\text{C}$; $V_{SS} = 0\text{V}$; $V_{CC} = 2.7\text{V}$ to 3.6V ; $F = 0$ to 48 MHz

$T_A = -40^\circ\text{C}$ to $+85^\circ\text{C}$; $V_{SS} = 0\text{V}$; $V_{CC} = 2.7\text{V}$ to 3.6V ; $F = 0$ to 48 MHz

Symbol	Parameter	Min	Typ	Max	Unit	Test Conditions
V_{IL}	Input Low Voltage	-0.5		$0.2 V_{CC} - 0.1$	V	
V_{IH}	Input High Voltage except RST, XTAL1	$0.2 V_{CC} + 0.9$		$V_{CC} + 0.5$	V	
V_{IH1}	Input High Voltage, RST, XTAL1	$0.7 V_{CC}$		$V_{CC} + 0.5$	V	
V_{OL}	Output Low Voltage, ports 1, 2, 3, 4 ⁽⁶⁾			0.45	V	$I_{OL} = 0.8\text{ mA}$ ⁽⁴⁾
V_{OL1}	Output Low Voltage, port 0, ALE, $\overline{\text{PSEN}}$ ⁽⁶⁾			0.45	V	$I_{OL} = 1.6\text{ mA}$ ⁽⁴⁾
V_{OH}	Output High Voltage, ports 1, 2, 3, 4	$0.9 V_{CC}$			V	$I_{OH} = -10\ \mu\text{A}$
V_{OH1}	Output High Voltage, port 0, ALE, $\overline{\text{PSEN}}$	$0.9 V_{CC}$			V	$I_{OH} = -40\ \mu\text{A}$
I_{IL}	Logical 0 Input Current ports 1, 2, 3, 4			-50	μA	$V_{IN} = 0.45\text{ V}$
I_{LI}	Input Leakage Current for P0 only			± 10	μA	$0.45\text{V} < V_{IN} < V_{CC}$
I_{TL}	Logical 1 to 0 Transition Current, ports 1, 2, 3,			-650	μA	$V_{IN} = 2.0\text{V}$
R_{RST}	RST Pulldown Resistor	50	200 ⁽⁵⁾	250	k Ω	
C_{IO}	Capacitance of I/O Buffer			10	pF	$F_C = 3\text{ MHz}$ $T_A = 25^\circ\text{C}$
I_{PD}	Power Down Current		10 ⁽⁵⁾	50	μA	$V_{CC} = 2.7\text{V}$ to 3.6V ⁽³⁾
I_{CCOP}	Power Supply Current on normal mode			$0.4 \times \text{Frequency (MHz)} + 5$	mA	$V_{CC} = 3.6\text{ V}$ ⁽¹⁾
I_{CCIDLE}	Power Supply Current on idle mode			$0.3 \times \text{Frequency (MHz)} + 5$	mA	$V_{CC} = 3.6\text{ V}$ ⁽²⁾
I_{CCProg}	Power Supply Current during flash Write / Erase		$0.4 \times \text{Frequency (MHz)} + 20$		mA	$V_{CC} = 5.5\text{V}$ ⁽⁸⁾

- Notes:
- Operating I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH} , $T_{CHCL} = 5\text{ ns}$ (see Figure 56.), $V_{IL} = V_{SS} + 0.5\text{V}$, $V_{IH} = V_{CC} - 0.5\text{V}$; XTAL2 N.C.; $\overline{\text{EA}} = \text{RST} = \text{Port 0} = V_{CC}$. I_{CC} would be slightly higher if a crystal oscillator used (see Figure 53).
 - Idle I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH} , $T_{CHCL} = 5\text{ ns}$, $V_{IL} = V_{SS} + 0.5\text{V}$, $V_{IH} = V_{CC} - 0.5\text{V}$; XTAL2 N.C.; Port 0 = V_{CC} ; $\overline{\text{EA}} = \text{RST} = V_{SS}$ (see Figure 54).
 - Power Down I_{CC} is measured with all output pins disconnected; $\overline{\text{EA}} = V_{SS}$, PORT 0 = V_{CC} ; XTAL2 NC.; RST = V_{SS} (see Figure 55).
 - Capacitance loading on Ports 0 and 2 may cause spurious noise pulses to be superimposed on the V_{OL} s of ALE and Ports 1 and 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make 1 to 0 transitions during bus operation. In the worst cases (capacitive loading 100pF), the noise pulse on the ALE line may exceed 0.45V with maxi V_{OL} peak 0.6V. A Schmitt Trigger use is not necessary.
 - Typical are based on a limited number of samples and are not guaranteed. The values listed are at room temperature and 5V.
 - Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
Maximum I_{OL} per port pin: 10 mA
Maximum I_{OL} per 8-bit port:
Port 0: 26 mA
Ports 1, 2 and 3: 15 mA
Maximum total I_{OL} for all output pins: 71 mA

If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

7. For other values, please contact your sales office.
8. I_{CC} Flash Write operation current while an on-chip flash write is on going.

AC Parameters

Explanation of the AC Symbols

Each timing symbol has 5 characters. The first character is always a "T" (stands for time). The other characters, depending on their positions, stand for the name of a signal or the logical status of that signal. The following is a list of all the characters and what they stand for.

Example: T_{AVLL} = Time for Address Valid to ALE Low.

T_{LLPL} = Time for ALE Low to PSEN Low.

(Load Capacitance for port 0, ALE and PSEN = 100 pF; Load Capacitance for all other outputs = 80 pF.)

Table 94 Table 97, and Table 99 give the description of each AC symbols.

Table 96, Table 98 and Table 100 give the AC parameter for each range.

Table 95, Table 96 and Table 101 gives the frequency derating formula of the AC parameter for each speed range description. To calculate each AC symbols, take the x value in the corresponding column (-M or -L) and use this value in the formula.

Example: T_{LLIU} for -M and 20 MHz, Standard clock.

$x = 35$ ns

$T = 50$ ns

$T_{CCIV} = 4T - x = 165$ ns

External Program Memory Characteristics

Table 94. Symbol Description

Symbol	Parameter
T	Oscillator clock period
T_{LHLL}	ALE pulse width
T_{AVLL}	Address Valid to ALE
T_{LLAX}	Address Hold after ALE
T_{LLIV}	ALE to Valid Instruction In
T_{LLPL}	ALE to \overline{PSEN}
T_{PLPH}	\overline{PSEN} Pulse Width
T_{PLIV}	\overline{PSEN} to Valid Instruction In
T_{PXIX}	Input Instruction Hold after \overline{PSEN}
T_{PXIZ}	Input Instruction Float after \overline{PSEN}
T_{AVIV}	Address to Valid Instruction In
T_{PLAZ}	\overline{PSEN} Low to Address Float

Shift Register Timing Waveforms

External Clock Drive Waveforms

AC Testing Input/Output Waveforms

AC inputs during testing are driven at $V_{CC} - 0.5$ for a logic "1" and $0.45V$ for a logic "0". Timing measurement are made at V_{IH} min for a logic "1" and V_{IL} max for a logic "0".

Float Waveforms

For timing purposes as port pin is no longer floating when a 100 mV change from load voltage occurs and begins to float when a 100 mV change from the loaded V_{OH}/V_{OL} level occurs. $I_{OL}/I_{OH} \geq \pm 20mA$.

Clock Waveforms

Valid in normal clock mode. In X2 mode XTAL2 must be changed to XTAL2/2.

Figure 57. Internal Clock Signals

This diagram indicates when signals are clocked internally. The time it takes the signals to propagate to the pins, however, ranges from 25 to 125 ns. This propagation delay is dependent on variables such as temperature and pin loading. Propagation also varies from output to output and component. Typically though ($T_A = 25^\circ\text{C}$ fully loaded) RD and WR propagation delays are approximately 50 ns. The other signals are typically 85 ns. Propagation delays are incorporated in the AC specifications.

Datasheet Revision History

Changes from Rev. A 01/04 - Rev. B 01/06

1. Added green product ordering information.

Changes from Rev. B 01/06 - Rev. C 06/06

1. Correction to ordering information concerning product marking on green products.

Changes from Rev. C 06/06 - Rev. D 02/08

1. Removed non green part numbers from ordering information.
