NOTE:

1. A16 is a NC for IDT70V3589.

Description:

The IDT70V3599/89 is a high-speed 128/64K x 36 bit synchronous Dual-Port RAM. The memory array utilizes Dual-Port memory cells to allow simultaneous access of any address from both ports. Registers on control, data, and address inputs provide minimal setup and hold times. The timing latitude provided by this approach allows systems to be designed with very short cycle times. With an input data register, the IDT70V3599/89 has been optimized for applications having unidirectional

or bidirectional data flow in bursts. An automatic power down feature, controlled by $\overline{CE_0}$ and $\overline{CE_1}$, permits the on-chip circuitry of each port to enter a very low standby power mode.

The 70V3599/89 can support an operating voltage of either 3.3V or 2.5V on one or both ports, controllable by the OPT pins. The power supply for the core of the device (V_{DD}) remains at 3.3V.

NOTES:

1. A_{16} is a NC for IDT70V3589.
2. V_{DD} , OPT_x , and V_{DDQX} must be set to appropriate operating levels prior to applying inputs on the I/Os and controls for that port.
3. OPT_x selects the operating voltage levels for the I/Os and controls on that port. If OPT_x is set to V_{IH} (3.3V), then that port's I/Os and controls will operate at 3.3V levels and V_{DDQX} must be supplied at 3.3V. If OPT_x is set to V_{IL} (0V), then that port's I/Os and address controls will operate at 2.5V levels and V_{DDQX} must be supplied at 2.5V. The OPT pins are independent of one another—both ports can operate at 3.3V levels, both can operate at 2.5V levels, or either can operate at 3.3V with the other at 2.5V.
4. When $\overline{REPEAT}_x$ is asserted, the counter will reset to the last valid address loaded via $\overline{ADS}_x$.
5. Chip Enables and Byte Enables are double buffered when $PL/\overline{FT} = V_{IH}$, i.e., the signals take two cycles to deselect.

NOTES:

- "H" = V_{IH}, "L" = V_{IL}, "X" = Don't Care.
- Read and write operations are controlled by the appropriate setting of R/ $\overline{W}$, $\overline{CE_0}$, CE_1 , $\overline{BE_n}$ and $\overline{OE}$.
- Outputs configured in flow-through output mode: if outputs are in pipelined mode the data out will be delayed by one cycle.
- $\overline{ADS}$ and $\overline{REPEAT}$ are independent of all other memory control signals including $\overline{CE_0}$, CE_1 and $\overline{BE_n}$.
- The address counter advances if $\overline{CNTEN}$ = V_{IL} on the rising edge of CLK, regardless of all other memory control signals including $\overline{CE_0}$, CE_1 , $\overline{BE_n}$.
- When $\overline{REPEAT}$ is asserted, the counter will reset to the last valid address loaded via $\overline{ADS}$. This value is not set at power-up: a known location should be loaded via $\overline{ADS}$ during initialization if desired. Any subsequent $\overline{ADS}$ access during operations will update the $\overline{REPEAT}$ address location.

NOTES:

1. The Pipelined output parameters (t_{CYC2}, t_{CD2}) apply to either or both left and right ports when $\overline{FT}/PIPE_x = V_{IH}$. Flow-through parameters (t_{CYC1}, t_{CD1}) apply when $\overline{FT}/PIPE = V_{IL}$ for that port.
2. All input signals are synchronous with respect to the clock except for the asynchronous Output Enable ($\overline{OE}$) and $\overline{FT}/PIPE$. $\overline{FT}/PIPE$ should be treated as a DC signal, i.e. steady state during operation.
3. These values are valid for either level of V_{DDQ} (3.3V/2.5V). See page 5 for details on selecting the desired operating voltage levels for each port.

Timing Waveform of Read Cycle for Flow-through Output ($\overline{\text{FT}}/\text{PIPE}^{\text{X}} = \text{V}_{\text{IL}}$)^(2,6)

5617 drw 07

NOTES:

1. $\overline{\text{OE}}$ is asynchronously controlled; all other inputs are synchronous to the rising clock edge.
2. $\text{ADS} = \text{V}_{\text{IL}}$ and $\text{REPEAT} = \text{V}_{\text{IH}}$.
3. The output is disabled (High-Impedance state) by $\overline{\text{CE}}_0 = \text{V}_{\text{IH}}$, $\text{CE}_1 = \text{V}_{\text{IL}}$, $\overline{\text{BE}}_n = \text{V}_{\text{IH}}$ following the next rising edge of the clock. Refer to Truth Table 1.
4. Addresses do not have to be accessed sequentially since $\overline{\text{ADS}} = \text{V}_{\text{IL}}$ constantly loads the address on the rising edge of the CLK; numbers are for reference use only.
5. If $\overline{\text{BE}}_n$ was HIGH, then the appropriate Byte of DATAout for $\text{Qn} + 2$ would be disabled (High-Impedance state).
6. "x" denotes Left or Right port. The diagram is with respect to that port.

2. $\overline{OE} = V_{IL}$ for Port "B", which is being read from. $\overline{OE} = V_{IH}$ for Port "A", which is being written to.
3. If $t_{co} \leq$ minimum specified, then data from Port "B" read is not valid until following Port "B" clock cycle (ie, time from write to valid read on opposite port will be $t_{co} + 2 \text{ tcyc2} + t_{cd2}$). If $t_{co} >$ minimum, then data from Port "B" read is available on first Port "B" clock cycle (ie, time from write to valid read on opposite port will be $t_{co} + \text{tcyc2} + t_{cd2}$).
4. All timing is the same for Left and Right ports. Port "A" may be either Left or Right port. Port "B" is the opposite of Port "A"

2. $\overline{OE} = V_{IL}$ for the Right Port, which is being read from. $\overline{OE} = V_{IH}$ for the Left Port, which is being written to.
3. If $t_{co} \leq$ minimum specified, then data from Port "B" read is not valid until following Port "B" clock cycle (i.e., time from write to valid read on opposite port will be $t_{co} + \text{tcyc} + t_{cd1}$). If $t_{co} >$ minimum, then data from Port "B" read is available on first Port "B" clock cycle (i.e., time from write to valid read on opposite port will be $t_{co} + t_{cd1}$).
4. All timing is the same for both left and right ports. Port "A" may be either left or right port. Port "B" is the opposite of Port "A".

Timing Waveform of Pipelined Read-to-Write-to-Read ($\overline{OE} = V_{IL}$)⁽²⁾

NOTES:

- Output state (High, Low, or High-impedance) is determined by the previous cycle control signals.
- $\overline{CE}_0$, $\overline{BE}_n$, and $\overline{ADS} = V_{IL}$; $\overline{CE}_1$ and $\overline{REPEAT} = V_{IH}$. "NOP" is "No Operation".
- Addresses do not have to be accessed sequentially since $\overline{ADS} = V_{IL}$ constantly loads the address on the rising edge of the CLK; numbers are for reference use only.
- "NOP" is "No Operation." Data in memory at the selected address may be corrupted and should be re-written to guarantee data integrity.

Timing Waveform of Pipelined Read-to-Write-to-Read ($\overline{OE}$ Controlled)⁽²⁾

NOTES:

- Output state (High, Low, or High-impedance) is determined by the previous cycle control signals.
- $\overline{CE}_0$, $\overline{BE}_n$, and $\overline{ADS} = V_{IL}$; $\overline{CE}_1$ and $\overline{REPEAT} = V_{IH}$.
- Addresses do not have to be accessed sequentially since $\overline{ADS} = V_{IL}$ constantly loads the address on the rising edge of the CLK; numbers are for reference use only.
- This timing does not meet requirements for fastest speed grade. This waveform indicates how logically it could be done if timing so allows.

- CLK**: Clock signal. Timing parameters: t_{CH1} (clock high), t_{CL1} (clock low).
- $\overline{CE}_0$** : Chip Enable 0. Timing parameters: t_{SC} (setup), t_{HC} (hold).
- CE_1** : Chip Enable 1. Timing parameters: t_{SB} (setup), t_{HB} (hold).

The diagram also shows the sequence of operations: READ, NOP⁽⁵⁾, WRITE, and READ. The data bus shows the flow of data between the device and the system, with specific data values like Q_n , Q_{n+1} , Q_{n+3} , and Q_{n+4} indicated.

The timing diagram illustrates the relationship between the clock (CLK) and various control and data signals. Key timing parameters include:

- t_{CYC1} : Clock cycle time.
- t_{CH1} : Clock high pulse width.
- t_{CL1} : Clock low pulse width.
- t_{SC} : Setup time for $\overline{CE}_0$.
- t_{HC} : Hold time for $\overline{CE}_0$.
- t_{SB} : Setup time for $\overline{CE}_1$.
- t_{HB} : Hold time for $\overline{CE}_1$.
- t_{SW} : Setup time for $\overline{BEn}$.
- t_{HW} : Hold time for $\overline{BEn}$.
- t_{SA} : Setup time for ADDRESS.
- t_{HA} : Hold time for ADDRESS.
- t_{SD} : Setup time for DATAin.
- t_{HD} : Hold time for DATAin.
- t_{CD1} : Data output delay from ADDRESS to DATAout.
- t_{DC} : Data output delay from DATAin to DATAout.
- t_{OEHZ} : Output enable delay from OE to DATAout.
- t_{OE} : Output enable delay from OE to DATAout.
- t_{CKLZ} : Output enable delay from OE to DATAout.
- t_{DC} : Data output delay from DATAin to DATAout.

The diagram is divided into three sections: READ, WRITE, and READ. The ADDRESS signal is labeled with An , $An+1$, $An+2$, $An+3$, $An+4$, and $An+5$. The DATAin signal is labeled with $Dn+2$, $Dn+3$, and $Dn+4$. The DATAout signal is labeled with Qn and $Qn+4$. The OE signal is labeled with $\overline{OE}$.

1. Output state (High, Low, or High-impedance) is determined by the previous cycle control signals.
2. $\overline{CE_0}$, $\overline{BEn}$, and $\overline{ADS} = V_{IL}$; CE_1 and $REPEAT = V_{IH}$.
3. Addresses do not have to be accessed sequentially since $\overline{ADS} = V_{IL}$ constantly loads the address on the rising edge of the CLK; numbers are for reference use only.
4. "NOP" is "No Operation." Data in memory at the selected address may be corrupted and should be re-written to guarantee data integrity.

Timing Waveform of Pipelined Read with Address Counter Advance⁽¹⁾

Timing Waveform of Flow-Through Read with Address Counter Advance⁽¹⁾

NOTES:

1. $\overline{CE_0}$, $\overline{OE}$, $\overline{BEn} = V_{IL}$; $\overline{CE_1}$, $R/\overline{W}$, and $\overline{REPEAT} = V_{IH}$.
2. If there is no address change via $\overline{ADS} = V_{IL}$ (loading a new address) or $\overline{CNTEN} = V_{IL}$ (advancing the address), i.e. $\overline{ADS} = V_{IH}$ and $\overline{CNTEN} = V_{IH}$, then the data output remains constant for subsequent clocks.

Timing Waveform of Write with Address Counter Advance (Flow-through or Pipelined Inputs)⁽¹⁾

Timing Waveform of Counter Repeat⁽²⁾

NOTES:

1. $\overline{CE}_0$, $\overline{BE}_n$, and $R/\overline{W}$ = V_{IL} ; CE_1 and $\overline{REPEAT}$ = V_{IH} .
2. $\overline{CE}_0$, $\overline{BE}_n$ = V_{IL} ; CE_1 = V_{IH} .
3. The "Internal Address" is equal to the "External Address" when $\overline{ADS}$ = V_{IL} and equals the counter output when $\overline{ADS}$ = V_{IH} .
4. Addresses do not have to be accessed sequentially since $\overline{ADS}$ = V_{IL} constantly loads the address on the rising edge of the CLK; numbers are for reference use only.
5. Output state (High, Low, or High-impedance) is determined by the previous cycle control signals.
6. No dead cycle exists during $\overline{REPEAT}$ operation. A READ or WRITE cycle may be coincidental with the counter $\overline{REPEAT}$ cycle: Address loaded by last valid $\overline{ADS}$ load will be accessed. Extra cycles are shown here simply for clarification. For more information on $\overline{REPEAT}$ function refer to Truth Table II.
7. $\overline{CNTEN}$ = V_{IL} advances Internal Address from 'An' to 'An + 1'. The transition shown indicates the time required for the counter to advance. The 'An + 1' Address is written to during this cycle.

Functional Description

The IDT70V3599/89 provides a true synchronous Dual-Port Static RAM interface. Registered inputs provide minimal set-up and hold times on address, data, and all critical control inputs. All internal registers are clocked on the rising edge of the clock signal, however, the self-timed internal write pulse is independent of the LOW to HIGH transition of the clock signal.

An asynchronous output enable is provided to ease asynchronous bus interfacing. Counter enable inputs are also provided to stall the operation of the address counters for fast interleaved memory applications.

A HIGH on $\overline{CE_0}$ or a LOW on CE_1 for one clock cycle will power down the internal circuitry to reduce static power consumption. Multiple chip enables allow easier banking of multiple IDT70V3599/89s for depth expansion configurations. Two cycles are required with $\overline{CE_0}$ LOW and CE_1 HIGH to re-activate the outputs.

Depth and Width Expansion

The IDT70V3599/89 features dual chip enables (refer to Truth Table I) in order to facilitate rapid and simple depth expansion with no requirements for external logic. Figure 4 illustrates how to control the various chip enables in order to expand two devices in depth.

The IDT70V3599/89 can also be used in applications requiring expanded width, as indicated in Figure 4. Through combining the control signals, the devices can be grouped as necessary to accommodate applications needing 72-bits or wider.
