2. Cases in which recovery is initiated by the peer
  - The receive lane becomes no longer electrically idle.
  - Typical example: The Endpoint issues a PME message for requesting a recovery itself and the peer makes a transition to Recovery.

After a recovery to L0, if the device is in the Non-D0 state and PM\_Enter\_L1 DLLP is transmitted from the downstream device, software should confirm that hardware is in the L0 state (PMSR.PMSTATE = L0) and initiate the L1 transition sequence again (write 1 to PMCTLR.L1IATN). In this case, the sequence is: L0 → L1 → L0 recovery → L1 again.

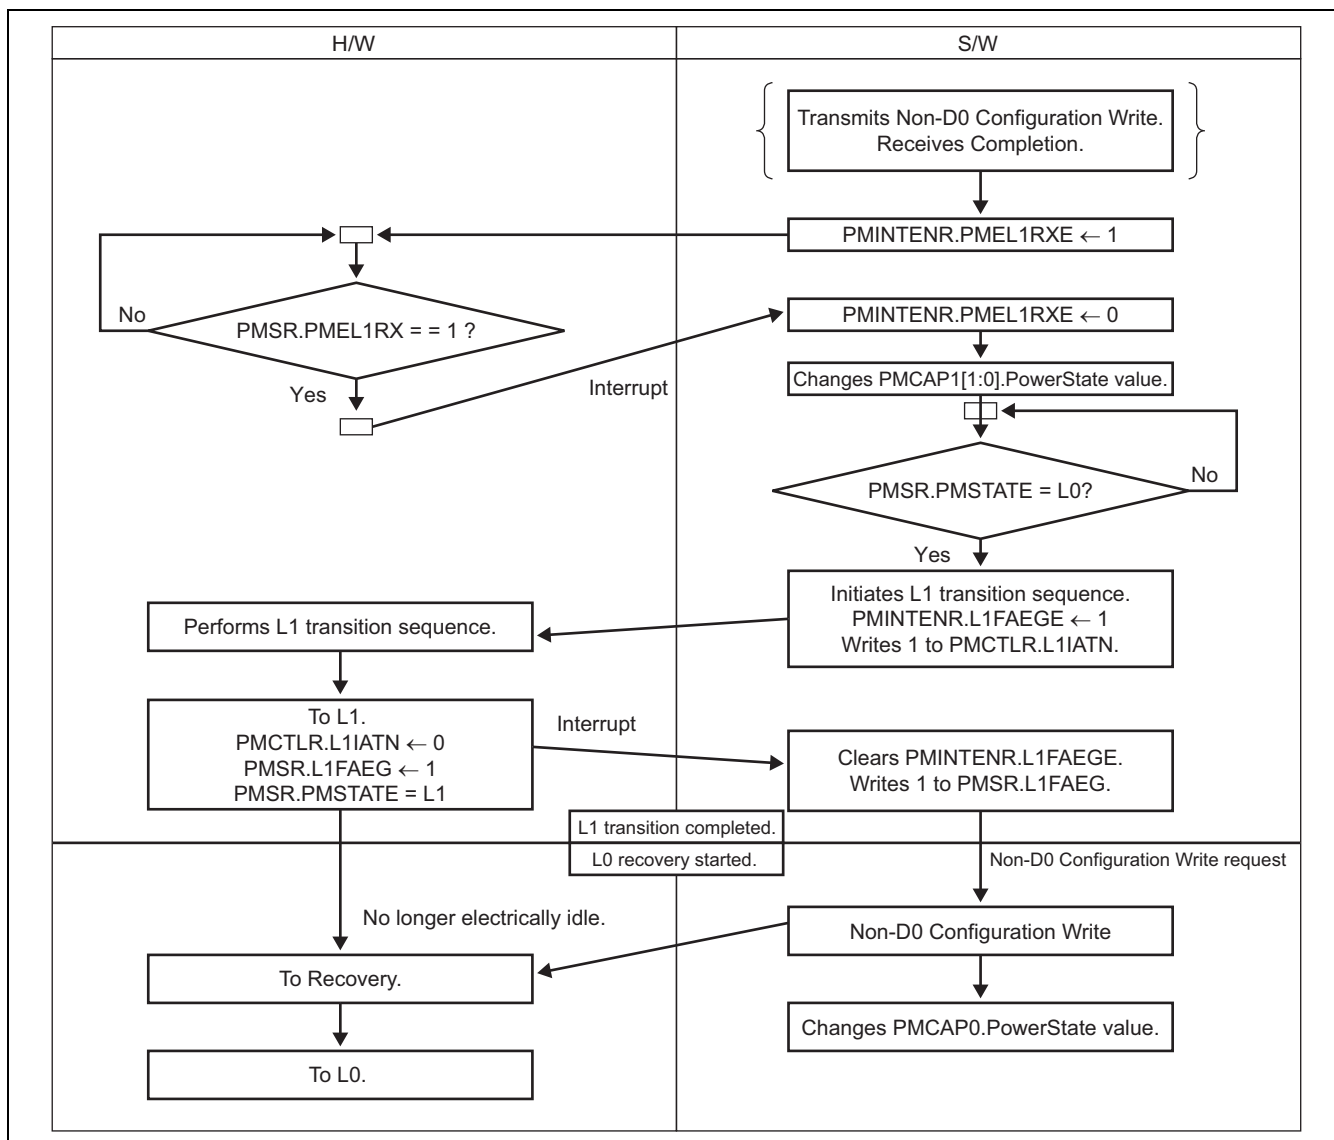

Figure 39.29 Transition from L0 to L1 to L0 (Root Port)

(2) Active State Power Management (ASPM)

This section describes PCI Express-specific power management mode. Table 39.12 shows power management operations in Active State Power Management (hereinafter referred to as ASPM) mode. ASPM is automatically controlled by hardware; software should take nothing particular into account.

Table 39.12 ASPM Operation

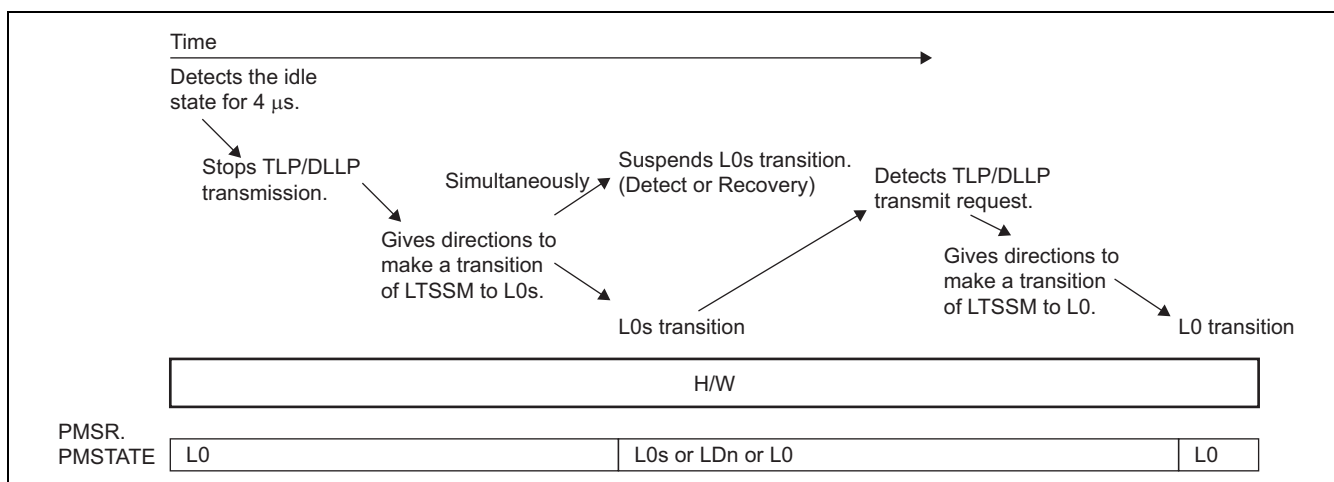

No.	Transition	Target Device
1	L0 → L0s → L0	Common to Endpoint and Root Port

**(a) L0 → L0s → L0**

When a link is in the idle state for 4 μs, hardware automatically initiates the L0s transition sequence. This module determines a link to be in the idle state in any of the following cases.

- Cases in which No TLP is transmitted
  1. No TLP to be transmitted is scheduled in the VC buffer.
  2. TLP is scheduled but there are not enough credits to transmit the TLP in the VC buffer.
  3. TLP is scheduled and there are enough credits but Non-posted cannot be issued according to the limitations on the number of Outstanding by this module.
- Cases in which no DLLP is scheduled for transmission

Figure 39.30 shows an overall overview of L0 → L0s → L0 transition.

**Figure 39.30 Overall Overview of L0 → L0s → L0 (Common to Endpoint/Root Port)**

The L0s transition sequence is as follows.

1. Detects the idle state for 4 μs.
2. Stops TLP/DLLP transmission.
3. Gives directions to make a transition to L0s.

Note that if the directions to make a transition to L0s and the directions to make a transition to Detect or Recovery are given simultaneously in this module, the directions to make a transition to Detect or Recovery are given priority. If the directions are given to make a transition to L0s and then the directions are given to make a transition to the other state (such as Detect and Recovery), a transition to L0s is first made and then a transition to the designated state is made.

The sequence for a recovery from L0s is: when there is TLP/DLLP to be transmitted, recovery from L0s to L0 is automatically made. After recovery, TLP/DLLP is transmitted.

### 39.3.11 Error Handling

This section describes handling of the errors detected by this module.

#### (1) Error Types

This module classifies detected errors into four types: three types defined in the PCI Express standard (correctable errors, non-fatal errors, and fatal errors) and other errors (system errors). It reports each type of error through the corresponding interrupt.

##### (a) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible through the PCI Express protocol. Recovery from the errors is performed by hardware.

When the conditions described later are satisfied, occurrence of a correctable error is signaled by the INT\_PCICERR interrupt.

##### (b) Non-Fatal Error

Non-fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol but which is not fatal. After this error, a single packet is discarded but the subsequent data communication can be continued. In most cases, error processing such as retransmission of the discarded packet is needed.

When the conditions described later are satisfied, occurrence of a non-fatal error is signaled by the INT\_PCINFERR interrupt.

##### (c) Fatal Error

Fatal errors are defined as the type of errors from which recovery is impossible through the PCI Express protocol and which is fatal. Specifically, the errors that require resetting the communication path or other appropriate processing fall into this type. In most cases, this module must be initialized.

When the conditions described later are satisfied, occurrence of a fatal error is signaled by the INT\_PCIFERR interrupt.

##### (d) Other Errors Detected by This Module (System Error)

The errors that do not fall into the above types are classified as system errors. The necessary processing depends on the cause of each error.

Occurrence of a system error is signaled by the INT\_PCISERR interrupt.

#### (2) Priority of Errors

Upon detecting multiple errors during reception of a single packet, this module reports only one error that it determines as the most important according to the following priority among errors.

Receiver Overflow

Malformed TLP

Unsupported request (UR), or unexpected completion

Poisoned TLP received

### (3) Correctable Error

Correctable errors are defined as the type of errors from which recovery is possible without loss of transfer data through hardware processing such as automatic retransmission request.

If a correctable error occurs, the EXPCAP2[16].CEDTCD bit is set to 1. If a correctable error occurs when the EXPCAP2[0].CERPE bit is 1 in Endpoint mode, the ERR\_COR message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT\_PCICERR interrupt is generated if EXPCAP7[0].SERRCEE is 1.

In Root Port mode, if the ERR\_COR message is received from an Endpoint when all of the PCICONF15[17].SERRE, EXPCAP2[0].CERPE, and EXPCAP7[0].SERRCEE bits are 1, the INT\_PCICERR interrupt is generated.

The following errors are classified as correctable errors.

#### (a) Receiver error

8b/10b decode error

Disparity error

Elastic buffer overflow

Elastic buffer underflow

#### (b) BAD TLP

LCRC error

Sequence number error

#### (c) BAD DLLP

16-bit CRC error

#### (d) Replay timeout

Ack/Nak timeout

#### (e) Replay Num rollover

Replay Num rollover

#### (4) Non-Fatal Error

A non-fatal error cannot be corrected through hardware control and one packet of data will be lost. Therefore, recovery processing by software, such as retransmission processing, is needed.

If a non-fatal error occurs, the EXPCAP2[17].NFEDTCD bit is set to 1. If a non-fatal error occurs when PCICONF1[8].SERRE is 1, the PCICONF1[30].SSE bit is set to 1. If a non-fatal error occurs when the EXPCAP2[1].NFERPE bit or PCICONF1[8].SERRE bit is 1 in Endpoint mode, the ERR\_NONFATAL message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT\_PCINFERR interrupt is generated if EXPCAP7[1].SERRNFEE is 1. However, if the error source is an unsupported request (described later), this module does not send the message or generate an interrupt when the conditions described later are satisfied.

In Root Port mode, if the ERR\_NONFATAL message is received, PCICONF7[30].RSE is set to 1. If the ERR\_NONFATAL message is received when the PCICONF15[17].SERRE and PCICONF1[8].SERRE bits are 1, the PCICONF1[30].SSE bit is set to 1. If the ERR\_NONFATAL message is received from an Endpoint when the PCICONF15[17].SERRE bit is 1, the EXPCAP2[1].NFERPE or PCICONF1[8].SERRE bit is 1, and the EXPCAP7[1].SERRNFEE bit is 1, the INT\_PCINFERR interrupt is generated. However, if the error source is an unsupported request (described later), this module does not generate an interrupt when the conditions described later are satisfied. In addition, if the non-fatal error comes under the advisory non-fatal error cases described later, separately defined processing is performed.

The following errors are classified as non-fatal errors.

##### (a) Poisoned TLP Reception

If a packet with the Poisoned attribute is written, it is handled as a non-fatal error.

This module does not transfer a write request of a packet from the PCI Express side to the internal bus side if the packet has the Poisoned attribute. If a request with the Poisoned attribute is received, the packet is discarded.

If the completion responding to the request issued by this module has the Poisoned attribute, the data in the completion is not transferred to the internal bus side.

If ConfigurationWrite Type0, I/O Write, Set\_Slot\_Power\_Limit, or MSI has the Poisoned attribute, it is handled also as an unsupported request.

##### (b) Unsupported Request (UR) Reception

The following requests are handled as unsupported requests.

- Access to the area other than the PCI address area specified with BAR
- Reception of memory/IO request in Root Port mode when PCICONF1[2].BME = 0
- Access to memory space when PCICONF1[1].MSE = 0
- Access to IO space when PCICONF1[0].IOSE = 0
- Reception of a message with an undefined message code
- Reception of MsgD with message code Msg
- Reception of a message to be received only by an Endpoint in Root Port mode
- Reception of a message to be received only by a Root/Switch in Endpoint mode
- Reception of a Type0 Vendor Defined Message
- Reception of TLP other than configuration access and message in the Non-D0 state
- Access to a configuration register not implemented
- Reception of a Type1 Configuration Request
- Reception of a Configuration Request in Root Port mode
- Reception of a packet without the No Snoop attribute when acceptance of a snoop transaction is rejected by VCCAP4[15].RJCTSNPTR

- Reception of a MRdLk request

If an unsupported request is received, the EXPCAP2[19].URDTCD bit is set to 1.

If an unsupported request is received when both the EXPCAP2[3].URRPE and PCICONF1[8].SERRE bits are 0, neither transmission of a message nor generation of an interrupt is performed.

If an unsupported request is received, the packet is discarded.

#### (c) Completer Abort (CA)

If an error occurs on the internal bus when the packet is transferred from the PCI Express to the internal bus, this module considers it as a Completer Abort and performs error handling. When the packet received from the PCI Express is a Non-Posted request, this module returns a completion with the Completer Abort (CA)– Completion Status thus setting the PCICONF1[27].STA bit to 1.

If the packet received by this module from the PCI Express side violates the PCI Express standard or is considered to be damaged, it is handled as an unsupported request or malformed TLP, not as a Completer Abort.

#### (d) Unexpected Completion Reception

If the completion not corresponding to the request issued by this module is received, it is considered as an unexpected completion and error handling is performed.

Reception of an unexpected completion falls into the advisory non-fatal error cases described later.

#### (5) Fatal Error

Fatal errors are defined as the type of errors from which recovery is impossible through hardware and which usually require system-level error recovery processing such as initialization of the PCI Express.

If a fatal error occurs, the EXPCAP2[18].FEDTCD bit is set to 1. If a fatal error occurs when the PCICONF1[8].SERRE bit is 1, the PCICONF1[30].SSE bit is set to 1. If a fatal error occurs when the EXPCAP2[2].FERPE or PCICONF1[8].SERRE bit is 1, in Endpoint mode the ERR\_FATAL message is transmitted to the Root Port to notify occurrence of an error. In Root Port mode, the INT\_PCINFERR interrupt is generated if EXPCAP7[2].SERRFEE is 1.

In Root Port mode, if the ERR\_FATAL message is received, PCICONF7[30].RSE is set to 1. If the ERR\_FATAL message is received when both of the PCICONF15[17].SERRE and PCICONF1[8].SERRE bits are 1, the PCICONF1[30].SSE bit is set to 1. If the ERR\_FATAL message is received from an Endpoint when the PCICONF15[17].SERRE bit is 1, the EXPCAP2[1].FERPE or PCICONF1[8].SERRE bit is 1, and the EXPCAP7[2].SERRFEE bit is 1, the INT\_PCIFERR interrupt is generated.

The following errors are classified as fatal errors.

- (a) Data Link Layer Protocol Error
- (b) Reception of malformed TLP

The following packets are considered as malformed TLPs, which cause a fatal error when received. These packets are discarded when received.

- Reception of a packet with data size exceeding the Max Payload Size
- Reception of a packet with data of different length from the length specified in the size field
- Reception of a TLP with TD field in header = 0 and with the digest field
- Reception of a TLP with TD field in header = 1 and without the digest field
- Reception of an Assert\_INTx/Deassert\_INTx message of non TC0
- Reception of a power management message of non TC0
- Reception of an error signal message of non TC0

- Reception of an unlock message of non TC0
- Reception of a Set\_Slot\_Power\_Limit message of non TC0
- Reception of a Set\_Slot\_Power\_Limit message without data
- Reception of a completion with data of different size from the size specified in the Length field
- Reception of a completion with data size exceeding the Max Payload Size
- Reception of a TLP of undefined type or fmt
- Reception of a TLP of the unassigned TC
- Reception of an IO request of TC!=0, Attr[1:0]!=0, Length[9:0]!=1, or Last DWBE[3:0]!=0
- Reception of a configuration request of TC!=0, Attr[1:0]!=0, Length[9:0]!=1, or Last DWBE[3:0]!=0
- Reception of an Assert\_INTx/Deassert\_INTx message in Endpoint mode
- Reception of a memory request with illegal DWBE
- Reception of a memory request crossing a 4-Kbyte boundary

## (6) System Error

System errors are defined as the errors that are not classified as any of the correctable, non-fatal, and fatal errors.

This module can signal the following events as the system errors by so setting PCIEERRFER.

- Internal bus error (reception of error response or disagreement of read data size)
- Posted/Non-Posted Buffer overflow
- CplLk reception
- Reception of an Unexpected Completion
- Disagreement of read data size requested and Completion data size
- Completion timeout
- Reception of a Completion with the CRS/CA/UR status
- Transmission of a Completion with the CA/UR status

If any system error occurs, the INT\_PCISERR interrupt is generated.

## (7) Advisory Non-Fatal Error Case

The PCI Express standard prescribes that some of non-fatal errors should not be processed when the applicable packet is received because the errors should be judged in terms of cause and significance by the packet transmission source, software, or system. These non-fatal errors are called advisory non-fatal error cases, which include the cases described in the following sections. If such a case is detected, general non-fatal error processing is not performed but processing prescribed individually is performed instead.

### (a) Return of Completion with Unsupported Request/Completer Abort Status

If a completion with unsupported request/Completer Abort status is returned, this module does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[0].SENDURCPL or PCIEERRFR[1].SENDACPL, and generates an INT\_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

### (b) Completion Timeout

If a completion timeout occurs, this module does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[8].CPLTIMEOUT, and generates an INT\_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1. When software determines that further retransmission is impossible, allow the software to perform error processing such as transmission of ERR\_COR.

**(c) Reception of Unexpected Completion**

If this module receives an unexpected completion, it does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[12].UNEXPECTED COMPLETION, and generates an INT\_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

**(d) Reception of Unsupported Request/Completer Abort Completion**

If this module receives a completion of unsupported request/Completer Abort, it does not perform non-fatal error processing defined in the PCI Express standard. This module records occurrence of an error in PCIEERRFR[4].RECEIVEURCPL or PCIEERRFR[5].RECEIVECACPL, and generates an INT\_PCISERR interrupt if the corresponding bit in PCIEERRFER is set to 1.

**(e) Reception of Poisoned TLP**

According to the PCI Express standard, the case in which a Poisoned TLP is received and reception is continued is also defined as an advisory non-fatal error case; however, an advisory non-fatal error of such a case does not occur with this module since this module prohibits continuation of Poisoned data processing. Although the cases related to the intermediate receiver are also defined by the standard, the corresponding processing is not performed since this module does not operate as an intermediate receiver.

### 39.3.12 Interrupts

Table 39.13 shows the interrupt signal lines of this module, definition, and the conditions under which interrupts are generated. The interrupt signals are synchronized with the internal bus clock.

**Table 39.13 List of Interrupt Signal Lines**

Name	Definition	Conditions of Generation	Related Registers
pci_int_serr	System error interrupt	<ul style="list-style-type: none"> <li>• Occurrence of a system error</li> <li>• Completion with the UR status is transmitted.</li> <li>• Completion with the CA status is transmitted.</li> <li>• Completion with the UR status is received.</li> <li>• Completion with the CA status is received.</li> <li>• Completion with the CRS status is received.</li> <li>• Completion timeout occurs.</li> <li>• Size error occurs.</li> <li>• Unexpected Completion is received.</li> <li>• CplLk is received.</li> <li>• Posted buffer overflows.</li> <li>• Non-Posted buffer overflows.</li> <li>• Transfer error occurs on the internal bus.</li> </ul>	<ul style="list-style-type: none"> <li>• PCIEINTR[0].INT_PCISERR</li> <li>• PCIEERRFR[0].SENDURCPL</li> <li>• PCIEERRFR[1].SENDACPL</li> <li>• PCIEERRFR[4].RCVURCPL</li> <li>• PCIEERRFR[5].RCVCACPL</li> <li>• PCIEERRFR[6].RCVCRSCPL</li> <li>• PCIEERRFR[8].CPLTOUT</li> <li>• PCIEERRFR[9].RCVSZECPL</li> <li>• PCIEERRFR[12].UNEXPCPL</li> <li>• PCIEERRFR[13].RCVCPCLK</li> <li>• PCIEERRFR[20].NPOVF</li> <li>• PCIEERRFR[21].POVF</li> <li>• PCIEERRFR[28].IBERR</li> </ul>

## 39.4 Usage Notes

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 39.4.1 Write/Read Attributes of Configuration Registers

Although the registers in the configuration space have the register attributes defined by the PCI Express standard, these registers have different attributes when accessed by the internal bus. This section shows the attributes required for control. software refers to the software running on the device (i.e., CPU) on the internal bus.

**Table 39.14 Write/Read Attributes**

Attributes of PCI Express Registers	Description	Attributes of IP Registers	Example
HWInit	Hardware initialized bit. Initialized by hardware or software.	R for fields initialized by hardware.	EXPCAP0[24].SLTI_MP
		RW for fields initialized by software.	EXPCAP3[31:24].Port Number
RO	Read-only bit. Cannot be modified by software.	R for fields initialized by hardware.	PCICONF0[31:16].Device ID
		RW for fields initialized by software.	EXPCAP0[23:20].Device Port Type
RW	Read/Write bit. Can be modified by software.	RW	PCICONF1[2].BME
RW1C	Read-only status bit. Writing 1 clears the bit. Writing 0 has no effect.	RW1C	PCICONF1[24].MDPE
ROS	Sticky-read-only bit. Cannot be modified by software. Not initialized by hot reset.	Applies to no IP registers.	—
RWS	Sticky-read write bit. Can be modified by software. Not initialized by hot reset.	RW	EXPCAP2[10].AUXPPME
RW1CS	Sticky-read-only status bit. Writing 1 clears the bit. Writing 0 has no effect. Not initialized by hot reset.	RW1C	PMCAP1[15].PMEST
RsvdP	Reserved bit. Read-only. May be used as a RW bit in the future. Reading the bit returns 0.	R	EXPCAP4[15:12]
RsvdZ	Reserved bit. Read-only. May be used as a RW1C bit in the future. Reading the bit returns 0.	R	EXPCAP2[31:22]

The following shows which PCI Configuration Capability is supported by this IP.

		Offset	Capability	Spec Requirements	Root Port Type01	Endpoint Type00	
PCI Configuration Space	PCI3.0 Compatible Configuration Space	H'000	PCI Compatible Configuration Registers	Required	√	√	
		H'03F					
		H'040	PCI Power Management Capability Structure	Required	√	√	
			MSI or MSI-X Capability Structure	Required if an interrupt resource is required	—	√	
			PCI Express Capability Structure	Required	√	√	
		H'0FF					
	PCI Express Extended Configuration Space	H'0100		Virtual Channel Capability	Optional	√	√
				Device Serial Number Capability	Optional	x	x
				Advanced Error Reporting Capability	Optional	x	x
				PCI Express Root Complex Link Declaration Capability	Optional	x	x
				PCI Express Root Complex Internal Link Control Capability	Optional	x	x
				Power Budgeting Capability	Optional	x	x
				PCI Express Root Complex Event Collector Endpoint Association Capability	Optional	x	x
				Multi-Function Virtual Channel Capability	Optional	x	x
			Vendor-Specific Capability	Optional	x	x	
			RCRB Header Capability	Optional	x	x	
	H'0FFF						

### 39.4.2 Notes on Accessing Configuration Registers

- In Endpoint mode, writing to the configuration registers of this IP is prohibited except at initialization.
- "PCI RW" in the column header of the table in the description section of each register indicates the attribute of configuration access from the PCI Express bus in Endpoint mode; it is invalid in Root Port mode. For the registers with the same attribute shared in Endpoint mode and Root Port, "—" is indicated.

### 39.4.3 Registers Which Affect Hardware Internal Operation in Root Port Mode

Since the Endpoint configuration space may be accessed by the peer Root Port, it should be set appropriately. The registers implemented according to the Root Port configuration space are not accessed by Endpoint. Therefore, in Root Port mode, the user should appropriately set the registers that have influence on hardware operation shown in Table 39.15 at initialization. For details on register setting, refer to description of each register.

#### 39.4.4 Power Management States

Do not stop inputting the reference clock signal in the power management states (L0s/L). Transition to the power management states (L0s/L1) is made from L0.

#### 39.4.5 State Transition

Transition to the L2 state is prohibited since L2 is not supported.

## 40. Serial Communication Interface with FIFO (SCIF)

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 40.1 Overview

This LSI has serial communication interfaces with FIFO buffers (SCIF) that handles asynchronous communication and clock synchronous serial communication. The SCIF has two 16-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. The following table lists the functions of each interface.

The presence of the SCK, RTS, and CTS pins depends on the product or channel. The synchronous mode and mode control functions are supported in the interface channel which has the pins related to these functions.

Name	Function	Pin	Base Address	Remarks	RZ/G series products			
					RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
0 SCIF-0	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX0, TX0, SCK0, RTS#0, and CTS#0	H'E6E6 0000	Transmission/reception clock can be supplied externally from SCK0 pin.	√	—	—	—
	Asynchronous mode	RX0*1, TX0*1	—	—	—	√	√	√
1 SCIF-1	Asynchronous mode (modem control is enabled) Clock synchronous mode	RX1, TX1, SCK1, RTS#1, and CTS#1	H'E6E6 8000	Transmission/reception clock can be supplied externally from SCK1*2 pin.	√	—	—	—
	Asynchronous mode Clock synchronous mode	RX1*2, TX1*2 and SCK1*2	—	—	—	√	√	√
2 SCIF-2	Asynchronous mode Clock synchronous mode	RX2*2, TX2*2 and SCK2*2	H'E6E5 6000 H'E6E5 8000	Transmission/reception clock can be supplied externally from SCK2*2 pin.	√ —	— √	— √	— √
	Asynchronous mode Clock synchronous mode	RX3*2, TX3*2 and SCK3*2	H'E6EA 8000	Transmission/reception clock can be supplied externally from SCK3*2 pin.	—	√	√	√
4 SCIF-4	Asynchronous mode	RX4*1, TX4*1	H'E6EE 0000	—	—	√	√	√
5 SCIF-5	Asynchronous mode	RX5*1, TX5*1	H'E6EE 8000	—	—	√	√	√

Notes: 1. RXm and TXm respectively refer to SCIFm\_RXD and SCIFm\_TXD in the RZ/G1E. (SCIF-0: m = 0, SCIF-4: m = 4, SCIF-5: m = 5)

2. RXn, TXn, and SCKn respectively refer to SCIFn\_RXD, SCIFn\_TXD, and SCIFn\_SCK in the RZ/G1E. SCKn refers to SCIFn\_SCK\_B in the RZ/G1M and RZ/G1N. (SCIF-1: n = 1, SCIF-2: n = 2, SCIF-3: n = 3)

### 40.1.1 Features

The SCIF has the following features.

- Asynchronous serial communication mode

The SCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). There is a choice of eight serial data transfer formats.

- Data length: 7 or 8 bits
- Stop bit length: 1 or 2 bits
- Parity: Even/odd/none
- Receive error detection: Parity, framing, and overrun errors
- Break detection:

A break is detected when a framing error lasts for more than 1 frame length at Space 0 (low level).

When a framing error occurs, a break can also be detected by reading the RX pin level directly from the serial port register (SCSPTR).

- Clock synchronous serial communication mode

The SCIF performs serial data communication synchronized with a clock. This feature enables serial data communication with other LSIs that support synchronous communication. There is a single serial data communication format for clock synchronous serial communication.

- Data length: 8 bits
- Receive error detection: Overrun errors

- Full-duplex communication capability

The SCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 16-stage FIFO buffer structure, enabling continuous serial data transmission and reception.

- On-chip baud rate generator, enabling any bit rate to be selected

The SCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.

- Eight interrupt sources

The SCIF has eight types of interrupt sources – receive-data-ready, receive-FIFO-data-full, break, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out and enables any of them to be requested independently.

- DMA data transfer

When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.

- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.

- In asynchronous mode, a receive data ready (DR) or a timeout error (TO) can be detected during reception.

40.1.2 Block Diagram

Figure 40.1 shows the SCIF block diagram.

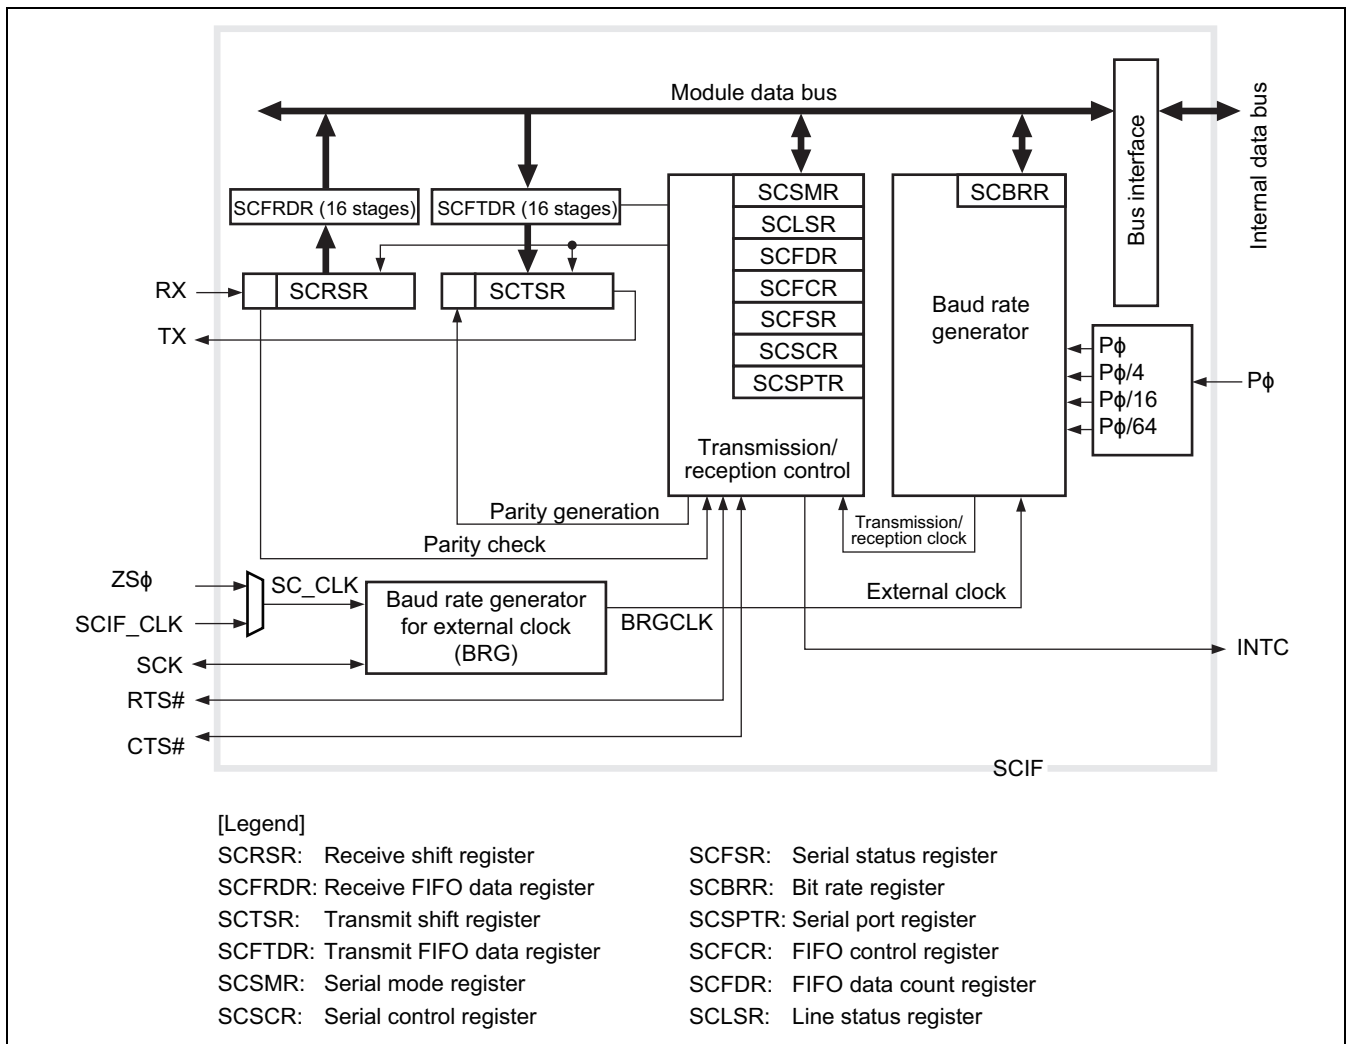

Figure 40.1 SCIF Block Diagram

### 40.1.3 Input/Output Pins

Table 40.1 shows the SCIF pin configuration. Pin functions can differ with the interface number. Other functions are also multiplexed on the same pins, so the multiplexed pin settings may restrict usage of the pins.

**Table 40.1 Pin Configuration**

Pin Name	Abbreviation	I/O	Function
Serial clock pin (SCKn*, SCIFn_SCK_B*, SCIFn_SCK*)	SCK	I/O	Synchronous clock I/O
Receive data pin (RXn*, SCIFn_RXD*)	RX	Input	Receive data input
Transmit data pin (TXn*, SCIFn_TXD*)	TX	Output	Transmit data output
Modem control pin (CTS#n*)	CTS#	I/O	Transmission enabled
Modem control pin (RTS#n*)	RTS#	I/O	Transmission request
Baud rate generation clock pin	SCIF_CLK	Input	Clock for input to the baud rate generator for the external clock

Note: These pins are made to function as serial pins by setting up SCIF operation using bit C/A# in SCSMR, bits TE, RE, CKE[1:0] in SCSCR, and bit MCE in SCFCR. SCSPTR of the SCIF can be used to handle the transmission and detection of break states.

\* n: Channel number

#### 40.1.4 Register Configuration

Table 40.2 shows the registers in the SCIF.

**Table 40.2 Register Configuration**

Register Name	Abbreviation	R/W	Offset from Base Address	Initial Value	Access Size
Serial mode register	SCSMR	R/W	H'00	H'0000	16
Bit rate register	SCBRR	R/W	H'04	H'FF	8
Serial control register	SCSCR	R/W	H'08	H'0000	16
Transmit FIFO data register	SCFTDR	W	H'0C	Undefined	8
Serial status register	SCFSR	R/W*1	H'10	H'0060	16
Receive FIFO data register	SCFRDR	R	H'14	Undefined	8
FIFO control register	SCFCR	R/W	H'18	H'0000	16
FIFO data count register	SCFDR	R	H'1C	H'0000	16
Serial port register	SCSPTR	R/W	H'20	H'00XX*3	16
Line status register	SCLSR	R/W*2	H'24	H'0000	16
Frequency division register	DL	R/W	H'30	H'0000	16
Clock Select register	CKS	R/W	H'34	H'0000	16

- Notes:
1. Only 0 can be written to bits 7 to 4, 1, and 0 to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
  2. Only 0 can be written to bits 2 and 1 to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.
  3. The initial values of SCSPTR bits 6, 4, 2, and 0 are undefined.

The table below lists the registers used in asynchronous mode, asynchronous mode with modem control, and clock synchronous mode. When setting up the registers, set the bits related to unsupported modes in each interface to their initial values. Otherwise, the SCIF may malfunction. Do not write to any registers other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from registers other than listed below are undefined.

**Table 40.3 Register Settings in Each Mode**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CKS	*	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## [Legend]

\* : Used in any mode.

A : Used in asynchronous mode.

M : Used in asynchronous mode (modem control is enabled) (in addition to A).

C : Used in clock synchronous mode.

0 : Reserved (the write value should always be 0.)

— : Undefined

## 40.2 Register Descriptions

### 40.2.1 Receive Shift Register (SCRSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCRSR is a register that receives serial data.

The SCIF sets serial data input to the SCRSR from the RX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO data register SCFRDR, automatically.

SCRSR cannot be read from and written to by the CPU.

### 40.2.2 Receive FIFO Data Register (SCFRDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCFRDR is a 16-stage FIFO register that stores received serial data.

When the SCIF has received one byte of serial data, it transfers the received data from the receive shift register (SCRSR) to SCFRDR for storage, and reception is thus completed. SCRSR is then ready for reception, and is capable of receiving up to 16 consecutive bytes of data before SCFRDR is full.

SCFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in SCFRDR. When SCFRDR is full of receive data, subsequent serial data is lost.

SCFRDR is read as an undefined value after a power-on reset.

### 40.2.3 Transmit Shift Register (SCTSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCTSR is a register that transmits serial data.

To perform serial data transmission, the SCIF first transfers transmit data from the transmit FIFO data register (SCFTDR) to SCTSR, then sends the data to the TX pin starting with the LSB (bit 0). When transmission of one byte is completed, the SCIF transfers the next transmit data from SCFTDR to SCTSR automatically, then starts transmission.

SCTSR cannot be read from and written to directly by the CPU.

Bit:	7	6	5	4	3	2	1	0
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

### 40.2.4 Transmit FIFO Data Register (SCFTDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCFTDR is an 8-bit FIFO register of 16 stages that stores data for serial transmission.

If SCTSR is empty after transmit data has been written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts serial transmission.

SCFTDR is a write-only register and cannot be read from by the CPU. Writing further data to SCFTDR is no longer possible when it is full (contains 16 bytes of transmit data). Attempts at writing data to the register in this situation are ignored.

SCFTDR is read as an undefined value on a power-on reset.

Bit:	7	6	5	4	3	2	1	0
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Initial value:	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W

### 40.2.5 Serial Mode Register (SCSMR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	—	—	—	—	—	—	—	—	C/A#	CHR	PE	O/E#	STOP	—	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

SCSMR is a 16-bit register that sets the SCIF's serial transfer format and selects the baud rate generator clock source.

SCSMR can always be read from and written to by the CPU.

SCSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	C/A#	0	R/W	Communication Mode Selects asynchronous mode or clock synchronous mode for the SCIF operation. 0: Asynchronous mode 1: Clock synchronous mode Note: Whether clock synchronous mode can be selected or not depends on the interface.
6	CHR	0	R/W	Character Length Selects 7 or 8 bits for asynchronous mode data length. In clock synchronous mode, the data length is fixed at 8 bits regardless of the CHR bit setting. 0: 8 bits 1: 7 bits* Note: * When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (SCFTDR) is not transmitted.
5	PE	0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception in asynchronous mode or not. In clock synchronous mode, the parity bit is not added and checked regardless of the PE bit setting. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.

Bit	Bit Name	Initial Value	R/W	Description
4	O/E#	0	R/W	<p>Parity Mode</p> <p>Selects either even or odd parity to use in parity addition and check.</p> <p>In asynchronous mode, the O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. In clock synchronous mode or when parity addition or check is disabled in asynchronous mode, the O/E# bit setting is invalid.</p> <p>0: Even parity*1 1: Odd parity*2</p> <p>Notes: 1. When even parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even.</p> <p>2. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.</p>
3	STOP	0	R/W	<p>Stop Bit Length</p> <p>Selects 1 bit or 2 bits as the stop bit length in asynchronous mode.</p> <p>The stop bit setting is valid only in asynchronous mode. Since the stop bit is not added in clock synchronous mode, the STOP bit setting is invalid in this mode.</p> <p>In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character.</p> <p>0: 1 stop bit*1 1: 2 stop bits*2</p> <p>Notes: 1. In transmission, a single 1-bit (stop bit) is added to the end of a transmit character before it is sent.</p> <p>2. In transmission, two 1-bits (stop bits) are added to the end of a transmit character before it is sent.</p>
2	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
1, 0	CKS[1:0]	00	R/W	<p>Clock Select 1 and 0</p> <p>These bits select the clock source for the on-chip baud rate generator.</p> <p>The clock source can be selected from P<math>\phi</math>, P<math>\phi</math>/4, P<math>\phi</math>/16, and P<math>\phi</math>/64, according to the setting of bits CKS1 and CKS0.</p> <p>00: P<math>\phi</math> 01: P<math>\phi</math>/4 10: P<math>\phi</math>/16 11: P<math>\phi</math>/64</p> <p>Note: P<math>\phi</math>: Peripheral clock (frequency dividing CPU clock into 12)</p>

### 40.2.6 Serial Control Register (SCSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCSCR is a register that enables or disables transmission/reception by the SCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the SCIF.

SCSCR can always be read from and written to by the CPU.

SCSCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	TEIE	—	—	—	TIE	RIE	TE	RE	REIE	TOIE	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: <ul style="list-style-type: none"> <li>Setting the TDFE flag in SCFSR</li> <li>Setting the TEND flag in SCFSR</li> </ul> 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in SCSCR is pulled 0, if the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>Serial transmit data has been transferred from SCFTDR to SCTSR,</li> <li>The number of data bytes in SCFTDR is equal to or less than the transmit trigger count, and</li> <li>The TDFE flag in SCFSR is set to 1.</li> </ul> <p>Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of SCSCR is set to 1, if the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>Transmission was ended because there is no valid data in SCFTDR when the last bit of the transmit character in SCTSR was transmitted, and</li> <li>The TEND flag of SCFSR is set to 1.</li> </ul> <p>0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request.* When the TEIE bit is 1, disables transmit-end interrupt (TEND) request.*</p> <p>1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in SCFSR is set to 1, a receive-data-ready interrupt request when the DR flag in SCFSR is set to 1, a receive-error interrupt request when the ER flag in SCFSR is set to 1, a break interrupt request when the BRK flag in SCFSR is set to 1, and an overrun error interrupt request when the ORER flag in SCLSR is set to 1.</p> <p>0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.</p> <p>1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>Enables or disables the start of SCIF serial transmission. The SCIF starts serial transmission when transmit data is written to the SCFTDR while TE is 1. Before setting TE to 1, set SCSMR and SCFCR to specify the transmission format and reset the transmit FIFO.</p> <p>0: Disables transmission.*</p> <p>1: Enables transmission.*</p>

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	<p>Receive Enable</p> <p>Enables or disables the start of SCIF serial reception. When RE is 1, the SCIF starts serial reception by detecting a start bit in asynchronous mode or by detecting a synchronization clock input in clock synchronous mode. Before setting RE to 1, set SCSMR and SCFCR to specify the reception format and reset the receive FIFO.</p> <p>0: Disables reception.* 1: Enables reception.</p> <p>Note: Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.</p>
3	REIE	0	R/W	<p>Receive Error Interrupt Enable</p> <p>Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.</p> <p>0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.* 1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.</p> <p>Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.</p>
2	TOIE	0	R/W	<p>Timeout Interrupt Enable</p> <p>Enables or disables generation of timeout interrupt (TO) requests when the TO flag in SCLSR is set to 1.</p> <p>0: Disables timeout interrupts (TO). 1: Enables timeout interrupts (TO).</p>
1, 0	CKE[1:0]	00	R/W	<p>Clock Enable 1 and 0</p> <p>These bits select the SCIF clock source and enables or disables the clock output from the SCK pin.</p> <p>Whether the SCK pin functions as a serial clock output pin or a serial clock input pin is determined by combination of the CKE[1:0] bits settings. To specify synchronization clock output in clock synchronous mode, set C/A# to 1 in SCSMR then set CKE[1:0].</p> <p>See Table 40.4 for the bit settings.</p>

**Table 40.4 Clock Selection**

<b>CKE[1:0]</b>	<b>Mode</b>	<b>Clock Source</b>	<b>SCK Pin</b>
00	Asynchronous mode	Internal clock (P $\phi$ , P $\phi$ /4, P $\phi$ /16, P $\phi$ /64)	The SCK pin is not used. The SCK pin functions as an input pin (Input signals are ignored). (Initial value)
	Clock synchronous mode		The SCK pin outputs the synchronization clock. (Initial value)
01	Asynchronous mode		The SCK pin outputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode		The SCK pin outputs the synchronization clock.
10	Asynchronous mode	Baud rate generator output for external clock or SCK	When SC_CLK is selected: The SCK pin is an input pin (Input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is 16 times the bit rate.
			When SCK is selected: The SCK pin inputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode	SCK*	The SCK pin inputs the synchronization clock.
11	Prohibited		

Notes: Some interfaces cannot select the clock synchronous mode.

- \* It is not allowed to set synchronous communication using SC\_CLK for input.

### 40.2.7 Serial Status Register (SCFSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Note: Only 0 can be written to clear the flag.

SCFSR is a 16-bit register. The lower 8 bits are a status flag that indicates the operating status of the SCIF, and the upper 8 bits indicate the number of reception errors of data in the receive FIFO register.

SCFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

SCFSR is initialized to H'0060 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	PER[3:0]	All 0	R	<p>Parity Error Count</p> <p>These bits indicate the number of parity errors of receive data stored in the receive FIFO data register (SCFRDR).</p> <p>After the ER is set in SCFSR, the value represented by bits 15 to 12 indicates the number of parity errors. If a parity error occurs in all 16-byte receive data in SCFRDR, PER3 to PER0 are cleared to 0.</p>
11 to 8	FER[3:0]	All 0	R	<p>Framing Error Count</p> <p>These bits indicate the number of framing errors of receive data stored in the receive FIFO data register (SCFRDR).</p> <p>After the ER bit is set in SCFSR, the value represented by bits 11 to 8 indicates the number of framing errors. If a framing error occurs in all 16-byte receive data in SCFRDR, FER3 to FER0 are cleared to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
7	ER	0	R/W*	<p>Receive Error</p> <p>Indicates that a framing error or a parity error has occurred in reception.*<sup>1</sup> The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in SCSCR.</p> <p>If a receive error occurs, receive data will be transferred to SCFRDR and reception operation will be continued. Whether there is a receive error in data read from SCFRDR can be determined by the FER and PER bits in SCFSR.</p> <p>0: Indicates that no framing or parity error has occurred in reception.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• 0 is written to ER.</li> </ul> <p>1: Indicates that a framing error or a parity error has occurred in reception.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• The SCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*<sup>2</sup></li> <li>• The number of 1-bits in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in SCSMR during reception.</li> </ul> <p>Note: In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.</p>
6	TEND	1	R/W*	<p>Indicates that transmission has been ended * because there was no valid data in SCFTDR when the last bit of the transmit character was transmitted.</p> <p>0: Indicates that transmission is in progress.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Transmit data is written to SCFTDR, and 0 is written to TEND.</li> <li>• Data is written to SCFTDR by the DMAC.</li> </ul> <p>1: Indicates that transmission has been ended.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• The TE bit in SCSCR is 0.</li> <li>• There is no transmit data in SCFTDR when the last bit of a 1-byte serial transmission character is transmitted.</li> </ul> <p>Note: When transmit data is written to SCFTDR by the DMAC In clock synchronous mode, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, the TEND flag should be read using the following procedure.</p> <ol style="list-style-type: none"> <li>1. Check that data transfer is completed in the DMAC.</li> <li>2. Read the TEND flag.</li> <li>3. If TEND = 1, clear the TEND flag to 0.</li> <li>4. Read the TEND flag again.</li> <li>5. Use the second read TEND flag.</li> </ol>

Bit	Bit Name	Initial Value	R/W	Description
5	TDFE	1	R/W*	<p>Transmit FIFO Data Empty</p> <p>Indicates that the SCIF has transferred data from SCFTDR to SCTSR, the number of data bytes in SCFTDR becomes equal to or less than the transmit trigger count specified by the TTRG1 and TTRG0 bits in SCFCR, and SCFTDR is ready to be written by new transmit data.</p> <p>SCFTDR is a 16-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is "16 – [the transmit trigger count]". If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in SCFTDR is indicated by the upper bits of SCFDR.</p> <p>If the number of data written in SCFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1.</p> <p>0: Indicates that the number of transmit data written to SCFTDR exceeds the transmit trigger count.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Transmit data exceeding the specified transmit trigger count have been written to SCFTDR, and 0 is written to TDFE.</li> <li>• Transmit data exceeding the specified transmit trigger count have been written to SCFTDR by the DMAC.</li> </ul> <p>1: Indicates that the number of transmit data in SCFTDR is equal to or less than the transmit trigger count.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• The number of transmit data in SCFTDR is equal to or less than the transmit trigger count after transmission.</li> </ul>
4	BRK	0	R/W*	<p>Break Detect</p> <p>Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to SCFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes.</p> <p>0: Indicates that no break signal has been received.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• 0 is written to BRK.</li> </ul> <p>1: Indicates that a break signal has been received.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• Data with a framing error is received, followed by the space "0" (low level) for at least one frame length.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
3	FER	0	R	<p>Framing Error</p> <p>Indicates that a framing error has been found in the data that is to be read next from SCFRDR in asynchronous mode.</p> <p>0: Indicates that there is no framing error in the receive data that is to be read from SCFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• There is no framing error in the data that is to be read next from SCFRDR.</li> </ul> <p>1: Indicates that there is a framing error in the receive data that is to be read from SCFRDR.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• There is a framing error in the data that is to be read next from SCFRDR.</li> </ul>
2	PER	0	R	<p>Parity Error</p> <p>This bit indicates that a parity error has been found in the data that is to be read next from SCFRDR in asynchronous mode.</p> <p>0: Indicates that there is no parity error in the receive data that is to be read from SCFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• There is no parity error in the data that is to be read next from SCFRDR.</li> </ul> <p>1: Indicates that there is a parity error in the receive data that is to be read from SCFRDR.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• There is a parity error in the data that is to be read next from SCFRDR.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
1	RDF	0	R/W*	<p>Receive FIFO Data Full</p> <p>Indicates that the received data has been transferred from SCRSR to SCFRDR, and the number of receive data bytes in SCFRDR becomes equal to or more than the receive trigger count specified by the RTRG1 and RTRG0 bits in SCFCR.</p> <p>SCFRDR is a 16-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When SCFRDR is empty, SCFRDR is read as an undefined value. The number of receive data bytes in SCFRDR is indicated by the lower bits of SCFDR.</p> <p>If the number of data in SCFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in SCFRDR is less than the trigger count, read RDF as 1, and then clear RDF.</p> <p>0: Indicates that the number of receive data bytes in SCFRDR is less than the specified receive trigger count.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• SCFRDR is read until the number of receive data bytes in SCFRDR is less than the receive trigger count, and 0 is written to RDF.</li> <li>• SCFRDR is read by the DMAC until the number of receive data bytes in SCFRDR is less than the receive trigger count.</li> </ul> <p>1: Indicates that the number of receive data bytes in SCFRDR is equal to or more than the specified receive trigger count.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• Receive data more than the receive trigger count have been stored in SDFRDR.</li> </ul>
0	DR	0	R/W*	<p>Receive Data Ready</p> <p>Indicates that the number of data bytes in SCFRDR is less than the receive trigger count and that no further data has been received for at least 15 etu after the stop bit of the data received last in asynchronous mode. This bit is not set in clock synchronous mode.</p> <p>0: Indicates that data is being received or has been successfully received, and there is no receive data in SCFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• All the receive data in SCFRDR has been read, and 0 is written to DR.</li> <li>• All the receive data in SCFRDR has been read by the DMAC.</li> </ul> <p>1: Indicates that no further receive data has been received.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• The receive FIFO data register (SCFRDR) has the number of data byte that is below the receive trigger number of data bytes and no further data has arrived for at least 15 etu after the stop bit of the data received last.</li> </ul> <p>Note: etu: Elementary Time Unit (time for transfer of 1 bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.</p>

Note: Writing 0 is only available to clear the flag.

### 40.2.8 Bit Rate Register (SCBRR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS1 and CKS0 bits in SCSMR. This baud rate generator is intended for  $P\phi$ ,  $P\phi/4$ ,  $P\phi/16$ , and  $P\phi/64$ . For details on the baud rate generator for external clock, see section 40.6, Baud Rate Generator for External Clock (BRG).

SCBRR can always be read from and written to by the CPU except for during transfer.

SCBRR is initialized to H'FF by a power-on reset.

The SCBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

[Clock synchronous mode]

$$N = \frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: SCBRR setting for the baud rate generator ( $0 \leq N \leq 255$ ) (which satisfies the electrical characteristics)

$P\phi$ : Peripheral module operating frequency (MHz)

n: Baud rate generator input clock ( $n = 0, 1, 2, 3$ )  
(See the Table 40.5 for the relation between n and the clock.)

**Table 40.5 SCSMR Settings**

n	Clock	SCSMR.CKS[1:0] Setting
0	$P\phi$	00
1	$P\phi/4$	01
2	$P\phi/16$	10
3	$P\phi/64$	11

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

### 40.2.9 FIFO Control Register (SCFCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCFCR is a register that resets data counts and sets the number of trigger data bytes for the transmit and receive FIFO registers. It also has a loopback test enable bit.

SCFCR can always be read from and written to by the CPU except for during transfer.

SCFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	RFRST	0	R/W	<p>Receive FIFO Data Register Reset</p> <p>Enables or disables a receive FIFO data register reset that empties the register.</p> <p>0: Disables the reset.*            1: Enables the reset.</p> <p>Note: The register is reset by a power-on reset.</p>
0	LOOP	0	R/W	<p>Loopback Test</p> <p>Enables or disables the loopback test by internally connecting the transmit output pin (TX) and receive input pin (RX), and the RTS# pin and CTS# pin. If the loopback test is specified, the signal on the RTS# pin is internally conveyed to CTS# pin, and data transmission is automatically suspended when RTS# is asserted.</p> <p>0: Disables the loopback test.            1: Enables the loopback test.</p> <p>Even if loopback test is specified by this bit, SCSPTR.RTSDT and SCSPTR.CTSDT bits does not reflect signal on loopback path, because those registers shows signals on RTS#/CTS# pins.</p>

**40.2.10 FIFO Data Count Register (SCFDR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCFDR is a 16-bit register that indicates the number of data bytes stored in SCFTDR and that in SCFRDR.

The upper 8 bits indicate the number of transmit data bytes in SCFTDR, and the lower 8 bits indicates the number of receive data bytes in SCFRDR.

SCFDR can always be read by the CPU.

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	T[4:0]	H'00	R	These bits show the number of data bytes untransmitted and still stored in SCFTDR. H'00 indicates that there is no transmit data in SCFTDR. H'10 indicates that SCFTDR is full of transmit data.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	R[4:0]	H'00	R	These bits show the number of receive data stored in SCFRDR in bytes. H'00 indicates that there is no receive data in SCFRDR. H'10 indicates that SCFRDR is full of receive data.

### 40.2.11 Serial Port Register (SCSPTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCSPTR controls multiplexed input/output and data on the serial communication interface (SCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the RX pin and writing output data to the TX pin. Bits 3 and 2 read input data from and write output data to the SCK pin. Bits 5 and 4 read input data from and write output data to the CTS# pin. Bits 7 and 6 read input data from and write output data to the RTS# pin.

SCSPTR is a 16-bit register that can always be read from and written to by the CPU.

All SCSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the interface.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB2I O	SPB2D T
Initial value:	0	0	0	0	0	0	0	0	0	—	0	—	0	—	0	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	0	R/W	Serial Port RTS# Pin Input/Output Specifies input or output for the serial port RTS# pin. To actually set the RTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the RTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the RTS# pin.
6	RTSDT	—	R/W	Serial Port RTS# Pin Data Specifies the input/output data level of the serial port RTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the RTS# pin. Regardless of the value of the RTSIO bit, the value of the RTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	0	R/W	Serial Port CTS# Pin Input/Output Specifies input or output for the serial port CTS# pin. To actually set the CTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the CTS# pin. 1: Indicates that the CTSDT bit value is output to the CTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTS DT	—	R/W	<p>Serial Port CTS# Pin Data</p> <p>Specifies the input/output data level of the serial port CTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTS DT bit is output to the CTS# pin. Regardless of the value of the CTSIO bit, the value of the CTS# pin is read from the CTS DT bit.</p> <p>The initial value of this bit is undefined after a power-on.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>
3	SCKIO	0	R/W	<p>Serial Port Clock Pin Input/Output</p> <p>Specifies input or output for the serial port SCK pin. To actually set the SCK pin as a port output pin to output the value set by the SCK DT bit, the CKE[1:0] bits in SCSCR should be cleared to 0.</p> <p>0: Indicates that the SCK DT bit value is not output to the SCK pin.</p> <p>1: Indicates that the SCK DT bit value is output to the SCK pin.</p>
2	SCK DT	—	R/W	<p>Serial Port Clock Pin Data</p> <p>Specifies the input/output data level of the serial port SCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCK DT bit is output to the SCK pin. Regardless of the value of the SCKIO bit, the value of the SCK pin is read from the SCK DT bit.</p> <p>The initial value of this bit is undefined after a power-on reset.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>
1	SPB2IO	0	R/W	<p>Serial Port Break Input/Output</p> <p>Specifies the output condition of the serial port TX pin. To actually set the TX pin as a port output pin to output the value set by the SPB2 DT bit, the TE bit in SCSCR should be cleared to 0.</p> <p>0: Indicates that the SPB2 DT bit value is not output to the TX pin.</p> <p>1: Indicates that the SPB2 DT bit value is output to the TX pin.</p>
0	SPB2 DT	—	R/W	<p>Serial Port Break Data</p> <p>Specifies the input level of the serial port RX pin and the output level of the TX pin. The TX pin output conditions are determined by the SPB2IO bit. When the TX pin is set for output, the value of the SPB2 DT bit is output to the TX pin. Regardless of the value of the SPB2IO bit, the value of the RX pin is read from the SPB2 DT bit.</p> <p>The initial value of this bit is undefined after a power-on reset.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>

1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	0	R/(W)*	<p>Overrun Error</p> <p>Indicates that an overrun error has occurred in reception and abnormal termination is caused.</p> <p>If an overrun error occurs, the receive data prior to the overrun error is retained in SCFRDR and the data received subsequently is discarded.</p> <p>Any subsequent serial reception is disabled while the ORER flag is 1.</p> <p>To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag.</p> <p>0: Indicates that data is being received or has been successfully received.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• 0 is written to ORER.</li> </ul> <p>1: Indicates that an overrun error has occurred in reception.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• The next serial reception has been completed while SCFRDR is full of 16-byte data.</li> </ul> <p>Note: When bit RE in SCSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.</p>

Note: Writing 0 is only available to clear the flag.

### 40.3 Operation

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

#### 40.3.1 Operation in Asynchronous Mode

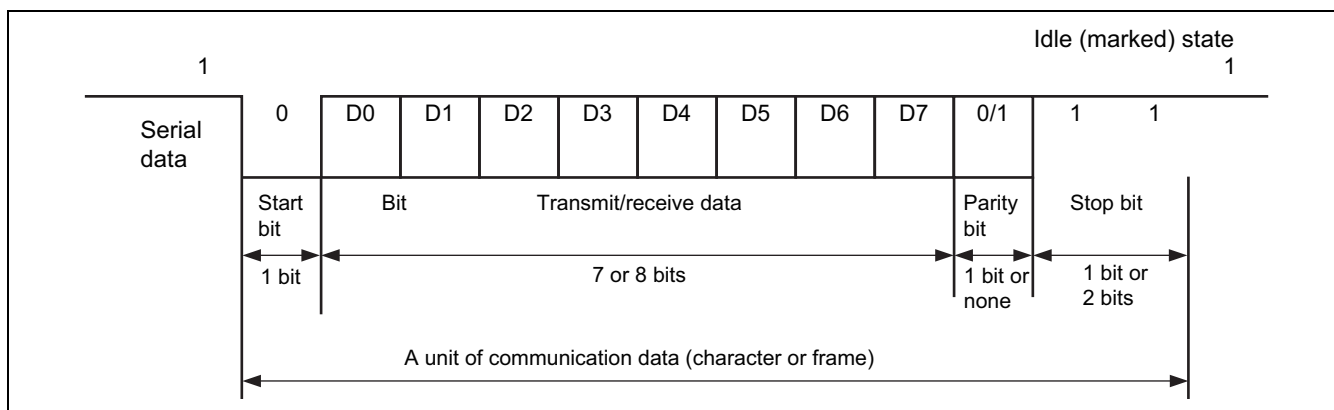

In asynchronous mode, the SCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 40.7 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The SCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the SCIF performs synchronization at the falling edge of the start bit. Communication data is acquired at the center of each bit because the SCIF samples data at the eighth pulse of the clock which has a frequency of 16 times the bit rate.

**Figure 40.7 Data Format in Asynchronous Mode  
(Example of 8-Bit Data with Parity and Two Stop Bits)**

**(1) Transmission/Reception Format**

Table 40.6 shows available data transfer formats. The SCIF supports 8 transfer formats, which can be specified by SCSMR.

**Table 40.6 Serial Transmission/Reception Formats (Asynchronous Mode)**

SCSMR Settings			Serial Transmission/Reception Format and Frame Length												
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	S	8-bit data							STOP				
		1	S	8-bit data							STOP	STOP			
1	0	0	S	8-bit data							P	STOP			
		1	S	8-bit data							P	STOP	STOP		
1	0	0	S	7-bit data						STOP					
		1	S	7-bit data						STOP	STOP				
	1	0	S	7-bit data						P	STOP				
		1	S	7-bit data						P	STOP	STOP			

[Legend]

- S: Start bit
- STOP: Stop bit
- P: Parity bit

**(2) Clock**

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

**(3) Data Transmission/Reception**

**(a) Initialization of SCIF (Asynchronous Mode)**

Before transmitting/receiving data or changing the operating mode or communication format, the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 40.8.

[Notes]

Clearing the TE bit to 0 initializes SCTSR. However, SCFSR, SCFTDR, and SCFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in SCFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in SCFCR to reset SCFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the SCIF.

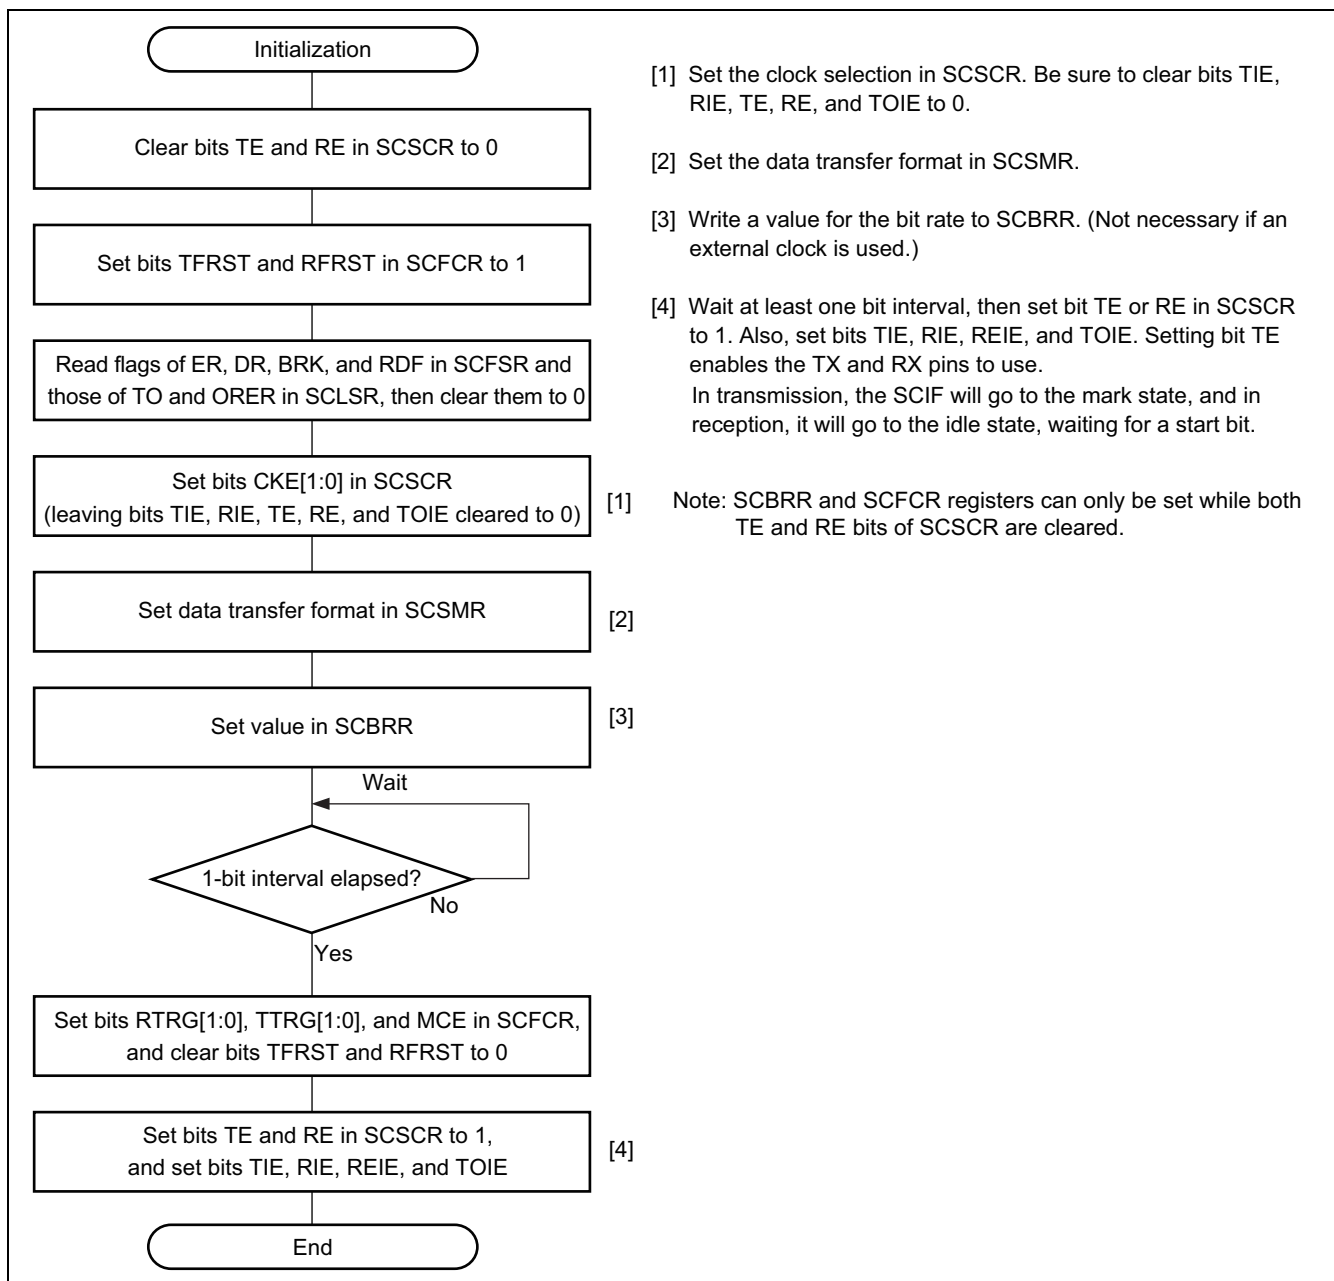

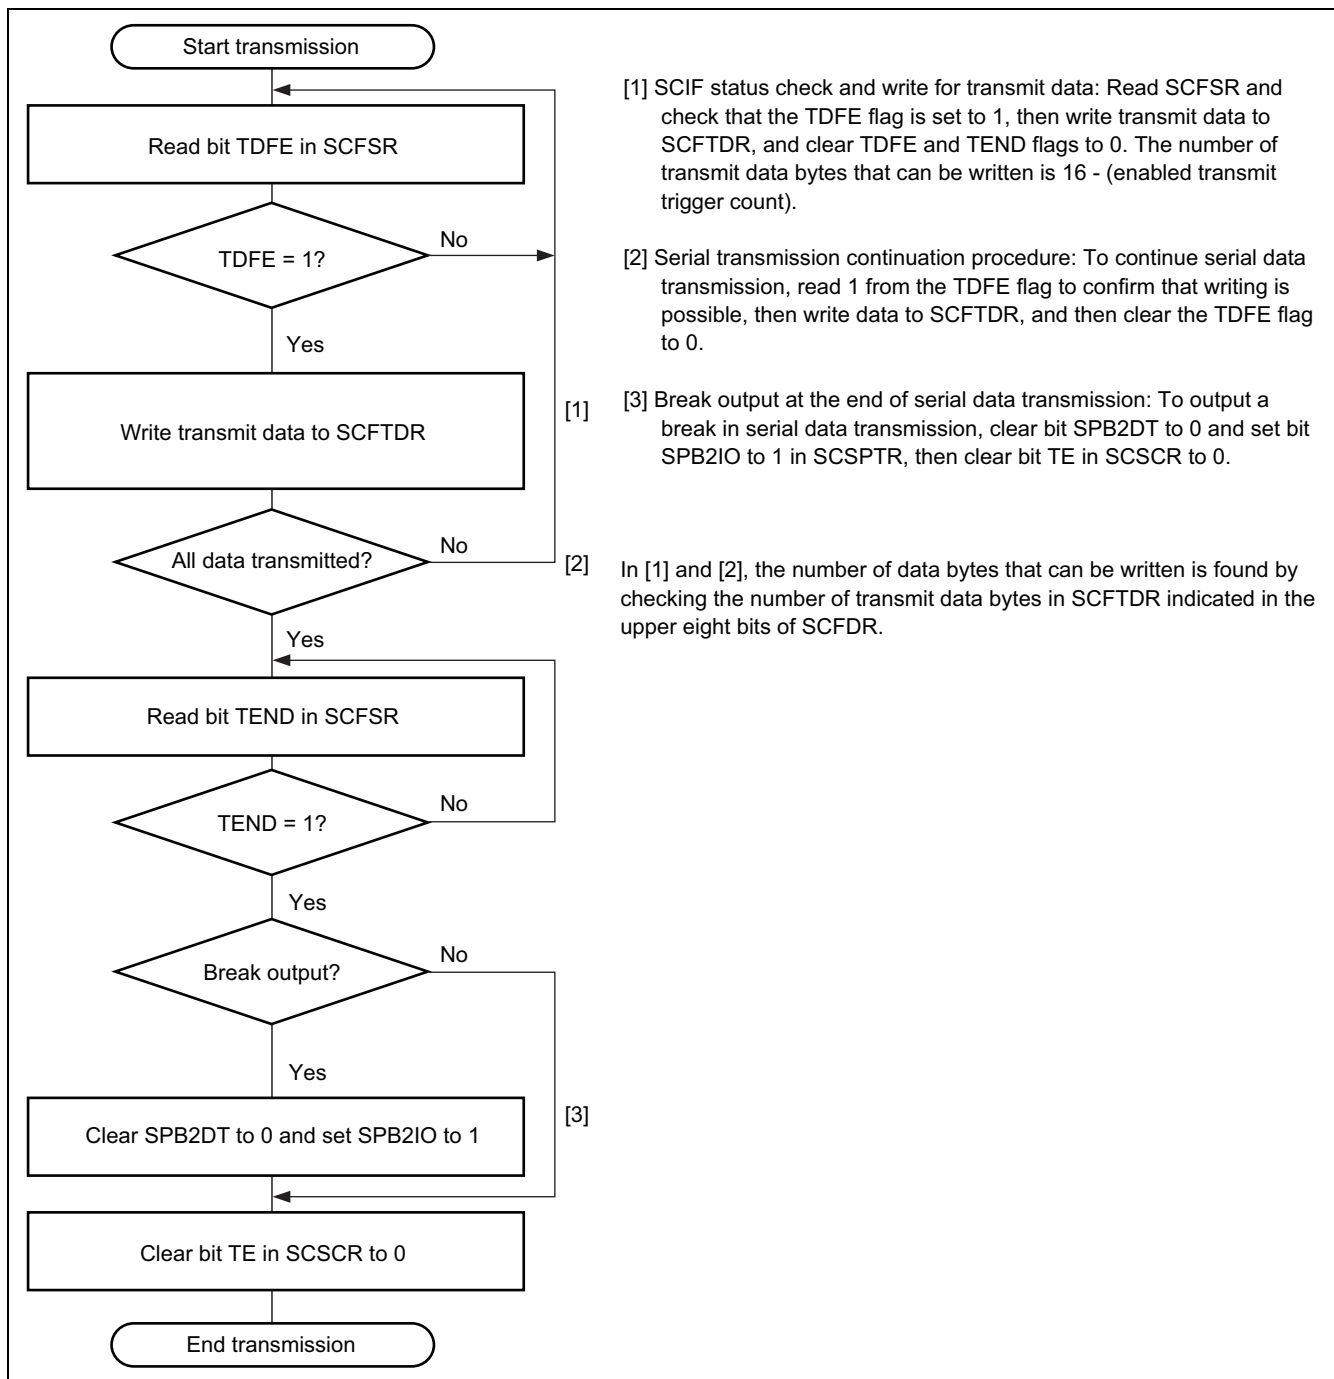

Figure 40.8 Sample Flowchart for Initializing the SCIF

**(b) Serial Data Transmission (Asynchronous Mode)**

Figure 40.9 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

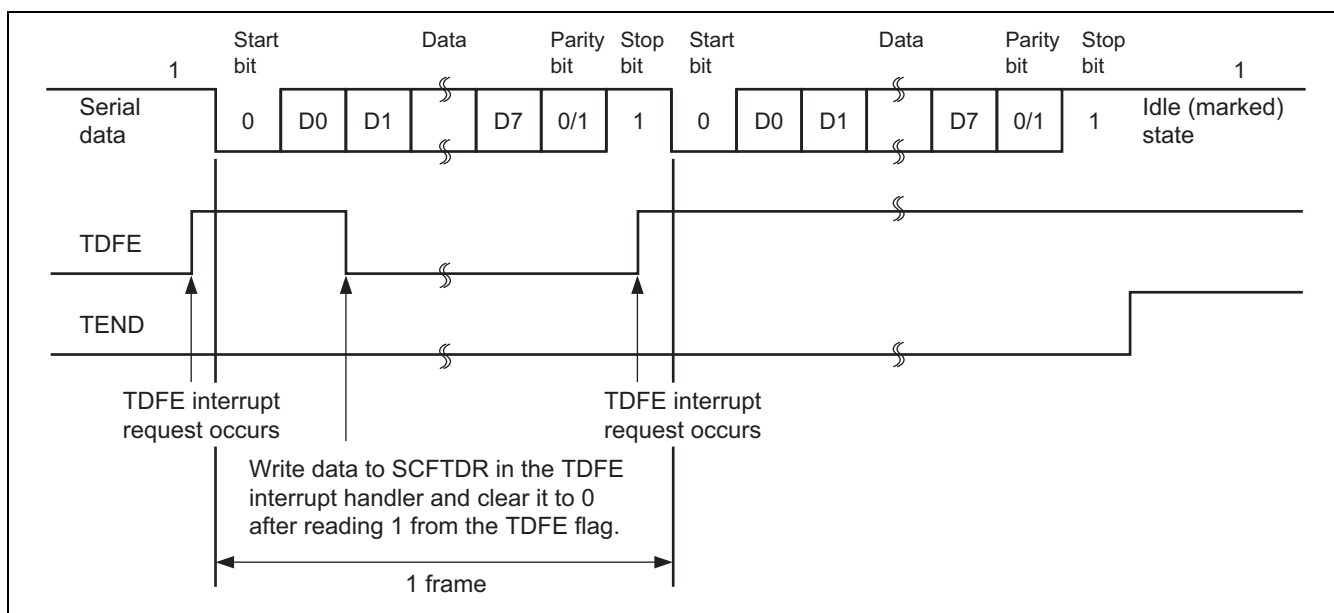

**Figure 40.9 Sample Flowchart for Serial Transmission**

In serial transmission, the SCIF operates as follows:

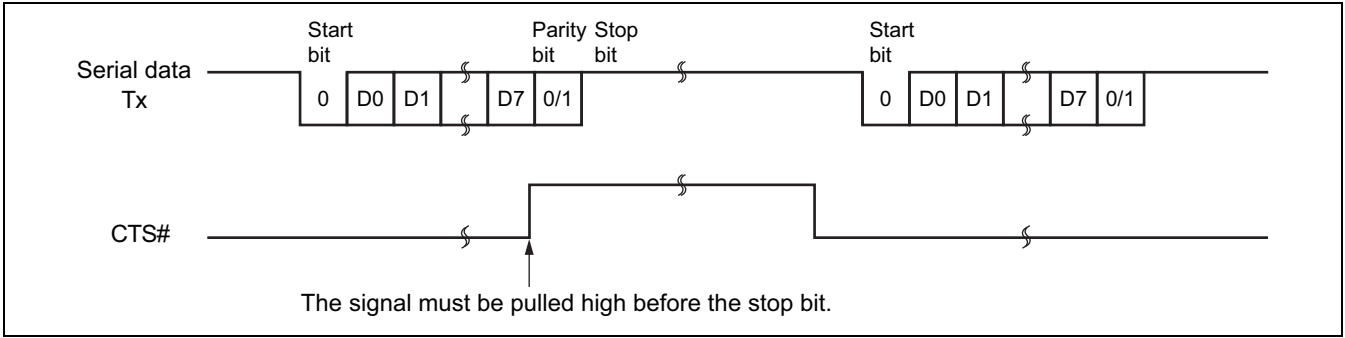

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (transmit trigger count)).
2. When data is transferred from SCFTDR to SCTSR and the SCIF starts transmission, consecutive transmission is performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count specified in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the TX pin in the following order:
  - A. Start bit: One 0-bit is output.
  - B. Transmit data: 8- or 7-bit data is output in LSB-first order.
  - C. Parity bit: One parity bit (even or odd parity) is output.  
A format that does not output a parity bit can also be selected.
  - D. Stop bit(s): One or two 1-bits (stop bits) are output.
  - E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks transmit data in SCFTDR when sending the stop bit. If there is data in it, the SCIF transfers the data from SCFTDR to SCTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the SCIF sets the TEND flag to 1 in SCFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 40.10 shows an example of transmission in asynchronous mode.

**Figure 40.10 Sample SCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the CTS# input value. When CTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting CTS# to 0 restarts outputting the next transmit data from the start bit. Figure 40.11 shows an example of the operation with modem control enabled.

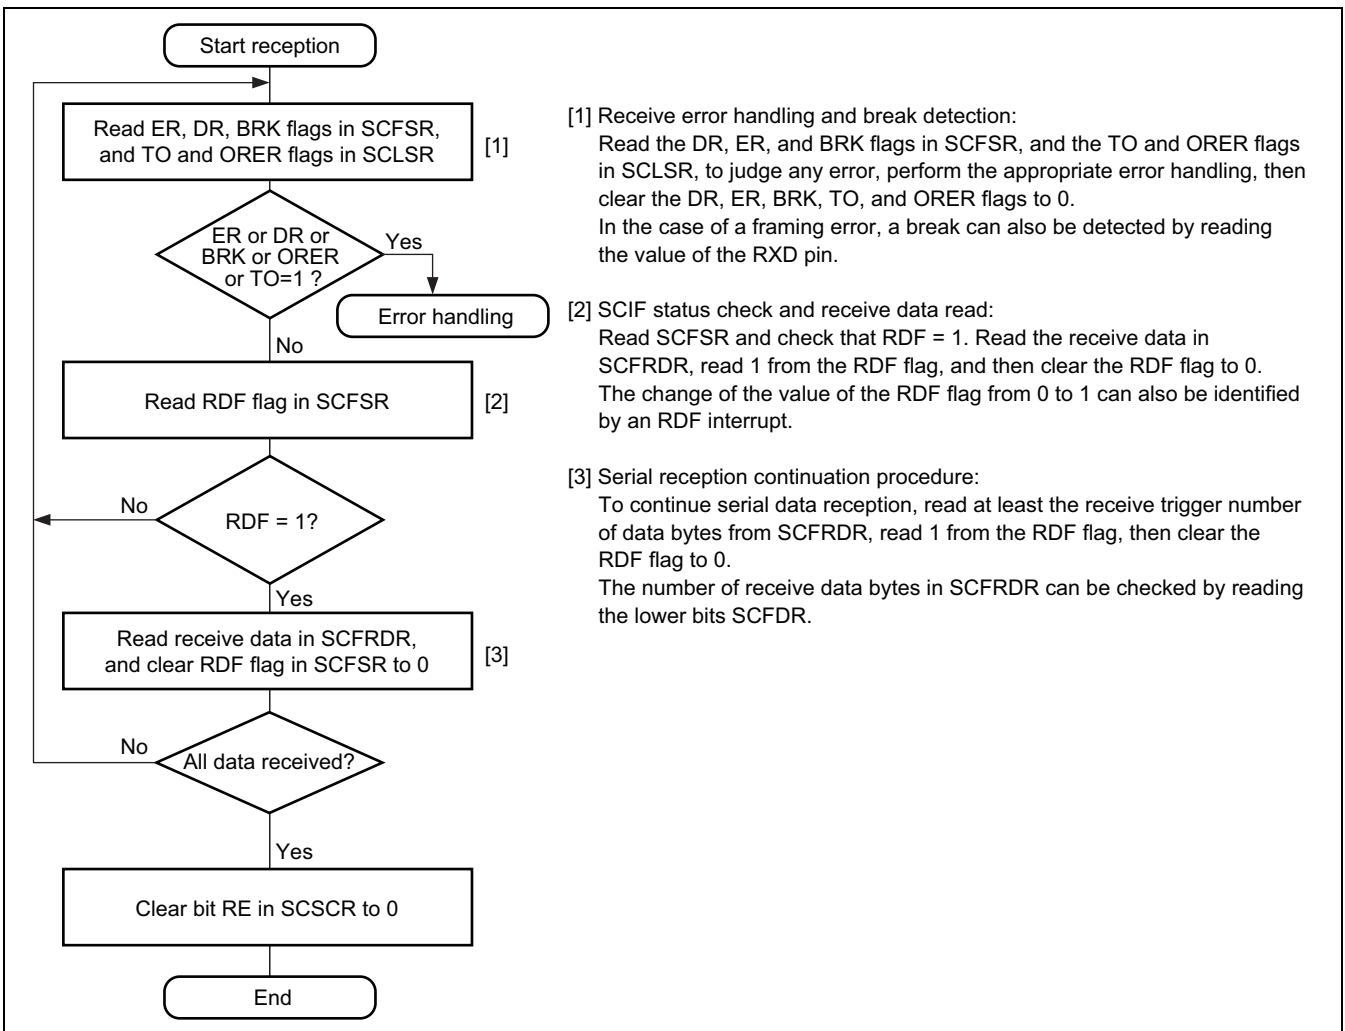

**Figure 40.11 Sample Operation with Modem Control Enabled (CTS#)**

**(c) Serial Data Reception (Asynchronous Mode)**

Figures 40.12 and 40.13 show sample flowcharts for serial reception.

After the SCIF reception operation is enabled, serial data reception can be performed using the following procedure:

**Figure 40.12 Sample Flowchart for Serial Reception (1)**

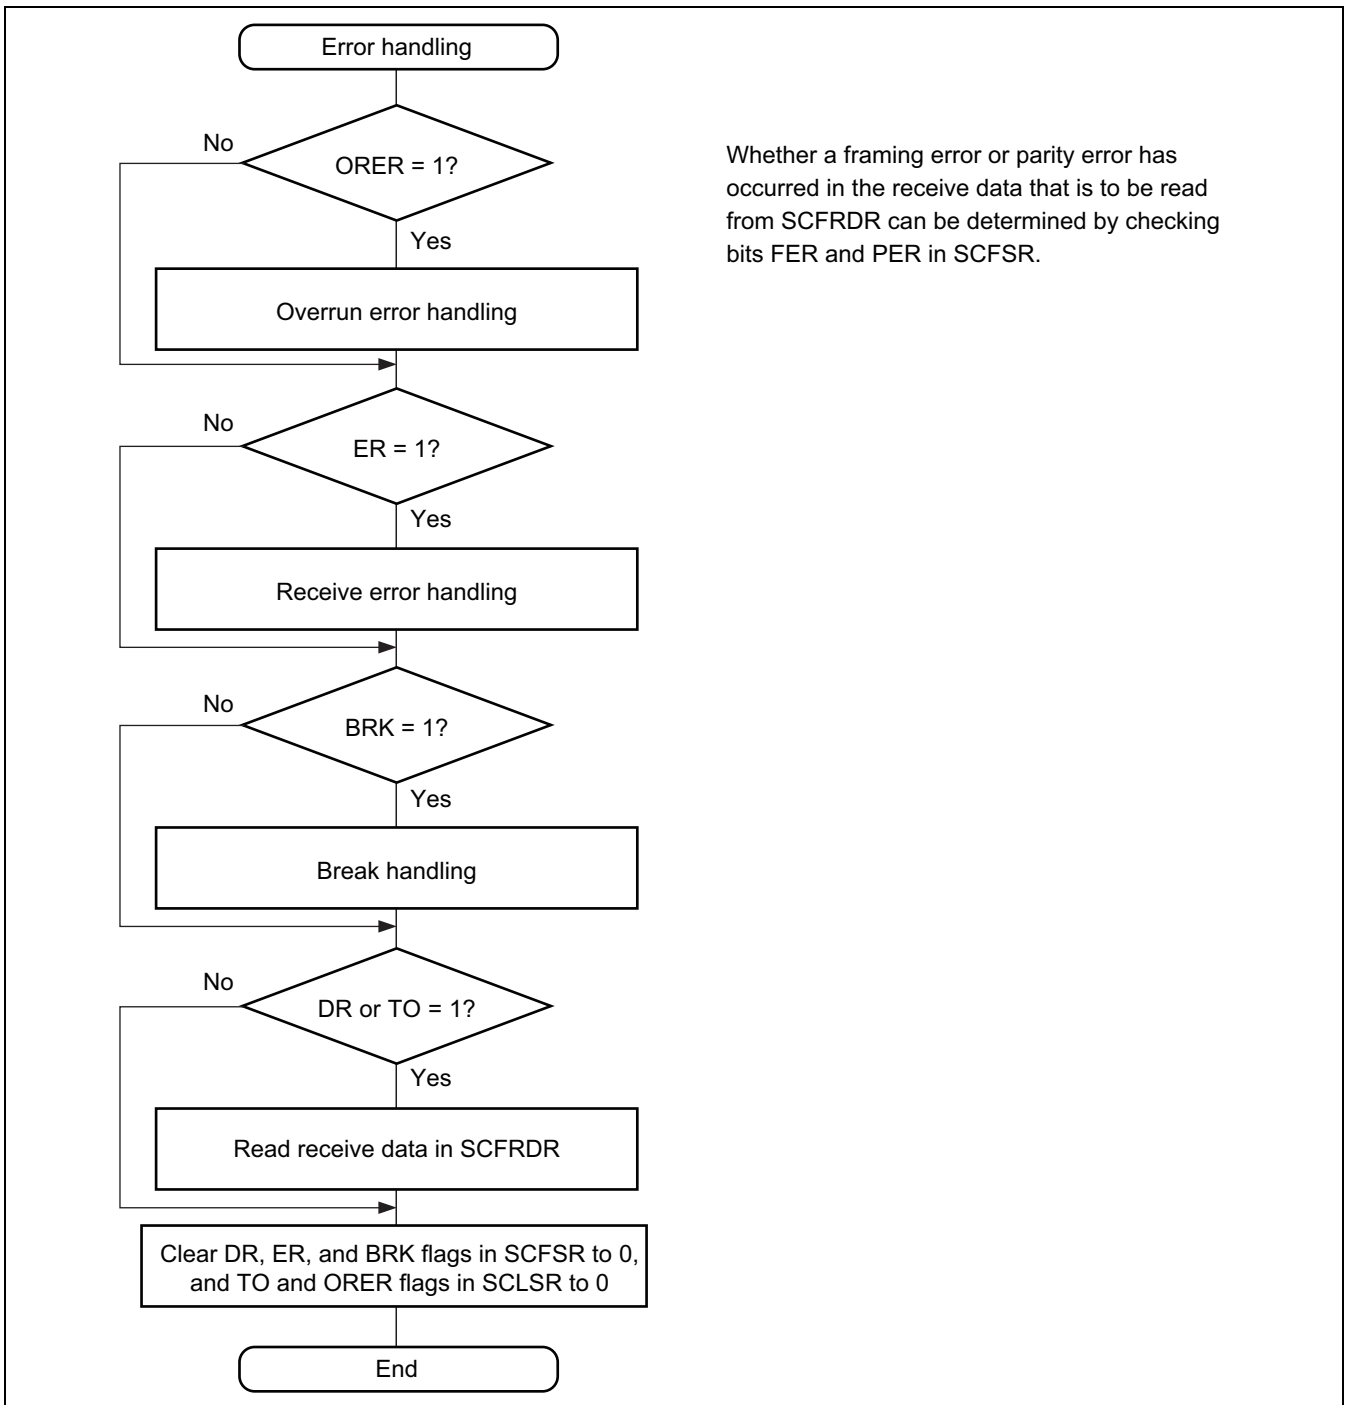

Figure 40.13 Sample Flowchart for Serial Reception (2)

In serial reception, the SCIF operates as follows:

1. The SCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The SCIF stores the received data in SCRSR in LSB-to-MSB order.
3. The SCIF receives the parity bit and stop bit.

After receiving these bits, the SCIF performs the following checks:

A. Stop bit: The SCIF checks whether the stop bit is 1.

If there are two stop bits, it checks only the first stop bit.

B. Receive data: The SCIF checks that receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.

C. Overrun error: The SCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.

D. Break state: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.

If the SCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in SCFRDR.

Note: The SCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.

If the DR flag changes to 1 while the RIE bit in SCSCR is 1, a receive-data-ready interrupt (DR) request occurs.

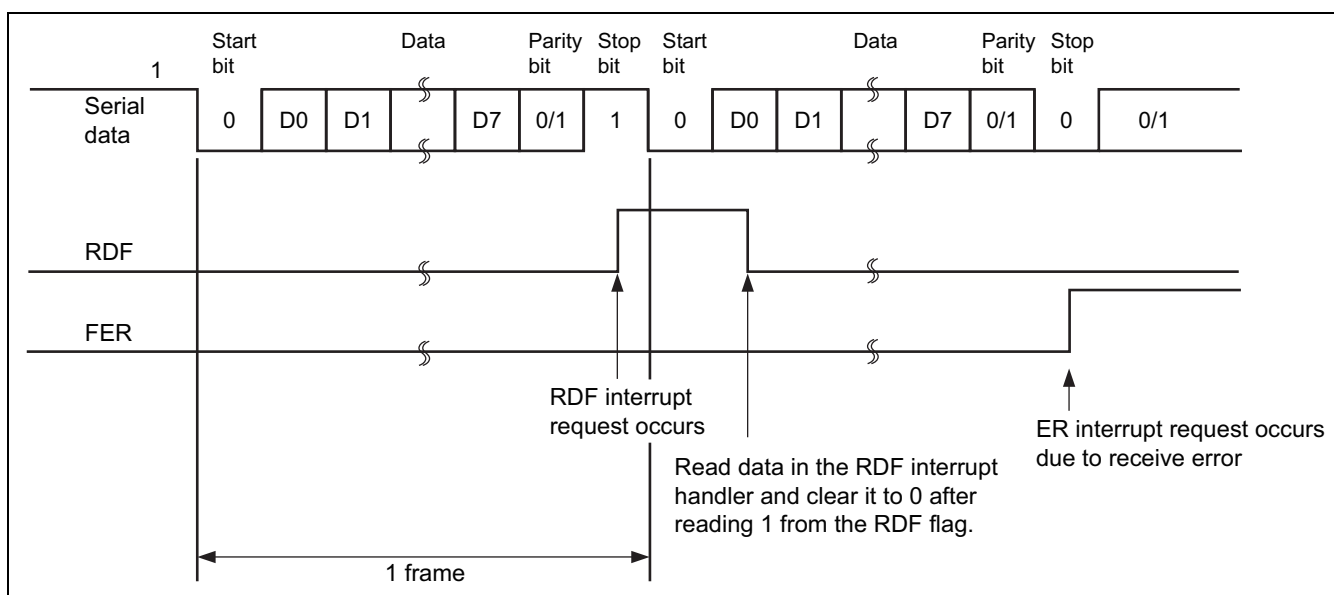

If the TO flag changes to 1 while the TOIE bit in SCSCR is 1, a timeout interrupt (TO) request occurs.

If the ER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a receive-error interrupt (ER) request occurs.

If the BRK flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRK) request occurs.

If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, an overrun-error interrupt (ORER) request occurs.

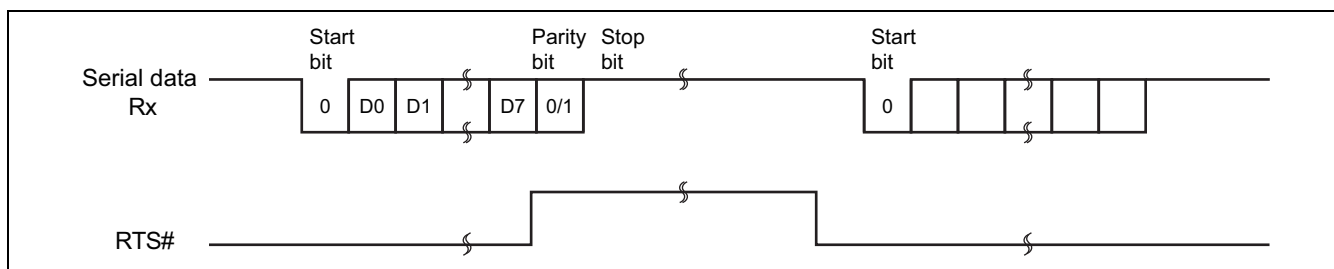

Figure 40.14 shows an example of reception in asynchronous mode.

**Figure 40.14 Sample SCIF Receive Operation  
(Example of 8-Bit Data with Parity and One Stop Bit)**

5. When modem control is enabled, the RTS# signal is output when SCFRDR is empty. When RTS# is 0, data can be received. When RTS# is set to 1, the number of data bytes in SCFRDR is equal to or more than the RTS# output active trigger count.

Figure 40.15 shows an example of the operation with modem control enabled.

**Figure 40.15 Example of the Operation with Modem Control Enabled (RTS#)**

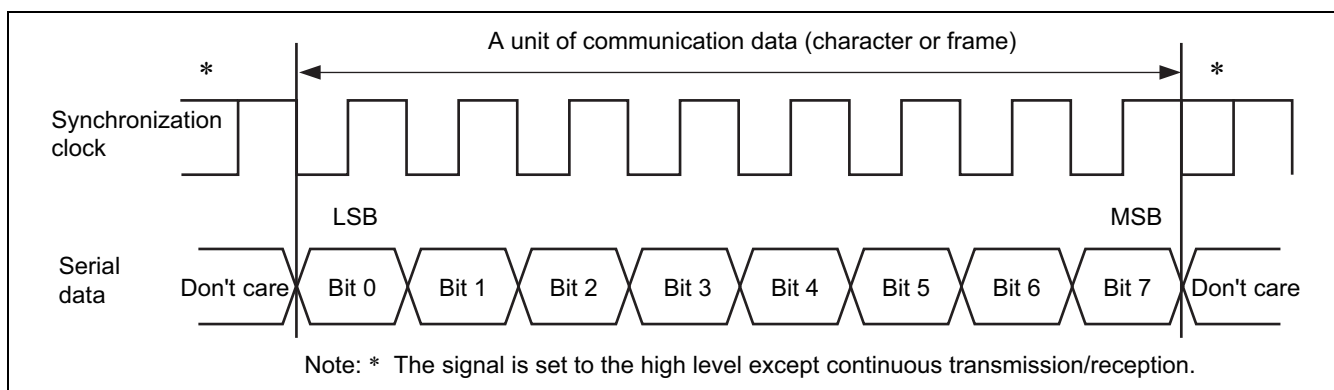

### 40.3.2 Operation in Clock Synchronous Mode

Clock synchronous mode, in which data is transmitted and received in synchronization with clock pulses, is suitable for fast serial communication.

Figure 40.16 shows the general format for clock synchronous serial communication. In the clock synchronous serial communication, data on the communication line is output between one falling edge of the synchronization clock and the next falling edge. The data decision is done at the rising edge of the clock.

In serial communication, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communication line retains the state of the last data.

In clock synchronous mode, the SCIF receives data in synchronization with a rising edge of the synchronization clock.

**Figure 40.16 Data Format for Clock Synchronous Communication**

#### (1) Data Transfer Format

The data transfer format is fixed to 8 bits. No parity bit can be added.

#### (2) Clock

The clock can be selected from the following two clocks using the C/A bit in SCSMR and the CKE[1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External synchronization clock input at the SCK pin

When the SCIF is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in one-character transfer, and when no transfer is performed the clock is fixed high. When only reception operation is performed, selecting an internal clock outputs clock pulses until the number of data bytes in the receive FIFO reaches the specified receive trigger count, while the RE bit in SCSCR is 1.

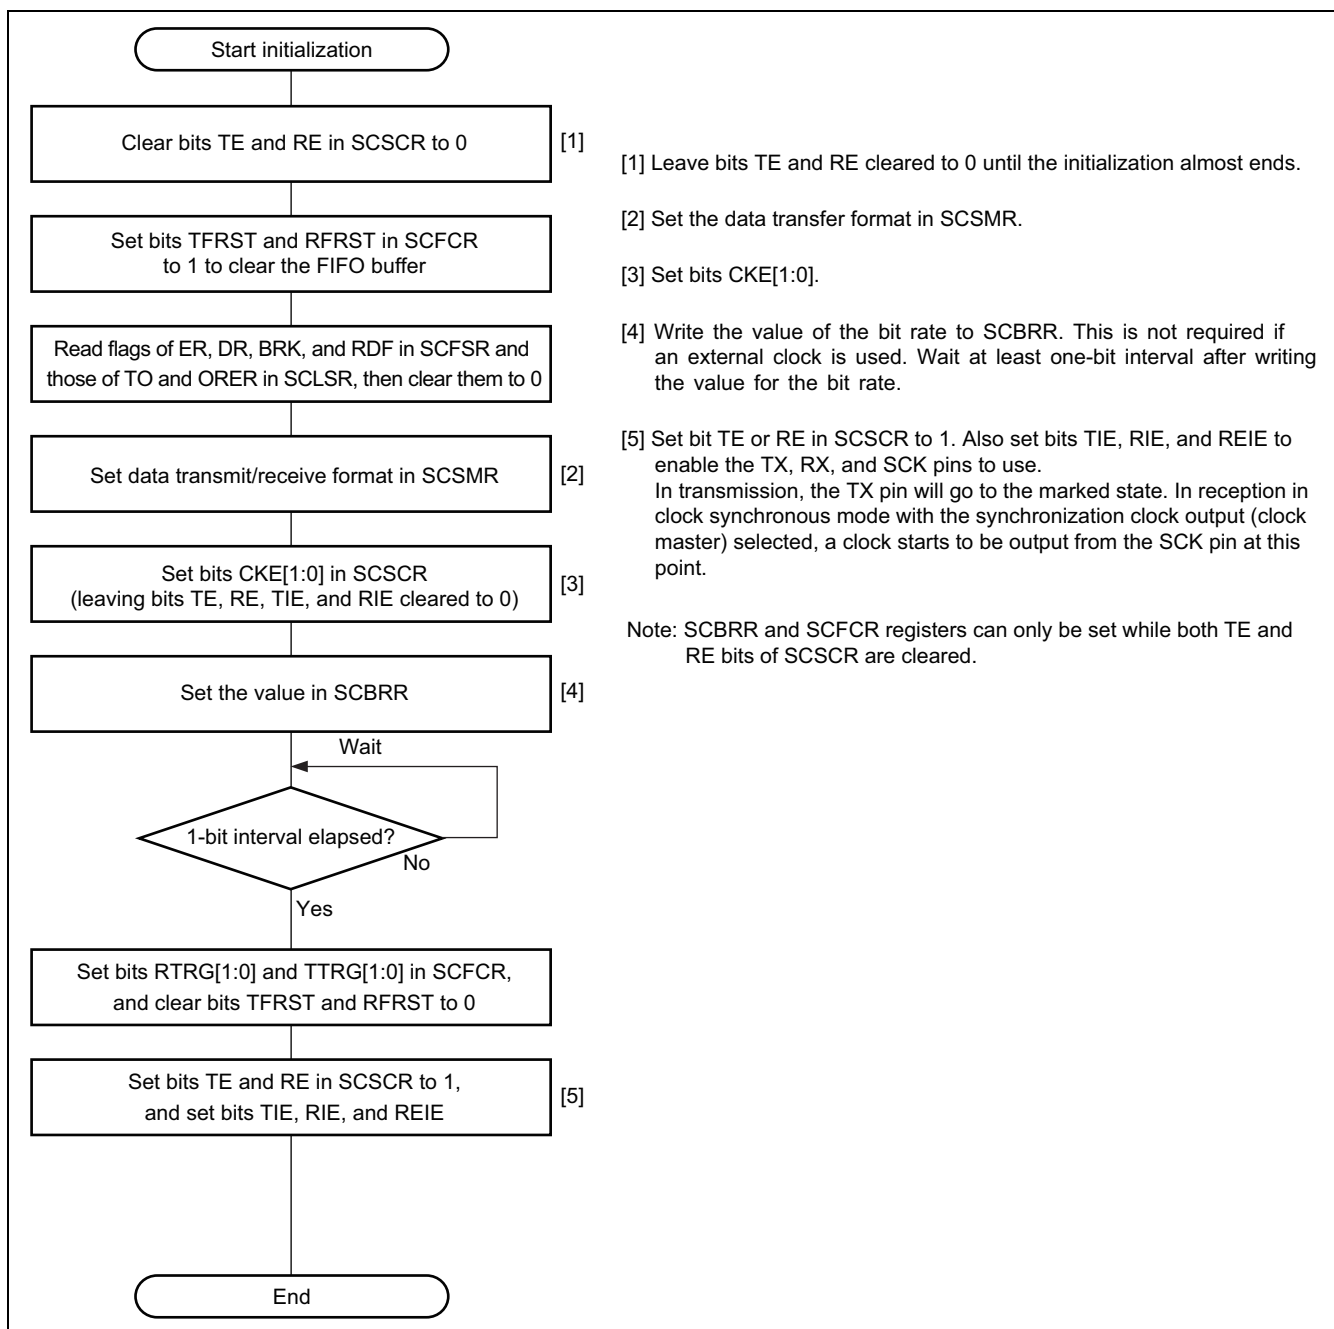

**(3) Data Transmission/Reception**

**(a) Initialization of SCIF (Synchronous Mode)**

Before transmitting/receiving data or changing the operating mode or communication format, the TE and RE bits in SCSCR to 0 and then the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 40.17.

[Note]

Clearing the TE bit to 0 initializes SCTSR. However, clearing the RE bit to 0 does not affect the RDF, PER, FER, and ORER flags and SCFRDR contents.

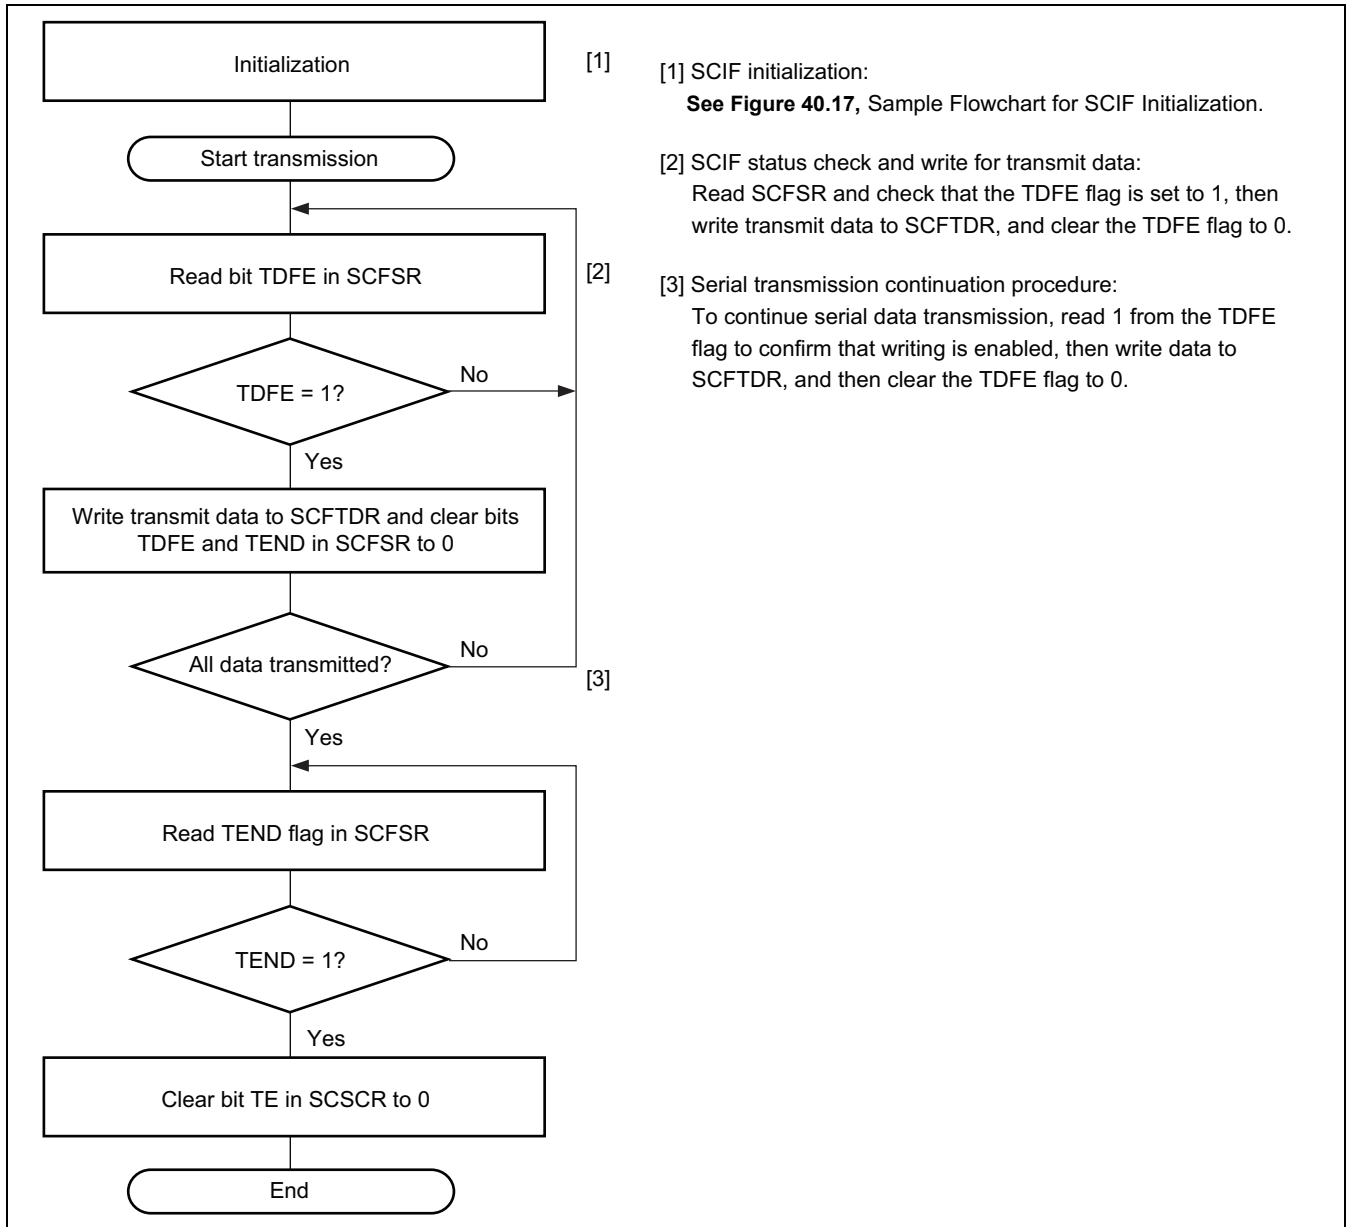

**Figure 40.17 Sample Flowchart for SCIF Initialization**

**(b) Serial Data Transmission (Clock Synchronous mode)**

Figure 40.18 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

**Figure 40.18 Sample Flowchart for Serial Transmission**

In serial data transmission, the SCIF operates as described below:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR to start transmission. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (the transmit trigger count)).
2. After the SCIF transfers data from SCFTDR to SCTSR and starts data serial transmission, the SCIF consecutively transmits it until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count set in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. When the external clock is selected, data is output in synchronization with the input clock. The serial transmit data is output at the TX pin in the LSB-first order.
3. The SCIF checks transmit data in SCFTDR when sending the last bit. If there is transmit data, the SCIF transfers the data to SCTSR, and starts serial transmission of the next frame. If there is no transmit data left, the TEND flag in SCFSR is set to 1, and the transmit data pin (TX pin) retains its state after the last bit is sent. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.
4. After serial transmission ends, the SCK pin is fixed high.

Note: In clock synchronous mode, when transmit data is written to SCFTDR by the DMAC, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, read the TEND flag in the following method.

1. Confirm that data transfer is completed in the DMAC.
2. Read the TEND flag.
3. Clear the TEND flag to 0 if TEND = 1.
4. Read the TEND flag again.
5. Use the second-read TEND flag.

Figure 40.19 shows an example of SCIF serial transmission in clock synchronous mode.

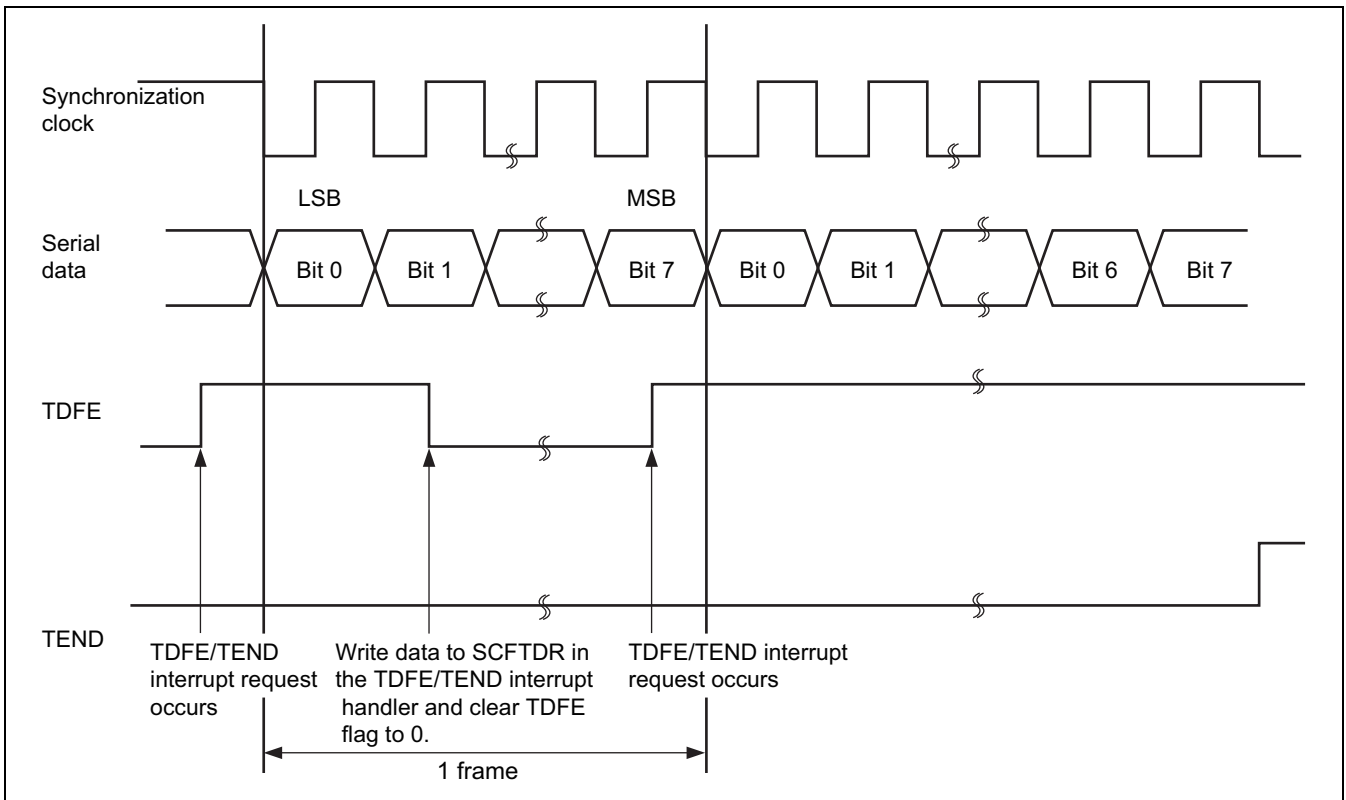

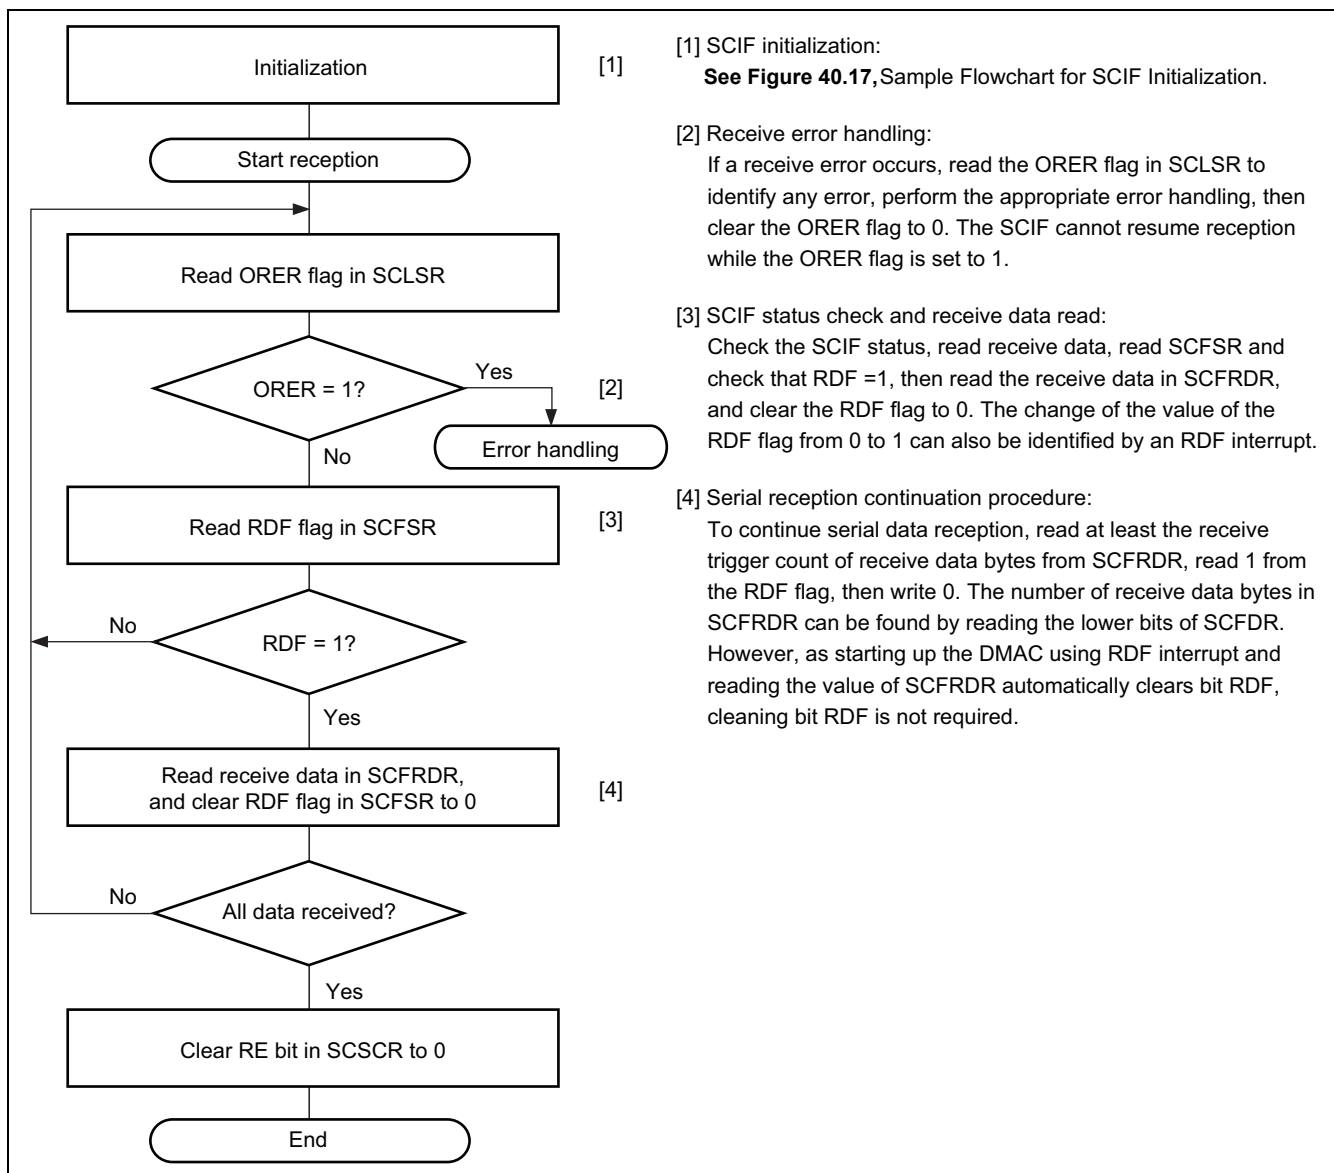

Figure 40.19 Example of SCIF Serial Transmission in Clock Synchronous Mode

**(c) Serial Data Reception (Clock Synchronous Mode)**

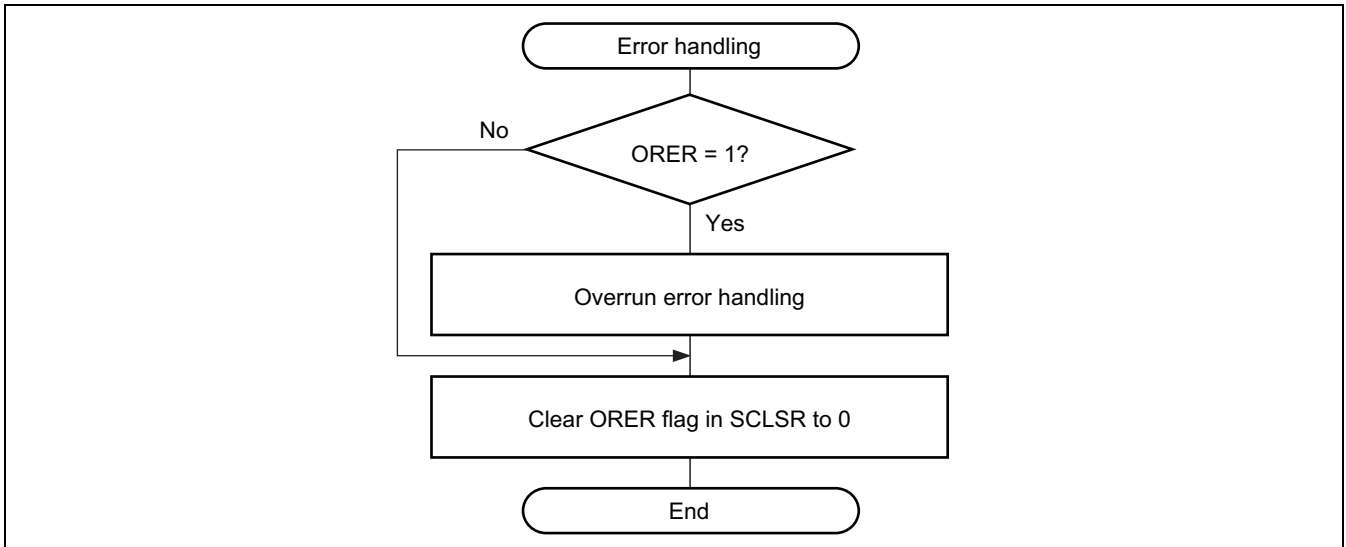

Figures 40.20 and 40.21 show sample flowcharts for serial reception.

The SCIF reception should be enabled before taking the following steps for serial data transmission.

When switching operating mode from asynchronous mode to clock synchronous mode without initializing the SCIF, check that the ORER, PER3 to PER0, and FER3 to FER0 flags are cleared to 0.

**Figure 40.20 Sample Flowchart for Serial Data Reception**

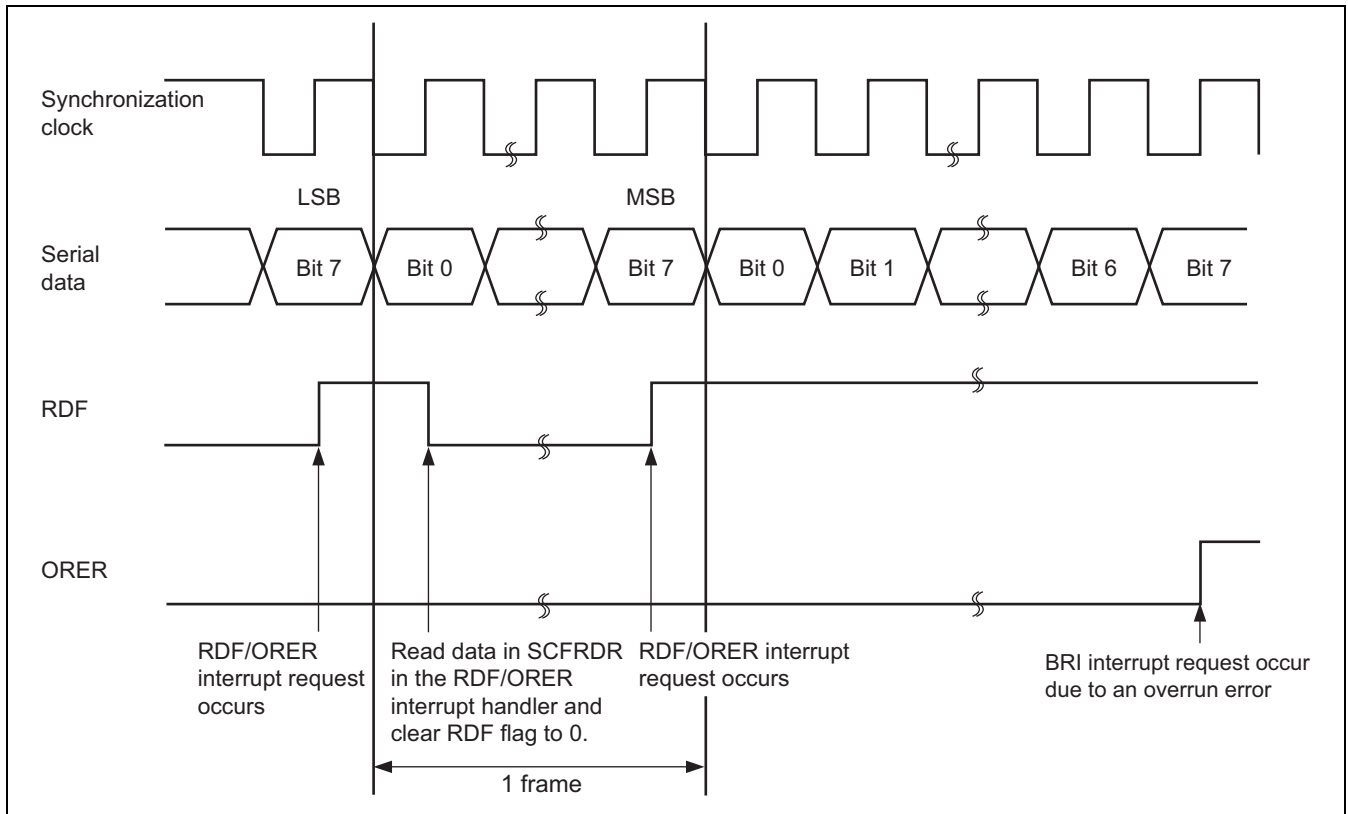

**Figure 40.21 Sample Flowchart for Serial Data Reception**

In serial data reception, the SCIF operates as described below:

1. The SCIF starts receiving data in synchronization with synchronization clock input or output.
2. The SCIF stores receive data in SCRSR in LSB-to-MSB order.  
After receiving the data, the SCIF first checks if the receive data can be transferred from SCRSR to SCFRDR, then starts storing the receive data in SCFRDR.  
If the SCIF detects an overrun error, the SCIF cannot receive subsequent data.
3. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs. If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRI) request occurs.

Figure 40.22 shows an example of SCIF reception in clock synchronous mode.

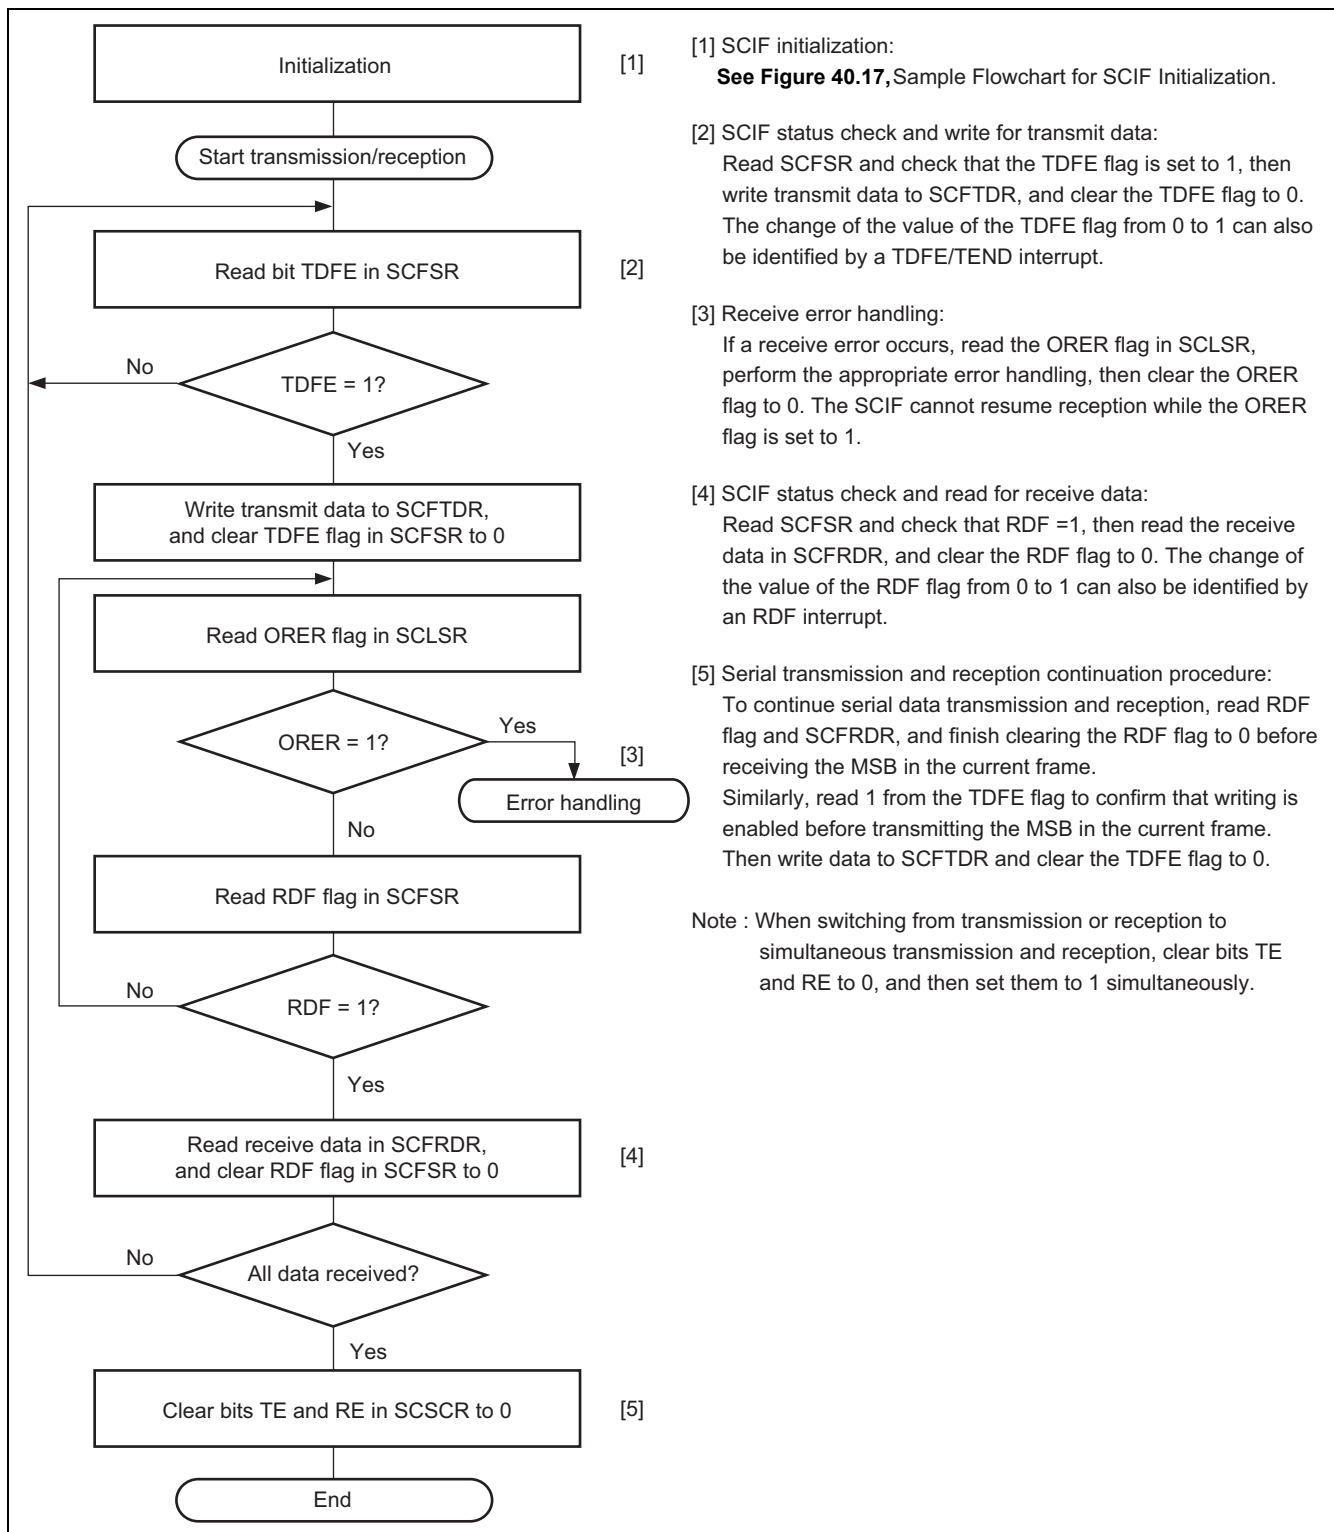

**Figure 40.22 Example of SCIF Reception in Clock Synchronous Mode**

**(d) Simultaneous Serial Data Transmission/Reception (Clock Synchronous Mode)**

Figure 40.23 shows a sample flowchart for simultaneous serial data transmission/reception.

The SCIF transmission and reception should be enabled before taking the following steps for simultaneous serial data transmission/reception.

**Figure 40.23 Sample Flowchart for Simultaneous Serial Data Transmission/Reception**

## 40.4 SCIF Interrupt Sources and the DMAC

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the SCIF.

### Transmission Interrupts and DMA Transfer:

If the TDFE/TEND flag in SCFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

### Reception Interrupts and DMA Transfer:

If the RDF/DR flag in SCFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in SCSCR to 0 and the REIE bit to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in SCFSR or the ORER flag in SCLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in SCLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

DR/TO interrupt requests generated by setting the DR or TO flag to 1 or receive-FIFO-data-full DMA transfer requests occur only in asynchronous mode.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

**Table 40.7 SCIF Interrupt Sources**

Interrupt Source	DMAC Activation	Priority on Reset Release
Interrupts generated by receive error flag (ER)	Disabled	High
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO) *	Enabled	↑ ↓
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled	
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled	Low

Note: \* RXI interrupts by means of the DR or TO flag are available only in asynchronous mode.

## 40.5 Usage Notes

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

Note the following on use of the SCIF.

### (1) Break Detection and Operation

Break signals can also be detected by reading the RX pin value directly when a framing error (FER) is detected. In the break state, the input values from the RX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the SCIF stops receive data transfer to SCFRDR after detecting a break, it continues data reception.

### (2) Sending a Break Signal

The input/output condition and level of the TX pin are determined by the SPB2IO and SPB2DT bits in SCSPTR. This enables to send a break signal.

The pin does not function as the TX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the TX pin outputs 0.

### (3) Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCIF operates on the base clock with a frequency 16 times the bit rate.

In reception, the SCIF performs the internal synchronization by sampling the fall edge of the start bit using the base clock. In addition, the SCIF takes receive data at the rising edge of the eighth pulse on the base clock.

Figure 40.24 shows the timing of this operation.

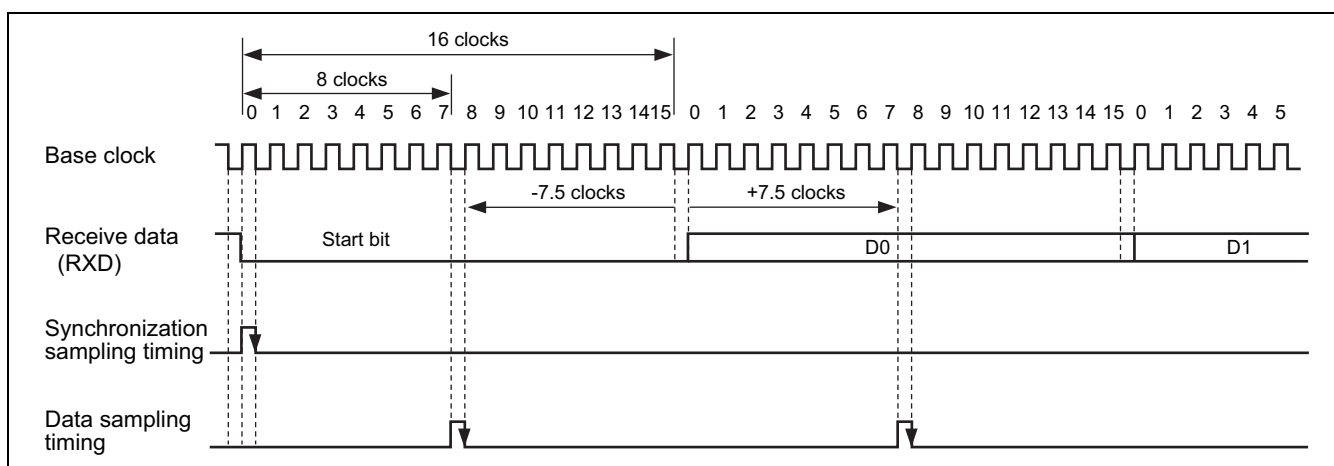

Figure 40.24 Timing Chart of Receive Data Sampling

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \dots\dots\dots \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0 and D = 0.5 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$$M = (0.5 - 1/(2 \times 16)) \times 100\%$$

$$= 46.875\% \dots\dots\dots \text{expression (2)}$$

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

#### (4) Reception Margin and Baud Rate Error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

$$F = \{(15/32 - M)/(L - 0.5)\} \times 100 (\%) \dots\dots\dots \text{expression (3)}$$

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

## 40.6 Baud Rate Generator for External Clock (BRG)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 40.6.1 Overview

The SCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the SCIF core by dividing the external clock SC\_CLK (selectable between SCIF\_CLK and ZSφ) by  $1$  to  $2^{16} - 1$ . In addition, the BRG switches the output between the external clock SCK and divided clock.

Figure 40.25 shows a block diagram of the BRG.

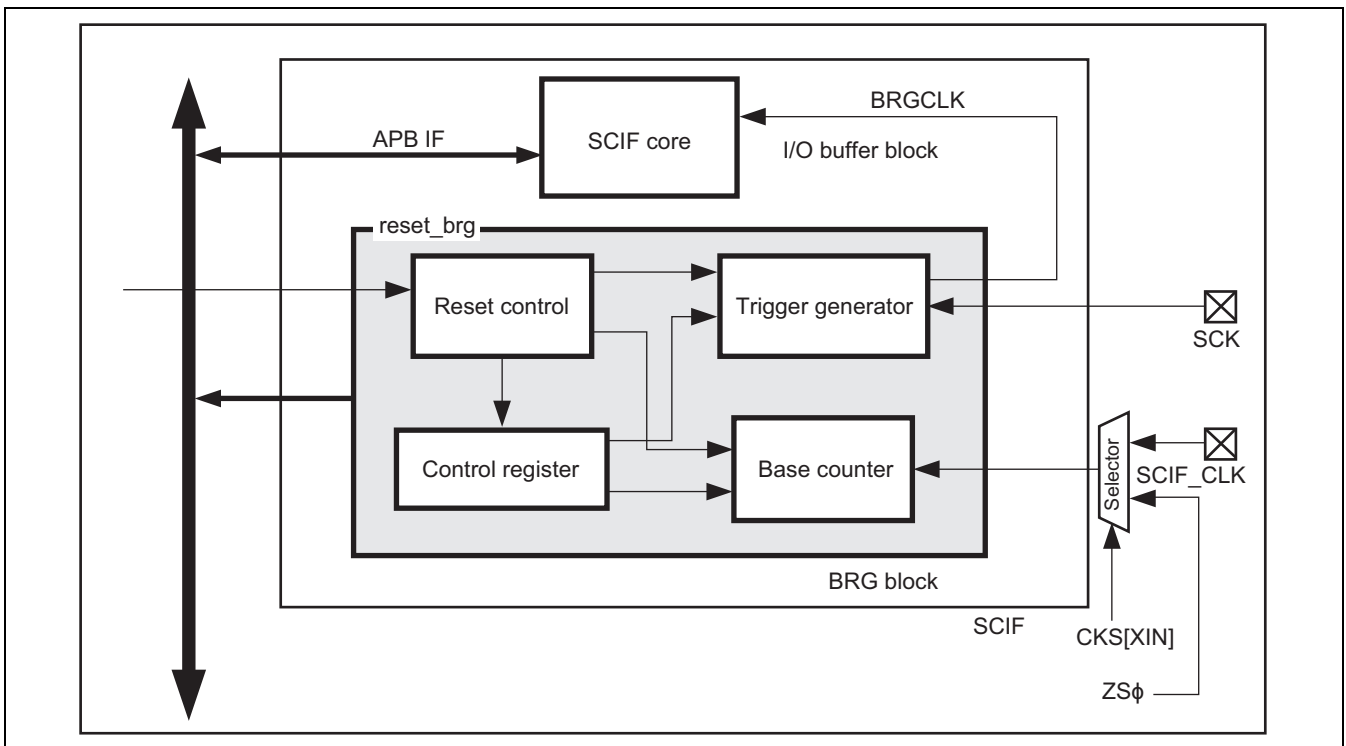

Figure 40.25 BRG Block Diagram

(1) Reset Controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(2) Control Register:

The control register has the frequency division register and clock select register.

(3) Base Counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(4) Trigger Generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the SCK (external clock input) and frequency divided clock.

## 40.6.2 Register Configuration

Table 40.8 shows the registers in the BRG block.

**Table 40.8 List of Registers**

Name	Abbreviation	R/W	Initial Value	Relative Address	Access Size
Frequency division register	DL	R/W	H'0000	H'30	16
Clock select register	CKS	R/W	H'0000	H'34	16

### 40.6.2.1 Frequency Division Register (DL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the range of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/(required baud rate × 16)

Table 40.9 shows how to use the baud rate generator with a 3.6864-MHz crystal resonator.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The value settings enabled in the range of 1 to 65535.

**Table 40.9 Baud Rate (3.6864-MHz clock)**

Baud Rate	Value of Frequency Division	Error Rate (*)
50	4608	—
75	3072	—
110	2095	-0.022
134.5	1713	0.001
150	1536	—
300	768	—
600	384	—
1200	192	—
1800	128	—
2000	115	0.174
2400	96	—
3600	64	—
4800	48	—
7200	32	—
9600	24	—
14400	16	—
19200	12	—
38400	6	—
76800	3	—
115200	2	—

Note: —: Indicates that the error rate is 0.

**40.6.2.2 Clock Select Register (CKS)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (SCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and ZSφ. 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (ZSφ).
13 to 0	All 0	0	R	Reserved These bits are always read as 0. Only 0 should be written to these bits.

### 40.6.3 Restrictions in BRG

#### (1) Notes on Setting Frequency Division Register

- For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.

(Example) One bit period when DL = 2

$$3.68 \text{ (MHz)} \times 1/2 \times 1/16 = 0.115 \text{ (MHz)} \rightarrow 8695 \text{ (ns)}$$

- For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.

The SCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC\_CLK external input)

SCIF		BRG	
Register Name	Setting Value	Register Name	Setting Value
SCSMR.C/A#	0	CKS	0000
SCSCR.CKE[1:0]	10	DL	1 to FFFF

- Asynchronous mode (SCK external input)

SCIF		BRG	
Register Name	Setting Value	Register Name	Setting Value
SCSMR.C/A#	0	CKS	8000
SCSCR.[1:0]	10	DL	Don't care

- Clock synchronous mode (external input)

SCIF		BRG	
Register Name	Setting Value	Register Name	Setting Value
SCSMR.C/A#	1	CKS	8000
SCSCR [1:0]	10	DL	Don't care

- The register settings for the baud rate generator for external clock should be made before starting initialization of the SCIF.

## 41. Serial Communications Interface with FIFO A (SCIFA)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

This LSI has six serial communications interfaces A incorporating FIFO buffers (SCIFA) that can perform both asynchronous and clocked synchronous serial communications.

Each interface includes two 64-stage buffers, one for the transmit FIFO register, and one for the receive FIFO register, enabling fast, for efficient and continuous communications.

### 41.1 Features

- 6 channels are implemented.
- Asynchronous mode
 

Serial data communications is executed using an asynchronous system in which synchronization is achieved character by character. Serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA).

There is a choice of 8 serial data communication formats.

  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even/odd/none
  - LSB-first transfer
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection: If a framing error is followed by at least one frame at the space "0" (low level), a break is detected.
- Clocked synchronous mode
 

Serial data communications is synchronized with a clock. Serial data communications can be carried out with other LSIs that have a clocked synchronous communications function.

  - Data length: 8 bits
  - Receive error detection: Overrun errors
  - A rising or falling edge of a clock is selectable as the data transmit/receive timing.
- On-chip baud rate generator allows any bit rate to be selected.
  - Maximum:  $MP\phi/5$  bps, Minimum:  $MP\phi/(27 \times 256 \times 64)$  bps (asynchronous)
  - Maximum:  $MP\phi/(2 \times 2)$  bps, Minimum:  $MP\phi/(2 \times 256 \times 64)$  bps (clocked synchronous)
- Serial clock source: Internal clock signal generated by the baud rate generator.
- Seven interrupt sources
 

There are seven interrupt sources— transmit-data-stop, transmit-FIFO-data-empty, receive-FIFO-data-full, receive-error (framing/parity error), break-receive, and receive-data-ready interrupts. The vectors of each interrupt source are the same.
- The DMA controller (DMAC) can be activated to execute a data transfer in the event of a transmit-FIFO-data-empty, transmit-data-stop, or receive-FIFO-data-full interrupt. The DMAC requests of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.
- DMA multi-byte data transfer supported
- On-chip modem control functions (CTS# and RTS#) [RZ/G1H only]
- On-chip transmit-data-stop functions
- When not in use, SCIFA can be stopped by halting its clock supply to reduce power consumption.

- The amount of data in the transmit/receive FIFO registers, and the number of receive errors in the receive data in the receive FIFO register, can be ascertained.

Figures 41.1a and 41.1b are block diagrams of SCIFA.

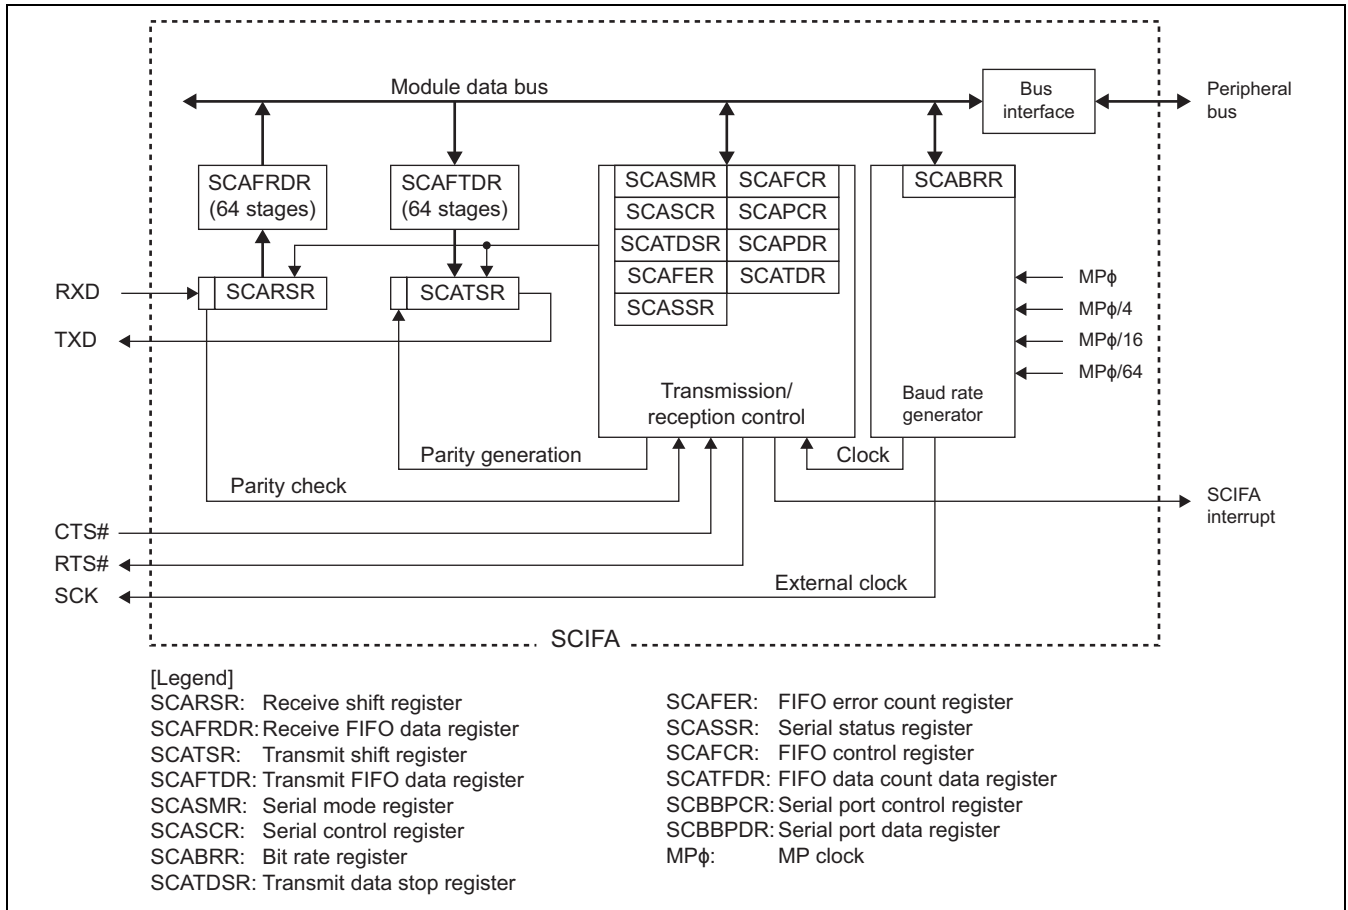

Figure 41.1a Block Diagram of SCIFA [RZ/G1H]

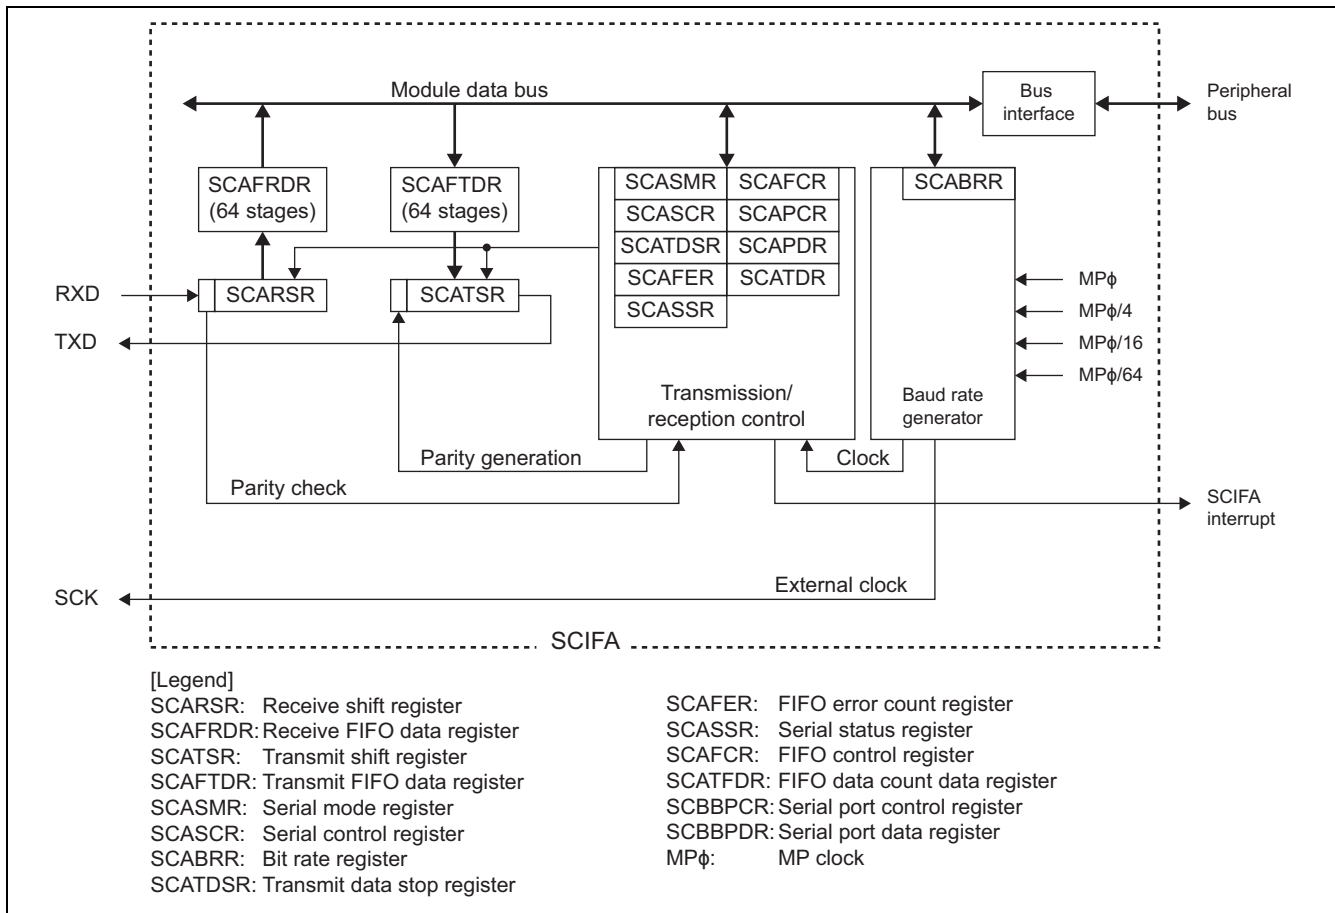

Figure 41.1b Block Diagram of SCIFA [RZ/G1M/N/E]

## 41.2 Input/Output Pins

Table 41.1 shows the SCIFA pin configuration.

**Table 41.1 Channel and Pin Configuration**

Pin Name	I/O	Function
SCIFAn_SCK	Output	Output pin for the clock signal n
SCIFAn_RXD	Input	Input pin for data for reception n
SCIFAn_TXD	Output	Output pin for data for transmission n
SCIFAn_CTS#	Input	Input pin for the transmit enable signal n [RZ/G1H only]
SCIFAn_RTS#	Output	Output pin for the transmit request signal n [RZ/G1H only]

Note: n is a channel number (n = 0 to 2 [RZ/G1H] / n = 0 to 5 [RZ/G1M/N/E]), and SCK, RXD, TXD, CTS#, and RTS# are used as generic terms in the following descriptions.

## 41.3 Register Descriptions

Table 41.2 shows the SCIFA registers. Table 41.3 shows the register states in the respective processing modes.

**Table 41.2 Register Configuration**

Register Name	Abbreviation		Address		RZ/G Series Products			
n: channel number			High order Address

n: Channel number (n = 0 to 2 [RZ/G1H] / n = 0 to 5 [RZ/G1M/N/E] )

### 41.3.1 Receive Shift Register An (SCARSRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCARSR is the register used to receive serial data.

SCIFA sets serial data input from the RXD pin in SCARSR in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is automatically transferred to SCAFRDR.

SCARSR cannot be directly read from or written to by the CPU.

### 41.3.2 Receive FIFO Data Register An (SCAFRDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCAFRDR is a 64-stage FIFO register that stores received serial data.

When SCIFA has received one byte of serial data, it transfers the received data from SCARSR to SCAFRDR where it is stored, and completes the receive operation. SCARSR is then enabled for reception, and consecutive receive operations can be performed until SCAFRDR is full (64-character data).

SCAFRDR is a read-only register, and cannot be written to by the CPU.

If a read is performed when there is no receive data in SCAFRDR, an undefined value will be returned. When SCAFRDR is full of receive data, subsequent serial data is lost.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFRD[7:0]	Undefined	R	Serial receive data FIFO

### 41.3.3 Transmit Shift Register An (SCATSRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCATSR is the register used to transmit serial data.

To perform serial data transmission, SCIFA first transfers a transmit data from SCAFTDR to SCATSR, and then sends the data to the TXD pin starting with the LSB (bit 0).

When transmission of one byte is completed, the next transmit data is transferred from SCAFTDR to SCATSR, and transmission starts automatically.

SCATSR cannot be directly read from or written to by the CPU.

#### 41.3.4 Transmit FIFO Data Register An (SCAFTDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCAFTDR is an 8-bit 64-stage FIFO data register that stores data for serial transmission.

If SCATSr is empty when transmit data has been written to SCAFTDR, SCIFA transfers the transmit data written in SCAFTDR to SCATSr and starts serial transmission.

SCAFTDR is a write-only register, and cannot be read by the CPU.

The next data cannot be written when SCAFTDR is filled with 64 bytes of transmit data. Data written in this case is ignored.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFTD[7:0]	Undefined	W	Serial transmit data FIFO

#### 41.3.5 Serial Mode Register An (SCASMRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCASMR is a 16-bit readable/writable register used to set an SCIFA's serial transfer format and select the baud rate generator clock source and the sampling rate.

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CKEDG	0	R/W	Transmit/Receive Clock Edge Select Selects the clock edge at which the serial data is output in clocked synchronous mode. 0: Serial data is transmitted at the falling edge of output clock. Serial data is received at the rising edge of output clock. 1: Serial data is transmitted at the rising edge of output clock. Serial data is received at the falling edge of output clock.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	SRC[2:0]	000	R/W	<p>Sampling Control</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>These bits select the sampling rate.</p> <p>000: Sampling rate 1/16            001: Sampling rate 1/5*            010: Sampling rate 1/7            011: Sampling rate 1/11            100: Sampling rate 1/13            101: Sampling rate 1/17            110: Sampling rate 1/19            111: Sampling rate 1/27</p> <p>Note: * In asynchronous mode, when the sampling rate is 1/5, first received data may become invalid. To avoid this problem, wait more than 1 serial data time (1 bit time x serial data number) after setting SCASCR.RE = 1, or use sampling rate other than 1/5.</p>
7	C/A#	0	R/W	<p>Communication Mode</p> <p>Selects asynchronous mode or clocked synchronous mode as the SCIFA operating mode.</p> <p>0: Asynchronous mode            1: Clocked synchronous mode</p>
6	CHR	0	R/W	<p>Character Length</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects 7 or 8 bits as the data length.</p> <p>0: 8-bit data            1: 7-bit data*</p> <p>Note: * When the 7-bit character is selected, the MSB (bit 7) in SCAFTDR is not transmitted.</p>
5	PE	0	R/W	<p>Parity Enable</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects whether or not parity bit addition is performed in transmission, and parity bit checking in reception.</p> <p>0: Parity bit addition and checking disabled            1: Parity bit addition and checking enabled*</p> <p>Note: * When the PE bit is set to 1, the parity (even or odd) specified by the O/E bit is added to transmit data before transmission. In reception, the parity bit is checked for the parity (even or odd) specified by the O/E bit.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	O/E	0	R/W	<p>Parity Mode</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects either even or odd parity for use in parity addition and checking. The O/E bit setting is only valid when the PE bit is set to 1, enabling parity bit addition and checking. The O/E bit setting is invalid when parity addition and checking are disabled.</p> <p>0: Even parity*1 1: Odd parity*2</p> <p>Notes: 1. When even parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even.</p> <p>2. When odd parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.</p>
3	STOP	0	R/W	<p>Stop Bit Length</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects 1 or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit; if it is 0, it is treated as the start bit of the next transmit character.</p> <p>0: 1 stop bit*1 1: 2 stop bits*2</p> <p>Notes: 1. In transmission, a single logic-1 bit (stop bit) is added to the end of a transmit character before it is sent.</p> <p>2. In transmission, two logic-1 bits (stop bits) are added to the end of a transmit character before it is sent.</p>
2	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
1, 0	CKS[1:0]	00	R/W	<p>Clock Select</p> <p>These bits select the clock sources for the on-chip baud rate generator.</p> <p>00: MP<math>\phi</math> 01: MP<math>\phi</math>/4 10: MP<math>\phi</math>/16 11: MP<math>\phi</math>/64</p> <p>Note: MP<math>\phi</math>: MP clock</p>

### 41.3.6 Serial Control Register An (SCASCRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCASCR is a 16-bit readable/writable register that enables or disables SCIFA transfer operations and interrupt requests, and selects the clock source for transmission and reception.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDRQE	RDRQE	—	TENDE	TSIE	ERIE	BRIE	DRIE	TIE	RIE	TE	RE	—	—	—	CKE0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TDRQE	0	R/W	Transmit Data Transfer Request Enable Switches the transmit-FIFO-data-empty interrupt or DMA transfer request when TIE = 1 and the transmit-FIFO-data-empty occurs. 0: Interrupt request to CPU is issued 1: Transmit data transfer request to DMAC is issued
14	RDRQE	0	R/W	Receive Data Transfer Request Enable Switches the receive-FIFO-data-full interrupt or DMA transfer request when RIE = 1 and the receive FIFO data full occurs. 0: Interrupt request to CPU is issued 1: Receive data transfer request to DMAC is issued
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	TENDE	0	R/W	Transmit End Interrupt Enable Enables or disables generation of a transmit-end interrupt when the TEND flag in SCASSR is set to 1. 0: Transmit-end interrupt disabled 1: Transmit-end interrupt enabled
11	TSIE	0	R/W	Transmit Data Stop Interrupt Enable Enables or disables generation of a transmit-data-stop interrupt when the TSE bit in SCAFCR is enabled and the TSF flag in SCASSR is set to 1. 0: Transmit-data-stop interrupt disabled* 1: Transmit-data-stop interrupt enabled Note: * The TDI interrupt request is cleared by clearing the TSF flag to 0 after reading 1 from it or clearing the TSIE bit to 0.
10	ERIE	0	R/W	Receive Error Interrupt Enable Enables or disables generation of a receive-error (framing or parity error) interrupt when the ER flag in SCASSR is set to 1. 0: Receive-error interrupt disabled* 1: Receive-error interrupt enabled Note: * The ERI interrupt request is cleared by clearing the ER flag to 0 after reading 1 from it or clearing the ERIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
9	BRIE	0	R/W	<p>Break Interrupt Enable</p> <p>Enables or disables generation of a break-receive interrupt when the BRK flag in SCASSR is set to 1.</p> <p>0: Break-receive interrupt disabled*</p> <p>1: Break-receive interrupt enabled</p> <p>Note: * The BRI interrupt request is cleared by clearing the BRK flag to 0 after reading 1 from it or clearing the BRIE bit to 0.</p>
8	DRIE	0	R/W	<p>Receive Data Ready Interrupt Enable</p> <p>Enables or disables generation of a receive-data-ready interrupt when the DR flag in SCASSR is set to 1.</p> <p>0: Receive-data-ready interrupt disabled*</p> <p>1: Receive-data-ready interrupt enabled</p> <p>Note: * The DRI interrupt request is cleared by clearing the DR flag to 0 after reading 1 from it or clearing the DRIE bit to 0.</p>
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>Enables or disables generation of a transmit-FIFO-data-empty interrupt request when the TDFE flag in SCASSR is set to 1.</p> <p>0: Transmit-FIFO-data-empty interrupt request disabled*</p> <p>1: Transmit-FIFO-data-empty interrupt request enabled</p> <p>Note: * Interrupt requests can be cleared by writing transmit data exceeding the transmit trigger set number to SCAFTDR, reading 1 from the TDFE flag, then clearing it to 0, or by clearing the TIE bit to 0.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>Enables or disables generation of a receive-FIFO-data-full interrupt request when the RDF flag in SCASSR is set to 1.</p> <p>0: Receive-FIFO-data-full interrupt request disabled*</p> <p>1: Receive-FIFO-data-full interrupt request enabled</p> <p>Note: * Interrupt requests can be cleared by reading 1 from the RDF flag, then clearing the flag to 0, or by clearing the RIE bit to 0.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>Enables or disables the start of serial transmission by SCIFA.</p> <p>0: Transmission disabled</p> <p>1: Transmission enabled*</p> <p>Note: * SCASMR and SCAFCR settings must be made, the transmit format decided, and the transmit FIFO reset, before the TE bit is set to 1.</p>
4	RE	0	R/W	<p>Receive Enable</p> <p>Enables or disables the start of serial reception by SCIFA.</p> <p>0: Reception disabled*<sup>1</sup></p> <p>1: Reception enabled*<sup>2</sup></p> <p>Notes: 1. Clearing the RE bit to 0 does not affect the DR, ER, BRK, RDF, FER, PER, and ORER flags, which retain their state.</p> <p>2. Serial mode register (SCASMR) and FIFO control register (SACFCR) settings must be made, the receive format decided, and the receive FIFO reset, before the RE bit is set to 1.</p>
3 to 1	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
0	CKE0	0	R/W	<p>Clock Enable</p> <p>Enables or disables the clock output from the SCK pin. The CKE0 bit must be set before determining the SCIFA operating mode with SCASMR.</p> <p>0: SCK pin disabled SCK pin state is Hi-Z.*<sup>1</sup></p> <p>1: Clock output from SCK*<sup>2</sup></p> <p>Notes: 1. Even if this bit is 0, the SCK pin outputs data specified by SCAPDRn[2].SCKD, if SCAPCRn[2].SCKC is 1.</p> <p>2. In clocked synchronous mode, outputs a clock with the same frequency as the bit rate.</p>

### 41.3.7 FIFO Error Count Register An (SCAFERn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCAFER is a 16-bit read-only register that indicates the number of receive errors (framing errors and parity errors)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	—	—	PER[5:0]					—	—	FER[5:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
13 to 8	PER[5:0]	000000	R	<p>Parity Error Count</p> <p>These bits indicate the number of data in which parity errors are generated, in receive data stored in SCAFRDR.</p> <p>After the ER bit in SCASSR is set, the value of bits PER5 to PER0 indicates the number of data in which parity errors are generated.</p> <p>When all 64 bytes of receive data in SCAFRDR have parity errors, these bits indicate 0.</p>
7, 6	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
5 to 0	FER[5:0]	000000	R	<p>Framing Error Count</p> <p>These bits indicate the number of data in which framing errors are generated, in receive data stored in SCAFRDR.</p> <p>After the ER bit in SCASSR is set, the value of bits FER5 to FER0 indicates the number of data in which framing errors are generated.</p> <p>When all 64 bytes of receive data in SCAFRDR have framing errors, these bits indicate 0.</p>

### 41.3.8 Serial Status Register An (SCASSRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCASSR is a 16-bit readable/writable register that indicates the SCIFA status.

However, 1 cannot be written to the ORER, TSF, ER, TDFE, BRK, RDF, and DR flags. Also note that in order to clear these flags to 0, they must be read as 1 beforehand. The TEND, FER, and PER flags are read-only flags and cannot be modified.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ORER	TSF	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ORER	0	R/(W)*	<p>Overrun Error</p> <p>Indicates that an overrun error occurred during reception.</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>0: Reception in progress, or reception has ended normally*<sup>1</sup></p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to ORER after reading ORER = 1</li> </ul> <p>1: An overrun error occurred during reception*<sup>2</sup></p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When serial reception is completed while receive FIFO is full</li> </ul> <p>Notes: 1. The ORER flag is not affected and retains its previous state when the RE bit in SCASCR is cleared to 0.</p> <p>2. The receive data prior to the overrun error is retained in SCAFRDR, and the data received subsequently is lost. Serial reception cannot be continued while the ORER flag is set to 1.</p>
8	TSF	0	R/(W)*	<p>Transmit Data Stop</p> <p>Indicates that the number of transmit data matches the value of SCATDSR.</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>0: Number of transmit data does not match value of SCATDSR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to TSF after reading TSF = 1</li> </ul> <p>1: Number of transmit data matches value of SCATDSR</p>

Bit	Bit Name	Initial Value	R/W	Description
7	ER	0	R/(W)*	<p>Receive Error</p> <p>Indicates that a framing error or parity error occurred during reception.*<sup>1</sup></p> <p>This bit setting is valid only in asynchronous mode.</p> <p>0: No framing error or parity error occurred during reception [Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to ER after reading ER = 1</li> </ul> <p>1: A framing error or parity error occurred during reception [Setting conditions]</p> <ul style="list-style-type: none"> <li>When SCIFA checks whether the stop bit at the end of the receive data is 1 when reception ends, and the stop bit is 0*<sup>2</sup></li> <li>When, in reception, the number of logic-1 bits in the receive data and in the parity bit does not match the parity setting (even or odd) specified by the O/E bit in SCASMR</li> </ul> <p>Notes: 1. The ER flag is not affected and retains its previous state when the RE bit in SCASCR is cleared to 0. When a receive error occurs, the receive data is still transferred to SCAFRDR, and reception continues. The FER and PER bits in SCASSR can be used to determine whether there is a receive error in the data read from SCAFRDR.</p> <p>2. When the stop length is 2 bits, only the first stop bit is checked for a value of 1; the second stop bit is not checked.</p>
6	TEND	1	R	<p>Transmit End</p> <p>Indicates that there is no valid data in SCAFTDR when the last bit of the transmit character is sent, and transmission has been ended.</p> <p>0: Transmission is in progress [Clearing condition]</p> <ul style="list-style-type: none"> <li>When data is written to SCAFTDR</li> </ul> <p>1: Transmission has been ended [Setting condition]</p> <ul style="list-style-type: none"> <li>When there is no transmit data in SCAFTDR on transmission of a 1-byte serial transmit character</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
5	TDFE	1	R/(W)*	<p>Transmit FIFO Data Empty</p> <p>Indicates that data has been transferred from SCAFTDR to SCATSR, the number of data bytes in SCAFTDR has fallen to or below the transmit trigger data number set by bits TTRG[1:0] in SCAFCR, and new transmit data can be written to SCAFTDR.</p> <p>0: A number of transmit data bytes exceeding the transmit trigger set number have been written to SCAFTDR</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When transmit data exceeding the transmit trigger set number is written to SCAFTDR, and 0 is written to TDFE after reading TDFE = 1</li> </ul> <p>1: The number of transmit data bytes in SCAFTDR does not exceed the transmit trigger set number</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When the number of SCAFTDR transmit data bytes falls to or below the transmit trigger set number as the result of a transmit operation*</li> </ul> <p>Note: * As SCAFTDR is a 64-byte FIFO register, the maximum number of bytes that can be written when TDFE = 1 is 64 – (transmit trigger set number). Data written in excess of this will be ignored. The number of data bytes in SCAFTDR is indicated by SCAFRDR.</p>
4	BRK	0	R/(W)*	<p>Break Detect</p> <p>Indicates that a receive data break signal has been detected. This bit setting is valid only in asynchronous mode.</p> <p>0: A break signal has not been received</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to BRK after reading BRK = 1</li> </ul> <p>1: A break signal has been received*</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When data with a framing error is received, followed by the space 0 level (low level) for at least one frame length</li> </ul> <p>Note: * When a break is detected, the receive data (H'00) following detection is not transferred to SCAFRDR. When the break ends and the receive signal returns to mark 1, receive data transfer is resumed.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	FER	0	R	<p>Framing Error</p> <p>Indicates a framing error in the data read from SCAFRDR. This bit setting is valid only in asynchronous mode.</p> <p>0: There is no framing error in the receive data read from SCAFRDR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When there is no framing error in SCAFRDR read data</li> </ul> <p>1: There is a framing error in the receive data read from SCAFRDR</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When there is a framing error in SCAFRDR read data</li> </ul>
2	PER	0	R	<p>Parity Error</p> <p>Indicates a parity error in the data read from SCAFRDR. This bit setting is valid only in asynchronous mode.</p> <p>0: There is no parity error in the receive data read from SCAFRDR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When there is no parity error in SCAFRDR read data</li> </ul> <p>1: There is a parity error in the receive data read from SCAFRDR</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When there is a parity error in SCAFRDR read data</li> </ul>
1	RDF	0	R/(W)*	<p>Receive FIFO Data Full</p> <p>Indicates that the received data has been transferred from SCARSR to SCAFRDR, and the number of receive data bytes in SCAFRDR is equal to or greater than the receive trigger number set by bits RTRG[1:0] in SCAFCR.</p> <p>0: The number of receive data bytes in SCAFRDR is less than the receive trigger set number</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When SCAFRDR is read until the number of receive data bytes in SCAFRDR falls below the receive trigger set number, and 0 is written to RDF after reading RDF = 1</li> </ul> <p>1: The number of receive data bytes in SCAFRDR is equal to or greater than the receive trigger set number</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When SCAFRDR contains at least the receive trigger set number of receive data bytes*</li> </ul> <p>Note: * SCAFRDR is a 64-byte FIFO register. When RDF = 1, at least the receive trigger set number of data bytes can be read. If data is read when SCAFRDR is empty, an undefined value will be returned. The number of receive data bytes in SCAFRDR is indicated by the lower bits of SCAFRDR.</p>

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	<p>Receive Data Ready</p> <p>Indicates that there are data bytes fewer than the receive trigger set number in SCAFRDR, and no further data will arrive at least 15 etu after the stop bit of the last data received.</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>0: Reception is in progress or has ended normally and there is no receive data left in SCAFRDR</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Power-on reset or manual reset</li> <li>• When all the receive data in SCAFRDR has been read, and 0 is written to DR after reading DR = 1</li> </ul> <p>1: No further receive data has arrived</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• When SCAFRDR contains data bytes fewer than the receive trigger set number, and no further data will arrive at least 15 etu after the stop bit of the last data received*</li> </ul> <p>Note: * Corresponds to 1.5 frame time in 8-bit one-stop-bit format. etu: Elementary time unit (time for transfer of 1 bit)</p>

Note: \* Only 0 can be written for clearing the flags.

### 41.3.9 Bit Rate Register An (SCABRRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCABRR is an 8-bit readable/writable register that sets the serial transfer bit rate in accordance with the baud rate generator operating clock selected by bits CKS[1:0] in SCASMR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCBRD[7:0]	H'FF	R/W	Bit Rate $0 \leq \text{SCBRD} \leq 255$ (asynchronous mode) $1 \leq \text{SCBRD} \leq 255$ (clocked synchronous mode)

The SCABRR setting is found by using the following equations.

#### (1) Asynchronous Mode:

When the sampling rate is 1/16,

$$N = \{ \text{MP}\phi / (16 \times 2^{2n} \times B) \} \times 10^6 - 1$$

When the sampling rate is 1/5,

$$N = \{ \text{MP}\phi / (5 \times 2^{2n} \times B) \} \times 10^6 - 1$$

When the sampling rate is 1/11,

$$N = \{ \text{MP}\phi / (11 \times 2^{2n} \times B) \} \times 10^6 - 1$$

When the sampling rate is 1/13,

$$N = \{ \text{MP}\phi / (13 \times 2^{2n} \times B) \} \times 10^6 - 1$$

When the sampling rate is 1/27,

$$N = \{ \text{MP}\phi / (27 \times 2^{2n} \times B) \} \times 10^6 - 1$$

#### (2) Clocked Synchronous Mode:

$$N = \{ \text{MP}\phi / (2 \times 2^{2n} \times B) \} \times 10^6 - 1$$

Where B: Bit rate (bits/s)

N: SCABRR setting for baud rate generator  
 Asynchronous mode ( $0 \leq N \leq 255$ )  
 Clocked synchronous mode ( $1 \leq N \leq 255$ )

MP $\phi$ : Mp clock frequency (MHz)

n: Baud rate generator input clock ( $n = 0$  to 3)  
 (See the table below for the relation between n and the clock.)

**Table 41.4 SCASMR Settings**

n	Clock	SCASMR Setting
		CKS[1:0]
0	MP $\phi$	B'00
1	MP $\phi$ /4	B'01
2	MP $\phi$ /16	B'10
3	MP $\phi$ /64	B'11

The bit rate error in asynchronous mode is found by using the following equations.

When the sampling rate is 1/16,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 16 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/5,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 5 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/11,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 11 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/13,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 13 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/27,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 27 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

### 41.3.10 FIFO Control Register An (SCAFCRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCAFCR is a 16-bit readable/writable register that clears all data and sets the trigger data number for the transmit and receive FIFO registers, and also contains a loopback test enable bit.

[RZ/G1H]

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSD	1	R/W	Specifies data output to the RTS# pin. [RZ/G1H] 0: Outputs 0. 1: Outputs 1.
	—	1	R	Reserved [RZ/G1M/N/E] This bit is always read as 1. The write value should always be 1.
3	CTSD	Undefined	R	Specifies the CTS# pin level. [RZ/G1H] 0: CTS# pin level is 0. 1: CTS# pin level is 1. This bit is valid only when SCAFCRn[3].MCE is 1, or SCAPCRn[3].CTSC is 1.
	—	1	R	Reserved [RZ/G1M/N/E] This bit is always read as 1. The write value should always be 1.
2	SCKD	0	R/W	Specifies data output to the SCK pin. 0: Outputs 0. 1: Outputs 1.

<b>Bit</b>	<b>Bit Name</b>	<b>Initial Value</b>	<b>R/W</b>	<b>Description</b>
1	RXDD	Undefined	R	Specifies the RXD pin level. 0: RXD pin level is 0. 1: RXD pin level is 1.
0	TXDD	0	R/W	Specifies data output to the TXD pin. 0: Outputs 0. 1: Outputs 1.

## 41.4 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 41.4.1 Overview

SCIFA supports serial communications in asynchronous mode, in which synchronization is achieved character by character, and in clocked synchronous mode, in which synchronization is achieved with clock pulses. 64-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling high-speed continuous communications.

### 41.4.2 Asynchronous Mode

In the asynchronous mode, the transfer format is selected by the setting in SCASMR as shown in Table 41.5. Features in this mode are as follows.

- Data length: 7 or 8 bits
- The addition of parity (even, odd or none) and the choice of stop-bit length (1 or 2 bits), along with the data length, determine the transfer format and character length.
- Receive error detection: Framing, parity, and overrun errors, receive-FIFO-data-full, receive-data-ready, and breaks.
- Independent indications of the number of data stored in the registers of transmit and receive FIFOs.
- Clock source: Internal clock signal generated by the baud-rate generator.

**Table 41.5 SCASMR Settings for Serial Transfer Format Selection**

SCASMR Settings				Mode	SCIFA Transfer Format		
Bit 7: C/A#	Bit 6: CHR	Bit 5: PE	Bit 3: STOP		Data Length	Parity Bit	Stop Bit Length
0	0	0	0	Asynchronous mode	8-bit data	No	1 bit
			1				2 bits
		1	0			Yes	1 bit
			1			2 bits	
	1	0	0		7-bit data	No	1 bit
			1				2 bits
		1	0			Yes	1 bit
			1			2 bits	
1	*	*	*	Clocked synchronous mode	8-bit data	No	No

Note: \* Don't care.

### 41.4.3 Serial Operation in Asynchronous Mode

#### (1) Data Transfer Format

Table 41.6 shows the transfer formats that can be used in asynchronous mode. Any of eight transfer formats can be selected according to the SCASMR settings.

**Table 41.6 Serial Transfer Formats**

SCASMR Settings			Serial Transfer Format and Frame Length												
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	S	8-bit data							STOP				
		1	S	8-bit data							STOP	STOP			
	1	0	S	8-bit data							P	STOP			
		1	S	8-bit data							P	STOP	STOP		
1	0	0	S	7-bit data						STOP					
		1	S	7-bit data						STOP	STOP				
	1	0	S	7-bit data						P	STOP				
		1	S	7-bit data						P	STOP	STOP			

[Legend]

S: Start bit

STOP: Stop bit

P: Parity bit

#### (2) Clock

An internal clock signal generated by the on-chip baud rate generator provides the transfer clock for SCIFA.

**(3) Data Transfer Operations:**

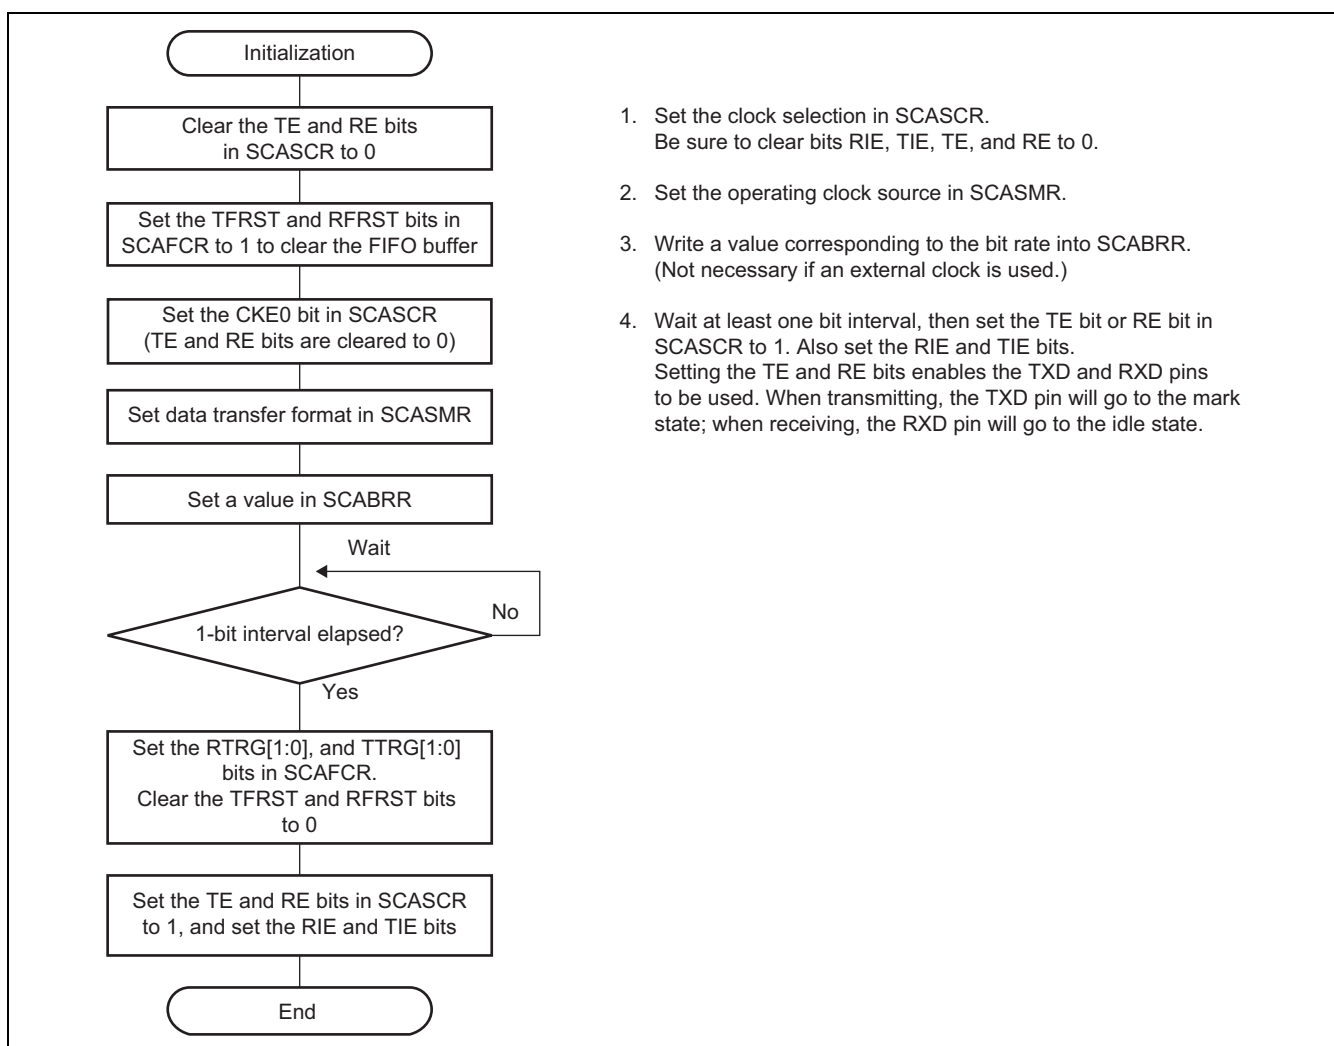

1. SCIFA initialization

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCASCR to 0, then initialize SCIFA as described below.

When the transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCATSR is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCASSR, SCAFTDR, or SCAFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCASSR has been set to 1. Clearing to 0 can also be performed during transmission, but the data lines that transmit the data will go to the high-impedance state after the clearance.

Before setting TE to 1 again to start transmission, the TFRST bit in SCAFCR should first be set to 1 to reset SCAFTDR.

Figure 41.2 is an example of flow for the SCIFA initialization.

1. Set the clock selection in SCASCR. Be sure to clear bits RIE, TIE, TE, and RE to 0.
2. Set the operating clock source in SCASMR.
3. Write a value corresponding to the bit rate into SCABRR. (Not necessary if an external clock is used.)
4. Wait at least one bit interval, then set the TE bit or RE bit in SCASCR to 1. Also set the RIE and TIE bits. Setting the TE and RE bits enables the TXD and RXD pins to be used. When transmitting, the TXD pin will go to the mark state; when receiving, the RXD pin will go to the idle state.

**Figure 41.2 Example of Flow for SCIFA Initialization**

## 2. Serial data transmission

Figure 41.3 is an example of flow for serial transmission.

Use the following procedure for serial data transmission after enabling SCIFA for transmission.

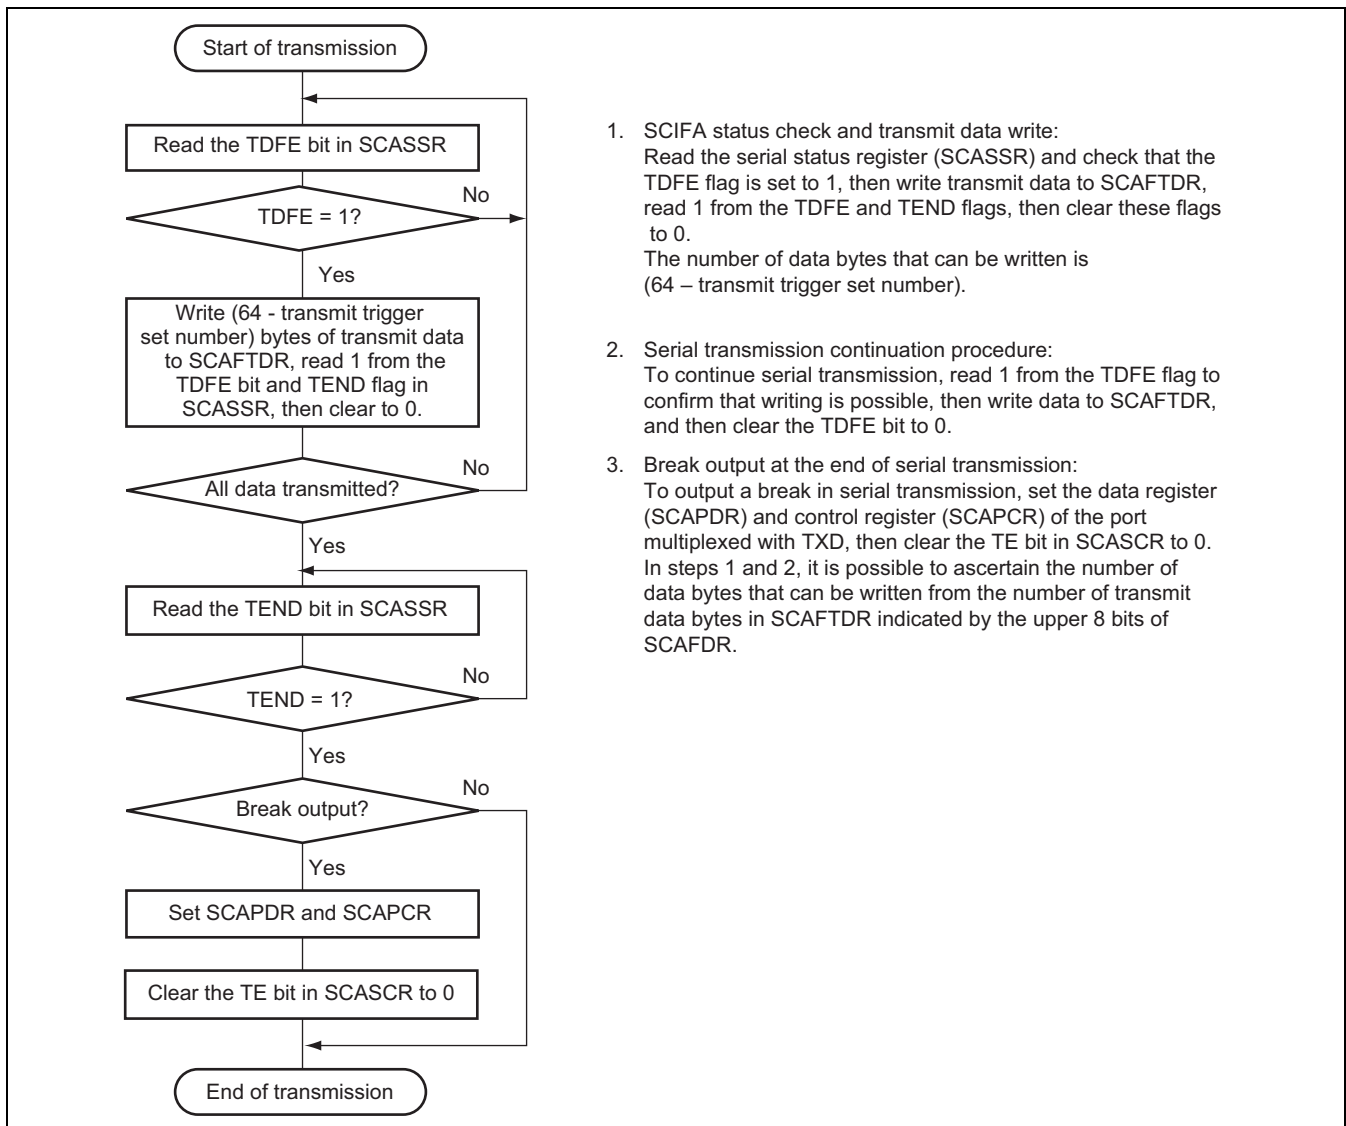

Figure 41.3 Example of Flow for Serial Transmission

In serial transmission, SCIFA operates as described below.

- A. When data is written into SCAFTDR, SCIFA transfers the data from SCAFTDR to SCATSR and starts transmitting. Confirm that the TDFE flag in SCASSR is set to 1 before writing transmit data to SCAFTDR. The number of data bytes that can be written is not less than (64 – transmit trigger set number).
- B. When data is transferred from SCAFTDR to SCATSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCAFTDR. When the number of transmit data bytes in SCAFTDR falls to or below the transmit trigger number set in SCAFCR, the TDFE flag is set. If the TIE bit in SCASCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

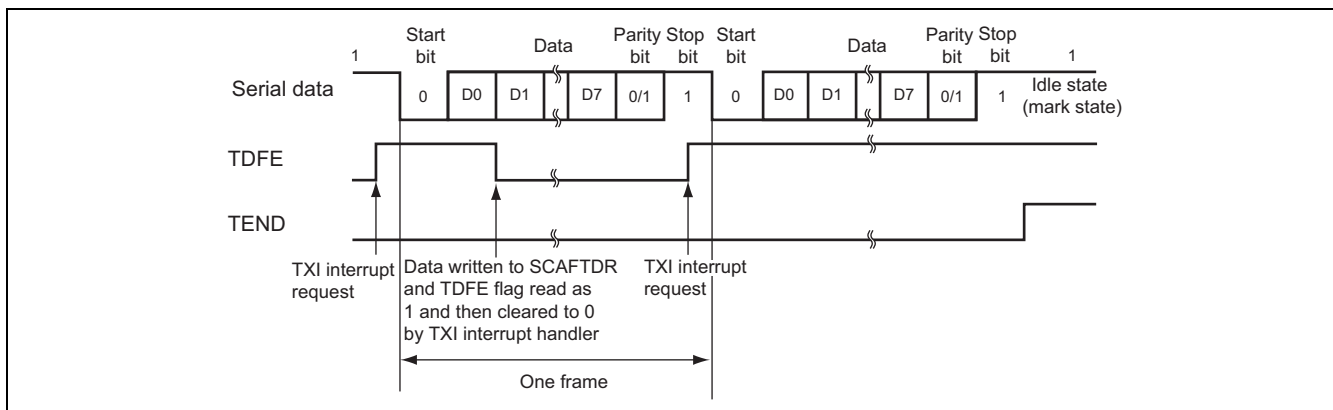

When the transmit data stop function is used and the number of data bytes set in SCATDSR is matched, transmit operation is stopped, and the TSF flag in SCASSR is set. If the TSIE bit in SCASCR is set to 1, a transmit-data-stop interrupt (TDI) request is generated. The vectors of TXI and TDI are the same.

The serial transmit data is sent from the TXD pin in the following order.

- a. Start bit: One logic-0 bit is output.
  - b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - c. Parity bit: One parity bit (even or odd parity) is output.
  - d. A format in which a parity bit is not output can also be selected.
  - e. Stop bit(s): One or two logic-1 bits (stop bits) are output.
  - f. Mark state: Output of 1 is continued until the start bit is sent to start the next transmission.
- C. SCIFA checks the SCAFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCAFTDR to SCATSR, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCASSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output.

Figure 41.4 is an example of the transmission in asynchronous mode.

**Figure 41.4 Example of Transmission  
(Example with 8-Bit Data, Parity, and One Stop Bit)**

- Transmit data stop function

When (value in SCATDSR + 1) is matched with the number of transmitted data bytes, this function stops the transmit operation. Interrupts can be generated and the DMAC can be activated by setting the TSIE bit (interrupt enable bit) to 1.

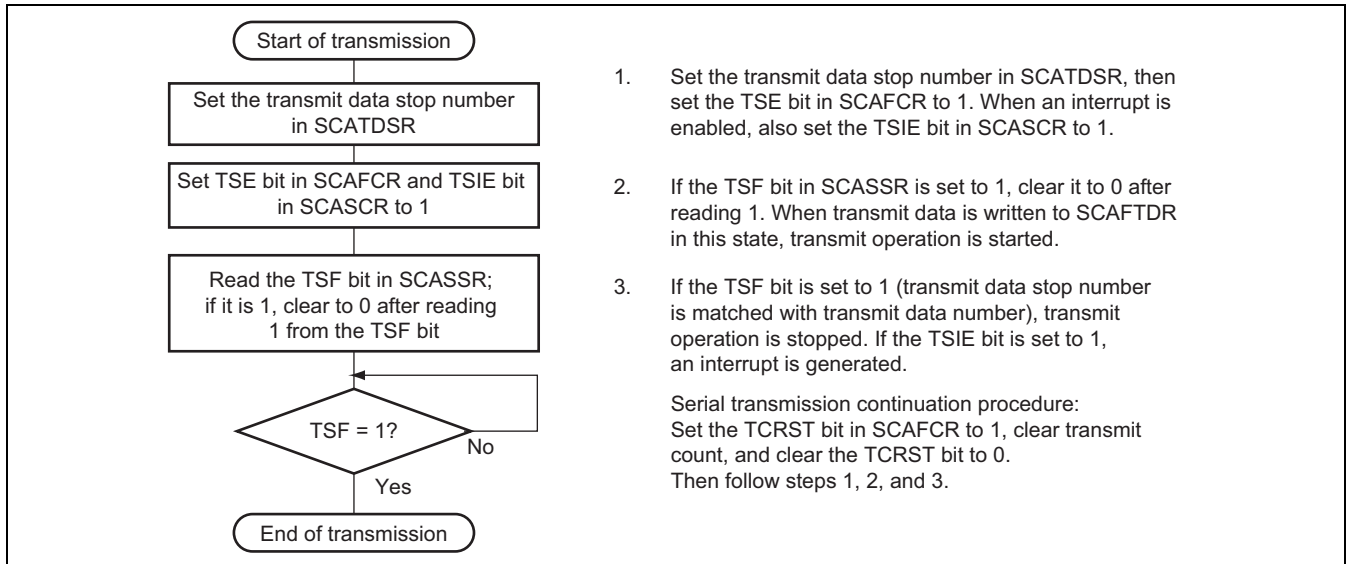

Figure 41.5 is an example of operation for the transmit data stop function.

**Figure 41.5 Example of Transmit Data Stop Function**

Figure 41.6 is a flow for the transmit data stop function.

Before using the transmit data stop function, set the TCRST bit in SCAFPCR to 1 to clear the transmit counter. After modifying SCASSR, always confirm that data has been updated.

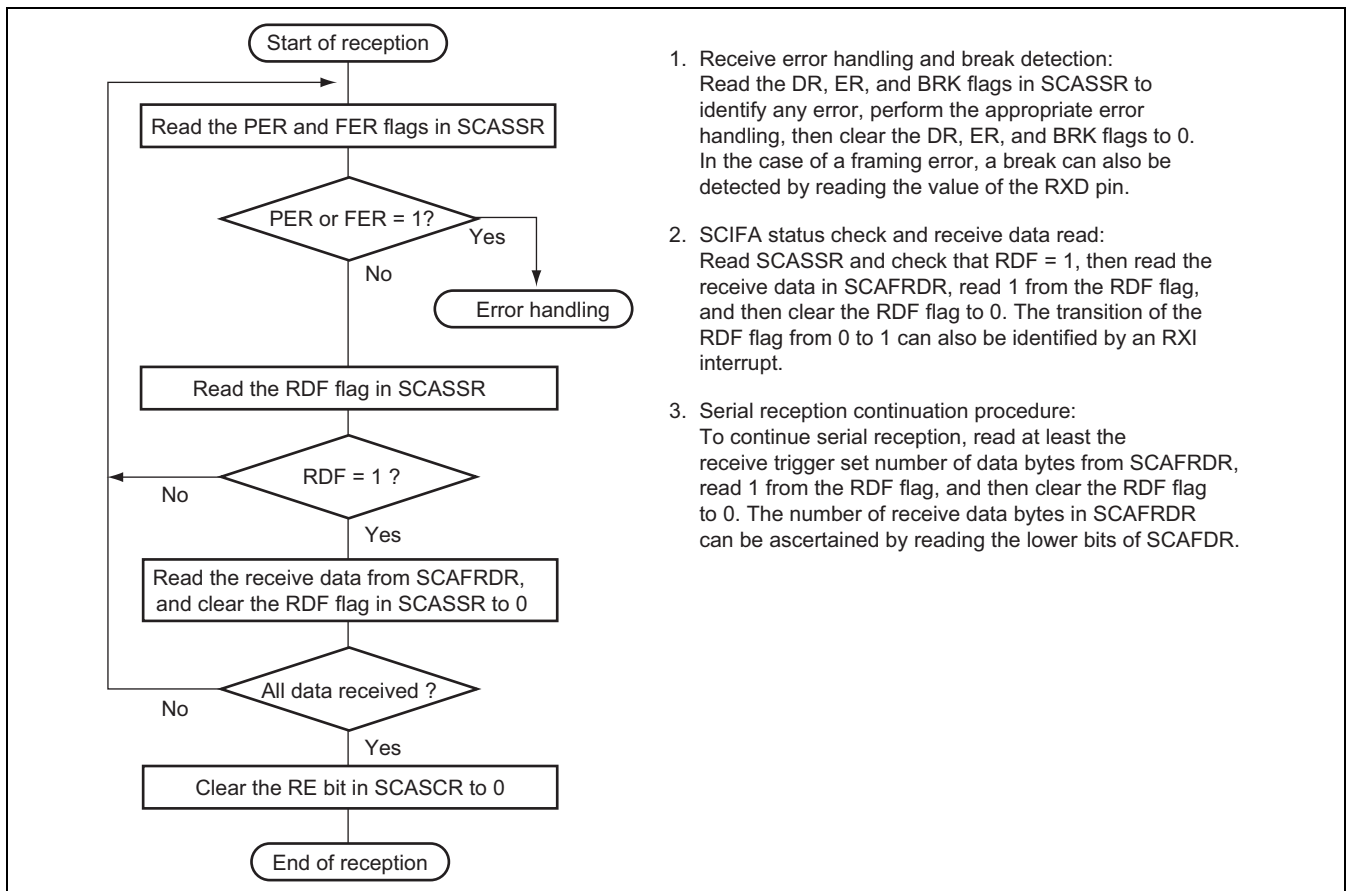

**Figure 41.6 Flow for Transmit Data Stop Function**

## 3. Serial data reception

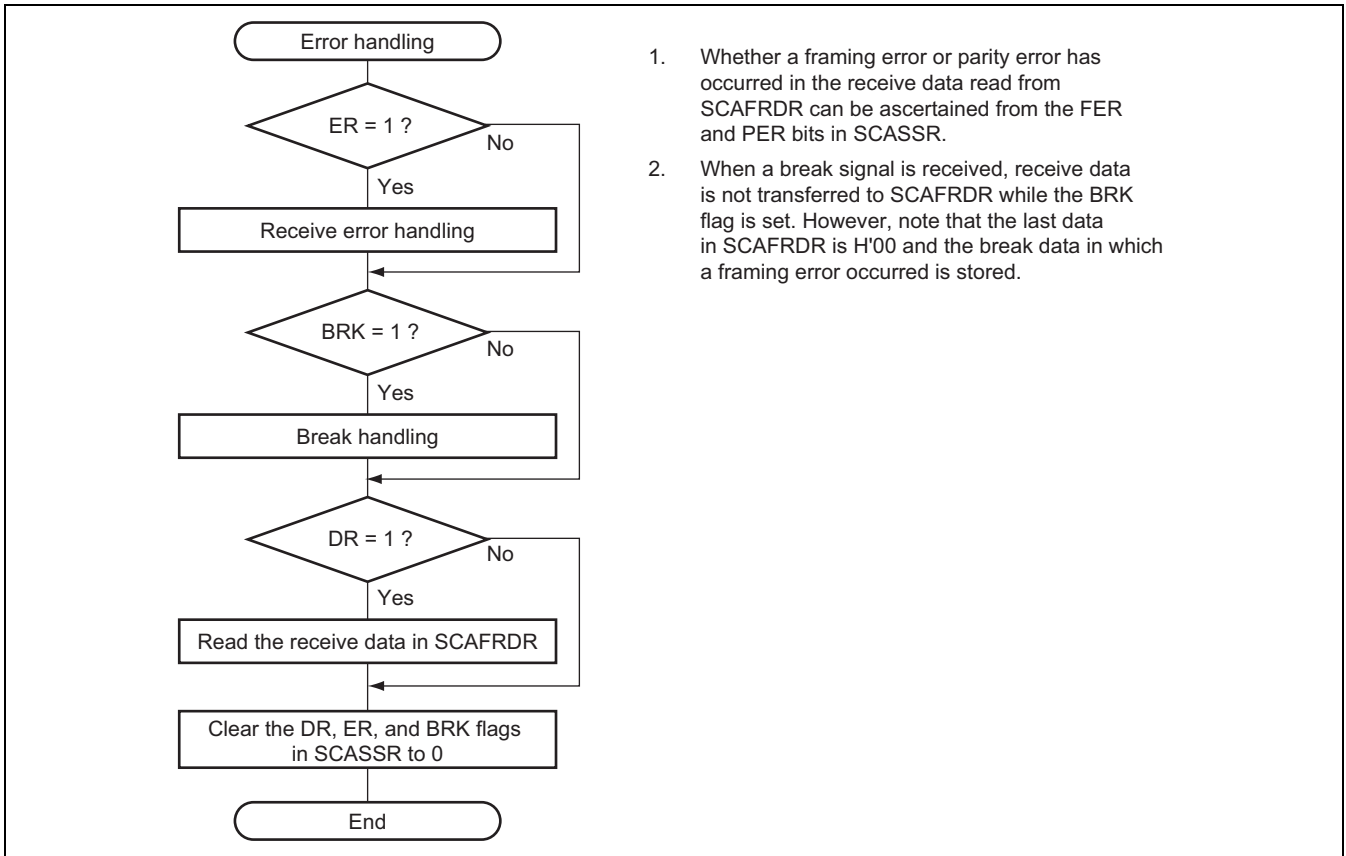

Figures 41.7 and 41.8 are examples of flows for serial reception.

Use the following procedure for serial data reception after enabling SCIFA for reception.

1. Receive error handling and break detection:  
Read the DR, ER, and BRK flags in SCASSR to identify any error, perform the appropriate error handling, then clear the DR, ER, and BRK flags to 0. In the case of a framing error, a break can also be detected by reading the value of the RXD pin.
2. SCIFA status check and receive data read:  
Read SCASSR and check that RDF = 1, then read the receive data in SCAFRDR, read 1 from the RDF flag, and then clear the RDF flag to 0. The transition of the RDF flag from 0 to 1 can also be identified by an RXI interrupt.
3. Serial reception continuation procedure:  
To continue serial reception, read at least the receive trigger set number of data bytes from SCAFRDR, read 1 from the RDF flag, and then clear the RDF flag to 0. The number of receive data bytes in SCAFRDR can be ascertained by reading the lower bits of SCAFDR.

**Figure 41.7 Example of Flow for Serial Reception (1)**

1. Whether a framing error or parity error has occurred in the receive data read from SCAFRDR can be ascertained from the FER and PER bits in SCASSR.
2. When a break signal is received, receive data is not transferred to SCAFRDR while the BRK flag is set. However, note that the last data in SCAFRDR is H'00 and the break data in which a framing error occurred is stored.

Figure 41.8 Example of Flow for Serial Reception (2)

In serial reception, SCIFA operates as described below.

- A. SCIFA monitors the communication line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
- B. The received data is stored in SCARSR in LSB-to-MSB order.
- C. The parity bit and stop bit are received.

After receiving these bits, SCIFA carries out the following checks.

- a. Stop bit check: SCIFA checks to see if the value in the stop bit position is 1. If the two-stop-bit setting has been made, only the value in the first stop-bit position is checked.
- b. SCIFA checks whether received data can be transferred from SCARSR to SCAFRDR.
- c. Break check: SCIFA checks to confirm that the BRK flag is 0, indicating that the break state has not been set.

If all the above checks are passed, the receive data is stored in SCAFRDR.

Note: Reception continues when a receive error (a framing error or parity error) occurs.

- D. If the RIE bit in SCASCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

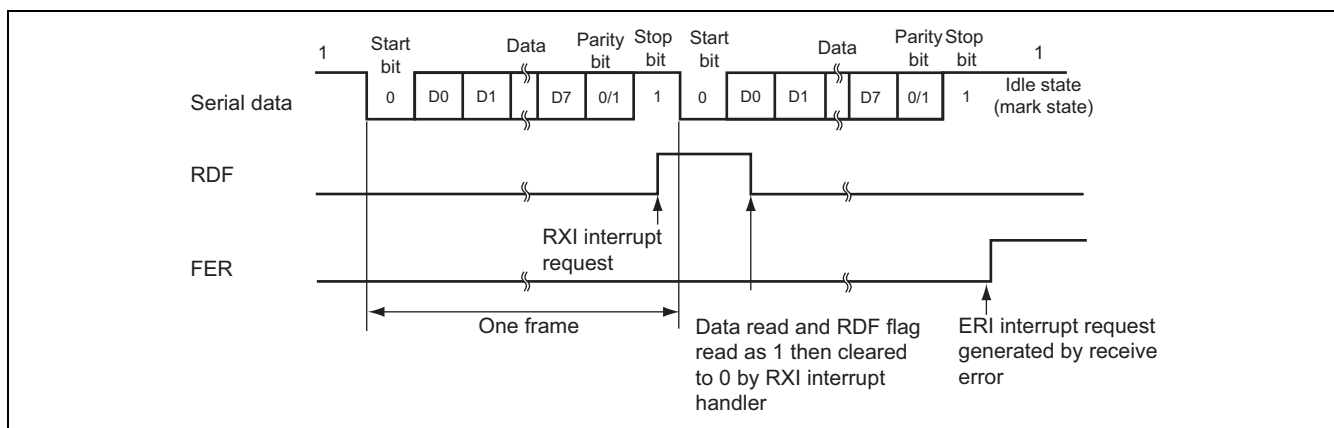

If the ERIE bit in SCASCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the BRIE bit in SCASCR is set to 1 when the BRK flag changes to 1, a break-receive interrupt (BRI) request is generated.

If the DRIE bit in SCASCR is set to 1 when the DR flag changes to 1, a receive-data-ready interrupt (DRI) request is generated.

The vectors of each interrupt source are the same.

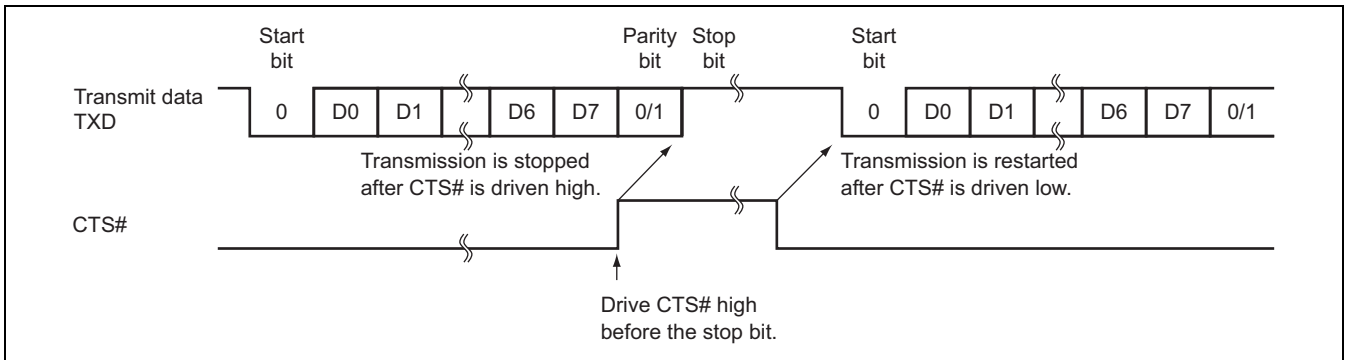

Figure 41.9 is an example of the reception in asynchronous mode.

**Figure 41.9 Example of SCIFA Receive Operation (Example with 8-Bit Data, Parity, One Stop Bit)**

SCIFA has a modem function that allows the stoppage and resumption of transmission according to the input value of CTS#. Setting CTS# to 1 places the transmission line in the mark state after transmission of the current frame. When CTS# is set to 0, the next frame for transmission is output, with a start bit as its leader.

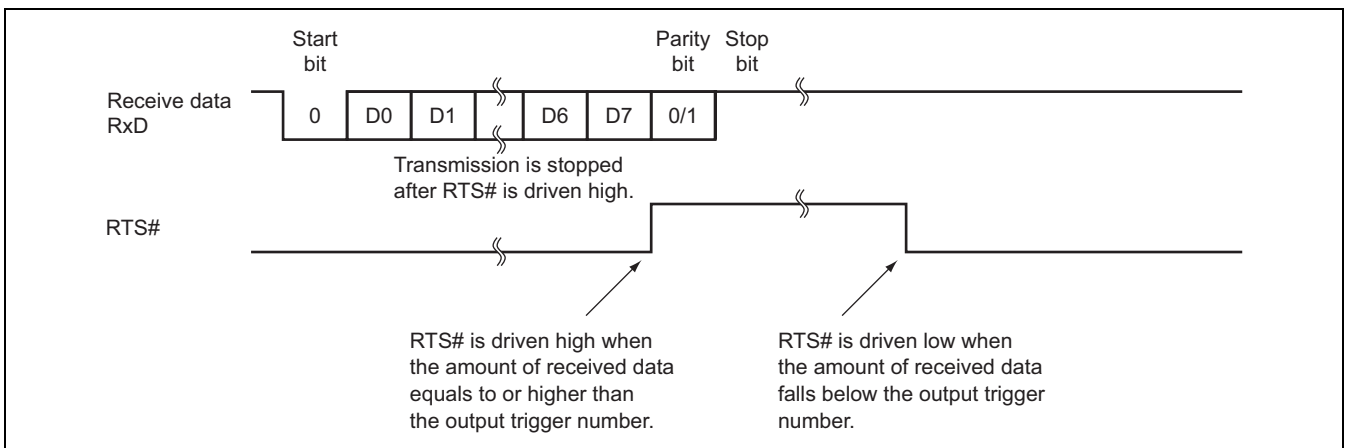

Figure 41.10 is an example of the operation of CTS# control.

**Figure 41.10 Example of CTS# Control Operation**

The RTS# signal is driven high when the modem function is in use and the received data stored in the receive FIFO register (SCAFRDR) equals or exceeds the number of the RTS# output triggers.

Figure 41.11 is an example of the operation for RTS# control.

**Figure 41.11 Example of RTS# Control Operation**

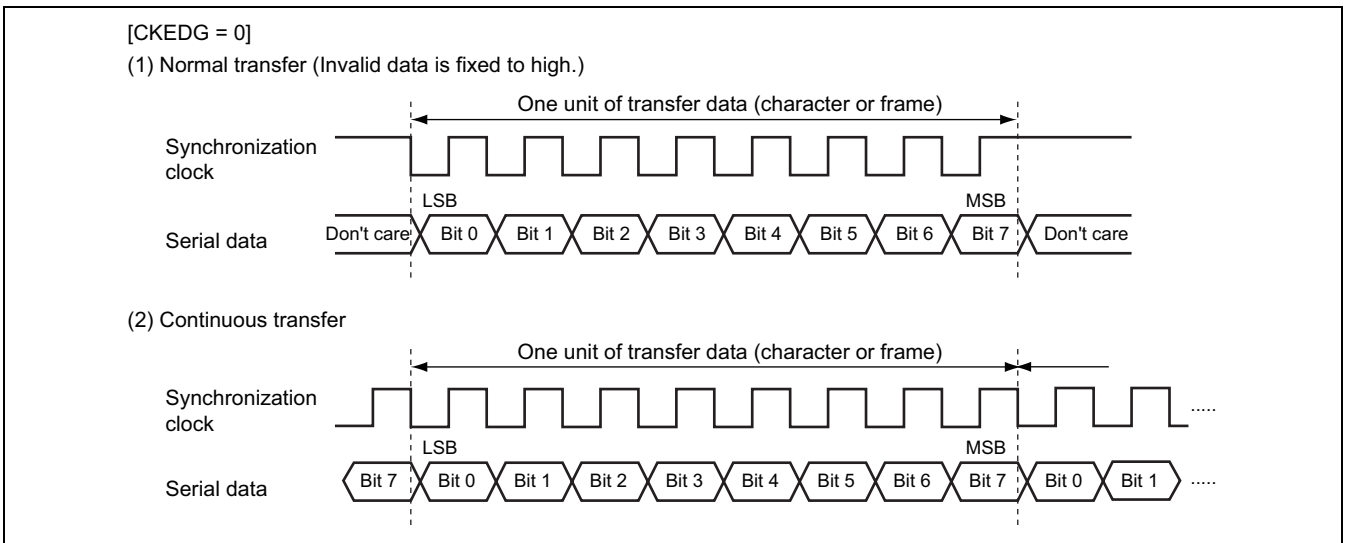

**41.4.4 Operation in Clocked Synchronous Mode**

Clocked synchronous mode, in which data is transmitted or received in synchronization with clock pulses, is suitable for fast serial communications.

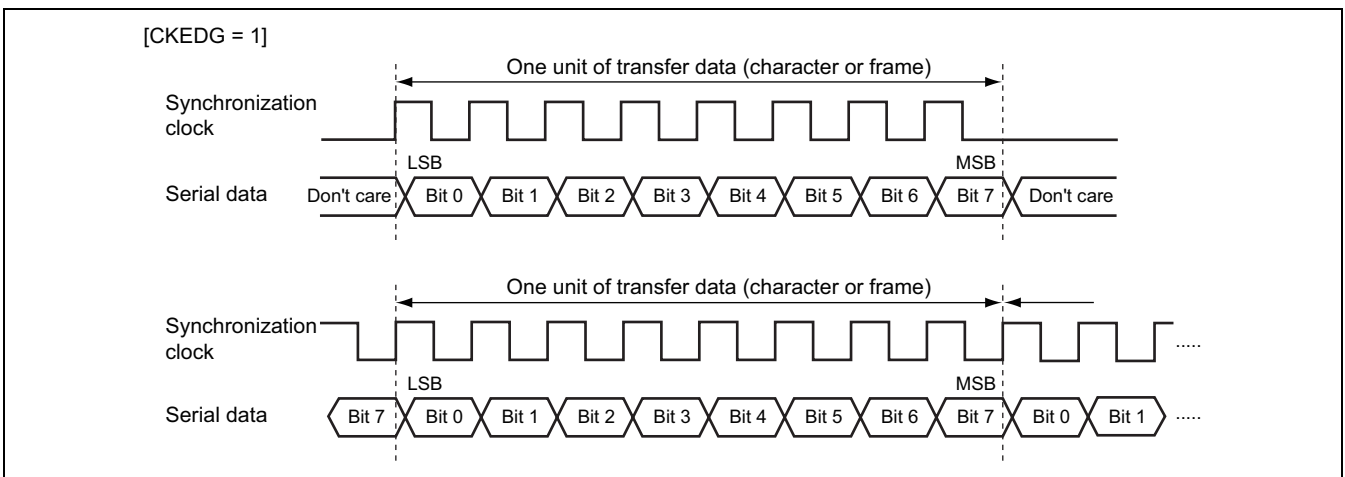

Since the transmitter and receiver are independent units in SCIFA, full-duplex communications can be achieved by sharing the clock. Both the transmitter and receiver have a 64-stage FIFO buffer structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Through the setting of the CKEDG bit, the format for clocked synchronous communications can be selected.

Figures 41.12 and 41.13 show the format for clocked synchronous communications.

**Figure 41.12 Data Format in Clocked Synchronous Communications (CKEDG = 0)**

**Figure 41.13 Data Format in Clocked Synchronous Communications (CKEDG = 1)**

In clocked synchronous serial communications, the data on the communications line is latched on one edge of the synchronization clock signal selected by the CKEDG bit and is output until the next edge. Accuracy of data is guaranteed on the next edge (i.e. that in the opposite direction to the latching edge).

In serial communications, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communications line remains in the state of the last bit.

Data is received on the opposite edge to that on which data is output.

### (1) Data Transfer Format

A fixed 8-bit data format is used. No parity bit can be added.

### (2) Clock

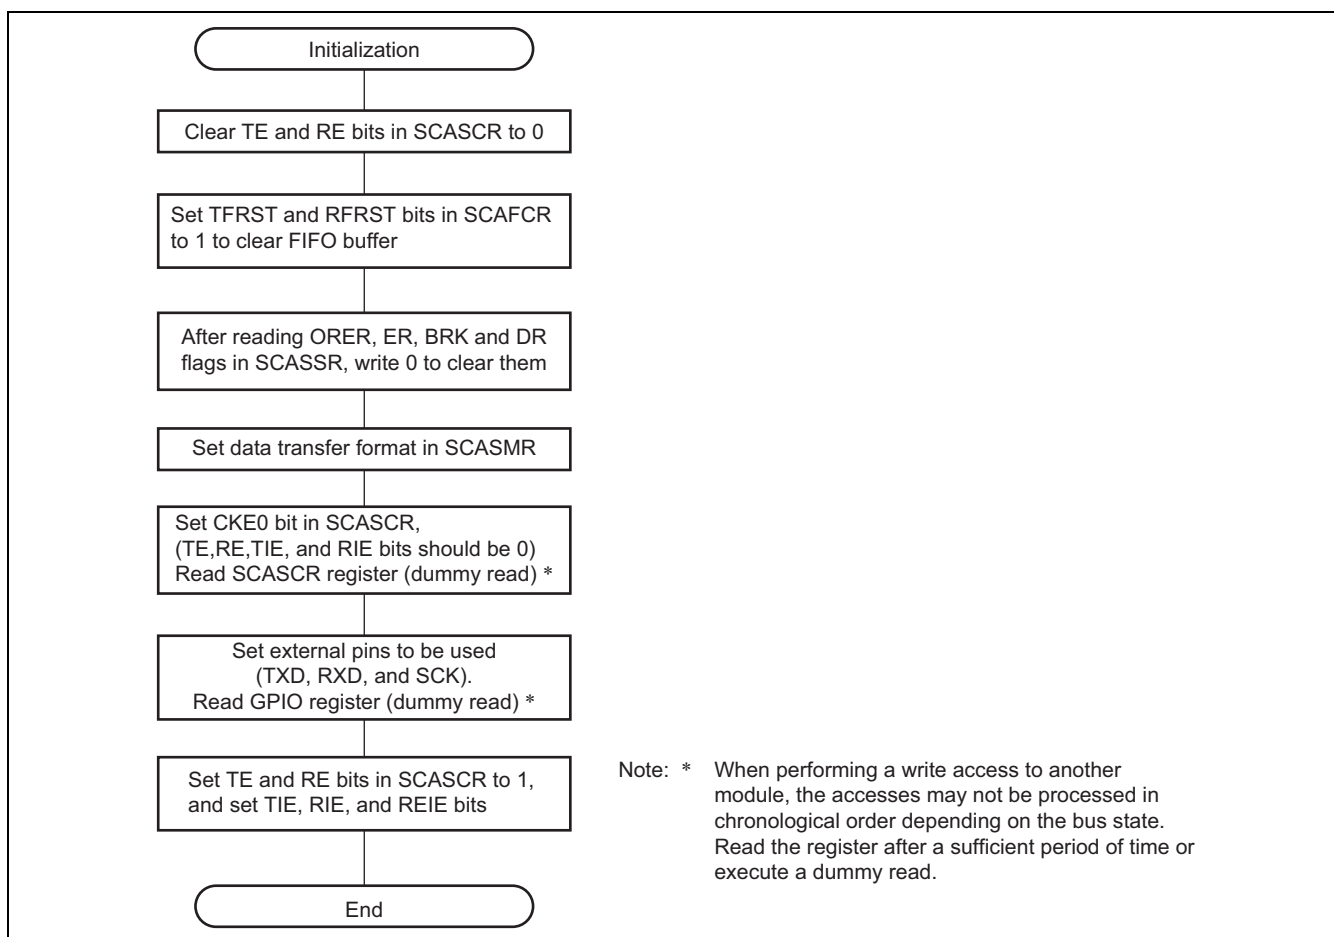

An internal clock signal generated by the on-chip baud rate generator provides the transfer clock for SCIFA. For details on SCIFA clock source selection, see Table 41.4.

### (3) SCIFA Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCASCR to 0, and then initialize SCIFA as described below.

When changing the operating mode or transfer format, etc., the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCATSR is initialized. Note that clearing the RE bit to 0 does not initialize the RDF, PER, FER, or ORER flag state or change the contents of SCAFRDR.

Figure 41.14 is an example of flow for the SCIFA initialization.

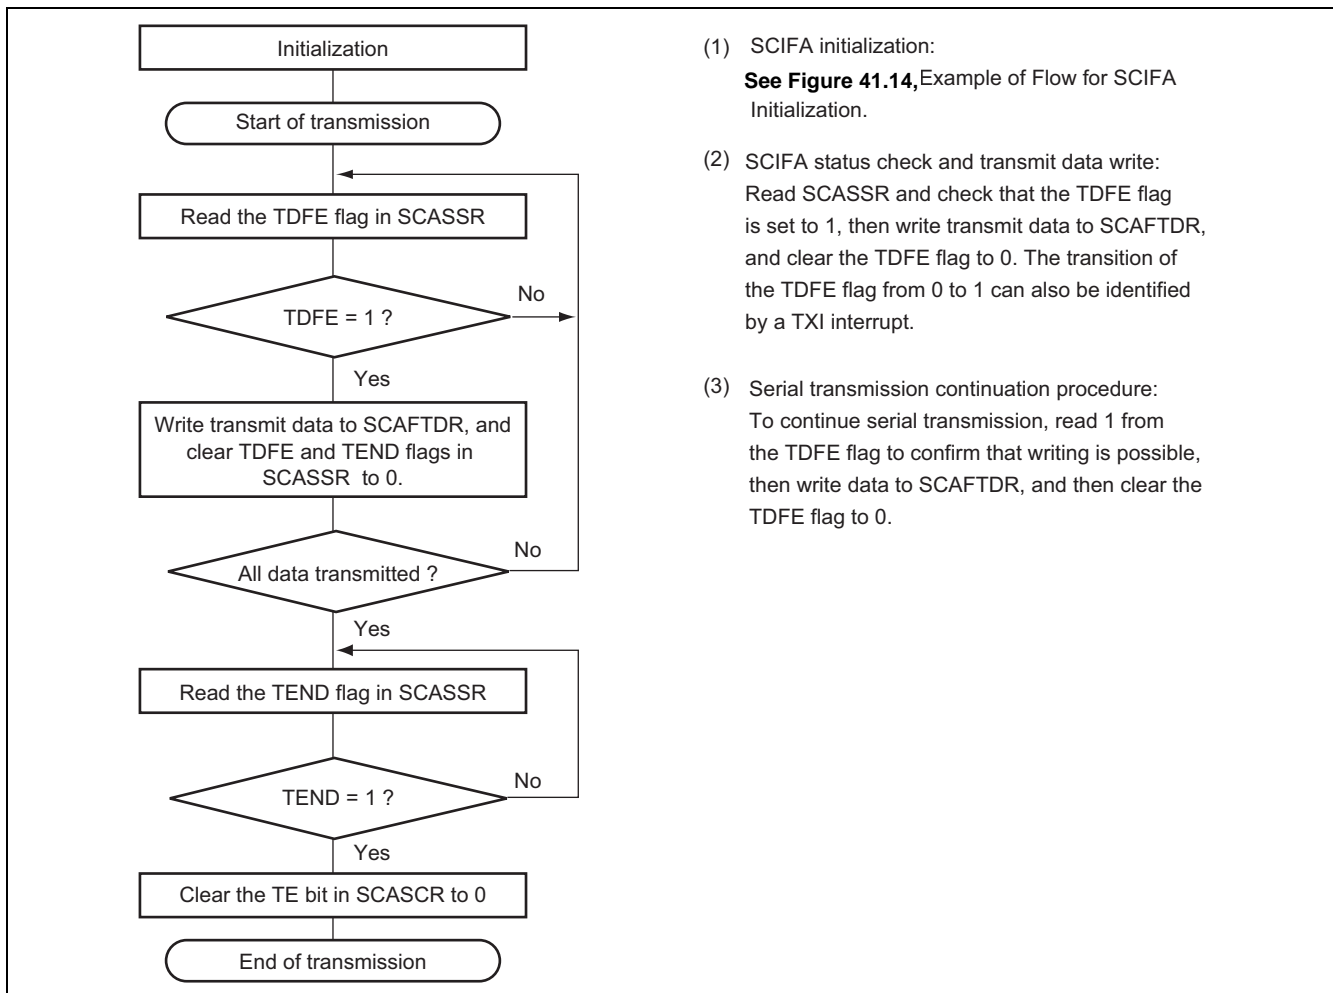

**Figure 41.14 Example of Flow for SCIFA Initialization**

**(4) Serial Data Transmission (Clocked Synchronous Mode)**

Figure 41.15 is an example of flow for serial transmission.

Use the following procedure for serial data transmission after enabling SCIFA for transmission.

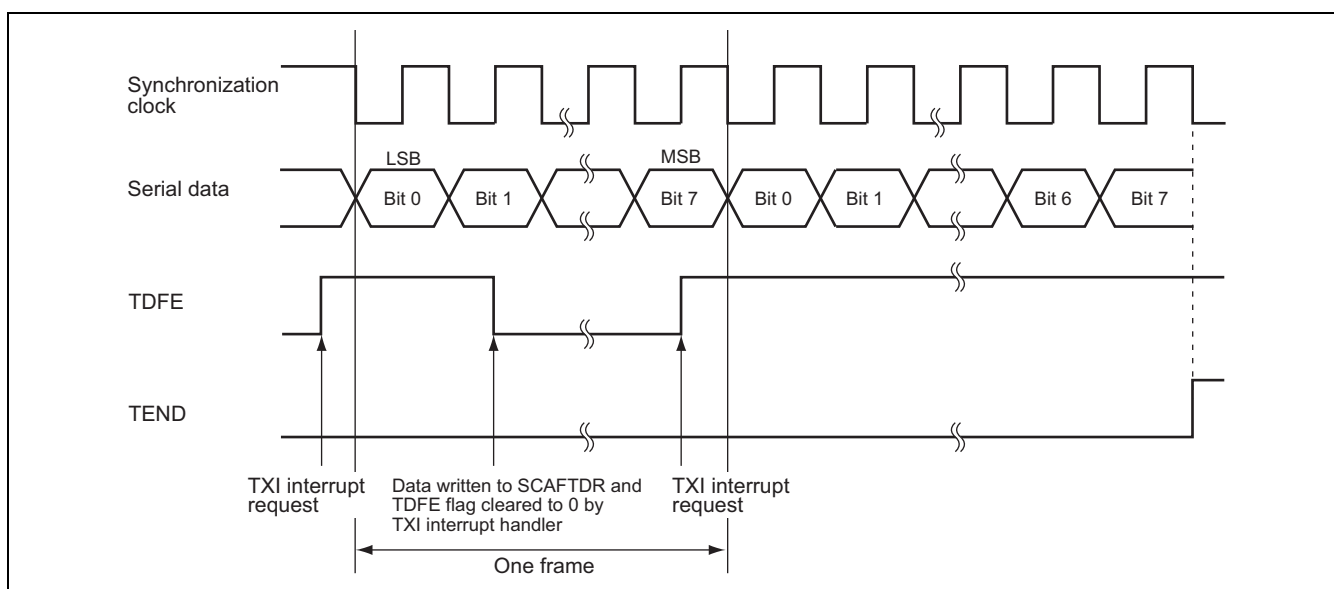

- (1) SCIFA initialization:  
**See Figure 41.14**, Example of Flow for SCIFA Initialization.
- (2) SCIFA status check and transmit data write:  
 Read SCASSR and check that the TDFE flag is set to 1, then write transmit data to SCAFTDR, and clear the TDFE flag to 0. The transition of the TDFE flag from 0 to 1 can also be identified by a TXI interrupt.
- (3) Serial transmission continuation procedure:  
 To continue serial transmission, read 1 from the TDFE flag to confirm that writing is possible, then write data to SCAFTDR, and then clear the TDFE flag to 0.

**Figure 41.15 Example of Flow for Serial Transmission**

In serial transmission, SCIFA operates as described below.

1. When data is written into SCAFTDR, SCIFA transfers data from SCAFTDR to SCATSR and starts transmitting. Confirm that the TDFE flag in SCASSR is set to 1 before writing transmit data to SCAFTDR. The number of data bytes that can be written is at least 16 – (transmit trigger set number).
2. When data is transferred from SCAFTDR to SCATSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCAFTDR. When the number of transmit data bytes in SCAFTDR falls to or below the transmit trigger number set in SCAFCR, the TDFE flag is set. If the TIE bit in SCASCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated. The SCIFA outputs data in synchronization with the synchronization clock. The serial transmit data is sent from the TXD pin in the LSB-first order.
3. SCIFA checks the SCAFTDR transmit data at the timing for sending the last bit. If data is present, the data is transferred from SCAFTDR to SCATSR, and then serial transmission of the next frame is started. If there is no transmit data, the TEND flag in SCASSR is set to 1 after the last bit is sent, and the transmit data pin (TXD pin) retains the output state of the last bit.

Figure 41.16 is an example of the SCIFA transmission in clocked synchronous mode.

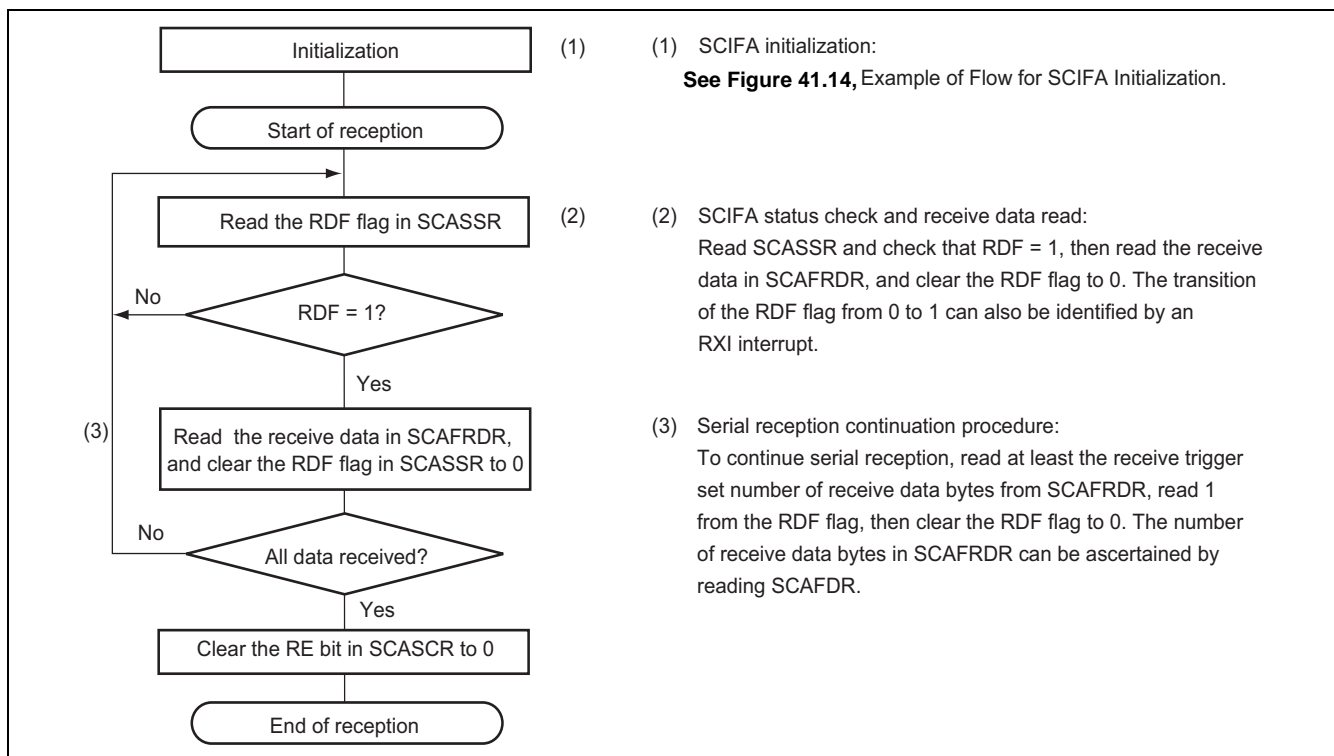

**Figure 41.16 Example of SCIFA Transmission in Clocked Synchronous Mode**

### (5) Serial Data Reception (Clocked Synchronous Mode)

Figure 41.17 is an example of flow for serial reception.

Use the following procedure for serial data reception after enabling SCIFA for reception.

When switching the operating mode from asynchronous mode to clocked synchronous mode without initializing SCIFA, make sure that the ORER flag in SCASSR, and PER and FER flags in SCASSR are cleared to 0.

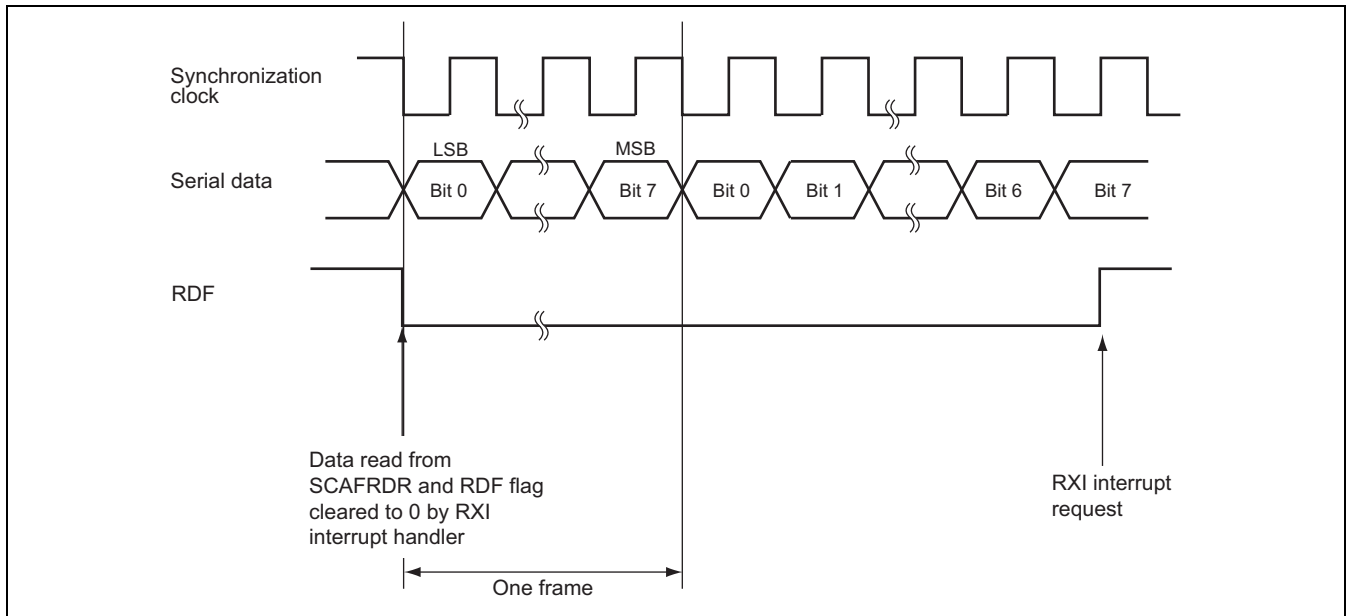

**Figure 41.17 Example of Flow for Serial Reception**

In serial reception, SCIFA operates as described below.

1. SCIFA starts reception in synchronization with the output of the synchronization clock.
2. The received data is stored in SCARSR in LSB-to-MSB order.  
After receiving the data, SCIFA checks whether the receive data can be transferred from SCARSR to SCAFRDR. If this check is passed, the receive data is stored in SCAFRDR. If an overrun error is detected in the error check, reception cannot continue.
3. If the RIE bit in SCASCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

Figure 41.18 is an example of the reception in clocked synchronous mode.

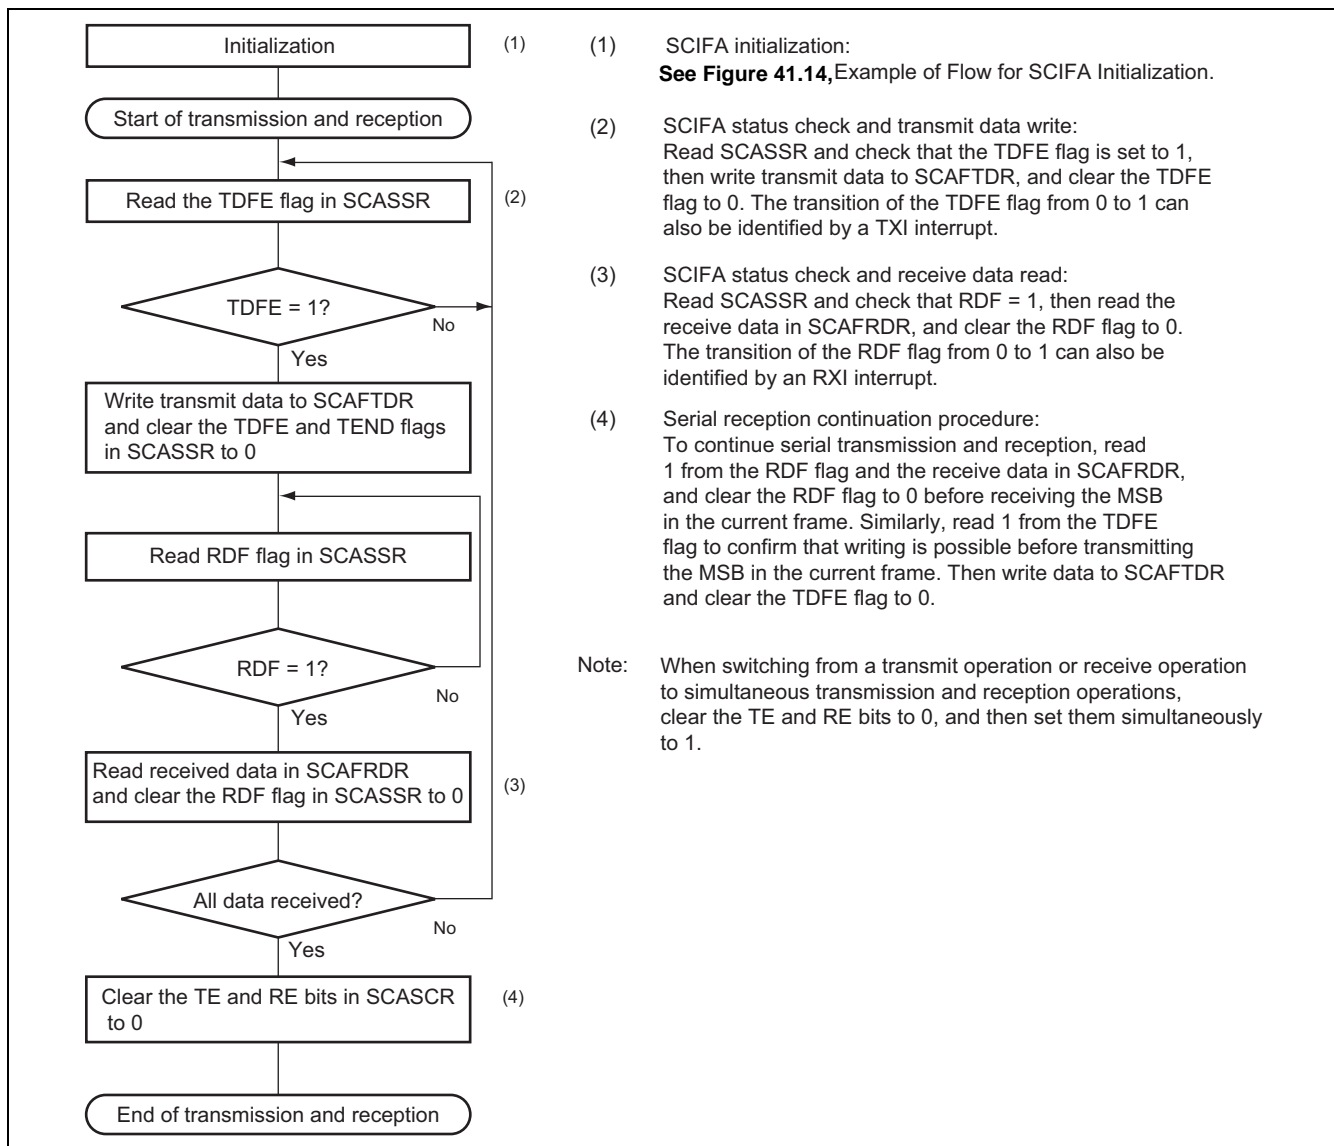

**Figure 41.18 Example of Reception in Clocked Synchronous Mode**

**(6) Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)**

Figure 41.19 is an example of flow for the simultaneous serial data transmission and reception.

Use the following procedure for simultaneous serial transmission and reception after enabling SCIFA for both the transmission and reception.

**Figure 41.19 Example of Flow for Simultaneous Serial Transmission and Reception**

## 41.5 SCIFA Interrupt Sources and DMAC

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

SCIFA supports seven interrupts: transmit-FIFO-data-empty (TXI), transmit-data-stop (TDI), receive-error (ERI), receive-FIFO-data-full (RXI), break (BRI), receive-data-ready (DRI), and transmit-end (TEND). The vectors of each interrupt source are the same.

Table 41.7 shows the interrupt sources. The TIE, RIE, ERIE, BRIE, DRIE, TSIE, and TENDE bits in SCASCR are used to enable or disable the respective interrupt sources.

If the TDFE flag in SCASSR is set to 1, a TXI interrupt request is generated. When the TSF flag in SCASSR is set to 1, a TDI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of TXI and TDI interrupt requests. When data exceeding the transmit trigger set number is written to SCAFTDR by the DMAC, the DMAC transfer request is automatically cleared to 0. The DMAC requests of TXI and TDI are the same.

When the RDF flag in SCASSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of an RXI interrupt request. When receive data in SCAFRDR is read by the DMAC until the amount left is less than the receive trigger set number, the DMAC transfer request is automatically cleared to 0.

When using the DMAC for transmission/reception, set the DMAC to the DMAC transfer enabled state before making the SCIFA settings. Transmission/reception is complete when the DMA transfer is terminated.

When the TEND flag in SCASSR is set to 1, the ER flag in SCASSR is set to 1, the BRK flag in SCASSR is set to 1, the DR flag in SCASSR is set to 1, or the TSF flag in SCASSR is set to 1, an interrupt request is generated. Note that the vectors of each interrupt source are the same.

**Table 41.7 SCIFA Interrupt Sources**

Interrupt Source Type	DMAC Activation
Interrupt initiated by receive error flag (ER), break flag (BRK), receive data ready flag (DR), transmit data stop flag (TSF), or transmit-end flag(TEND)	Not possible
Interrupt initiated by receive FIFO data full flag (RDF)	Possible
Interrupt initiated by transmit FIFO data empty flag (TDFE)	Possible

## 41.6 Usage Notes

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

Note the following when using SCIFA.

### (1) SCAFTDR Writing and the TDFE Flag

The TDFE flag in SCASSR is set when the number of transmit data bytes written in SCAFTDR has fallen to or below the transmit trigger number set by bits TTRG[1:0] in SCAFCCR. After TDFE is set, transmit data up to the number of empty bytes in SCAFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCAFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE clearing should therefore be carried out when SCAFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCAFTDR can be found from the T[6:0] bits in SCAFDR.

### (2) SCAFRDR Reading and the RDF Flag

The RDF flag in SCASSR is set when the number of receive data bytes in SCAFRDR has become equal to or greater than the receive trigger number set by bits RTRG[1:0] in SCAFCCR. After RDF is set, receive data equivalent to the trigger number can be read from SCAFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCAFRDR is still equal to or greater than the trigger number after a read, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all received data has been read.

The number of receive data bytes in SCAFRDR can be found from the R[6:0] bits in SCAFDR.

### (3) Break Detection and Processing

Break signals can be detected by reading the RXD pin directly when a framing error (FER) is detected. In the break state, the input from the RXD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

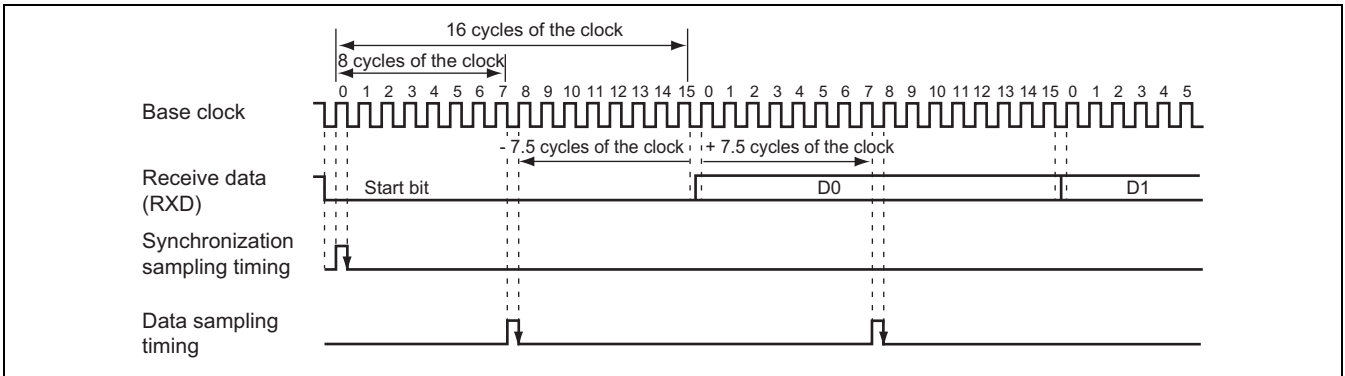

Although SCIFA stops transferring receive data to SCAFRDR after receiving a break, the receive operation continues.

**(4) Receive Data Sampling Timing and Receive Margin**

As an example, when the sampling rate is 1/16, SCIFA operates on a base clock with a frequency of 8 times the transfer rate.

In reception, SCIFA synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse (when the sampling rate is 1/16).

The timing is shown in Figure 41.20.

**Figure 41.20 Receive Data Sampling Timing**

The receive margin can therefore be expressed as shown in equation (1).

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \dots (1)$$

- M: Receive margin (%)
- N: Ratio of clock frequency to bit rate (N = 16)
- D: Clock duty cycle (D = 0 to 1.0)
- L: Frame length (L = 9 to 12)
- F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation (2).

When D = 0.5 and F = 0:

$$M = (0.5 - 1/(2 \times 16)) \times 100\% = 46.875\% \dots (2)$$

This is a theoretical value. A reasonable margin to allow in system designs is the value above (46.875%) plus 20% to 30%.

**(5) State of the PAD Pin when the Pin for SCIFA is Selected**

The table below shows the state of the PAD pin when the pin for SCIFA is selected.

**Table 41.8 State of PAD Pin**

<b>When the Pin for SCIFA is Selected</b>	<b>TXD</b>	<b>RXD</b>	<b>RTS#</b>	<b>CTS#</b>	<b>SCK</b>
PAD enable	1 (enabled)	1 (enabled)	RTSC in SCAPCR (initial value:1, serial port enabled), and MCE in SCAFCCR (initial value: 0, disabled)	MCE in SCAFCCR (initial value: 0, disabled)	SCKC in SCAPCR (initial value:1, serial port enabled), and CKE0 in SCASCR (Initial value: 0, disabled)
Pin state	Output (initial value: 1)	Input	Port output (initial value: 1)	Input	Port output (initial value: 0)
Pull-up/-down	—	Pull-up required	—	Pull-up required	—
Remarks	—	SCIFA fixes RXD to 1 internally when RE in SCASCR = 0.	RTS# is Hi-Z when RTSC in SCAPCR = 0, and MCE in SCAFCCR = 0.	SCIFA fixes CTS# to 1 internally when MCE in SCAFCCR = 0.	SCK is Hi-Z when SCKC in SCAPCR = 0, and CKE0 in SCASCR = 0.

## 42. Serial Communications Interface with FIFO B (SCIFB)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

This LSI has three serial communications interfaces B incorporating FIFO buffers (SCIFB) that can perform both asynchronous and clocked synchronous serial communications.

Each interface includes two 256-stage buffers, one for the transmit FIFO register and, one for the receive FIFO register, enabling fast, efficient, and continuous communications.

### 42.1 Features

- 3 channels are implemented.
- Asynchronous mode
 

Serial data communications are executed using an asynchronous system in which synchronization is achieved character by character. Serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA).

There is a choice of eight serial data communication formats.

  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even/odd/none
  - LSB-first transfer
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection: If a framing error is followed by at least one frame at the space "0" (low level), a break is detected.
- Clocked synchronous mode
 

Serial data communications in synchronization with a clock can be carried out with other LSIs that have a clocked synchronous communications function.

  - Data length: 8 bits
  - Receive error detection: Overrun error
  - A rising or falling edge of a clock is selectable as the data transmit/receive timing.
- On-chip baud rate generator allows any bit rate to be selected.
  - Maximum:  $MP\phi/5$  bps, Minimum:  $MP\phi/(27 \times 256 \times 64)$  bps (asynchronous)
  - Maximum:  $MP\phi/(2 \times 2)$  bps, Minimum:  $MP\phi/(2 \times 256 \times 64)$  bps (clocked synchronous)
- Serial clock source: Internal clock signal generated by the baud rate generator.
- Nine interrupt sources
 

There are nine interrupt sources — receive-FIFO-data-full (RXI), transmit-FIFO-data-empty (TXI), receive-data-ready (DRI), break (BRI), receive-error (ERI), transmit-data-stop (TDI), transmit-end (TENDPOSE), receive-data-count-compare (RCE), and receive-reading-count-compare (RRCC). The vectors of each interrupt source are the same.
- The DMA controller (DMAC) can be activated to execute a data transfer in the event of a transmit-FIFO-data-empty, transmit-data-stop, or receive-FIFO-data-full interrupt. The DMAC requests of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.
- Supports multibyte DMA transfers.
- On-chip modem control functions (CTS# and RTS#)
- On-chip transmit-data-stop function
- When not in use, the SCIFB can be stopped by halting its clock supply to reduce power consumption.

- The amount of data in the transmit/receive FIFO registers, and the number of receive errors in the receive data in the receive FIFO register, can be ascertained.
- Interrupt can be generated at each receive reading frequency end set by using the receive-reading-count-compare interrupt.

Figure 42.1 shows a block diagram of SCIFB.

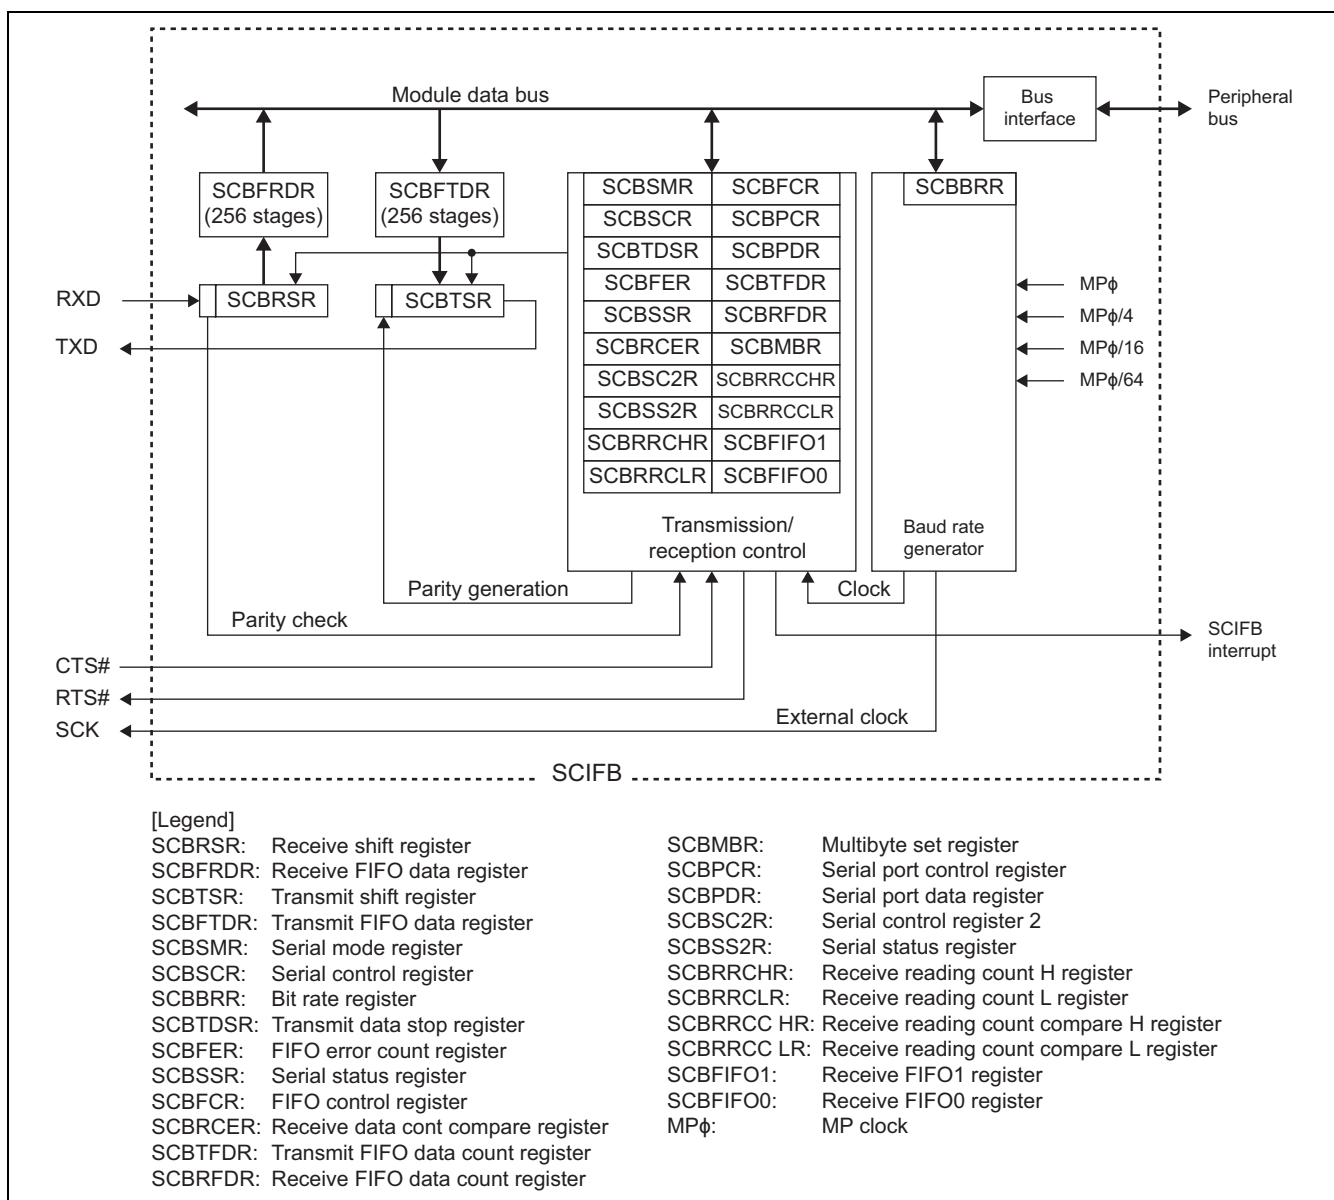

Figure 42.1 Block Diagram of SCIFB

## 42.2 Input/Output Pins

Table 42.1 shows the SCIFB pin configuration.

**Table 42.1 Channel and Pin Configuration**

Abbreviation	Input/output	Description
SCIFBn_SCK	Output	Output pin for the clock signal n
SCIFBn_RXD	Input	Input pin for data for reception n
SCIFBn_TXD	Output	Output pin for data for transmission n
SCIFBn_CTS#	Input	Input pin for the transmit enable signal n
SCIFBn_RTS#	Output	Output pin for transmit request signal n

Note: n is a channel number (n = 0 to 2).

SCK, RXD, TXD, CTS#, and RTS# are used as generic terms in the following descriptions.

## 42.3 Register Descriptions

Table 42.2 shows the SCIFB registers. Table 42.3 shows the register states in the respective processing modes.

**Table 42.2 Register Configuration**

Register Name	Abbreviation	Address	RZ/G Series Products

**42.3.1 Receive Shift Register Bn (SCBRSRn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRSR is the register used to receive serial data.

SCIFB sets serial data input from the RXD pin in SCBRSR in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is automatically transferred to SCBFRDR.

SCBRSR cannot be directly read from or written to by the CPU.

**42.3.2 Transmit Shift Register Bn (SCBTSRn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBTSR is the register used to transmit serial data.

To perform serial data transmission, SCIFB first transfers a transmit data from SCBFTDR to SCBTSR, and then sends the data to the TXD pin starting with the LSB (bit 0).

When transmission of one byte is completed, the next transmit data is transferred from SCBFTDR to SCBTSR, and transmission starts automatically.

SCBTSR cannot be directly read from or written to by the CPU.

### 42.3.3 Serial Mode Register Bn (SCBSMRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBSMR is a 16-bit readable/writable register used to set an SCIFB's serial transfer format and select the baud rate generator clock source and the sampling rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CKEDG	—	SRC[2:0]		C/A#	CHR	PE	O/E	STOP	—	CKS[1:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CKEDG	0	R/W	Transmit/Receive Clock Edge Select Selects the clock edge at which the serial data is output in clocked synchronous mode. 0: Serial data is transmitted at the falling edge of output clock. Serial data is received at the rising edge of output clock. 1: Serial data is transmitted at the rising edge of output clock. Serial data is received at the falling edge of output clock.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	SRC[2:0]	000	R/W	Sampling Control This bit setting is valid only in asynchronous mode. These bits select the sampling rate. 000: Sampling rate 1/16 001: Sampling rate 1/5* 010: Sampling rate 1/7 011: Sampling rate 1/11 100: Sampling rate 1/13 101: Sampling rate 1/17 110: Sampling rate 1/19 111: Sampling rate 1/27 Note: * In asynchronous mode, when the sampling rate is 1/5, first received data may become invalid. To avoid this problem, wait more than 1 serial data time (1bit time x serial data number) after setting SCBSCR.RE=1, or use sampling rate other than 1/5.
7	C/A#	0	R/W	Communication Mode Selects asynchronous mode or clocked synchronous mode as the SCIFB operating mode. 0: Asynchronous mode 1: Clocked synchronous mode

Bit	Bit Name	Initial Value	R/W	Description
6	CHR	0	R/W	<p>Character Length</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects 7 or 8 bits as the data length.</p> <p>0: 8-bit data 1: 7-bit data*</p> <p>Note: * When the 7-bit character is selected, the MSB (bit 7) in SCBFTDR is not transmitted.</p>
5	PE	0	R/W	<p>Parity Enable</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects whether or not parity bit addition is performed in transmission, and parity bit checking in reception.</p> <p>0: Parity bit addition and checking disabled 1: Parity bit addition and checking enabled*</p> <p>Note: * When the PE bit is set to 1, the parity (even or odd) specified by the O/E bit is added to transmit data before transmission. In reception, the parity bit is checked for the parity (even or odd) specified by the O/E bit.</p>
4	O/E	0	R/W	<p>Parity Mode</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects either even or odd parity for use in parity addition and checking. The O/E bit setting is only valid when the PE bit is set to 1, enabling parity bit addition and checking. The O/E bit setting is invalid when parity addition and checking are disabled.</p> <p>0: Even parity*<sup>1</sup> 1: Odd parity*<sup>2</sup></p> <p>Notes: 1. When even parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even.</p> <p>2. When odd parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.</p>
3	STOP	0	R/W	<p>Stop Bit Length</p> <p>This bit setting is valid only in asynchronous mode.</p> <p>Selects 1 or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit; if it is 0, it is treated as the start bit of the next transmit character.</p> <p>0: 1 stop bit*<sup>1</sup> 1: 2 stop bits*<sup>2</sup></p> <p>Notes: 1. In transmission, a single logic-1 bit (stop bit) is added to the end of a transmit character before it is sent.</p> <p>2. In transmission, two logic-1 bits (stop bits) are added to the end of a transmit character before it is sent.</p>
2	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>

### 42.3.4 Bit Rate Register Bn (SCBBRRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBBRR is an 8-bit readable/writable register that sets the serial transfer bit rate in accordance with the baud rate generator operating clock selected by bits CKS[1:0] in SCBSMR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCBRD[7:0]	H'FF	R/W	Bit Rate $0 \leq \text{SCBRD} \leq 255$ (asynchronous) $1 \leq \text{SCBRD} \leq 255$ (clocked synchronous)

The SCBBRR setting is found by using the following equations.

#### (1) Asynchronous Mode:

- When the sampling rate is 1/16,  

$$N = \{ \text{MP}\phi / (16 \times 2^{2n} \times B) \} \times 10^6 - 1$$
- When the sampling rate is 1/5,  

$$N = \{ \text{MP}\phi / (5 \times 2^{2n} \times B) \} \times 10^6 - 1$$
- When the sampling rate is 1/11,  

$$N = \{ \text{MP}\phi / (11 \times 2^{2n} \times B) \} \times 10^6 - 1$$
- When the sampling rate is 1/13,  

$$N = \{ \text{MP}\phi / (13 \times 2^{2n} \times B) \} \times 10^6 - 1$$
- When the sampling rate is 1/27,  

$$N = \{ \text{MP}\phi / (27 \times 2^{2n} \times B) \} \times 10^6 - 1$$

#### (2) Clocked Synchronous Mode:

$$N = \{ \text{MP}\phi / (2 \times 2^{2n} \times B) \} \times 10^6 - 1$$

- Where
- B: Bit rate (bits/s)
  - N: SCBBRR setting for baud rate generator  
Asynchronous mode ( $0 \leq N \leq 255$ )  
Clocked synchronous mode ( $1 \leq N \leq 255$ )
  - MP $\phi$ : MP clock frequency (MHz)
  - n: Baud rate generator input clock ( $n = 0$  to 3)  
(See the table below for the relation between n and the clock.)

**Table 42.4 SCBSMR Setting**

n	Clock	SCBSMR Setting
		CKS[1:0]
0	MP $\phi$	B'00
1	MP $\phi$ /4	B'01
2	MP $\phi$ /16	B'10
3	MP $\phi$ /64	B'11

The bit rate error in asynchronous mode is found by using the following equations.

When the sampling rate is 1/16,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 16 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/5,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 5 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/11,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 11 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/13,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 13 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

When the sampling rate is 1/27,

$$\text{Error (\%)} = \{ \{ \text{MP}\phi / ((N + 1) \times 27 \times 2^{2n} \times B) \} \times 10^6 - 1 \} \times 100$$

### 42.3.5 Serial Control Register Bn (SCBSCRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBSCR is a 16-bit readable/writable register that enables or disables SCIFB transfer operations and interrupt requests, and selects the clock source for transmission and reception.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
15	TDRQE	0	R/W	<p>Transmit Data Transfer Request Enable</p> <p>Switches the transmit-FIFO-data-empty interrupt or DMA transfer request when TIE = 1 and the transmit FIFO data empty occurs.</p> <p>0: Interrupt request to CPU is issued.</p> <p>1: Transmit data transfer request to DMAC is issued.</p>
14	RDRQE	0	R/W	<p>Receive Data Transfer Request Enable</p> <p>Switches the receive-FIFO-data-full interrupt or DMA transfer request when RIE = 1 and the receive FIFO data full occurs.</p> <p>0: Interrupt request to CPU is issued.</p> <p>1: Receive data transfer request to DMAC is issued.</p>
13	RCEE	0	R/W	<p>Receive Data Count Compare Interrupt Enable</p> <p>Generates an interrupt when the receive data count comparison counter matches the current receive data count.</p> <p>0: Receive-data-count-compare interrupt disabled*</p> <p>1: Receive-data-count-compare interrupt enabled</p> <p>Note: * This interrupt request is cleared by clearing the RCEF flag to 0 after reading 1 from it or clearing the RCEE bit to 0.</p>
12	TENDPOSE	0	R/W	<p>Transmit End Interrupt Enable</p> <p>Enables or disables generation of a transmit-end interrupt when the TENDPOS flag in SCBSSR is set to 1.</p> <p>0: Transmit-end interrupt disabled*</p> <p>1: Transmit-end interrupt enabled</p> <p>Note: * This interrupt request is cleared by clearing the TENDPOS flag to 0 after reading 1.</p>
11	TSIE	0	R/W	<p>Transmit Data Stop Interrupt Enable</p> <p>Enables or disables generation of a transmit-data-stop interrupt when the TSE bit in SCBFCR is enabled and the TSF flag in SCBSSR is set to 1.</p> <p>0: Transmit-data-stop interrupt disabled*</p> <p>1: Transmit-data-stop interrupt enabled</p> <p>Note: * The TDI interrupt request is cleared by clearing the TSF flag to 0 after reading 1 from it or clearing the TSIE bit to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
10	ERIE	0	R/W	<p>Receive Error Interrupt Enable</p> <p>Enables or disables generation of a receive-error (framing or parity error) interrupt when the ER flag in SCBSSR is set to 1.</p> <p>0: Receive-error interrupt disabled*</p> <p>1: Receive-error interrupt enabled</p> <p>Note: * The ERI interrupt request is cleared by clearing the ER flag to 0 after reading 1 from it or clearing the ERIE bit to 0.</p>
9	BRIE	0	R/W	<p>Break Interrupt Enable</p> <p>Enables or disables generation of a break-receive interrupt when the BRK flag in SCBSSR is set to 1.</p> <p>0: Break-receive interrupt disabled*</p> <p>1: Break-receive interrupt enabled</p> <p>Note: * The BRI interrupt request is cleared by clearing the BRK flag to 0 after reading 1 from it or clearing the BRIE bit to 0.</p>
8	DRIE	0	R/W	<p>Receive Data Ready Interrupt Enable</p> <p>Enables or disables generation of a receive-data-ready interrupt when the DR flag in SCBSSR is set to 1.</p> <p>0: Receive-data-ready interrupt disabled*</p> <p>1: Receive-data-ready interrupt enabled</p> <p>Note: * The DRI interrupt request is cleared by clearing the DR flag to 0 after reading 1 from it or clearing the DRIE bit to 0.</p>
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>Enables or disables generation of a transmit-FIFO-data-empty interrupt request when the TDFE flag in SCBSSR is set to 1.</p> <p>0: Transmit-FIFO-data-empty interrupt request disabled*</p> <p>1: Transmit-FIFO-data-empty interrupt request enabled</p> <p>Note: * This interrupt request is cleared by writing transmit data exceeding the transmit trigger set number to SCBFTDR, reading 1 from the TDFE flag, then clearing it to 0, or by clearing the TIE bit to 0.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>Enables or disables generation of a receive-FIFO-data-full interrupt request when the RDF flag in SCBSSR is set to 1.</p> <p>0: Receive-FIFO-data-full interrupt request disabled*</p> <p>1: Receive-FIFO-data-full interrupt request enabled</p> <p>Note: * This interrupt request is cleared by reading 1 from the RDF flag, then clearing the flag to 0, or by clearing the RIE bit to 0.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>Enables or disables the start of serial transmission by SCIFB.</p> <p>0: Transmission disabled</p> <p>1: Transmission enabled*</p> <p>Note: * Make SCBSMR and SCBFCR settings, decide the transmit format, and reset the transmit FIFO before setting the TE bit to 1.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	<p>Receive Enable</p> <p>Enables or disables the start of serial reception by SCIFB.</p> <p>0: Reception disabled*<sup>1</sup></p> <p>1: Reception enabled*<sup>2</sup></p> <p>Notes: 1. Clearing the RE bit to 0 does not affect the DR, ER, BRK, RDF, FER, PER, and ORER flags, which retain their state.</p> <p>2. Make SCBSMR and SCBFCR settings, decide the receive format, and reset the receive FIFO before setting the RE bit to 1.</p>
3 to 1	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
0	CKE0	0	R/W	<p>Clock Enable</p> <p>Enables or disables the clock output from the SCK pin. The CKE0 bit must be set before determining the SCIFB operating mode with SCBSMR.</p> <p>0: SCK pin disabled*<sup>1</sup></p> <p>1: Clock output from SCK*<sup>2</sup></p> <p>Notes: 1. Even if this bit is 0, the SCK pin outputs data specified by SCBPDRn[2].SCKD, if SCBPCRn[2].SCKC is 1.</p> <p>2. In clocked synchronous mode, the SCK pin outputs a clock with the same frequency as the bit rate.</p>

#### 42.3.6 Transmit Data Stop Register Bn (SCBTDSRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBTDSR is a 16-bit readable/writable register that sets the number of transmit data bytes. SCBTDSR is valid only when the TSE bit in SCBFCR is enabled. Transmit operation is stopped when the number of data bytes set in SCBTDSR is transmitted. The setting value should be H'0000 (one byte) to H'FFFF (65536 bytes). SCBTDSR is initialized to H'FFFF.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TDSRD[15:0]	H'FFFF	R/W	Transmit Data Stop Setting

**42.3.7 FIFO Error Count Register Bn (SCBFERn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFER is a 16-bit read-only register that indicates the number of receive errors (framing errors and parity errors).

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	PER[7:0]	H'00	R	<p>Parity Error Count</p> <p>These bits indicate the number of data in which parity errors are generated, in receive data stored in SCBFRDR.</p> <p>After the ER bit in SCBSSR is set, the value of bits PER7 to PER0 indicates the number of data in which parity errors are generated.</p> <p>When all 256 bytes of receive data in SCBFRDR have parity errors, these bits indicate 0.</p>
7 to 0	FER[7:0]	H'00	R	<p>Framing Error Count</p> <p>These bits indicate the number of data in which framing errors are generated, in receive data stored in SCBFRDR.</p> <p>After the ER bit in SCBSSR is set, the value of bits FER7 to FER0 indicates the number of data in which framing errors are generated.</p> <p>When all 256 bytes of receive data in SCBFRDR have framing errors, these bits indicate 0.</p>

### 42.3.8 Serial Status Register Bn (SCBSSRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBSSR is a 16-bit readable/writable register that indicates the SCIFB status.

However, 1 cannot be written to the RCEF, TENDPOS, ORER, TSF, ER, TDFE, BRK, RDF, and DR flags. Before these flags can be cleared to 0, they must first be read as 1. The TEND, FER, and PER flags are read-only flags and cannot be modified.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RCEF	TEND POS	—	—	ORER	TSF	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*	R/(W)*	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RCEF	0	R/(W)*	Receive Data Count Match Indicates that the receive data count matches the receive data count comparison counter. 0: Receive data count does not match the receive data count comparison counter. [Clearing conditions] <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to RCEF after reading RCEF = 1</li> </ul> 1: Receive data count matches the receive data count comparison counter.* [Setting condition] <ul style="list-style-type: none"> <li>When the receive data count matches the counter value</li> </ul> Note: * Enable this bit by setting RCE bit in SCBFRC to 1.
12	TENDPOS	0	R/(W)*	Transmit End Detect Indicates that the transmission ends. 0: Transmit end has not been detected. [Clearing conditions] <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to TENDPOS after reading TENDPOS = 1</li> </ul> 1: The TEND flag in SCBSSR is set to 1 [Setting condition] <ul style="list-style-type: none"> <li>When the TEND flag in SCBSSR is set to 1.</li> </ul>
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ORER	0	R/(W)*	<p>Overrun Error</p> <p>Indicates that an overrun error occurred during reception.</p> <p>This bit is valid only in asynchronous mode.</p> <p>0: Reception is in progress or has been completed normally.*<sup>1</sup></p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to ORER after reading ORER = 1</li> </ul> <p>1: An overrun error occurred during reception.*<sup>2</sup></p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When serial data reception is completed while receive FIFO is full</li> </ul> <p>Notes: 1. The ORER flag is not affected and retains its previous state when the RE bit in SCBSCR is cleared to 0.</p> <p>2. The receive data prior to the overrun error is retained in SCBFRDR, and the data received subsequently is lost. Serial data reception cannot be continued with the ORER flag set to 1.</p>
8	TSF	0	R/(W)*	<p>Transmit Data Stop</p> <p>Indicates that the number of transmit data matches the value of SCBTDSR.</p> <p>This bit is valid only in asynchronous mode.</p> <p>0: The number of transmit data does not match the SCBTDSR value.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to TSF after reading TSF = 1</li> </ul> <p>1: The number of transmit data matches the SCBTDSR value.</p>

Bit	Bit Name	Initial Value	R/W	Description
7	ER	0	R/(W)*	<p>Receive Error</p> <p>Indicates that a framing error or parity error occurred during reception.*1 This bit is valid only in asynchronous mode.</p> <p>0: No framing error or parity error occurred during reception.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Power-on reset or manual reset</li> <li>• When 0 is written to ER after reading ER = 1</li> </ul> <p>1: A framing error or parity error occurred during reception.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• When the SCIFB checks whether the stop bit at the end of the receive data is 1 when reception ends, and the stop bit is 0*2</li> <li>• When, in reception, the number of logic-1 bits in the receive data and in the parity bit does not match the parity setting (even or odd) specified by the O/E bit in SCBSMR</li> </ul> <p>Notes: 1. The ER flag is not affected and retains its previous state when the RE bit in SCBSCR is cleared to 0. When a receive error occurs, the receive data is still transferred to SCBFRDR, and reception continues. The FER and PER bits in SCBSSR can be used to determine whether there is a receive error in the data read from SCBFRDR.</p> <p>2. When the stop-bit length is 2 bits, only the first stop bit is checked for a value of 1 and the second stop bit is not checked.</p>
6	TEND	1	R	<p>Transmit End</p> <p>Indicates that there is no valid data in SCBFTDR when the last bit of the transmit character is sent and that transmission has been completed.</p> <p>0: Transmission is in progress.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>• When data is written to SCBFTDR</li> </ul> <p>1: Transmission has been completed.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• When there is no transmit data in SCBFTDR during transmission of a 1-byte serial transmit character</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
5	TDFE	1	R/(W)*	<p>Transmit FIFO Data Empty</p> <p>Indicates that data has been transferred from SCBFTDR to SCBTSR, the number of data bytes in SCBFTDR has fallen to or below the transmit trigger data number set by bits TTRG[1:0] in SCBFCR, and new transmit data can be written to SCBFTDR.</p> <p>0: A number of transmit data bytes exceeding the transmit trigger set number have been written to SCBFTDR.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When transmit data exceeding the transmit trigger set number is written to SCBFTDR, and 0 is written to TDFE after reading TDFE = 1</li> </ul> <p>1: The number of transmit data bytes in SCBFTDR is equal to or less than the transmit trigger set number.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When the number of SCBFTDR transmit data bytes falls to or below the transmit trigger set number after a transmit operation*</li> </ul> <p>Note: * As SCBFTDR is a 256-byte FIFO register, the maximum number of bytes that can be written when TDFE = 1 is 256 – (transmit trigger set number). Data written in excess of this will be ignored. The number of data bytes in SCBFTDR is indicated by SCBTFDR.</p>
4	BRK	0	R/(W)*	<p>Break Detect</p> <p>Indicates that a receive data break signal has been detected. This bit is valid only in asynchronous mode.</p> <p>0: A break signal has not been received.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to BRK after reading BRK = 1</li> </ul> <p>1: A break signal has been received.*</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When data with a framing error is received, followed by the space 0 level (low level) for at least one frame length</li> </ul> <p>Note: * When a break is detected, the receive data (H'00) following the detection is not transferred to SCBFRDR. When the break ends and the receive signal returns to mark 1, receive data transfer is resumed.</p>
3	FER	0	R	<p>Framing Error</p> <p>Indicates a framing error in the data read from SCBFRDR. This bit is valid only in asynchronous mode.</p> <p>0: There is no framing error in the receive data read from SCBFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When there is no framing error in SCBFRDR read data</li> </ul> <p>1: There is a framing error in the receive data read from SCBFRDR.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>When there is a framing error in SCBFRDR read data</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
2	PER	0	R	<p>Parity Error</p> <p>Indicates a parity error in the data read from SCBFRDR. This bit is valid only in asynchronous mode.</p> <p>0: There is no parity error in the receive data read from SCBFRDR. [Setting condition]</p> <p>When there is a parity error in SCBFRDR read data</p>
1	RDF	0	R/(W)*	<p>Receive FIFO Data Full</p> <p>Indicates that the received data has been transferred from SCBRSR to SCBFRDR, and the number of receive data bytes in SCBFRDR is equal to or greater than the receive trigger number set by bits RTRG[1:0] in SCBFCR.</p> <p>0: The number of receive data bytes in SCBFRDR is less than the receive trigger set number. [Clearing conditions]</p> <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When SCBFRDR is read until the number of receive data bytes in SCBFRDR falls below the receive trigger set number, and 0 is written to RDF after reading RDF = 1</li> </ul> <p>1: The number of receive data bytes in SCBFRDR is equal to or greater than the receive trigger set number. [Setting condition]</p> <ul style="list-style-type: none"> <li>When SCBFRDR contains at least the receive trigger set number of receive data bytes*</li> </ul> <p>Note: * SCBFRDR is a 256-byte FIFO register. When RDF = 1, at least the receive trigger set number of data bytes can be read. If data is read when SCBFRDR is empty, an undefined value will be returned. The number of receive data bytes in SCBFRDR is indicated by SCBRFDR.</p>

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W) *	<p>Receive Data Ready</p> <p>Indicates that there are data bytes fewer than the receive trigger set number in SCBFRDR, and no further data will arrive at least 15 etu after the stop bit of the last data received.</p> <p>This bit is valid only in asynchronous mode.</p> <p>0: Reception is in progress or has ended normally and no receive data is left in SCBFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Power-on reset or manual reset</li> <li>• When all the receive data in SCBFRDR has been read, and 0 is written to DR after reading DR = 1</li> </ul> <p>1: No further receive data has arrived.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• When SCBFRDR contains data bytes fewer than the receive trigger set number, and no further data will arrive at least 15 etu after the stop bit of the last data received*</li> </ul> <p>Note: * Corresponds to 1.5 frame time in 8-bit one-stop-bit format. etu: Elementary time unit (time for transfer of 1 bit)</p>

Note: \* Only 0 can be written for flag clearing.

### 42.3.9 FIFO Control Register Bn (SCBFCRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFCR is a 16-bit readable/writable register that clears all data and sets the trigger data number for the transmit and receive FIFO registers. The register also contains a loopback test enable bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSE	TCRST	RCE	RCRST	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RFRST	LOOP

0	LOOP	0	R/W	<p>Loopback Test</p> <p>Internally connects the transmit output pin (TXD) to receive input pin (RXD) and RTS# pin to CTS# pin, enabling loopback testing.</p> <p>0: Loopback test disabled</p> <p>1: Loopback test enabled</p>

**42.3.10 Receive Data Count Compare Register Bn (SCBRCERn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRCER is a 16-bit readable/writable register that sets the number of receive data bytes. SCBRCER is valid only when the RCE bit in SCBFCR is set to 1 (enabled). The data reception stops when the number of receive data bytes reaches the value of this register. A value between H'0000 (1 byte) to H'FFFF (65536 bytes) can be set. SCBRCER is initialized to H'FFFF.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RCERD[15:0]	H'FFFF	R/W	Receive Data Stop

### 42.3.11 Multibyte Set Register Bn (SCBMBRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBMBR is a 16-bit readable/writable register for multibyte transfer setting. Settings for transmission in SCBMBR is valid when the TDRQE bit in SCBSCR is set to 1, and settings for reception is valid when the RDRQE bit in SCBSCR is set to 1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADD REQ	—	—	—	—	—	—	—	—	—	—	—	RCECR ON	—	MBR ON	MBT ON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	ADDREQ	0	R/W	Enables or disables receive data transfer until the receive FIFO data count is decreased to 0. 0: Receive data transfer disabled until the receive FIFO data count is decreased to 0. 1: Receive data transfer enabled until the receive FIFO data count is decreased to 0.
14 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	RCECRON	0	R/W	Enables or disables receive data transfer in conjunction with the RCEF bit in SCBSSR. Receive data transfer requests are made until the receive FIFO data count is decreased to 0. 0: Receive data transfer in conjunction with RCEF in SCBSSR enabled 1: Receive data transfer in conjunction with RCEF in SCBSSR disabled
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	MBRON	0	R/W	Enables or disables multibyte receive data transfer 0: Multibyte receive data transfer disabled 1: Multibyte receive data transfer enabled
0	MBTON	0	R/W	Enables or disables multibyte transmit data transfer 0: Multibyte transmit data transfer disabled 1: Multibyte transmit data transfer enabled

### 42.3.12 Serial Port Control Register Bn (SCBPCRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBPCR is a 16 bit readable/writable register. This register specifies whether the TXD, SCK and RTS# pins function as output ports with fixed values specified by SCBPDRn, or as the TXD, SCK and RTS# pins, respectively. It also specifies whether the RXD and CTS# pins function as input ports for general purpose, or as RXD and CTS# pins, respectively.

The initial value of this register is H'0000. This register function is valid only when the SCIFB pin function is selected through the pin function controller (PFC).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RTSC	CTSC	SCKC	RXDC	TXDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSC	1	R/W	Selects the RTS# pin function. 0: The RTS# pin functions as the RTS# pin. 1: The RTS# pin functions as an output port.
3	CTSC	0	R/W	Selects the CTS# pin function. 0: The CTS# pin functions as the CTS# pin. 1: The CTS# pin functions as an input port.
2	SCKC	1	R/W	Selects the SCK pin function. 0: The SCK pin functions as the SCK pin. 1: The SCK pin functions as an output port.
1	RXDC	0	R/W	Selects the RXD pin function. 0: The RXD pin functions as the RXD pin. 1: The RXD pin functions as an input port.
0	TXDC	0	R/W	Selects the TXD pin function. 0: The TXD pin functions as the TXD pin. 1: The TXD pin functions as an output port.

### 42.3.13 Serial Port Data Register Bn (SCBPDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBPDR is a 16-bit readable/writable register. This register specifies data output to the TXD, SCK and RTS# pins when the SCIFB pin function is selected by SCBPCR. It also specifies the pin level of the RXD and CTS# pins.

This register function is valid only when the SCIFB pin function is selected through the pin function controller (PFC).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RTSD	CTSD	SCKD	RXDD	TXDD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	—	0	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSD	1	R/W	Specifies data output to the RTS# pin. 0: Outputs 0. 1: Outputs 1.
3	CTSD	Undefined	R	Specifies the CTS# pin level. 0: CTS# pin level is 0. 1: CTS# pin level is 1. This bit is valid only when SCBFCRn[3].MCE is 1, or SCBPCRn[3].CTSC is 1.
2	SCKD	0	R/W	Specifies data output to the SCK pin. 0: Outputs 0. 1: Outputs 1.
1	RXDD	Undefined	R	Specifies the RXD pin level. 0: RXD pin level is 0. 1: RXD pin level is 1. This bit is valid only when SCBSCRn[4].RE is 1, or SCBPCRn[1].RXDC is 1.
0	TXDD	0	R/W	Specifies data output to the TXD pin. 0: Outputs 0. 1: Outputs 1.

### 42.3.14 Transmit FIFO Data Count Register Bn (SCBTFDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBTFDR is a 16-bit read-only register that indicates the number of data bytes stored in SCBFTDR. The T8 to T0 bits indicate the number of transmit data bytes in SCBFTDR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	T[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	T[8:0]	H'000	R	Indicate the number of data bytes remaining in SCBFTDR. H'000 shows that SCBFTDR contains no transmit data, and H'100 shows that SCBFTDR is filled with transmit data.

### 42.3.15 Receive FIFO Data Count Register Bn (SCBRFDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRFDR is a 16-bit read-only register that indicates the number of data bytes stored in SCBFRDR. The R8 to R0 bits indicate the number of receive data bytes in SCBFRDR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	R[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	R[8:0]	H'000	R	Indicate the number of data bytes remaining in SCBFRDR. H'000 shows that SCBFRDR contains no receive data, and H'100 shows that SCBFRDR is filled with receive data.

### 42.3.16 Transmit FIFO Data Register Bn (SCBFTDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFTDR is an 8-bit 256-stage FIFO data register that stores data for serial transmission.

If SCBTSR is empty when transmit data has been written to SCBFTDR, the SCIFB transfers the transmit data written in SCBFTDR to SCBTSR and starts serial transmission.

SCBFTDR is a write-only register, and cannot be read by the CPU.

The next data cannot be written when SCBFTDR is filled with 256 bytes of transmit data. Data written in this case is ignored.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFTD[7:0]	Undefined	W	Serial transmit data FIFO

### 42.3.17 Receive FIFO Data Register Bn (SCBFRDRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFRDR is 256-stage FIFO register that stores received serial data.

When the SCIFB has received one byte of serial data, it transfers the received data from SCBRSR to SCBFRDR where it is stored, and completes the receive operation. SCBRSR is then enabled for reception, and consecutive receive operations can be performed until SCBFRDR is full (256-byte data).

SCBFRDR is a read-only register, and cannot be written to by the CPU.

If a read is performed when there is no receive data in SCBFRDR, an undefined value will be returned. When SCBFRDR is full of receive data, subsequent serial data is lost.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFRD[7:0]	Undefined	R	Serial receive data FIFO

**42.3.18 Serial Control Register 2 Bn (SCBSC2Rn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBSC2R is a 16-bit readable/writable register that enables or disables the interrupt request.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RRCCE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RRCCE	0	R/W	Receive Reading Count Compare Enable Enables or disables generation of a receive-reading-count-compare interrupt when the RRCCF bit in SCBSS2R is set to 1. 0: Receive-reading-count-compare interrupt disabled 1: Receive-reading-count-compare interrupt enabled

### 42.3.19 Serial Status Register 2 Bn (SCBSS2Rn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBSS2R is a 16-bit readable/writable register that indicates the SCIFB status. However, 1 cannot be written to the RRCCF flag. The RRCCF flag is cleared to 0 after reading 1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RRCCF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RRCCF	0	R/W*	Receive Reading Count Compare Indicates the result of comparison between a value of the receive reading count SCBRRCR and a value of the receive reading count compare SCBRRCCR. 0: A value of the receive reading count SCBRRCR is less than a value of the receive reading count compare SCBRRCCR. [Clearing conditions] <ul style="list-style-type: none"> <li>Power-on reset or manual reset</li> <li>When 0 is written to RRCCF after reading RRCCF = 1</li> </ul> 1: A value of the receive reading count SCBRRCR is greater than a value of the receive reading count compare SCBRRCCR. [Setting condition] <ul style="list-style-type: none"> <li>When a value of the receive reading count SCBRRCR is greater than a value of the receive reading count compare SCBRRCCR.</li> </ul>

Note: \* Only 0 can be written to clear the flag.

### 42.3.20 Receive Reading Count H Register Bn (SCBRRCHRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRRCHR is a 16-bit readable/writable register. It is the upper 16 bits of the SCBRRCR register used by the receive-reading-count interrupt.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DAT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DAT[15:0]	H'0000	R/W	Upper 16 bits of the receive reading count data

### 42.3.21 Receive Reading Count L Register Bn (SCBRRCLRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRRCLR is a 16-bit readable/writable register. It is the lower 16 bits of the SCBRRCR register used by the receive-reading-count-compare interrupt.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DAT[15:0]	H'0000	R/W	<p>Lower 16 bits of the receive reading count data</p> <p>These bits function as 32-bit receive reading count data SCBRRCR together with the upper 16 bits of receive reading count data SCBRRCHR.</p> <p>It is incremented by 1 when SCBRFDR is read.</p> <p>When RRCCF bit in SCBSS2R is 1 and a value of SCBRRCR is greater than a value of SCBRRCCR, its value is updated by subtracting the SCBRRCCR value (SCBRRCR - SCBRRCCR).</p>

### 42.3.22 Receive Reading Count Compare H register Bn (SCBRRCCHRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRRCCHR is a 16-bit readable/writable register. It is the upper 16 bits of the SCBRRCCR register used by the receive-reading-count-compare interrupt.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DAT[15:0]	H'0000	R/W	Upper 16 bits of the receive reading count compare data

### 42.3.23 Receive Reading Count Compare L Register Bn (SCBRRCLRn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBRRCLR is a 16-bit readable/writable register. It is the lower 16 bits of the SCBRRCCR register used by the receive-reading-count-compare interrupt.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DAT[15:0]	H'0000	R/W	Lower 16 bits of the receive reading count compare data It functions as 32-bit receive reading count compare data SCBRRCCR together with the upper 16 bits of receive reading count compare data SCBRRCCR. The data in comparison with receive reading count register is set up. When RRCCF = 0 and the value of SCBRRCCR is greater than the value of SCBRRCCR, this counter value is initialized to H'0000.

### 42.3.24 Receive FIFO1 Register Bn (SCBFIFO1n)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFIFO1 is a read-only 8-bit register. A receive-reading-count-compare interrupt occurs when the number of times data have been received reaches (receive reading count compare value - 1). If the receive reading count value immediately after the interrupt generation is two or more, it does not change.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	DAT[7:0]	H'00	R	A receive-reading-count-compare interrupt indicates that the number of times data have been received has reached (SCBRRCCR-1).

**42.3.25 Receive FIFO0 Register Bn (SCBFIFO0n)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SCBFIFO0 is a read-only 8-bit register. When a receive-reading-count-compare interrupt occurs, it is the receive data equal to receive reading count compare value. If the receive reading count value immediately after the interrupt generation is two or more, it does not change.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	DAT[7:0]	H'00	R	A receive-reading-count-compare interrupt indicates that the number of times data have been received has reached SCBRRCR.

## 42.4 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 42.4.1 Overview

The SCIFB supports serial communications in asynchronous mode, in which synchronization is achieved character by character, and in clocked synchronous mode, in which synchronization is achieved with clock pulses. 256-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling high-speed continuous communications.

### 42.4.2 Asynchronous Mode

In the asynchronous mode, the transfer format is selected by the setting in SCBSMR as shown in Table 42.5. Features in this mode are as follows.

- Data length: 7 or 8 bits
- The addition of parity (even, odd or none) and the choice of stop-bit length (1 or 2 bits), along with the data length, determine the transfer format and character length.
- Receive error detection: Framing, parity, and overrun errors, receive-FIFO-data-full, receive-data-ready, and breaks.
- Independent indications of the number of data stored in the transmit and receive FIFOs.
- Clock source: Internal clock signal generated by the baud rate generator.

**Table 42.5 SCBSMR Settings for Serial Transfer Format Selection**

SCBSMR Setting				Mode	SCIFB Transfer Format		
Bit 7	Bit 6	Bit 5	Bit 3		Data Length	Parity Bit	Stop Bit Length
C/A#	CHR	PE	STOP				
0	0	0	0	Asynchronous mode	8-bit data	None	1 bit
			1				2 bits
		1	0			Provided	1 bit
			1			2 bits	
	1	0	0		7-bit data	None	1 bit
			1				2 bits
		1	0			Provided	1 bit
			1			2 bits	
1	*	*	*	Clocked synchronous mode	8-bit data	None	None

Note: \* Don't care

### 42.4.3 Serial Operation in Asynchronous Mode

#### (1) Data Transfer Format

Table 42.6 shows the transfer formats that can be used in asynchronous mode. Any of eight transfer formats can be selected according to the SCBSMR settings.

**Table 42.6 Serial Transfer Formats**

SCBSMR Settings			Serial Transfer Format and Frame Length												
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	S	8-bit data								STOP			
		1	S	8-bit data								STOP	STOP		
	1	0	S	8-bit data								P	STOP		
		1	S	8-bit data								P	STOP	STOP	
1	0	0	S	7-bit data							STOP				
		1	S	7-bit data							STOP	STOP			
	1	0	S	7-bit data							P	STOP			
		1	S	7-bit data							P	STOP	STOP		

[Legend]

S: Start bit

STOP: Stop bit

P: Parity bit

#### (2) Clock

An internal clock signal generated by the on-chip baud rate generator provides the transfer clock for SCIFB.

#### (3) Data Transfer Operations:

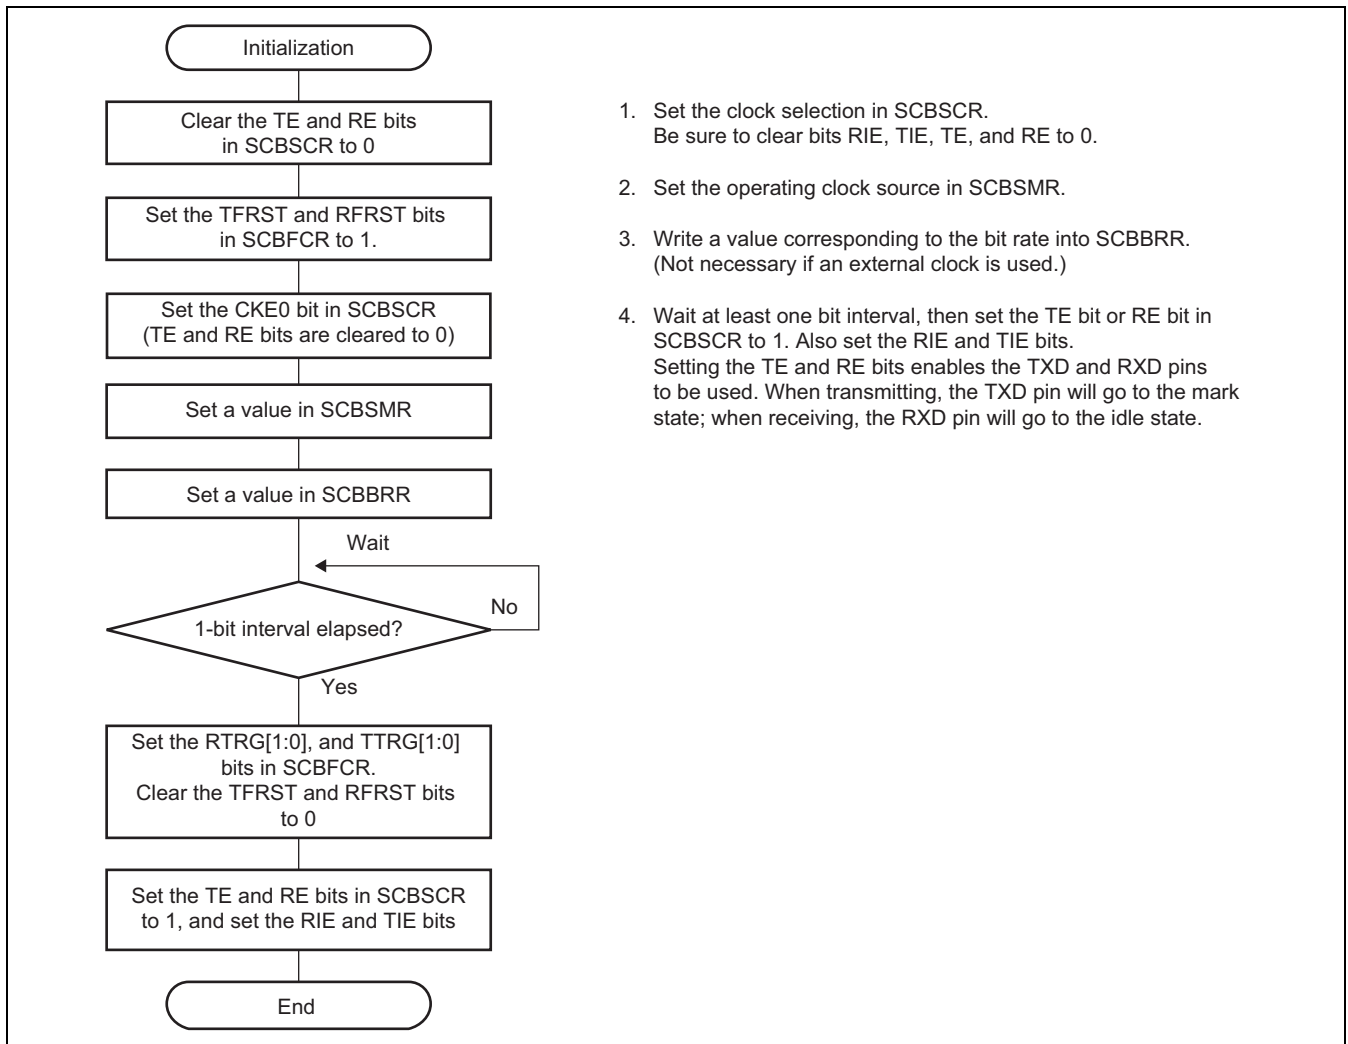

##### 1. SCIFB initialization

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCBSCR to 0, then initialize the SCIFB as described below.

When the transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCBTSR is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCBSSR, SCBFTDR, or SCBFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCBSSR has been set to 1. Clearing to 0 can also be performed during transmission, but the data lines that transmit the data will go to the high-impedance state after the clearance.

Before setting TE to 1 again to start transmission, the TFRST bit in SCBFCR should first be set to 1 to reset SCBFTDR.

Figure 42.2 is an example of flow for the SCIFB initialization.

1. Set the clock selection in SCBSCR. Be sure to clear bits RIE, TIE, TE, and RE to 0.
2. Set the operating clock source in SCBSMR.
3. Write a value corresponding to the bit rate into SCBBRR. (Not necessary if an external clock is used.)
4. Wait at least one bit interval, then set the TE bit or RE bit in SCBSCR to 1. Also set the RIE and TIE bits. Setting the TE and RE bits enables the TXD and RXD pins to be used. When transmitting, the TXD pin will go to the mark state; when receiving, the RXD pin will go to the idle state.

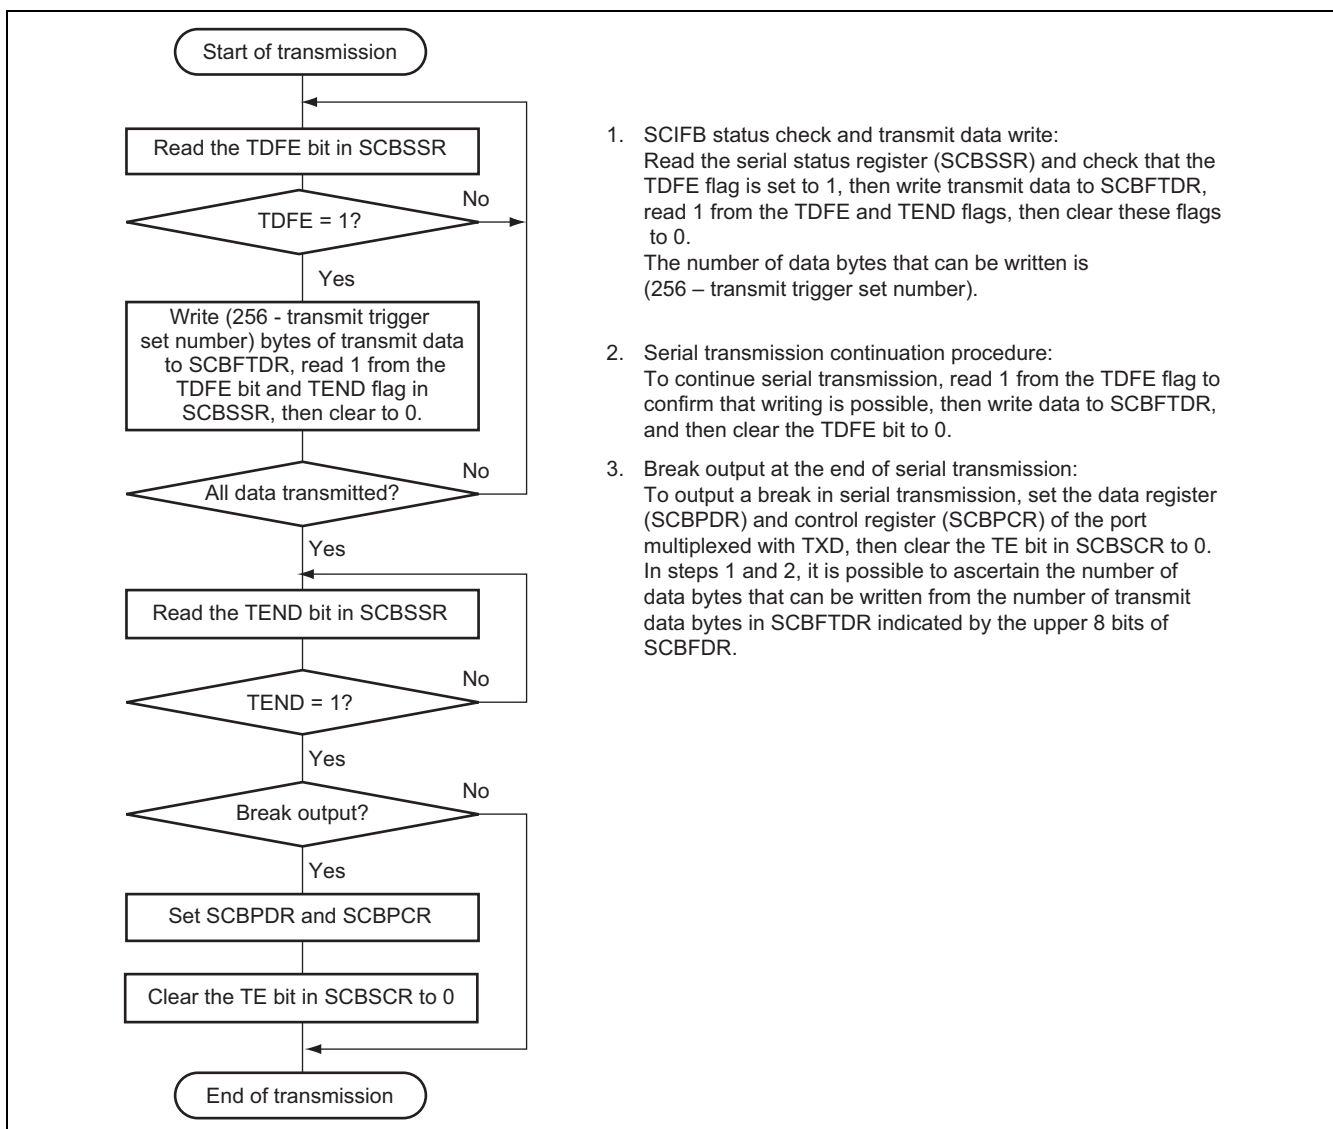

Figure 42.2 Example of Flow for SCIFB Initialization

2. Serial data transmission

Figure 42.3 an example of flow for the serial transmission.

Use the following procedure for serial data transmission after enabling the SCIFB for transmission.

1. SCIFB status check and transmit data write:  
Read the serial status register (SCBSSR) and check that the TDFE flag is set to 1, then write transmit data to SCBFTDR, read 1 from the TDFE and TEND flags, then clear these flags to 0.  
The number of data bytes that can be written is (256 – transmit trigger set number).
2. Serial transmission continuation procedure:  
To continue serial transmission, read 1 from the TDFE flag to confirm that writing is possible, then write data to SCBFTDR, and then clear the TDFE bit to 0.
3. Break output at the end of serial transmission:  
To output a break in serial transmission, set the data register (SCBPDR) and control register (SCBPCR) of the port multiplexed with TXD, then clear the TE bit in SCBSCR to 0. In steps 1 and 2, it is possible to ascertain the number of data bytes that can be written from the number of transmit data bytes in SCBFTDR indicated by the upper 8 bits of SCBFDR.

Figure 42.3 Example of Flow for Serial Transmission

In serial transmission, the SCIFB operates as described below.

- A. When data is written into SCBFTDR, the SCIFB transfers the data from SCBFTDR to SCBTSR and starts transmitting. Confirm that the TDFE flag in SCBSSR is set to 1 before writing transmit data to SCBFTDR. The number of data bytes that can be written is not less than (256 – transmit trigger set number).
- B. When data is transferred from SCBFTDR to SCBTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCBFTDR. When the number of transmit data bytes in SCBFTDR falls to or below the transmit trigger number set in SCBFCR, the TDFE flag is set. If the TIE bit in SCBSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

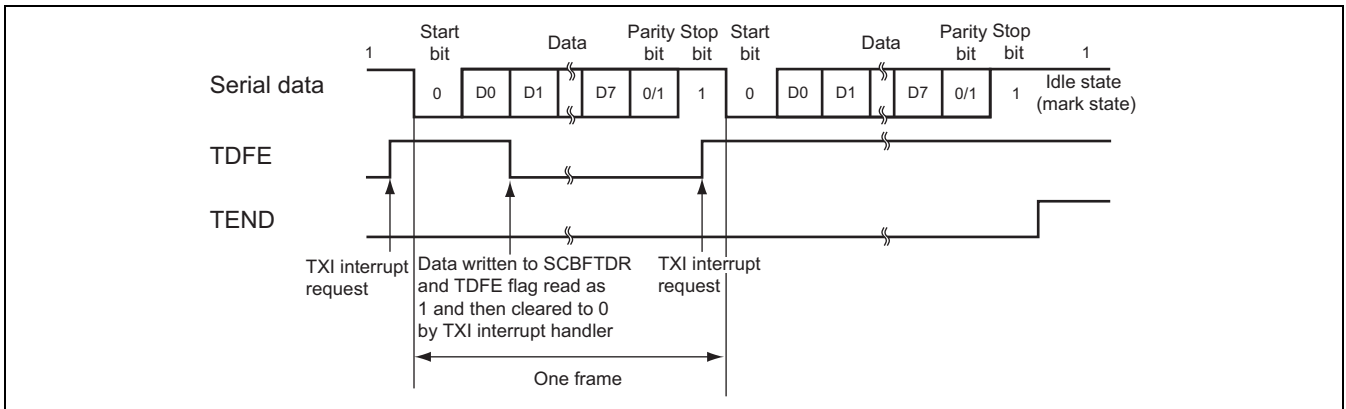

When the transmit data stop function is used and the number of data bytes set in SCBTDSR is matched, transmit operation is stopped and the TSF flag in SCBSSR is set. If the TSIE bit in SCBSCR is set to 1, a transmit-data-stop interrupt (TDI) request is generated. The vectors of TXI and TDI are the same.

The serial transmit data is sent from the TXD pin in the following order.

- a. Start bit: One logic-0 bit is output.
  - b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - c. Parity bit: One parity bit (even or odd parity) is output.
  - d. A format in which a parity bit is not output can also be selected.
  - e. Stop bit(s): One or two logic-1 bits (stop bits) are output.
  - f. Mark state: Output of 1 is continued until the start bit is sent to start the next transmission.
- C. The SCIFB checks the SCBFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCBFTDR to SCBTSR, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCBSSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output.

Figure 42.4 shows an example of the operation for transmission in asynchronous mode.

**Figure 42.4 Example of Transmit Operation (Example with 8-Bit Data, Parity, and One Stop Bit)**

- Transmit data stop function

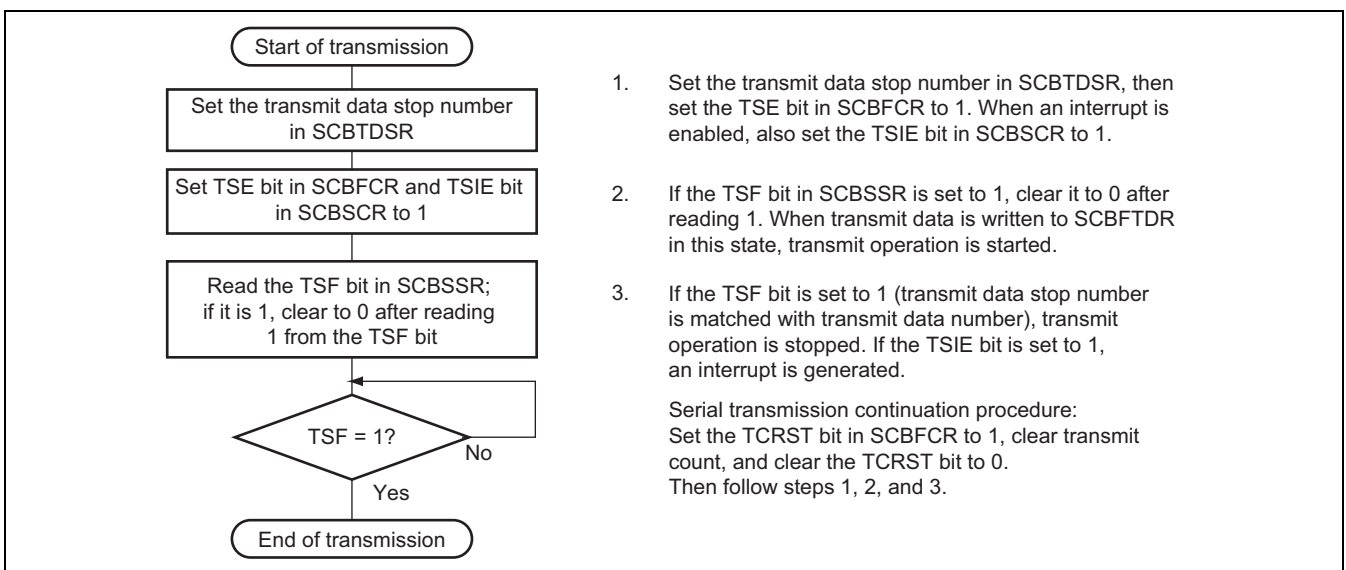

When the value in SCBTDSR equals the number of transmitted data bytes, this function stops the transmit operation. Interrupts can be generated and the DMAC can be activated by setting the TSIE bit (interrupt enable bit) to 1.

Figure 42.5 shows an example of operation for the transmit data stop function.

**Figure 42.5 Example of Transmit Data Stop Function**

Figure 42.6 shows a flowchart for the transmit data stop function.

**Figure 42.6 Transmit Data Stop Function Flowchart**

## 3. Serial data reception

Figures 42.7 and 42.8 are examples of flow for the serial reception.

Use the following procedure for serial data reception after enabling the SCIFB for reception.

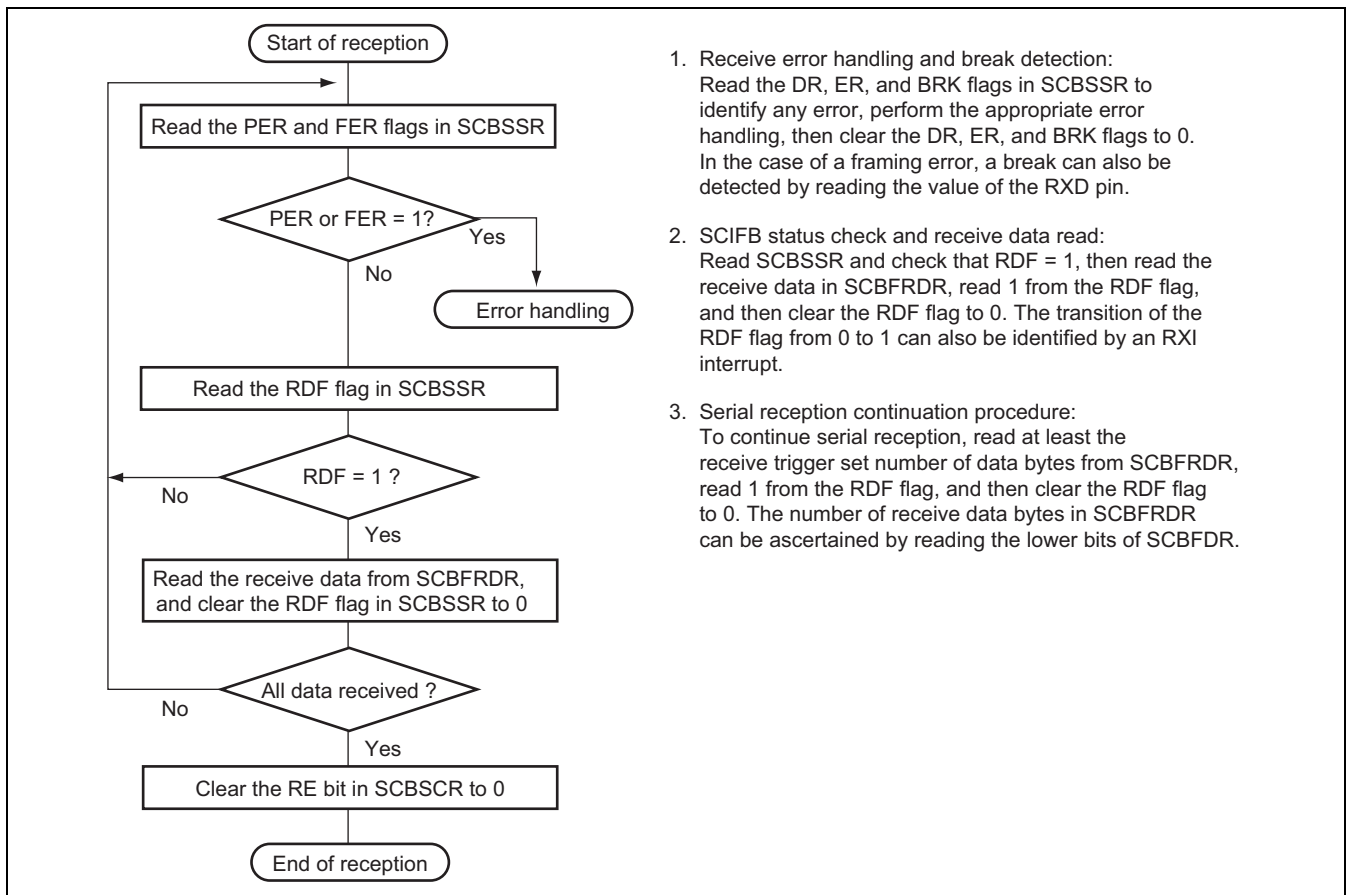

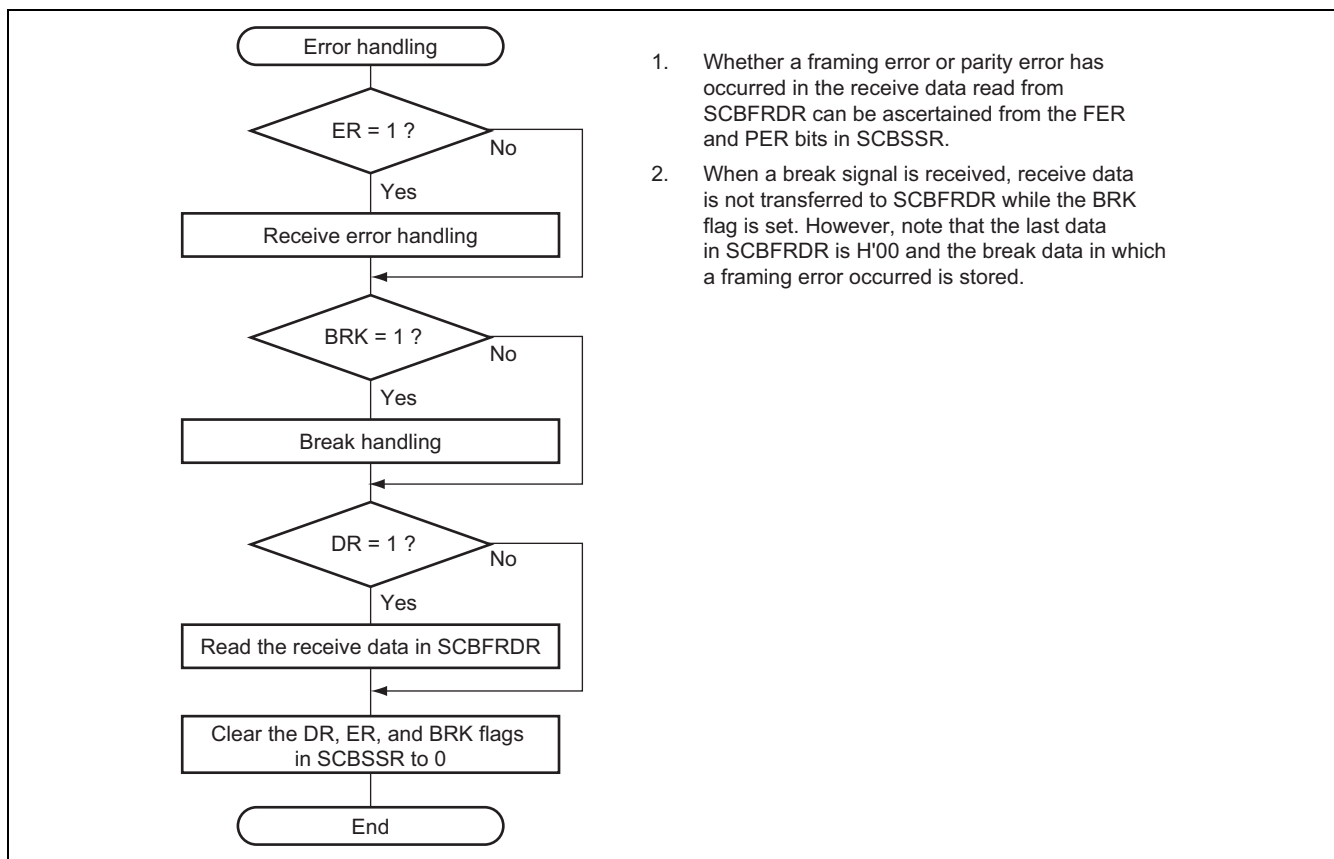

Figure 42.7 Example of Flow for Serial Reception (1)

**Figure 42.8 Example of Flow for Serial Reception (2)**

In serial reception, the SCIFB operates as described below.

- A. The SCIFB monitors the communication line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
- B. The received data is stored in SCBRSR in LSB-to-MSB order.
- C. The parity bit and stop bit are received.

After receiving these bits, the SCIFB carries out the following checks.

- a. Stop bit check: The SCIFB checks to see if the value in the stop bit position is 1. If the two-stop-bit setting has been made, only the value in the first stop-bit position is checked.
- b. The SCIFB checks whether received data can be transferred from SCBRSR to SCBFRDR.
- c. Break check: The SCIFB checks to confirm that the BRK flag is 0, indicating that the SCIFB is not in the break state.

If all the above checks are passed, the receive data is stored in SCBFRDR.

Note: Reception continues when a receive error (framing error or parity error) occurs.

- D. If the RIE bit in SCBSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

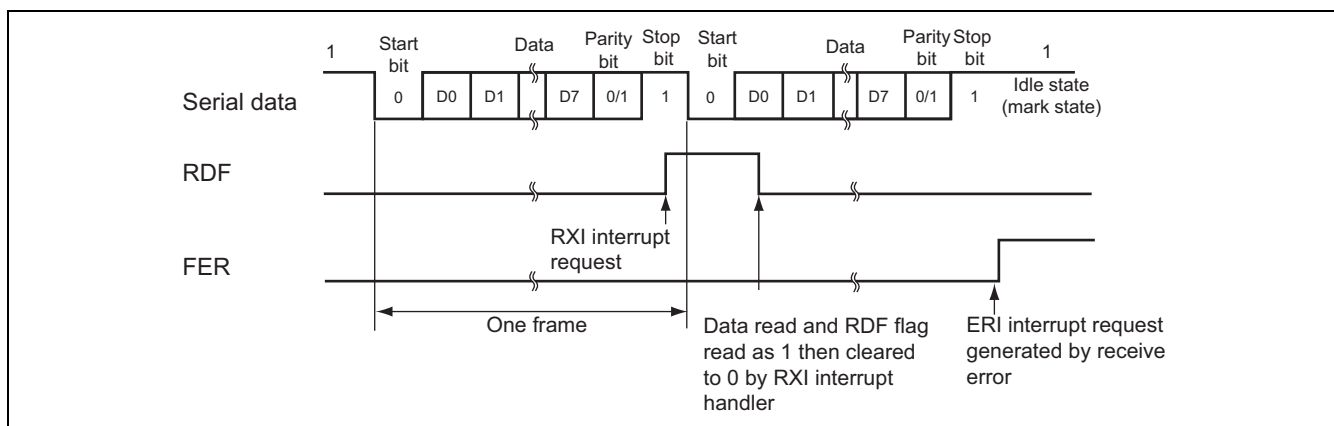

If the ERIE bit in SCBSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the BRIE bit in SCBSCR is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

If the DRIE bit in SCBSCR is set to 1 when the DR flag changes to 1, a receive-data-ready interrupt (DRI) request is generated.

The vectors of each interrupt source are the same.

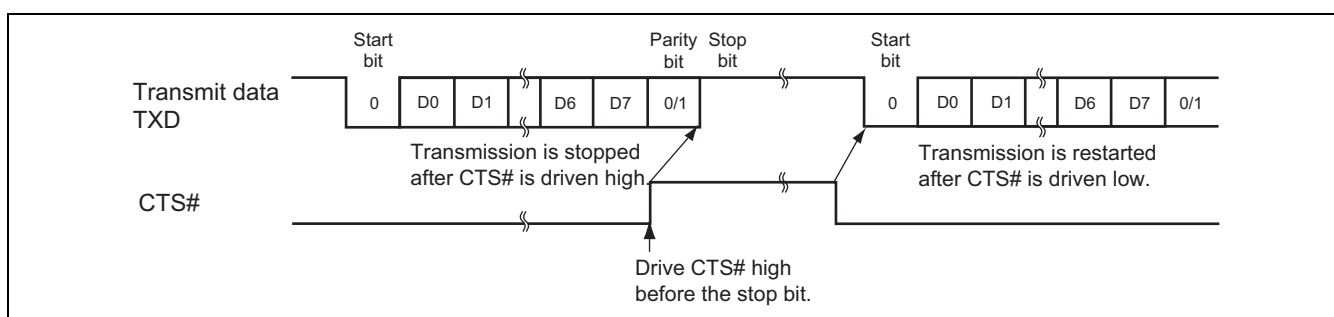

Figure 42.9 shows an example of the operation for reception in asynchronous mode.

**Figure 42.9 Example of SCIFB Receive Operation (Example with 8-Bit Data, Parity, One Stop Bit)**

The SCIFB has a modem function that allows the stoppage and resumption of transmission according to the input value of CTS#. Setting CTS# to 1 places the transmission line in the mark state after transmission of the current frame. When CTS# is set to 0, the next frame for transmission is output, with a start bit as its leader.

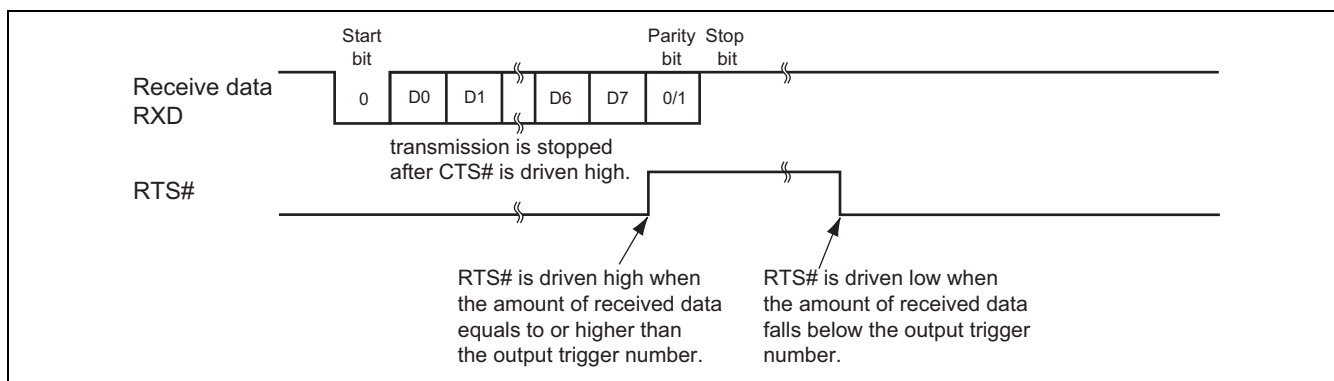

Figure 42.10 shows an example of the operation of CTS# control.

**Figure 42.10 Example of CTS# Control Operation**

The RTS# signal is driven high when the modem function is in use and the received data stored in the receive FIFO register (SCBFRDR) equals or exceeds the number of the RTS# output triggers.

Figure 42.11 shows an example of the operation for RTS# control.

**Figure 42.11 Example of RTS# Control Operation**

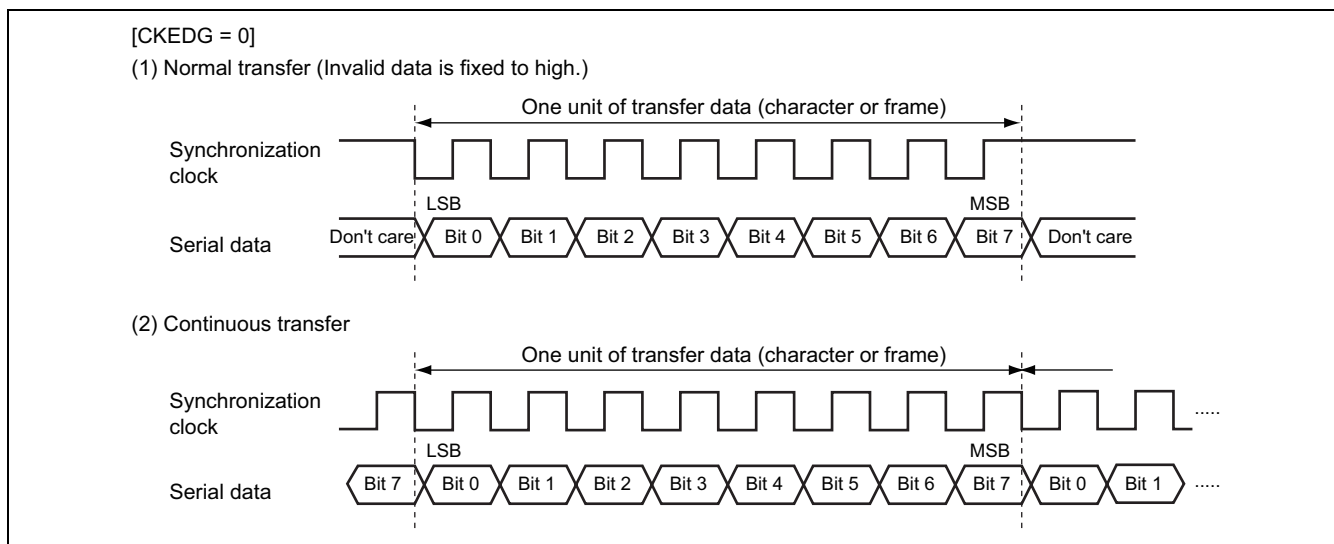

#### 42.4.4 Operation in Clocked Synchronous Mode

Clocked synchronous mode, in which data is transmitted or received in synchronization with clock pulses, is suitable for fast serial communications.

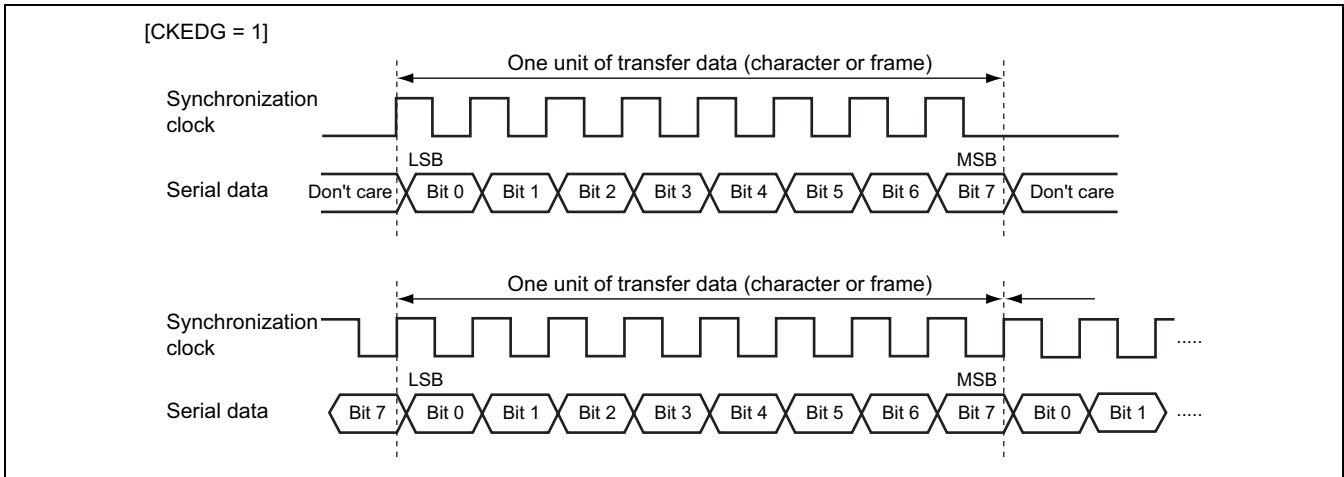

Since the transmitter and receiver are independent units in SCIFB, full-duplex communications can be achieved by sharing the clock. Both the transmitter and receiver have a 256-stage FIFO buffer structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Through the setting of the CKEDG bit, the format for clocked synchronous communications can be selected.

Figures 42.12 and 42.13 show the format for clocked synchronous communications.

**Figure 42.12 Data Format in Clocked Synchronous Communications (CKEDG = 0)**

**Figure 42.13 Data Format in Clocked Synchronous Communications (CKEDG = 1)**

In clocked synchronous serial communications, the data on the communications line is latched on one edge selected by the CKEDG bit in SCBSMR and is output until the next edge. Accuracy of data is guaranteed on the next edge (i.e. that in the opposite direction to the latching edge).

In serial communications, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communications line remains in the state of the last bit.

Data is received on the opposite edge to that on which data is output.

### (1) Data Transfer Format

A fixed 8-bit data format is used. No parity bit can be added.

### (2) Clock

An internal clock signal generated by the on-chip baud rate generator provides the transfer clock for SCIFB. For details on SCIFB clock source selection, see Table 42.4.

### (3) SCIFB Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCBSCR to 0, and then initialize the SCIFB as described below.

When changing the operating mode or transfer format, etc., the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCBTSR is initialized. Note that clearing the RE bit to 0 does not initialize the RDF, PER, FER, or ORER flag state or change the contents of SCBFRDR.

Figure 42.14 is an example of flow for the SCIFB initialization.

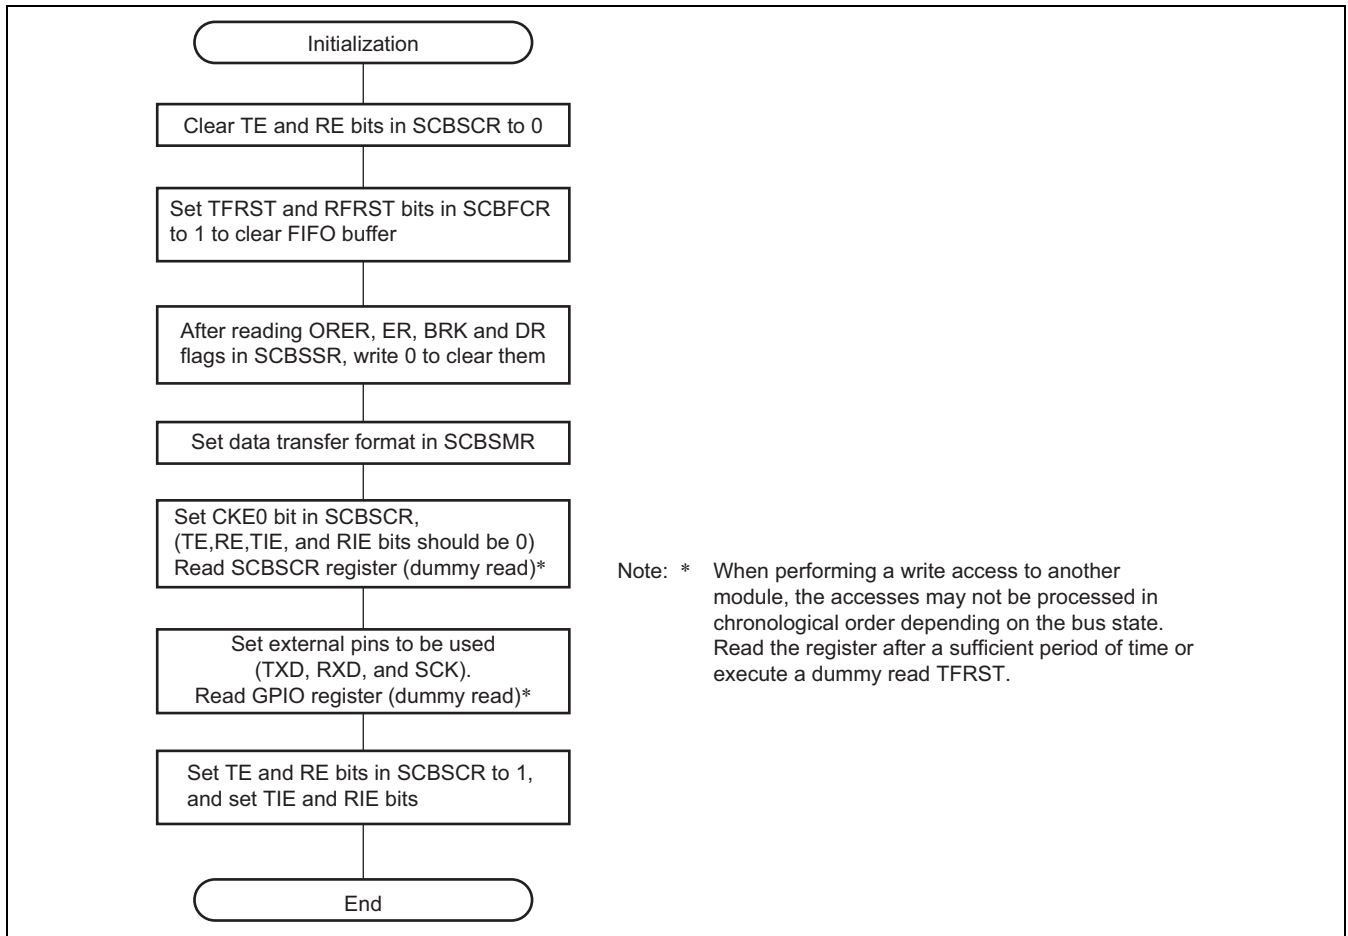

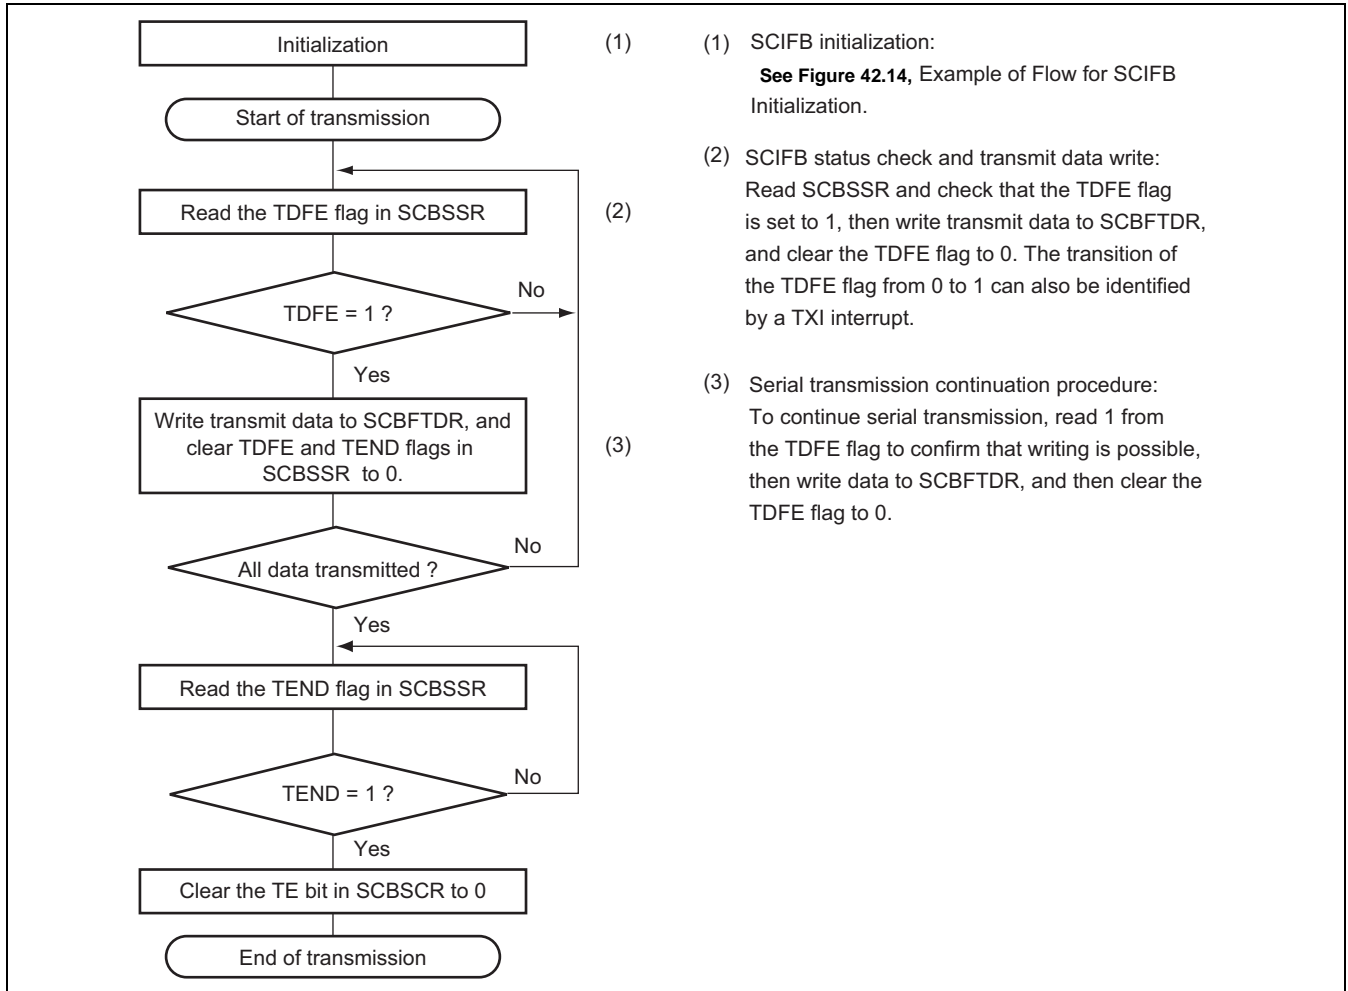

Figure 42.14 Example of Flow for SCIFB Initialization

**(4) Serial Data Transmission (Clocked Synchronous Mode)**

Figure 42.15 is an example of flow for the serial transmission.

Use the following procedure for serial data transmission after enabling the SCIFB for transmission.

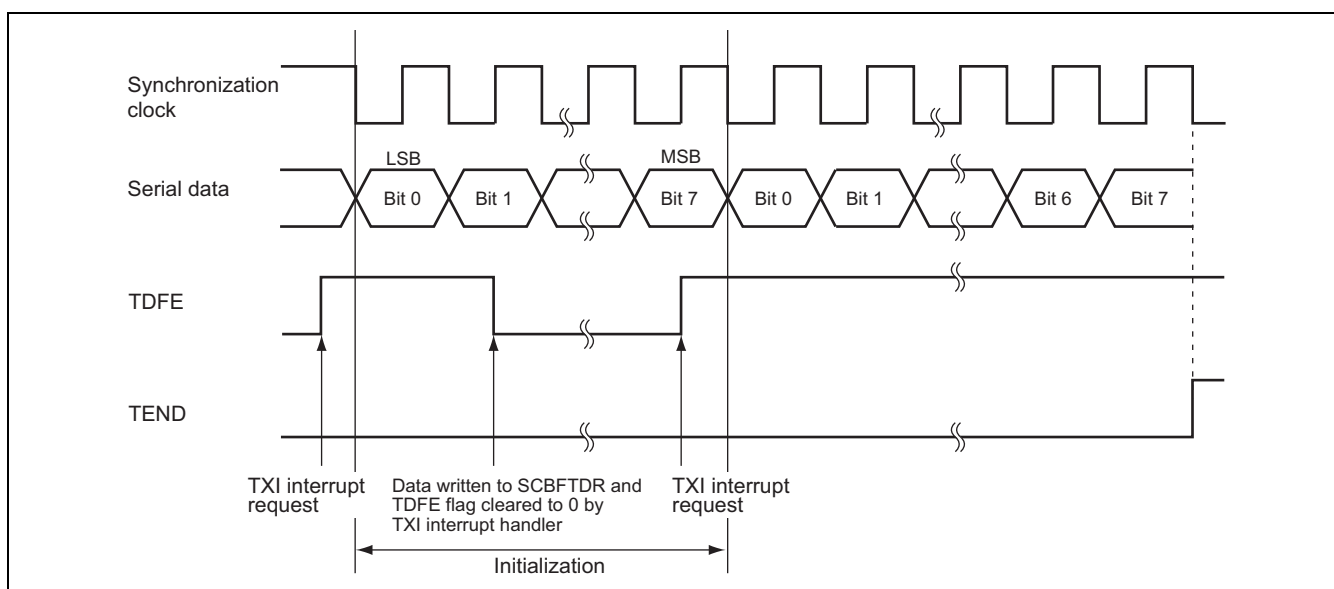

**Figure 42.15 Example of Flow for Serial Transmission**

In serial transmission, the SCIFB operates as described below.

1. When data is written into SCBFTDR, the SCIFB transfers data from SCBFTDR to SCBTSR and starts transmitting. Confirm that the TDFE flag in SCBSSR is set to 1 before writing transmit data to SCBFTDR. The number of data bytes that can be written is at least 16 – (transmit trigger set number).
2. When data is transferred from SCBFTDR to SCBTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCBFTDR. When the number of transmit data bytes in SCBFTDR falls to or below the transmit trigger number set in SCBFCR, the TDFE flag is set. If the TIE bit in SCBSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated. The SCIFB outputs data in synchronization with the synchronization clock. The serial transmit data is sent from the TXD pin in the LSB-first order.
3. The SCIFB checks the SCBFTDR transmit data at the timing for sending the last bit. If data is present, the data is transferred from SCBFTDR to SCBTSR, and then serial transmission of the next frame is started. If there is no transmit data, the TEND flag in SCBSSR is set to 1 after the last bit is sent, and the transmit data pin (TXD pin) retains the output state of the last bit.

Figure 42.16 shows an example of the SCIFB operation for transmission in clocked synchronous mode.

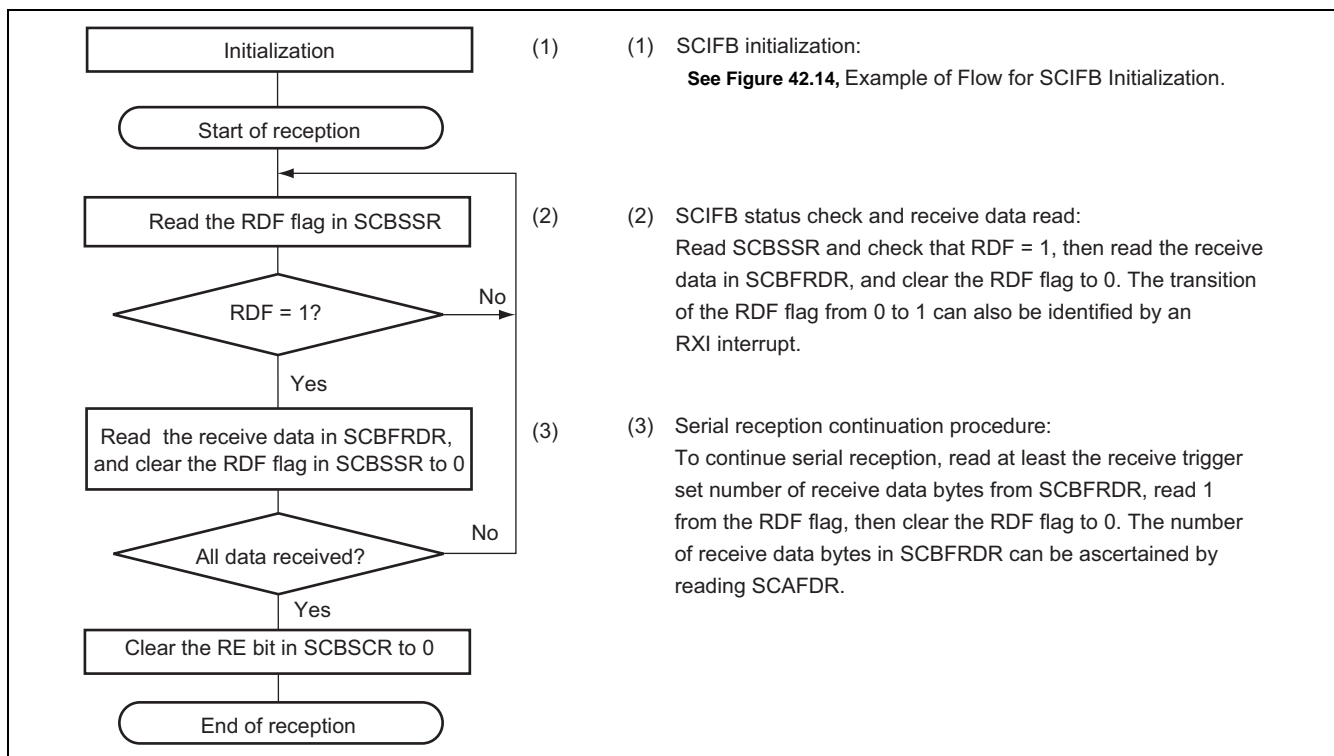

**Figure 42.16 Example of SCIFB Transmission in Clocked Synchronous Mode**

### (5) Serial Data Reception (Clocked Synchronous Mode)

Figure 42.17 is an example of flow for serial reception.

Use the following procedure for serial data reception after enabling the SCIFB for reception.

When switching the operating mode from asynchronous mode to clocked synchronous mode without initializing SCIFB, make sure that the ORER flag in SCBSSR, and PER and FER flags in SCBSSR are cleared to 0.

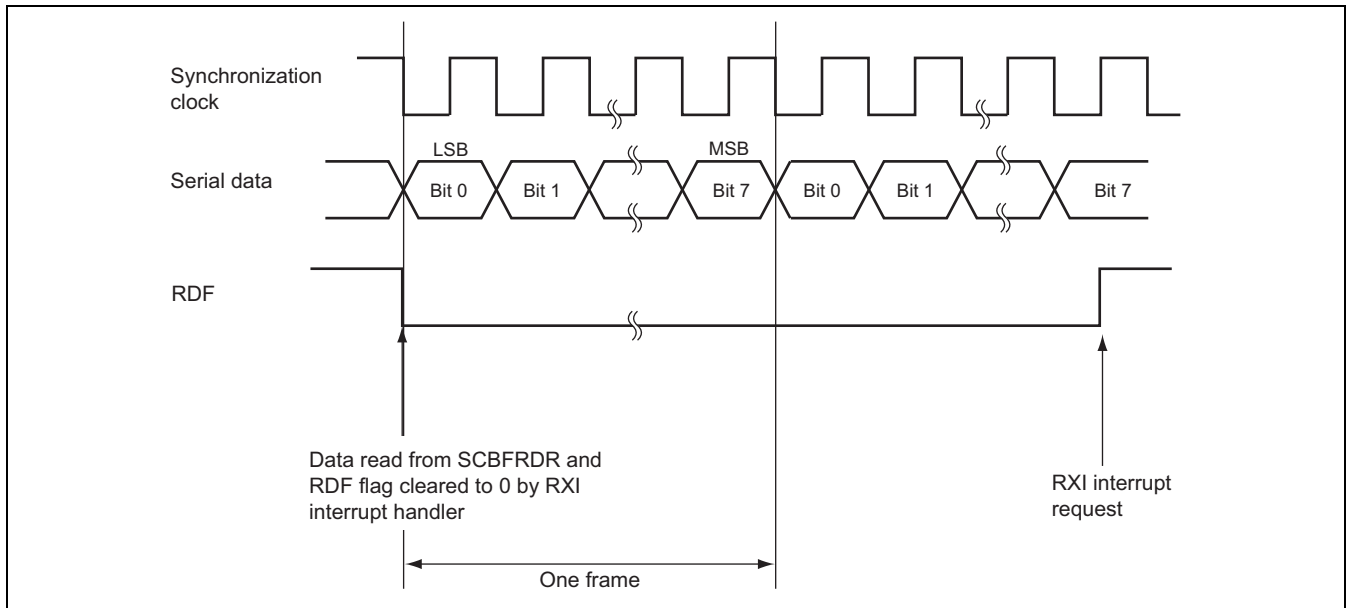

**Figure 42.17 Example of Flow for Serial Reception**

In serial reception, the SCIFB operates as described below.

1. The SCIFB starts reception in synchronization with the output of the synchronization clock.
2. The received data is stored in SCBRSR in LSB-to-MSB order.  
After receiving the data, the SCIFB checks whether the receive data can be transferred from SCBRSR to SCBFRDR. If this check is passed, the receive data is stored in SCBFRDR. If an overrun error is detected in the error check, reception cannot continue.
3. If the RIE bit in SCBSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

Figure 42.18 is an example of the reception in clocked synchronous mode.

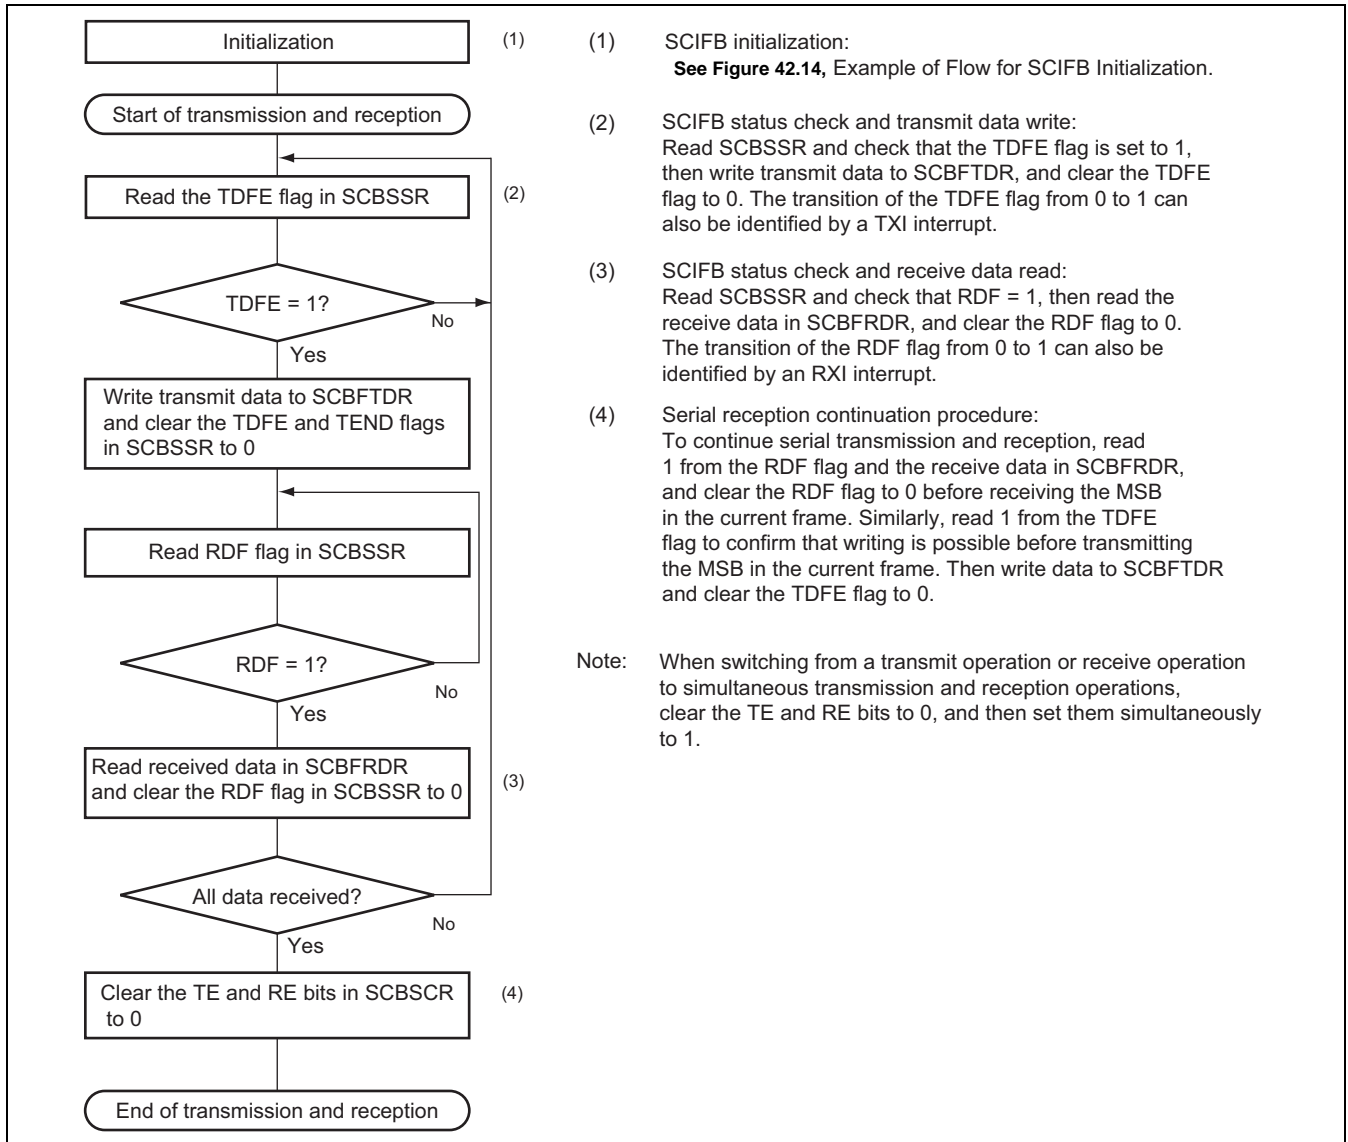

**Figure 42.18 Example of Reception in Clocked Synchronous Mode**

**(6) Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)**

Figure 42.19 is an example of flow for the simultaneous serial data transmission and reception.

Use the following procedure for simultaneous serial data transmission and reception after enabling the SCIFB for both the transmission and reception.

**Figure 42.19 Example of Flow for Simultaneous Serial Transmission and Reception**

## 42.5 SCIFB Interrupt Sources and DMAC

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

The SCIFB supports nine interrupts: receive-FIFO-data-full (RXI), transmit-FIFO-data-empty (TXI), receive-data-ready (DRI), break-receive (BRI), receive-error (ERI), transmit-data-stop (TDI), transmit-end (TENDPOSE), receive-data-count-compare (RCE), and receive-reading-count-compare (RRCC). The vectors of each interrupt source are the same.

Table 42.7 shows the interrupt sources. The RIE, TIE, DRIE, BRIE, ERIE, TSIE, TENDPOSE, and RCEE bits in SCBSCR, and RRCCE bit in SCBSC2R are used to enable or disable the respective interrupt sources.

If the TDFE flag in SCBSSR is set to 1, a TXI interrupt request is generated. When the TSF flag in SCBSSR is set to 1, a TDI interrupt request is generated. The DMAC can be activated for data transfer on generation of TXI and TDI interrupt requests. When data exceeding the transmit trigger set number is written to SCBFTDR by the DMAC, the DMAC transfer request is automatically cleared to 0. The DMAC requests of TXI and TDI are the same.

When the RDF flag in SCBSSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated for data transfer on generation of an RXI interrupt request. When receive data in SCBFRDR is read by the DMAC until the amount left is less than the receive trigger set number, the DMAC transfer request is automatically cleared to 0.

When using the DMAC for transmission/reception, set the DMAC to the DMAC transfer enabled state before making the SCIFB settings. Transmission/reception is complete when the DMA transfer is terminated.

When the ER, BRK, DR, RCEF, TENDPOS or TSF flag in SCBSSR or RRCCF flag in SCBSS2R is set to 1, an interrupt request is generated. Note that the vectors of each interrupt source are the same.

**Table 42.7 SCIFB Interrupt Sources**

Interrupt Source Type	DMAC Activation
Interrupt initiated by receive error (ER) , break (BRK), receive data count match (RCEF), receive reading counter compare (RRCCF), transmit end detect (TENDPOS), receive data ready (DR) or transmit data stop (TSF) flag	Not possible
Interrupt initiated by receive FIFO data full (RDF) flag	Possible
Interrupt initiated by transmit FIFO data empty (TDFE) flag	Possible

## 42.6 Receive-Reading-Count-Compare Interrupt

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

The receive-reading-count-compare interrupt occurs when a value of the receive reading count SCBRRCR is greater than a value of the receive-reading-count-compare SCBRRCCR.

The value of receive-reading-count-compare is set to SCBRRCCR.

The receive-reading-count-compare interrupt is enabled by setting the RRCCE bit in SCBSC2R to 1.

The SCBRRCR value is incremented by 1 when SCBRFDR is read.

When the receive-reading-count-compare interrupt occurs, it is followed by the operations below.

- The RRCCF bit in SCBSS2R is set to 1.
- The value of SCBRRCCR is subtracted from that of SCBRRCR.
- SCBRRCCR is initialized to H'0000.

When using DMA transfer for the received data, there is a difference (of two max.) between the count value of the SCBRRCR and the data number transferred to RAM and so on because of the time lag. When SCBRRCR value is less than two after the interrupt occurrence, the DMA transfer may not be completed. In this case, the data should be read from SCBFIFO0 and SCBFIFO1.

SCBFIFO1: Indicates the (SCBRRCR-1)th data before SCBRRCR is subtracted when a receive-reading-count-compare interrupt occurs.

SCBFIFO0: Indicates the (SCBRRCR)th data before SCBRRCR is subtracted when a receive-reading-count-compare interrupt occurs.

The interrupt source clearance should be executed after setting the next interrupts and just before return from the interrupt.

## 42.7 Multibyte Transfer

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 42.7.1 Basic Multibyte Settings

Table 42.8 shows the SCIFB settings and DMA settings for multibyte transfer.

**Table 42.8 SCIFB Settings and DMA Settings for Multibyte Transfer**

Transfer Mode	Transmission/ Reception	SCIFB				DMAC	
		SCBMBR		SCBFCR		DMACHCR TS[3:0]	DMATCR TCR[23:0]
		MBTON	MBRON	RTRG [1:0]	TTRG [1:0]		
1-byte transfer	Transmission	1	—	B'11	—	B'0000	Transfer count
	Reception	—	1	—	B'11	B'0000	Transfer count
16-byte transfer	Transmission	1	—	B'10	—	B'1010	Transfer count/16 (roundup)
	Reception	—	1	—	B'10	B'1010	Transfer count/16 (roundup)
32-byte transfer	Transmission	1	—	B'01	—	B'1101	Transfer count/32 (roundup)
	Reception	—	1	—	B'01	B'1101	Transfer count/32 (roundup)

### 42.7.2 Specifying Transfer Count

#### (1) Number of Transfer Data Bytes for Transmission

In 16-byte or 32-byte transfer mode, data more than the transfer count is transferred to the transmit FIFO buffer. Therefore, specify the transfer count in SCBTDSR, and set the TSE bit in SCBFCR to 1 to enable the transmit data stop function before starting DMA transfer.

#### (2) Number of Transfer Data Bytes for Reception

In 16-byte or 32-byte transfer mode, when the receive data remaining in the receive FIFO buffer is less than 16 bytes (or 32 bytes), the data is still left in the FIFO buffer. When the RCEF bit in SCBSSR is set to 1 by setting the RCE bit in SCBFCR and the RCECRON bit in SCBMBR to 1, 16-byte (or 32-byte) transfer requests are made continuously to the DMAC until the receive FIFO buffer becomes empty. In this case, the DMAC attempts to transfer data more than the number of received data bytes, causing an underflow error.

When the ADDREQ bit in SCBMBR is set to 1 after the reception is completed, 16-byte (or 32-byte) transfer requests are made to the DMAC until the receive FIFO buffer becomes empty.

## 42.8 Usage Notes

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

Note the following when using SCIFB.

### (1) Writing Data to SCBFTDR and TDFE Flag

The TDFE flag in SCBSSR is set when the number of transmit data bytes written in SCBFTDR has fallen to or below the transmit trigger number set by bits TTRG[1:0] in SCBFCR. After TDFE is set, transmit data up to the number of empty bytes in SCBFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCBFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE should therefore be cleared when SCBFTDR contains transmit data more than the transmit trigger number bytes.

The number of transmit data bytes in SCBFTDR is indicated by the T[8:0] bits in SCBTFDR.

### (2) Reading Data from SCBFRDR and RDF Flag

The RDF flag in SCBSSR is set when the number of receive data bytes in SCBFRDR has become equal to or greater than the receive trigger number set by bits RTRG[1:0] in SCBFCR. After RDF is set, receive data equivalent to the trigger number can be read from SCBFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCBFRDR is still equal to or greater than the trigger number after a read, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all receive data has been read.

The number of receive data bytes in SCBFRDR is indicated by the R[8:0] bits in SCBRFDR.

### (3) Break Detection and Processing

Break signals can be detected by reading the RXD pin directly when a framing error (FER) is detected. Since the input from the RXD pin is always 0 in the break state, the FER flag is set and the parity error (PER) flag may also be set.

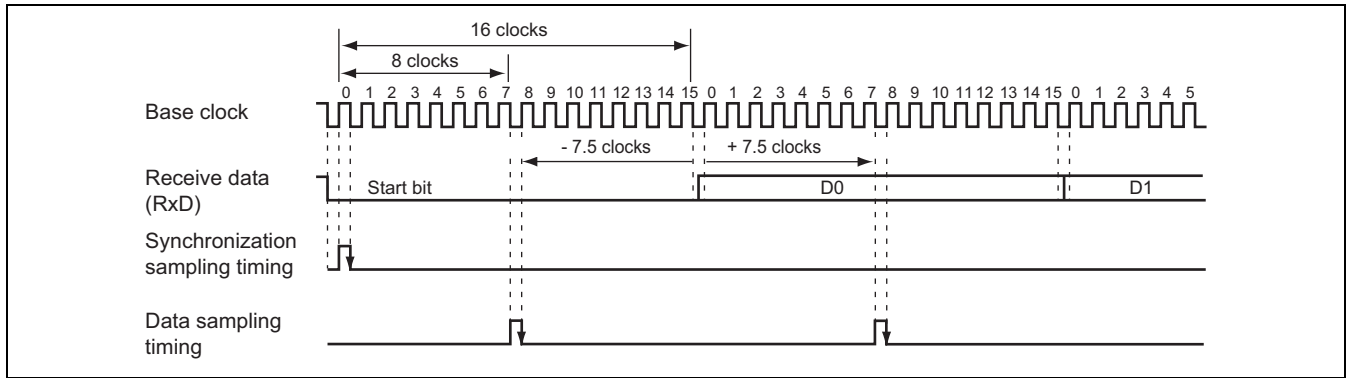

Although the SCIFB stops transferring receive data to SCBFRDR after receiving a break, it continues the receive operation.

### (4) Receive Data Sampling Timing and Receive Margin

As an example, when the sampling rate is 1/16, the SCIFB operates on a base clock with a frequency of 8 times the transfer rate.

In reception, the SCIFB synchronizes internally by sampling the fall of the start bit with the base clock. Receive data is latched at the rising edge of the eighth base clock pulse (when the sampling rate is 1/16).

The receive data sampling timing is shown in Figure 42.20.

**Figure 42.20 Receive Data Sampling Timing**

The receive margin can therefore be expressed as shown in equation (1).

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \dots (1)$$

- M: Receive margin (%)
- N: Ratio of clock frequency to bit rate (N = 16)
- D: Clock duty cycle (D = 0 to 1.0)
- L: Frame length (L = 9 to 12)
- F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation (2).

When D = 0.5 and F = 0:

$$M = (0.5 - 1 / (2 \times 16)) \times 100\% = 46.875\% \dots (2)$$

This is a theoretical value. A reasonable margin to allow in system designs is the value above (46.875%) plus 20 to 30%.

**(5) State of the PAD Pin when the Pin for SCIFB is Selected**

The table below shows the PAD pin state when the pin for the SCIFB is selected.

**Table 42.9 State of PAD**

When the pin for SCIFB is selected	TXD	RXD	RTS#	CTS#	SCK
PAD enable	1 (enabled)	1 (enabled)	RTSC in SCBPCR (initial value:1 serial port enabled), and MCE in SCBFCR (initial value: 0, disabled)	MCE in SCBFCR (initial value: 0, disabled)	SCKC in SCBPCR (initial value:1 serial port enabled), and CKE0 in SCBSCR (initial value: 0, disabled)
Pin state	Output (initial value: 1)	Input	Port output (initial value: 1)	Input	Port output (initial value: 0)
Pull-up/-down	—	Pull-up required	—	Pull-up required	—
Remarks	—	SCIFB fixes RXD to 1 internally when RE in SCBSCR = 0.	RTS# is Hi-Z when RTSC in SCBPCR = 0, and MCE in SCBFCR = 0.	SCIFB fixes CTS# to 0 internally when MCE in SCBFCR = 0.	SCK is Hi-Z when SCKC in SCBPCR = 0, and CKE0 in SCBSCR = 0.

## 43. High Speed Serial Communication Interface with FIFO (HSCIF)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 43.1 Overview

The RZ/G series products have a high speed serial communication interface with built-in FIFO buffers (high-speed serial communication interface with FIFO: HSCIF) that handles asynchronous communication. The HSCIF has two 128-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. RZ/G1H have 2 channels of HSCIF. RZ/G1M, RZ/G1N and RZ/G1E have 3 channels. All functions of each channel are same.

#### 43.1.1 Features

The HSCIF has the following features.

- Asynchronous serial communication mode
 

The HSCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support universal asynchronous receiver/transmitter (UART) or asynchronous communication interface adapter (ACIA). There is a choice of eight serial data transfer formats.

  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even/odd/none
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection:
 

A break is detected when a framing error lasts for more than 1 frame length at space 0 (low level).

When a framing error occurs, a break can also be detected by reading the HRX pin level directly from the serial port register (HSSPTR).
  - Sampling rate: Variable (integer number from 8 to 32)
- Capable of full-duplex communication
 

The HSCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 128-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected
 

The HSCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources
 

The HSCIF has eight types of interrupt sources: receive-data-ready, receive-FIFO-data-full, break detection, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out, and enables any of them to be requested independently.
- DMA data transfer
 

When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- Modem control functions (HRTS# and HCTS#) are stored.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- A receive data ready (DR) or a timeout error (TO) can be detected during reception.

43.1.2 Block Diagram

Figure 43.1 shows the HSCIF block diagram.

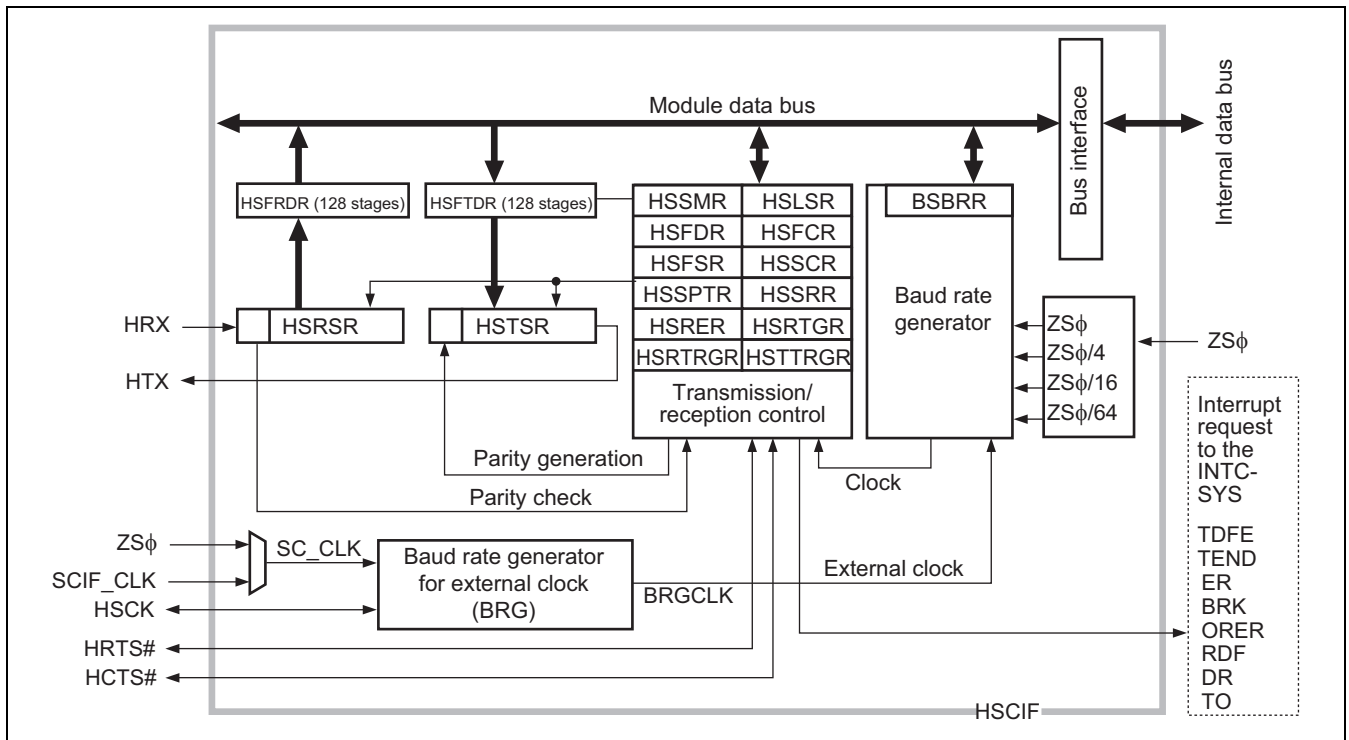

Figure 43.1 HSCIF Block Diagram

### 43.1.3 Pin Configuration

Table 43.1 shows the HSCIF pin configuration. These pins are multiplexed in other functions, so that the usage of the pins are may be restricted depending on the multiplexed pin settings.

**Table 43.1 Pin Configuration**

				<b>RZ/G Series Products</b>			
<b>Name</b>	<b>Function</b>	<b>I/O</b>	<b>Descriptions</b>	<b>RZ/G1H</b>	<b>RZ/G1M</b>	<b>RZ/G1N</b>	<b>RZ/G1E</b>
HSCK0	Serial clock pin	I/O	Clock I/O	√	√	√	√
HSCK1	Serial clock pin	I/O	Clock I/O	√	√	√	√
HSCK2	Serial clock pin	I/O	Clock I/O	—	√	√	√

Notes: 1. Only 0 can be written to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.

2. Only 0 can be written to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.

## 43.2 Register Descriptions

### 43.2.1 Receive Shift Register (HSRSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSRSR is a register that receives serial data.

The HSCIF sets serial data input to the HSRSR from the HRX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO register HSFRDR, automatically.

HSRSR cannot be read from and written to by the CPU.

### 43.2.2 Receive FIFO Data Register (HSFRDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSFRDR is a 128-stage FIFO register that stores received serial data.

When HSCIF has received one byte of serial data, it transfers the received data from the receive shift register (HSRSR) to HSFRDR for storage, and reception is thus completed. HSRSR is then ready for reception, and is capable of receiving up to 128 consecutive bytes of data before HSFRDR is full.

HSFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in HSFRDR. When HSFRDR is full of receive data, subsequent serial data is lost.

HSFRDR is read as an undefined value after a power-on reset.

### 43.2.3 Transmit Shift Register (HSTSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSTSR is a register that transmits serial data.

To perform serial data transmission, the HSCIF first transfers transmit data from the transmit fifo data register (HSFTDR) to HSTSR, then sends the data to the HTX pin starting with the LSB (bit 0). When transmission of one byte is completed, the HSCIF transfers the next transmit data from HSFTDR to HSTSR automatically, then starts transmission.

HSTSR cannot be read from and written to directly by the CPU.

### 43.2.4 Transmit FIFO Data Register (HSFTDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSFTDR is an 8-bit FIFO register of 128 stages that stores data for serial transmission.

If HSTSR is empty after transmit data has been written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts serial transmission.

HSFTDR is a write-only register and cannot be read from by the CPU. Writing further data to HSFTDR is no longer possible when it is full. Attempts at writing data to the register in this situation are ignored.

HSFTDR is read as an undefined value on a power-on reset.

### 43.2.5 Serial Mode Register (HSSMR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CHR	PE	O/E#	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W

HSSMR is a 16-bit register that sets the HSCIF's serial transfer format and selects the baud rate generator clock source.

HSSMR can always be read from and written to by the CPU.

HSSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	CHR	0	R/W	Character Length Selects 7 or 8 bits for data length. When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (HSFTDR) is not transmitted. 0: 8 bits 1: 7 bits
5	PE	0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception or not. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.
4	O/E#	0	R/W	Parity Mode Selects either even or odd parity to use in parity addition and check. The O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. 0: Even parity 1: Odd parity When even parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is even. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is odd.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	<p>Stop Bit Length</p> <p>Selects 1 bit or 2 bits as the stop bit length.</p> <p>In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character.</p> <p>0: 1 stop bit*<sup>1</sup></p> <p>1: 2 stop bits*<sup>2</sup></p> <p>Notes: 1. In transmission, a single 1-bit (stop bit) is added to the end of a transmit character before it is sent.</p> <p>2. In transmission, two 1-bit (stop bits) are added to the end of a transmit character before it is sent.</p>
2	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
1, 0	CKS[1:0]	00	R/W	<p>Clock Select 1 and 0</p> <p>These bits select the clock source for the on-chip baud rate generator.</p> <p>The clock source can be selected from <math>ZS\phi</math>, <math>ZS\phi/4</math>, <math>ZS\phi/16</math>, and <math>ZS\phi/64</math>, according to the setting of bits CKS[1:0].</p> <p>00: <math>ZS\phi</math></p> <p>01: <math>ZS\phi/4</math></p> <p>10: <math>ZS\phi/16</math></p> <p>11: <math>ZS\phi/64</math></p>

**43.2.6 Serial Control Register (HSSCR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSSCR is a register that enables or disables transmission/reception by the HSCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the HSCIF.

HSSCR can always be read from and written to by the CPU.

HSSCR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TOT[1:0]	00	R/W	Set the time for a data ready (DR) or a timeout (TO) to be set in asynchronous mode. 00: 15 etu* 01: 31 etu 10: 47 etu 11: 63 etu Note: * ETU: Elementary Time Unit (time for transfer of one bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: • Setting the TDFE flag in HSFSR • Setting the TEND flag in HSFSR 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in HSSCR is pulled 0, if the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>Serial transmit data has been transferred from HSFTDR to HSTSR,</li> <li>The number of data bytes in HSFTDR is equal to or less than the transmit trigger count, and</li> <li>The TDFE flag in HSFSR is set to 1.</li> </ul> <p>Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of HSSCR is set to 1, if the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>Transmission was ended because there is no valid data in HSFTDR when the last bit of the transmit character in HSTSR was transmitted, and</li> <li>The TEND flag of HSFSR is set to 1.</li> </ul> <p>0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, disables transmit-end interrupt (TEND) request.</p> <p>1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.</p>
6	RIE	0	R/W	<p>Receive Interrupt Enable</p> <p>Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in HSFSR is set to 1, a receive-data-ready interrupt request when the DR flag in HSFSR is set to 1, a receive-error interrupt request when the ER flag in HSFSR is set to 1, a break interrupt request when the BRK flag in HSFSR is set to 1, and an overrun error interrupt request when the ORER flag in HSLSR is set to 1.</p> <p>0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.</p> <p>1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.</p>
5	TE	0	R/W	<p>Transmit Enable</p> <p>Enables or disables the start of HSCIF serial transmission. The HSCIF starts serial transmission when transmit data is written to the HSFTDR while TE is 1. Before setting TE to 1, set HSSMR and HSFCR to specify the transmission format and reset the transmit FIFO.</p> <p>0: Disables transmission.</p> <p>1: Enables transmission.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	<p>Receive Enable</p> <p>Enables or disables the start of HSCIF serial reception. When RE is 1, the HSCIF starts serial reception by detecting a start bit. Before setting RE to 1, set HSSMR and HSFCR to specify the reception format and reset the receive FIFO.</p> <p>0: Disables reception.*</p> <p>1: Enables reception.</p> <p>Note: * Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.</p>
3	REIE	0	R/W	<p>Receive Error Interrupt Enable</p> <p>Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.</p> <p>0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.*</p> <p>1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.</p> <p>Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.</p>
2	TOIE	0	R/W	<p>Timeout Interrupt Enable</p> <p>Enables or disables generation of timeout interrupt (TO) requests when the TO flag in HSLSR is set to 1.</p> <p>0: Disables timeout interrupts (TO).</p> <p>1: Enables timeout interrupts (TO).</p>
1, 0	CKE[1:0]	00	R/W	<p>Clock Enable 1 and 0</p> <p>These bits select the HSCIF clock source and enables or disables the clock output from the HSCK pin.</p> <p>Whether the HSCK pin functions as a serial clock output pin or a serial clock input pin is determined by CKE[1: 0] bit settings.</p> <p>See Table 43.3 for the bit settings.</p>

**Table 43.3 Clock Selection**

CKE[1]	CKE[0]	Clock Source	HSCK Pin
0	0	Internal clock (ZS $\phi$ , ZS $\phi$ /4, ZS $\phi$ /16, and ZS $\phi$ /64)	The HSCK pin is not used.
0	1		The HSCK pin functions as an input pin (input signals are ignored). (Initial value)
1	0	Baud rate generator output for external clock or HSCK	When SC_CLK is selected: The HSCK pin is an input pin (input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is multiplied by the sampling rate.
1	1		When HSCK is selected: The HSCK pin inputs the clock (with the bit rate multiplied by the sampling rate).
	1	Prohibited	

Note: It is not allowed to set synchronous communication using SC\_CLK for input.

### 43.2.7 Serial Status Register (HSFSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSFSR is a 16-bit register. The lower 8 bits are status flags that indicate the operating status of the HSCIF, and the upper 8 bits are all reserved.

HSFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

HSFSR is initialized to H'0060 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Note: \* Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	ER	0	R/(W)*	<p>Receive Error</p> <p>Indicates that a framing error or a parity error has occurred in reception. The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in HSSCR.</p> <p>If a receive error occurs, receive data will be transferred to HSFRDR and reception operation will be continued. Whether there is a receive error in data read from HSFRDR can be determined by the FER and PER bits in HSFSR.</p> <p>0: Indicates that no framing or parity error has occurred in reception.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>A power-on reset is executed.</li> <li>0 is written to ER.</li> </ul> <p>1: Indicates that a framing error or a parity error has occurred in reception.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>The HSCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*</li> <li>The number of 1-bit in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in HSSMR during reception.</li> </ul> <p>Note: * In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.</p>

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R/(W)*	<p><b>Transmit End</b></p> <p>Indicates that transmission has been ended because there was no valid data in HSFTDR when the last bit of the transmit character was transmitted.</p> <p>0: Indicates that transmission is in progress.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Transmit data is written to HSFTDR, and 0 is written to TEND.</li> <li>• Data is written to HSFTDR by the DMAC.</li> </ul> <p>1: Indicates that transmission has been ended.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• The TE bit in HSSCR is 0.</li> <li>• There is no transmit data in HSFTDR when the last bit of a 1-byte serial transmission character is transmitted.</li> </ul>
5	TDFE	1	R/(W)*	<p><b>Transmit FIFO Data Empty</b></p> <p>Indicates that the HSCIF has transferred data from HSFTDR to HSTSR, the number of data bytes in HSFTDR becomes equal to or less than the transmit trigger count specified by the HSTTRGR, and HSFTDR is ready to be written by new transmit data.</p> <p>HSFTDR is a 128-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is "128 – [the transmit trigger count]". If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in HSFTDR is indicated by the upper bits of HSFDR.</p> <p>If the number of data written in HSFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1.</p> <p>0: Indicates that the number of transmit data written to HSFTDR exceeds the transmit trigger count.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• Transmit data exceeding the specified transmit trigger count have been written to HSFTDR, and 0 is written to TDFE.</li> <li>• Transmit data exceeding the specified transmit trigger count have been written to HSFTDR by the DMAC.</li> </ul> <p>1: Indicates that the number of transmit data in HSFTDR is equal to or less than the transmit trigger count.</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• The number of transmit data in HSFTDR is equal to or less than the transmit trigger count after transmission.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	0	R/(W)*	<p>Break Detect</p> <p>Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to HSFRDR is stopped. Bit	Bit Name	Initial Value	R/W	Description
1	RDF	0	R/(W)*	<p>Receive FIFO Data Full</p> <p>Indicates that the received data has been transferred from HRSR to HSFRDR, and the number of receive data bytes in HSFRDR becomes equal to or more than the receive trigger count specified by the HSRTRGR.</p> <p>HSFRDR is a 128-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When HSFRDR is empty, HSFRDR is read as an undefined value. The number of receive data bytes in HSFRDR is indicated by the lower bits of HSFRDR.</p> <p>If the number of data in HSFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in HSFRDR is less than the trigger count, read RDF as 1, and then clear RDF.</p> <p>0: Indicates that the number of receive data bytes in HSFRDR is less than the specified receive trigger count.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• HSFRDR is read until the number of receive data bytes in HSFRDR is less than the receive trigger count, and 0 is written to RDF.</li> <li>• HSFRDR is read by the DMAC until the number of receive data bytes in HSFRDR is less than the receive trigger count.</li> </ul> <p>1: Indicates that the number of receive data bytes in HSFRDR is equal to or more than the specified receive trigger count.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• Receive data more than the receive trigger count have been stored in HSFRDR.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	<p>Receive Data Ready</p> <p>Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.</p> <p>0: Indicates that data is being received or has been successfully received, and there is no receive data in HSFRDR.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• All the receive data in HSFRDR has been read, and 0 is written to DR.</li> <li>• All the receive data in HSFRDR has been read by the DMAC.</li> </ul> <p>1: Indicates that no further receive data has been received.</p> <p>[Setting condition]</p> <p>The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.</p> <p>Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format.</p> <p>etu: Elementary Time Unit (time for transfer of one bit)</p>

Note: \* Only 0 can be written to clear the flag.

### 43.2.8 Bit Rate Register (HSBRR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS[1:0] bits in HSSMR. This baud rate generator is intended for  $ZS\phi$ ,  $ZS\phi/4$ ,  $ZS\phi/16$ , and  $ZS\phi/64$ . For details on the baud rate generator for external clock, see section 43.5, Baud Rate Generator for External Clock (BRG).

HSBRR can always be read from and written to by the CPU except for during transfer.

HSBRR is initialized to H'FF by a power-on reset.

The HSBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{ZS\phi}{Sr \times 2^{2n+1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: HSBRR setting for the baud rate generator ( $0 \leq N \leq 255$ ) (which satisfies the electrical characteristics)

$ZS\phi$ : AXI bus clock operating frequency (MHz)

n: Baud rate generator input clock ( $n = 0, 1, 2, 3$ )  
(See the Table 43.4 for the relation between n and the clock.)

Sr: Sampling rate (8 to 32)

**Table 43.4 HSSMR Settings**

n	Baud Rate Generator Input Clock	HSSMR Setting	
		CKS[1]	CKS[0]
0	$ZS\phi$	0	0
1	$ZS\phi/4$	0	1
2	$ZS\phi/16$	1	0
3	$ZS\phi/64$	1	1

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{ZS\phi \times 10^6}{(N+1) \times B \times Sr \times 2^{2n+1}} - 1 \right\} \times 100$$

### 43.2.9 FIFO Control Register (HSFCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSFCR is a register that resets data counts for the transmit and receive FIFO registers. It also has a modem control and a loopback test enable bit.

HSFCR can always be read from and written to by the CPU except for during transfer.

HSFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MCE	TFRST	RFRST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	MCE	0	R/W	Modem Control Enable Enables or disables modem control signals HCTS# and HRTS#. 0: Disables modem signals.* 1: Enables modem signals. Note: * HCTS# and HRTS# control ports.
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Enables or disables a transmit FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
1	RFRST	0	R/W	Receive FIFO Data Register Reset Enables or disables a receive FIFO data register (HSFRDR) reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
0	LOOP	0	R/W	Loopback Test Enables or disables the loopback test by internally connecting the transmit output pin (HTX) and receive input pin (HRX), and the HRTS# pin and HCTS# pin. 0: Disables the loopback test. 1: Enables the loopback test.

**43.2.10 FIFO Data Count Register (HSFDR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSFDR is a 16-bit register that indicates the number of data bytes stored in HSFTDR and that in HSFRDR.

The upper 8 bits indicate the number of transmit data bytes in HSFTDR, and the lower 8 bits indicates the number of receive data bytes in HSFRDR.

HSFDR can always be read by the CPU.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	T[7:0]	H'00	R	These bits indicate the number of data bytes untransmitted and still stored in HSFTDR. H'00 indicates that there is no transmit data in HSFTDR, and H'80 indicates that HSFTDR is full of transmit data.
7 to 0	R[7:0]	H'00	R	These bits indicate the number of receive data stored in HSFRDR. H'00 indicates that there is no receive data in HSFRDR, and H'80 indicates that HSFRDR is full of receive data.

### 43.2.11 Serial Port Register (HSSPTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

HSSPTR controls multiplexed input/output and data on the high speed serial communication interface (HSCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the HRX pin and writing output data to the HTX pin. Bits 3 and 2 read input data from and write output data to the HSCK pin. Bits 5 and 4 read input data from and write output data to the HCTS# pin. Bits 7 and 6 read input data from and write output data to the HRTS# pin.

HSSPTR is a 16-bit register that can always be read from and written to by the CPU.

All HSSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the channel.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB 2IO	SPB 2DT
Initial value:	0	0	0	0	0	0	0	0	0	—	0	—	0	—	0	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	0	R/W	Serial Port – RTS Port Input/Output Specifies input or output for the serial port HRTS# pin. To actually set the HRTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the HRTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the HRTS# pin.
6	RTSDT	—	R/W	Serial Port – RTS Port Data Specifies the input/output data level of the serial port HRTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the HRTS# pin. Regardless of the value of the RTSIO bit, the value of the HRTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	0	R/W	Serial Port – CTS Port Input/Output Specifies input or output for the serial port HCTS# pin. To actually set the HCTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the HCTS# pin. 1: Indicates that the CTSDT bit value is output to the HCTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTS DT	—	R/W	<p>Serial Port – CTS Port Data</p> <p>Specifies the input/output data level of the serial port HCTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTS DT bit is output to the HCTS# pin. Regardless of the value of the CTSIO bit, the value of the HCTS# pin is read from the CTS DT bit.</p> <p>The initial value of this bit is undefined after a power-on reset.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>
3	SCKIO	0	R/W	<p>Serial Port – Clock Port Input/Output</p> <p>Specifies input or output for the serial port HSCK pin. To actually set the HSCK pin as a port output pin to output the value set by the SCKDT bit, the CKE1 and CKE0 bits in HSSCR should be cleared to 0.</p> <p>0: Indicates that the SCKDT bit value is not output to the HSCK pin.</p> <p>1: Indicates that the SCKDT bit value is output to the HSCK pin.</p>
2	SCKDT	—	R/W	<p>Serial Port – Clock Port Data</p> <p>Specifies the input/output data level of the serial port HSCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCKDT bit is output to the HSCK pin. Regardless of the value of the SCKIO bit, the value of the HSCK pin is read from the SCKDT bit.</p> <p>The initial value of this bit is undefined after a power-on reset.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>
1	SPB2IO	0	R/W	<p>Serial Port – Break Input/Output</p> <p>Specifies the output condition of the serial port HTX pin. To actually set the HTX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in HSSCR should be cleared to 0.</p> <p>0: Indicates that the SPB2DT bit value is not output to the HTX pin.</p> <p>1: Indicates that the SPB2DT bit value is output to the HTX pin.</p>
0	SPB2DT	—	R/W	<p>Serial Port – Break Data</p> <p>Specifies the input level of the serial port HRX pin and the output level of the HTX pin. The HTX pin output conditions are determined by the SPB2IO bit. When the HTX pin is set for output, the value of the SPB2DT bit is output to the HTX pin. Regardless of the value of the SPB2IO bit, the value of the HRX pin is read from the SPB2DT bit.</p> <p>The initial value of this bit is undefined after a power-on reset.</p> <p>0: Indicates that the input/output data is low level.</p> <p>1: Indicates that the input/output data is high level.</p>

**43.2.12 Line Status Register (HLSLR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Note: \* Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TO	0	R/(W)*	Timeout Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. 0: Indicates that data is being received or has been successfully received and that there is no receive data in HSFRDR. [Clearing conditions] <ul style="list-style-type: none"> <li>A power-on reset is executed.</li> <li>All the receive data in the HSFRDR has been read, and 0 is written to TO.</li> </ul> 1: Indicates that no further receive data has been received (receive timeout). [Setting condition] <ul style="list-style-type: none"> <li>The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.*</li> </ul> Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format. etu: Elementary Time Unit (time for transfer of one bit)
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	0	R/(W)*	<p>Overrun Error</p> <p>Indicates that an overrun error has occurred in reception and abnormal termination is caused.</p> <p>If an overrun error occurs, the receive data prior to the overrun error is retained in HSFRDR and the data received subsequently is discarded.</p> <p>Any subsequent serial reception is disabled while the ORER flag is 1.</p> <p>To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag.</p> <p>0: Indicates that data is being received or has been successfully received.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• A power-on reset is executed.</li> <li>• 0 is written to ORER.</li> </ul> <p>1: Indicates that an overrun error has occurred in reception.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• The next serial reception has been completed while HSFRDR is full of 128-byte data.</li> </ul> <p>Note: When bit RE in HSSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.</p>

Note: \* Only 0 can be written to clear the flag.

### 43.2.13 Sampling Rate Register (HSSRR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRE	SRDE	—	—	SRHP[3:0]				—	—	—	SRCYC[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	SRE	0	R/W	Sampling Rate Register Enable (SRE) 0: Set the SRCYC[4: 0] bits to 15 (initial value). 1: Validates the setting of the SRCYC[4:0] bits.
14	SRDE	0	R/W	Sampling Point Register Enable (SRDE) 0: Invalidates the setting of the SRHP[3:0] bits and the sampling point will be (S+1)/2 for an odd sampling rate (S) and S/2 for an even sampling rate. 1: Validates the setting of the SRHP[3: 0] bits.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	SRHP[3:0]	0000	R/W	Sampling Point Register (SRHP) The sampling point can be moved by setting the SDRE bit to 1 and setting a value in these bits. Normally, the sampling point is the point of S/2 or (S+1)/2 for a sampling rate of S. By setting a signed 4-bit integer in these bits, the sampling point can be shifted by the amount of the specified sampling clock cycles. This will improve the receive margin. When setting a value in these bits, take notice that the sampling point does not become a negative value or it does not exceed the sampling rate. The shifted sampling point must satisfy the setup margin and hold margin.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	SRCYC[4:0]	01111	R/W	Bits 4 to 0: Sampling Rate Register (SRCYC) Data transfer at a desired sampling rate can be enabled by setting the SRE bit to 1 and setting a value in these bits. Set a value of "S - 1" in these bits for a sampling rate of S. Note that the sampling rate must be from 8 to 32 (a value from 7 to 31 can be set in these bits). Set these bits to 15 (initial value) when the SRE bit is set to 0.

**43.2.14 Serial Error Register (HSRER)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	PER[6:0]						—	FER[6:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 8	PER[6:0]	H'00	R	Parity Error Count These bits indicate the number of data items in which a parity error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 14 to 8 will be the number of data items in which a parity error occurred. If all 128 bytes of receive data in HSFRDR have parity errors, bits PER[6:0] will have the value 0.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 0	FER[6:0]	H'00	R	Framing Error Count These bits indicate the number of data items in which a framing error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 6 to 0 will be the number of data items in which a framing error occurred. If all 128 bytes of receive data in HSFRDR have framing errors, bits FER[6:0] will have the value 0.

### 43.2.15 RTS Output Active Trigger Register (HSRTGR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RSTRG[6:0]	H'0F	R/W	RTS Output Active Trigger Count The HRTS# signal goes high when the number of receive data items stored in the receive FIFO data register (HSFRDR) exceeds the value set in these bits. The initial value is 15.

### 43.2.16 Receive FIFO Data Count Trigger Register (HSRTRGR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RTRG[6:0]	H'01	R/W	Receive FIFO Data Count Trigger These bits set the receive data item count at which the receive data full (RDF) flag in the serial status register (HSFSR) is set. The RDF flag is set when the number of receive data items stored in the receive FIFO data register (HSFRDR) equals or exceeds the value set in these bits. The initial value is 1.

**43.2.17 Transmit FIFO Data Count Trigger Register (HSTTRGR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	TTRG[6:0]	H'08	R/W	Transmit FIFO Data Count Trigger These bits set the untransmitted data item count at which the transmit FIFO data register empty (TDFE) flag in the serial status register (HSFSR) is set. The TDFE flag is set when the number of transmit data items in the transmit FIFO data register (HSFTDR) falls under the value set in these bits due to transmit operations. The initial value is 8.

## 43.3 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 43.3.1 Operation in Asynchronous Serial Communication Mode

In asynchronous serial communication mode, the HSCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

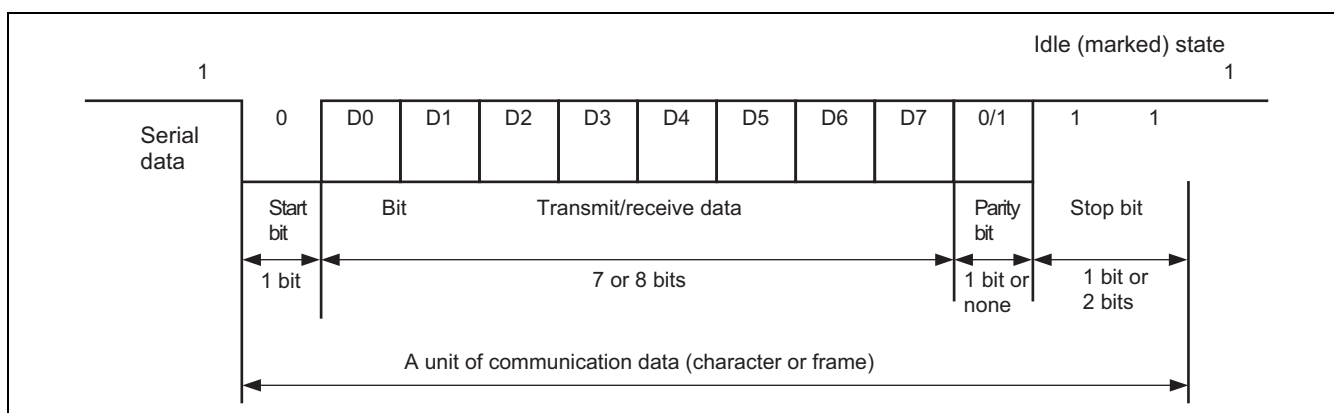

Figure 43.2 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The HSCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the HSCIF performs synchronization at the falling edge of the start bit. Transferred data is acquired at the center of each bit because the HSCIF samples on  $S/2$ th cycles of the clock which has a frequency of  $S$  times the bit rate, when the sampling rate as set in the sampling rate register (HSSRR) is  $S$  (if the sampling-rate setting is an odd number, the data is sampled on every  $(S+1)/2$ th pulse).

In addition, when the setting of the SRDE bit makes the setting of the sampling point bits effective, the point where the bits are latched can be intentionally moved from the centers of each bit.

**Figure 43.2 Data Format in Asynchronous Mode  
(Example of 8-Bit Data with Parity and Two Stop Bits)**

**(1) Transmission/reception format**

Table 43.5 shows available data transfer formats. The HSCIF supports 8 transfer formats, which can be specified by HSSMR.

**Table 43.5 Serial Transmission/Reception Formats (Asynchronous Mode)**

SCSMR settings			Serial transmission/reception format and frame length												
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	S	8-bit data								STOP			
0	0	1	S	8-bit data								STOP	STOP		
0	1	0	S	8-bit data								P	STOP		
0	1	1	S	8-bit data								P	STOP	STOP	
1	0	0	S	7-bit data							STOP				
1	0	1	S	7-bit data							STOP	STOP			
1	1	0	S	7-bit data							P	STOP			
1	1	1	S	7-bit data							P	STOP	STOP		

[Legend]

S : Start bit  
 STOP: Stop bit  
 P : Parity bit

**(2) Clock**

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in HSSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

### (3) Data transmission/reception

#### (a) Initialization of HSCIF (asynchronous mode)

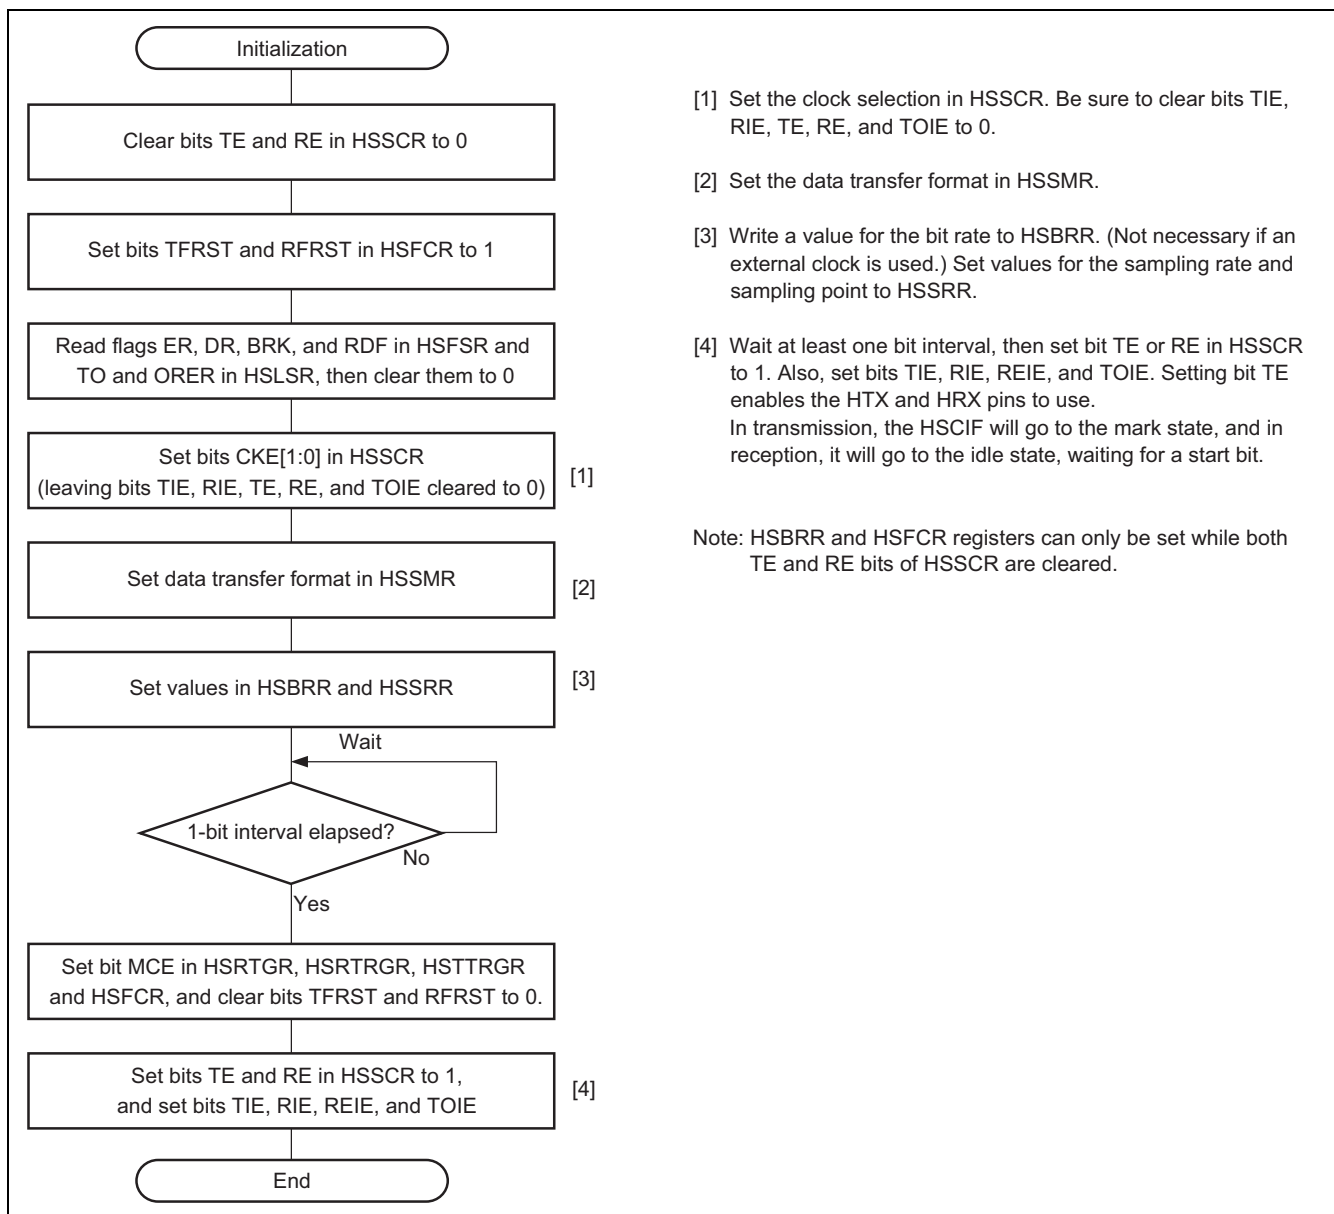

Before transmitting/receiving data or changing the operating mode or communication format, the HSCIF should be initialized using the sample flowchart for HSCIF initialization shown in Figure 43.3.

[Notes]

Clearing the TE bit to 0 initializes HSTSR. However, HSFSR, HSFTDR, and HSFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in HSFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in HSFCR to reset HSFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the HSCIF.

**Figure 43.3 Sample Flowchart for Initializing the HSCIF**

**(b) Serial data transmission (asynchronous mode)**

Figure 43.4 shows a sample flowchart for serial transmission.

After the HSCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

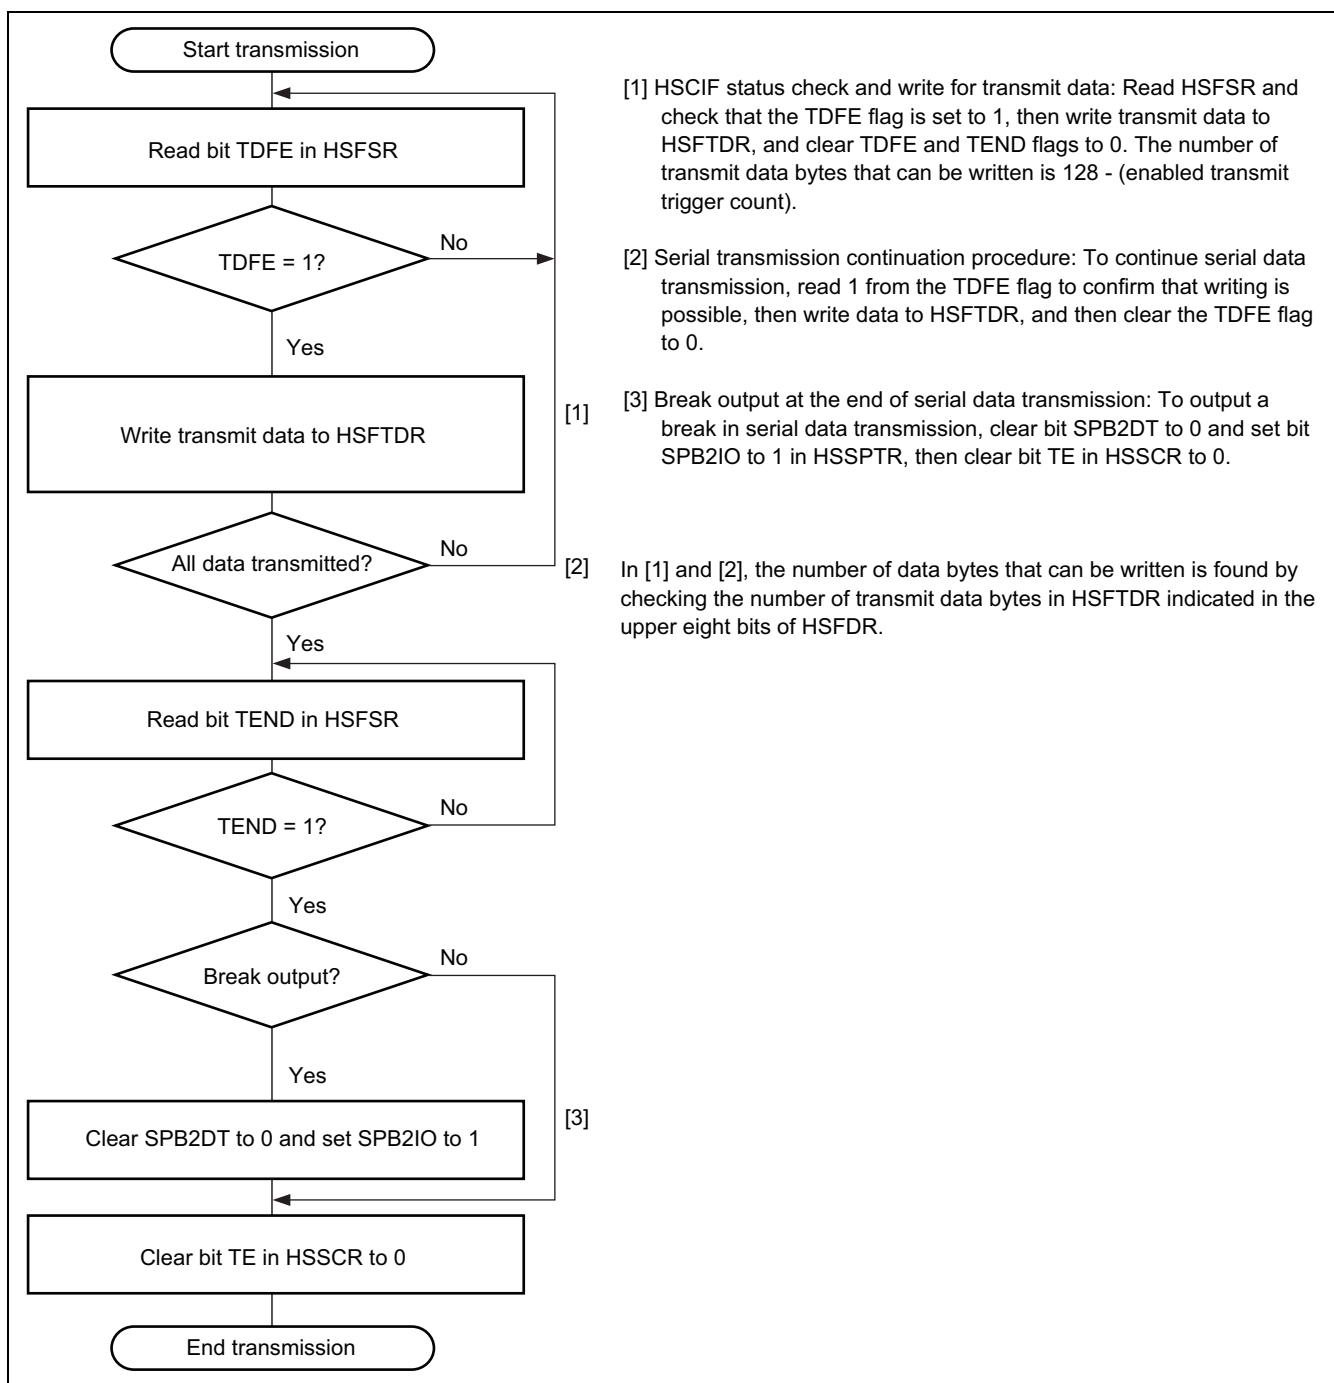

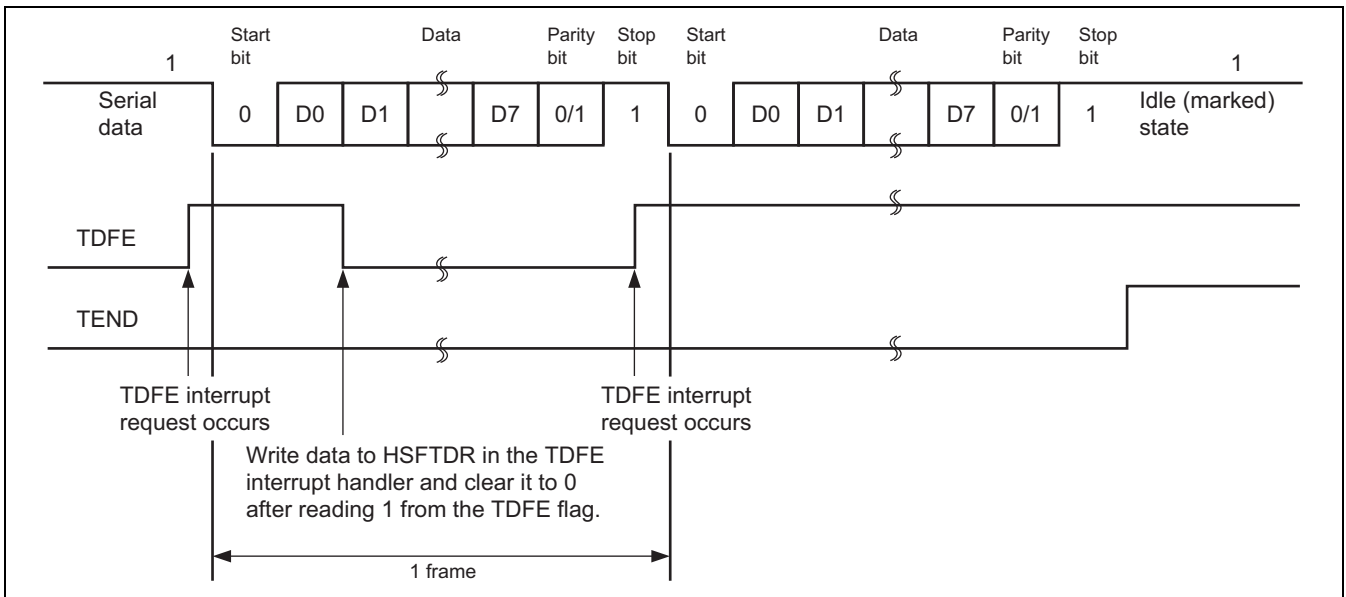

Figure 43.4 Sample Flowchart for Serial Transmission

In serial transmission, the HSCIF operates as follows:

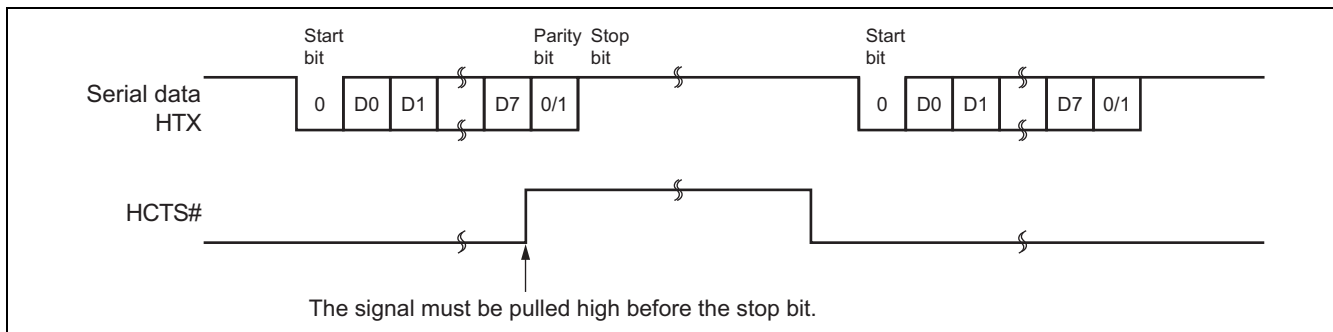

1. When data is written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts transmitting. Confirm that the TDFE flag in HSF SR is set to 1 before writing transmit data to HSFTDR. The number of data bytes that can be written is at least 128 - (transmit trigger count).
2. When data is transferred from HSFTDR to HSTSR and the HSCIF starts transmission, consecutive transmission is performed until there is no transmit data left in HSFTDR. When the number of transmit data bytes in HSFTDR is equal to or less than the transmit trigger count specified in HSTTRGR, the TDFE flag is set. If the TIE and TEIE bits in HSSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the HTX pin in the following order:
  - A. Start bit: One 0-bit is output.
  - B. Transmit data: 8- or 7-bit data is output in LSB-first order.
  - C. Parity bit: One parity bit (even or odd parity) is output.  
A format that does not output a parity bit can also be selected.
  - D. Stop bit(s): One or two 1-bit (stop bits) are output.
  - E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The HSCIF checks transmit data in HSFTDR when sending the stop bit. If there is data in it, the HSCIF transfers the data from HSFTDR to HSTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the HSCIF sets the TEND flag to 1 in HSF SR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in HSSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 43.5 shows an example of transmission in asynchronous mode.

**Figure 43.5 Sample HSCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)**

- When modem control is enabled, transmission can be stopped or resumed in accordance with the HCTS# input value. When HCTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting HCTS# to 0 restarts outputting the next transmit data from the start bit. Figure 43.6 shows an example of the operation with modem control enabled.

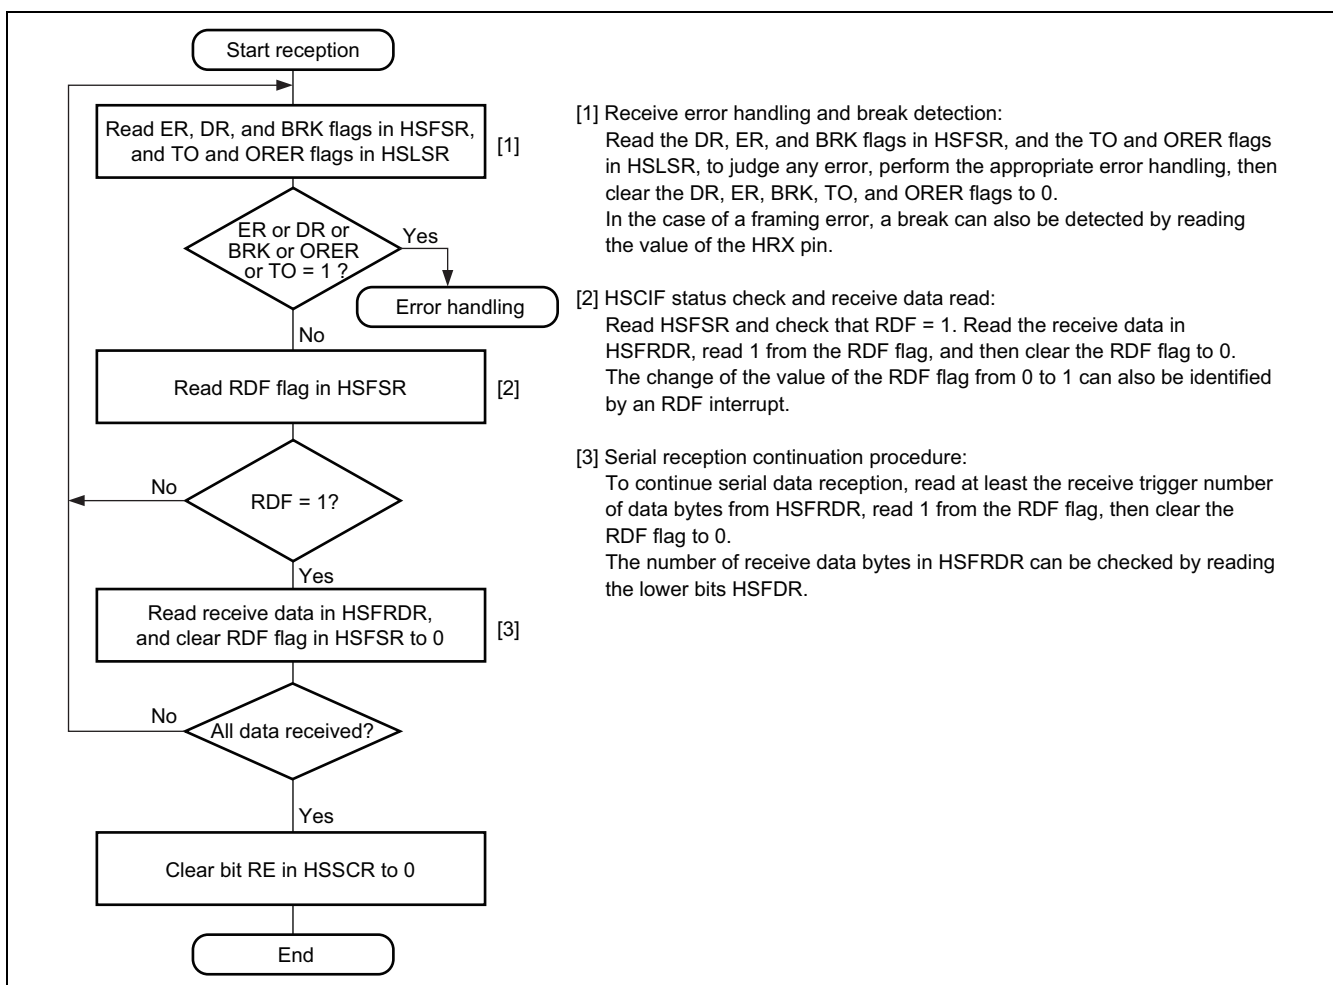

**Figure 43.6 Sample Operation with Modem Control Enabled (HCTS#)**

**(c) Serial data reception (asynchronous mode)**

Figures 43.7 and 43.8 show sample flowcharts for serial reception.

After the HSCIF reception operation is enabled, serial data reception can be performed using the following procedure:

**Figure 43.7 Sample Flowchart for Serial Reception (1)**

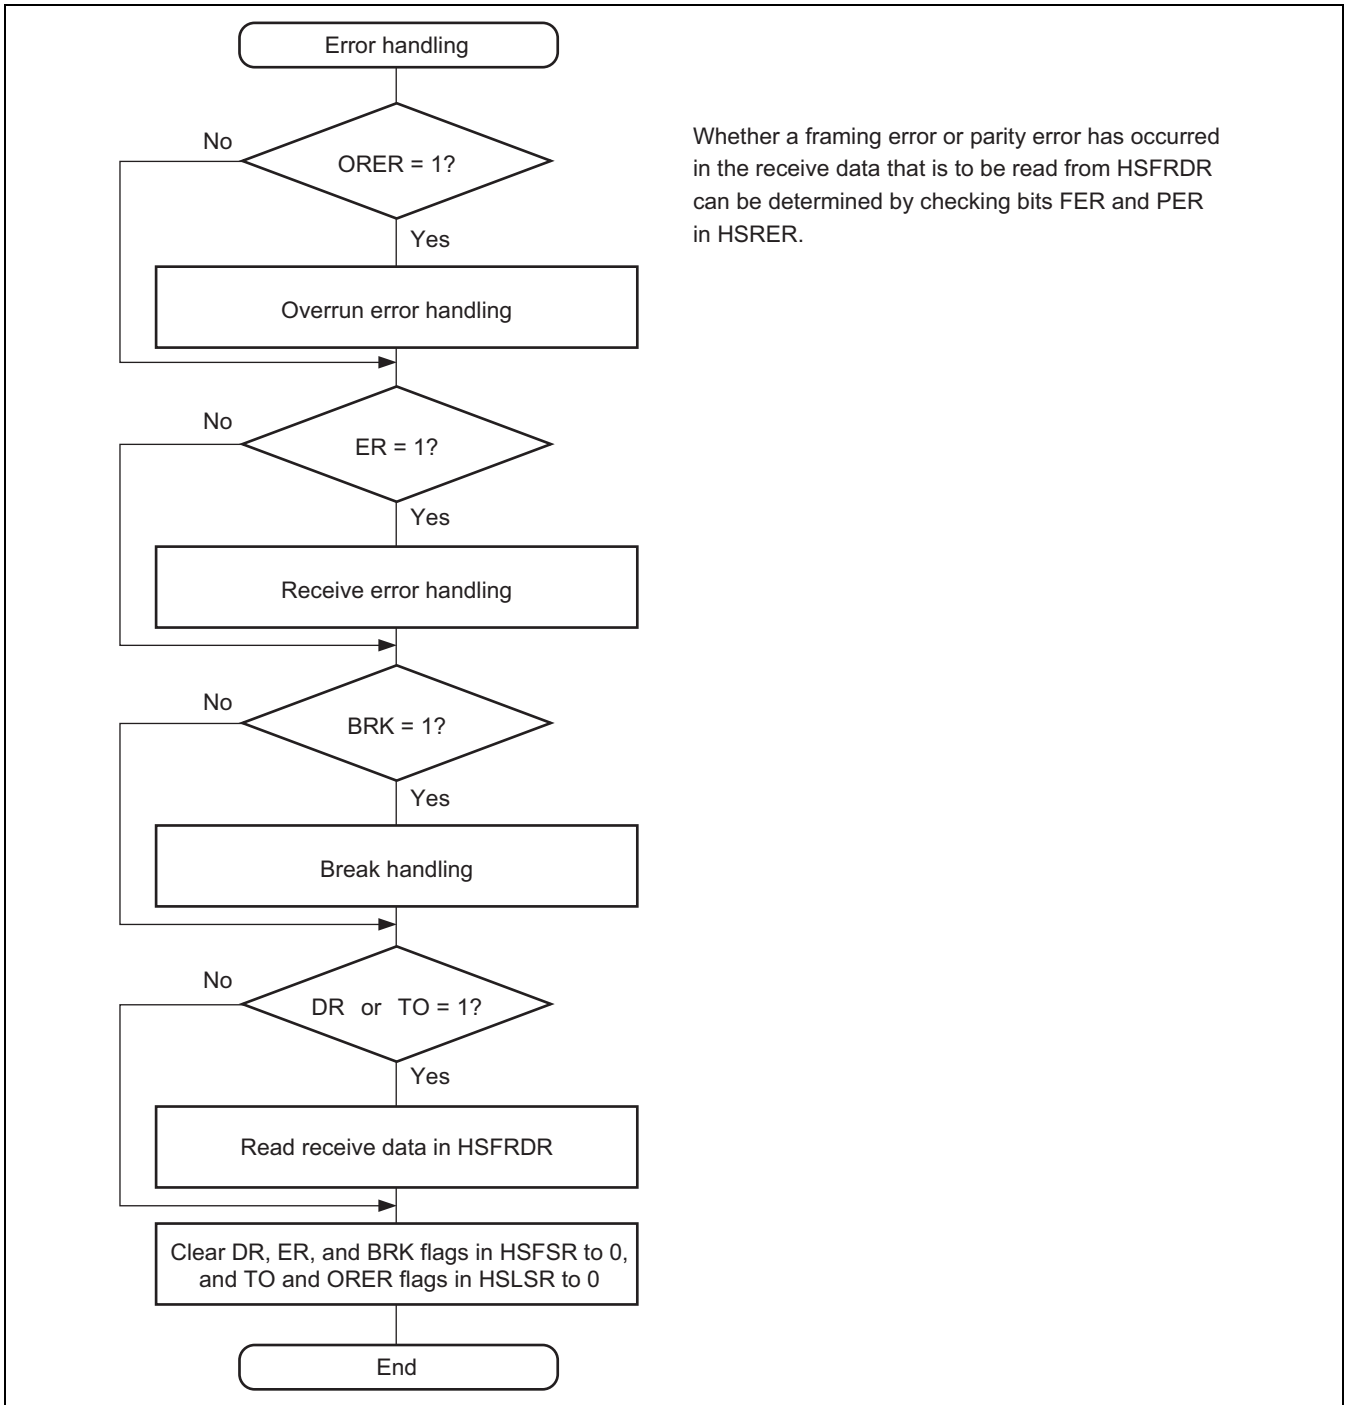

Figure 43.8 Sample Flowchart for Serial Reception (2)

In serial reception, the HSCIF operates as follows:

1. The HSCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The HSCIF stores the received data in HRSR in LSB-to-MSB order.
3. The HSCIF receives the parity bit and stop bit.

After receiving these bits, the HSCIF performs the following checks:

- A. Stop bit: The HSCIF checks whether the stop bit is 1.  
If there are two stop bits, it checks only the first stop bit.
- B. Receive data: The HSCIF checks that receive data can be transferred from the receive shift register (HRSR) to HSFRDR.
- C. Overrun error: The HSCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
- D. Break state: The HSCIF checks that the BRK flag is 0, indicating that the break state is not set.

If the HSCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in HSFRDR.

Note: The HSCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in HSSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.

If the DR flag changes to 1 while the RIE bit in HSSCR is 1, a receive-data-ready interrupt (DR) request occurs.

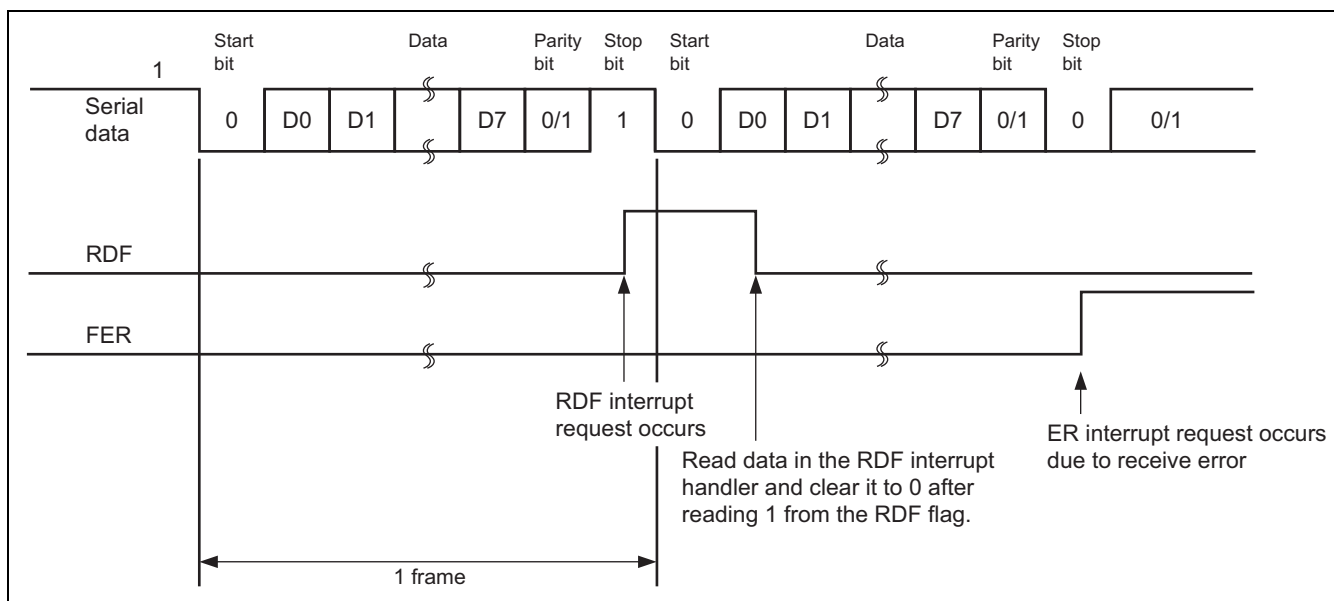

If the TO flag changes to 1 while the TOIE bit in HSSCR is 1, a timeout interrupt (TO) request occurs.

If the ER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a receive-error interrupt (ER) request occurs.

If the BRK flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a break interrupt (BRK) request occurs.

If the ORER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 43.9 shows an example of reception in asynchronous mode.

**Figure 43.9 Sample HSCIF Receive Operation  
(Example of 8-Bit Data with Parity and One Stop Bit)**

- When modem control is enabled, the HRTS# signal is output when HSRDR is empty. When HRTS# is 0, data can be received. When HRTS# is set to 1, the number of data bytes in HSRDR is equal to or more than the RTS output active trigger count.

Figure 43.10 shows an example of the operation with modem control enabled.

**Figure 43.10 Example of the Operation with Modem Control Enabled (HRTS#)**

### 43.3.2 HSCIF Interrupt Sources and the DMAC

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the HSCIF.

#### Transmission interrupts and DMA transfer:

If the TDFE/TEND flag in HSFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

#### Reception interrupts and DMA transfer:

If the RDF/DR flag in HSFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in HSSCR to 0 and the REIE bit to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in HSFSR or the ORER flag in HSLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in HSLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

**Table 43.6 HSCIF Interrupt Sources**

Interrupt Source	DMAC Activation
Interrupts generated by receive error flag (ER)	Disabled
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO)	Enabled
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled

**43.4 Usage Notes**

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

Note the following on use of the HSCIF.

**(1) Break detection and operation**

Break signals can also be detected by reading the HRX pin value directly when a framing error (FER) is detected. In the break state, the input values from the HRX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the HSCIF stops receive data transfer to HSRDR after detecting a break, it continues data reception.

**(2) Sending a break signal**

The input/output condition and level of the HTX pin are determined by the SPB2IO and SPB2DT bits in HSSPTR. This enables to send a break signal.

The pin does not function as the HTX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

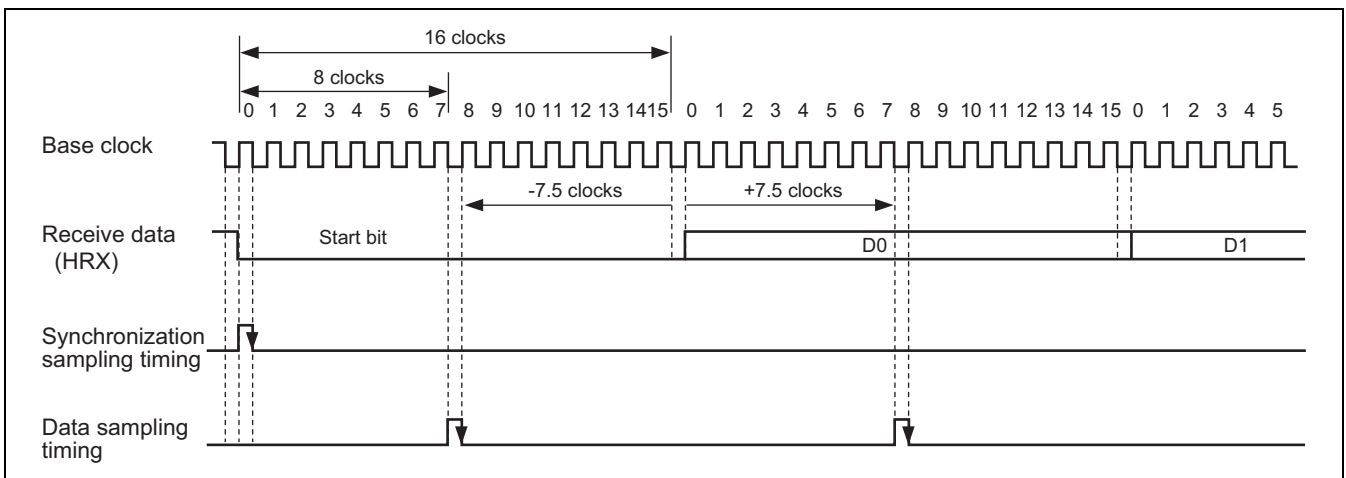

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the HTX pin outputs 0.

**(3) Data sampling timing and reception margin in asynchronous mode**

The HSCIF operates on the base clock with a frequency multiplied by the number which is set as a sampling rate for the bit rate.

In reception, the HSCIF performs the internal synchronization by sampling the falling edge of the start bit using the base clock. In addition, the HSCIF takes receive data at the rising edge of the S/2 pulse (when S is an even number) or (S+1)/2 pulse (when S is an odd number) on the base clock when sampling rate is S.

Figure 43.11 shows the timing of this operation when S = 16.

**Figure 43.11 Timing Chart of Receive Data Sampling**

The reception margin in asynchronous mode is given by formula (1).

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \quad \text{..... Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = sampling rate)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0, D = 0.5 and sampling rate = 16 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$$M = (0.5 - 1/(2 \times 16)) \times 100\% \\ = 46.875\% \quad \text{.....expression (2)}$$

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

#### (4) Reception margin and baud rate error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

$$F = \{(15/32 - M)/(L - 0.5)\} \times 100 (\%) \quad \text{.....expression (3)}$$

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

**(5) Usage method of SRHP bits**

The method for using the SRHP bits in the sampling rate register is described below.

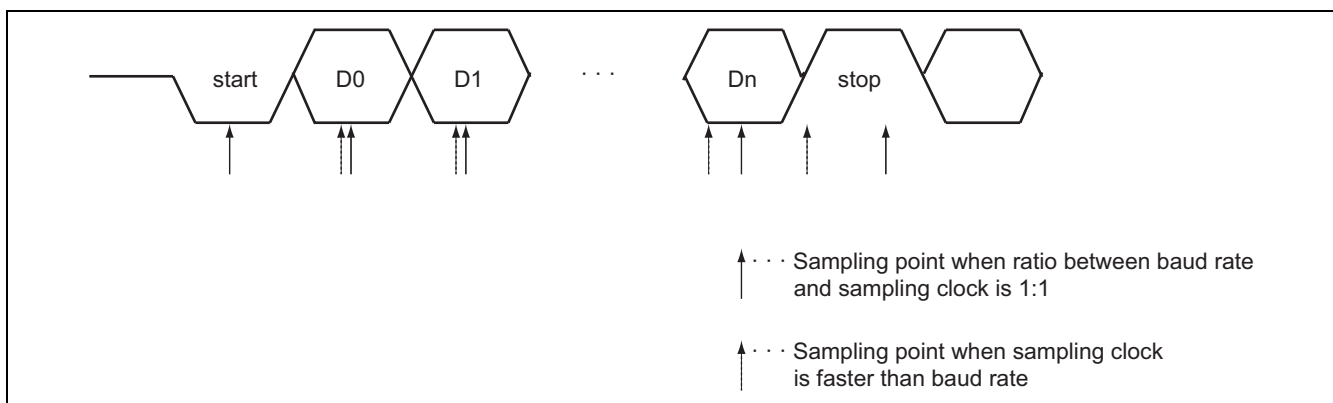

**Figure 43.12 Sampling with Invalid SRHP Bits**

Figure 43.12 shows a sampling example in which the SRHP bits are invalid (sampling rate = 8). In this case, the HSCIF samples data at half of the sampling rate, which is at the rising edge of the fourth pulse of the clock. This allows a setup margin and hold margin of 50% each to be provided.

However, if the ratio between the baud rate and sampling clock is not 1:1, either the setup margin or hold margin is omitted in data reception of a single frame. If the setup margin is omitted, the hold margin increases. On the other hand, if the hold margin is omitted, the setup margin increases. Figures 43.13 and 43.14 show examples.

**Figure 43.13 Sampling Point with Sampling Clock Slower Than Baud Rate**

**Figure 43.14 Sampling Point with Sampling Clock Faster Than Baud Rate**

The ratio between the baud rate and sampling clock can be used to determine which margin among the setup margin and hold margin is to be omitted and which is to be increased. Based on this, the margin within a single frame can be increased by intentionally increasing the margin to be omitted in advance. The sampling point can be moved by setting a value in the SRHP bits. Figure 43.15 shows an example.

**Figure 43.15 Sampling Point Moved by SRHP Bits**

#### (6) Sampling rate and bit rate settings and respective margin

To set the baud rate in the HSCIF, in addition to setting the clock division ratio, the two registers, bit rate register (HSBRR) and sampling rate register (HSSRR), need to be set. These registers must be set so that the margin calculated by expression (1) in section 43.5 (3) will be a sufficient value.

The bit rate error is small when the value obtained by dividing the divided clock frequency used in the HSCIF with the sampling rate is near the desired baud rate. If there are many combinations of bit rate and sampling rate with the same bit rate error, choosing a combination with a large sampling rate provides a large margin. This is because when the bit rate error is constant in expression (1) in section 43.5 (3), that is, when the "absolute value of clock frequency deviation (F)" is constant, the margin (M) increases in accordance with the sampling rate (N).

If the sampling rate is made larger in a combination of bit rate and sampling rate with different bit rate errors, the bit rate error is increased. Accordingly, the "absolute value of clock frequency deviation (F)" on the right side in expression (1) in section 43.5 (3) gets larger and the margin (M) smaller.

Refer to the following procedure when selecting the sampling rate and bit rate settings.

1. Obtain the bit rate with the smallest bit rate error for sampling rates from 8 to 32.
2. Using expression (1) in section 43.5 (3), calculate the margin for each combination of sampling rate and bit rate which was obtained in step 1.
3. Select the combination with the largest margin among the combinations of sampling rate and bit rate.

## 43.5 Baud Rate Generator for External Clock (BRG)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 43.5.1 Overview

The HSCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the HSCIF core by dividing the external clock SC\_CLK (selectable between SCIF\_CLK and ZSφ) by 1 to  $2^{16} - 1$ . In addition, the BRG switches the output between the external clock HSCK and divided clock.

### 43.5.2 Block Descriptions

Figure 43.16 shows a block diagram of the BRG.

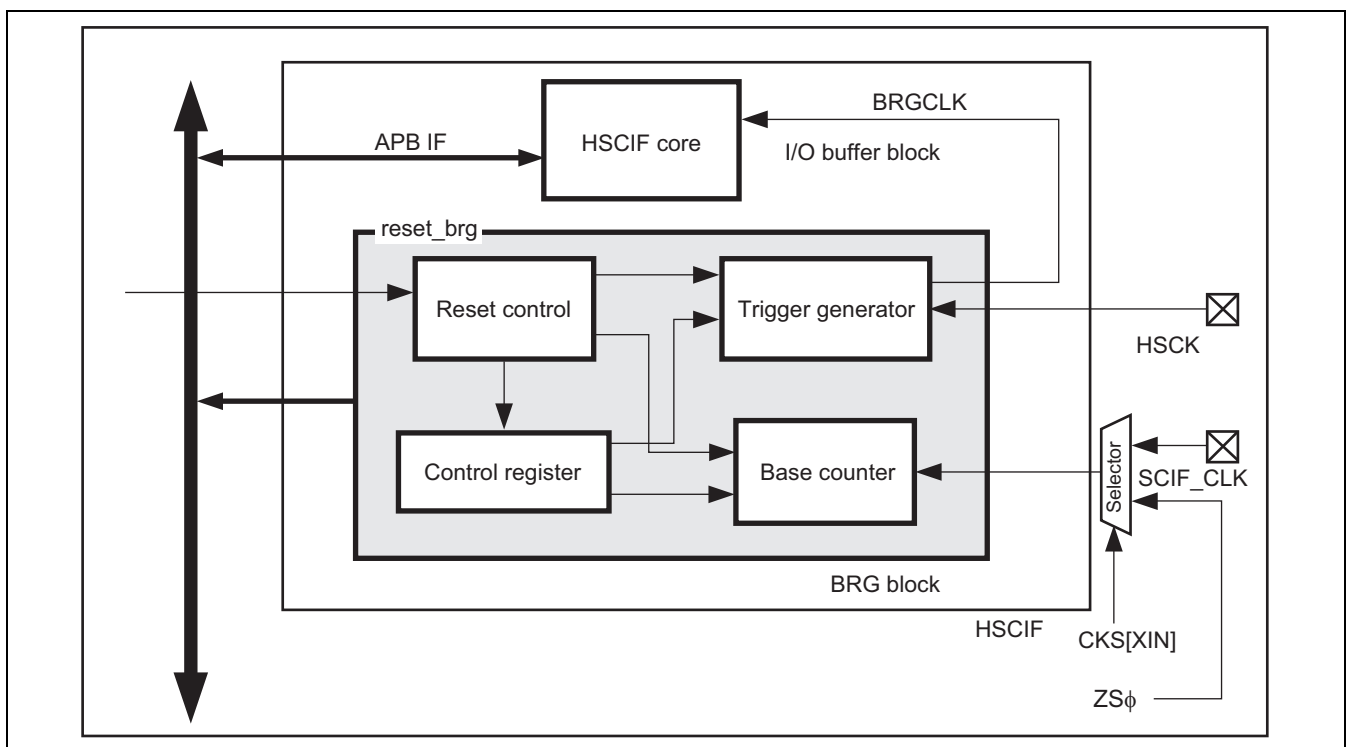

Figure 43.16 BRG Block Diagram

(1) Reset controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(2) Control register:

The control register has the frequency division register and clock select register.

(3) Base counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(4) Trigger generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the HSK (external clock input) and frequency divided clock.

### 43.5.3 BRG Register Configuration

Table 43.7 shows the registers in the BRG block.

**Table 43.7 List of Registers**

Ch. No.	Name	Code	R/W	Initial Value	Address	Access Size	RZ/G Series Products			
							RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
0	Frequency division register 0	DL	R/W	H'00	H'E62C 0030	16	√	√	√	√
	Clock select register 0	CKS	R/W	H'00	H'E62C 0034	16	√	√	√	√

	Clock select register 2	CKS	R/W	H'00	H'E62D 0034	16	—	√	√	√

#### 43.5.3.1 Frequency Division Register (DL)

This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the range of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/(required baud rate × sampling rate)

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The setting value is enabled in the range of 1 to 65535.

Tables 43.8 and 43.9 show how to use the baud rate generator with a 3.6864-MHz crystal resonator, and a 26-MHz crystal resonator.

**Table 43.8 Baud Rate (3.6864-MHz clock)**

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
50	4608	16	—
75	3072	16	—
110	4189	8	-0.002
134.5	1713	16	0.001
150	1536	16	—
300	768	16	—
600	384	16	—
1200	192	16	—
1800	128	16	—
2000	123	15	0.098
2400	96	16	—
3600	64	16	—

19200	12	16	—
38400	6	16	—
76800	3	16	—
115200	2	16	—

Note: \* "—" Indicates that the error rate is 0.

**Table 43.9 Baud Rate (26-MHz clock)**

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
9600	129	21	0.025
19200	52	26	-0.160
38400	26	26	-0.160
57600	15	30	-0.309
115200	9	25	-0.309
230400	4	28	-0.756
460800	2	28	-0.756
921600	1	28	-0.756
1843200	1	14	-0.756
3250000	1	8	—

Note: \* "—" Indicates that the error rate is 0.

### 43.5.3.2 Clock Select Register (CKS)

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (HSCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and ZS $\phi$ . 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (ZS $\phi$ ).
13 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

#### 43.5.4 Restrictions in BRG

##### (1) Notes on setting frequency division register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.

(Example) One bit period when DL = 2

$$3.68 \text{ (MHz)} \times 1/2 \times 1/16 = 0.115 \text{ (MHz)} \rightarrow 8695 \text{ (ns)}$$

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.

The HSCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC\_CLK external input)

HSCIF		BRG	
Register Name	Setting Value	Register Name	Setting Value
HSSCR.CKE[1:0]	B'10	CKS	H'0000
		DL	H'1 to H'FFFF

- Asynchronous mode (HSC external input)

HSCIF		BRG	
Register Name	Setting Value	Register Name	Setting Value
HSSCR.CKE[1:0]	B'10	CKS	H'8000
		DL	Don't care

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the HSCIF.

## 44. I2C Bus Interface (I2C)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 44.1 Features

RZ/G series products have up to six I2C bus interfaces conformant with the Philips Semiconductors (now NXP Semiconductors) I2C bus (Inter-IC bus) specification. However, the configuration of registers that control the I2C bus differs partly from the NXP Semiconductors register configuration. The I2C bus interface has the following features. Note that "module clock (MOD\_CLK)" refers to the peripheral module clock (HP $\phi$ ) in this section.

- The I2C interfaces support the I2C bus specification from NXP Semiconductors
- Multi-master compatible
- Seven- or ten-bit address compatible master
- Seven-bit slave address
- Fast mode compatible
- Variable clock frequencies

Figure 44.1 shows a block diagram of the I2C bus interface.

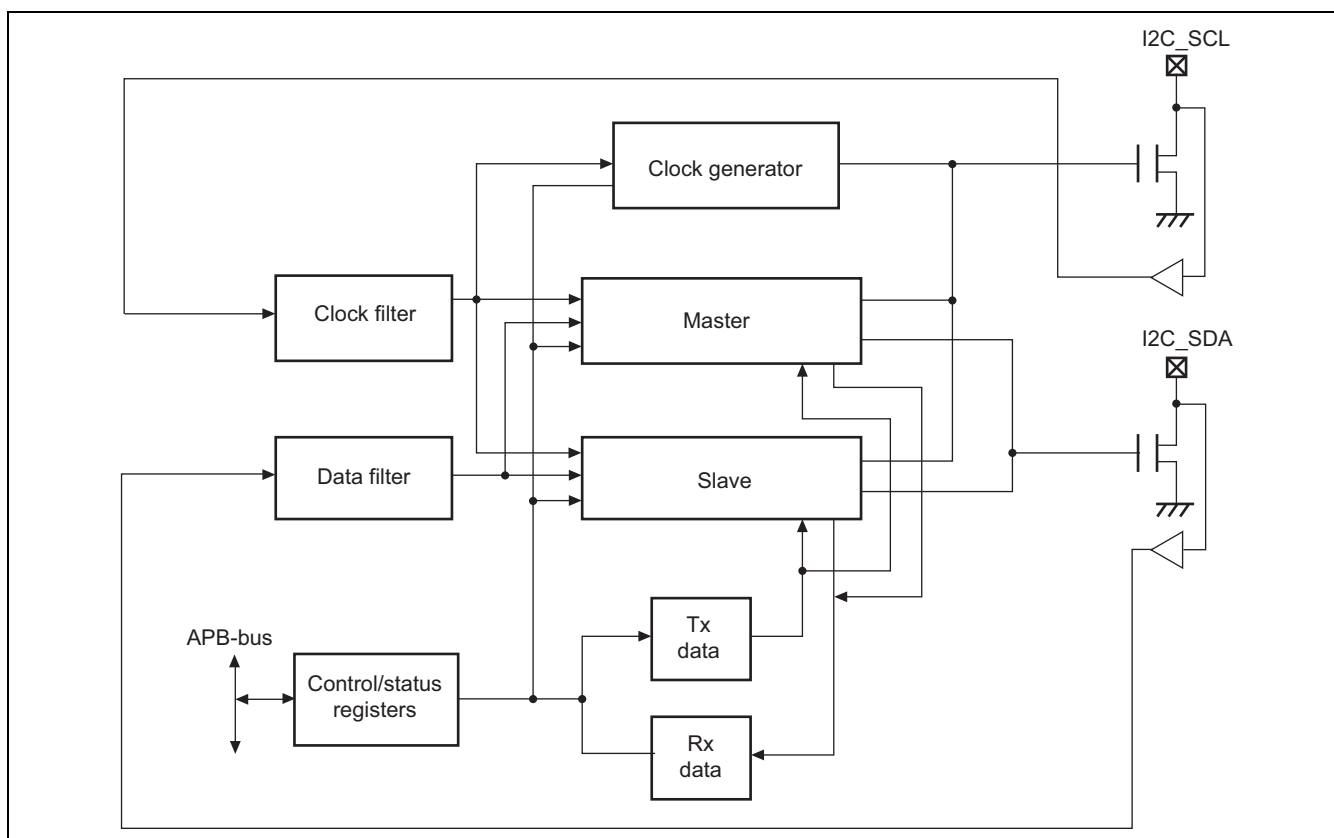

Figure 44.1 Block Diagram of I2C Bus Interface

## 44.2 Input/Output Pins

Table 44.1 lists the pins used in the I2C bus interface.

**Table 44.1 I2C Bus Interface**

Channel Number	Pin Name* <sup>1</sup>	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
				Output Buffer Type* <sup>2</sup>			
0	SCL	I/O	SCL:	OD* <sup>3</sup>	LVTTTL	LVTTTL	LVTTTL
	SDA		I2C serial clock input/output pin				
1	SCL		SDA:	LVTTTL* <sup>3</sup>	LVTTTL	LVTTTL	LVTTTL
	SDA		I2C serial data input/output pin				
2	SCL			LVTTTL* <sup>3</sup>	LVTTTL	LVTTTL	LVTTTL
	SDA						
3	SCL			OD* <sup>3</sup>	LVTTTL	LVTTTL	LVTTTL
	SDA						
4	SCL			—	LVTTTL	LVTTTL	LVTTTL
	SDA						
5	SCL			—	OD	OD	LVTTTL
	SDA						

Notes: 1. The actual pin names are I2Cn\_SCL and I2Cn\_SDA (n = 0 to 3 for RZ/G1H and 0 to 5 for RZ/G1M, N). These are referred to as I2C\_SCL and I2C\_SDA in this section.

2. Output buffer type: "OD" is open drain buffer and "LVTTTL" is low level drive only LVTTTL buffer. OD assigned channel pins are 1.8 V I/O and input/output 3.3 V tolerant; LVTTTL assigned channel pins are 3.3 V I/O.

3. For only RZ/G1H, these pins are shared with IIC module pins. Select one of the modules either I2C or IIC for each channel.

The I2C buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source (3.3 V) of this LSI, turn off the power source of the pull-up resistors connected to the I2C pins.

Note: When using 1.8V I2C/IIC pins (OD assigned channel) as 3.3 V tolerant, all the external pull-up voltage power supply to the I2C/IIC of this LSI must keep the same power on/off sequence as the VCCQ (3.3 V) of this LSI.

### 44.3 Register Descriptions

The base address for each channel of registers of the I2C bus interface is as follows:

- I2C0: H'E650\_8000 (RZ/G1H, M/N, E)
- I2C1: H'E651\_8000 (RZ/G1H, M/N, E)
- I2C2: H'E653\_0000 (RZ/G1H, M/N, E)
- I2C3: H'E654\_0000 (RZ/G1H, M/N, E)
- I2C4: H'E652\_0000 (RZ/G1M/N, E)
- I2C5: H'E652\_8000 (RZ/G1M/N, E)

Note. Number of I2C channels:  
 4 channels for RZ/G1H (channels 0 to3)  
 6 channels for RZ/G1M/N, E (channels 0 to 5)

Each channel of the I2C bus interface has the registers below.

**Table 44.2 Register Configuration (1)**

Register Name	Abbreviation	R/W	Offset Address from Base Address	Size	RZ/G Series Products			
					RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Slave control register	ICSCR	R/W	H'00	32	√	√	√	√
Master control register	ICMCR	R/W	H'04	32	√	√	√	√
Slave status register	ICSSR	R/(W)* <sup>1</sup>	H'08	32	√	√	√	√
Master status register	ICMSR	R/(W)* <sup>2</sup>	H'0C	32	√	√	√	√
Slave interrupt enable register	ICSIER	R/W	H'10	32	√	√	√	√
Master interrupt enable register	ICMIER	R/W	H'14	32	√	√	√	√
Clock control register	ICCCR	R/W	H'18	32	√	√	√	√
Slave address register	ICSAR	R/W	H'1C	32	√	√	√	√
Master address register	ICMAR	R/W	H'20	32	√	√	√	√
Receive data register	ICRXD	R	H'24	32	√	√	√	√
Transmit data register	ICTXD	W	H'24	32	√	√	√	√

Notes: Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed above are undefined.

Although the actual register name and its abbreviation have channel number as a suffix respectively, it is omitted in this section.

1. Only 0 can be written to bits 4 to 0 to clear the flags.
2. Only 0 can be written to bits 6 to 0 to clear the flags.

**Table 44.2 Register Configuration (2)**

<b>Name</b>	<b>Abbreviation</b>	<b>Power-On Reset</b>	<b>Module Standby</b>
Slave control register	ICSCR	H'0000 0000	Retained
Master control register	ICMCR	H'0000 0000*	Retained

Master address register	ICMAR	H'0000 0000	Retained
Receive data register	ICRXD	H'0000 0000	Retained
Transmit data register	ICTXD	—	—

Note: \* Bits 30, 29, 22, 21, 14, 13, 6, and 5 are undefined.

### 44.3.1 Slave Control Register (ICSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SDBS	SIE	GCAE	FNA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
3	SDBS	0	R/W	Slave Data Buffer Select This bit is used to select the data buffer. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
2	SIE	0	R/W	Slave Interface Enable This bit must be set for the slave operation. If this bit is low, the slave interface is reset.
1	GCAE	0	R/W	General Call Acknowledgement Enable When slave devices are to issue an acknowledgement in response to a general call address sent from a master, this bit must be set to 1.
0	FNA	0	R/W	Forced Non Acknowledgement In the slave receive mode, the level of this bit is sent to the transmitting device as the acknowledge signal. This bit is set to 0 during the period that the data packet is being received, and set to 1 on completion of data reception. Forced non acknowledgement is returned to the master during slave reception. When the slave has received the last byte of data in a data packet, the slave communicates with the master by sending a NACK, meaning that the acknowledgement is not driven. The master issues a stop on the bus after receiving a NACK. The setting of this bit does not affect the acknowledgement of the slave address.

### 44.3.2 Slave Status Register (ICSSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bits 0 to 4 among the status bits in the slave status register are cleared by writing 0 to the respective status bit positions. The individual bits are held 1 until 0 is written to (other than the GCAR and STM bits).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	GCAR	STM	SSR	SDE	SDT	SDR	SAR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6	GCAR	0	R	General Call Address Received Indicates that the address received from the bus is a general call address (H'00). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in this register) is set to 1.
5	STM	0	R	Slave Transmit Mode Indicates whether the current slave transmit mode is read or write. When this bit is set to 0, the mode is write (slave reception). When this bit is set to 1, the mode is read (slave transmission). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in the slave status register) is set to 1.
4	SSR	0	R/W*	Slave Stop Received A stop condition has been output on the bus. This status bit becomes active after the rising edge of SDA during reception of a stop bit.
3	SDE	0	R/W*	Slave Data Empty Indicates that data to be transmitted has been loaded into the shift register. At the start of byte data transmission, the contents of the ICTXD register are loaded into a shift register ready for outputting data on the bus. This status bit indicates that data has been loaded and the ICTXD register is again ready for further data. This status bit becomes active on the falling edge of SCL before reception of the first data bit. During the single-buffer mode, this bit must be reset every time new data has been written to ICTXD. This is because the slave holds SCL low to stop the bus while this bit is set to 1 even if a slave transmission cycle is started.

Bit	Bit Name	Initial Value	R/W	Description
2	SDT	0	R/W*	<p>Slave Data Transmitted</p> <p>A byte of data has been transmitted to the bus. This bit becomes active after the falling edge of SCL during reception of the last data bit.</p>
1	SDR	0	R/W*	<p>Slave Data Received</p> <p>A byte of data has been received from the bus and is ready for reading from the receive data register. This bit becomes active after the falling edge of SCL during reception of the last data bit. During the single-buffer mode, this bit must be reset after data has been read from the ICRXD register.</p> <p>When SDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared.</p>
0	SAR	0	R/W*	<p>Slave Address Received</p> <p>Indicates that the slave has recognized its own address on the bus (defined by the contents of the slave address register). If the general call acknowledgement enable bit is enabled in the slave control register, then this status bit is also set to 1 even if the address on the bus is a general call address. In this case, the GCAR bit in this register is used to determine whether or not the address is a general call address. The STM bit indicates whether the access is read (high) or write (low). This status becomes active after the falling edge of SCL during reception of the last address bit. The slave holds the SCL signal low from the start of the ACK phase until the software resets this status bit.</p>

Note: \* This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

**44.3.3 Slave Interrupt Enable Register (ICSIER)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6 to 0	SADD0_6 to SADD0_0	All 0	R/W	Slave Address This is the unique 7-bit address allocated to the slave on the I2C bus. The slave interface compares this address with the first seven bits transmitted as the slave address, at the beginning of a data packet transmission.

### 44.3.5 Master Control Register (ICMCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	—	—	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MDBS	FSCL	FSDA	OBPC	MIE	TSBE	FSB	ESG
Initial value:	0	—	—	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0, except bits 30, 29, 22, 21, 14, and 13, in which case, initial value is undefined.	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7	MDBS	0	R/W	Master Data Buffer Select This bit is used to select the data buffer mode. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
6	FSCL	—	R/W	Forced SCL This bit controls the status of the I2C_SCL pin (reading reflects the current status of the I2C_SCL pin). When the OBPC bit is set, this bit directly controls the SCL line on the bus. During a read cycle, the level on this bit (which includes the reset level) will change depending on the level on I2C_SCL since it directly reflects the level on the I2C_SCL.
5	FSDA	—	R/W	Forced SDA This bit controls the status of the I2C_SDA pin (reading reflects the busy status level on the I2C bus). When the OBPC bit is set, then this bit directly controls the SDA line on the bus. During a read cycle, the level on this bit (which includes the reset level) will show the busy status of the I2C bus (1 for busy; 0 for not busy).
4	OBPC	0	R/W	Override Bus Pin Control When this bit is set to 1, the FSDA and FSCL bits in this register control SDA and SCL directly. This mode is used for testing purposes only.

Bit	Bit Name	Initial Value	R/W	Description
3	MIE	0	R/W	<p>Master Interface Enable</p> <p>When this bit is set to 1, the master interface is enabled.</p> <p>This bit is automatically cleared to 0 when this interface loses in arbitration of bus mastership. If 0 is not subsequently written to the bit, the value of the bit is restored to 1 on detection of a STOP condition on the I2C bus, and data transmission is retried.</p> <p>Regarding the state following a loss in arbitration of bus mastership, see the description of the MAL bit in ICMSR.</p>
2	TSBE	0	R/W	<p>Start Byte Transmission Enable</p> <p>When this bit is set to 1, if the master issues a START or a repeated START condition, it continues by transmitting a start byte (01H) over the bus. The start byte is used for interfacing with slower microcontrollers that have I2C bus interfaces.</p>
1	FSB	0	R/W	<p>Forced Stop onto the Bus</p> <p>When this bit is set to 1, the master transmits a STOP condition on the bus at the end of the current transfer. If ESG is also set, the master immediately transmits a START condition and begins transmitting a new data packet. If ESG is not set, the master enters the idle state.</p>
0	ESG	0	R/W	<p>Enable Start Generation</p> <p>When this bit is set to 1, the master starts transmission of a data packet. If the bus is idle when ESG is set, the master transmits a START condition on the bus and then transmits the slave address. If the master is transferring data when ESG is set, at the end of that data byte transfer, the master transmits a repeated START condition before transmitting the slave address. When transmitting a data packet, the software must reset this bit when the slave address has been transmitted, otherwise a repeated START condition is transmitted after every transmission is completed.</p>

### 44.3.6 Master Status Register (ICMSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

The status bits (bits 0 to 6) in the master status register are cleared by writing 0 to the respective status bit positions. The individual status bits are held 1 until a reset by writing 0 to the appropriate bit position.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MNR	MAL	MST	MDE	MDT	MDR	MAT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6	MNR	0	R/W*	Master NACK Received When this bit is set to 1, this bit indicates that the master has received a NACK response (the SDA line is high during the acknowledge cycle on the bus) to either an address or data transmission.
5	MAL	0	R/W*	Master Arbitration Lost In a multi-master system, when this bit is set to 1, it indicates that the master has lost arbitration to other masters on the bus. At this point, MIE is reset and the master interface is disabled.
4	MST	0	R/W*	Master Stop Transmitted When this bit is set to 1, it indicates that the master has sent a STOP condition on the bus. A STOP condition can be sent either as a result of the setting of the forced stop bit in the control register, or from a NACK being received from a slave during a slave receive data packet.
3	MDE	0	R/W*	Master Data Empty At the start of a byte data transmission, the contents of the transmit data register are loaded into a shift register ready for transmitting on the bus. When this bit is set to 1, it indicates that the shift register has been loaded, so the transmit data register is ready to accept further data. During master transmission, the MDE bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you need to clear the MDE and MAT bits after the ICMSR's ESG bit is cleared. The clearing will restart the data transmission.
2	MDT	0	R/W*	Master Data Transmitted Byte data has been sent to the slave on the bus. This status bit becomes active after the falling edge of SCL during reception of the last data bit.

Bit	Bit Name	Initial Value	R/W	Description
1	MDR	0	R/W*	<p>Master Data Received</p> <p>Byte data has been received from the bus and is in the receive data register. This status bit becomes active after the falling edge of SCL during reception of the last data bit. During single-buffer mode, this status bit must be reset after data has been read from the receive data register.</p> <p>When MDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared.</p> <p>During master reception mode, the MDR bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you must clear the MDR and MAT bits after the ICMCR's ESG bit is cleared. Clearing will start the data reception</p>
0	MAT	0	R/W*	<p>Master Address Transmitted</p> <p>The master has been transmitted the slave address byte of a data packet. This bit becomes active after the falling edge of SCL during reception of the ACK bit following transmission of the address.</p>

Note: \* This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7 to 1	SADD1_6 to SADD1_0	All 0	R/W	Slave Address These bits are the address of the slave which the master communicates with.
0	STM1	0	R/W	Slave Transfer Mode This bit specifies the mode in which the slave operates. Bit STM1 sets the operating mode (transmit or receive mode) of the slave, which is an external slave device whose address matches the slave address (SADD1) sent from the master. The slave device is automatically set to transmit/receive mode by hardware on reception of the STM1 signal. When this bit is set to 1, it indicates a read operation. When this bit is cleared to 0, it indicates a write operation.

### 44.3.9 Clock Control Register (ICCCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
8 to 3	SCGD	All 0	R/W	SCL Clock Generation Divider When operation is in master mode, the SCL clock is generated from the internal clock by using SCGD as the ratio. This is also the operating clock in slave-mode operation while SCL is being held low to stop the bus after an overflow has occurred. SCGD must be specified in both master and slave modes. The formula expressing the relationship is: Equation 2: SCL rate calculation $SCLfreq = I2Cck / (20 + SCGD \times 8 + F[(tICF + tr + IntDelay) \times I2Cck])$ I2Cck: I2C internal clock frequency tICF: I2C SCL falling time (depending on external load) tr: I2C SCL rising time (depending on external load) IntDelay: LSI internal delay corresponds to output buffer type. Open drain buffer: 50 ns (typ.), 110 ns (max.) LVTTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.). F[n]: n rounded up to an integer Suggested settings for CDF and SCGD for CPU speeds and the two I2C bus speeds are given in Table 44.3.
2 to 0	CDF	All 0	R/W	Clock Division Factor The internal clock used in most blocks in the I2C module is a divided module clock. The internal I2C clock is generated from the module clock using the CDF as the division ratio: Equation 1: I2C internal clock frequency calculation $I2Cck = MOD\_CLK / (1 + CDF)$ MOD_CLK: module clock frequency Ensure that minimum values for setup and hold times of the SDA signal relative to the SCL signal on the bus are satisfied. The clock frequency is to ensure that the glitch filtering will operate with glitches of up to 50 ns as described in the fast mode I2C specification. Note: CDF must be set so that the clock frequency (I2Cck) is lower than 20 MHz.

**Table 44.3 Recommended Settings for CDF and SCGD\*1**

- Recommended register values for open drain buffer

Module Clock Frequency	100 kHz		400 kHz	
	CDF(*2)	SCGD(*3)	CDF(*2)	SCGD(*3)
130 MHz	6	20	6	3
Error		+0.93%		-3.27%

- Recommended register values for LVTTTL buffer (low drive only)

Module Clock Frequency	100 kHz		400 kHz	
	CDF(*2)	SCGD(*3)	CDF(*2)	SCGD(*3)
130 MHz	6	20	6	3
Error		+2.04%		+0.93%

Notes: 1. These recommended values are for the SCL rate with an external load that produces  $t_{ICF} = 20$  ns and  $t_r = 35$  ns.

Recalculate to obtain the actual values after measuring  $t_{ICF}$  and  $t_r$  under actual conditions of usage.

- Recommended value for CDF bit of ICCCR.
- Recommended value for SCGD bit of ICCCR.

### 44.3.10 Receive and Transmit Data Registers (ICRXD and ICTXD)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Reading from or writing to these registers access different physical internal registers. When data is to be transmitted, the contents of the shift register are loaded via TXD. After data has been received into the shift register from the I2C bus, it is then loaded into RXD.

#### (1) Receive data register (ICRXD)

## 44.4 Operations

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 44.4.1 Data and Clock Filters

These blocks filter out glitches on signals coming from the I2C bus. Glitches up to one internal clock period in width are rejected (for details on the internal clock frequency, see section 44.3.9, Clock Control Register (ICCCR)). This is for the faster I2C bus rate (400 kHz) but does not violate the slower I2C bus rate specification.

These blocks also resynchronize bus signals with the internal clock.

### 44.4.2 Clock Generator

The clock generator has two functions. Firstly, it generates the SCL (I2C bus clock) according to commands of the master or slave interface. Secondly, it controls the internal clock rate, used by filtering blocks and the master and slave interfaces. This clock functions as a clock enable signal of the registers in these blocks.

### 44.4.3 Master/Slave Interfaces

These two interfaces run independently and in parallel. The master interface controls the transmission of address and data on the I2C bus. The slave interface monitors the I2C bus and takes part in transmissions if its programmed address is seen on the bus. The interfaces communicate with the control/status registers independently. There is only one interrupt line output from the I2C module. The interrupt source is either the master or the slave.

### 44.4.4 Software Status Interlocking

To make the software interface with the I2C module as robust and thus simple as possible, various interlocking status mechanisms have been included in the operation of the master and slave interfaces. The status bits involved are:

#### (1) MDR and SDR

MDR or SDR is set to 1 when data is received. Clear the status after reading the receive data register. If data is received while MDR or SDR is set, the hardware recognizes that unread data remains in the receive data register and automatically holds SCL at the low level to suspend data transmission. In this case, transmission can be resumed by clearing the status after reading the receive data.

Consequently, when receiving data continuously, be sure to clear the status bit (MDR or SDR) after reading the receive data register.

#### (2) MDE and SDE

If the MDE or SDE status bit is still set when data in the transmit data register is to be transmitted on the I2C bus by the slave or master, the SCL line must be held low until the MDE or SDE status bit is reset. The MDE or SDE status bit being set indicates that the data currently held in the transmit data register has already been transmitted on the I2C bus.

The software must clear this status bit when it writes to the transmit data register after transmission of the next data byte has become possible. This is not required for the first byte of data to be transmitted on the bus.

#### (3) MAL

When the master loses arbitration, the MAL bit (of the master status register) is set and the MIE bit (of the master control register) is reset. At this point, master mode is invalid and the I2C bus interface enters the slave mode. When master operation is restarted, data transfer from the master begins after the MAL bit has been cleared.

#### (4) SAR

The SAR status bit is set when the slave identifies its address on the I2C bus. At this point the slave interface forces the SCL line low until the SAR status bit is reset.

This is particularly important when a slave transmit is about to take place on the bus, and the slave will transmit the data from the transmit data register. The software responds to the SAR status by writing the required data into the transmit data register and then resetting the SAR status bit. This allows the slave interface to continue the access.

Unless the SAR bit is in use, when the slave is about to receive data, the software might still be reading out data that was loaded in previous access from the receive data register. In this case the valid data still held in the receive data register is overwritten. However, this is avoided using the SAR status bit. After the software has read data in the receive data register, reset the SAR bit (if it is set). Then overwriting the receive data register is avoided.

#### 44.4.5 I2C Bus Data Format

Figure 44.2 shows a timing chart for the I2C bus interface. Table 44.4 describes the meaning of each symbol in Figure 44.2.

Figure 44.2 I2C Bus Timing

Table 44.4 Description on Symbols of I2C Bus Data Format

Symbol	Description
S	Indicates a start condition. A master device changes SDA from high to low while SCL is high level.
SLA	Indicates a slave address. A slave address is used when a master device selects a slave device.
R/W	Indicates the direction of data transmission. If the R/W bit is 1, the data flows from the slave to the master device. If the bit is 0, the data flows from the master to the slave device.
A	Indicates data acknowledge. Data receiving device makes SDA low level (the slave device returns a data acknowledge signal in master transmission mode, and vice versa).
DATA	Indicates transmit or receive data. The data length is eight bits, which are transferred in the MSB first.
P	Indicates a stop condition. A master device changes SDA from low to high while SCL is high.

**44.4.6 7-Bit Address Format**

Figure 44.3 shows the format of data transfer from a master to a slave device (master data transmit format). Figure 44.4 shows the data transfer format (master data receive format) when a master device reads the second and the following byte data from a slave device.

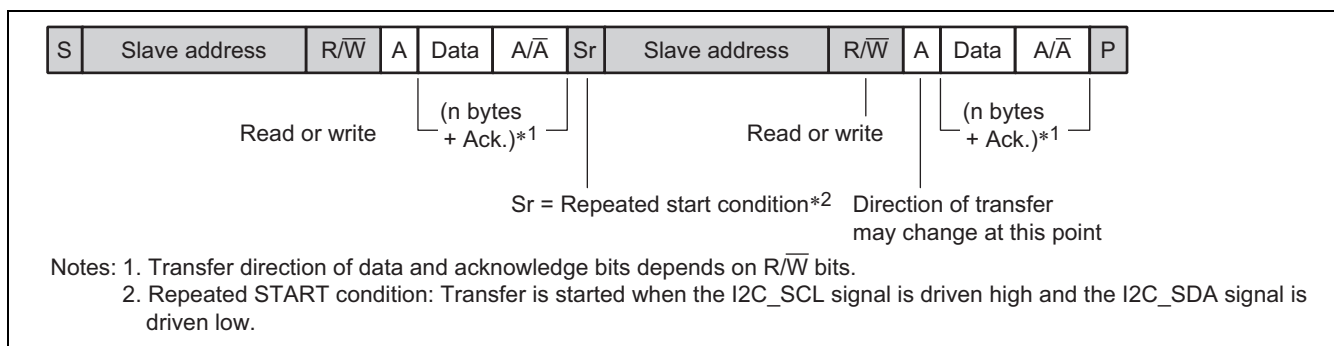

**Figure 44.3 Master Data Transmit Format**

**Figure 44.4 Master Data Receive Format**

Figure 44.5 shows the combined format when the data transfer direction changes during one transfer. When changing the direction after the first transfer, the repeated START condition (Sr), slave address and R/W bits are transmitted. In this case, the R/W bit is set to the direction opposite to the first transfer direction. The repeated START condition is issued by the master at the end of a transmit or receive cycle if the enable start generation bit in the master control register has been set.

**Figure 44.5 Combination Transfer Format of Master Transfer**

### 44.4.7 10-Bit Address Format

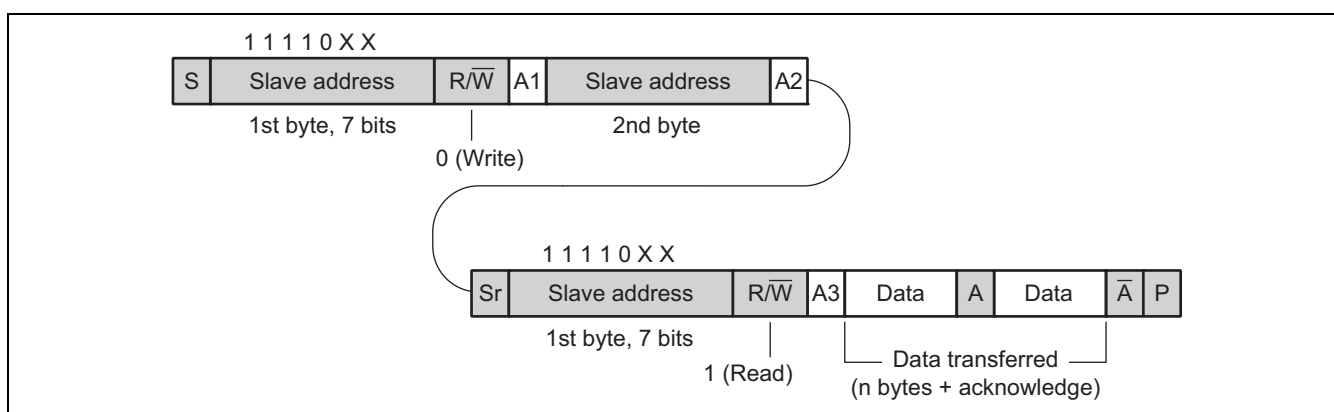

Description is given below on the 10-bit address transfer format supported in master mode. This format has three transfer methods as the 7-bit address transfer format.

Figure 44.6 shows the data transmit format. The set value in the master address register is output in one byte following the first START condition (S). The value set in the transmit data register (TXD) is transmitted as a slave address in the second byte. Data on and after the third byte is transferred in the same way as the 7-bit address data.

**Figure 44.6 10-Bit Address Data Transmit Format**

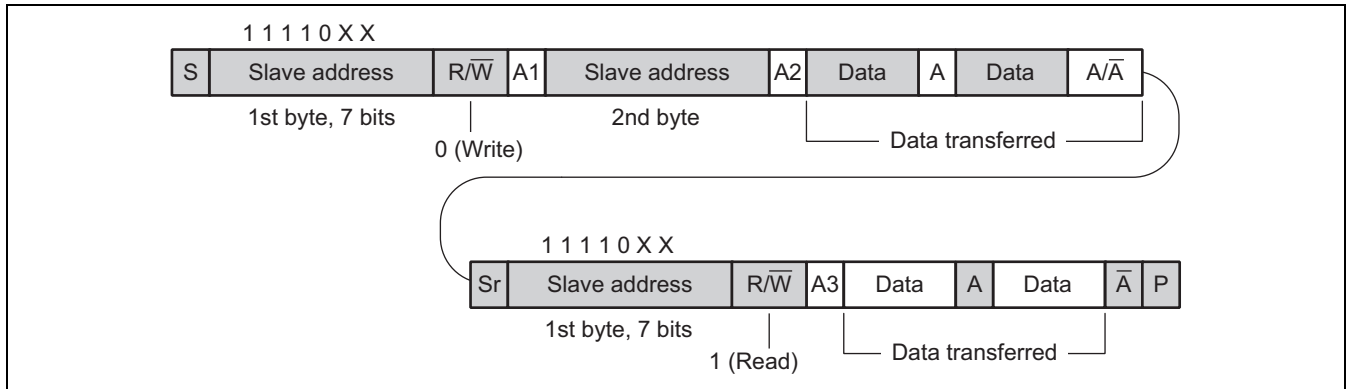

Figure 44.7 shows the data receive format. Two bytes of an address is transmitted in the same way as in the data transmit format. Then, repeated START condition (Sr) is transmitted and the value set in the address register is output. At this time, STM1 must be set to 1 (receive mode). Data is transferred in the same way as in the 7-bit address data receive format.

**Figure 44.7 10-Bit Address Data Receive Format**

Figure 44.8 shows the data transmit/receive combined format.

In the data transmit/receive combined format, data is transmitted after an address is transmitted with the first two bytes. Then, the repeated START condition (Sr) is transmitted instead of STOP condition (P). After Sr is transmitted, the procedure is the same as that in the data receive format.

**Figure 44.8 10-Bit Address Transmit/Receive Combined Format**

#### 44.4.8 Master Transmit Operation

The procedure and operations for transmission in master transmit mode are described below. Figure 44.9 shows the timing chart in master transmit mode. Setting the MDBS bit in the master control register allows the I2C to operate in single-buffer mode.

1. Set up the initial state by setting the slave address register, transmission data register, clock control register, and master interrupt enable register. Note that the setting of the clock control register must be in accord with the rate of transmission. Since slave mode is also required even when master mode is used, set the device address in the slave address register.
2. Monitor the FSDA bit in the master control register. Confirm that this bit is low, meaning that other I2C devices are not using the bus. After confirmation, set the MIE (bit 3) and ESG (bit 0) bits in the master control register to 1 to start master transmission.
3. After the transmit START condition, slave address, and data transfer direction bits are transmitted, an interrupt due to the MAT and MDE bits in the master status register is generated at the timing of (1) in Figure 44.9. At this time, clear the ESG bit to 0. To suspend the data transmission, the master device will hold SCL low until the MDE bit is cleared.
4. An interrupt due to the SAR bit is generated at the timing of (3) shown in Figure 44.9. If the IRQ handling in the slave device is delayed, the slave device extends the SCL period to suspend data transmission (at the timing of (7) in Figure 44.9). The slave device drives SDA low at the ninth clock and returns ACK.
5. Data is transmitted in units of nine bits: 8-bit data and 1-bit ACK. An interrupt of MDE (bit 3) is generated at the ninth clock before data transfer (at the timing of (2) in Figure 44.9). An interrupt of MDT (bit 2) is generated at the eighth clock after 1-byte data transfer (at the timing of (4) in Figure 44.9). Clear MDE to 0 after setting transmit data. An interrupt of SDR (slave data receive) of the slave device is generated at the eighth clock (at the timing of (6) in Figure 44.9). Clear SDR after the slave device reads the receive data. If this processing is delayed, the slave device extends the SCL period to suspend data transmit (at the timing of (8) in Figure 44.9).
6. To end data transfer, an interrupt of MNR (bit 6) in the master status register is generated at the ninth clock (at the timing of (5) in Figure 44.9) when ACK from the slave device is 1 (NACK). The master device receives this NACK and outputs the STOP condition. When data transmission ends on the master device side, set FSB (bit 1) in the master control register to 1 to output the STOP condition. After the I2C module fetches FSB on completion of transmission or reception of the last bit of byte data, it enters the stop state. Therefore in order to stop the communication after the predetermined number of byte data is transferred, the FSB bit needs to be set before the last byte data transfer is started.
7. The FSB bit needs to be set before the last byte data is transferred. In master transmit mode, after the last byte data is set, the MST (master stop transmitted) bit is checked by either interrupt or polling. At the same time MNR (master NACK received) bit must be checked. If NACK is returned, an error routine is executed to retransmit the last byte data.

Signal level changes of (1) to (6) in Figure 44.9 are generated after the falling edge of the clock.

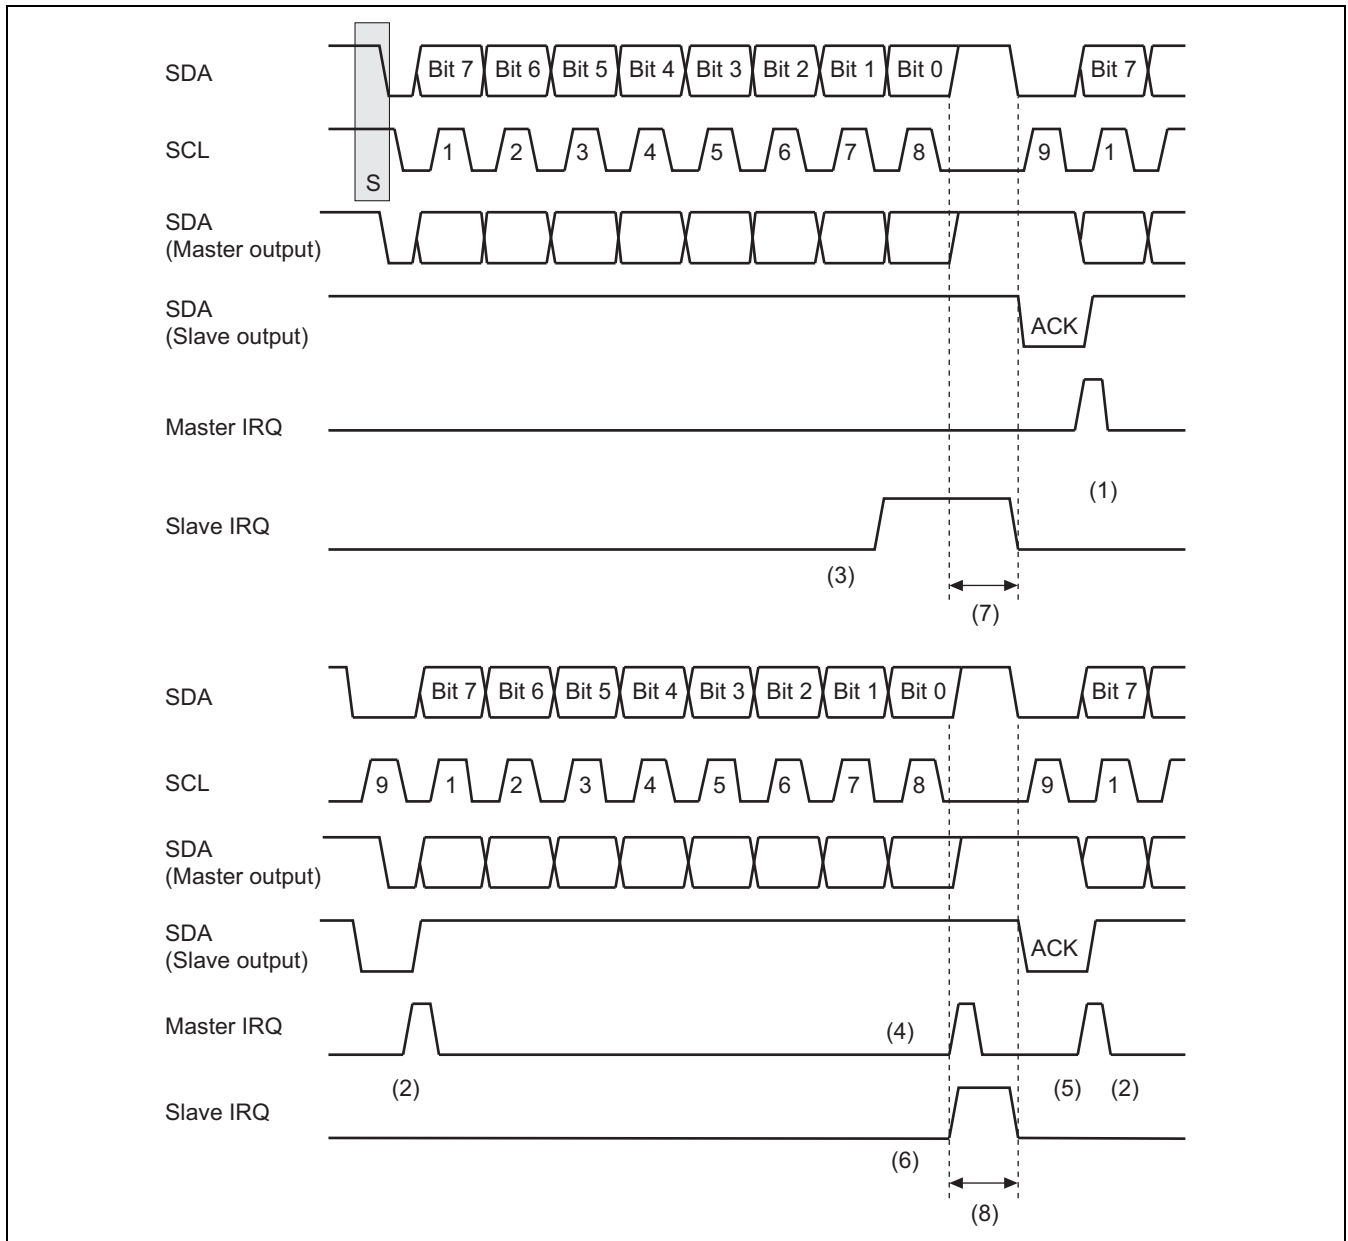

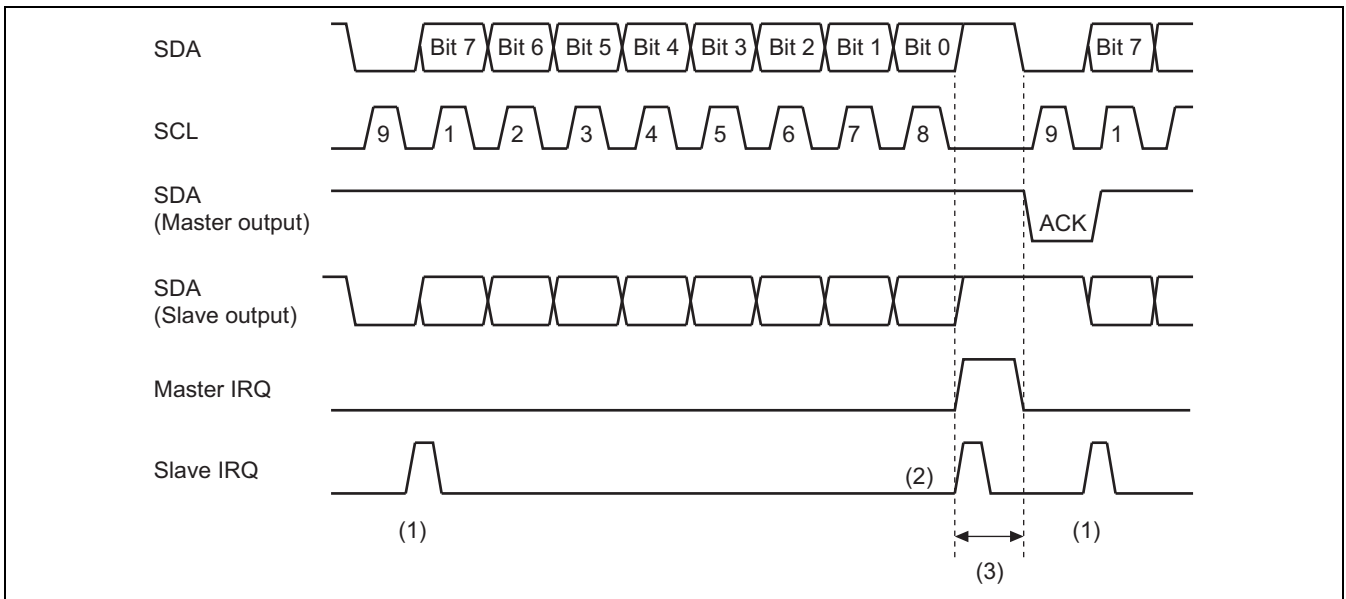

Figure 44.9 Data Transmit Mode Operation Timing

**44.4.9 Master Receive Operation**

The data receive procedure and operation in master receive mode are described below. Figure 44.10 shows the timing chart in master receive mode. Setting the MDBS bit in the master control register allows the I2C to operate in single-buffer mode.

1. In master receive mode, as to transmit of a slave address and a 1-bit signal indicating the data transfer direction, operation is the same as that in master transmit mode. At this time, set the data transfer direction to 1 (reception).
2. The slave device automatically enters the data transmit mode according to the signal that indicates the data transfer direction, and transmits 1-byte data in synchronization with the SCL clock output from the master device. The master device generates an interrupt of MDR (bit 1) at the eighth clock (at the timing of (2) in Figure 44.10). Clear the MDR bit after the master device reads receive data. If this processing is delayed, the master device extends the SCL period to suspend data transmission (at the timing of (3) in Figure 44.10).
3. The slave device generates an interrupt of the status SDT (bit 2) indicating 1-byte data transfer end at the eighth clock (at the timing of (2) in Figure 44.10) and an interrupt of the status SDE (bit 3) indicating data empty at the ninth clock (at the timing of (1) in Figure 44.10). Clear SDE after writing slave transmit data to TXD.
4. To end data transfer, set FSB (bit 1) in the master control register of the master device and output STOP condition. After the I2C module fetches FSB on completion of transmission or reception of the last of byte data, it enters the stop state. Therefore in order to stop the communication after predetermined number of byte data is transferred, FSB bit needs to be set before the last byte data transfer is started. After confirming reception of the last byte, even when the master receiver has completed the reception transaction, the protocol layer will inform the slave transmitter that retransmission is necessary if the last byte is incorrect.

Signal level changes of (1) to (3) in Figure 44.10 are generated after the falling edge of the clock.

**Figure 44.10 Data Receive Mode Operation Timing**

## 44.5 Programming Examples

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 44.5.1 Master Transmitter

In order to set up the master interface to transmit a data packet on the I2C bus, follow the procedure below (an example for I2C0):

#### (1) Load value for the clock control register

(When the module clock frequency is 130 MHz and SCL clock frequency is set to 400 kHz)

1. Set the SCL clock generation divider bit (SCGD) to H'3.
2. Set the clock division ratio bit (CDF) to H'6 (I2C internal clock I2Cck: 18.57 MHz).

#### (2) Load value for the master control register, first data byte, and address

1. Master address register = address of slave being accessed and STM1 bit (write mode: 0)
2. Transmit data register = first data byte to be transmitted
3. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)

#### (3) Wait for outputting address

1. Wait for master event (an interrupt of the MAT and MDE bits in the master status register).
2. Set the master control register to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDE bit is cleared).

If only one byte of data is transmitted, set the master control register to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.

3. Reset the MAT and MDE bits.

#### (4) Monitor transmission of data

1. Wait for master event, MDE in the master status register.
2. Transmit data register = subsequent data.
3. Reset the MDE bit.

Clear MDE after setting the last byte to be transmitted. After the last byte data is transmitted, MDE is generated. Before clearing MDE, you must set the master control register to H'8A (set the force stop control bit).

#### (5) Wait for end of transmission

1. Wait for the master event, MST in the master status register.
2. Reset the MST bit after confirming MNR (master NACK received).

### 44.5.2 Master Receiver

In order to set up the master interface to receive a data packet on the I2C bus, follow the procedure below:

#### (1) Load value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

#### (2) Load value for the master control register and address

1. Master address register = address of slave being accessed and STM1 bit (read mode: 1)
2. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)

#### (3) Wait for outputting address

1. Wait for master event (an interrupt of the MAT and MDR bits in the master status register).
2. Set the master control register to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDR bit is cleared).

If only one byte of data is transmitted, set the master control register to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.

3. Reset the MAT and MDR bits.

#### (4) Monitor reception of data

1. Wait for master event (the MDR bit in the master status register).
2. Read data from the received data register.

If the next byte of data is the second to last byte to be transmitted by the slave device, the following applies to the receive interrupt (that is, MDR interrupt) in the second to last byte.

3. Set the master control register to H'8A (set the force stop control bit).
4. Reset the MDR bit.

#### (5) Wait for end of reception

1. Handle the receive interrupt (MDR) in the last byte: that is, read the data and clear the MDR.
2. Wait for master event, MST in the master status register.
3. Reset the MST bit.

### 44.5.3 Master Transmitter—Repeated START—Master Receiver

In order to set up the master interface to transmit a data packet on the I2C bus, issue a repeated START condition, then read byte data back from the slave, follow the procedure below:

#### (1) Load value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

#### (2) Load value for the master control register and address

1. Master address register = address of slave being accessed and STM1 bit (write mode: 0)
2. Transmit data register = first data byte to be transmitted
3. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)
4. Wait until slave-address transfer have started, and set master control register to H'88 (MDBS=1, MIE=1, ESG=0). (Start of slave address transfer can be checked by FSDA bit, or waiting enough time after setting ESG bit).

#### (3) Wait for outputting slave-address for master transmission

1. Wait for master event (an interrupt of the MAT and MDE bits in the master status register).
2. Set the master address register to address of slave being accessed and STM1 bit (read mode: 1).  
When the enable start generation bit in the master control register is still set, at the end of the byte transmission the master will issue a repeated START condition. Since the new address has been loaded above, the bus direction will be changed.
3. Reset the MAT and MDE bits.

#### (4) Monitor transmission of data

1. Wait for master event (an interrupt of the MDE bit in the master status register).
2. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)
3. Reset the MDE bit.

#### (5) Wait for outputting slave-address for master reception

1. Wait for master event (an interrupt of the MAT and MDR bits in the master status register).
2. Set the master control register to H'88. (To suspend stop the data transmission, the master device will hold the SCL low until the MDR bit is cleared.)
3. Reset the MAT and MDR bits.

#### (6) Monitor reception of data

1. Wait for master event (the MDR bit in the master status register).
2. Read data from the received data register.  
If the next byte of data is the second to last byte to be transmitted by the slave device, the following applies to the receive interrupt (that is, MDR interrupt) in the second to last byte.
3. Set the master control register to H'8A (set the force stop control bit).
4. Reset the MDR bit.

#### (7) Wait for end of reception

1. Handle the receive interrupt (MDR) in the last byte: that is, read the data and clear the MDR.
2. Wait for master event, MST in the master status register.
3. Reset the MST bit.

## 44.6 Usage Note

### 44.6.1 SCL frequency calculation equation

In section 44.3.9, Clock Control Register (ICCCR), in the description of SCGD and CDF, following equation is described.

$$\text{SCLfreq} = \text{I2Cck} / (20 + \text{SCGD} \times 8 + F[(\text{tICF} + \text{tr} + \text{IntDelay}) \times \text{I2Cck}])$$

I2Cck: I2C internal clock frequency

tICF: I2C SCL falling time (depending on external load)

tr: I2C SCL rising time (depending on external load)

IntDelay: LSI internal delay corresponds to output buffer type.

Open drain buffer: 50 ns (typ.), 110 ns (max.)

LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.).

F[n]: n rounded up to an integer

$$\text{I2Cck} = \text{MOD\_CLK} / (1 + \text{CDF})$$

MOD\_CLK: module clock frequency

Based on parameter described above, this equation approximately estimates the SCL frequency, but includes some error in the resulting frequency. Before finalizing register setting to be used, measure actual SCL frequency on the board, and confirm that observed frequency satisfy the constraint. The reason why calculated result includes some error is parameters used in this equation varies depending on the characteristics of each sample. For example, tICF and tr depend on logical threshold of IO-cell, and intDelay depends on variation of fabrication process.

For adjustment of SCL frequency, modifying the setting of ICCCR[2:0].CDF and ICCCR[8:3].SCGD will be effective. Increasing the value of CDF or SCGD value will make SCL frequency lower. However, how they decrease SCL frequency is different. So, by increasing one register value and decreasing the other, SCL frequency can be adjusted.

## 45. IIC Bus Interface (IIC)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

The IIC bus interface uses only one data line (SDA) and one clock line (SCL) to transfer data, saving board and connector space.

### 45.1 Features

The RZ/G series products have up to four IIC bus interface modules (IIC0, IIC1, IIC2, and IIC3).

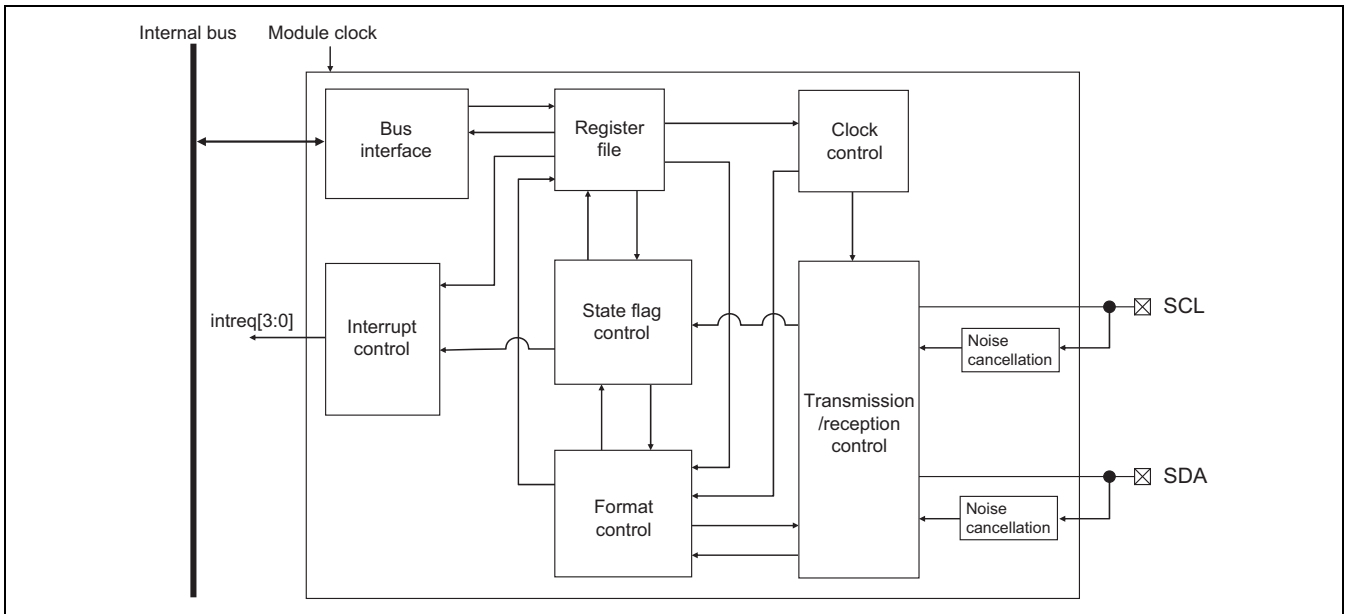

The module clock for the IIC0, IIC1, and IIC2 is HP $\phi$ .

The module clock for the IIC3 is CP $\phi$ .

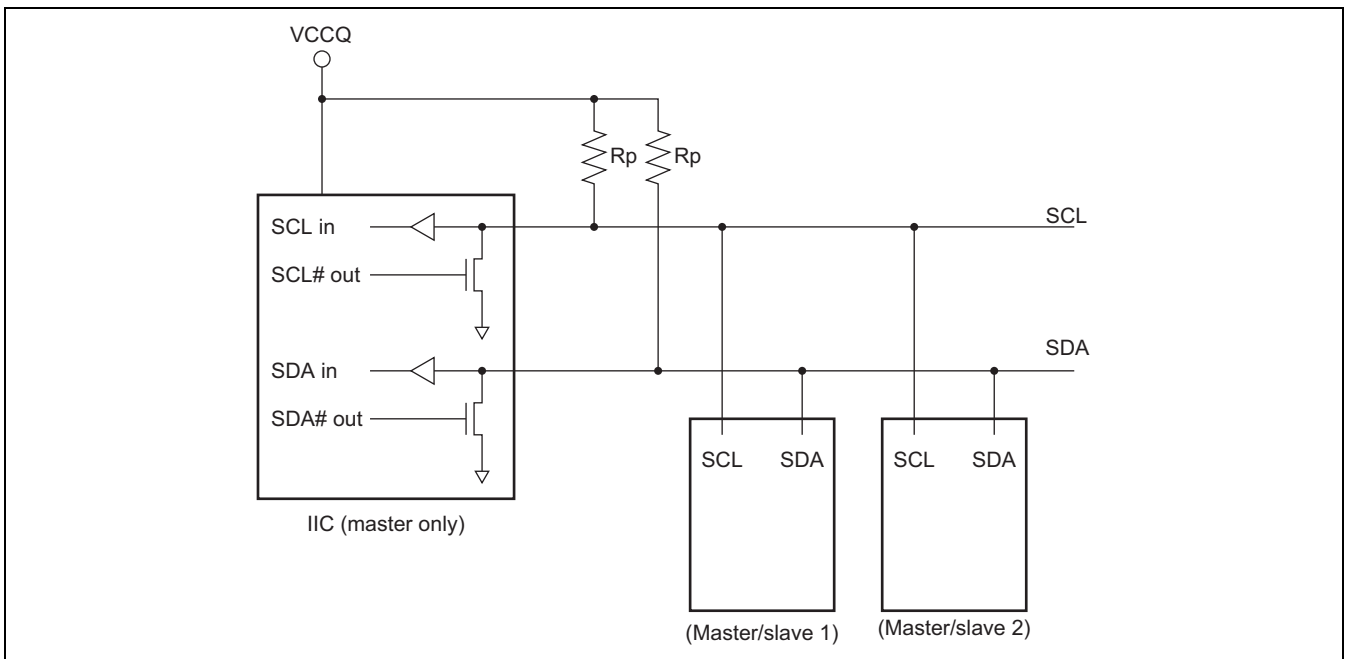

- Data transfer based on I2C bus format from Philips Semiconductor (now NXP Semiconductors)
- Automatic generation of START and STOP conditions
- Control of acknowledge level after receiving data
- Automatic checking of acknowledge bit after transmitting data
- Wait function
  - A wait can be inserted by driving the SCL pin low after data transfer, excluding acknowledgement.
  - The wait can be canceled by clearing the interrupt flag.
- This module supports only master mode.
  - If arbitration is lost, data transfer is stopped and I2C bus is released.
- Four interrupt sources
  - Data transfer enable
  - Wait state
  - Non-acknowledge detection
  - Arbitration lost
- Data transfer speed
  - Supports standard-mode (100 kHz) and fast-mode (400 kHz)
  - SCL clock frequency can be controlled by register setting.
- Supports clock synchronization of SCL line
  - A hazard (transient spike) in the SCL high-count period is detected as a loss of arbitration.
- DMA transfer
  - Supports DMA transfer (for both transmission and reception).

Note: Automatic transmission for PMIC control (DVFS) is not available because the RZ/G series products do not support the DVFS function (automatic transmission can be used as a hardware function, but this is not meaningful for actual use cases).

Figure 45.1 shows a block diagram of the IIC bus interface module.

**Figure 45.1 Block Diagram of IIC Bus Interface Module**

**Figure 45.2 Connection Example of IIC Bus Interface Module**

## 45.2 Input/Output Pins

Table 45.1 summarizes the input/output pins used by the IIC bus interface.

**Table 45.1 IIC Bus Interface Pins**

Channel Number	Pin Name* <sup>1</sup>	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
				Output Buffer Type* <sup>2</sup>			
0	SCL	I/O	SCL:	OD* <sup>3</sup>	LVTTL	LVTTL	LVTTL
	SDA		IIC serial clock input/output pin				
1	SCL		SDA:	LVTTL* <sup>3</sup>	LVTTL	LVTTL	OD
	SDA		IIC serial data input/output pin				
2	SCL			LVTTL* <sup>3</sup>	—	—	—
	SDA						
3	SCL			OD* <sup>3</sup>	OD	OD	—
	SDA						

Notes: 1. The actual pin names are IICn\_SCL and IICn\_SDA (n = 0 to 3 for RZ/G1H, and 0, 1 and 3 for RZ/G1M, N). These are referred to as SCL and SDA in this section.

2. Output buffer type: "OD" is open drain buffer and "LVTTL" is low level drive only LVTTL buffer. OD assigned channel pins are 1.8 V I/O and input/output 3.3 V tolerant; LVTTL assigned channel pins are 3.3 V I/O.

3. These pins are shared with the I2C module. Select either I2C or IIC for each channel.

The IIC buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source (3.3 V) of this LSI, turn off the power source of the pull-up resistors connected to the I2C pins.

Note: When using 1.8V I2C/IIC pins (OD assigned channel) as 3.3 V tolerant, all the external pull-up voltage power supply to the I2C/IIC of this LSI must keep the same power on/off sequence as the VCCQ (3.3 V) of this LSI.

### 45.3 Register Descriptions

Table 45.2 shows the register configuration of the IIC bus interface. Table 45.3 shows the register state in each processing mode.

The base address for each channel of the IIC bus interface registers is as follows:

- IIC0: H'E650\_0000 (RZ/G1H, M, N and E)
- IIC1: H'E651\_0000 (RZ/G1H, M, N and E)
- IIC2: H'E652\_0000 (RZ/G1H only)
- IIC3\*: H'E60B\_0000 (RZ/G1H, M and N)

Note:\* Automatic transmission for PMIC control (DVFS) is not available because the RZ/G series products do not support the DVFS function (automatic transmission can be used as a hardware function, but this is not meaningful for actual use cases).

Each channel of the IIC bus interface module has the registers below.

**Table 45.2 Register Configuration of Bus Interface**

### 45.3.1 IIC Bus Data Register (ICDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICDR is an 8-bit readable/writable register that is used as a transmit data register when transmitting and a receive data register when receiving.

In transmission mode, write transmit data to this register when the DTE bit in the IIC bus status register (ICSR) is 1.

In receive mode, read receive data from this register when the DTE bit in the IIC bus status register (ICSR) is 1.

### 45.3.2 IIC Bus Control Register (ICCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICCR is an 8-bit readable/writable register that enables or disables the IIC bus interface, specifies the transmission/receive mode, issues START/STOP conditions, and confirms the IIC bus interface bus status.

**Table 45.4 ICCR Settings**

Operation	Write Data to ICCR (Transmission Mode)	Write Data to ICCR (Receive Mode)
START condition	H'94	—
Repeated START condition	H'94	—
Repeated START condition with transmission/receive mode change	H'81 (Change from transmission mode to receive mode)	H'D4 (Change from receive mode to transmission mode)
STOP condition	H'90	H'C0

When this bit is cleared to 0 during data transmission, the I2C bus is released and all registers in this module are initialized. (See section 45.6, Usage Note.)</p> <p>When this bit is cleared to 0 after data transmission, all registers in this module are initialized.</p> <p>When the ICCR is updated while this module is operating, this bit must be set to 1.</p> <p>0: IIC bus interface module is disabled. (All internal registers are initialized.)</p> <p>1: IIC bus interface module is enabled.</p>
6	RACK	0	R/W	<p>Receive Acknowledge</p> <p>Specifies the acknowledge level in receive mode.</p> <p>In reception, this bit provides the acknowledge level for output on the SDA line after the IIC module receives data.</p> <p>0: In receive mode, 0 is output to SDA at acknowledge output timing.</p> <p>1: In receive mode, 1 is output to SDA at acknowledge output timing.</p>
5	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
4	TRS	0	R/W	<p>Transmit/Receive Select</p> <p>Specifies either transmission mode or receive mode.</p> <p>The setting of this bit can be rewritten even during data transfer, but actual operating mode is changed after completion of ongoing transfer including acknowledge bit.</p> <p>0: Master reception mode.</p> <p>1: Master transmission mode.</p> <p>When writing 1 to this bit, also set BBSY and SCP bits at the same time.</p>
3	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
2	BBSY	0	R/W	<p>Bus Busy</p> <p>This bit is used to issue START and STOP conditions.</p> <p>To issue a START condition, write 1 to this bit and 0 to the SCP bit. A repeated START condition is issued in the same way. To issue a STOP condition, write 0 to this bit and 0 to the SCP bit.</p> <p>0: A STOP condition is issued (the SCP bit is also used).</p> <p>1: A START or repeated START condition is issued (the SCP bit is also used).</p>
1	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
0	SCP	1	(R/W)*	<p>START Condition/STOP Condition Prohibit</p> <p>Controls issuance of START and STOP conditions. To issue a START condition, write 1 to the BBSY bit and 0 to this bit. A repeated START condition is issued in the same way. To issue a STOP condition, write 0 to the BBSY bit and 0 to this bit. This bit is always read as 1. Writing 1 to this bit is ignored.</p> <p>0: Writing 0 to this bit issues a START or STOP condition, in combination with the BBSY flag.</p> <p>1: Writing 1 to this bit is ignored.</p>

Note: \* For the SCP bit, only writing 0 is valid. Always read as 1.

### 45.3.3 IIC Bus Status Register (ICSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICSR is an 8-bit readable/writable register that performs interrupt request.

Bit:	7	6	5	4	3	2	1	0
	SCLM	SDAM	—	BUSY	AL	TACK	WAIT	DTE
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R

Bit	Bit Name	Initial Value	R/W	Description
7	SCLM	1	R	<p>SCL Monitor</p> <p>Indicates the SCL state sampled by the module clock.</p> <p>0: Indicates that SCL is 0.</p> <p>1: Indicates that SCL is 1.</p>
6	SDAM	1	R	<p>SDA Monitor</p> <p>Indicates the SDA state sampled by the module clock.</p> <p>0: Indicates that SDA is 0.</p> <p>1: Indicates that SDA is 1.</p>
5	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
4	BUSY	0	R	<p>IIC Transmit State Bit</p> <p>Indicates the IIC state. After the START condition is generated, the IIC enters the transfer state and this bit is set to 1. After the STOP condition is generated, the IIC enters the non-transfer state and this bit is cleared to 0.</p> <p>When a loss of arbitration is detected, the SDA line is immediately released, but output of the clock signal on SCL continues until frame acknowledgement is completed. This bit is cleared to 0 after end of frame transfer.</p> <p>0: The IIC module is not busy (transfer by the IIC module is not in progress).</p> <p>1: The IIC module is busy (transfer by the IIC module is in progress).</p> <p>Setting condition:</p> <p>The IIC module issues the START condition.</p> <p>Clearing condition:</p> <p>The IIC module issues the STOP condition.</p> <p>A loss of arbitration is detected (cleared after SCL clock output is stopped).</p>

Bit	Bit Name	Initial Value	R/W	Description
3	AL	0	R/(W)*	<p><b>Arbitration Lost</b></p> <p>Indicates a loss of arbitration.</p> <p>The IIC bus interface monitors the SDA. If the IIC bus interface detects data different from the data it sent, it sets this bit to 1 to indicate that the bus has been conflicted. This bit is reset by writing 0 to this bit or performing write access to ICDR in transmit mode or read access to ICDR in receive mode when the DTE bit is 1.</p> <p>When a loss of arbitration is detected during data transfer, the SDA line is immediately released. Output of the clock line on SCL continues until frame acknowledgement is completed. This bit does not depend on the ALE bit in ICIC and is always updated. When the ALE bit in ICIC is 0, an arbitration lost interrupt request is not issued to the interrupt controller. When other masters issue the START condition, a loss of arbitration is detected and operation is stopped.</p> <p>0: Bus arbitration won</p> <ul style="list-style-type: none"> <li>• When data are written to IDCR (transmit mode) or read from IDCR (receive mode)</li> <li>• When 0 is written to this bit after reading AL = 1</li> </ul> <p>1: Arbitration lost</p> <ul style="list-style-type: none"> <li>• When the level of the data being received changes during counting of the period at high level for the SCL clock in master receive mode</li> <li>• When the level on the SCL line becomes low during counting of the period at high level for the SCL clock</li> <li>• When a START condition is detected before this module issues its own START condition</li> <li>• When the monitored external SDA and data being output from this module not being equal</li> </ul>
2	TACK	0	R/(W)*	<p><b>Transmit Acknowledge Bit</b></p> <p>Indicates the level of the SDA line during acknowledge cycle in transmit mode. This bit is cleared by writing 0. This bit is always 0 when the TACK bit in ICIC is 0.</p> <p>0: Indicates that acknowledge (low level on SDA line) have been detected during acknowledge cycle.</p> <p>1: Indicates that no acknowledge (high level on SDA line) have been detected during acknowledge cycle.</p>
1	WAIT	0	R/(W)*	<p><b>Wait</b></p> <p>Indicates that this module have entered the wait state after data transmission other than the acknowledge bit.</p> <p>When the value of the WAITE bit in ICIC is 1, this module enters the wait state after data transfer (except for acknowledge bit), with driving the SCL to the low level. At this time, this bit is automatically set to 1 and a WAIT interrupt is generated. By writing 0 to this bit, this module recovers from the wait state.</p> <p>This bit is always 0 when WAITE in ICIC is 0.</p> <p>0: This module is in the normal state.</p> <p>1: This module is in the wait state.</p>

Bit	Bit Name	Initial Value	R/W	Description
0	DTE	0	R	<p>Data Transmit Enable</p> <p>Indicates the transmit state between ICDR and internal transmit/receive buffer. This bit is read only and automatically set or cleared.</p> <p>0: With the TACK bit set to 1,</p> <ul style="list-style-type: none"> <li>• When reset is performed</li> <li>• When data is written to ICDR in transmit mode (TRS = 1).</li> <li>• When data is read from ICDR in receive mode (TRS = 0).</li> <li>• When the TRS bit is changed.</li> <li>• When the repeated START condition/STOP conditions are written to the BBSY and SCP bits in ICCR.</li> </ul> <p>1:</p> <ul style="list-style-type: none"> <li>• When the START/repeated START conditions are generated.</li> <li>• When transmit data is sent to the transmit buffer from ICDR in transmit mode (TRS = 1).</li> <li>• When receive data is sent to ICDR in receive mode (TRS = 0).</li> </ul>

Note: \* Only 0 can be written for clearing the flag.

### 45.3.4 IIC Interrupt Control Register (ICIC)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICIC is an 8-bit register that enables or disables an interrupt request.

Bit:	7	6	5	4	3	2	1	0
	ICCLB8	ICCHB8	TDMAE	RDMAE	ALE	TACKE	WAITE	DTEE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ICCLB8	0	R/W	IIC Clock Control Low Bit 8 Sets the low-level period of SCL when the period setting for the module in {ICIC[7], ICCL} is H'100 to H'1FF. Table 45.5 shows transfer rate settings.
6	ICCHB8	0	R/W	IIC Clock Control High Bit 8 Sets the high-level period of SCL when the period setting for the module in {ICIC[6], ICCH} is H'100 to H'1FF. Table 45.5 shows transfer rate settings.
5	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable When DTEE is 1, this bit specifies whether data transmit interrupt in transmission mode (TRS = 1) is used as an interrupt to the CPU or a DMA transfer request. When DMA is used for automatic transmission*, setup of this bit is unnecessary. 0: Uses TDMAE as an interrupt to the CPU. 1: Uses TDMAE as a DMA transfer request to DMAC.
4	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable When the DTEE bit is 1, this bit specifies whether data receive interrupt in receive mode (TRS = 0) is used as an interrupt to the CPU or a DMA transfer request. When DMA is used for automatic transmission*, setup of this bit is unnecessary. 0: Uses RDMAE as an interrupt to the CPU. 1: Uses RDMAE as a DMA transfer request to DMAC.
3	ALE	0	R/W	Arbitration Lost Interrupt Enable and Function Enable Enables or disables arbitration lost interrupt request. An arbitration lost interrupt is generated if a loss of arbitration occurs when this bit is 1. At this time, the AL bit in ICSR is set to 1. Do not clear this bit to 0 with the AL bit set to 1. 0: Disables an arbitration lost Interrupt. 1: Enables an arbitration lost interrupt.

Bit	Bit Name	Initial Value	R/W	Description
2	TACKE	0	R/W	<p>Non-acknowledge Detection Interrupt Enable and Function Enable</p> <p>Enables or disables a non-acknowledge detection interrupt request.</p> <p>A non-acknowledge interrupt is generated if non-acknowledge is received when this bit is 1. At this time, the TACK bit in ICSR is set to 1. Do not clear this bit to 0 with the TACK bit set to 1.</p> <p>0: Disables non-acknowledge detection Interrupt.</p> <p>1: Enables non-acknowledge detection interrupt.</p>
1	WAITE	0	R/W	<p>Wait Interrupt Enable and Function Enable</p> <p>Enables or disables a wait interrupt request.</p> <p>When WAITE is 1, a wait state in which SCL is driven to the low level follows the transmission of data other than the acknowledge bit.</p> <p>At this time, a WAIT interrupt is generated and the WAIT bit in ICSR is set to 1. Do not clear this bit to 0 with the WAIT bit in ICSR set to 1.</p> <p>0: Disables an interrupt.</p> <p>1: A wait interrupt is generated.</p>
0	DTEE	0	R/W	<p>Data Transmit Enable Interrupt</p> <p>Enables or disables a data transmit enable interrupt request.</p> <p>An interrupt request is issued if the DTE bit in ICSR is set to 1 when this bit is 1.</p> <p>0: Disables an interrupt.</p> <p>1: A data transmit enable interrupt is generated.</p>

Note: \* Automatic transmission for PMIC (DVFS) is not available.

### 45.3.5 IIC Clock Control Register Low (ICCL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICCL is an 8-bit readable/writable register that specifies the low-level period of SCL.

ICCL is initialized to H'00 by a reset.

Note: No SCL clock is generated when {ICIC[7], ICCL} = H'000 to H'0FF or H'1FF.

### 45.3.6 IIC Clock Control Register High (ICCH)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICCH is an 8-bit readable/writable register that specifies the high-level period of SCL.

ICCH is initialized to H'00 by a reset.

Note: No SCL clock is generated when {ICIC[7], ICCL} = H'000 to H'0FF or H'1FF.

### 45.3.7 IIC Transmit Register (ICTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICTR is an 8-bit register that indicates transmit data of the IIC bus interface.

### 45.3.8 IIC Receive Register (ICRR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICRR is an 8-bit register that monitors receive data of the IIC bus interface.

### 45.3.9 IIC Transmit Monitor Register (ICTA)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICTA is an 8-bit register that indicates the repeated START condition.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	Rsetup	—	—	—
Initial value:	—	—	—	—	0	—	—	—
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	—	R	Reserved Writing to these bits is prohibited.
3	Rsetup	0	R	Repeated START Condition Setup Specifies whether retransmission condition have been specified or not. This bit is 1 from the repeated START condition being specified (by writing H'94 to ICCR) until the repeated START condition is actually generated.
2 to 0	—	—	R	Reserved Writing to these bits is prohibited.

**45.3.10 IIC Transmit Buffer Monitor Register (ICTB)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICTB is an 8-bit register that indicates the communication status of the IIC bus interface.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	Sbflg	Tbflg	Rbflg	Drflg
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	—	R	Reserved
3	Sbflg	0	R	ICSF Buffer Flag 0: ICSF has no transmit data. 1: ICSF has transmit data.
2	Tbflg	0	R	ICTR Buffer Flag 0: ICTR has no transmit data. 1: ICTR has transmit data.
1	Rbflg	0	R	ICRR Buffer Flag 0: ICRR has no transmit data. 1: ICRR has transmit data.
0	Drflg	0	R	ICDR Buffer Flag 0: ICDR has no transmit data. 1: ICDR has transmit data.

**45.3.11 IIC Transmit Control Register (ICTC)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICTC is an 8-bit register that specifies SDA delay adjustment and SCL synchronization.

ICTC is initialized to H'00 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	sda_dly[4:0]	00000	R/W	<p>SDA Data Delay Select</p> <p>These bits set the SDA data output delay from the SCL.</p> <p>00000: No SDA data delay (recommended)</p> <p>00001: SDA data is delayed by one cycle of the module clock.</p> <p>00010: SDA data is delayed by two cycles of the module clock.</p> <p>...</p> <p>11110: SDA data is delayed by 30 cycles of the module clock.</p> <p>11111: SDA data is delayed by 31 cycles of the module clock.</p> <p>When SDA data output is delayed, the AC specifications of the IIC bus may not be satisfied. Therefore, setting these bits to 00000 is recommended.</p>
2	sync_en	0	R/W	<p>SCL Synchronization Select</p> <p>Specifies whether the SCL line synchronizing function is activated or not.</p> <p>0: SCL line synchronization is activated (recommended).</p> <p>1: SCL line synchronization is not activated.</p> <p>When this bit is set to 1, the AC specifications of the IIC bus may not be satisfied. Therefore, setting this bit to 0 is recommended.</p>
1, 0	—	—	R	<p>Reserved</p> <p>The write value should always be 0.</p>

### 45.3.12 IIC Transmit Control Status Monitor Register (ICTD)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICTD is an 8-bit register that indicates the communication status of the IIC bus interface.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	IIC_req 0	—	—	—	IIC_ack 0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved
4	IIC_req0	0	R	IIC Communication Request 0 0: No communication request 1: Under communication request
3 to 1	—	All 0	R	Reserved
0	IIC_ack0	0	R	IIC Communication Status 0 0: No communication 1: Under Communication

### 45.3.13 IIC Shift Register (ICSF)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

ICSF is an 8-bit register that indicates data being transmitted by the IIC bus interface.

Bit:	7	6	5	4	3	2	1	0
	ICSF							
Initial value:	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R

### 45.3.14 IIC Option Enabling Register (ICVCON)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√*

Note: \* Some restrictions apply.

ICVCON is an 8-bit register that enables or disable the optional feature of the IIC module.

Do not change the value of this register during IIC communication.

Bit:	7	6	5	4	3	2	1	0
	—	—	Req_Hold	D16EN	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	Req_Hold	0	R/W	Reserved This bit is always read as 0. The write value should always be 0.
4	D16EN	0	R/W	IIC Terminal Using 16-case Select Mode Enable 0: DVFS 16-case select is not used. 1: DVFS 16-case select is used. [RZ/G1H, M and N] Setting prohibited [RZ/G1E] Set D16EN to 1 for automatic transmission. Note that the RZ/G series products do not support the DVFS function.
3 to 0	—	All 0	R	Reserved When writing, always write 0.

### 45.3.15 IIC Automatic Transmission\* Interrupt Mask Register (ICIMSK)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICIMSK is an 8-bit register that enables or disables the interrupt request output of automatic transmission\*.

An interrupt is output to AL interrupt event code. The generated interrupt can be checked by ICINT.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

Bit:	7	6	5	4	3	2	1	0
	AEND M	TMC2M	TMC1M	TMOUT M	ALM	TACKM	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDM	0	R/W	Automatic Transmission* End Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of the end of automatic transmission*. 1: Interrupt is output to INTC-SYS at the time of the end of automatic transmission*.
6	TMC2M	0	R/W	Timer Count 2 End Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of the end of timer count 2. 1: Interrupt is output to INTC-SYS at the time of the end of timer count 2.
5	TMC1M	0	R/W	Timer Count 1 End Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of the end of timer count 1. 1: Interrupt is output to INTC-SYS at the time of the end of timer count 1.
4	TMOUTM	0	R/W	Timeout Error Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of a timeout error. 1: Interrupt is output to INTC-SYS at the time of a timeout error.
3	ALM	0	R/W	AL Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of the automatic transmission* AL. 1: Interrupt is output to INTC-SYS at the time of the automatic transmission* AL.
2	TACKM	0	R/W	TACK Interrupt Mask 0: Interrupt is not output to INTC-SYS at the time of the automatic transmission* TACK. 1: Interrupt is output to INTC-SYS at the time of the automatic transmission* TACK.
1, 0	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.16 IIC Automatic Transmission\* Interruption Flag Register (ICINT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICINT is an 8-bit register that indicates the interrupt state during automatic transmission\*.

The interrupt bit can be cleared by writing 1 to ICSTART[7] or clearing ICCR[7] to 0 at the start of automatic operation.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

Bit:	7	6	5	4	3	2	1	0
	AEND	TMC2	TMC1	TMOUT	AAL	ATACK	AWAIT	ADTE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	AEND	0	R	Automatic Transmission* End Flag 0: Under automatic transmission* 1: End of automatic transmission*
6	TMC2	0	R	Timer Count 2 End Flag 0: Timer count 2 is not ended. 1: End of timer count 2
5	TMC1	0	R	Timer Count 1 End Flag 0: Timer count 1 is not ended. 1: End of timer count 1
4	TMOUT	0	R	Timeout Error Flag 0: No timeout error 1: Timeout error is detected.
3	AAL	0	R	Automatic Transmission* AL Flag 0: No AL 1: AL is detected.
2	ATACK	0	R	Automatic Transmission* TACK Flag 0: No TACK 1: TACK is detected.
1	AWAIT	0	R	Automatic Transmission* WAIT Flag 0: No WAIT 1: WAIT is detected.
0	ADTE	0	R	Automatic Transmission* DTE Flag 0: No DTE 1: DTE is detected.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.17 IIC Automatic Transmission\* Processing Enabling Register (ICACE)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICACE is an 8-bit register that specifies the usage of each function during automatic transmission\*.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

Bit:	7	6	5	4	3	2	1	0
	AENDE	TMC2E	TMC1E	TMOU E	ALE	TACKE	WAITE	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDE	0	R/W	Automatic Transmission* End Detection Enable 0: End of automatic transmission is not detected. 1: Detects the end of automatic transmission and outputs it to ICINT.
6	TMC2E	0	R/W	Timer Count 1 Enable, Timer Count 2 Enable
5	TMC1E	0	R/W	Specify whether wait by TMC1 or TMC2 timer is inserted before assertion of an automatic transmission* interrupt and a timeout error detection interrupt. Refer to Figure 45.3 for the wait timing of TMC1 and TMC2. ICACE[6:5] = 00: TMC1 and TMC2 are not used. ICACE[6:5] = 01: Interrupt is asserted after counting by TMC1 is finished. ICACE[6:5] = 11: Interrupt is asserted after counting by TMC1 and TMC2 is finished. ICACE[6:5] = 10: Setting prohibited
4	TMOUTE	0	R/W	Timeout Error Enable When SCL/SDA is driven to low even after the STOP condition is generated and counting by TMC1 and TMC2 is finished, a timeout error is detected. 0: Timeout error is not detected. 1: Timeout error is detected and recorded in ICINT.
3	ALE	0	R/W	Automatic Transmission* AL Error-Handling Enable Specifies whether handling for AL errors detected during automatic transmission is performed or not. 0: No automatic AL error handling (AL is not detected) 1: Automatic AL error handling is performed (to release the SDA bus, continue output of SCL until the time corresponding to 1 byte + ACK, and perform retry or stop processing).
2	TACKE	0	R/W	Automatic Transmission* ACK Error-Handling Enable Specifies whether handling for ACK error is performed or not (when error handling is selected, either retry or stop processing is performed). 0: No automatic ACK error handling 1: Automatic ACK error handling is performed (retry or stop processing is performed).

Bit	Bit Name	Initial Value	R/W	Description
1	WAITE	0	R/W	WAIT Processing Enable Specifies whether wait processing is inserted during automatic transmission*. 0: No automatic WAIT processing. 1: Automatic WAIT processing is performed (waiting for the period specified by the ICTMCW register).
0	—	0	R/W	Reserved The write value should always be 0.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.18 IIC Automatic Transmission\* Timer Control Register 1 (ICTMC1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICTMC1 is an 8-bit register that specifies the delay time for the timing of detection of automatic transmission\* being completed and timeout errors.

The delay time is specified by ICTMC1 by following formula.

$$\text{Delay time} = (\text{ICTMC1})_{10} \times 200 \times t_{\text{Module clock}}$$

(When the frequency of the module clock is 104 MHz, the delay time can be specified within the range from 0 μs up to 490 μs in 2-μs increments.)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.19 IIC Automatic Transmission\* Timer Control Register 2 (ICTMC2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICTMC2 is an 8-bit register that specifies the delay time for the timing of detection of automatic transmission\* being completed and timeout errors.

The delay time is specified by ICTMC2 by the following formula.

$$\text{Delay time} = (\text{ICTMC2}) \times 10 \times 200 \times t_{\text{Module clock}}$$

(When the frequency of the module clock is 104 MHz, the delay time can be specified within the range from 0 μs up to 490 μs in 2-μs increments.)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

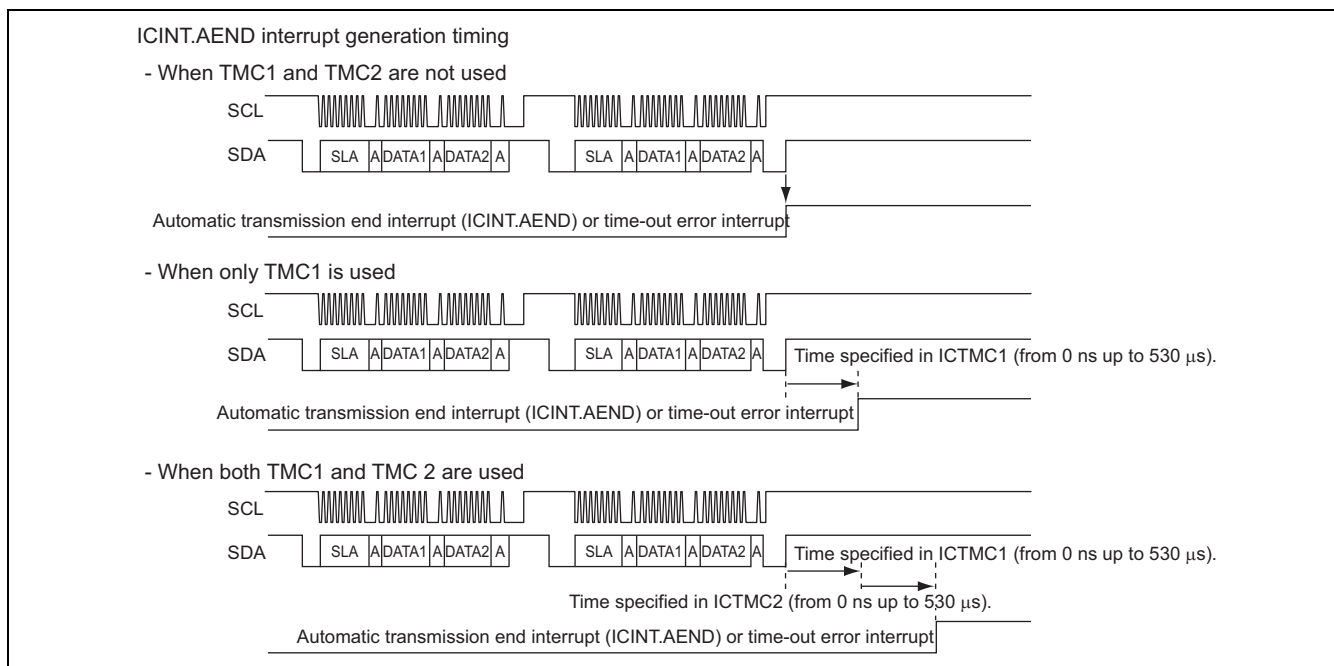

Figure 45.3 Wait Timing Chart of TMC1 and TMC2

### 45.3.20 IIC Automatic Transmission\* Wait Control Register (ICTMCW)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICTMCW is an 8-bit register that specifies the wait time during automatic transmission\*. When ICACE[1].WAITE is set to 1 for activating the wait processing function, set a value other than H'00 to this register.

The wait time is specified by ICTMCW by following formula.

$$\text{Delay time} = (\text{ICTMCW})_{10} \times 20 \times t_{\text{Module clock by ICTMCW}}$$

(When the frequency of the module clock is 104 MHz, the delay time can be specified within the range from 0 μs up to 49 μs in 2-μs increments.)

Although a wait time can be specified by this register, the period of waiting may be different from the specified value because a transition of the actual SCL bus may be delayed by a clock cycle. Also, in the case of automatic transmission\*, 1 cycle of waiting is always inserted automatically before the acknowledge cycle.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.21 IIC Automatic Transmission\* Transmit Start Register (ICSTART)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICSTART is an 8-bit register that specifies start, reset, and abort of automatic transmission\*.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

Bit:	7	6	5	4	3	2	1	0
	Auto Start	AutoTransReset	Auto Stop	—	—	—	ATDMA	ARDMA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AutoStart	0	R/W	Automatic Transmission* Start Automatic transmission* starts by writing 1 to this bit. Do not clear this bit to 0 during automatic transmission*.
6	AutoTransReset	0	R/W	Automatic Transmission* Reset The internal state of automatic transmission* is reset by writing 1 to this bit. After reset, write 0 to this bit. Writing 1 to this bit does not initialize automatic transmission-related registers. For register initialization, use reset function by writing 0 to ICCR[7].ICE.
5	AutoStop	0	R/W	Automatic Transmission* Stop By writing 1 to this bit, the STOP condition is generated at the boundary of a 1byte + ACK-cycle unit and automatic transmission* stops. Writing 1 to this bit may result in stopping transmission such that the transfer format is not as expected. 0: Normal operation 1: STOP condition is generated and automatic transmission* stops.
4 to 2	—	All 0	R/W	Reserved The write value should always be 0.
1	ATDMA	0	R/W	Automatic Transmission* DMA Enable 0: DMA is not used for data transmission by automatic transmission*. 1: DMA is used for all data transmission by automatic transmission*.
0	ARDMA	0	R/W	Automatic Reception DMA Enable 0: DMA is not used for data reception by automatic transmission*. 1: DMA is used for all data reception by automatic transmission*.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.22 IIC Automatic Transmission\* Transmit Control Register (ICATFR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICATFR is an 8-bit register that specifies an automatic transmission\* format and the number of retry processing.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	Format[3:0]	0000	R/W	<p>IIC Automatic Transmission*<sup>1</sup> Format Selection</p> <p>Specify the format of automatic transmission*<sup>1</sup>. Refer to Figure 45.5 for a communication format.</p> <p>S = START condition, Sr = Repeated START condition, P = STOP condition</p> <p>0000: S → Transmission 1 → P</p> <p>0001: S → Transmission 1 → Reception 1 → P</p> <p>0010: S → Transmission 1 → Sr → Transmission 2 → P</p> <p>0011: S → Transmission 1 → Sr → Transmission 2 → Receive 1 → P</p> <p>0100: S → Transmission 1 → Reception 1 → Sr → Transmission 2 → P</p> <p>0101: S → Transmission 1 → Reception 1 → Sr → Transmission 2 → Reception 2 → P</p> <p>Others: Setting prohibited</p>
3 to 0	Retry[3:0]	0000	R/W	<p>Retry Number for Automatic Transmission*<sup>1:2</sup></p> <p>Specify the maximum number of retry when an AL error or non-acknowledge error occurs. When either of errors has reached the specified number, AL or TACK error is reported.</p> <p>H'0: No retry</p> <p>H'1: Retry once.</p> <p>H'2: Retry up to twice.</p> <p>-</p> <p>H'E: Retry up to 14 times.</p> <p>H'F: Setting prohibited.</p>

- Notes: 1. Automatic transmission for PMIC control (DVFS) is not available.  
 2. Retry processing cannot be performed when using DMA transfer.

### 45.3.23 IIC Automatic Transmission\* Transmit Time Register 1 (ICATSET1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICATSET1 is an 8-bit register that specifies the number of data of the transmission 1 in the format specified by ICATFR[7:4].

The maximum value which can be specified in this register is 10 when using the ICATD00 to ICATD09 registers, and 256 when using a DMA transfer.

A slave address is also contained in the transmission data.

Specify the values as follows when ICATD00 to ICATD09 are in use.

1-byte transmission      ICATSET1[7:0] = H'00

2-byte transmission      ICATSET1[7:0] = H'01

10-byte transmission      ICATSET1[7:0] = H'09

Specify the size of transmission for a DMA transfer.

256-byte transmission      ICATSET1[7:0] = H'FF (maximum)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.24 IIC Automatic Transmission\* Transmit Time Register 2 (ICATSET2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICATSET2 is an 8-bit register that specifies the number of data of the transmission 2 in the format specified by ICATFR[7:4].

The maximum number which can be specified in this register is 10 when using the ICATD10 to ICATD19 registers, and 256 when using a DMA transfer.

A slave address is also contained in the transmission data.

Specify the values as follows when ICATD10 to ICATD19 are in use.

1-byte transmission      ICATSET2[7:0] = H'00

2-byte transmission      ICATSET2[7:0] = H'01

10-byte transmission      ICATSET2[7:0] = H'09

Specify the size of transmission for a DMA transfer.

256-byte transmission      ICATSET2[7:0] = H'FF (maximum)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

**45.3.25 IIC Automatic Transmission\* Reception Time Register 1 (ICARSET1)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICARSET1 is an 8-bit register that specifies the number of data of the reception 1 in the format specified by ICATFR[7:4].

The maximum number which can be specified in this register is 10 when using the ICARD00 to ICARD09 registers, and 256 when using a DMA transfer.

Specify the values as follows when ICARD00 to ICARD09 are in use.

- 1-byte transmission      ICARSET1[7:0] = H'00
- 2-byte transmission      ICARSET1[7:0] = H'01
- 10-byte transmission      ICARSET1[7:0] = H'09

Specify the size of transmission for a DMA transfer.

- 256-byte transmission      ICARSET1[7:0] = H'FF (maximum)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.26 IIC Automatic Transmission\* Receipt Time Register 2 (ICARSET2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICARSET2 is an 8-bit register that specifies the number of data of the reception 1 in the format specified by ICATFR[7:4].

The maximum number which can be specified in this register is 10 when using the ICARD10 to ICARD19 registers, and 256 when using a DMA transfer.

Specify the values as follows when ICARD10 to ICARD19 are in use.

1-byte transmission      ICARSET2[7:0] = H'00

2-byte transmission      ICARSET2[7:0] = H'01

10-byte transmission      ICARSET2[7:0] = H'09

Specify the size of transmission for a DMA transfer.

256-byte transmission      ICARSET2[7:0] = H'FF (maximum)

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

### 45.3.27 IIC Automatic Transmission\* Transmit Data 00 to 09 (ICATD00 to ICATD09)

**45.3.30 IIC Automatic Transmission\* Receipt Data 10 to 19 (ICARD10 to ICARD19)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

ICARD10 to ICARD19 are 8-bit registers that are used to store the received data of reception 2.

Note: \* Automatic transmission for PMIC control (DVFS) is not available.

**45.3.31 Transfer Rate**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

The IIC transfer rate can be specified by the settings in ICCL, ICCH, ICIC[7], and ICIC[6] and is based on the module clock.

Table 45.5 lists transfer rate settings, and Figure 45.5 shows SCL waveforms.

**Table 45.5 Transfer Rate Maximum Settings Example**

	Module clock	ICIC[7] + ICCL	ICIC[6] + ICCH	Transfer Rate*
Standard	7.5 MHz	H'14	H'0E	101.35 kHz
	10 MHz	H'1B	H'14	100.00 kHz
	13 MHz	H'24	H'1A	100.00 kHz
	15 MHz	H'29	H'1F	100.00 kHz
	32.5 MHz	H'5A	H'46	99.69 kHz
	52 MHz	H'90	H'71	100.00 kHz
	78 MHz	H'D8	H'AB	100.00 kHz
	104 MHz	H'120	H'E5	100.00 kHz
	130 MHz	H'169	H'11E	100.00 kHz
Fast-mode	7.5 MHz	H'05	H'02	375.00 kHz
	10 MHz	H'06	H'03	416.67 kHz
	13 MHz	H'09	H'05	382.35 kHz
	15 Hz	H'0A	H'06	394.74 kHz
	32.5Hz	H'16	H'10	396.34 kHz
	52 MHz	H'24	H'1A	400.00 kHz
	78 MHz	H'36	H'29	397.96 kHz
	104 MHz	H'48	H'37	400.00 kHz
	130 MHz	H'5A	H'46	398.77 kHz

Note: \* The transfer rates in above settings are theoretical values. The actual transfer rates are generally smaller than those theoretical values due to the pull-up resistor (Rp) and the capacitance (Cp). However, there is no harm in communication because the actual transfer rates satisfy the I2C bus specifications. (Smaller ICCL and ICCH can increase the actual transfer rates. In this case, though, set ICCL and ICCH to ensure that t<sub>LOW</sub> and t<sub>HIGH</sub> are within the specifications.)

**Calculation example of ICCL and ICCH:**

- Conditions

Module clock: 104 MHz

IIC transfer rate: 100 kHz

L/H sample ratio in SCL: L/H = 5/4

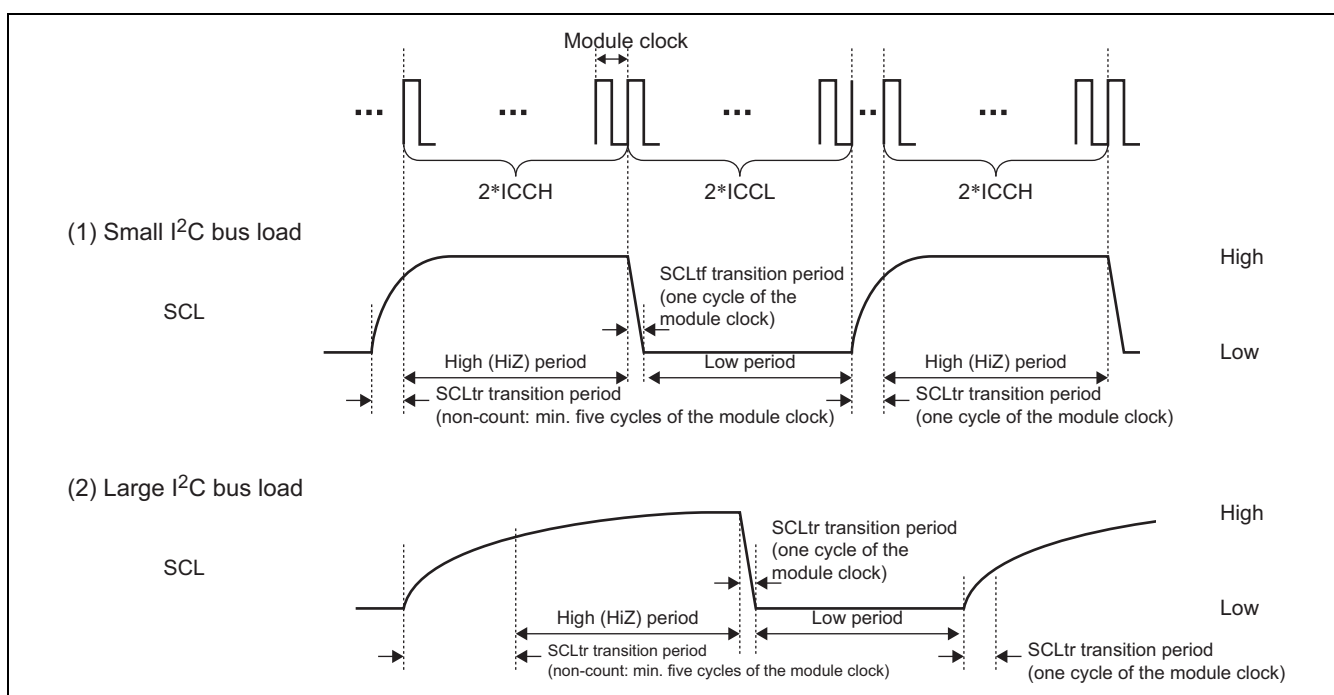

- Result

$$ICIC[7] + ICCL = ((Module\ clock / IIC\ transfer\ rate) \times (L / (L + H)) - 1) / 2$$

$$= (((104 \times 10^6) / (100 \times 10^3)) \times (5 / (5 + 4)) - 1) / 2 = 288 = H'120$$

$$ICIC[6] + ICCH = ((Module\ clock / IIC\ transfer\ rate) \times (H / (L + H)) - 5) / 2$$

$$= (((104 \times 10^6) / (100 \times 10^3)) \times (4 / (5 + 4)) - 5) / 2 = 229 = H'0E5$$

## 45.4 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 45.4.1 I2C Bus Data Format

The I2C bus is based on protocol, which contains the slave address, data, and an acknowledge bit. These are shown in Figure 45.5. The first frame following a START condition always consists of 8 bits.

The symbols used in Figure 45.5 are explained in Table 45.6.

**Table 45.6 I2C Bus Data Format Symbols**

Symbol	Description
S	START condition. The master device drives SDA from high to low while SCL is high.
Sr	Repeated START condition. The master device drives SDA from high to low while SCL is high.
SLA	Slave address. The master device selects a slave device.
R/W	Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.
A	Acknowledge. The receiving device (the slave device in master transmit mode, or the master device in master receive mode) drives SDA low to acknowledge a transfer.
DATA	Transmitted or received data. The bit length is 8 bits.
P	STOP condition. The master device drives SDA from low to high while SCL is high.

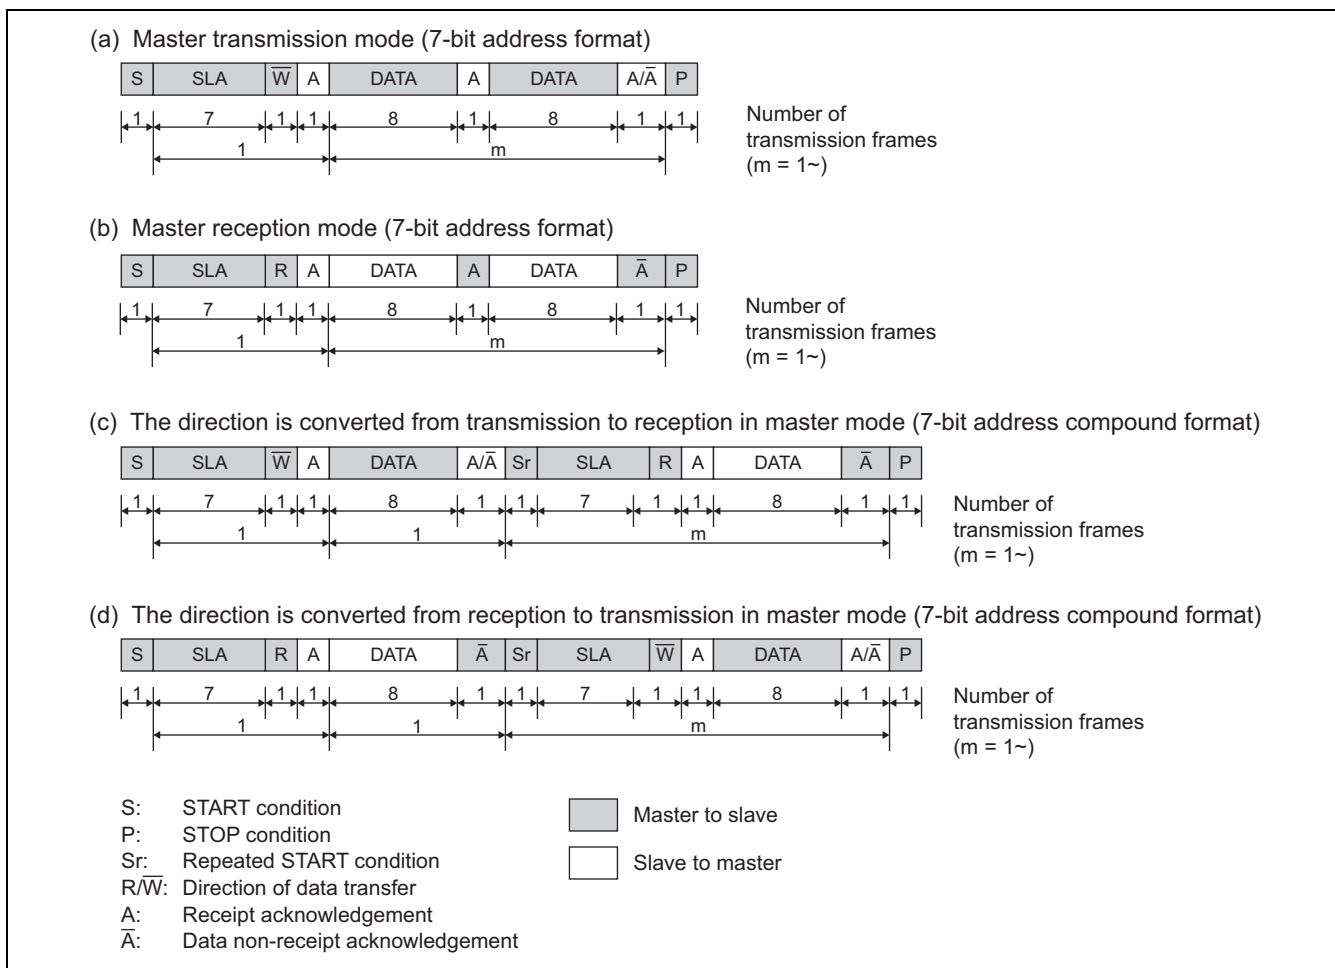

Figure 45.5 I2C Bus Data Formats (7-Bit Address Format)

#### 45.4.2 Master Transmit Operation (Using WAIT Function)

In master transmit mode, the master device outputs the transmission clock and transmission data, and receives the acknowledge signal after receiving data. The transmission procedure and operations are described below.

1. Set ICCR.ICE to activate the IIC module.
2. Set ICCL, ICCH, and ICIC[1:0], according to the operating mode.
3. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
4. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
5. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.  
And write transmission data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared.  
Data transmission starts after data is sent to the internal transmit buffer.
6. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
7. If more transmission data remains, write transmission data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT state, go back to step 6.
8. If no more transmission data remains, write H'90 to ICCR to issue the STOP condition.  
And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 9.
9. Wait until ICSR.BUSY is cleared to keep AC specification of  $t_{SU;STO}$ .
10. Clear ICCR.ICE to 0 to reset the IIC module.

Figure 45.6 shows the flowchart of the master transmission procedure.

By repeating steps 6 and 7, data can be transmitted consequently.

A non-acknowledge interrupt occurs if the received acknowledge signal is 1 (TACK = 1). If the received acknowledge bit is 1, it is recommended to STOP transmission after the STOP condition is generated. Refer to section 45.4.9, Non-Acknowledge Operation, for the stop method.

To change the transmission mode to the receive mode, write H'81 to ICCR, instead of generating the STOP condition in step 8.

To generate a repeated START condition, write H'94 to ICCR, instead of generating the STOP condition in step 8.

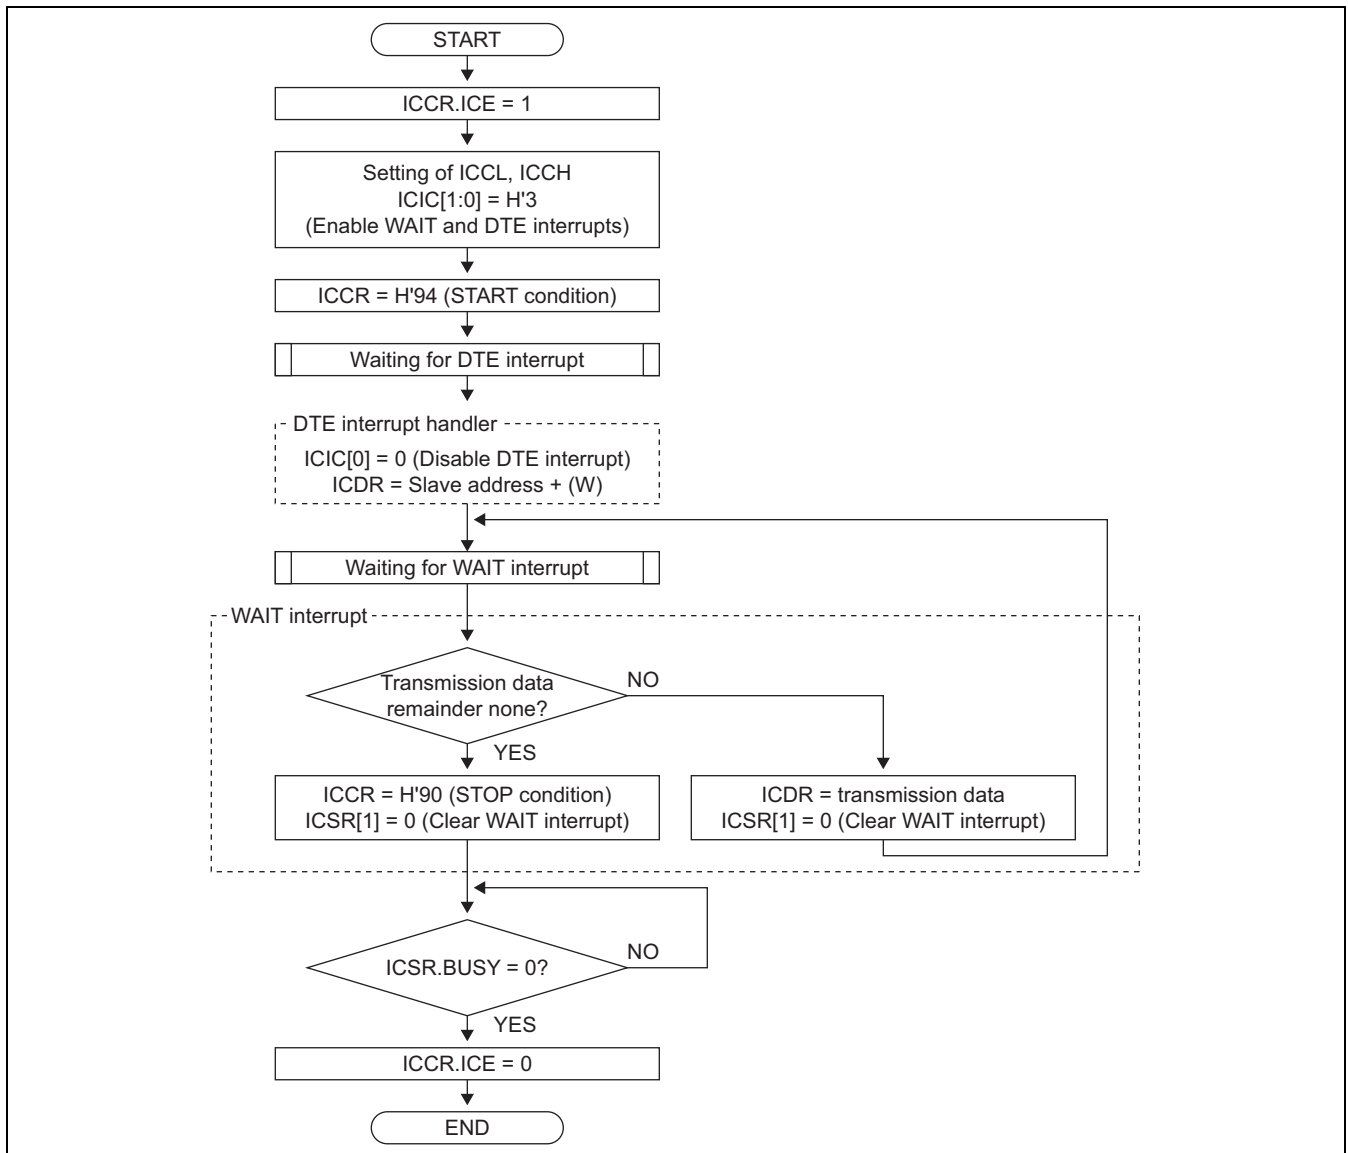

Figure 45.6 Example Flow for Transmission (a) Master Transmission Mode (Using WAIT Function)

### 45.4.3 Master Receive Operation (Using WAIT Function)

In master receive mode, the master device outputs the receive clock, and returns an acknowledge signal after the slave device transmits data. The reception procedure and operations in master receive mode are described below.

#### (1) When two or more bytes of data are received continuously

1. Set ICCR.ICE to activate the IIC module.
2. Set ICCL, ICCH, and ICIC [1:0], according to the operating mode.
3. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
4. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
5. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1.  
And write the data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts when data is sent to the internal transmit buffer.
6. Wait for a WAIT interrupt or until CSR.WAIT becomes 1.
7. If more transmission data remains, write data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT status, go back to step 6.
8. If no more transmission data remains, write H'94 to ICCR to issue the repeated START condition. Set ICIC.DTEE to enable a DTE interrupt. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 9.
9. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
10. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. And write the data (ex. slave address and read bit) to ICDR. The ICSR.DTE bit is then automatically cleared.
11. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
12. If more transmission data remains, write data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting from the WAIT status, go back to step 11.
13. If no more transmission data remains, write H'81 to ICCR to change the transmission mode to the receive mode. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 14.
14. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
15. If two or more receive data remains,  
and if ICSR.DTE = 0, go to step 17,  
else if ICSR.DTE = 1 and three or more data remains, read data from ICDR then go to step 17.  
else if ICSR.DTE = 1 and two data remains, read data from ICDR and set ICCR = H'C0 for the STOP condition, then go to step 17.
16. If one receive data remains, set ICCR to H'C0 for the STOP condition then go to step 17.
17. Set ICIC.DTEE to enable a DTE interrupt. And clear ICSR.WAIT to exit from the WAIT status.
18. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
19. If two or more receive data remains, read data from ICDR. The ICSR.DTE bit is then automatically cleared. After that, go back to step 14.
20. If one receive data remains, set ICIC.WAITE to disable a WAIT interrupt. And read data from ICDR. The ICSR.DTE bit is then automatically cleared.
21. Wait until ICSR.BUSY is cleared to keep AC specification of  $t_{SU;STO}$ .
22. Clear ICCR.ICE to 0 to reset the IIC module.

Figure 45.7 is the flow of this.

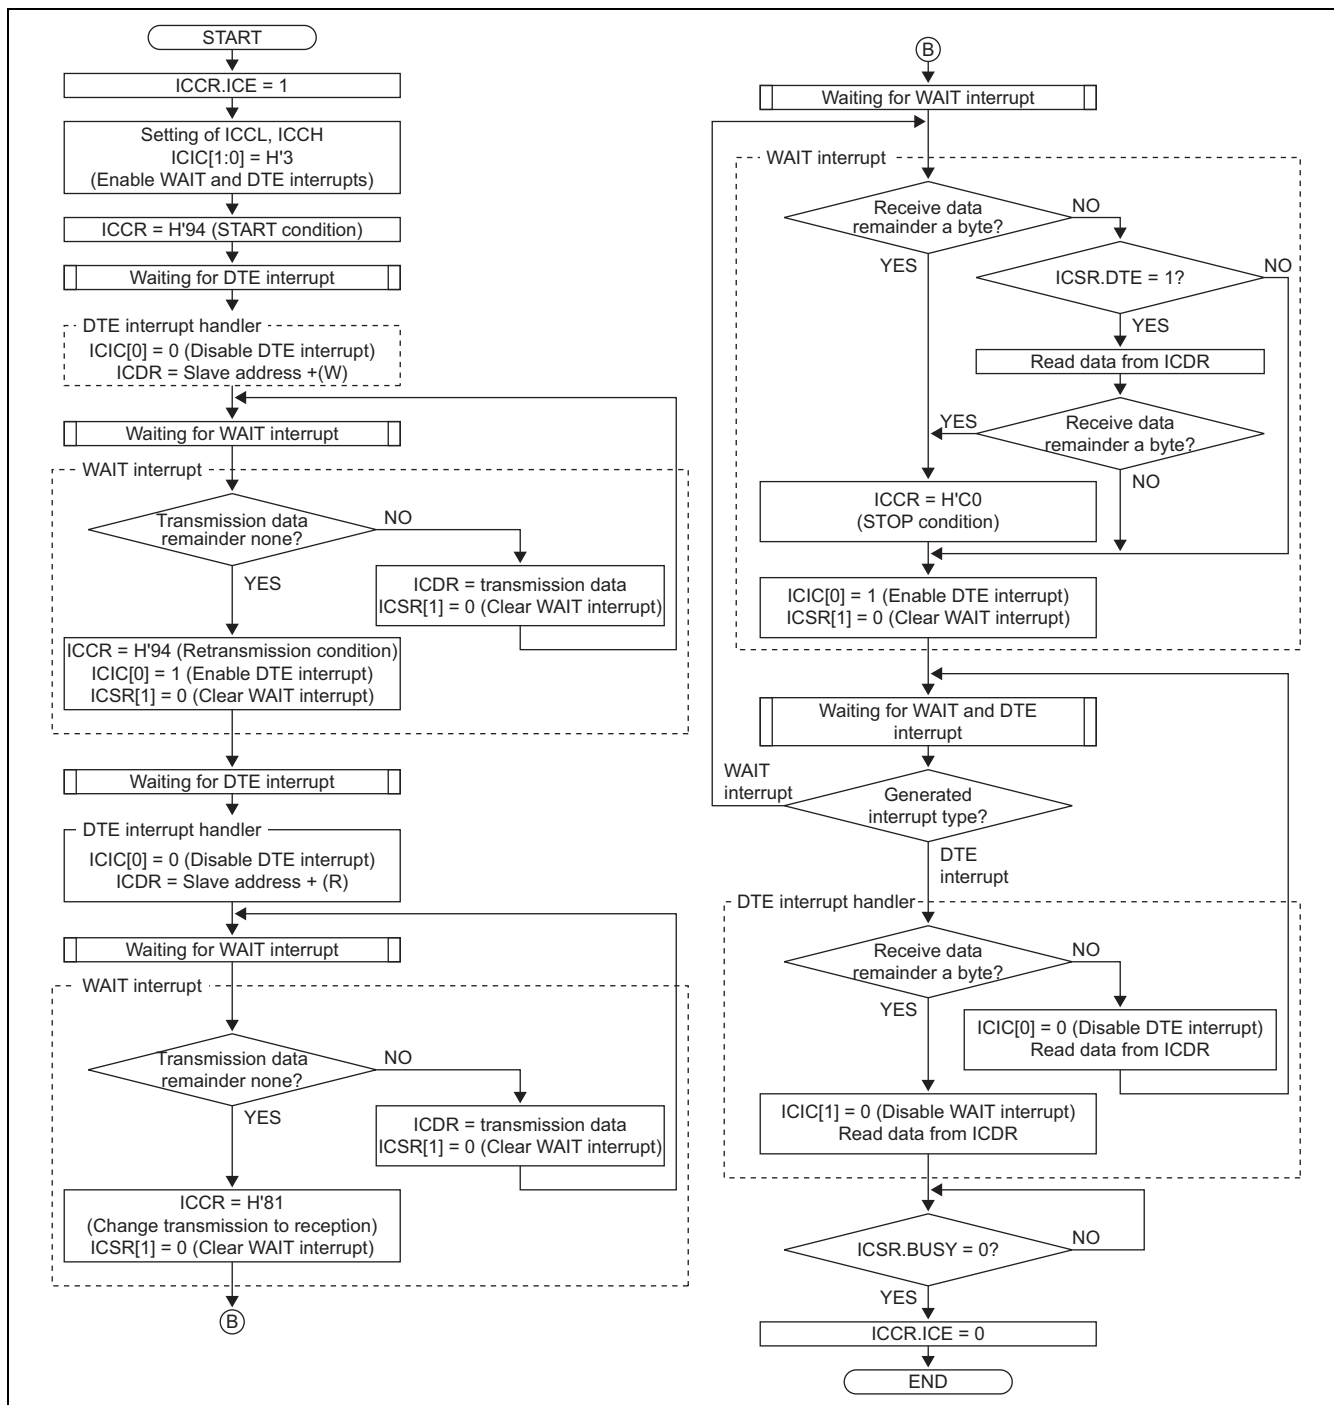

Figure 45.7 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted from Transmission to Reception (Using WAIT Function)

**(2) When only one byte of data is received**

When only one byte data is received, use a WAIT interrupt to issue the STOP or repeated START condition by writing to ICCR.

1. Set ICCR.ICE to activate the IIC module.
2. Set ICCL, ICCH, and ICIC[1:0], according to the operating mode.
3. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
4. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
5. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE becomes 1.  
And write data (ex. slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts when data is sent to the internal transmit buffer.
6. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
7. Write H'81 to ICCR to issue the repeated START condition for changing the transmission mode to the receive mode.  
And clear ICSR.WAIT to exit from the WAIT status.
8. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
9. Set ICCR to H'C0 for the STOP condition. Set ICIC.DTEE to enable a DTE interrupt, then clear ICSR.WAIT to exit from the WAIT status.
10. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
11. Read data from ICDR. The ICSR.DTE bit is then automatically cleared.
12. Wait until ICSR.BUSY is cleared to keep AC specification of  $t_{SU:STO}$ .
13. Clear ICCR.ICE to 0 to reset the IIC module.

Figure 45.8 shows the flowchart of 1-byte reception.

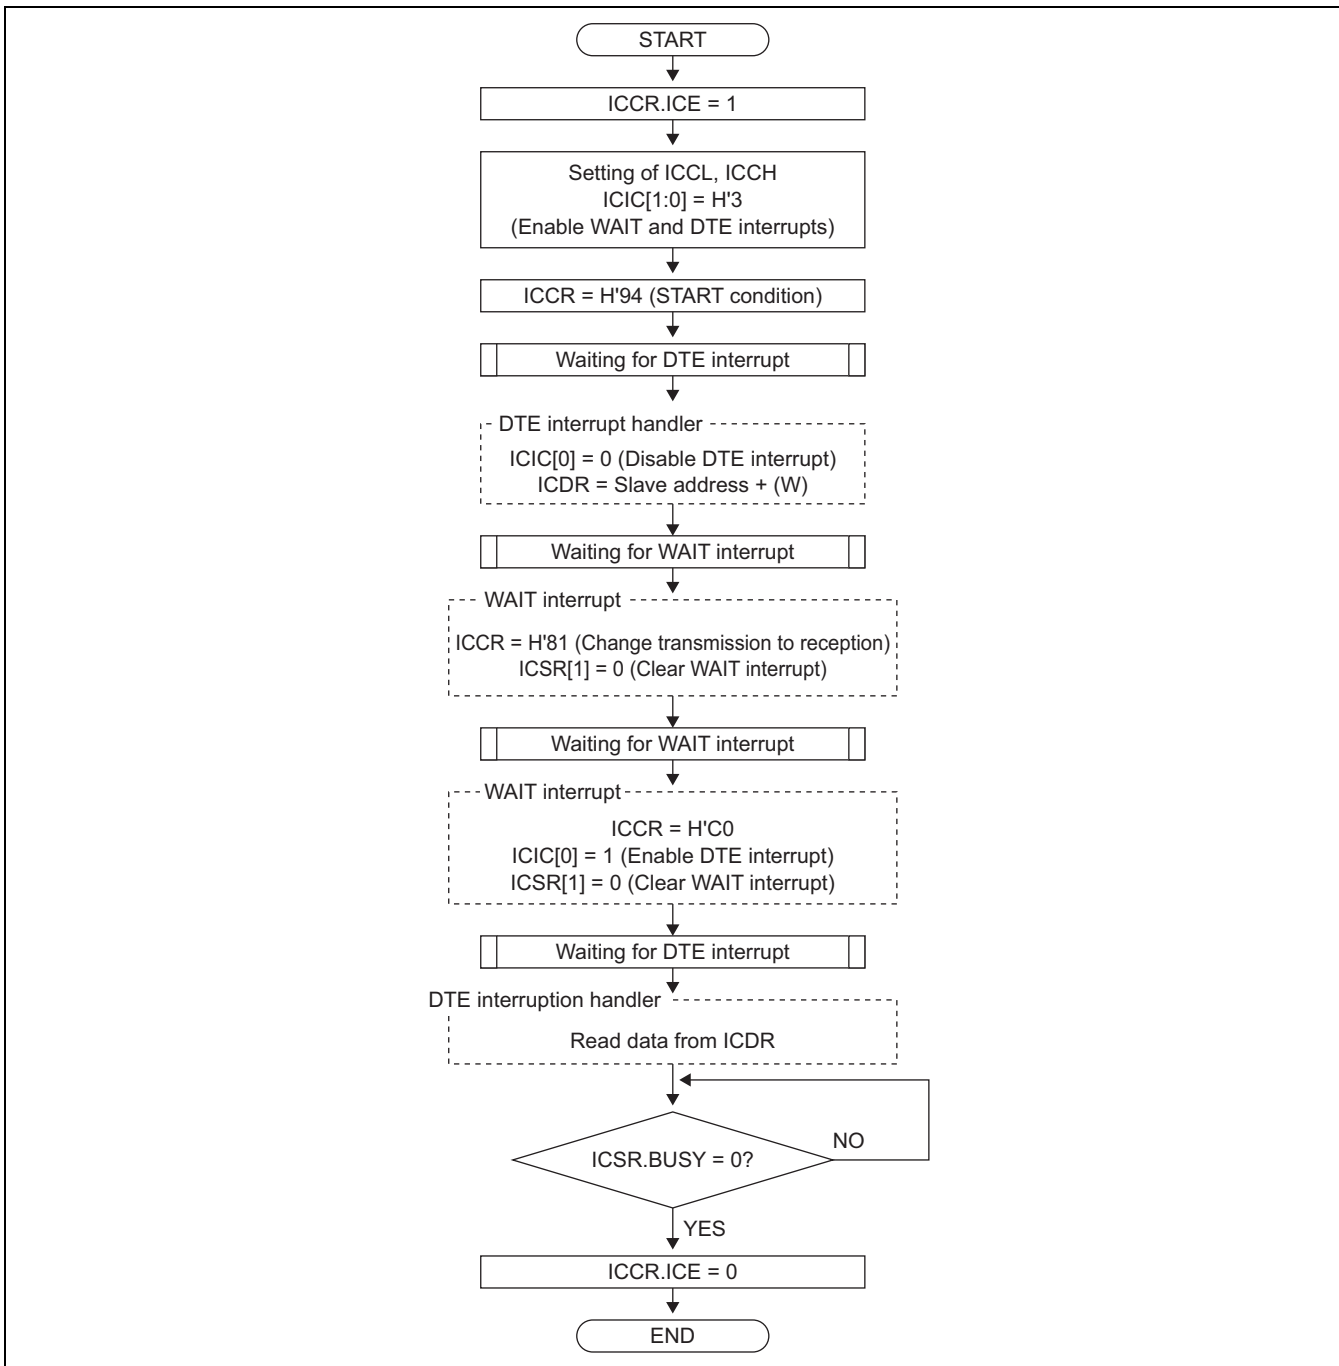

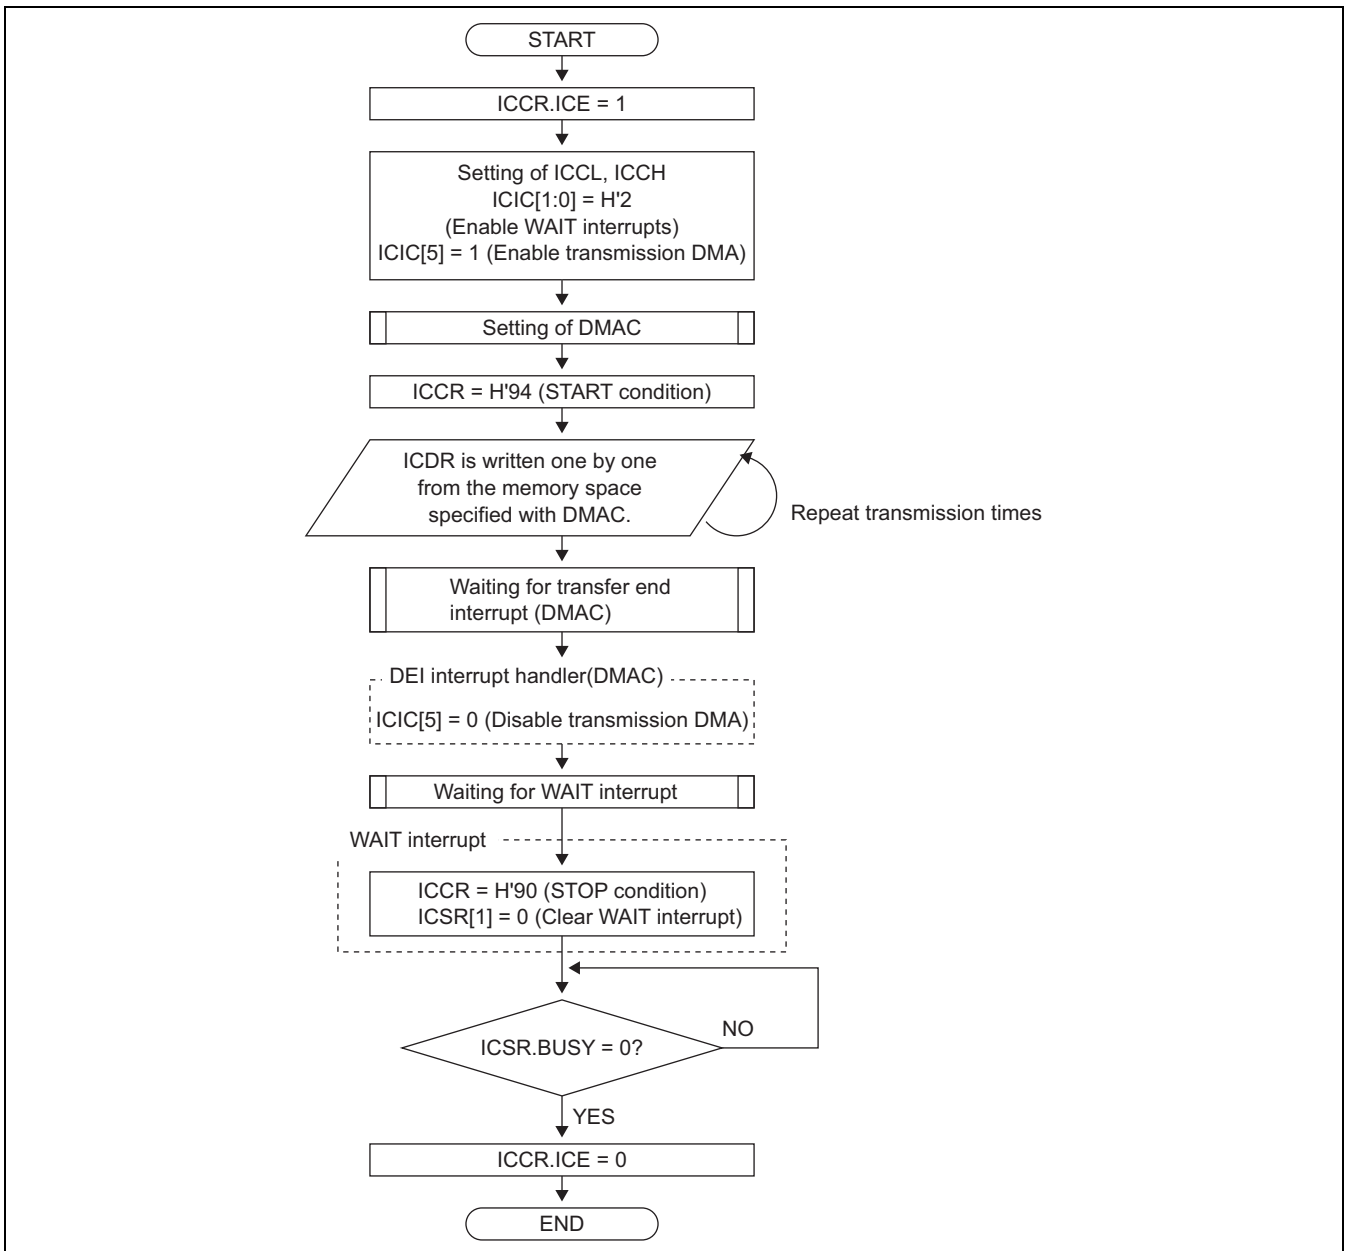

Figure 45.8 Example of Software Flow for 1-Byte Write/1-Byte Read (Using WAIT Function)

#### 45.4.4 IIC Continuous Transmission by DMA

In DMA transmit mode, the IIC module asserts a DMA request to the DMAC. The received DMAC writes data to ICDR, and returns DMARACK to the IIC module. The transmission procedure and operations are described below.

1. Set ICCR.ICE to activate the IIC module.
2. Set ICCL, ICCH, ICIC[1], and ICIC[5], according to the operating mode for DMA transmission. And set DMAC including number of transmission data.
3. Write H'94 to ICCR to issue the START condition.
4. DMAC writes the transmit data to ICDR from the memory space specified by DMAC register until transmission finishes.
5. Wait for a transfer end interrupt from DMAC.
6. Clear ICIC.TDMA to disable DMA transmission after a transfer end interrupt is asserted.
7. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
8. Clear ICSR.WAIT to exit from the WAIT status. After the acknowledge clock, the STOP condition is generated and operation is stopped.
9. Wait until ICSR.BUSY is cleared to keep AC specification of  $t_{SU;STO}$ .
10. Clear ICCR.ICE to 0 to reset the IIC module.

Figure 45.9 shows the flow of data transmission with DMA.

**Figure 45.9 Example Flow for Transmission (a) Master Transmission Mode (Using WAIT and DMA Function)**

#### 45.4.5 IIC Continuous Receive by DMA

In DMA receive mode, the master device asserts DMA request to DMAC. The DMAC that received the request reads the received data from ICDR, and returns DMARACK to the IIC module. In case of receiving data continuously by DMA, 4 bytes or more receive data is required. The reception procedure and operations are described below.

1. Set ICCR.ICE to activate the IIC module.
2. Set ICCL, ICCH, and ICIC[1:0], according to the operating mode for DMA reception. And set DMAC register including number of receive data.
3. Write H'94 to ICCR to issue the START condition. The DTE bit in ICSR is then set to 1.
4. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
5. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE becomes 1.  
And write data (slave address and write bit) to ICDR. The ICSR.DTE bit is then automatically cleared. Data transmission starts when data is sent to the internal transmit buffer.
6. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
7. If one or more transmission data remains, write data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go back to step 6.
8. If no more transmission data remains, write H'94 to ICCR to issue the repeated START condition. Set ICIC.DTEE to enable a DTE interrupt. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 9.
9. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
10. Clear ICIC.DTEE to disable a DTE interrupt when the ICSR.DTE bit becomes 1. And write data (slave address and read bit) to ICDR. The ICSR.DTE is then automatically cleared.
11. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
12. If one or more transmission data remains, write data (ex. register address or data) to ICDR. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go back to step 11.
13. If no more transmission data remains, write H'81 to ICCR to issue the repeated START condition for changing the transmission mode to the receive mode. And clear ICSR.WAIT to exit from the WAIT status. After exiting, go to step 14.
14. DMAC reads the received data from ICDR, and stores them into the destination area until receiving data is finished.
15. Wait for a transfer end interrupt of DMAC.
16. Clear ICIC.RDMA to disable the received DMA, and set ICIC[1:0] to enable DTE and WAIT interrupts, when the transfer end interrupt is asserted.
17. Wait for a DTE interrupt or until ICSR.WAIT becomes 1.
18. Clear ICIC.DTEE to disable a DTE interrupt, and read data from ICDR. The ICSR.DTE bit is then automatically cleared.
19. Wait for a WAIT interrupt or until ICSR.WAIT becomes 1.
20. One receive data is remaining. And ICCR = H'C0 for the STOP condition.
21. Set ICIC.DTEE to enable a DTE interrupt. And clear ICSR.WAIT to exit from the WAIT status.
22. Wait for a DTE interrupt or until ICSR.DTE becomes 1.
23. Set ICIC.WAITE to disable a WAIT interrupt. And read data from ICDR. The ICSR.DTE bit is then automatically cleared.
24. Wait until CSR.BUSY is cleared to keep AC specification of  $t_{SU:STO}$ .
25. Clear ICCR.ICE to 0 to reset the IIC module.

Figure 45.10 is the flow of this.

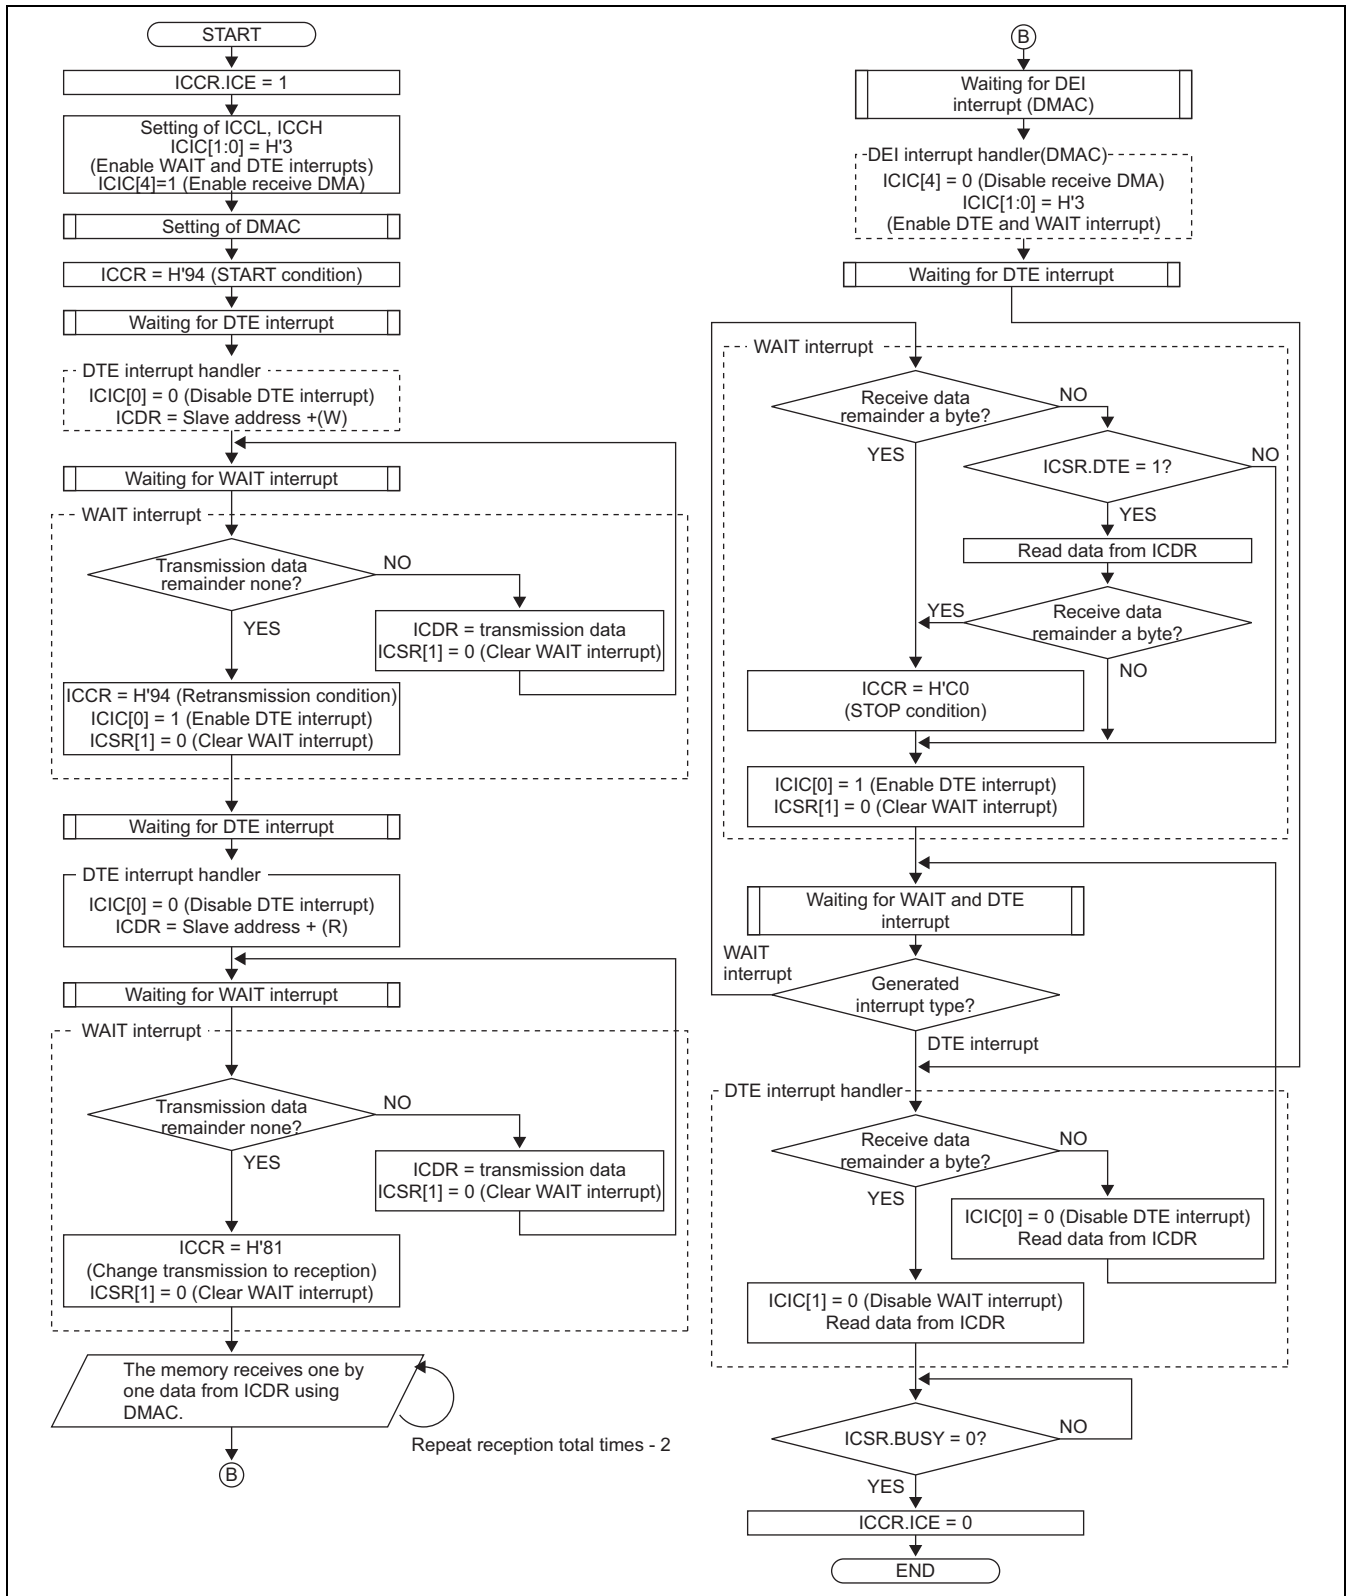

Figure 45.10 Example Flow for n-Byte Write/n-Byte Read (c) The Direction is Converted From Transmission to Reception (Using WAIT and DMA Function)

#### 45.4.6 Synchronizing SCL Line

When the SCL line state is changed from high to low, connected devices may start counting in the low period. When the clock of a device becomes low, the device holds the SCL line low until its clock becomes high (see Figure 45.11). However, even if the clock of the device is changed from low to high, the SCL line state does not change when clocks of other devices are in the low period. Therefore, the low period of the SCL line is determined by the device with the longest low period. At this time, a device with the short low period waits in the high state.

When all devices complete the low period, the clock line is open and in the high state. Therefore, the device clock and SCL line are in the same state, and start counting both of pulses in high level period. The SCL line enters the low state again by the device that has first completed the high period.

The low period is determined by the device with the longest low period, and the high period is determined by the device with the shortest high period. The SCL line is then synchronized.

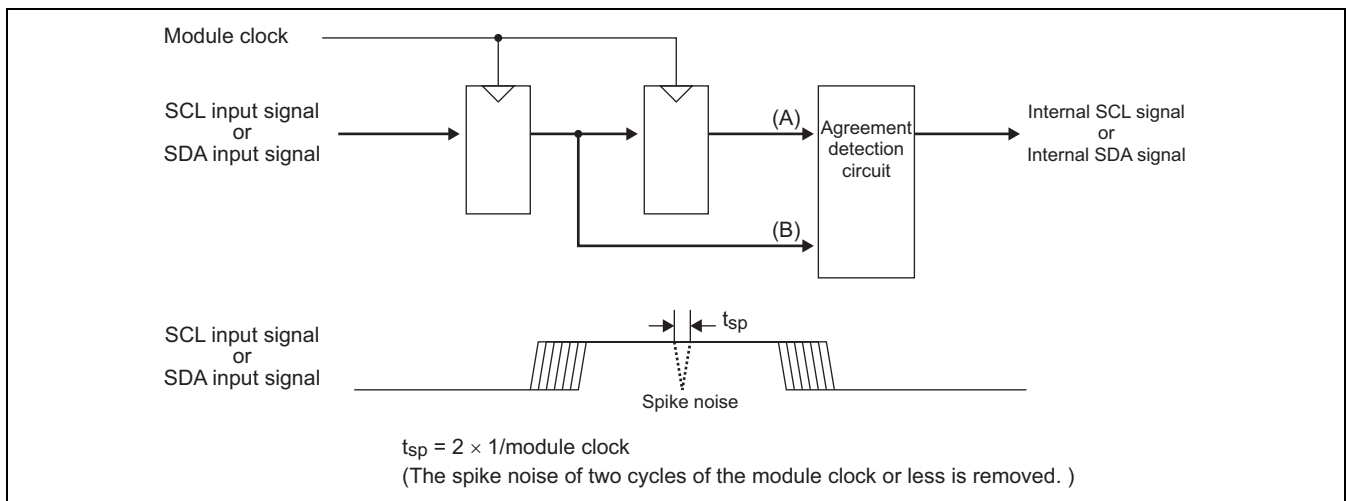

Figure 45.11 Synchronizing SCL Line

#### 45.4.7 Noise Canceller

For removing spike noise on the SCL and SDA line, the noise canceller circuit is implemented. Figure 45.12 shows a block diagram of the noise canceller circuit.

The noise canceller consists of two cascaded FFs and a match detector. The SCL/SDA signal is sampled by FFs with module clock, and recognize that SCL/SDA signals are toggled if both of two FF's outputs have toggled. If only one output of FFs have toggled, previously latched value is output to the internal logic.

**Figure 45.12 Block Diagram of Noise Canceller**

#### 45.4.8 Arbitration Lost Operation

This module can assert an arbitration lost interrupt request when bus conflict is detected.

Interrupt assert conditions are described below.

- When the level of the data being received changes during counting of the period at high level for the SCL clock.
- When the level on the SCL line becomes low, while the SCL clock is controlled by this module, and not driven by this module.
- When this module detects the START condition before issuing the START condition.
- When the SDA data driven by this module and monitored SDA signals are not equal.

In case of conditions above, the AL bit in ICSR is set to 1 and an arbitration lost interrupt is asserted.

When a loss of arbitration is detected in transmission mode, the SDA line is released right now. For SCL clock line, clocks kept be output until the end of the frame including acknowledge cycle and released. Figure 45.13 shows an example of arbitration lost interrupt operation timing.

In case of conditions below, the AL bit in ICSR is set to 0.

- When data is written to ICDR (in transmission mode), or data is read (in receive mode) while DTE = 1.
- When 0 is written to the AL bit in ICSR.

When arbitration is lost by the acknowledge bit, hold SCL and SDA at a low level.

ICE reset must be performed by the software to release the bus.

Do not clear the ALE bit to 0 while the AL bit is 1. It is recommended to set ALE bit only before the start of communication.

**Figure 45.13 Example of Arbitration Lost Interrupt Operation Timing**

### 45.4.9 Non-Acknowledge Operation

This module can assert a non-acknowledge interrupt when there is no acknowledge from the receiving device in transmission.

An acknowledge bit from the receiving device is stored in the TACK bit in ICSR. A non-acknowledge interrupt is asserted if the TACK bit is set to 1 when TACKE in ICIC is 1.

Generating a STOP condition after a non-acknowledge interrupt is recommended. The STOP condition should be generated even if the ICCR is already set for further processing (for example, generating the repeated START condition). Figure 45.15 shows an example processing of generating the STOP condition when non-acknowledge interrupt is asserted.

Do not set the TACKE bit in ICIC if processing for non-acknowledgement is not required. Do not clear TACKE bit to 0 while TACK bit is 1. It is recommended to set TACKE bit only before start of communication.

Figure 45.14 shows an example of non-acknowledge operation timing.

**Figure 45.14 Example of Non-Acknowledge Operation Timing**

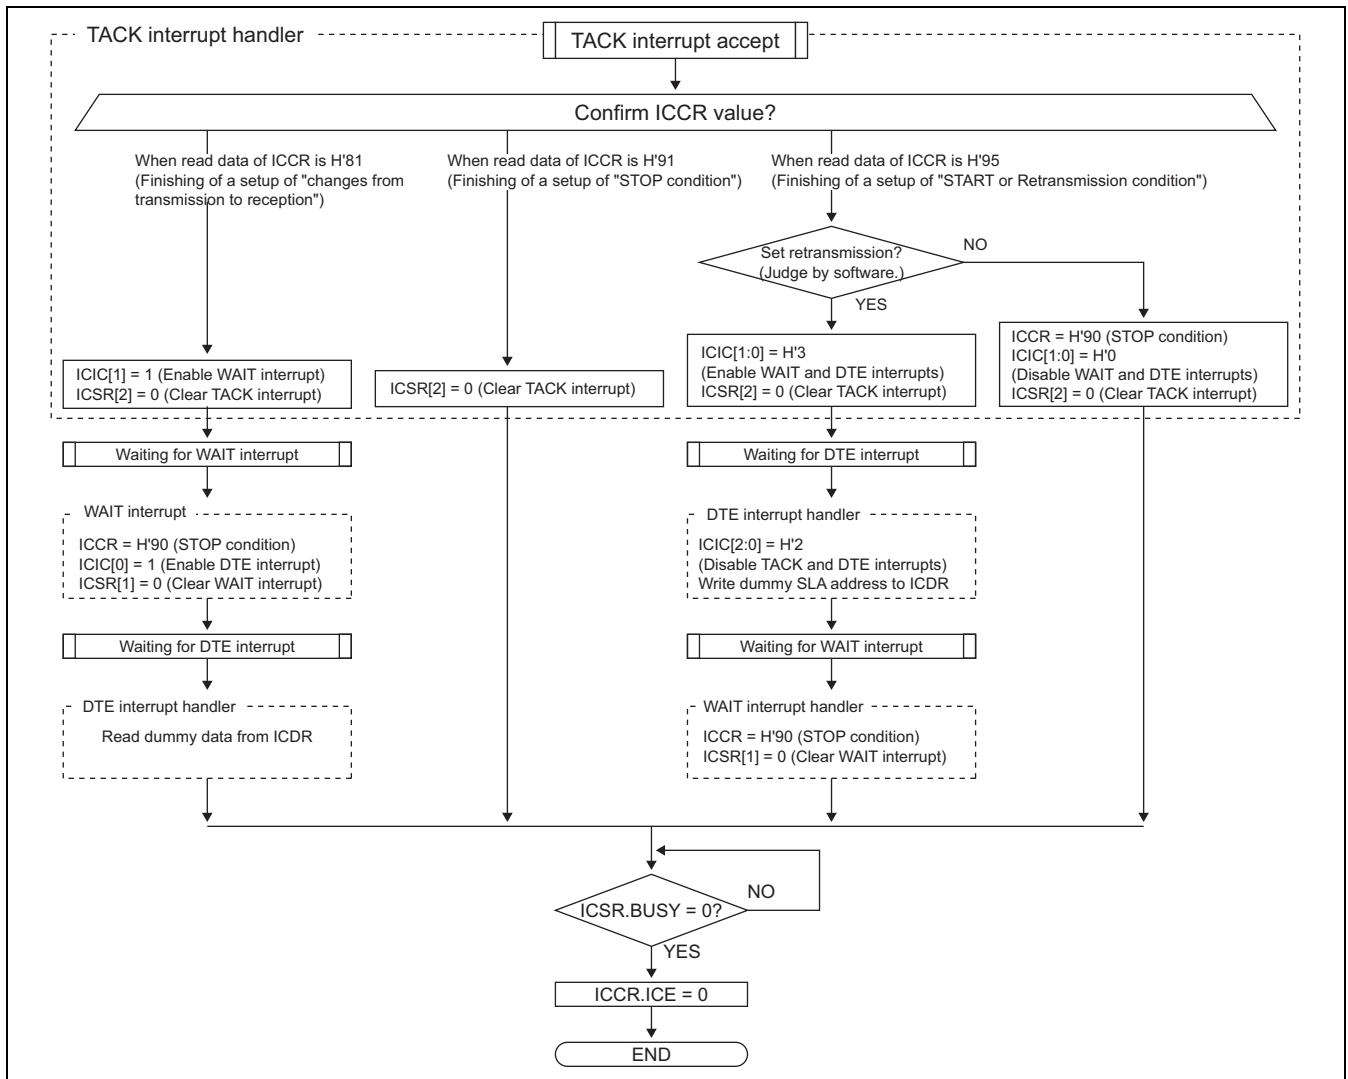

Figure 45.15 Generating a STOP Condition When Non-Acknowledge Interrupt Asserted

### 45.4.10 Wait Operation

This module can go into the wait state by assert of WAIT bit in ICSR. WAIT is set to 1 at the falling edge of the eighth transmit clock while this module is operating in master mode.

After that, the transmit clock is fixed to low until the WAIT bit is cleared to 0.

When the WAIT bit is cleared to 0, the ninth transmit clock is generated and the state is recovered from the wait state.

In case of using WAIT interrupt, data transfer by the I2C bus is suspended from the time WAIT is asserted by the hardware until the time WAIT is cleared by software.

It is recommended to set the WAITE bit only before the start of communication

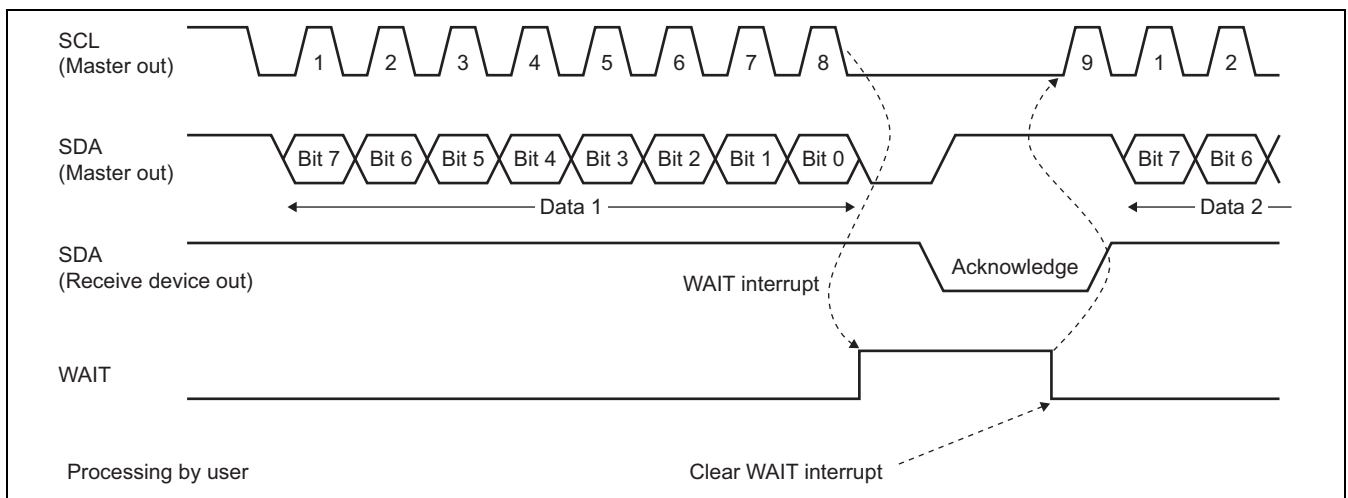

Figure 45.16 Example of Wait Operation Timing

## 45.5 Usage Note

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### (1) Arbitration lost

When a loss of arbitration is detected, the I2C bus may not be released soon depending on the status of slave devices. Reset the IIC module by the ICE bit in ICCR register when re-starting data transfer after a loss of arbitration is detected.

### (2) ICE reset

When asserting ICE reset during data transfer, SCL clock is stopped immediately and the bus may not be released depending on the status of the slave device.

### (3) Processing for stop condition generation

When data is transmitted or received after a STOP condition is generated, it may not be possible to generate a STOP condition hereafter. Initialize all registers in the IIC module by clearing the ICE bit in ICCR to 0, after a STOP condition has been generated or before making settings to trigger data transmission or reception after a STOP condition has been generated.

### (4) Handling of IIC when not in use

Set the ICE bit in ICCR to 0 to disable the unused channels while the IIC bus interface is not used.

### (5) Abort of data transfer in the middle of IIC communication

Aborting data transfer may violate the I2C protocol. Make sure that the external device accepts such violations when you need to abort transfer in progress.

### (6) IIC Selection for Automatic Transmission (RZ/G1H, M and N)

When IIC3 is selected as automatic transmission control, initialize by software reset of the IIC (software reset for the IIC all channels must be performed before using the IIC3 as automatic transmission control).

## 46. Clock-Synchronized Serial Interface with FIFO (MSIOF)

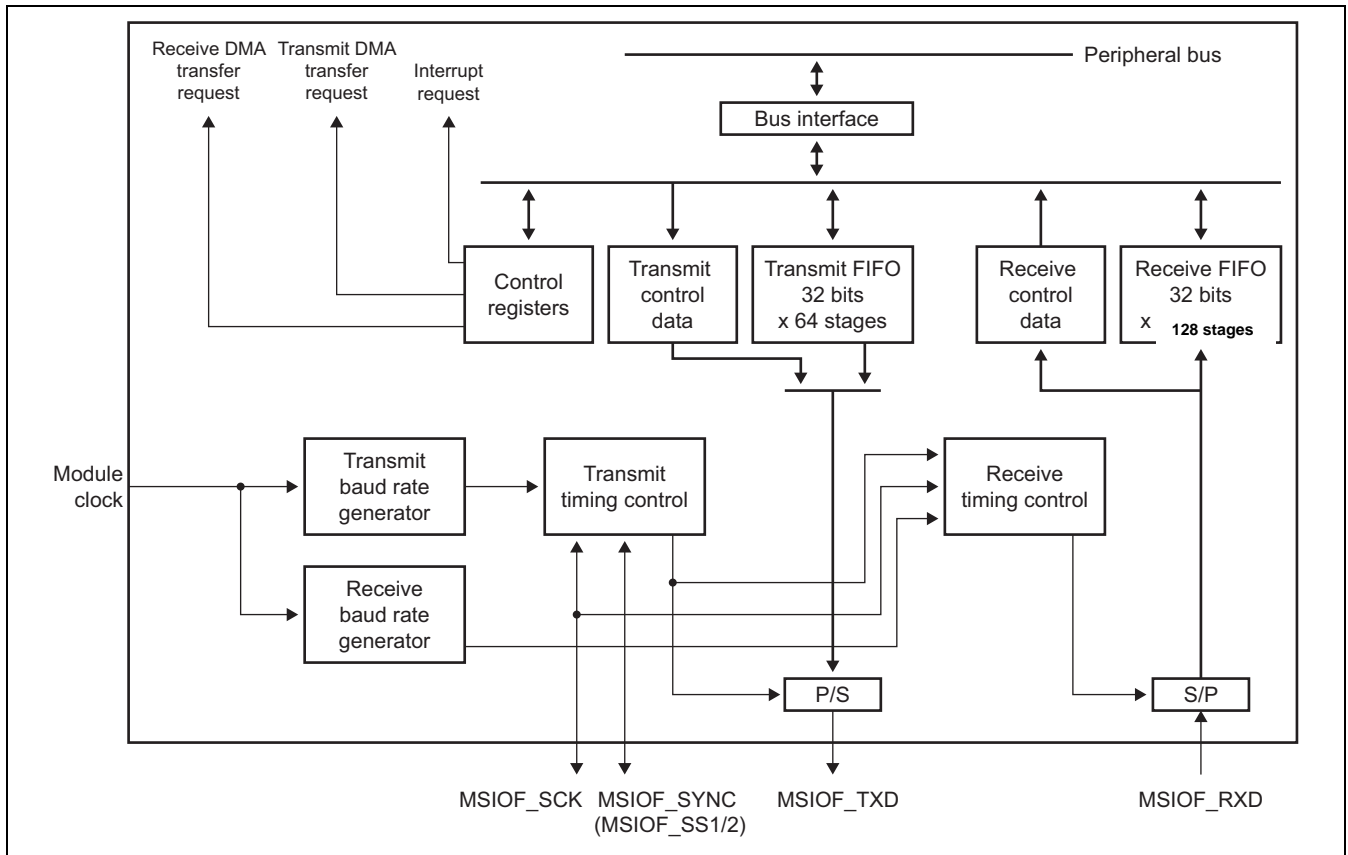

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

This LSI includes clock-synchronized serial I/O module with FIFO (MSIOF). In this module, MP $\phi$  is used as a module clock.

### 46.1 Features

- Number of channels: Four channels (RZ/G1H), three channels (RZ/G1M, N and E)
- FIFO capacity: 32 bits  $\times$  64 stages for transmission and 32 bits  $\times$  128 stages for reception
  - For reception FIFO, receiving 1 FRAME with 2 group with 64 words requires at most 128 FIFO stages.
- MSB first or LSB first selectable for data transmission and reception
- Synchronization by frame synchronization pulse, level, or left/right channel switch
- Supports master and slave modes
- Interrupts: One type
- Serial clock
- DMA transfer
- Serial format
  - Supports serial formats: IIS, SPI (master and slave\* modes).
  - Note: For SPI slave mode, refer to section 46.4.12, Limitation of SPI Mode.
- CLK/SYNC (SPI) in common transmit/receive mode
  - Up to 13 MHz for channels 0, 1 and 3 of RZ/G1H
  - Up to 26 MHz for channel 2 of RZ/G1H, and for all channels of RZ/G1M, RZ/G1N, and RZ/G1E

Figure 46.1 shows a block diagram of the MSIOF.

**Figure 46.1 Block Diagram of MSIOF**

## 46.2 Input/Output Pins

The pin configuration of this module is shown in Table 46.1.

**Table 46.1 Pin Configuration**

Name	Abbreviation	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
MSIOF_SCK	SCK	I/O	MSIOF serial clock for transmission Works as SCK when a common clock is used for transmission and reception.	√	√	√	√
MSIOF_SYNC	SYNC	I/O	MSIOF frame synchronization signal for transmission Works as SYNC when a common synchronization signal is used for transmission and reception.	√	√	√	√
MSIOF_SS1	SS1	Output	MSIOF frame synchronization signal 1 for transmission This signal can work only master mode.	√	√	√	√
MSIOF_SS2	SS2	Output	MSIOF frame synchronization signal 2 for transmission This signal can work only master mode.	√	√	√	√
MSIOF_TXD (MOSI/MISO)	MOSI/MISO (TXD)	Output	MSIOF transmit data	√	√	√	√

### 46.3.1 MSIOF Transmit Mode Register 1 (SITMDR1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SITMDR1 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	PCON	SYNCMD[1:0]	SYNCCH[1:0]	SYNCA C	BITLSB	—	DTDL[2:0]	—	SYNCDL[2:0]	—	—	—	—	—	—
Initial value:	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	FLD[1:0]	—	TXSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	PCON	0	R/W	Transfer Signal Connection 0: Setting prohibited 1: MSIOF_SCK and MSIOF_SYNC are used as common signals for transmission and reception (MSIOF_SCK and MSIOF_SYNC).
29, 28	SYNCMD[1:0]	00	R/W	SYNC Mode These bits specify the mode for the MSIOF_SYNC signal. 00: Frame start synchronization pulse 01: Reserved 10: Level mode/SPI 11: L/R mode
27, 26	SYNCCH[1:0]	00	R/W	Synchronization Signal Channel Select These bits are valid only in master mode. 00: The frame synchronization signal output at MSIOF_SYNC. 01: The frame synchronization signal output at MSIOF_SS1. 10: The frame synchronization signal output at MSIOF_SS2. 11: Setting prohibited
25	SYNCA C	0	R/W	MSIOF_SYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first

Bit	Bit Name	Initial Value	R/W	Descriptions
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDLD[2:0]	001	R/W	Data Pin Bit Delay for MSIOF_SYNC Pin The value specified with TXDIZ in SICTR is output during transmission. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDLD and SYNCDDL becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDDL[2:0]	000	R/W	Frame Synchronization Signal Timing Delay These bits extend the transmit frame synchronization signal. The value specified with TXDIZ in SICTR is output during transmission. These bits are invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDLD and SYNCDDL becomes an integer value. When L/R mode, these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval Specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. When L/R mode, these bits should always be set to 00. When SPI mode, these bits shall not be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	TXSTP	0	R/W	Transmission Stop 0: Setting prohibited 1: Temporarily stops transmission when the number of transmit FIFO stages is not enough to valid.

### 46.3.2 MSIOF Transmit Mode Register 2 (SITMDR2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SITMDR2 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

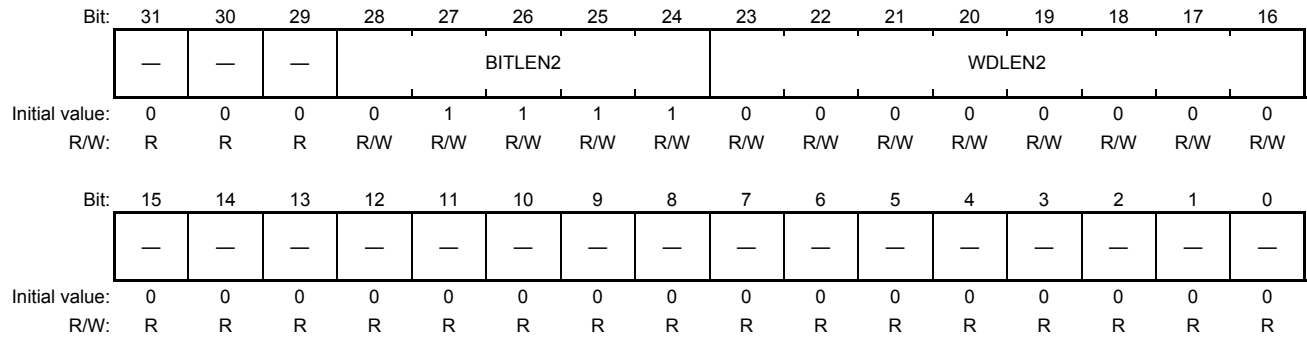

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	GRP	—	BITLEN1				WDLEN1								
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	GRP	0	R/W	Group Count The number of groups is set to the value specified in this bit + 1.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0]	01111	R/W	Data Size (8 to 32 bits) The word size (bits) of groups 1 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size.
23 to 16	WDLEN1[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 1 is set to WDLEN1 + 1 respectively. 8-bit value is set to WDLEN1.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

**46.3.3 MSIOF Transmit Mode Register 3 (SITMDR3)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SITMDR3 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2	01111	R/W	Word Size (1 to 32 bits) The word size of groups 2 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size.
23 to 16	WDLEN2	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 2 are set to WDLEN2 + 1. 8-bit value is set to WDLEN2.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

### 46.3.4 MSIOF Receive Mode Register 1 (SIRMDR1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIRMDR1 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	—	SYNCCMD[1:0]	—	—	SYNCA C	BITLSB	—	—	DTDL[2:0]	—	—	—	—	—	—
Initial value:	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. This bit should be set to 0.
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCCMD [1:0]	00	R/W	SYNC Mode The mode setting in these bits should be the same as that in SITMDR1.SYNCCMD. 00: Frame start synchronization pulse 01: Reserved 10: Level mode/SPI 11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SYNCCAC	0	R/W	SYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode This bit must have the same setting as the SYNCCAC bit of SITMDR1.
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
22 to 20	DTDLD[2:0]	001	R/W	<p>Data Pin Bit Delay for MSIOF_SYNC Pin</p> <p>000: No bit delay            001: 1-clock-cycle delay            010: 2-clock-cycle delay            101: 0.5-clock-cycle delay            110: 1.5-clock-cycle delay            Other than above: Setting prohibited</p> <p>In case of SPI mode, only 000 is allowed to set to this field.</p>
19	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
18 to 16	SYNCDL [2:0]	000	R/W	<p>MSIOF_SYNC Timing Delay</p> <p>The synchronization signal is extended for the clock cycles specified in these bits.</p> <p>These bits are invalid when SYNCMD[1:0] = B'01.</p> <p>In L/R mode, these bits should always be set to 000.</p> <p>000: No bit delay            001: 1-clock-cycle delay            010: 2-clock-cycle delay            011: 3-clock-cycle delay            101: 0.5-clock-cycle delay            110: 1.5-clock-cycle delay            Other than above: Setting prohibited</p> <p>In case of SPI mode, only 000 is allowed to set to this field.</p>
15 to 0	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

### 46.3.5 MSIOF Receive Mode Register 2 (SIRMDR2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIRMDR2 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	GRP	—	BITLEN1[4:0]				WDLEN1[7:0]								
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	GRP	0	R/W	Group Count The number of groups is set to the value specified in this bit + 1. Set the same value as the value specified by the GRP bit in SITMDR2.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0]	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. Set the same value as the value specified by the BITLEN1 bits in SITMDR2.
23 to 16	WDLEN1[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 1 is set to WDLEN1 + 1. When one or two groups are used, the 8-bit value is set to WDLEN1. Set the same value as the value specified by the WDLEN1 bits in SITMDR2.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

### 46.3.6 MSIOF Receive Mode Register 3 (SIRMDR3)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIRMDR3 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16			
	—	—	—	BITLEN2[4:0]				WDLEN2[7:0]											
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0			
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0			
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R			

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0]	01111	R/W	Word Size (1 to 32 bits) The word size is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. Set the same value as the value specified by the BITLEN2 bits in SITMDR3.
23 to 16	WDLEN2[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 2 is set to WDLEN2 + 1. 8-bit value is set to WDLEN2. Set the same value as the value specified by the WDLEN2 bits in SITMDR3.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

### 46.3.7 MSIOF Control Register (SICTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SICTR is a 32-bit readable/writable register that specifies the MSIOF operating state.

The values written to the TXE, RXE, TFSE, RFSE, TSCKE, and RSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified at the same time. Modify one bit at a time, and check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	RSCKE	RFSE	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	00	R/W	<p>Transmit Clock Input/Output Polarity Select in SPI Mode When Transmission is Disabled</p> <p>When SPI mode is not used, these bits must always be set to 00. These bits must always be set 10 or 11 when SPI mode.</p> <p>[Master mode]</p> <p>00: Outputs MSIOF_SCK when transmission is disabled.</p> <p>01: Setting prohibited</p> <p>10: Outputs 0.</p> <p>11: Outputs 1.</p> <p>[Slave mode]</p> <p>00: Inputs MSIOF_SCK when transmission is disabled.</p> <p>01: Setting prohibited</p> <p>10: Inputs 0 through MSIOF_SCK when transmission is disabled.</p> <p>11: Inputs 1 through MSIOF_SCK when transmission is disabled.</p>
29, 28	RSCKIZ[1:0]	00	R/W	<p>Receive Clock Polarity Select in SPI Mode</p> <p>Set the same value as the value specified by the TSCKIZ bits. Other setting is prohibited.</p>
27	TEDG	0	R/W	<p>Transmit Timing</p> <p>0: Outputs transmit data at the rising edge of the clock.</p> <p>1: Outputs transmit data at the falling edge of the clock.</p>
26	REDG	0	R/W	<p>Receive Timing</p> <p>0: Samples receive data at the falling edge of the clock.</p> <p>1: Samples receive data at the rising edge of the clock.</p>
25, 24	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Descriptions
23, 22	TXDIZ[1:0]	00	R/W	<p>Pin Output When Transmission is Disabled</p> <p>These bits specify the MSIOF_TXD pin output state when transmission is disabled.</p> <p>00: Outputs 0. 01: Outputs 1. 10: Output is in high-impedance state. 11: Setting prohibited</p>
21 to 16	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
15	TSCKE	0	R/W	<p>Transmit Serial Clock Output Enable</p> <p>This bit is valid in master mode.</p> <p>When this bit is set to 1, the MSIOF initializes the baud rate generator and initiates the operation. At the same time, the MSIOF outputs the clock generated by the baud rate generator to the MSIOF_SCK pin. After the clock is output, 1 can be read.</p> <p>When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0.</p> <p>[Write data] 0: Disables the MSIOF_SCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the MSIOF_SCK output.</p> <p>[Read data] 0: Does not output MSIOF_SCK. (Outputs the value specified with TSCKIZ.) 1: Outputs MSIOF_SCK.</p>
14	TFSE	0	R/W	<p>Transmit Frame Synchronization Signal Output Enable</p> <p>This bit is valid in master mode.</p> <p>When this bit is set to 1, the MSIOF initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame.</p> <p>[Write data] 0: Disables the MSIOF_SYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the MSIOF_SYNC output.</p> <p>[Read data] 0: Does not output MSIOF_SYNC. (Outputs the value specified with SYNCAC.) 1: Outputs MSIOF_SYNC.</p>
13	RSCKE	0	R/W	<p>Receive Serial Clock Output Enable</p> <p>The write value should always be 0.</p>
12	RFSE	0	R/W	<p>Receive Frame Synchronization Signal Output Enable</p> <p>The write value should always be 0.</p>
11, 10	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Descriptions
9	TXE	0	R/W	<p>Transmit Enable</p> <p>When this bit is set to 1, the MSIOF starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). After the valid data is output, 1 can be read.</p> <p>When value 1 set to this bit becomes valid, the MSIOF issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the MSIOF_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame.</p> <p>This bit is initialized upon a transmit reset.</p> <p>[Write data]</p> <p>0: Disables the MSIOF_TXD output. (Outputs the value specified with TXDIZ.)</p> <p>1: Enables the MSIOF_TXD output.</p> <p>[Read data]</p> <p>0: Does not output MSIOF_TXD. (Outputs the value specified with TXDIZ.)</p> <p>1: Outputs MSIOF_TXD.</p>
8	RXE	0	R/W	<p>Receive Enable</p> <p>When this bit is set to 1, the MSIOF starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal).</p> <p>When value 1 set to this bit becomes valid, the MSIOF starts receiving data through the MSIOF_RXD pin. When receive data is stored in the receive FIFO, the MSIOF issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR.</p> <p>This bit is initialized upon a receive reset.</p> <p>[Write data]</p> <p>0: Disables data reception through MSIOF_RXD.</p> <p>1: Enables data reception through MSIOF_RXD.</p> <p>[Read data]</p> <p>0: Data is not received through MSIOF_RXD.</p> <p>1: Data can be received through MSIOF_RXD.</p>

No data should be written to SICTR or read the receive FIFO during this time period.</p> <p>[Write data]</p> <p>0: Does not reset receive operation. 1: Resets receive operation.</p> <p>[Read data]</p> <p>0: Receive operation reset is completed. 1: Receive operation is being reset.</p>

### 46.3.8 MSIOF Transmit Clock Select Register (SITSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.

For the channels 0, 1 and 3 of the RZ/G1H, maximum transfer rate is limited up to 13 MHz. Please specify this register, to make transfer rate equal or less than 13 MHz.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]				—	—	—	—	—	BRDV[2:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects module clock as the source of master clock. Others: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select 0: Selects the clock output from the baud rate generator as the serial clock. 1: Setting prohibited
12 to 8	BRPS[4:0]	00000	R/W	Prescaler Setting These bits specify the master clock (MP $\phi$ ) division ratio in the count value of the prescaler in the baud rate generator. The specifiable value is from B'00000 ( $\times 1/1$ ) to B'11111 ( $\times 1/32$ ).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
2 to 0	BRDV[2:0]	000	R/W	<p>Baud Rate Generator's Division Ratio</p> <p>These bits specify the frequency division ratio for the output stage of the baud rate generator.</p> <p>The final frequency division ratio of the baud rate generator is determined as <math>BRPS \times BRDV</math> (1/1024 max.).</p> <p>000: Prescalar output <math>\times 1/2</math>            001: Prescalar output <math>\times 1/4</math>            010: Prescalar output <math>\times 1/8</math>            011: Prescalar output <math>\times 1/16</math>            100: Prescalar output <math>\times 1/32</math>            101: Setting prohibited            110: Setting prohibited            111: Prescalar output <math>\times 1/1</math></p> <p>Note: B'111 is valid only when the BRPS[4:0] bits are set to B'00000 or B'00001.</p>

### 46.3.9 MSIOF Transmit FIFO Data Register (SITFDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the MSIOF.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	W	These bits specify the upper 16 bits of the FIFO data to be output through MSIOF_TXD.
15 to 0	SITFD2[15:0]	H'0000	W	These bits specify the lower 16 bits of the FIFO data to be output through MSIOF_TXD.

### 46.3.10 MSIOF Receive FIFO Data Register (SIRFDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the MSIOF.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	Undefined	R	Store the upper 16 bits of the FIFO data received through MSIOF_RXD.
15 to 0	SIRFD2[15:0]	Undefined	R	Store the lower 16 bits of the FIFO data received through MSIOF_RXD.

### 46.3.11 MSIOF Status Register (SISTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Each bit in SISTR becomes an MSIOF interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFS ERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RFFUL	RDREQ	—	—	—	—	REOF	—	RFS ERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	TFEMP	0	R/W	Transmit FIFO Empty This bit is set to 1, when the TXE bit in SICTR is 1, and transmit FIFO is empty. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	0	R	Transmit Data Transfer Request This bit is set, when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	0	R/W	<p>Frame Transmission End</p> <p>This bit is set, when one-frame data transmission is completed.</p> <p>This bit is valid when the TXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: One-frame transmission end is not detected.</p> <p>1: One-frame transmission end is detected.</p>
22	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
21	TFSERR	0	R/W	<p>Transmit Frame Synchronization Error</p> <p>This bit is set, when the next transmit frame synchronization timing arrives before the previous data or control data transmission has been completed.</p> <p>If a transmit frame synchronization error occurs, the MSIOF performs transmission only for the slots that can be transferred.</p> <p>This bit is valid when the TXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No transmit frame synchronization error has occurred.</p> <p>1: A transmit frame synchronization error has occurred.</p>
20	TFOVF	0	R/W	<p>Transmit FIFO Overflow</p> <p>A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full.</p> <p>If a transmit FIFO overflow occurs, the MSIOF ignores the write operation causing the overflow.</p> <p>This bit is valid when the TXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No transmit FIFO overflow has occurred.</p> <p>1: A transmit FIFO overflow has occurred.</p>
19	TFUDF	0	R/W	<p>Transmit FIFO Underflow</p> <p>A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. Output data is unknown when under flow is occurred.</p> <p>This bit is valid when the TXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No transmit FIFO underflow has occurred.</p> <p>1: A transmit FIFO underflow has occurred.</p>

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RFFUL	0	R/W	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.
12	RDREQ	0	R	Receive Data Transfer Request This bit is set, when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring receive data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOF	0	R/W	Frame Reception End The MSIOF issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
5	RFSERR	0	R/W	<p>Receive Frame Synchronization Error</p> <p>A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data or control data reception has been completed.</p> <p>If a receive frame synchronization error occurs, the MSIOF performs reception only for the slots that can be transferred.</p> <p>This bit is valid when the RXE bit in SICTR is 1.</p> <p>Writing 1 to this bit will clear this bit.</p> <p>Writing 0 to this bit will be ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No receive frame synchronization error has occurred 1: A receive frame synchronization error has occurred</p>
4	RFUDF	0	R/W	<p>Receive FIFO Underflow</p> <p>A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty.</p> <p>If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed.</p> <p>This bit is valid when the RXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.</p>
3	RFOVF	0	R/W	<p>Receive FIFO Overflow</p> <p>A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full.</p> <p>If a receive FIFO overflow occurs, the receive data causing the overflow is lost.</p> <p>This bit is valid when the RXE bit in SICTR is 1.</p> <p>Writing 1 to this bit clears this bit.</p> <p>Writing 0 to this bit is ignored.</p> <p>If the interrupt request from this bit is enabled, an MSIOF interrupt is issued.</p> <p>0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.</p>
2 to 0	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

### 46.3.12 MSIOF Interrupt Enable Register (SIER)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIER is a 32-bit readable/writable register that enables the issuance of MSIOF interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the MSIOF issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	—	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29	TFEMPE	0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty. 1: Enables interrupts due to transmit FIFO empty.
28	TDREQE	0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.

Bit	Bit Name	Initial Value	R/W	Descriptions
20	TFOVFE	0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow. 1: Enables interrupts due to transmit FIFO overflow.
19	TFUDFE	0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
14	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	RFFULE	0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSEERE	0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.
3	RFOVFE	0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

## 46.3.13 MSIOF FIFO Control Register (SIFCTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12 to 4	RFUA[8:0]	All 0	R	<p>Receive FIFO Usable Area</p> <p>Indicate the number of words that can be transferred by the CPU or DMAC as B'0000000 (empty) to B'1000000 (full).</p>
3 to 0	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

## 46.4 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 46.4.1 Operating Mode

#### (1) Common transmit/receive mode

Common clock and frame synchronization signals are used for transmission and reception.

Master mode: MSIOF\_SCK and MSIOF\_SYNC are output.

Slave mode: MSIOF\_SCK and MSIOF\_SYNC are input.

### 46.4.2 Serial Clocks

#### (1) Clock output in master mode

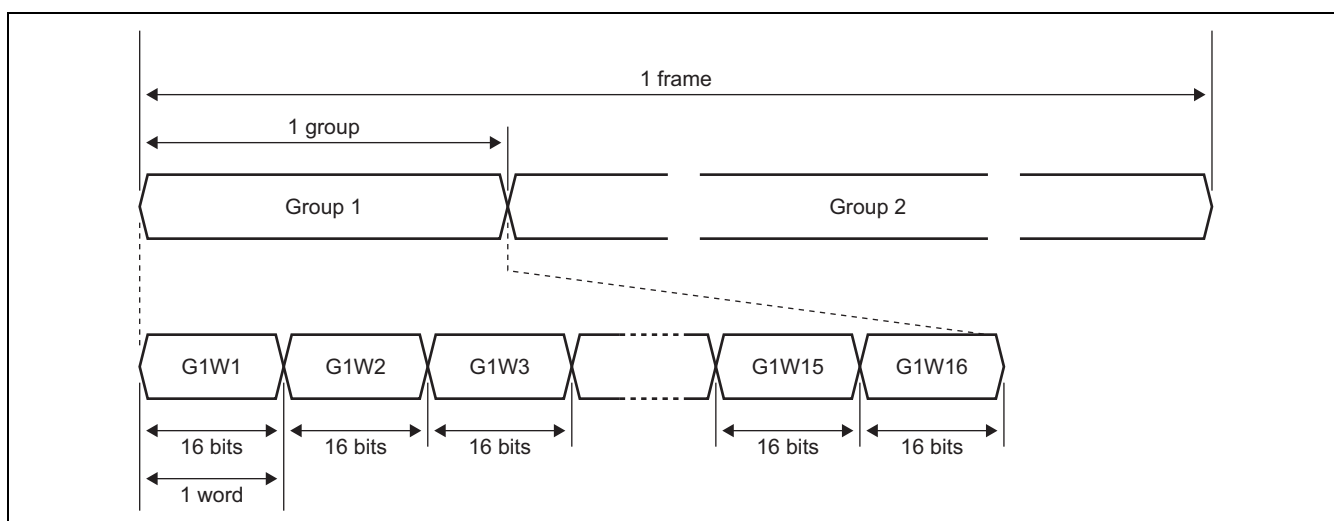

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

#### (2) Clock input in slave mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

#### (3) Multiple channel function

This module provides the multiple channel function as shown in Figure 46.2.

**Figure 46.2 Multiple Channel Structure**

The following conditions can be specified for the multiple channel function.

- Up to 2 groups in one frame
- Up to 64 words in one group
- 8, 16, 24, or 32 bits one word

### 46.4.3 Serial Timing

#### (1) MSIOF\_SYNC

The MSIOF\_SYNC is a frame synchronization signal. The following four modes are available.

- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figures 46.3 to 46.5 show the synchronization timing in these modes using the MSIOF\_SYNC signal.

#### (a) Frame start synchronization pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

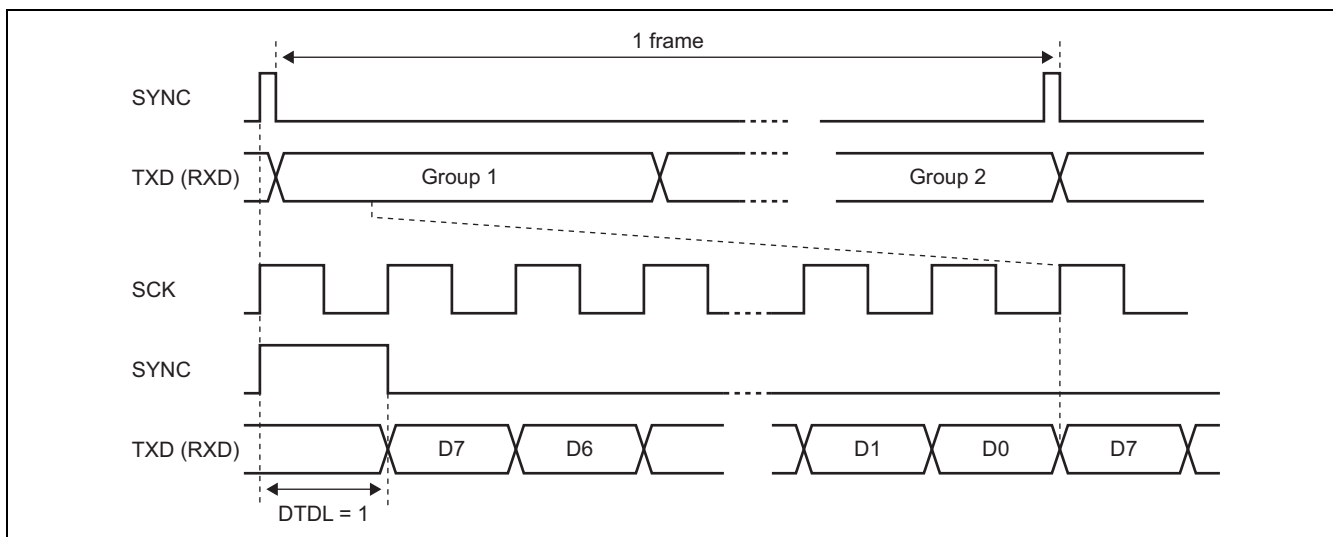

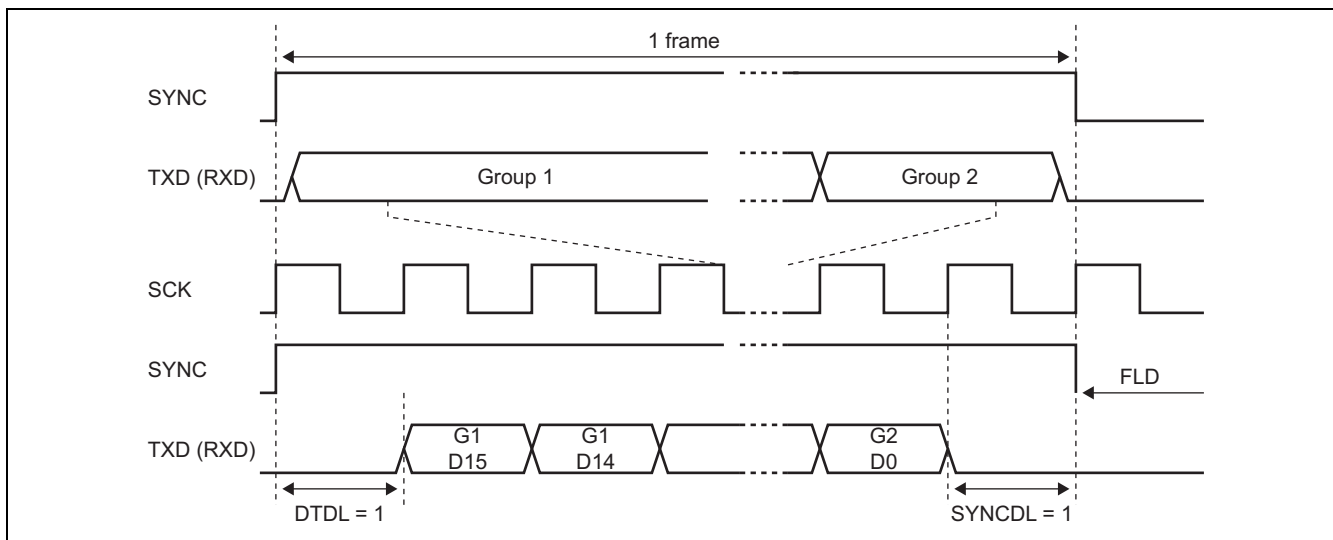

Figure 46.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

**(b) Level synchronization**

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCNL bits (DTDL = 0 to 2 and SYNCNL = 0 to 3). This mode is available for the SPI master or slave operation.

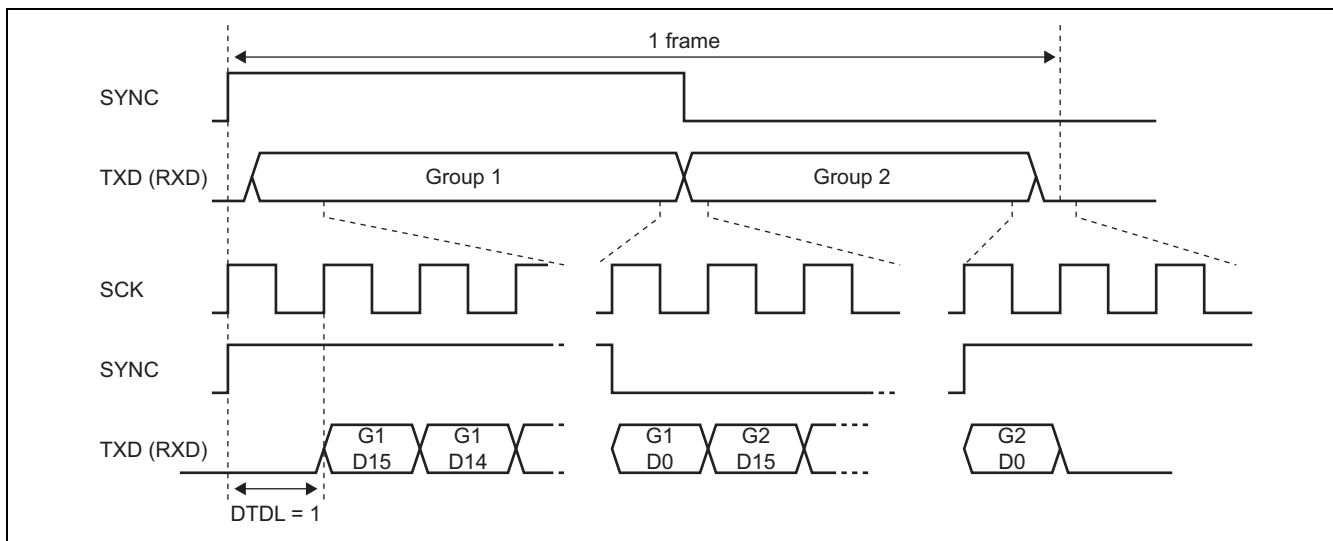

**Figure 46.4 Synchronization Timing in Level Synchronization Mode**

**(c) L/R synchronization**

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits.

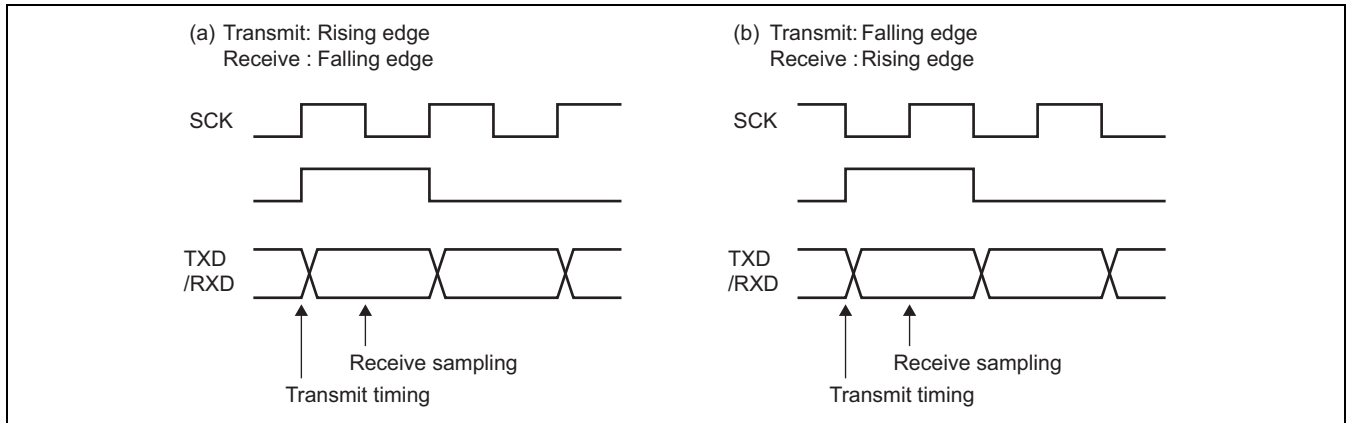

**Figure 46.5 Synchronization Timing in L/R Synchronization Mode**

**(2) Transmit/receive timing**

The timing of MSIOF\_TXD transmission relative to MSIOF\_SCK and of MSIOF\_RXD can be specified as sampling on either edge, as listed below. The respective settings are made in TEDG and REDG bits of SICTR.

- Falling-edge sampling
- Rising-edge sampling

**Figure 46.6 Transmit/Receive Timing.**

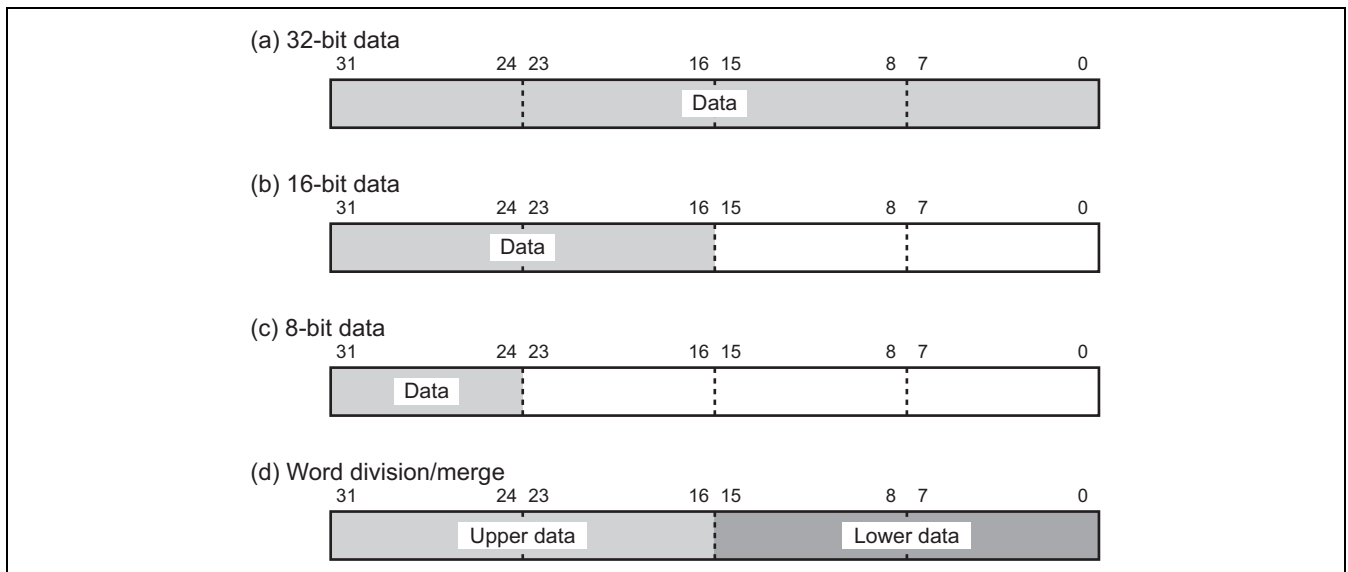

**46.4.4 Transfer Data Allocation to Registers**

**(1) Transmit/receive data**

Transmit/receive data (FIFO data and control data) should be written to or read from the following registers.

- Transmit FIFO data writing: SITFDR (32-bit access)
- Receive FIFO data reading: SIRFDR (32-bit access)

Figure 46.7 shows the bit alignment of these registers.

**Figure 46.7 Transmit/Receive Data Bit Alignment**

### 46.4.5 FIFO

#### (1) Overview

The transmit and receive FIFOs of the MSIOF have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 128 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

#### (2) Transfer request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

**Table 46.5 Condition for Issuing Transmit Request**

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
000	1	64 stages of empty area	Smallest
001	32	32 or more stages of empty area	
010	40	24 or more stages of empty area	
011	48	16 or more stages of empty area	
100	52	12 or more stages of empty area	
101	56	8 or more stages of empty area	
110	60	4 or more stages of empty area	
111	64	1 or more stages of empty area	

**Table 46.6 Condition for Issuing Receive Request**

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
000	1	1 or more stages of valid data	Smallest
001	4	4 or more stages of valid data	
010	8	8 or more stages of valid data	
011	16	16 or more stages of valid data	
100	32	32 or more stages of valid data	
101	64	64 or more stages of valid data	
110	128	128 stages of valid data	
111	128	128 stages of valid data	

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

**(3) Number of FIFOs**

The number of transmit and receive FIFO stages used are indicated by the following registers.

- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA[6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA[8:0] bits in SIFCTR.

These registers show the number of data stages that can be transferred by the CPU. DMA transfer should be set the number of stage 1.

**46.4.6 Transmit and Receive Procedures**

**(1) Transmission in master mode**

Figure 46.8 shows an example of settings and operation for transmission in master mode.

No.	Operating flow	Description	Operation
1	SITMDR1/2/3 SITSCR SIFCTR SIIER setting	Operating mode Clock setting FIFO water mark Setting interrupt/DMA enable	
2	SICTR Set SICTR.TSCKE to 1	Transmission rate setting Baud rate generator starting	Output serial clock
3		Read SICTR.TSCKE = 1	
4	SITFDR SITMDR1/2 setting	Write transmission data to FIFO	
5	Set SICTR.TXE to 1	Transmission enable	
6		Read SICTR.TXE = 1	
7	Set SICTR.TFSE to 1	Starting MSIOF_SYNC output	
8		Read SICTR.TFSE = 1	
9	Starting transmission		Data transmission
10			Generating interrupt/DMA request
11	Write transmission data to FIFO		
12			
13	Set SICTR.TFSE to 0	Frame sync disable	
14		Read SICTR.TFSE = 0	
15	Set SICTR.TXE to 0	Transmission disable	
16		Read SICTR.TXE = 0	

**Figure 46.8 Example of Transmit Procedure in Master Mode**

(2) Reception in master mode (with SITMDR1.PCON = 1)

Figure 46.9 shows an example of settings and operation for reception in master mode with SITMDR1.PCON = 1.

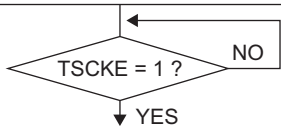

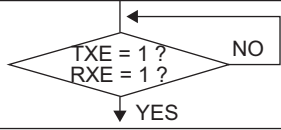

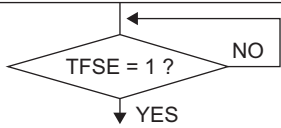

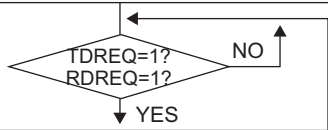

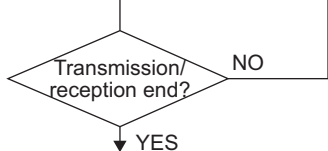

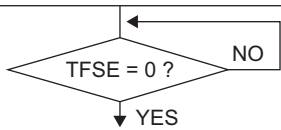

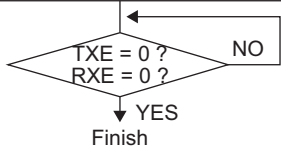

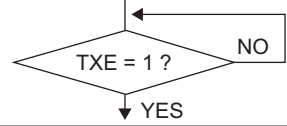

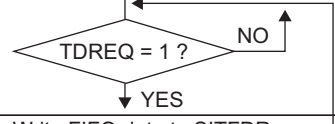

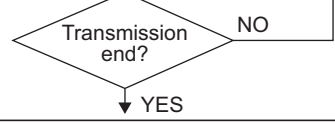

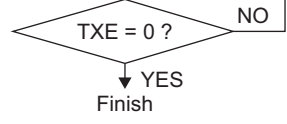

No.	Operating flow	Description	Operation
1	SIRMDR1/2/3 SITMDR1/2/3 SITSCR SIFCTR SIIER setting	Operating mode Operating mode (for SPI dummy transmission) Serial clock FIFO water mark Interrupt/DMA setting	
2	SICTR Set SICTR.TSCKE to 1	Baud rate setting Baud rate generator starting	Output serial clock
3		Read SICTR.TSCKE = 1	
4	SITFDR  SITMDR1/2 setting	Write dummy transmission data to SITFDR The number of dummy data should equal the number of reception data.	
5	Set SICTR.TXE to 1 Set SICTR.RXE to 1	Transmission enable Reception enable	
6		Read SICTR.TXE = 1 Read SICTR.RXE = 1	
7	Set SICTR.TFSE to 1	Frame sync enable	Output MSIOF_SYNC
8		Read SICTR.TFSE = 1	
9	Synchronizing with MSIOF_SYNC (1) Transmission FIFO dummy data (2) Reception data		Transmission and reception
10			Generating interrupt/DMA request
11	Write dummy data to FIFO Read fifo data from SIRFDR	Transmission dummy data Reception data reading	
12			
13	Set SICTR.TFSE to 0	Disable frame sync enable	
14		Read SICTR.TFSE = 0	
15	Set SICTR.TXE and SICTR.RXE to 0	Disable transmission enable and reception enable	
16		Read SICTR.TXE = 0 Read SICTR.RXE = 0	

Figure 46.9 Example of Receive Procedure in Master Mode (SITMDR1.PCON = 1)

**(3) Transmission in slave mode**

Figure 46.10 shows an example of settings and operation for transmission in slave mode.

No.	Operating flow	Description	Operation
1	Master device setting	Depend on master device	Signal polarity
2	SITMDR1/2/3 SIFCTR SIIER setting	Operating mode FIFO water mark Interrupt/DMA enable	
3	SITFDR SITMDR1/2 setting	Transmission data setting	
4	Set SICTR.TXE to 1	Setting transmission enable	
5		Read SICTR.TXE = 1	
6	Data transmission synchronize with MSIOF_SYNC		Data transmission
7			Generating interrupt/DMA request
8	Write FIFO data to SITFDR	Data transmission	
9			
10	Set SICTR.TXE to 0	Transmission disable	
11		Read SICTR.TXE = 0	

**Figure 46.10 Example of Transmit Procedure in Slave Mode**

**(4) Reception in slave mode**

Figure 46.11 shows an example of settings and operation for reception in slave mode.

No.	Operating flow	Description	Operation
1	Master device setting	Depend on master device	Signal polarity
2	SIRMDR1/2/3 SIFCTR SIIER setting	Operating mode FIFO water mark Interrupt/DMA enable	
3	Set SICTR.RXE to 1	Setting receive enable	
4		Read SICTR.RXE = 1	
5	Data reception		Receive data
6			Generating interrupt/DMA request
7	Read SIRFDR	Data read from FIFO	
8			
9	Set SICTR.RXE to 0	Reception disable	
10		Read SICTR.RXE = 0	

**Figure 46.11 Example of Receive Procedure in Slave Mode**

**(5) Reset**

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about 20 cycles of module clock to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The MSIOF can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

**Table 46.7 Transmit and Receive Reset**

Type	Objects Initialized
Transmit reset	SITFDR (Transmit FIFO write pointer) TDREQ bit in SISTR TXE bit in SICTR
Receive reset	SIRFDR (Receive FIFO read pointer) RDREQ bit in SISTR RXE bit in SICTR

**(6) Initial operating mode**

After a power-on reset, both transmit and receive units are initialized to master mode (0 is output through MSIOF\_SCK and MSIOF\_SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

### 46.4.7 Interrupts

The MSIOF has one type of interrupt.

#### (1) Interrupt sources

Interrupts can be generated by several sources. Each source is shown as an MSIOF status in SISTR. Table 46.8 lists the MSIOF interrupt sources.

**Table 46.8 MSIOF Interrupt Sources**

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame transmission end	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
8		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
9		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
10		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
11		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
12		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, an MSIOF interrupt is issued.

#### (2) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the MSIOF.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

**(3) Processing when errors occur**

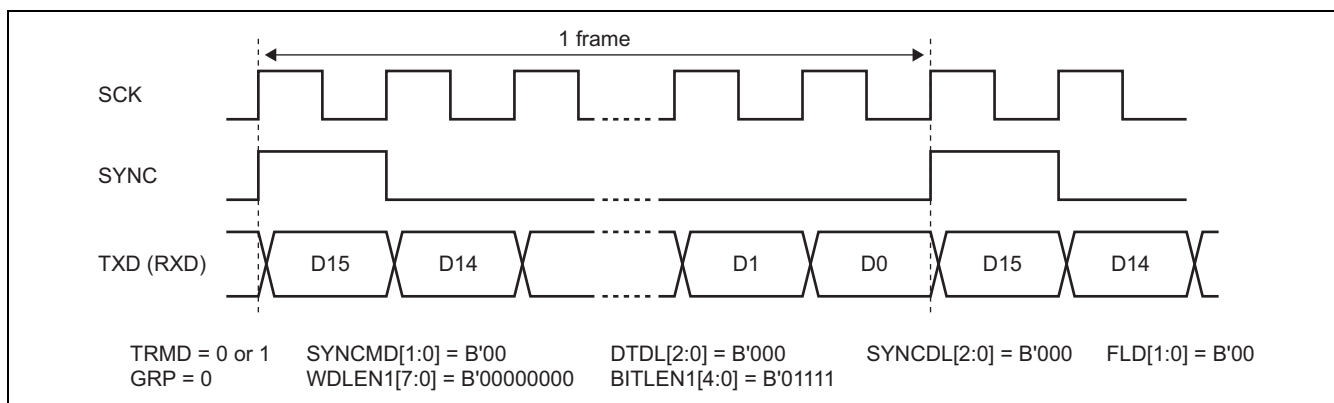

- Transmit FIFO underflow (TFUDF)  
The value specified with TXDIZ in SICTR is output.
- Transmit FIFO overflow (TFOVF)  
The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)  
Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)  
An undefined value is output on the bus.
- Transmit FS error (TFSERR)  
The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)  
The internal counter is reset according to the synchronization signal in which an error occurs.

**46.4.8 Transmit and Receive Timing**

Examples of the MSIOF serial transmission and reception are shown in Figures 46.12 and 46.13.

**(1) 16-bit synchronization pulse**

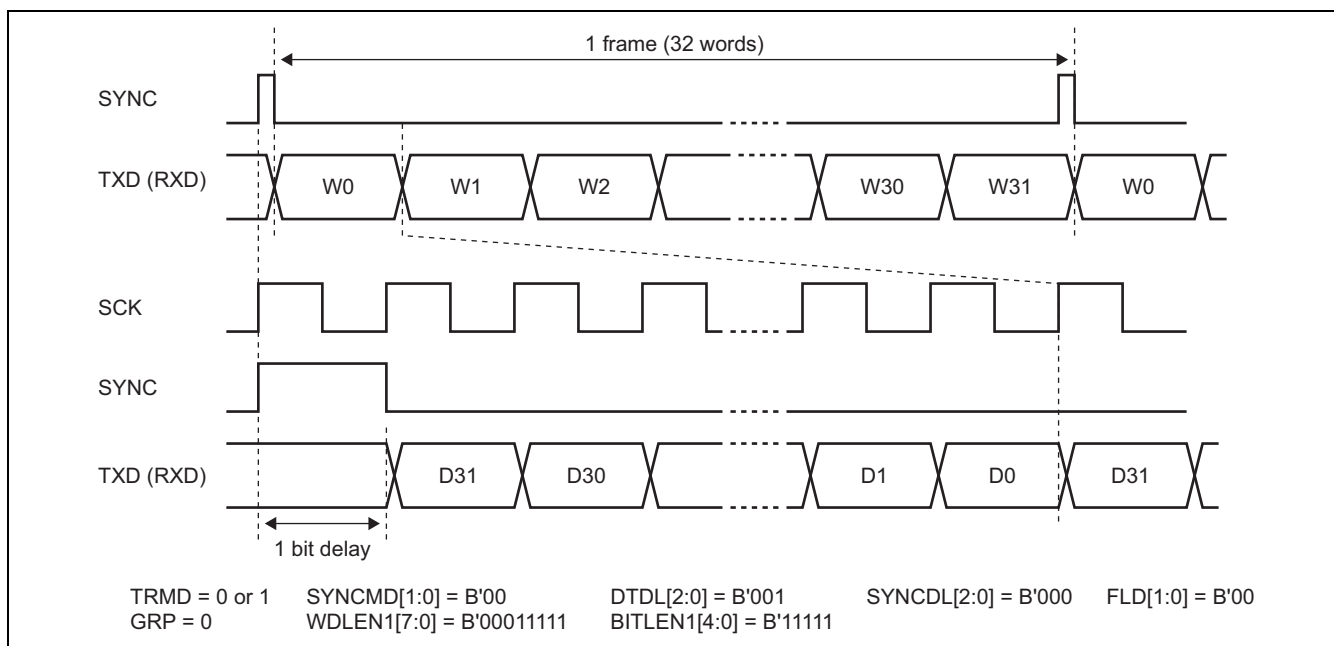

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

**Figure 46.12 Transmit and Receive Timing (16 Bits)**

**(2) 32-bit synchronization pulse**

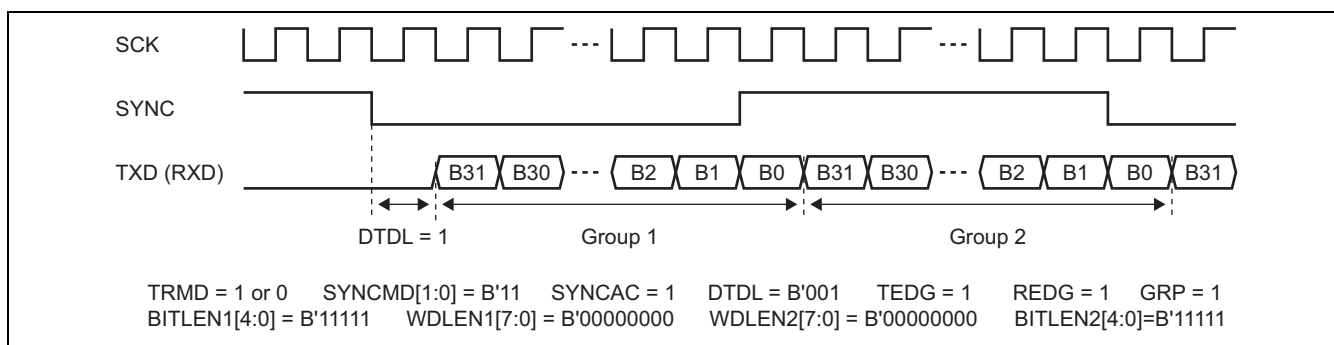

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

**Figure 46.13 Transmit and Receive Timing (32 Bits)**

**(3) 32-bit iis transmission**

L/R mode, 2 groups, 1 word for each group, 32-bit word for each group, 1-bit delay

**Figure 46.14 Transmit Timing (24-Bit IIS)**

### 46.4.9 SPI

With the appropriate register settings, the MSIOF can be used as an SPI device.

#### (1) Example of SPI device connection

Figure 46.15 shows an example of connection with an SPI device.

**Figure 46.15 Example of SPI Device Connection**

(2) SPI serial clock timing

Figures 46.16 and 46.17 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.

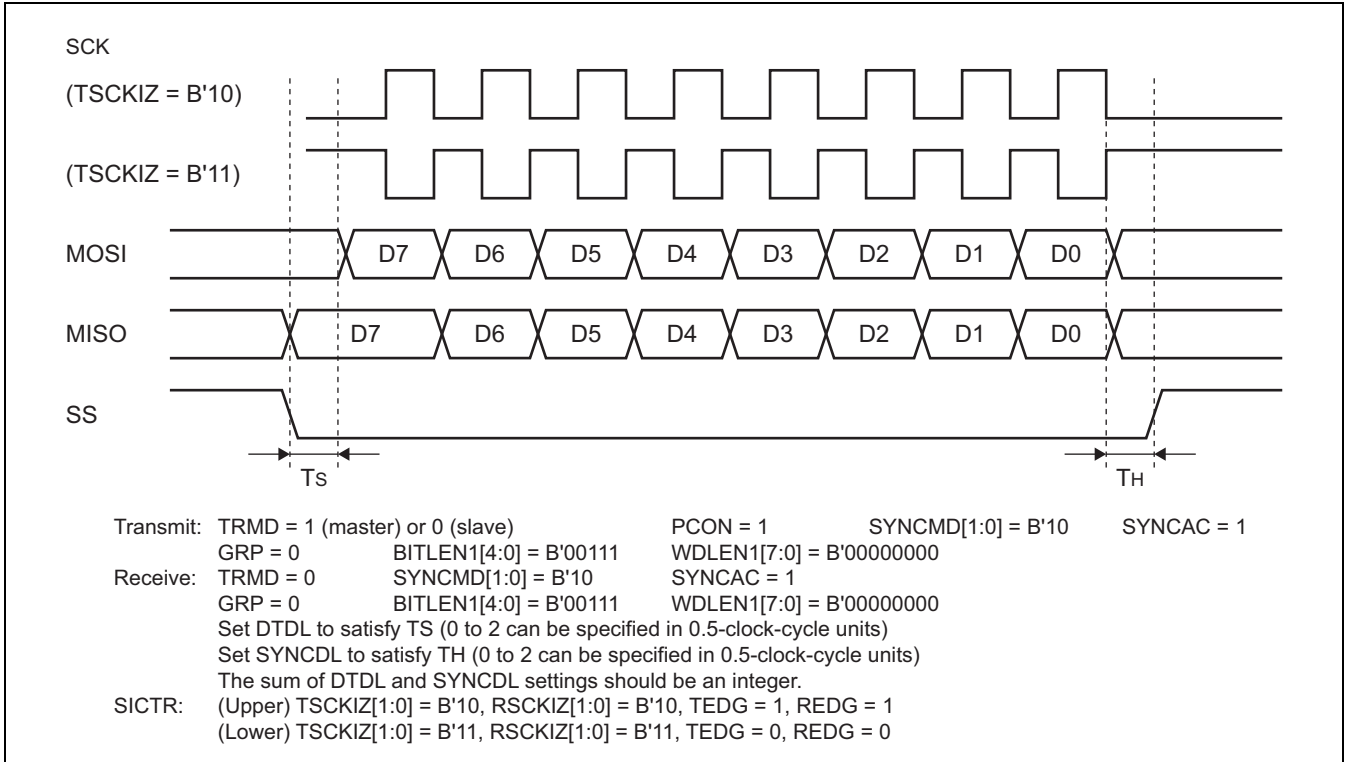

Figure 46.16 SPI Clock and Data Timing 1

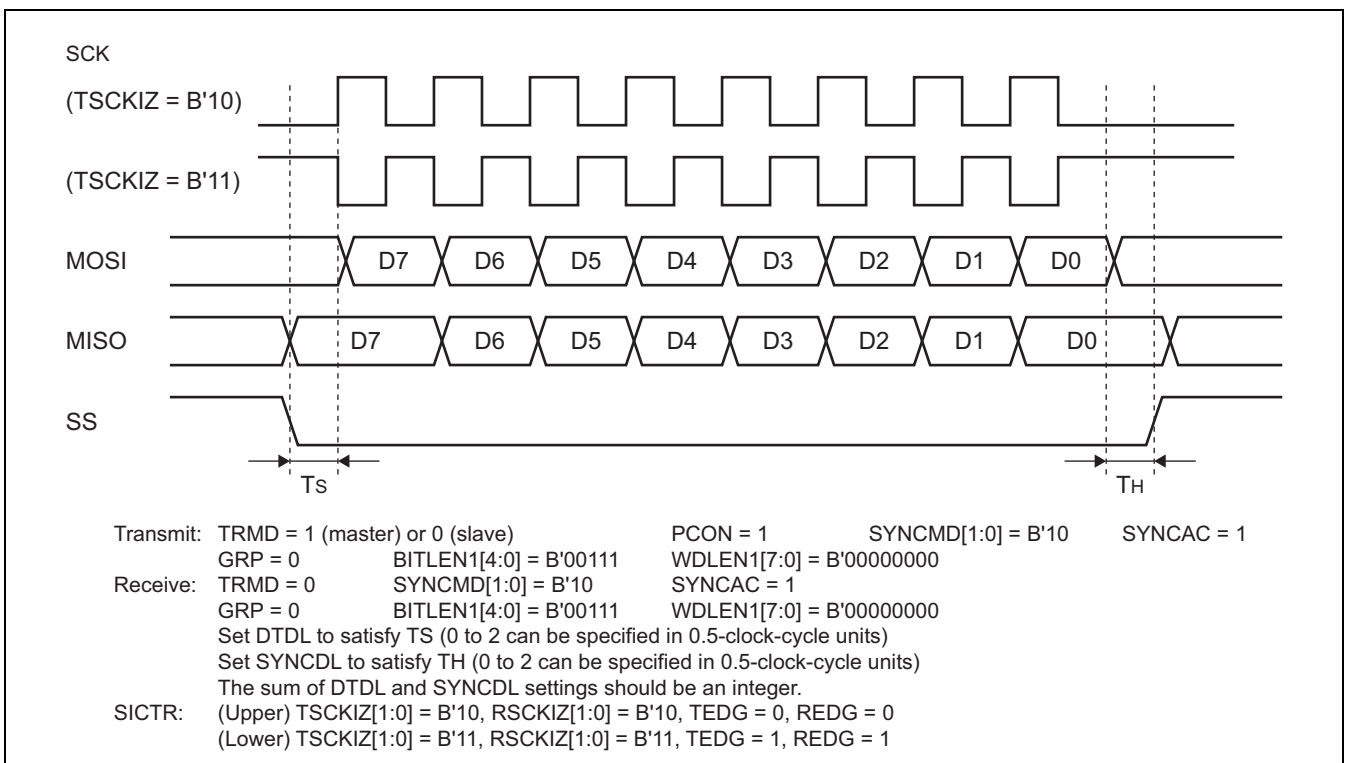

Figure 46.17 SPI Clock and Data Timing 2

#### 46.4.10 Notes for Using SPI Mode

- For SPI master mode operation, set the FLD bits in SITMDR1 for at least 3 cycles of module clock.
- For SPI slave mode operation, set the frame synchronization signal interval to at least 4 cycles of module clock.
- For SPI slave mode operation, the setting for data delay should be always set to 0.
- For SPI slave mode operation, TXDIZ bits work on SS signal invalid state.

#### 46.4.11 SPI Mode Transfer Rate Limitation of RZ/G1H

For channels 0, 1 and 3 of the RZ/G1H, maximum transfer rate is limited to 13 MHz. Please specify SITSCR to make the bit rate equal to or less than 13 MHz.

#### 46.4.12 Limitation of SPI Mode

When the MSIOF operates with all of the following condition 1 to 3, the MSIOF in SPI slave mode cannot start the next transmission. The MSIOF cannot support SPI mode under following condition.

- Condition
  - 1) MSIOF is in SPI slave mode (SITMDR1.TRMD=0, SITMDR1.SYNCMD[1:0]=10)
  - 2) SYNC (CS) signal is being asserted from master
  - 3) TXE or RXE in SICTR is set to 1 during SYNC (CS) is asserted

This limitation means the MSIOF cannot respond to the SYNC (CS).

It is necessary to control the MSIOF enabling timing by the master and system.

[Workaround]

Use master mode for SPI.

If use slave mode for SPI, consider following alternative.

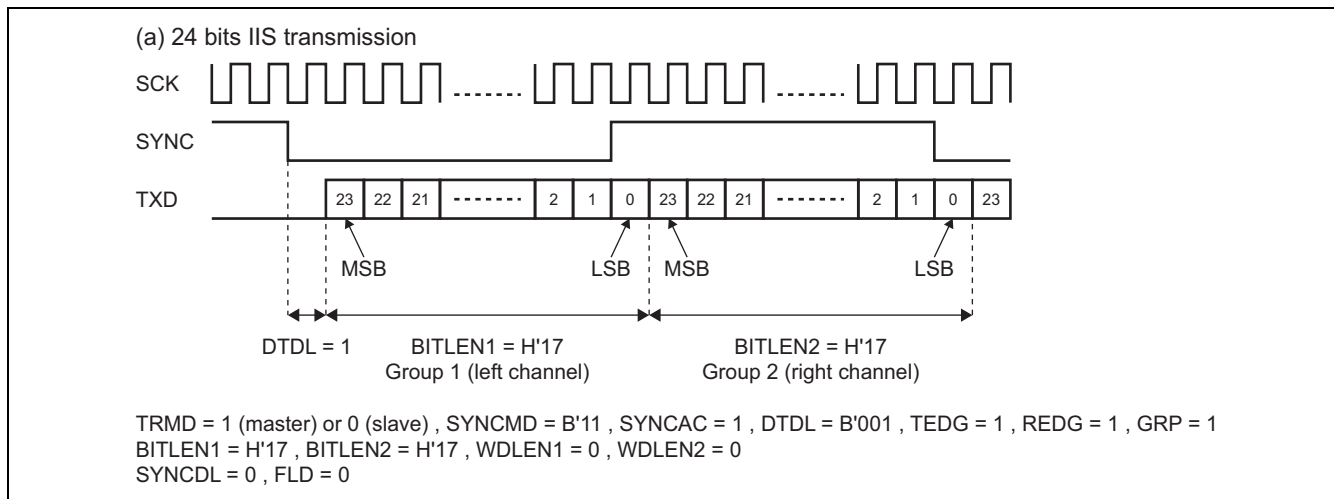

[Alternative]

If the master device can support handshaking, use the handshaking transmission.

For the MSIOF in SPI slave mode, use with the GPIO output for SPI handshaking; the system operation must be tested and evaluated thoroughly by user.

**46.4.13 IIS**

This module can support IIS format with following setting which is shown in Figures 46.18 and 46.19. BITLEN1 and BITLEN2 bits will change by usage.

**Figure 46.18 24 Bits IIS Transmission**

**Figure 46.19 24 Bits IIS Transmission with 8 Bits Padding Data**

## 47. Quad Serial Peripheral Interface

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 47.1 Overview

The RZ/G series products have one channel of QSPI. Features and functions of each product are basically the same, however, read value of WSWAP bit of SPCR register and BSWAP bit of SPCR register for RZ/G1H and RZ/G1M are always 0. See section 47.4.1.

### 47.2 Features

This module has the following features.

- Capable of serial communications through single-/dual-/quad-SPI operation
  - Single-SPI operation
    - Use of MOSI (master out–slave in), MISO (master in–slave out), SSL (slave select), and SPCLK (SPI clock) signals allows for serial access (four-wire method).
    - Single-direction MOSI and MISO pins.
    - Only master mode is available.
    - SSL and SPCLK serve as output pins.
  - Dual-SPI operation
    - Use of IO1, IO0, SSL, and SPCLK signals allows for serial access (four-wire method).
    - Bidirectional IO1 and IO0 pins.
    - Only master mode is available.
  - Quad-SPI operation
    - Use of IO3 to IO0, SSL, and SPCLK signals allow for serial access (six-wire method).
    - Bidirectional IO3 to IO0 pins.
    - Only master mode is available.
- Transfer data length
  - Transfer data length is selectable from 8 bits to 128 Gbits in single-SPI master mode or dual-/quad-SPI modes.
  - Data is continuously transferred one through 4,294,967,296 times in 8-, 16-, or 32-bit units.
- Bit rate
  - SPCLK is generated by the on-chip baud rate generator, by dividing QSPI $\phi$  with division rate 1 to 4080 in master mode.
  - (SPCLK can be generated by dividing QSPI $\phi$  by the on-chip baud rate generator.)
- Buffer configuration
  - 8 bits  $\times$  32 buffers for transmission and 8 bits  $\times$  32 buffers for reception
- Shift registers
  - 32 bits each for transmission and reception
- SSL pin control function
  - Master mode: Controllable delay from SSL output assertion to SPCLK operation (clock delay)
    - Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
    - Controllable delay from SPCLK stoppage to SSL output negation (SSL negation delay)
      - Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
      - Controllable wait for next-access SSL output assertion (next-access delay)
        - Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
  - Capable of holding SSL output value from transfer end to next access
  - Function for changing SSL polarity

- Master transfer control

A transfer of up to four commands can be executed sequentially in looped execution.

Single-SPI mode or dual-/quad-SPI write operation: A transfer can be started when data is written to the transmit buffer.

Dual-/quad-SPI read operation: A transfer can be started when the SPI function is enabled while there is enough space for receiving the specified length of data in the receive buffer.

IO3 to IO0 and MOSI output values can be specified during SSL negation.

IO3 and IO2 output values can be specified in single-/dual-SPI modes.

- Interrupt sources

Maskable interrupt sources:

Receive buffer full interrupt

Transmit buffer empty interrupt

Error interrupt (underrun error, overrun error, and mode fault error)

- Others

Provides loop back mode.

Provides a function for initializing this module.

Hereafter, the single-/dual-/quad-SPI master modes are collectively called the maser mode.

### 47.3 Input/Output Pins

Table 47.1 shows the pin configuration.

**Table 47.1 Pin Configuration**

Name	Pin Name	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Clock pin	SPCLK	I/O	Clock input/output	√	√	√	√
Master transmit data pin/data 0 pin* <sup>1</sup>	MOSI/IO0	I/O	Master transmit data/data 0	√	√	√	√
Slave transmit data pin/data 1 pin* <sup>1</sup>	MISO/IO1	I/O	Slave transmit data/data 1	√	√	√	√
Data 2 pin* <sup>2</sup>	IO2	I/O	Data 2	√	√	√	√
Data 3 pin* <sup>2</sup>	IO3	I/O	Data 3	√	√	√	√
Slave select pin	SSL	I/O	Slave selection	√	√	√	√

Notes: 1. In single-SPI mode, MOSI and MISO are enabled; IO0 and IO1 in dual-/quad-SPI modes.

2. In single-/dual-SPI modes, a fixed value according to register setting is output; IO2 and IO3 are output in quad-SPI mode.

## 47.4 Register Descriptions

Table 47.2 shows the register configuration. The base address is H'E6B1\_0000.

**Table 47.2 Register Configuration**

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size	RZ/G Series Products			
						RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Control register	SPCR	R/W	H'00	H'00	8, 16, 32	√	√	√	√
Slave select polarity register	SSLP	R/W	H'00	H'01	8, 16, 32	√	√	√	√
Pin control register	SPPCR	R/W	H'06	H'02	8, 16, 32	√	√	√	√
Status register	SPSR	R/(W)*	H'60	H'03	8, 16, 32	√	√	√	√
Data register	SPDR	R/W	Undefined	H'04	8, 16, 32	√	√	√	√
Sequence control register	SPSCR	R/W	H'00	H'08	8, 16, 32	√	√	√	√

Transfer data length multiplier setting register 3	SPBMUL3	R/W	H'00000001	H'28	32	√	√	√	√

Note: \* Only 0 can be written to clear the flag.

### 47.4.1 Control Register (SPCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPCR sets the operating mode. If the master/slave mode select bit (MSTR) is modified while the SPI function enable bit (SPE) is set to 1 (that is, this module is enabled), the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	—	WSWA P	BSWA P
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	SPRIE	0	R/W	<p>Receive Interrupt Enable</p> <p>Enables or disables generation of receive interrupt requests when the number of receive data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number and the receive buffer full flag (SPRFF) in the status register (SPSR) is set to 1.</p> <p>0: Disables the generation of receive interrupt requests. 1: Enables the generation of receive interrupt requests.</p>
6	SPE	0	R/W	<p>SPI Function Enable</p> <p>Setting this bit to 1 enables the SPI module function. Setting this bit to 0 initializes a part of the module function.</p> <p>0: Disables the module function. 1: Enables the module function.</p>
5	SPTIE	0	R/W	<p>Transmit Interrupt Enable</p> <p>Enables or disables generation of transmit interrupt requests when the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number and the transmit buffer empty flag (SPTEF) in SPSR is set to 1.</p> <p>0: Disables the generation of transmit interrupt requests. 1: Enables the generation of transmit interrupt requests.</p>
4	SPEIE	0	R/W	<p>Error Interrupt Enable</p> <p>Enables or disables generation of error interrupt requests when an underrun error, an overrun error, or a mode fault error is detected and the corresponding flag in SPSR is set to 1.</p> <p>0: Disables the generation of error interrupt requests. 1: Enables the generation of error interrupt requests.</p> <p>Note: This setting is valid only in single-SPI slave mode.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	MSTR	0	R/W	<p>Master/Slave Mode Select</p> <p>Selects the master or slave mode.</p> <p>This bit specifies the direction of the signals through the SPCLK and SSL pins. The slave mode can be selected only when the SPI operating mode is set to single-SPI. Master/slave switching should be done only while the SPE bit is 0; otherwise, the subsequent operation cannot be guaranteed.</p> <p>This module supports only the master mode; be sure to set this bit to 1 to use this module.</p> <p>0: Slave mode 1: Master mode</p>
2	—	0	R/W	<p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p>
1	WSWAP	0	R/W	<p>Word Swap</p> <p>Selects word-swap of read-data for DMAC.</p> <p>By setting this bit to 1, read-data to DMAC is swapped in word units. That is, bit[31:16] and bit[15:0] are swapped.</p> <p>0: No word swap for read-data for DMAC. 1: Perform word swap for read-data for DMAC.</p> <p>Note: The read value of this bit is always 0 [RZ/G1H, M].</p>
0	BSWAP	0	R/W	<p>Byte Swap</p> <p>Selects byte-swap of read-data for DMAC.</p> <p>By setting this bit to 1, read-data to DMAC is swapped in byte units. That is, bit[31:24] and bit[23:16] are swapped, and at the same time, bit[15:8] and bit[7:0] are also swapped.</p> <p>0: No byte swap for read-data for DMAC. 1: Perform byte swap for read-data for DMAC.</p> <p>Note: The read value of this bit is always 0 [RZ/G1H, M].</p>

#### 47.4.2 Slave Select Polarity Register (SSLP)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SSLP sets the polarity of the SSL signal. If the contents of SSLP are modified while the SPE bit in the control register (SPCR) is set to 1, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SSLP
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
0	SSLP	0	R/W	SSL Signal Polarity Setting Sets the polarity of the SSL signal. 0: SSL signal low-active 1: SSL signal high-active

### 47.4.3 Pin Control Register (SPPCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPPCR sets the modes of the pins. If the contents of SPPCR are modified while the SPE bit in SPCR is set to 1, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	MOIFE	MOIFV	—	IO3FV	IO2FV	SPLP
Initial value:	0	0	0	0	0	1	1	0
R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5	MOIFE	0	R/W	Master-Mode Output Idle Value Fixing Enable Fixes the pin output value in an SSL negation period or the SSL keeping period during a burst transfer in master mode. In single-SPI mode, this bit setting applies to MOSI. In dual-SPI mode, the setting of this bit is applied to IO1 and IO0. In quad-SPI mode, the setting of this bit is applied to IO3 to IO0. 0: Output value equals final data from previous transfer. 1: Output value equals the value set in the MOIFV bit. Note: In dual-/quad-SPI modes, IO1 and IO0/IO3 to IO0 are driven to the Hi-Z state regardless of the setting of this bit (see section 47.5.2, Pin Control).
4	MOIFV	0	R/W	Master-Mode Output Idle Fixed Value If the MOIFE bit is 1 in master mode, this module, according to the setting of this bit, determines the output value during the SSL negation period. 0: Output pin idle fixed value equals 0. 1: Output pin idle fixed value equals 1.
3	—	0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2	IO3FV	1	R/W	Single-/Dual-SPI Mode IO3 Output Fixed Value Fixes the output direction of the IO3 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the value of MOIFE or MOIFV bit. 0: IO3 output fixed value equals 0. 1: IO3 output fixed value equals 1.
1	IO2FV	1	R/W	Single-/Dual-SPI Mode IO2 Output Fixed Value Fixes the output direction of the IO2 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the value of MOIFE or MOIFV bit. 0: IO2 output fixed value equals 0. 1: IO2 output fixed value equals 1.

---

Bit	Bit Name	Initial Value	R/W	Description
0	SPLP	0	R/W	<p>Loopback Mode</p> <p>When the SPLP bit is set to 1, this module shuts off the path between the data I/O pin and the transmit/receive shift register, and connects the input path and the output path for the transmit/receive shift register.</p> <p>0: Normal mode 1: Loopback mode</p> <p>Note: When the loopback mode is specified in dual-/quad-SPI modes, the SPI read/write access setting bit (SPRW) in command registers 0 to 3 (SPCMD0 to SPCMD3) should be set to 0 (write operation).</p> <p>Do not modify the setting of this bit during data transfer.</p>

---

#### 47.4.4 Status Register (SPSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPSR indicates the operating status.

Bit:	7	6	5	4	3	2	1	0
	SPRFF	TEND	SPTEF	—	—	—	—	—
Initial value:	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Note: Only 0 can be written to the flags after 1 is read.

Bit	Bit Name	Initial Value	R/W	Description
7	SPRFF	0	R	<p>Receive Buffer Full Flag</p> <p>Indicates that the number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number specified in the buffer control register.</p> <p>0: The number of receive data units in the receive buffer is less than the receive buffer data triggering number.</p> <p>1: The number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>The receive buffer data is read until the number of data units in the receive buffer becomes less than the specified receive buffer data triggering number.</li> <li>Receive buffer data reset is enabled.</li> <li>Power-on reset.</li> </ul> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>The number of data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number.</li> </ul>

Bit	Bit Name	Initial Value	R/W	Description
5	SPTEF	1	R	<p>Transmit Buffer Empty Flag</p> <p>Indicates that the number of transmit data units in the transmit buffer is equal to or less than the transmit buffer data triggering number specified in the buffer control register.</p> <p>0: The number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number.</p> <p>1: The number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When data is written to the transmit buffer until the number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number.</li> </ul> <p>[Setting conditions]</p> <ul style="list-style-type: none"> <li>When the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number.</li> <li>When transmit buffer data reset is enabled.</li> <li>Power-on reset.</li> </ul>
4 to 0	—	All 0	R	<p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p>

**47.4.5 Data Register (SPDR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPDR accesses transmit/receive data buffer.

The transmit buffer (SPTXB) and receive buffer (SPRXB) are independent and are mapped to SPDR.

When data is written to SPDR, the data will be written to the transmit buffer.

When data is read from SPDR, the data will be read from the receive buffer.

SPDR should be read or written to in byte, word, or longword units.

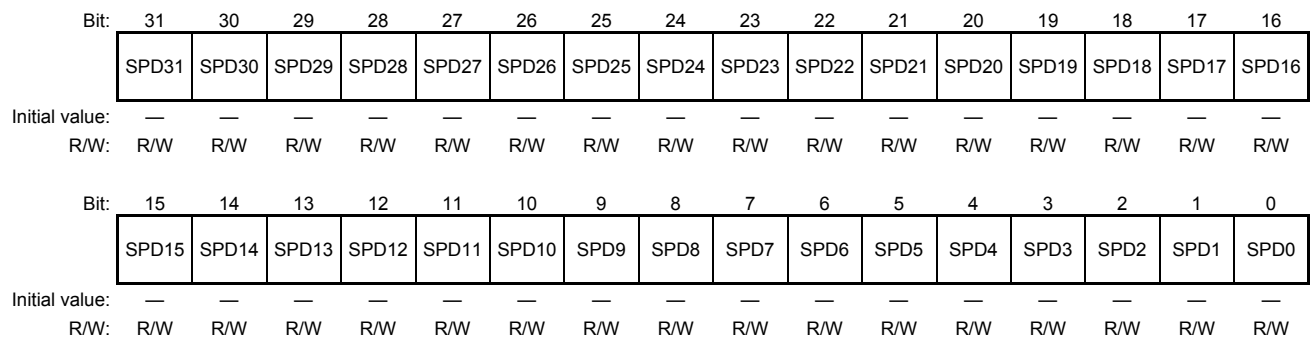

When SPDR is read or written to with the longword-, word-, or byte-access width, the receive or transmit data should be read from or written to the following bits.

Longword: Bits 31 to 0

Word: Bits 15 to 0

Byte: Bits 7 to 0

Note: The QSPI data is in little endian.

#### 47.4.6 Sequence Control Register (SPSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPSCR sets the sequence control method when this module operates in master mode. If the contents of SPSCR are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SPSC[1:0]	
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1, 0	SPSC[1:0]	00	R/W	Sequence Control Specification These bits specify sequential operations when this module operates in master mode. In master mode, this module references SPCMD0 to SPCMD3 in the order according to the setting of these bits. 00: 0 → 0 → ... 01: 0 → 1 → 0 → ... 10: 0 → 1 → 2 → 0 → ... 11: 0 → 1 → 2 → 3 → 0 → ...

**47.4.7 Sequence Status Register (SPSSR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPSSR indicates the sequence control status when this module operates in master mode.

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1, 0	SPSS[1:0]	00	R	Sequence Status During sequence control, these bits indicate one of SPCMD0 to SPCMD3 that is currently referenced. 00: SPCMD0 01: SPCMD1 10: SPCMD2 11: SPCMD3

### 47.4.8 Bit Rate Register (SPBR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPBR sets the bit rate when this module operates in master mode. If the contents of SPBR are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

The bit rate is determined by combinations of SPBR settings and the values in the bit rate division setting bits (BRDV[1:0]) in SPCMD0 to SPCMD3.

In single-SPI slave mode, the bit rate depends on the input clock bit rate regardless of the setting of SPBR[1:0] and BRDV[1:0] bits.

When SPBR is set to 0, the base bit rate is selected.

The equation for calculating the bit rate when SPBR is not 0 is given below. In the equation, n denotes an SPBR setting (1, ..., 255), and N denotes bit settings in the bits BRDV[1:0] (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(\text{QSPI}\phi)}{2 \times n \times 2^N}$$

Table 47.3 shows examples of the relationship between SPBR and BRDV[1:0] bits settings.

**Table 47.3 Relationship between SPBR and BRDV[1:0] Settings**

SPBR[7:0] (n)	BRDV[1:0] (N)	Division Ratio	Bit Rate	
			QSPIφ = 78 MHz	QSPIφ = 97.5 MHz
0	0	1	78.0 Mbps	97.50 Mbps
1	0	2	39.0 Mbps	48.75 Mbps
2	0	4	19.5 Mbps	24.38 Mbps
3	0	6	13.0 Mbps	16.25 Mbps
4	0	8	9.75 Mbps	12.19 Mbps
5	0	10	7.80 Mbps	9.75 Mbps
6	0	12	6.50 Mbps	8.13 Mbps
6	1	24	3.25 Mbps	4.06 Mbps
6	2	48	1.625 Mbps	2.03 Mbps
6	3	96	812.5 kbps	1.02 Mbps
255	3	4080	19.12 kbps	23.90 kbps

**47.4.9 Data Control Register (SPDCR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPDCR enables or disables dummy data transmission when this module operates in master mode.

Bit:	7	6	5	4	3	2	1	0
	TXDMY	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	TXDMY	0	R/W	<p>Dummy Data Transmission Enable</p> <p>Enables or disables dummy data transmission from the MOSI pin when the transmit buffer is empty in single-SPI master mode. The last output value in the previous transmit data is used as dummy data.</p> <p>Specifically, if this bit is set to 1 when the transmit buffer is empty, 0 is output from the MOSI pin as dummy data.</p> <p>This bit setting can be changed while the transmit end flag (TEND) in SPSR is 1. Otherwise, operation cannot be guaranteed.</p> <p>0: Disables dummy data transmission. 1: Enables dummy data transmission.</p>
6 to 0	—	All 0	R	<p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p>

**47.4.10 Clock Delay Register (SPCKD)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPCKD sets a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation when the clock delay setting enable bit (SCKDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SPCKD are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCKDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SCKDL[2:0]	000	R/W	Clock Delay Setting These bits set a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation when the SCKDEN bit in SPCMD0 to SPCMD3 is 1. 000: 1 SPCLK cycle 001: 2 SPCLK cycles 010: 3 SPCLK cycles 011: 4 SPCLK cycles 100: 5 SPCLK cycles 101: 6 SPCLK cycles 110: 7 SPCLK cycles 111: 8 SPCLK cycles

#### 47.4.11 Slave Select Negation Delay Register (SSLND)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SSLND sets a period (SSL negation delay) from the transmission of a final SPCLK edge to the negation of the SSL signal during a serial transfer when the SSL negation delay setting enable bit (SLNDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SSLND are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SLNDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SLNDL[2:0]	000	R/W	SSL Negation Delay Setting These bits set a period (SSL negation delay) from the transmission of a final SPCLK edge to the negation of the SSL signal during a serial transfer when the SLNDEN bit in SPCMD0 to SPCMD3 is 1. 000: 0.5 SPCLK cycle 001: 1.5 SPCLK cycles 010: 2.5 SPCLK cycles 011: 3.5 SPCLK cycles 100: 4.5 SPCLK cycles 101: 5.5 SPCLK cycles 110: 6.5 SPCLK cycles 111: 7.5 SPCLK cycles

**47.4.12 Next-Access Delay Register (SPND)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPND sets a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the next-access delay enable bit (SPNDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SPND are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SPNDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SPNDL[2:0]	000	R/W	Next-Access Delay Setting These bits set a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the SPNDEN bit in SPCMD0 to SPCMD3 is 1. 000: 1 SPCLK cycle 001: 2 SPCLK cycles 010: 3 SPCLK cycles 011: 4 SPCLK cycles 100: 5 SPCLK cycles 101: 6 SPCLK cycles 110: 7 SPCLK cycles 111: 8 SPCLK cycles

**47.4.13 Command Register n (SPCMDn) (n = 0 to 3)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

This module has four command registers (SPCMD0 to SPCMD3). SPCMD0 to SPCMD3 are used to set a transfer format in master mode. In master mode, this module sequentially references SPCMD0 to SPCMD3 according to the settings in the sequence control register (SPSCR), and executes the serial transfer that is set in the referenced SPCMD.

If the contents of currently referred-to SPCMD are modified while the TEND bit in SPSR indicates that communication has not been completed, the subsequent operation cannot be guaranteed. The currently referred-to SPCMD can be checked by reading the sequence status register (SPSSR). In addition, if the contents of SPCMD0 are modified during operation in single-SPI slave mode, the subsequent operation cannot be guaranteed.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SCKDEN	SLNDEN	SPNDEN	LSBF	SPB[3:0]			SSLKP	SPIMOD[1:0]	SPRW	BRDV[1:0]	CPOL	CPHA			
Initial value:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	SCKDEN	1	R/W	<p>Clock Delay Setting Enable</p> <p>Sets a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation in master mode. If this bit is 0, this module sets the clock delay to 0 SPCLK cycle. If this bit is 1, this module starts SPCLK oscillation in compliance with the clock delay register (SPCKD) settings. For the continuous access in which SSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is the second or subsequent one. Otherwise, this bit should be set to 1.</p> <p>0: A clock delay of 0 SPCLK cycle 1: A clock delay equal to SPCKD settings.</p>
14	SLNDEN	1	R/W	<p>SSL Negation Delay Setting Enable</p> <p>Sets a period (SSL negation delay) from SPCLK oscillation stoppage to SSL signal negation in master mode. If this bit is 0, this module sets the SSL negation delay to 0 SPCLK cycle. If this bit is 1, this module negates the SSL signal in compliance with the slave select negation delay register (SSLND) settings. For the continuous access in which SSL is kept asserted over the multiplier commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1.</p> <p>When using this module in single-SPI slave mode, set this bit to 1 and the slave select negation delay register (SSLND) to H'0.</p> <p>0: An SSL negation delay of 0 SPCLK cycle 1: An SSL negation delay equal to SSLND settings.</p>

Bit	Bit Name	Initial Value	R/W	Description
13	SPNDEN	1	R/W	<p>Next-Access Delay Enable</p> <p>Sets the period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer in master mode. If this bit is 0, this module sets the next-access delay to 0 SPCLK cycle. If this bit is 1, this module starts next serial transfer in compliance with the next-access delay register (SPND) settings. For the continuous access in which SSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1.</p> <p>When using this module in single-SPI slave mode, set this bit to 1 and the next-access delay register (SPND) to B'000.</p> <p>0: A next-access delay of 0 SPCLK cycle. 1: A next-access delay equal to SPND settings.</p>
12	LSBF	0	R/W	<p>LSB First</p> <p>Sets the data format to MSB first or LSB first in master mode or single-SPI slave mode.</p> <p>0: MSB first 1: LSB first</p>
11 to 8	SPB[3:0]	0000	R/W	<p>Transfer Data Length Setting</p> <p>These bits set the basic transfer data length for serial transfer. For LSB-first transfer, the transfer data is reversed within the data width specified with these bits. The actual amount of data to be transferred is determined by multiplying the value set with these bits by the value set with SPBMUL0 to SPBMUL3.</p> <p>0000: 8 bits (1 byte) 0001: 16 bits (2 bytes) 0010: 32 bits (4 bytes) 0011 to 1111: Setting prohibited</p>
7	SSLKP	0	R/W	<p>SSL Signal Level Keeping</p> <p>Specifies whether or not the SSL signal level for the current command is to be kept from the end of the transfer for the current command to the beginning of the transfer for the next command in master mode.</p> <p>Setting this bit to 1 enables a transition to the next access while the SSL signal is kept asserted.</p> <p>0: Negates all SSL signals upon completion of transfer. 1: Keeps the SSL signal level from the end of the transfer to the beginning of the next access.</p>
6, 5	SPIMOD[1:0]	00	R/W	<p>SPI Operating Mode</p> <p>These bits select the operating mode of this module from single-, dual-, or quad-SPI.</p> <p>00: Single-SPI 01: Dual-SPI 10: Quad-SPI 11: Setting prohibited</p>

Bit	Bit Name	Initial Value	R/W	Description
4	SPRW	0	R/W	<p>SPI Read/Write Access</p> <p>Sets an access direction in dual-/quad-SPI modes. This bit is invalid in single-SPI mode</p> <p>0: Write operation (IO1 and IO0/IO3 to IO0: Output)</p> <p>1: Read operation (IO1 and IO0/IO3 to IO0: Input)</p>
3, 2	BRDV[1:0]	00	R/W	<p>Bit Rate Frequency Division Setting</p> <p>These bits are used to determine the bit rate in master mode. The settings of these bits and of the bit rate register (SPBR) together determine the bit rate. The base bit rate depends on the setting of the SPBR.</p> <p>The setting of this field selects division of the base bit rate by one, two, four, or eight.</p> <p>Individual BRDV[1:0] values can be set in each of command registers 0 to 3. Therefore, serial transfers can be at different bit rates for each of the commands.</p> <p>00: Base bit rate</p> <p>01: Two division of the base</p> <p>10: Four division of the base</p> <p>11: Eight division of the base</p>
1	CPOL	0	R/W	<p>SPCLK Polarity Setting</p> <p>Sets an SPCLK polarity. When data communication is performed between this quad serial peripheral interface module and another module, the same SPCLK polarity should be set for both modules.</p> <p>0: Positive (SPCLK = 0 when idle)</p> <p>1: Negative (SPCLK = 1 when idle)</p>
0	CPHA	1	R/W	<p>SPCLK Phase Setting</p> <p>Sets an SPCLK edge for latching and shifting data to be transferred. When data communication is performed between this quad serial peripheral interface module and another module, the same SPCLK edge should be set for both modules.</p> <p>0: Data latch on odd edge, data shift on even edge</p> <p>1: Data shift on odd edge, data latch on even edge</p> <p>Note: The first SPCLK edge is treated as the first edge.</p>

Reference: Some serial flash memory datasheets refer to SPCLK specifications, which are determined by what this document refers to as CPOL and CPHA bits, as SPI modes 0 to 3. Assuming that SPI modes 0 to 3 are controlled by SPI mode bits [1:0], CPOL and CPHA in this document correspond to SPI mode bits 1 and 0, respectively.

In this module, the initial values of CPOL and CPHA are 0 and 1, respectively, selecting SPI mode 1 as the initial mode.

- Notes:
1. When setting any or all of the clock delay period, SSL negation delay period, and next-access delay period to 0, be sure to set SSLKP to 1 to select the continuous access in which SSL is not negated. Otherwise, operation cannot be guaranteed. For the method of setting the various delay periods for the continuous access in which SSL is not negated, see below.
  2. For the continuous access in which SSL is not negated, SPCLK clock stopping is followed by the SSL negation delay period, next-access delay period, and next command clock delay period, in this order. When setting any of the setting enable bit (SPCKDEN), SSL negation delay setting enable bit (SLNDEN), and next-access delay enable bit (SPNDEN) to 0, be sure to set the bit corresponding to the later period prior to the bit corresponding to the earlier period.

In the above figure, (1), (2), and (3) refer to the SSL negation delay period, next-access delay period, and next command clock delay period, respectively. When setting any of these bits to 0, be sure to set (3) first. In other words, setting 1 after 0 as in  $\{(1), (2), (3)\} = \{0, 0, 1\}, \{0, 1, 1\}, \{0, 1, 0\} \dots$  is prohibited. Allowed setting is  $\{(1), (2), (3)\} = \{1, 1, 1\}, \{1, 1, 0\}, \{1, 0, 0\}, \{0, 0, 0\}$ . If set otherwise, operation cannot be guaranteed.

3. When changing BRDV[1:0] or CPOL for each command for the continuous access in which the SSL level is held, be sure to insert the SSL negation delay period, next-access delay period, and clock delay period between commands. Otherwise, operation cannot be guaranteed.
4. When changing SPIMOD[1:0] or CPHA for each command for the continuous access in which the SSL level is held, be sure to insert one cycle or more between commands. Otherwise, operation cannot be guaranteed.

**47.4.14 Buffer Control Register (SPBFCR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPBFCR resets the number of data units in the transmit buffer (SPTXB) or receive buffer (SPRXB) and sets the number of triggering data units.

2 to 0	RXTRG[2:0]	000	R/W	<p>Receive Buffer Data Triggering Number</p> <p>Specify the timing at which the receive buffer full state is determined, that is when the SPRFF flag in the status register is set. When the number of bytes of data in the receive buffer (SPRXB) is equal to or greater than the specified triggering number, the SPRFF flag is set to 1.</p> <p>000: 1 byte (31 bytes available)            001: 2 bytes (30 bytes available)            010: 4 bytes (28 bytes available)            011: 5 bytes (27 bytes available)            100: 8 bytes (24 bytes available)            101: 16 bytes (16 bytes available)            110: 24 bytes (8 bytes available)            111: 32 bytes (0 byte available)</p>

**47.4.15 Buffer Data Count Register (SPBDCR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPBDCR indicates the number of data units stored in the transmit buffer (SPTXB) and receive buffer (SPRXB). The upper eight bits indicate the number of transmit data units in the transmit buffer and the lower eight bits indicate the number of receive data units in the receive buffer.

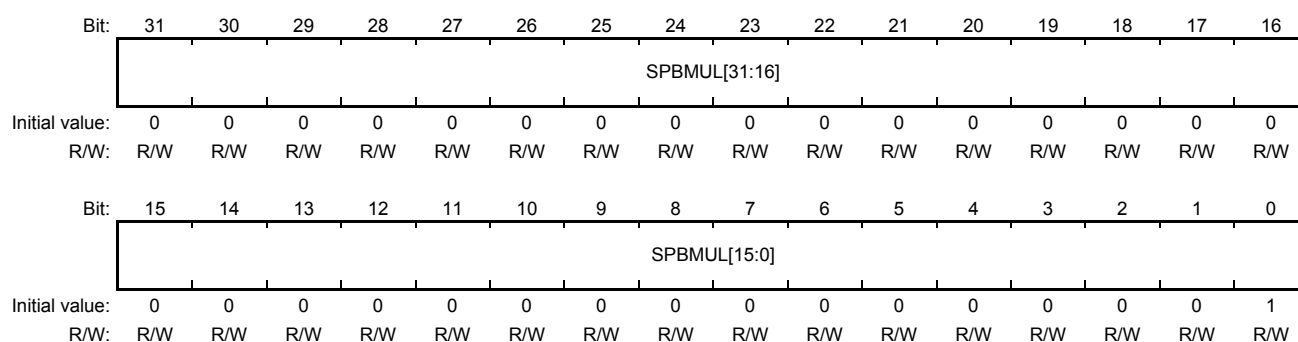

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
13 to 8	TXBC[5:0]	000000	R	Transmit Data Byte Counter Indicate the number of transmit data bytes in the transmit data buffer (SPTXB). B'000000 indicates that SPTXB is empty. B'100000 indicates that SPTXB is full.
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5 to 0	RXBC[5:0]	000000	R	Receive Data Byte Counter Indicates the number of receive data bytes in the receive data buffer (SPRXB). B'000000 indicates that SPRXB is empty. B'100000 indicates that SPRXB is full.

**47.4.16 Transfer Data Length Multiplier Setting Register n (SPBMULn) (n = 0, 1, 2, 3)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SPBMUL0 to SPBMUL3 set the number of times to transfer the specific length of data defined by the transfer data length setting bits (SPB[3:0]) in SPCMD0 to SPCMD3. SPBMUL0 to SPBMUL3 correspond to SPCMD0 to SPCMD3, respectively. This register setting is valid only in master mode. In single-SPI slave mode, this register should be set to the initial value; other values are prohibited.

If a command register is referred to while the TEND bit in SPSR indicates that communication has not been completed and SPBMUL corresponding to the referred-to command register is modified, the subsequent operation is not guaranteed. The currently referred-to command register can be checked by reading the sequence status register (SPSSR).

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPBMUL [31:0]	H'0000 0001	R/W	<p>Transfer Data Length Multiplier Setting</p> <p>These bits set the multiplier for transfer data; that is, the number of times to transfer the specific length of data defined by SPB[3:0] bits in SPCMD0 to SPCMD3.</p> <p>The actual amount of data to be transferred is determined by <math>SPB[3:0] \times SPBMUL[31:0]</math>.</p> <p>Setting these bits to H'00000000 allows the defined size of data to be transferred 4,294,967,296 times.</p>

## 47.5 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data, and the SSL negation period means the idle period.

### 47.5.1 Overview of Operations

This module is capable of serial transfers in single-/dual-/quad-SPI master modes and single-SPI slave mode. Table 47.4 gives the features of single-/dual-/quad-SPI modes.

**Table 47.4 Features of Each SPI Mode**

	Single-SPI	Dual-SPI	Quad-SPI
Number of data lines	One input line and one output line	Two IO lines	Four IO lines
Data line direction	Single-directional	Bidirectional	Bidirectional
Slave operation	Not supported	Not supported	Not supported
Simultaneous transmission/reception	Supported	Not supported	Not supported

Table 47.5 gives the overview of master-mode operation.

**Table 47.5 Overview of Master Mode**

Items	Master Mode
MSTR bit setting in the control register	1
SPCLK signal	Output
MOSI signal (single-SPI)	Output
MISO signal (single-SPI)	Input
IO1 and IO0 (dual-SPI)/ IO3 to IO0 (quad-SPI)	Input/output
SSL signal	Output
Switching SSL polarity	Supported
Transfer rate	Up to QSPI $\phi$
Clock source	On-chip baud rate generator
Clock polarity	Positive/negative
Clock phase	Latch at rising/output at falling Latch at falling/output at rising
Transfer bit order	MSB first/LSB first
Transfer data length	(8/16/32) $\times$ (1 to 4,294,967,296) bits
Burst transfer	Supported
SPCLK delay control	Supported
SSL negation delay control	Supported
Next-access delay control	Supported
Transfer start method	Writing data to the transmit buffer when SPE = 1 There is space in the receive buffer when SPE = 1*
Sequence control	Supported
Transmit buffer empty detection	Supported
Receive buffer full detection	Supported
Overrun error detection	Not supported
Underrun error detection	Not supported
Mode fault error detection	Not supported

Note: \* During single-SPI operation and dual-/quad-SPI mode write operation, a transfer is started by setting SPE to 1 and writing data to the transmit buffer. During dual-/quad-SPI mode read operation, a transfer is started by setting SPE to 1 when there is space for the specified length of data in the receive buffer.

### 47.5.2 Pin Control

This module automatically switches the pin states according to the status after write/read transfer in single-SPI master or slave mode or dual-/quad-SPI mode. The status of the data pins (MOSI/MISO/IO[3:0]) in the idle state depends on the MOIFE and MOIFV bit settings, the single-/dual-SPI mode IO3 output fixed value bit (IO3FV) setting, and the single-/dual-SPI mode IO2 output fixed value bit (IO2FV) setting. Table 47.6 shows the pin states in single-SPI master mode. Table 47.7 shows the pin states in dual-/quad-SPI modes.

**Table 47.6 Pin States in Single-SPI Master Mode**

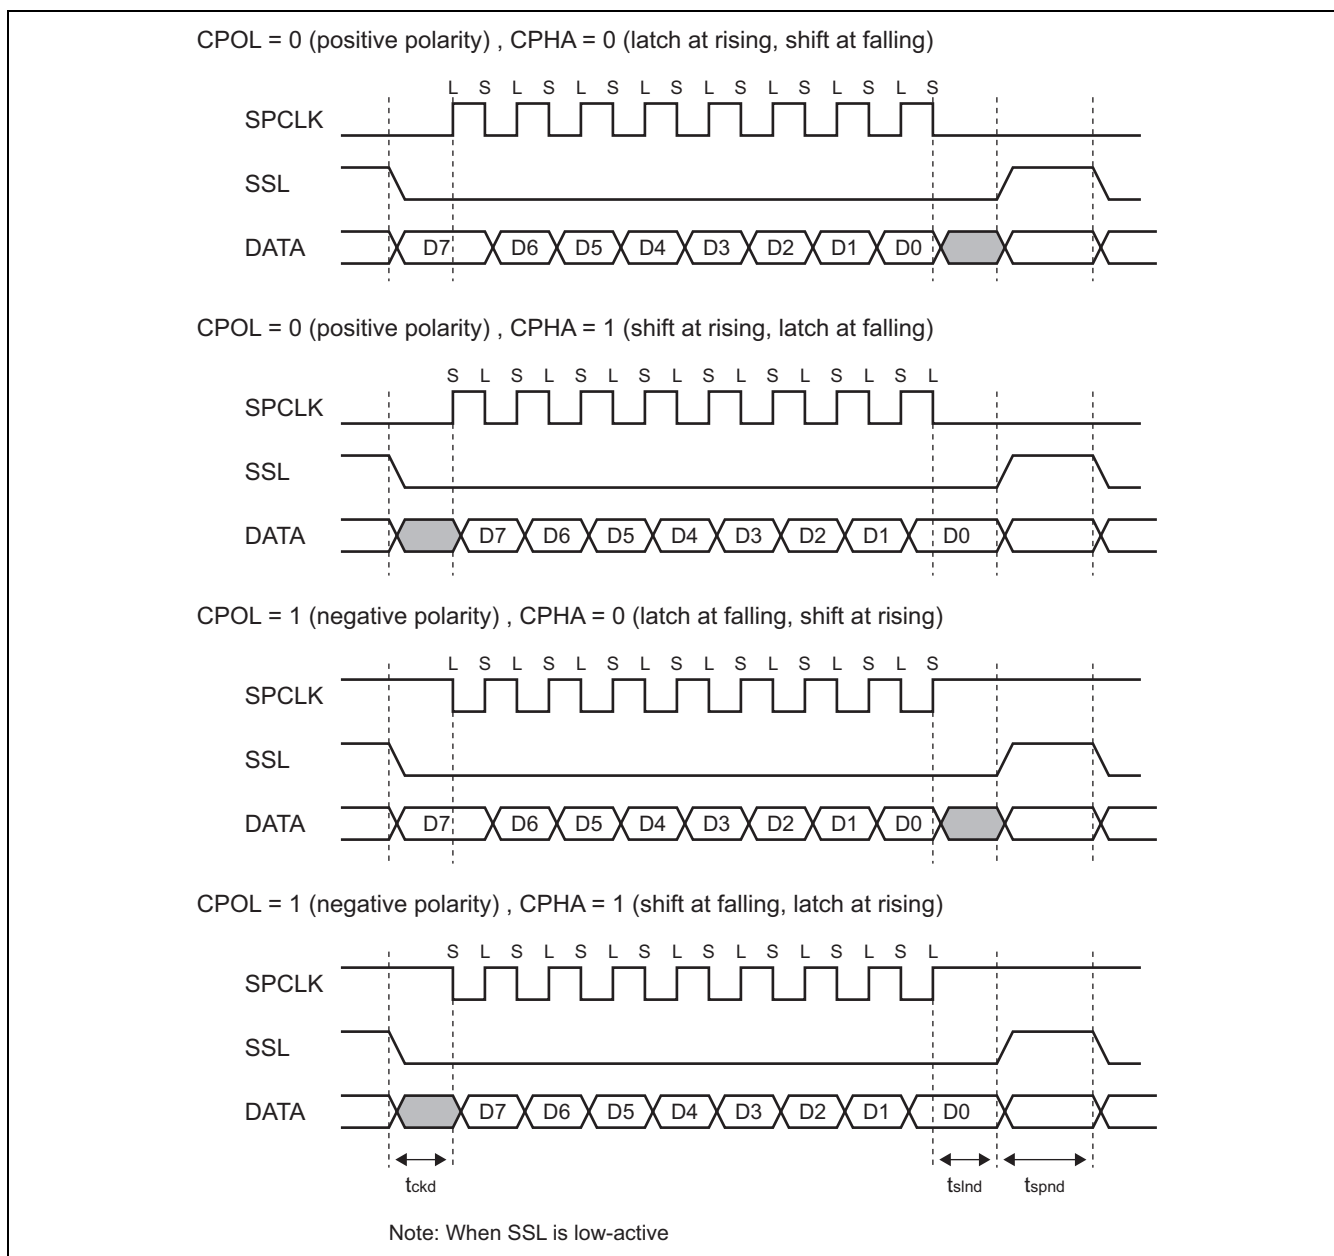

Items	Single-SPI Master Mode
SSL	Output
SPCLK	Output
MOSI	Output
MISO	Input
MOSI in the idle state	MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value
MISO in the idle state	—
IO2	IO2FV setting value output or not used
IO3	IO3FV setting value output or not used

**Table 47.7 Pin States in Dual-/Quad-SPI Modes**

Items	Dual-SPI Mode	Quad-SPI Mode
SSL	Output	Output
SPCLK	Output	Output
IO0	I/O	I/O
IO1	I/O	I/O
IO2	IO2FV setting value output or not used	I/O
IO3	IO3FV setting value output or not used	I/O
IO0 in the idle state	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO1 in the idle state	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO2 in the idle state	IO2FV setting value output or not used	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO3 in the idle state	IO3FV setting value output or not used	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z

### 47.5.3 Transfer Format

The SPI has four clock settings determined by the SPCLK polarity setting (CPOL) and SPCLK phase setting (CPHA) bits in SPCMD0 to SPCMD3. Figure 47.1 shows the data latch/shift timing based on each setting in an 8-bit MSB first transfer. In Figure 47.1, L indicates the latch timing and S indicates the shift timing. DATA corresponds to MISO/MOSI in single-SPI mode; IO1 and IO0 in dual-SPI mode; or IO3 to IO0 in quad-SPI mode.  $t_{ckd}$  indicates the clock delay period when the SCKDEN bit in SPCMD0 to SPCMD3 is set to 1. Similarly,  $t_{slnd}$  indicates the SSL negation delay period when the SLNDEN bit in SPCMD0 to SPCMD3 is set to 1, and  $t_{spnd}$  indicates the next-access delay period when the SPNDEN bit in SPCMD0 to SPCMD3 is set to 1.

**Figure 47.1 SPI Clock Setting and Transfer Timing**

Note that when the base bit rate is used, transmission and reception when CPHA = 0 is not available.

The following describes 8-bit MSB first transfer in single-/dual-/quad-SPI modes when CPOL = 0 and CPHA = 0.

**(1) Single-SPI mode**

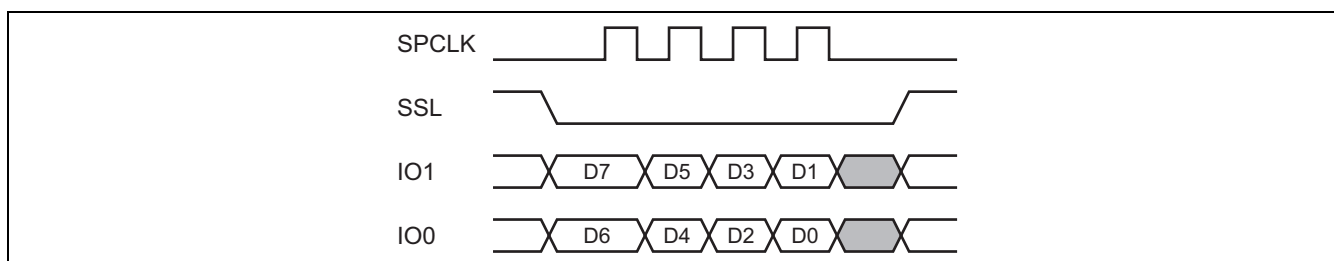

Figure 47.2 shows the transfer format in single-SPI mode. This mode provides transmission and reception simultaneously. Since one data line is used for serial communication both in transmission and reception, the communication speed is 1 bit per SPCLK clock cycle. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 47.5.4, Transfer Data.

**Figure 47.2 Transfer Format in Single-SPI Mode**

**(2) Dual-SPI mode**

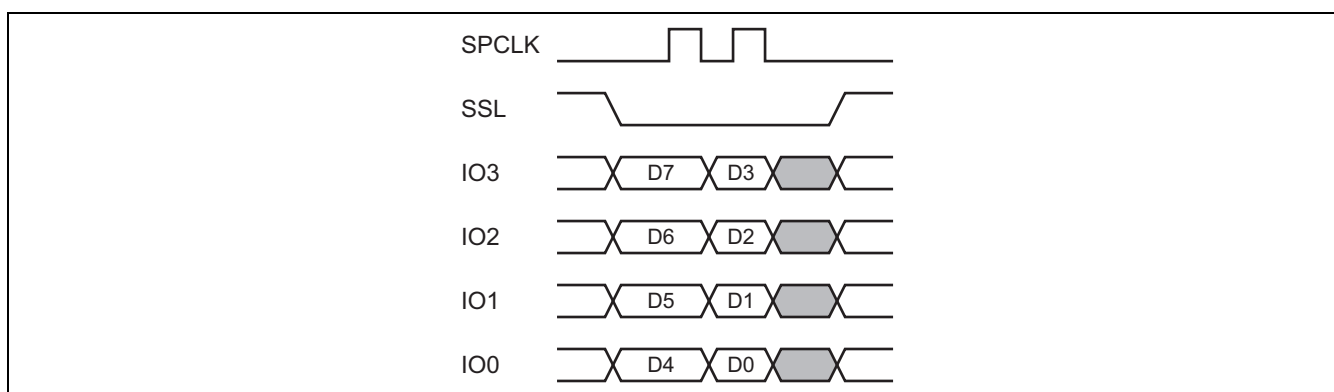

Figure 47.3 shows the transfer format in dual-SPI mode. This mode only provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPI read/write access setting bit (SPRW) in SPCMD0 to SPCMD3. Transmission is carried out by write operation and reception by read operation. The I/O directions of IO1 and IO0 are switched accordingly. Since two data lines are used for serial communication both in transmission and reception, the communication speed is 2 bits per SPCLK clock cycle. The start bit of the transfer data is output from IO1. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 47.5.4, Transfer Data.

**Figure 47.3 Transfer Format in Dual-SPI Mode**

### (3) Quad-SPI mode

Figure 47.4 shows the transfer format in quad-SPI mode. This mode provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPRW bit in SPCMD0 to SPCMD3. Transmission and reception are accomplished by writing and reading, respectively. The I/O directions of IO3 to IO0 are switched accordingly. Since four data lines are used for serial communication both in transmission and reception, the communication speed is 4 bits per SPCLK clock cycle. The start bit of the transfer data is output from IO3. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 47.5.4, Transfer Data.

**Figure 47.4 Transfer Format in Quad-SPI Mode**

#### 47.5.4 Transfer Data

The data format is determined by the SPB[3:0] and the LSB first (LSBF) bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. In both MSB first and LSB first transfers, this module treats the specified size of data beginning at the MSB of the transmit shift register as transmit data, and the specified length of data beginning at the LSB of the receive shift register as receive data, regardless of whether the actual arrangement is MSB- or LSB-first. The following sections describe MSB-first and LSB-first transfers in 32-bit, 16-bit, and 8-bit data units.

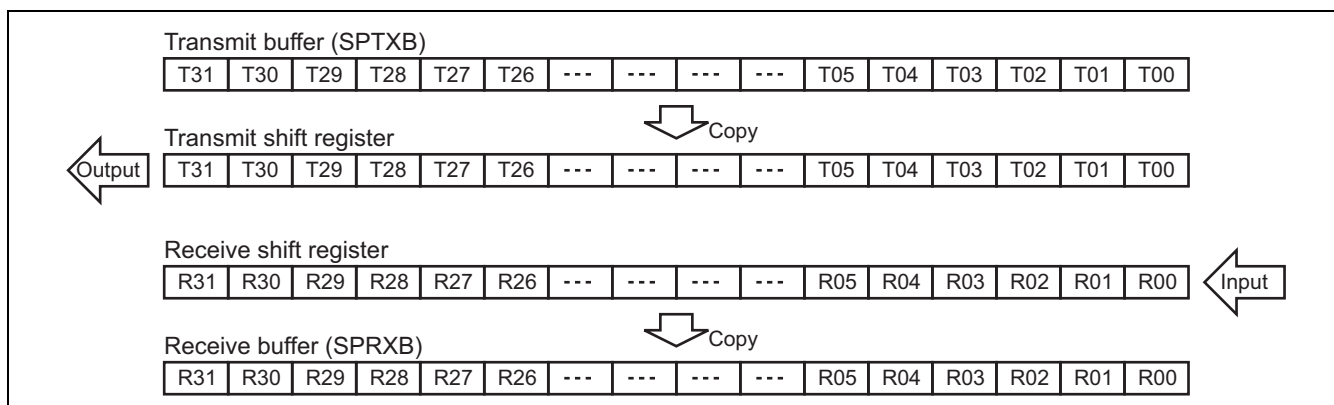

**(1) MSB-first transfer (32-bit data)**

Figure 47.5 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module copies the 32-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.5 MSB-First Transfer (32-Bit Data)**

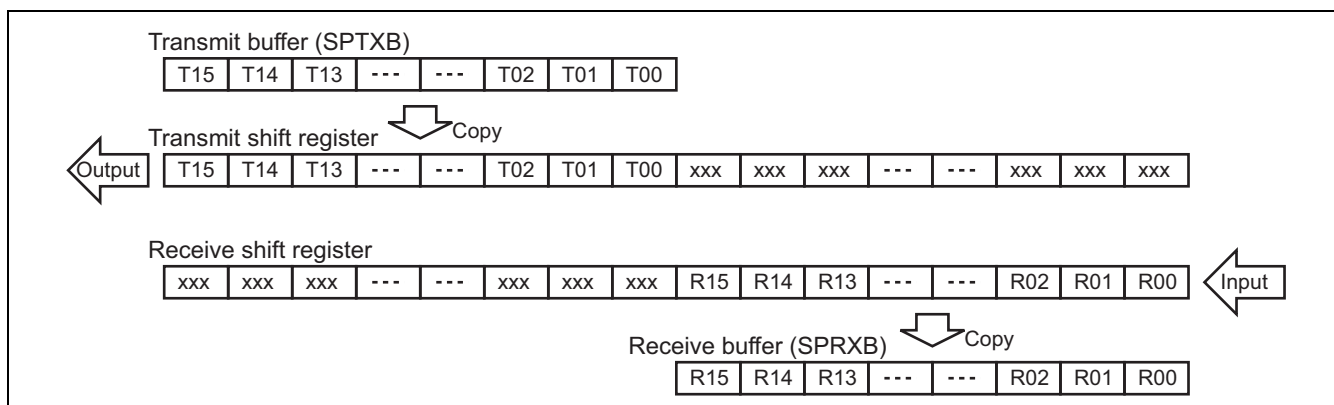

**(2) MSB-first transfer (16-bit data)**

Figure 47.6 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module copies the 16-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.6 MSB-First Transfer (16-Bit Data)**

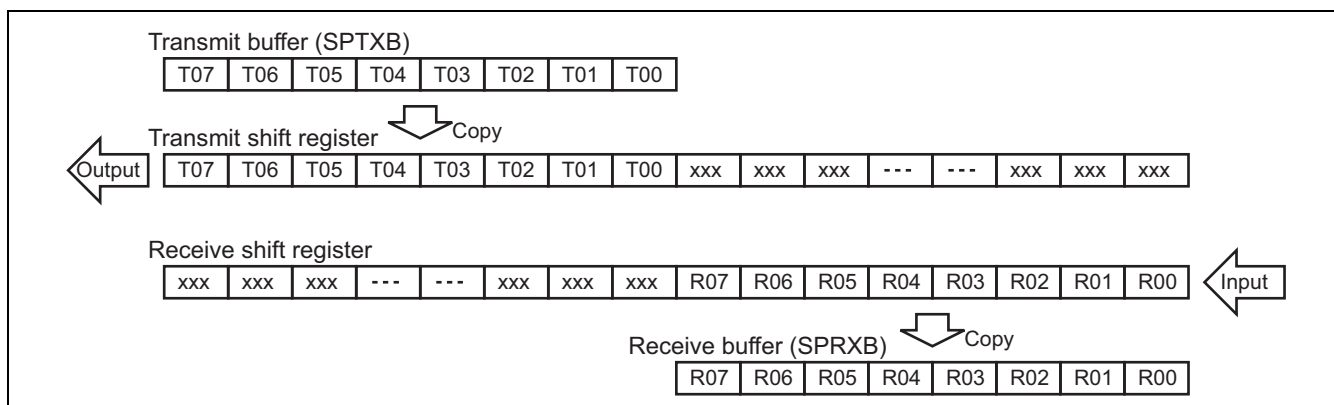

**(3) MSB-first transfer (8-bit data)**

Figure 47.7 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module copies the 8-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more in master mode, data reception is not carried out. In order to start reception, data for the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.7 MSB-First Transfer (8-Bit Data)**

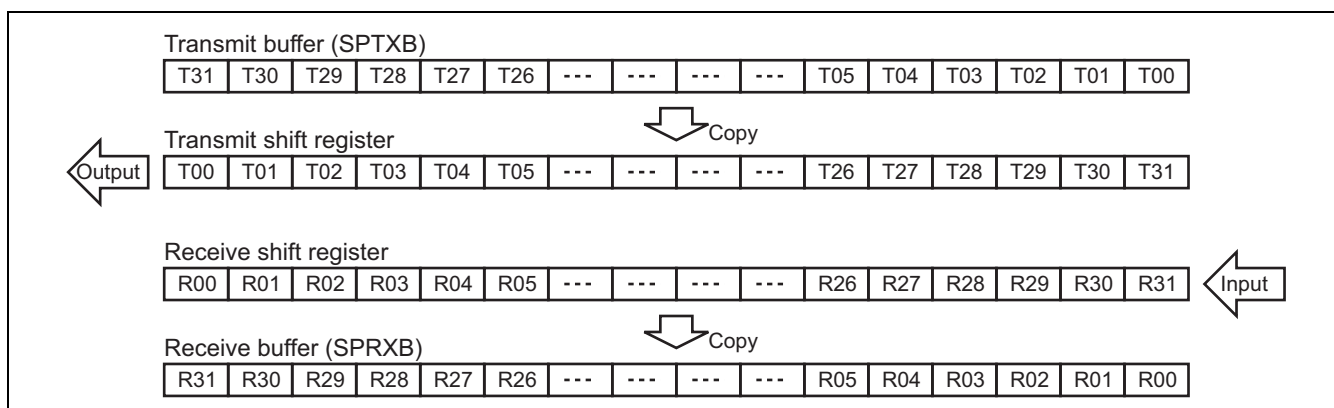

**(4) LSB-first transfer (32-bit data)**

Figure 47.8 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 32-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module reverses the order of the bits of the 32-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.8 LSB-First Transfer (32-Bit Data)**

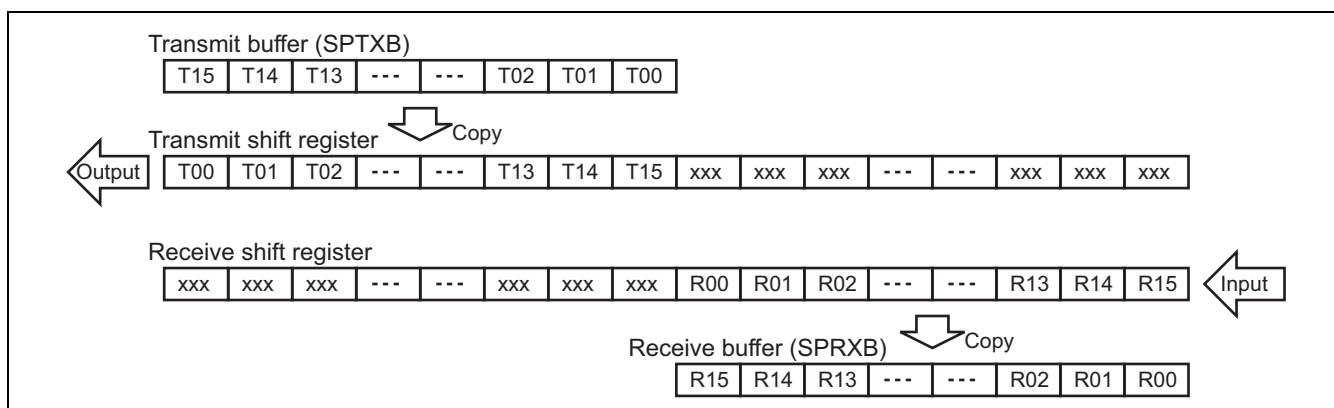

**(5) LSB-first transfer (16-bit data)**

Figure 47.9 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 16-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module reverses the bit order in the 16-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.9 LSB-First Transfer (16-Bit Data)**

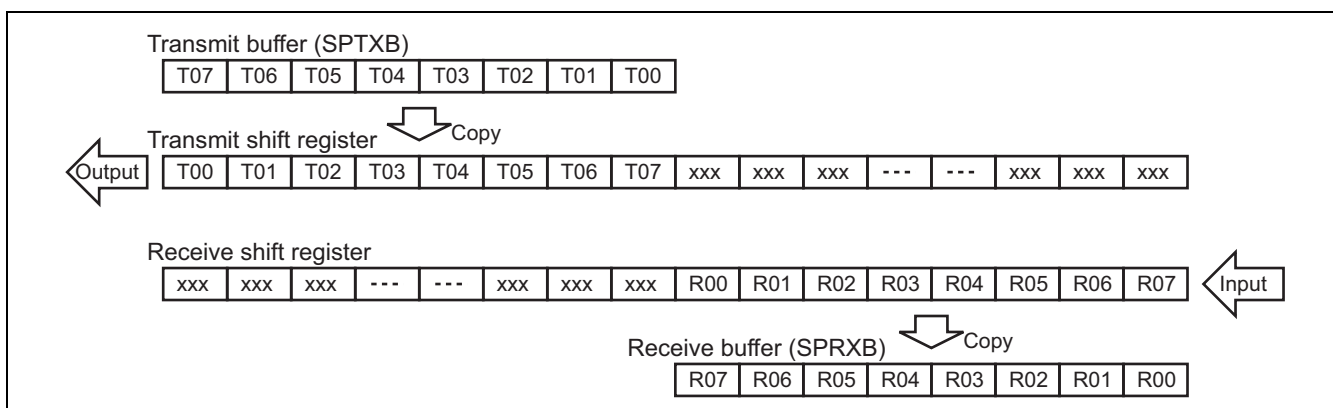

**(6) LSB-first transfer (8-bit data)**

Figure 47.10 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 8-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the received shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module reverses the bit order in the 8-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

**Figure 47.10 LSB-First Transfer (8-Bit Data)**

### 47.5.5 Error Detection

In the normal serial transfer, the data written from SPDR to the transmit buffer is serially transmitted, and the serially received data can be read from the receive buffer of SPDR. If access is made to SPDR or serial transfer is started or completed, depending on the status of the transmit buffer/receive buffer, non-normal transfers may be executed in some cases.

This module detects certain types of non-normal transfers as underrun, overrun, or mode fault errors. Table 47.8 shows the relationship between non-normal transfer operations and the error detection function.

**Table 47.8 Relationship between Non-Normal Transfer Operations and Error Detection Function**

	<b>Occurrence Condition</b>	<b>Operation</b>	<b>Error Detection</b>
A	SPDR is written when the transmit buffer is full.	Missing write data.	Not detected
C	SPDR is read when the receive buffer is empty.	The output data is undefined.	Not detected

On operation A shown in Table 47.8, this module detects no error. Whether SPDR can be written to or not can be checked using the transmit data byte counter bits (TXBC[5:0]) in the buffer data count register (SPBDCR).

Similarly, on operation C shown in Table 47.8, this module detects no error. Whether the valid data is stored in the receive buffer or not can be checked by reading the receive data byte counter bits (RXBC[5:0]) in SPBDCR.

### 47.5.6 Initialization

If 0 is written to the SPE bit in SPCR, or a mode fault error is detected and the SPE bit is cleared to 0, this module disables the module function, and initializes a part of the module function. When a power-on reset is generated, this module initializes all of the module function.

When the SPE bit in SPCR is cleared to 0, this module performs the following initialization:

- Suspending any serial transfer that is being executed
- Initializing the transmit shift register and the receive shift register
- Initializing the internal state machine
- Initializing the sequence
- Initializing the TEND bit in SPSR

Initialization by clearing the SPE bit to 0 does not initialize the control bits of this module and the transmit/receive buffer. For this reason, this module can be started in the same transfer mode as prior to the initialization if the SPE bit is re-set to 1. However, clearing the SPE bit to 0 initializes the transmit shift register and the receive shift register and allows the data that is being transferred to be discarded.

### 47.5.7 SPI Operation

The operating modes of this module are listed below.

- Single-SPI master mode
- Dual-SPI mode/quad-SPI mode

The operation in each mode is described below.

#### (1) Single-SPI master mode

##### (a) Starting serial transfer

The serial transfer start conditions are: there is the specified length of data in the transmit buffer; and there is space for the specified length of data in the receive buffer.

##### (b) Terminating serial transfer

Irrespective of the clock setting, this module terminates the serial transfer after transmitting an SPCLK edge corresponding to the final sampling timing. After the serial transfer is completed, receive data is copied from the receive shift register to the receive buffer. If there is not enough space for the specified length of data in the receive buffer after receive data is copied from the receive shift register to the receive buffer, another serial transfer will not be performed.

##### (c) Sequence control

In single-SPI master mode, according to the sequence length that is assigned to the sequence control register (SPSCR), this module makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. This module contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading SPSSR.

When the SPE bit in SPCR is set to 1 and the function of this module is enabled, this module loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 and SPBMUL0 settings into the transfer format at the beginning of serial transfer. This module increments the pointer each time the next-access delay period for a data transfer that corresponds to the referenced SPCMD0 to SPCMD3 ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, this module sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

The following items are set in command registers SPCMD0 to SPCMD3: basic transfer data length, MSB or LSB first, clock settings, some of the bit rate settings, SPI transfer mode and transfer direction (only in dual-/quad-SPI modes), whether SSL level is held, a clock delay period, an SSL negation delay period, and a next-access delay period. The total amount of data to be transferred is determined by multiplying the basic length of data to be transferred by the value set with SPBMUL0 to SPBMUL3.

Figure 47.11 shows an operation example when SPSCR is set to H'02, and the sequence is configured based on SPCMD0 to SPCMD2 settings. In Figure 47.11, shaded areas of MOSI/MISO indicate invalid data. Periods (1) to (3) in Figure 47.11 indicate the followings.

- (1) Clock delay period (SPCKD) setting value = B'000 (one SPCLK cycle)
- (2) SSL negation delay period (SSLND) setting value = B'000 (one SPCLK cycle)
- (3) Next-access delay period (SPND) setting value = B'000 (one SPCLK cycle)

**Figure 47.11 Sequence Control Operation**

**(d) Burst transfer**

This module can execute burst transfer with the following two methods in single-SPI master mode.

One method uses the SPB[3:0] bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. Setting SPB[3:0] to select 8, 16, or 32 bits and setting SPBMUL0 to SPBMUL3 to select one through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by SPB[3:0] and the number of times is specified by SPBMUL0 to SPBMUL3. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by SPB[3:0], the clock is stopped until transfer is resumed. Figure 47.12 shows a burst transfer example in which SPB[3:0] are set to select 32 bits and SPBMUL to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

- (1) First 32-bit data transfer
- (2) Second 32-bit data transfer
- (3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, the MOSI continues outputting the previous value. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.
- (4) Third and fourth 32-bit data transfer

**Figure 47.12 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Single-SPI Master Mode Used)**

In the other method, SSL is kept asserted after a serial transfer is completed until the next serial transfer. Setting the SSL signal level keeping bit (SSLKP) to 1 in SPCMD0 to SPCMD3 allows the SSL signal to be kept asserted after the transfer corresponding to the pertinent command register is completed until the next transfer. Figure 47.13 shows a burst transfer example in which the SSL signal level keeping function is used. The following describes operations (1) to (6) in the figure.

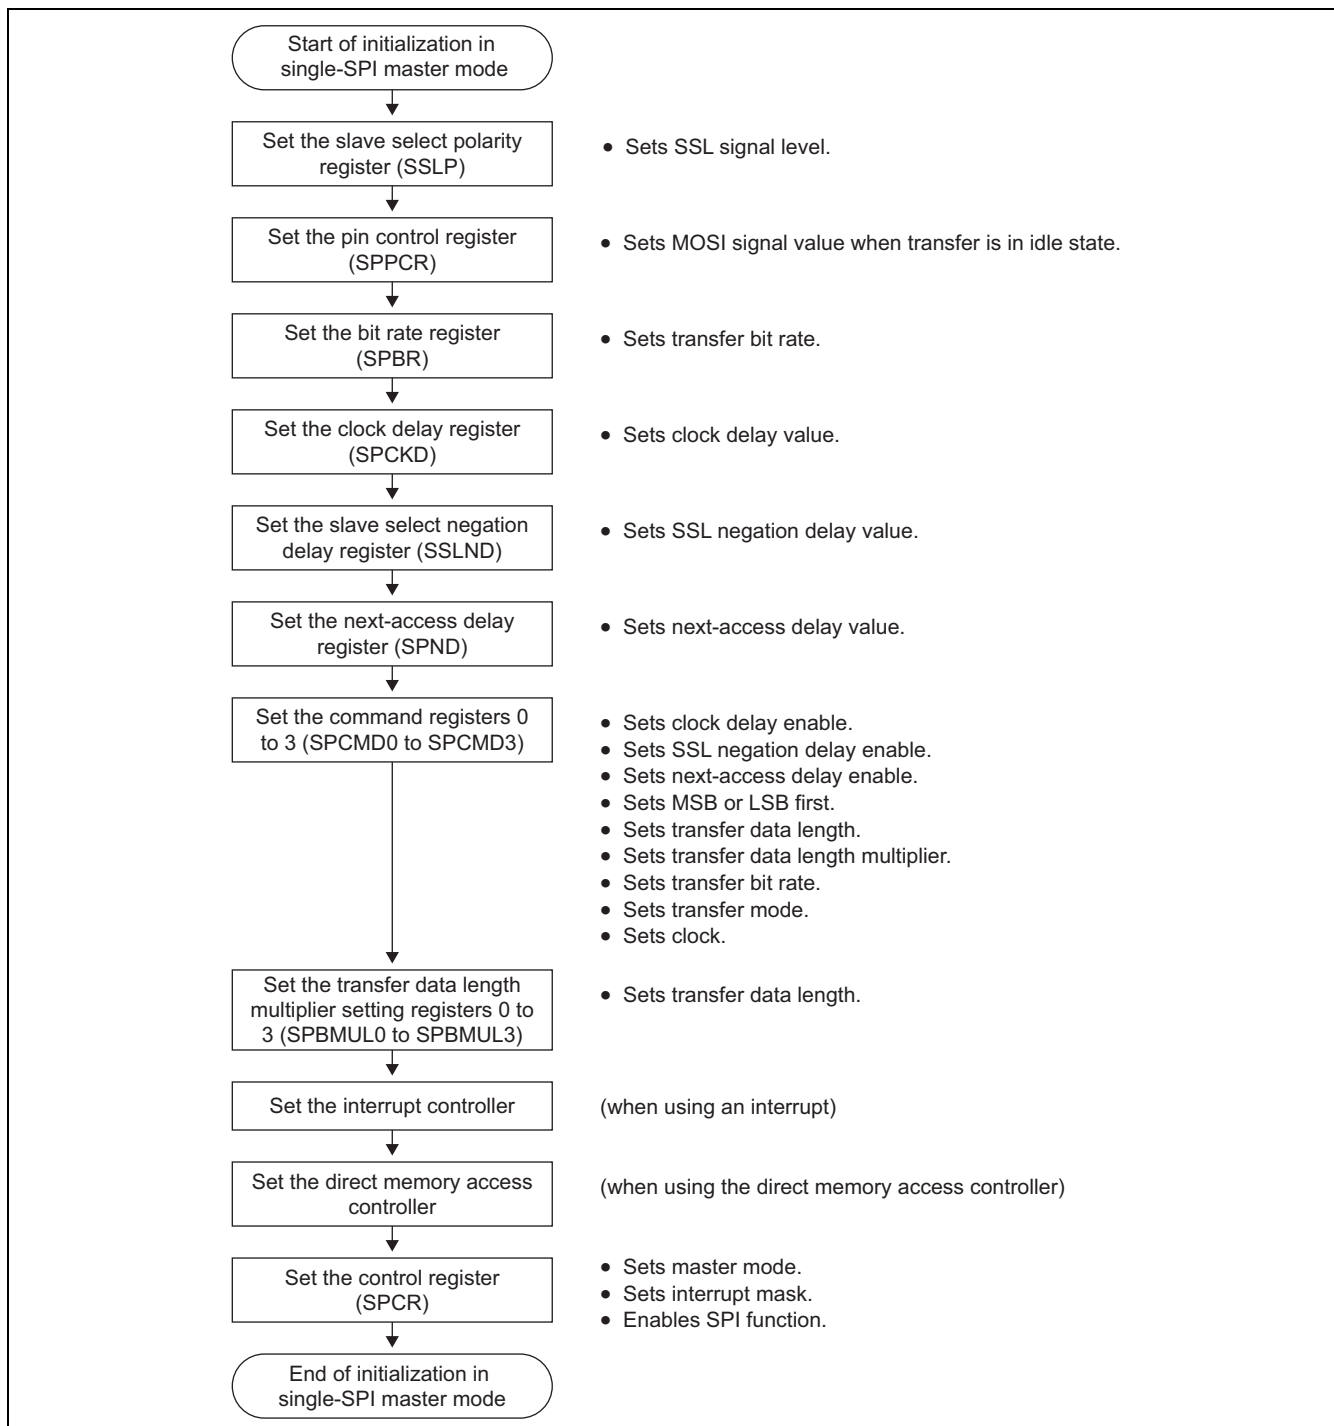

- (1) Clock delay period according to the SPCMD0 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the first transfer in the burst transfer.
- (2) SSL negation delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even after SSL negation delay period is over. The SSL negation delay period depends on the SLNDEN bit setting in SPCMD0. When SLNDEN is 1, the SSL negation delay period is determined by the SSLND setting, and the delay period is 0 SPCLK cycle when SLNDEN is 0.
- (3) Next-access delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even during the next-access delay period. The next-access delay period depends on the SPNDEN bit setting in SPCMD0. When SPNDEN is 1, the next-access delay period is determined by the SPND setting, and the delay period is 0 SPCLK cycle when SPNDEN is 0.
- (4) Clock delay period according to the SPCMD1 setting. The clock delay period depends on the SCKDEN bit setting in SPCMD1. When SCKDEN is 1, the clock delay period is determined by the SPCKD setting, and the delay period is 0 SPCLK cycle when SCKDEN is 0.
- (5) SSL negation delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Since SSLKP in SPCMD1 is set to 0, SSL is negated after SSL negation delay period is over.
- (6) Next-access delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Be sure to set SSLKP to 0 to negate SSL.

**Figure 47.13 Burst Transfer Example in which SSL Signal Level Keeping Function is Used (Single-SPI Mode)**

**(e) Initialization flowchart**

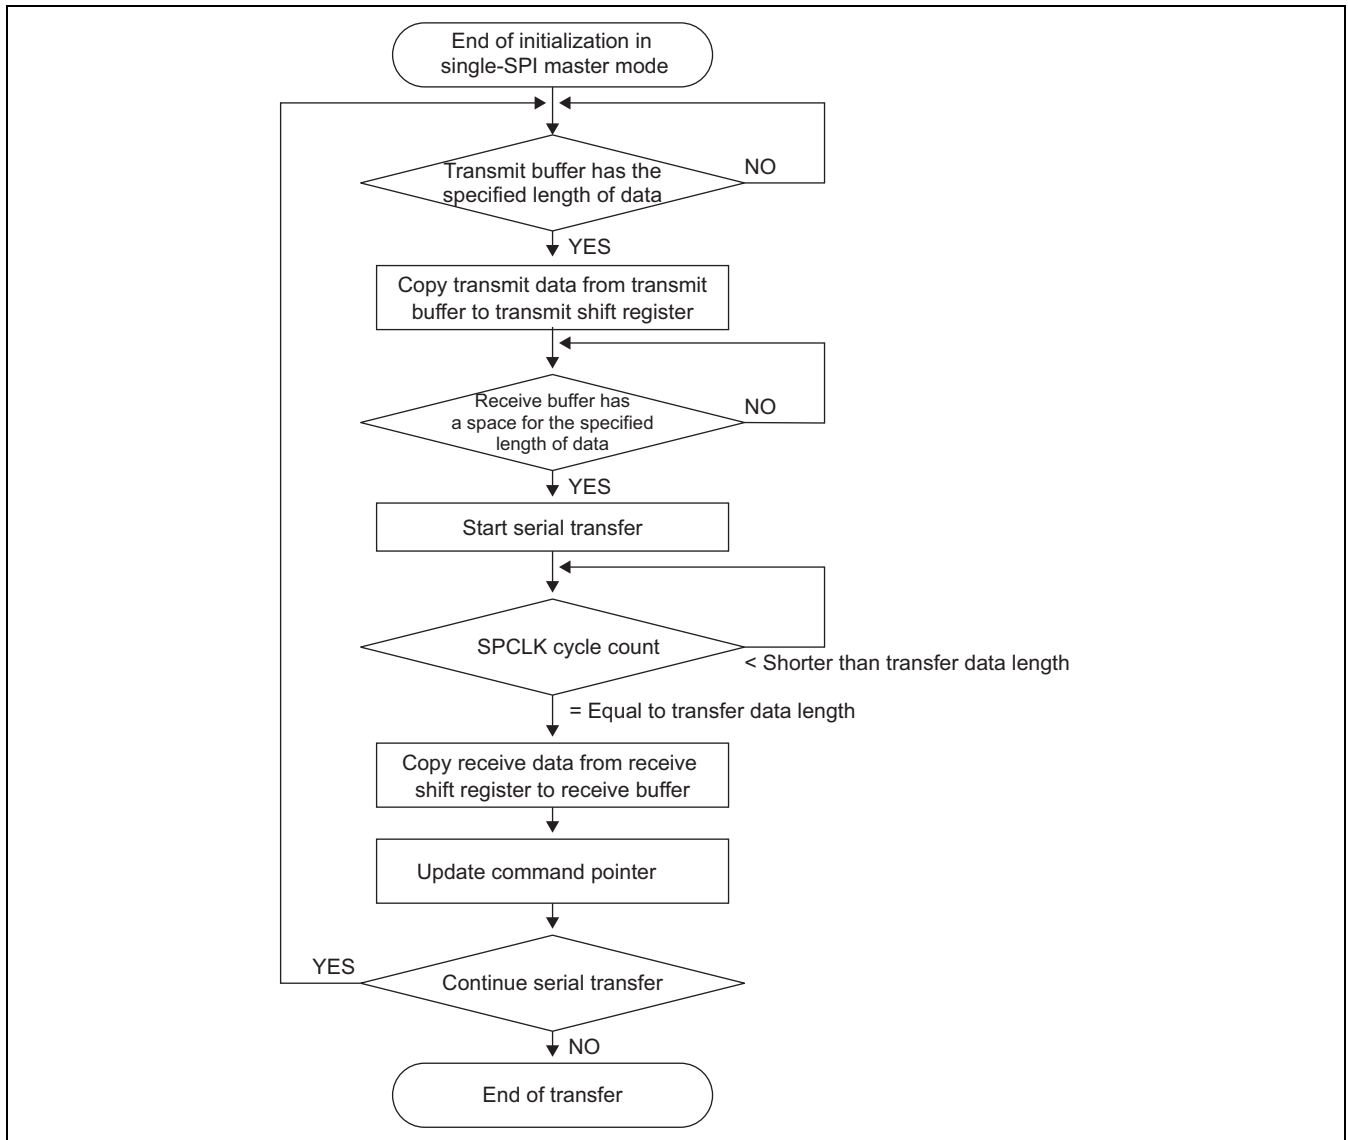

Figure 47.14 is a flowchart illustrating an example of initialization in SPI operation when this module is used in single-SPI master mode. For a description of how to set up the interrupt controller and direct memory access controller, see the descriptions given in the individual blocks.

**Figure 47.14 Example of Initialization Flowchart in Single-SPI Master Mode**

**(f) Transfer operation flowchart**

Figure 47.15 is a flowchart illustrating a transfer in SPI operation when this module is used in single-SPI master mode. Burst transfer by setting the transfer data length is also executed based on this flowchart.

**Figure 47.15 Transfer Operation Flowchart in Single-SPI Master Mode**

## (2) Dual-SPI/Quad-SPI mode

### (a) Starting serial transfer

In dual-/quad-SPI modes, the serial transfer start condition differs depending on the data transfer direction (transmission or reception).

In data transmission, the serial transfer start condition is that there is the specified length of data in the transmit buffer.

In data reception, the serial transfer start condition is that there is a space for the specified length of data in the receive buffer.

### (b) Terminating serial transfer

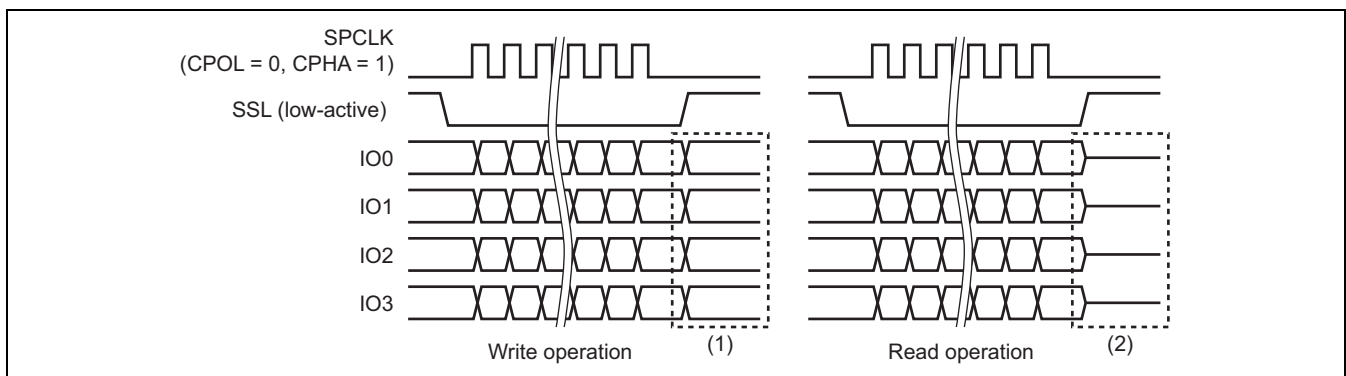

Irrespective of data transmission or reception, this module terminates the serial transfer after transmitting an SPCLK edge corresponding to the final sampling timing.

During idle cycles in dual-/quad-SPI modes, the IO pins are controlled differently depending on whether it is after write or read operation. Specifically, the IO pins output either the last output data or the fixed level depending on the register setting after write operation, whereas the IO pins are driven to the Hi-Z state after read operation. Figure 47.16 shows an example of the pin states after quad-SPI mode access is completed. The following describes operations (1) and (2) in the figure.

(1) During write operation, IO0 to IO3 serve as output pins. Thus, when SSL is negated upon completion of write operation, IO0 to IO3 output different values depending on the value of MOIFE in the SPPCR. Specifically, the IO pins output the level specified by MOIFV when MOIFE is 1, whereas the IO pins output the last output data when MOIFE is 0.

(2) During read operation, IO0 to IO3 serve as input pins. Thus, when SSL is negated upon completion of read operation, IO0 to IO3 are driven to Hi-Z state irrespective of the values of MOIFE and MOIFV.

For details on the pin control in dual-/quad-SPI modes, see section 47.5.2, Pin Control.

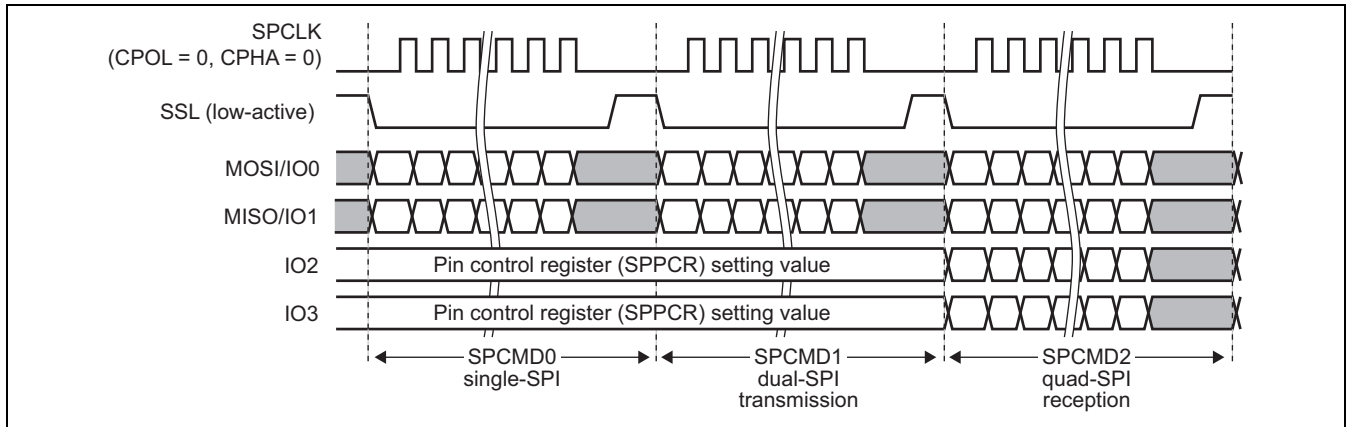

**Figure 47.16 Example of Pin States after Quad-SPI Mode Access is Completed**

### (c) Sequence control

As with the single-SPI master mode, in dual-/quad-SPI modes, according to the sequence length that is assigned to SPSCR, this module makes up a sequence comprised of SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. For details on operation, see section 47.5.7 (1) (c), Sequence control.

Dual-/quad-SPI modes only provide operation of a single direction, that is, either transmission or reception for serial transfer. Transmission or reception is set using the SPI read/write access setting bit (SPRW) in SPCMD0 to SPCMD3. One of the three operating modes including dual-SPI mode, quad-SPI mode, and single-SPI master mode is set using the SPI operating mode setting bits (SPIMOD[1:0]) in SPCMD0 to SPCMD3. Combining these bits allows switching single-SPI master mode, dual-SPI mode transmission/reception, and quad-SPI mode transmission/reception to control sequence. Figure 47.17 shows an example of sequence configuration with transfer mode switching.

**Figure 47.17 Example of Sequence Configuration with Transfer Mode Switching**

Note the following when configuring a sequence in dual-/quad-SPI modes.

When all the commands configuring a sequence are dual-/quad-SPI read operations, the sequential operation is continued as long as the receive buffer has an enough space for the receive data.

To terminate read operation, clear the SPE bit to 0 in SPCR after receiving the required length of data, or execute write operation for the last sequence to empty the transmit buffer.

**(d) Burst transfer**

This module can execute burst transfer with the following two methods in dual/quad SPI modes.

One method uses the SPB[3:0] bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. As with the single-SPI master mode, setting SPB[3:0] to select 8, 16, or 32 bits and setting SPBMUL0 to SPBMUL3 to select one through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by SPB[3:0] and the number of times is specified by SPBMUL0 to SPBMUL3. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by SPB[3:0], the clock is stopped until transfer is resumed. This method is effective to transfer a large amount of data in dual-/quad SPI modes. Figure 47.18 shows a burst transfer example in which SPB[3:0] are set to select 32 bits and SPBMUL to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

- (1) First 32-bit data transfer
- (2) Second 32-bit data transfer
- (3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, when IO3 to IO0 serve as output pins, IO3 to IO0 continue outputting the previous value. When IO3 to IO0 serve as input pins, the inputs to IO3 to IO0 depend on the output value of the device to communicate with. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.
- (4) Third and fourth 32-bit data transfers

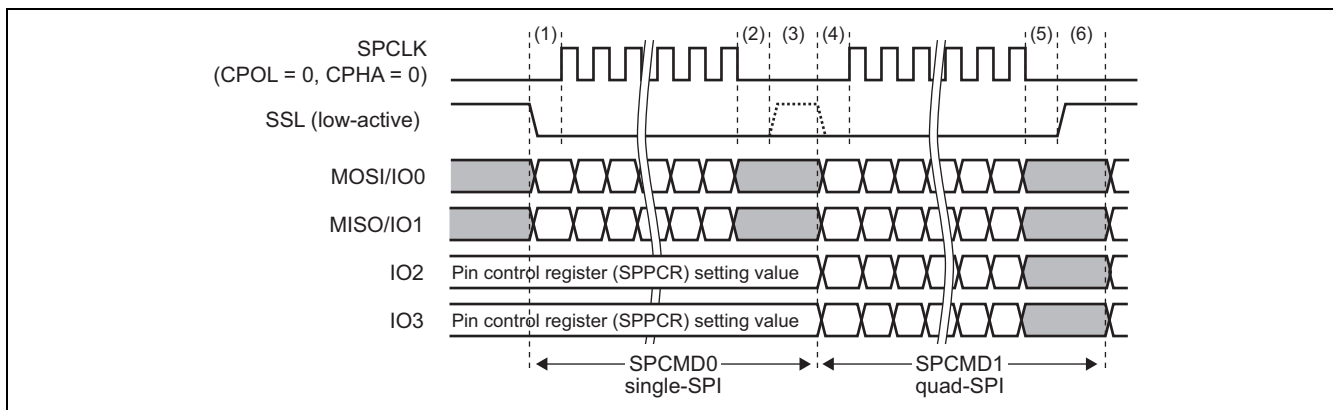

**Figure 47.18 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Quad-SPI Mode)**

The other method uses the SSL signal level keeping function as in single-SPI master mode. Since this method allows switching the SPI transfer modes (single-/dual-/quad-SPI) during a transfer, it is particularly convenient when used with devices such as serial flash memory, where command data is written in single-SPI mode and data to be stored in memory is written in quad-SPI mode. Note, however, that at least one delay cycle should be inserted between transfers when switching the SPI transfer modes. Figure 47.19 shows a burst transfer example in which both single-SPI and quad-SPI modes are used. The following describes operations (1) to (6) in the figure.

- (1) Clock delay period according to the SPCMD0 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the first transfer in the burst transfer.
- (2) SSL negation delay period according to the SPCMD0 setting. Since SSLKP in SPCMD0 is set to 1, SSL is not negated even after SSL negation delay period is over. The SSL negation delay period depends on the SLNDEN bit setting in SPCMD0. When SLNDEN is 1, the SSL negation delay period is determined by the SSLND setting, and the delay period is 0 SPCLK cycle when SLNDEN is 0.
- (3) Next-access delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even during the next-access delay period. The next-access delay period depends on the SPNDEN bit setting in SPCMD0. When SPNDEN is 1, the next-access delay period is determined by the SPND setting, and the delay period is 0 SPCLK cycle when SPNDEN is 0.

- (4) Clock delay period according to the SPCMD1 setting. The clock delay period depends on the SCKDEN bit setting in SPCMD1. When SCKDEN is 1, the clock delay period is determined by the SPCKD setting, and the delay period is 0 SPCLK cycle when SCKDEN is 0.
- (5) SSL negation delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Since SSLKP in SPCMD1 is set to 0, SSL is negated after SSL negation delay period is over.
- (6) Next-access delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Be sure to set SSLKP to 0 to negate SSL.

**Figure 47.19 Burst Transfer Example in which SSL Signal Level Keeping Function is Used (Single- and Quad-SPI Modes Used)**

(e) Initialization flowchart

Figure 47.20 is a flowchart illustrating an example of initialization in SPI operation when this module is used in dual-/quad-SPI mode. For a description of how to set up the interrupt controller and direct memory access controller, see the descriptions given in the individual blocks.

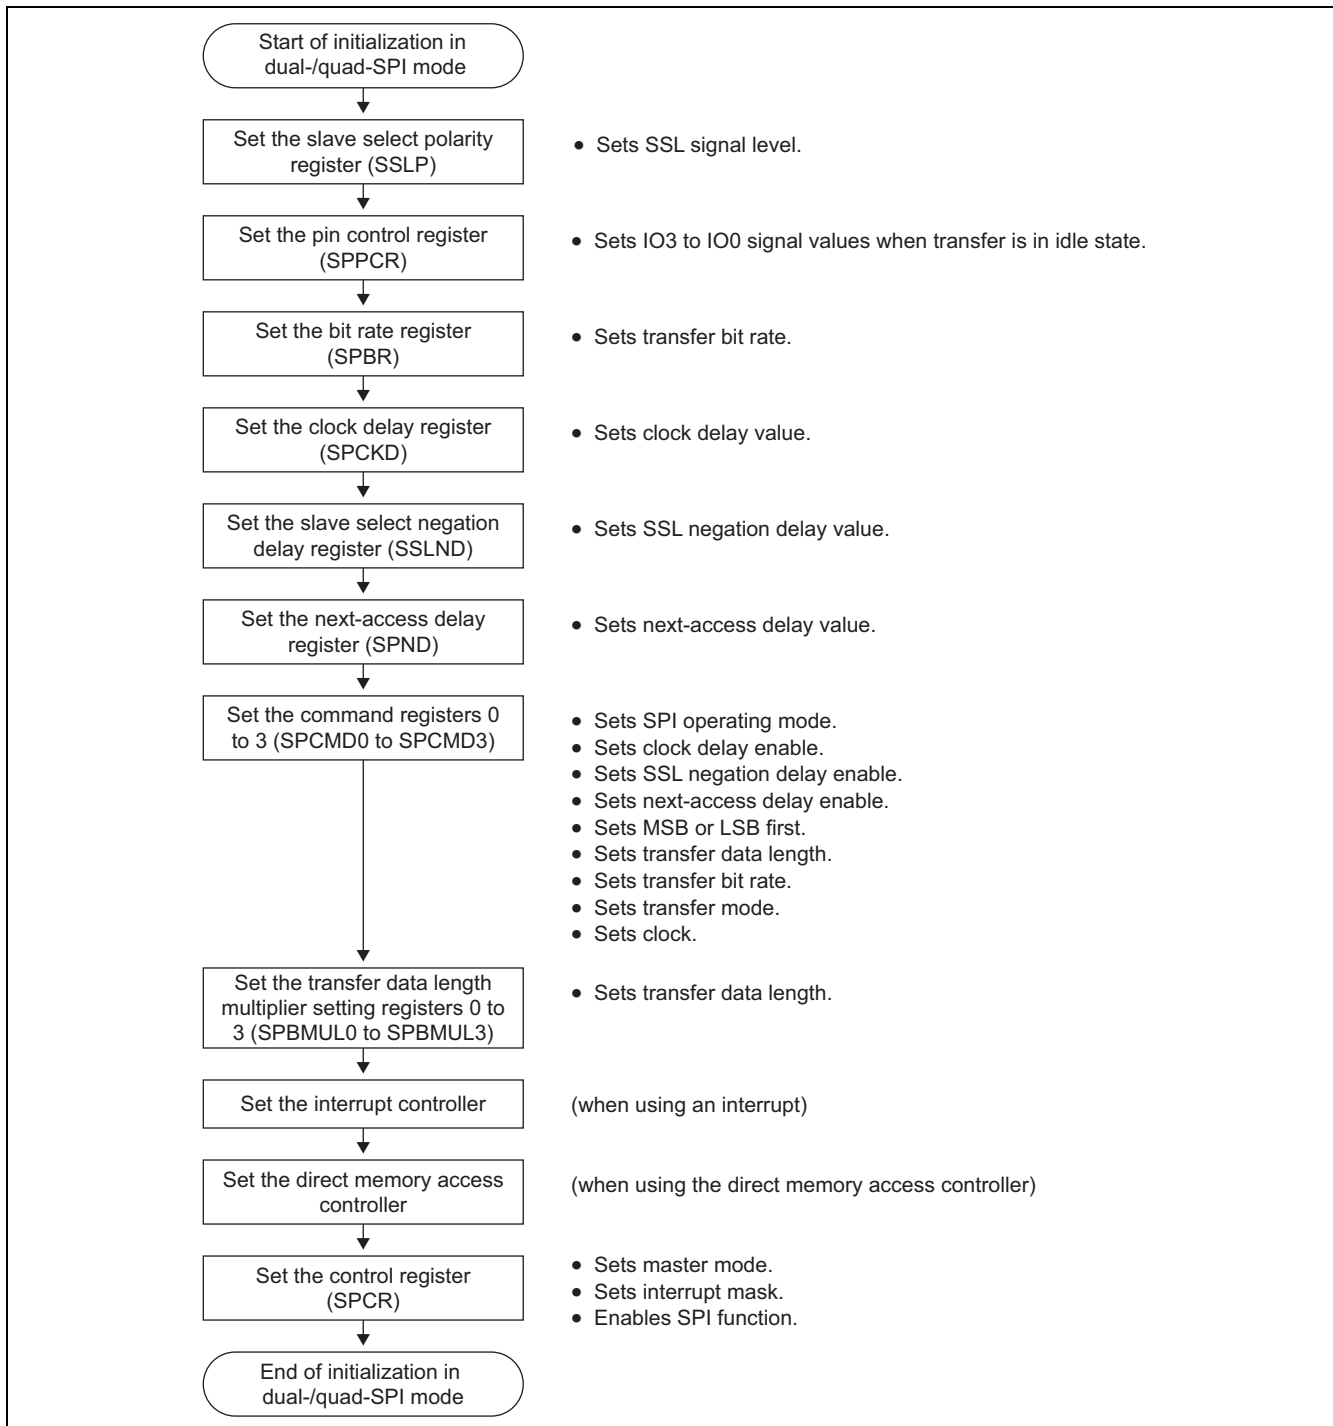

Figure 47.20 Example of Initialization Flowchart in Dual-/Quad-SPI Mode

(f) Transfer operation flowchart

Figure 47.21 is a flowchart illustrating a transfer in SPI operation when this module is used in dual-/quad-SPI mode.

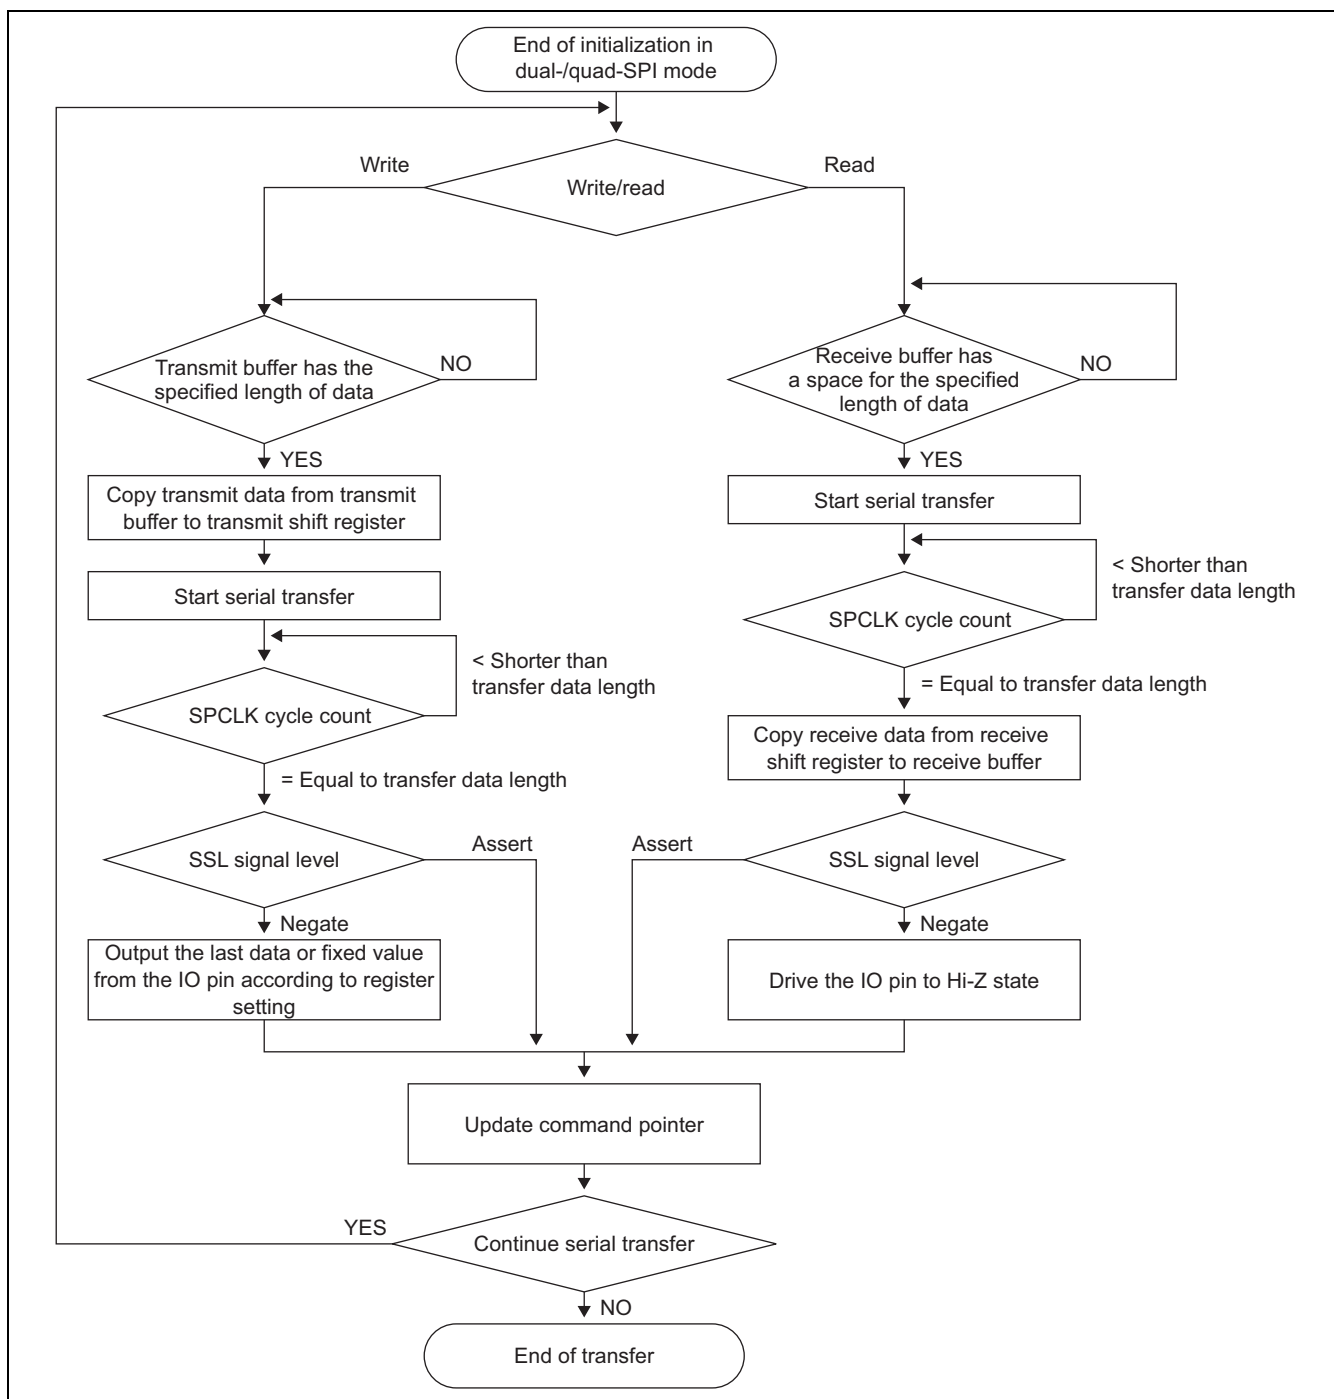

Figure 47.21 Transfer Operation Flowchart in Dual-/Quad-SPI Mode

### 47.5.8 Interrupt Sources

This module has interrupt sources of receive buffer full, transmit buffer empty, underrun error, overrun error, and mode fault error. In addition, the direct memory access controller can be activated by the receive buffer full or transmit buffer empty interrupt for data transfer.

Table 47.9 shows the interrupt sources.

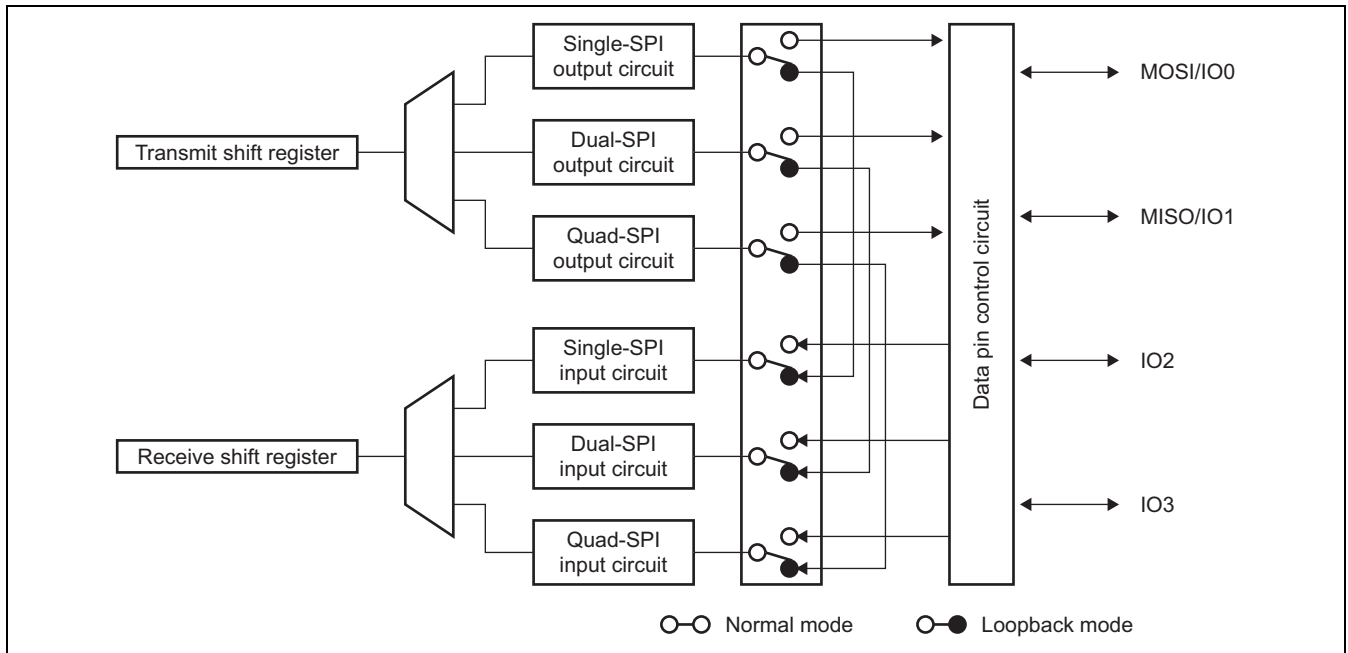

When any of the interrupt conditions in Table 47.9 is met, an interrupt is generated. The interrupt sources should be cleared with data transfer by the CPU or direct memory access controller.

**Table 47.9 Interrupt Sources**

Name	Interrupt Source	Abbreviation	Interrupt Condition	Activation of Direct Memory Access Controller
SPRI	Receive buffer full	RXI	SPRIE = 1 and SPRFF = 1	Possible
SPTI	Transmit buffer empty	TXI	SPTIE = 1 and SPTEF = 1	Possible
SPEI	Underrun error	UDI	SPEIE = 1 and UDRF = 1	Not possible
	Overrun error	OVI	SPEIE = 1 and OVRF = 1	Not possible
	Mode fault error	MOI	SPEIE = 1 and MODF = 1	Not possible

### 47.5.9 Loopback Mode

This module provides loopback mode for testing. Writing 1 to the loopback mode bit (SPLP) in the pin control register (SPPCR) enables loopback mode. In loopback mode, this module disconnects the paths between the transmit/receive shift registers and the MISO/MOSI and IO3 to IO0 pins, and connects the outputs from the transmit shift register to the inputs to the receive shift register instead. Figure 47.22 shows a schematic internal connection in loopback mode.

**Figure 47.22 Schematic Internal Connection in Loopback Mode**

## 48. SD Card Host Interface (SDHI)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 48.1 Overview

This LSI provides an SD card host interface (SDHI) module.

This section only introduces the features of the SDHI module. Contact your local Renesas sales representative if you need detailed information on the SDHI module, including registers, usage, and other information.

Note: The number of interfaces depends on the product.  
The RZ/G1H has four, and RZ/G1M/N and RZ/G1E have three interface.

#### 48.1.1 Features

- SD memory or I/O card interface (1-bit or 4-bit SD bus)
- SD clock frequency  $\leq 195$  MHz (for interfaces 0 and 1) (SDR104)  
SD clock frequency  $\leq 97.5$  MHz (for interfaces 2 and 3) (SDR50)
- Error check functions: CRC7 (command and response) and CRC16 (data)
- Authentication and encryption/decryption function: Not available
- Interrupt requests: Card access interrupt, SDIO access interrupt, and card detection interrupt
- DMA transfer request: SD\_BUF write/SD\_BUF read
- Support for four cards (with simultaneous operation possible)
- SDXC supported
- Card detection function
- Write protection supported

	RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
SDR104	√ <sup>1</sup>	√ <sup>2</sup>	√ <sup>2</sup>	√ <sup>2</sup>
SDR50	√	√	√	√
High-speed	√	√	√	√
Default	√	√	√	√

Notes: 1. Interfaces 0 and 1  
2. Interface 0

Figures 48.1 to 48.2 are block diagrams of the SDHI.

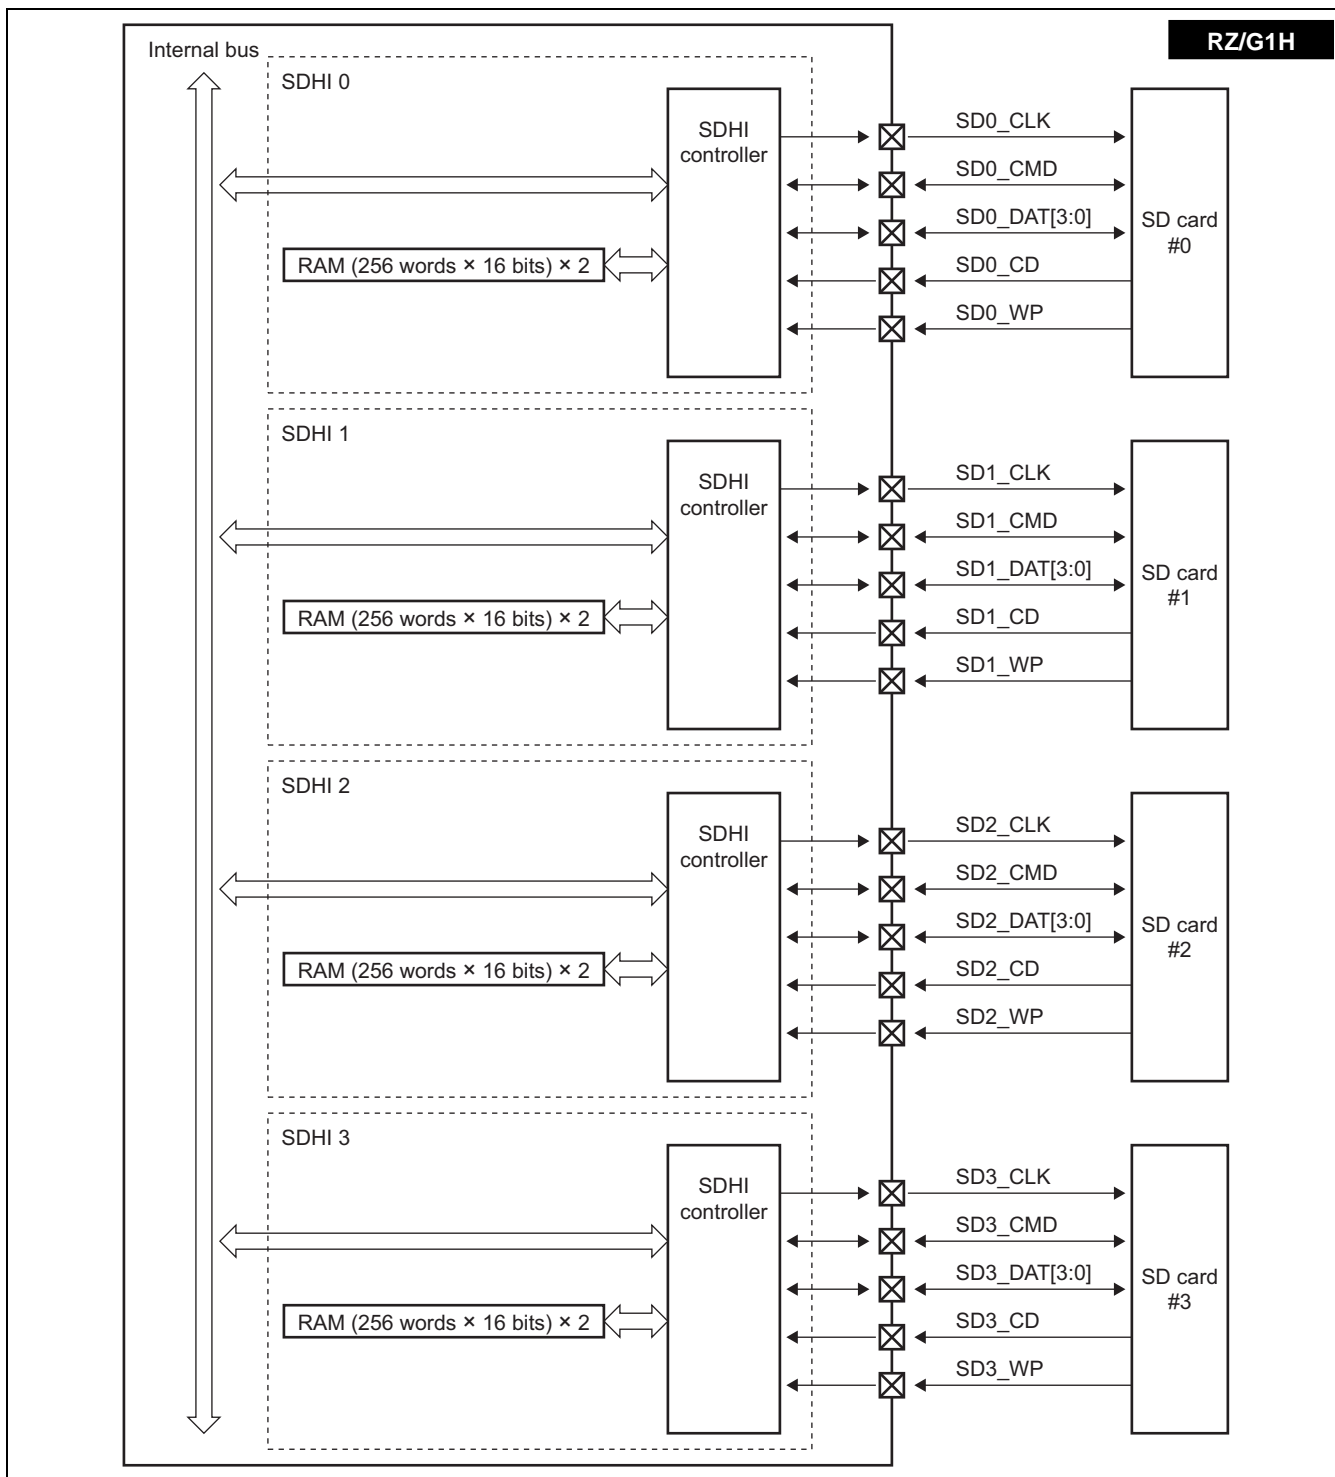

Figure 48.1 Block Diagram of SDHI [RZ/G1H]

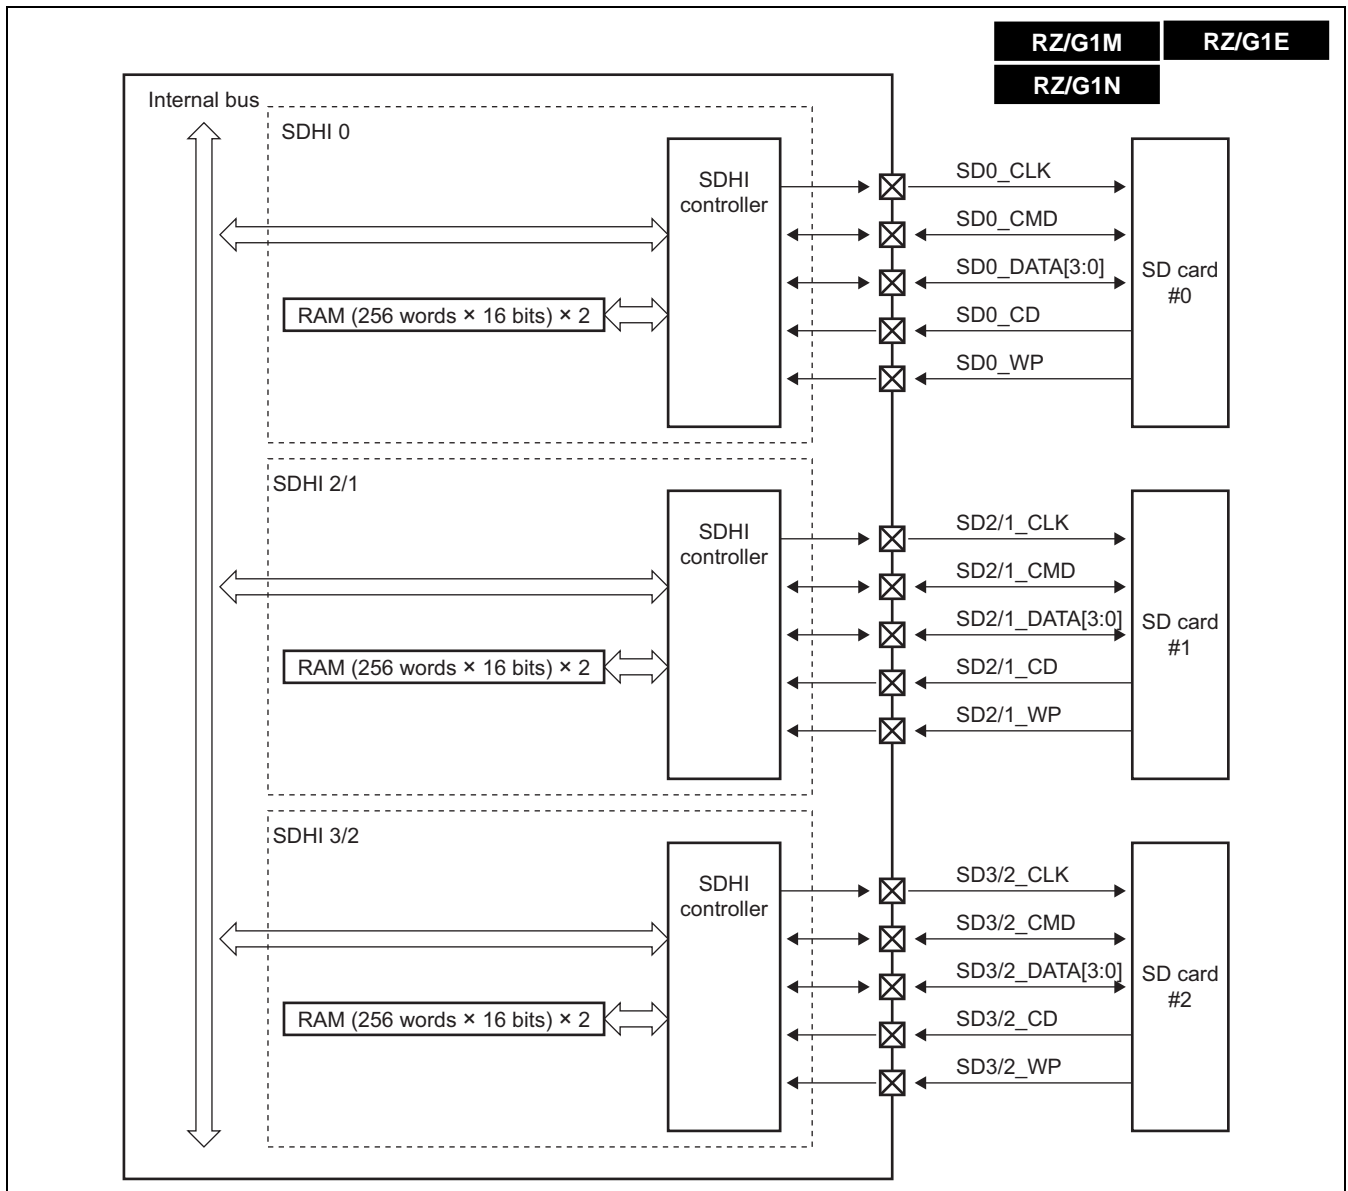

Figure 48.2 Block Diagram of SDHI [RZ/G1M, N, E]

### 48.1.2 Input/Output Pins

**Table 48.1 Pin Configuration**

				<u>RZ/G Series Products</u>			
Pin Name	Function	I/O	Description	RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
SDn_CLK	SD clock	Output	SD clock	√	√	√	√
SDn_CMD	Command response signal	Input/output	Command/response	√	√	√	√
SDn_DAT0 or SDn_DATA0	Data input/output	Input/output	Data [bit 0]	√	√	√	√
SDn_DAT1 or SDn_DATA1	Data input/output SDIO interrupt	Input/output	Data [bit 1]/SDIO interrupt	√	√	√	√
SDn_DAT2 or SDn_DATA2	Data input/output Read wait	Input/output	Data [bit 2]/read wait	√	√	√	√
SDn_DAT3 or SDn_DATA3	Data input/output card detection	Input/output	Data [bit 3]/card detection	√	√	√	√
SDn_CD	Card detection	Input	Card detection	√	√	√	√
SDn_WP	Write protection	Input	Write protection	√	√	√	√

Note: n = 0 to 3 [RZ/G1H], n = 0, 2, 3 [RZ/G1M, N], n = 0 to 2 [RZ/G1E]

### 48.1.3 Register Description

**Table 48.2 Register Configuration**

		<u>RZ/G Series Products</u>			
Register	Address	RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
SDHI 0	H'00 EE100000 to H'00 EE11FFFF	√	√	√	√
SDHI 1	H'00 EE120000 to H'00 EE13FFFF	√	—	—	—
SDHI 2 (SDHI 1*)	H'00 EE140000 to H'00 EE15FFFF	√	√	√	√
SDHI 3 (SDHI 2*)	H'00 EE160000 to H'00 EE17FFFF	√	√	√	√

Note: \* Applicable to the RZ/G1E.

## 49. Multi Media Card Interface (MMC)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 49.1 Overview

#### 49.1.1 Features

##### (1) MMC interface

- Compliant with JEDEC STANDARD JESD84-A441 (neither DDR mode nor 1.8-V operation is supported)
- Supports 1-/4-/8-bit MMC bus width
- MMC clock frequency = MMCxf clock frequency/ $2^n$  (n = 1 to 10)
- Supports block transfer\*<sup>1</sup>
- Supports boot operation\*<sup>2</sup>
- MMC clock frequency settings are adjustable in boot mode.
- Supports high priority interrupt (HPI)\*<sup>3</sup>
- Supports background operation
- Two types of interrupt requests: normal operation interrupts and error/timeout interrupts
- DMA transfer requests: buffer write and buffer read

Notes: 1. Stream transfer is not supported.

2. The alternative boot operation is not supported.

3. HPIs in the sequence of CMD6, CMD24, CMD25 (pre-defined), and CMD38 are supported.

#### 49.1.2 Block Diagram

Figure 49.1 Block Diagram of MMC [RZ/G1H]

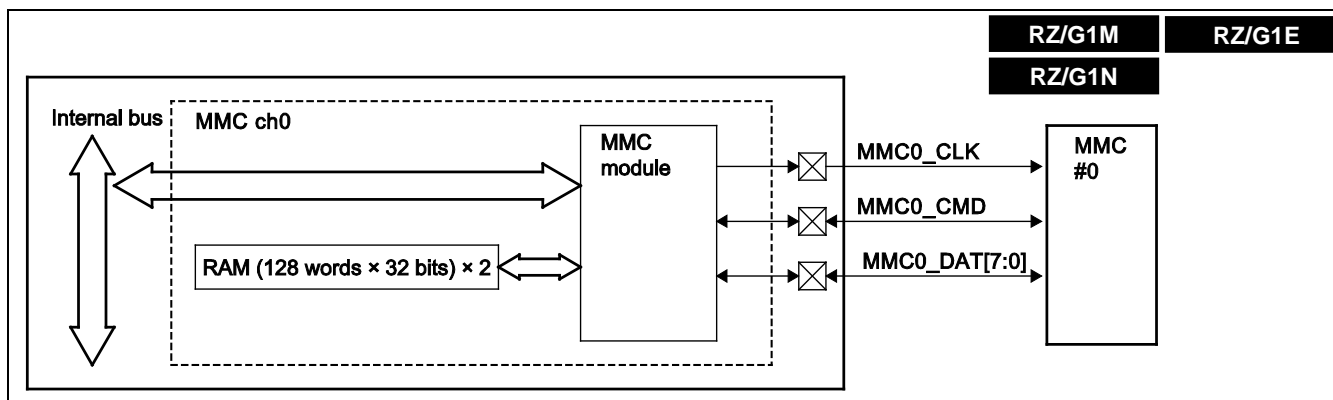

Figure 49.2 Block Diagram of MMC [RZ/G1M, RZ/G1N, RZ/G1E]

### 49.1.3 External Pins

Table 60.1 shows the pin configuration of the MMC.

Table 49.1 Pin Configuration

Name	Pin Name*	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
MMCCLK	MMcN_CLK	Output	MMC clock	√	√	√	√
MMCCMD	MMcN_CMD	Input/output	MMC command/response	√	√	√	√
MMCDAT[7:0]	MMcN_D[7:0]	Input/output	MMC data [7:0]	√	√	√	√

Note: \* n represents 0 or 1.

#### 49.1.4 Register Configuration

Table 60.2 shows the register configuration of the MMC.

The base address of each channel is as follows:

Channel 0: H'EE20\_0000

Channel 1: H'EE22\_0000\*

Note: \* Channel 1 applies to only RZ/G1H.

**Table 49.2 Register Configuration**

Register Name	Abbreviation	R/W	Address	Initial Value	Access Size	RZ/G Series Products			
						RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Command setting register	CE_CMD_SET	R/W	H'00	H'0000_0000	16, 32	√	√	√	√
Argument register	CE_ARG	R/W	H'08	H'0000_0000	16, 32	√	√	√	√
Argument register for automatically-issued CMD12	CE_ARG_CMD12	R/W	H'0C	H'0000_0000	16, 32	√	√	√	√
Command control register	CE_CMD_CTRL	R/W	H'10	H'0000_0000	16, 32	√	√	√	√
Transfer block setting register	CE_BLOCK_SET	R/W	H'14	H'0000_0200	16, 32	√	√	√	√
Clock control register	CE_CLK_CTRL	R/W	H'18	H'0000_0000	16, 32	√	√	√	√
Buffer access configuration register	CE_BUF_ACC	R/W	H'1C	H'0000_0000	16, 32	√	√	√	√
Response register 3	CE_RESP3	R	H'20	H'0000_0000	16, 32	√	√	√	√
Response register 2	CE_RESP2	R	H'24	H'0000_0000	16, 32	√	√	√	√
Response register 1	CE_RESP1	R	H'28	H'0000_0000	16, 32	√	√	√	√
Response register 0	CE_RESP0	R	H'2C	H'0000_0000	16, 32	√	√	√	√
Response register for automatically-issued CMD12	CE_RESP_CMD12	R	H'30	H'0000_0000	16, 32	√	√	√	√
Data register	CE_DATA	R/W	H'34	H'0000_0000	16*1, 32	√	√	√	√
Boot operation setting register	CE_BOOT	R/W	H'3C	H'0000_0000	16, 32	√	√	√	√
Interrupt flag register	CE_INT	R/(W)*2	H'40	H'0000_0000	16, 32	√	√	√	√
Interrupt enable register	CE_INT_EN	R/(W)*2	H'44	H'0000_0000	16, 32	√	√	√	√
Status register 1	CE_HOST_STS1	R	H'48	H'X0XX_0000	16, 32	√	√	√	√
Status register 2	CE_HOST_STS2	R	H'4C	H'0000_0000	16, 32	√	√	√	√
Clock control register 2	CE_CLK_CTRL2	R/W	H'70	H'00X0_XX00	16, 32	√	√	√	√
Version register	CE_VERSION	R/W	H'7C	H'0000_0003	16, 32	√	√	√	√
Data output phase select register	CE_ODATSEL	R/W	H'80	H'0000_0000	16, 32	√	√	√	√

Notes: Do not write to addresses other than those listed above. Otherwise, correct operation is not guaranteed.

1. For 16-bit access, H'34 is the only address for access.

2. Only 0 can be written to clear the flag.

## 49.2 Register Description

The registers of the MMC interface are assigned to and arranged in the internal bus address space.

### Legend for register description:

Initial value: Register value after a reset

$\frac{3}{4}$ : Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only.

$\frac{3}{4}$ /WB: Write-only. The read value is undefined.

### 49.2.1 Command Setting Register (CE\_CMD\_SET)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_CMD\_SET sets a command sequence. For the setting values of CE\_CMD\_SET, see section 60.3.4 (13), Setting values of CE\_CMD\_SET. The command sequence starts when the settings have been made in bits 31 to 16. Note that writing to CE\_CMD\_SET is disabled while a command sequence is proceeding (the CMDSEQ bit in CE\_HOST\_STS1 is 1).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	BOOT	CMD[5:0]							RTYP[1:0]	RBSY	—	WDAT	DWEN	CMLTE	CMD 12EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RIDXC[1:0]	RCRC7C[1:0]	—	CRC 16C	BOOT ACK	CRC STE	TBIT	OPDM	—	—	SBIT	—	DATW[1:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	¾	0	R	Reserved The write value should always be 0.
30	BOOT	0	R/W	Boot Operation 0: Command sequence other than for boot operations 1: Command sequence for boot operations
29 to 24	CMD[5:0]	H'00	R/W	Command Index Set a command index ([45:40]).
23, 22	RTYP[1:0]	00	R/W	Response Type 00: No response 01: 6-byte response (R1, R1b, R3, R4, R5) 10: 17-byte response (R2) 11: Setting prohibited
21	RBSY	0	R/W	Response Busy Select Selects whether "busy" is involved in response reception. 0: No response busy 1: Response busy involved (R1b)
20	¾	0	R/W	Reserved The write value should always be 0.
19	WDAT	0	R/W	Presence/Absence of Data 0: No data 1: With data
18	DWEN	0	R/W	Read/Write (valid when "with data" is selected) 0: Read from the card. 1: Write to the card.

Bit	Bit Name	Initial Value	R/W	Description
17	CMLTE	0	R/W	Single/Multi Block Transfer Select (valid when "with data" is selected) 0: Single-block transfer 1: Multi-block transfer
16	CMD12EN	0	R/W	Automatic CMD12 Issuance (valid when multi-block transfer is selected)* 0: Disables automatic CMD12 issuance. 1: Enables automatic CMD12 issuance. For details of automatic CMD12 issuance, see section 60.3.3 (4), Automatic CMD12 issuance. Note: Set the transfer block size to 512 bytes. Set the RBSY bit to 0.
15, 14	RIDXC[1:0]	00	R/W	Response Index Check Specify the items to be checked in bits [45:40] of a 6-byte response or bits [133:128] of a 17-byte response. 00: Checks the response index (check whether matched with a command index). 01: Checks the check bits (check whether all the bits are set to 1). 10: No checking 11: Setting prohibited
13, 12	RCRC7C [1:0]	00	R/W	Response CRC7 Check Specify the items to be checked in bits [7:1] of a 6-byte response or of a 17-byte response. 00: Checks CRC7 (set the response type to 01). 01: Checks the check bits (check whether all the bits are set to 1) (set the response type to 01). 10: Checks internal CRC7 (R2 only) (set the response type to 10). 11: No checking
11	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
10	CRC16C	0	R/W	CRC16 Check in Reception (valid when "with data" and "read" are selected) 0: Checks CRC16 in reception. 1: Does not check CRC16 in reception (used when CMD14).
9	BOOTACK	0	R/W	Receive Boot Acknowledge (valid in boot mode) 0: Boot acknowledge is not received. 1: Boot acknowledge is received.
8	CRCSTE	0	R/W	CRC Status Reception (valid when "with data" and "write" are selected) 0: Receives CRC status. 1: Does not receive CRC status (used when CMD19).
7	TBIT	0	R/W	Transmission Bit Setting 0: Sets the transmission bit ([46]) to 1. 1: Sets the transmission bit ([46]) to 0.
6	OPDM	0	R/W	Open-Drain Output Mode 0: Normal output 1: Open-drain output Note: This setting is only applied to the MMC_CMD line.

Bit	Bit Name	Initial Value	R/W	Description
5	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
4	$\frac{3}{4}$	0	R	Reserved The write value should always be 0.
3	SBIT	0	R/W	Read Data Start Bit Detection Setting (valid when "with data" and "read" are selected) 0: Detects a start bit when the valid MMCDAT signals specified by the DATW bits are all 0. 1: Detects a start bit when MMCDAT[0] is 0.
2	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
1, 0	DATW[1:0]	00	R/W	Data Bus Width Setting (valid when "with data" is selected) 00: 1 bit 01: 4 bits 10: 8 bits 11: Setting prohibited

Note: \* It is recommended to use the pre-defined multi-block transfer by setting this bit to 0 for a higher data transfer rate.

### 49.2.2 Argument Register (CE\_ARG)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_ARG sets the argument for the command to be transmitted. Set this register before starting a command sequence.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ARG[31:0]	All 0	R/W	Set bits [39:8] of the command. Note: Set the argument of automatically-issued CMD12 by CE_ARG_CMD12.

### 49.2.3 Argument Register for Automatically-Issued CMD12 (CE\_ARG\_CMD12)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_ARG\_CMD12 is used to set the argument for the automatically-issued CMD12. This register is valid when issuing CMD12 automatically in multi-block transfer. For automatic issuance of CMD12, see section 60.3.3 (4), Automatic CMD12 issuance. Set this register before starting a command sequence.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	C12ARG[31:0]	All 0	R/W	Set bits [39:8] of the automatically-issued CMD12.

#### 49.2.4 Command Control Register (CE\_CMD\_CTRL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_CMD\_CTRL is used to terminate a command sequence forcibly.

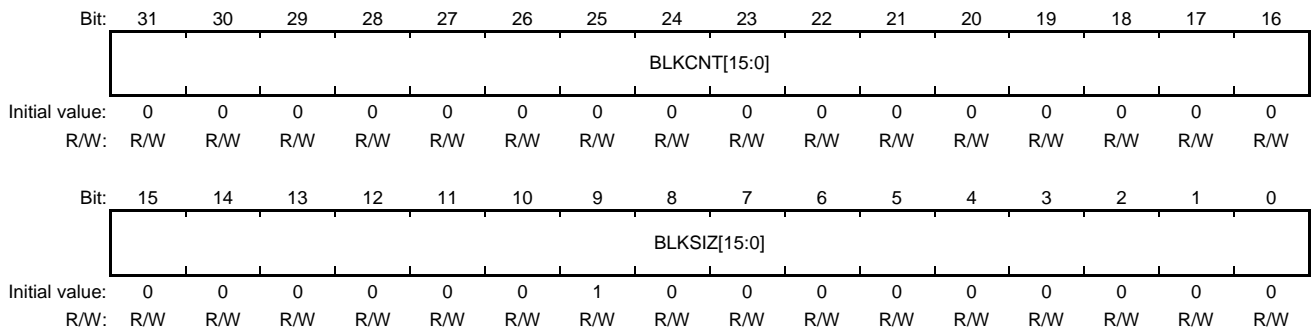

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BREAK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
15 to 2	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
1	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
0	BREAK	0	R/W	Forcible Termination of Command Sequence Writing 1 to this bit while it is 0 and then writing 0 to it discontinues the current command sequence. After this bit is set as described above, check if the value of the CMDSEQ bit in CE_HOST_STS1 has become 0. If this is the case, execute software reset. Note: A software reset initializes the value of this register, so the setting in this register needs to be remade.

### 49.2.5 Transfer Block Setting Register (CE\_BLOCK\_SET)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_BLOCK\_SET specifies the size of the block and the number of blocks for the data to be transferred. Set this register before starting a command sequence.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	BLKCNT[15:0]	H'0000	R/W	Number of Blocks for Transfer Note: This setting is valid for multi-block transfer.
15 to 0	BLKSIZ[15:0]	H'0200	R/W	Transfer Block Size Note: Transfer block size should be set as follows. <ul style="list-style-type: none"> <li>· Single-block transfer: 1 to 512 bytes</li> <li>· Multi-block transfer: 512 bytes</li> </ul>

### 49.2.6 Clock Control Register (CE\_CLK\_CTRL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_CLK\_CTRL controls the MMC clock and sets timeout values. Do not change the setting of this register while a command sequence is in progress.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	CLKEN	—	—	—	—	CLKDIV[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
24	CLKEN	0	R/W	MMC Clock Output Control 0: Does not output the MMC clock (fixed to low level). 1: Outputs the MMC clock.
23 to 20	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
19 to 16	CLKDIV[3:0]	H'0	R/W	MMC Clock Frequency Setting 0000: MMCxf /2 <sup>1</sup> 0001: MMCxf /2 <sup>2</sup> : 0111: MMCxf /2 <sup>8</sup> 1000: MMCxf /2 <sup>9</sup> 1001: MMCxf /2 <sup>10</sup> 1001 to 1111: Setting prohibited For details of MMC clock frequency settings in boot operations, see section 60.3.3 (5), MMC clock frequency in boot operations and section 60.2.11, Boot Operation Setting Register (CE_BOOT).
15	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
14	$\frac{3}{4}$	0	R	Reserved The write value should always be 0.
13, 12	SRSPTO[1:0]	00	R/W	Response Timeout Setting 00: 64 MMC clock cycles 01: 128 MMC clock cycles 10: 256 MMC clock cycles 11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	SRBSYTO[3:0]	0000	R/W	Response Busy Timeout Setting 0000: $2^{14}$ ´ MMC clock cycles 0001: $2^{15}$ ´ MMC clock cycles : 1110: $2^{28}$ ´ MMC clock cycles 1111: $2^{29}$ ´ MMC clock cycles
7 to 4	SRWDTO[3:0]	0000	R/W	Write Data/Read Data Timeout Setting 0000: $2^{14}$ ´ MMC clock cycles 0001: $2^{15}$ ´ MMC clock cycles : 1110: $2^{28}$ ´ MMC clock cycles 1111: $2^{29}$ ´ MMC clock cycles
3 to 0	$\frac{3}{4}$	All 0	R/W	Reserved The write value should always be 0.

### 49.2.7 Buffer Access Configuration Register (CE\_BUF\_ACC)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_BUF\_ACC configures the method of accessing data registers and mode of DMA transfer. Do not set this register again during a command sequence. For explanation of the buffers, see section 60.3.3 (3), Buffer structure and buffer access.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	DMAW EN	DMARE N	—	—	—	—	—	—	BUSW	ATYP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
26	$\frac{3}{4}$	0	R/W	Reserved The write value should always be 0.
25	DMAWEN	0	R/W	Buffer Write DMA Transfer Request Enable 0: Disables DMA transfer request for buffer writing. 1: Enables DMA transfer request for buffer writing.
24	DMAREN	0	R/W	Buffer Read DMA Transfer Request Enable 0: Disables DMA transfer request for buffer reading. 1: Enables DMA transfer request for buffer reading.
23, 22	$\frac{3}{4}$	All 0	R/W	Reserved The write value should always be 0.
21 to 18	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.
17	BUSW	0	R/W	Data register access size selection 0: When access to CE_DATA in 32 bits. 1: When access to CE_DATA in 16 bits.
16	ATYP	0	R/W	Buffer access selection 0: When not swapped byte-wise. 1: When swapped byte-wise. Note: For buffer access, see section 60.3.3 (3), Buffer structure and buffer access.
15 to 0	$\frac{3}{4}$	All 0	R	Reserved The write value should always be 0.

**49.2.8 Response Registers 3 to 0 (CE\_RESP3 to CE\_RESP0)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_RESP3 to CE\_RESP0 are the registers in which the response that has been received is stored. For the formats of response values, see section 60.3.3 (1), Command/response formats.

• CE\_RESP3

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP3)
31 to 0	RSP[127:96]	All 0	R	Bits [127:96] of a 17-byte response are stored.

• CE\_RESP2

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP2)
31 to 0	RSP[95:64]	All 0	R	Bits [95:64] of a 17-byte response are stored.

• CE\_RESP1

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP1)
31 to 0	RSP[63:32]	All 0	R	Bits [63:32] of a 17-byte response are stored.

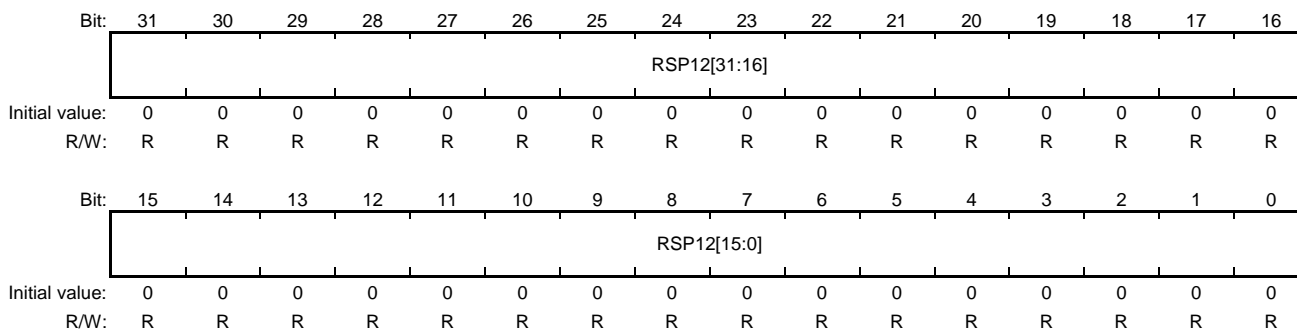

• CE\_RESP0

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP0)
31 to 0	RSP[31:0]	All 0	R	Bits [39:8] of a 6-byte response or bits [31:0] of a 17-byte response are stored. Note: The response to an automatically issued CMD12 is stored in the CE_RESP_CMD12 register.

**49.2.9 Response Register for Automatically-Issued CMD12 (CE\_RESP\_CMD12)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_RESP\_CMD12 is a register in which the response to the automatically-issued CMD12 is stored.

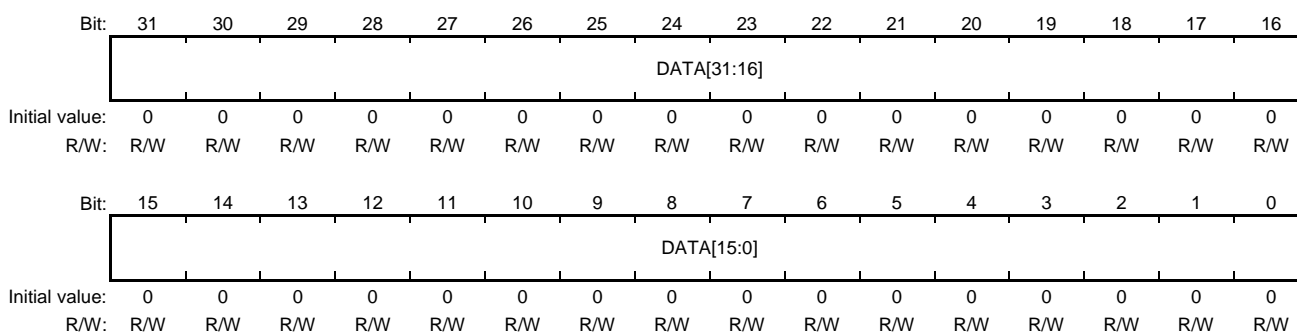

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RSP12[31:0]	All 0	R	Bits [39:8] of the response to automatically-issued CMD12 are stored.

**49.2.10 Data Register (CE\_DATA)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_DATA is used to access the buffers of this module. In 16-bit access, only DATA[31:16] are accessible. For the write/read data formats, see section 60.3.3 (2), Data block format.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	All 0	R/W	Buffer write/read data [31:0]

### 49.2.11 Boot Operation Setting Register (CE\_BOOT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_BOOT controls the MMC clock and sets timeout values in boot mode. Do not set this register again during a command sequence.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BTCLKDIV[3:0]				SBTACKTO[3:0]				S1STBTDATTO[3:0]				SBTDATTO[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	BTCLKDIV[3:0]	0000	R/W	MMC Clock Frequency Setting in Boot Mode 0000: $MMCxf / 2^1$ 0001: $MMCxf / 2^2$ 0010: $MMCxf / 2^3$ 0011: $MMCxf / 2^4$ 0100 to 1111: Settings prohibited Set these bits to a value lower than that in the CLKDIV bits of CE_CLK_CTRL. For MMC clock frequency in boot mode, see section 60.3.3 (5), MMC clock frequency in boot operations.
27 to 24	SBTACKTO[3:0]	0000	R/W	Boot Acknowledge Timeout Setting 0000: $2^{14}$ ´ MMC clock cycles 0001: $2^{15}$ ´ MMC clock cycles : 1110: $2^{28}$ ´ MMC clock cycles 1111: $2^{29}$ ´ MMC clock cycles
23 to 20	S1STBTDATTO [3:0]	0000	R/W	1st Boot Data Timeout Setting 0000: $2^{14}$ ´ MMC clock cycles 0001: $2^{15}$ ´ MMC clock cycles : 1110: $2^{28}$ ´ MMC clock cycles 1111: $2^{29}$ ´ MMC clock cycles
19 to 16	SBTDATTO[3:0]	0000	R/W	Interval Between Boot Data Timeout Setting 0000: $2^{14}$ ´ MMC clock cycles 0001: $2^{15}$ ´ MMC clock cycles : 1110: $2^{28}$ ´ MMC clock cycles 1111: $2^{29}$ ´ MMC clock cycles

---

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	¾	All 0	R	Reserved The write value should always be 0.

---

### 49.2.12 Interrupt Flag Register (CE\_INT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_INT indicates various statuses during execution of a command sequence. Each bit is set when its setting condition has been met. To clear flag(s), write 0 only to the bit(s) to be cleared and write 1 to the other bits.

For the handling of this module in the case of an error or timeout, see section 60.3.3 (8), Handling of this module in the case of error/timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CRCSTE	0	R	CRC Status Error This bit is set to 1 when an error is found in the CRC status value.
30	CRC16E	0	R	Read Data CRC16 Error This bit is set to 1 when an error is found in CRC16 in the read data.
29	AC12CRCE	0	R	Automatic CMD12 Response CRC7 Error This bit is set to 1 when an error is found in bits [7:1] of the response to the automatically-issued CMD12. Note: The items to be checked are set by RCRC7C in CE_CMD_SET.
28	RSPCRC7E	0	R	Command Response CRC7 Error (other than automatically-issued CMD12) This bit is set to 1 when an error is found in bits [7:1] of a 6-byte response or a 17-byte response. Note: The items to be checked are set by RCRC7C in CE_CMD_SET.
27	CRCSTEBE	0	R	CRC Status End Bit Error This bit is set to 1 when an error is found in the end bits in CRC status.
26	RDATEBE	0	R	Read Data End Bit Error This bit is set to 1 when an error is found in the end bits in the read data.
25	AC12REBE	0	R	Automatic CMD12 Response End Bit Error This bit is set to 1 when an error is found in the end bits of the response to the automatically-issued CMD12.
24	RSPEBE	0	R	Command Response End Bit Error (other than automatically-issued CMD12) This bit is set to 1 when an error is found in the end bits of the response.
23	AC12IDXE	0	R	Automatic CMD12 Response Index Error This bit is set to 1 when an error is found in bits [45:40] of the response to the automatically-issued CMD12. Note: The items to be checked are set by RIDXC in CE_CMD_SET.

Bit	Bit Name	Initial Value	R/W	Description
22	RSPIDX	0	R	Command Response Index Error (other than automatically-issued CMD12) This bit is set to 1 when an error is found in bits [45:40] of a 6-byte response or bits [133:128] of a 17-byte response. Note: The items to be checked are set by RIDXC in CE_CMD_SET.
21	BTACKPATE	0	R	Boot Acknowledge Pattern Error This bit is set to 1 when an error is found in the boot acknowledge pattern.
20	BTACKEBE	0	R	Boot Acknowledge End Bit Error This bit is set to 1 when an error is found in the end bits of the boot acknowledge.
19	¾	0	R	Reserved The write value should always be 0.
18 to 16	CRCST[2:0]	00	R	CRC Status/Boot Acknowledge Pattern Indication This bit indicates the value for CRC status that was received or the pattern value from the boot-acknowledge.
15	¾	0	R	Reserved The write value should always be 0.
14	STRDATTO	0	R	Read Data Timeout (valid other than in boot operations) <ul style="list-style-type: none"> <li>This bit is set to 1 if read data is not received within the period set by the SRWDTO bits in CE_CLK_CTRL after a read command was transmitted.</li> <li>This bit is set to 1 if read data is not received within the period set by the SRWDTO bits in CE_CLK_CTRL after a read data was received.</li> </ul>
13	DATBSYTO	0	R	Data Busy Timeout This bit is set to 1 if busy status remains unchanged after the period set by the SRWDTO bits in CE_CLK_CTRL after the CRC status was received.
12	CRCSTTO	0	R	CRC Status Timeout This bit is set to 1 if CRC status could not be received.
11	AC12BSYTO	0	R	Automatic CMD12 Response Busy Timeout This bit is set to 1 if busy state remains unchanged after the period set by the SRBSYTO bits in CE_CLK_CTRL after the automatically-issued CMD12 was transmitted.
10	RSPBSYTO	0	R	Response Busy Timeout This bit is set to 1 if busy state remains unchanged after the period set by the SRBSYTO bits in CE_CLK_CTRL after a command (other than automatically-issued CMD12) was transmitted.
9	AC12RSPTO	0	R	Automatic CMD12 Response Timeout This bit is set to 1 if the response is not received within the period set by the SRSPTO bits in CE_CLK_CTRL after the automatically-issued CMD12 was transmitted.
8	STRSPTO	0	R	Response Timeout This bit is set to 1 if the response is not received within the period set by the SRSPTO bits in CE_CLK_CTRL after a command (other than automatically-issued CMD12) was transmitted.

Bit	Bit Name	Initial Value	R/W	Description
7	BTACKTO	0	R	<p>Boot Acknowledge Timeout</p> <p>In boot operations, this bit is set to 1 if boot acknowledge is not received within the period set by the SBTACKTO bits in CE_BOOT.</p>
6	1STBTDATTO	0	R	<p>1st Boot Data Timeout</p> <p>In boot operations, this bit is set to 1 if the 1st read data is not received within the period set by the S1STBTDATTO bits in CE_BOOT.</p>
5	BTDATTO	0	R	<p>Interval between Boot Data Timeout</p> <p>In boot operations, this bit is set to 1 if read data is not received within the period set by the SBTDATTO bits in CE_BOOT after a read data was received.</p>
4 to 0	¾	All 0	R	<p>Reserved</p> <p>The write value should always be 0.</p>

### 49.2.16 Clock Control Register 2 (CE\_CLK\_CTRL2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_CLK\_CTRL2 is a register used for initialization of the MMC. Set the MMC\_CLKU bits (bits 27 to 24) and the MMC\_CLKL bits (bits 19 to 16) to H'F before using the MMC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	MMC_CLKU				—	—	—	—	MMC_CLKL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	—	0	0	0	—	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/WC0	R/WC0	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The write value should always be 0.
27 to 24	MMC_CLKU	H'0	R/W	Set these bits to H'F before using the MMC.
23 to 20	—	—	R	Reserved The write value should always be 0.
19 to 16	MMC_CLKL	H'0	R/W	Set these bits to H'F before using the MMC.
15	—	0	R	Reserved The write value should always be 0.
14	—	—	R	Reserved The write value should always be 0.
13, 12	—	All 0	R/WC0	Reserved The write value should always be 1.
11	—	0	R	Reserved The write value should always be 0.
10	—	—	R	Reserved The write value should always be 0.
9 to 0	—	All 0	R	Reserved The write value should always be 0.

**49.2.17 Version Register (CE\_VERSION)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_VERSION indicates the version number and controls software reset of this module.

Bit	Bit Name	Initial Value	R/W	Description
31	SWRST	0	R/W	Software Reset 0: Software reset cleared (normal operation). 1: Executes software reset. When this bit is set to 1, the values of all registers are initialized. (SWRST is not initialized.)
30 to 24	¾	All 0	R	Reserved The write value should always be 0.
23 to 16	¾	All 0	R/W	Reserved The write value should always be 0.
15 to 0	VERSION [15:0]	H'0003	R	Version Information Indicates the version number of this module.

**49.2.18 Data Output Phase Select Register (CE\_ODATSEL)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CE\_ODATSEL is a register which adjusts data output timing.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ODTS	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved The write value should be 0.
8	ODTS	0	R/W	Output Data Timing Select 0: Data being output are changed 1/4 of an MMC_CLK cycle before rising edges of MMC_CLK. 1: Data being output are changed on falling edges of MMC_CLK.
7 to 0	—	All 0	R	Reserved The write value should be 0.

(Waveform)

## 49.3 Operations

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 49.3.1 Interrupt Requests

Table 60.3 shows the specification of the interrupt requests. This module generates two types of interrupt requests: normal operation and error/timeout. When a bit in the flag register is set to 1 and also the corresponding bit in the interrupt enable register is set to 1 (enabled), an interrupt request is asserted.

**Table 49.3 Specification of Interrupt Requests**

Flag Register	Bit	Enable Register	Bit	Interrupt Request
CE_INT	CMD12DRE	CE_INT_EN	MCMD12DRE	Normal operation interrupt
	CMD12RBE		MCMD12RBE	
	CMD12CRE		MCMD12CRE	
	DTRANE		MDTRANE	
	BUFRE		MBUFRE	
	BUFWEN		MBUFWEN	
	BUFREN		MBUFREN	
	RBSYE		MRBSYE	
	CRSPE		MCRSPE	
	CMDVIO		MCMDVIO	
	BUFVIO		MBUFVIO	
	WDATERR		MWDATERR	
	RDATERR		MRDATERR	
	RIDXERR		MRIDXERR	
	RSPERR		MRSPERR	
	CRCSTO		MCRSTO	
	WDATTO		MWDATTO	
	RDATTO		MRDATTO	
	RBSYTO		MRBSYTO	
	RSPTO		MRSPTO	

### 49.3.2 DMA Specifications

This module has two types of DMA transfer requests: for buffer reading and for buffer writing.

The method of DMA transfer is configured by CE\_BUF\_ACC.

#### (1) DMA for buffer writing

The DMA transfer request is asserted for buffer writing when the buffer has become empty while the DMAWEN bit in CE\_BUF\_ACC is set to 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE\_BLOCK\_SET) ´ BLKCNT (the number of blocks for transfer set in CE\_BLOCK\_SET), and negated after the last block has been transferred. Note that the BUFWEN bit in CE\_INT will not be asserted during DMA transfer.

If an error has occurred during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

#### (2) DMA for buffer reading

The DMA transfer request is asserted for buffer reading when the buffer stores data of the block size specified in CE\_BLOCK\_SET while the DMAREN bit in CE\_BUF\_ACC is set to 1.

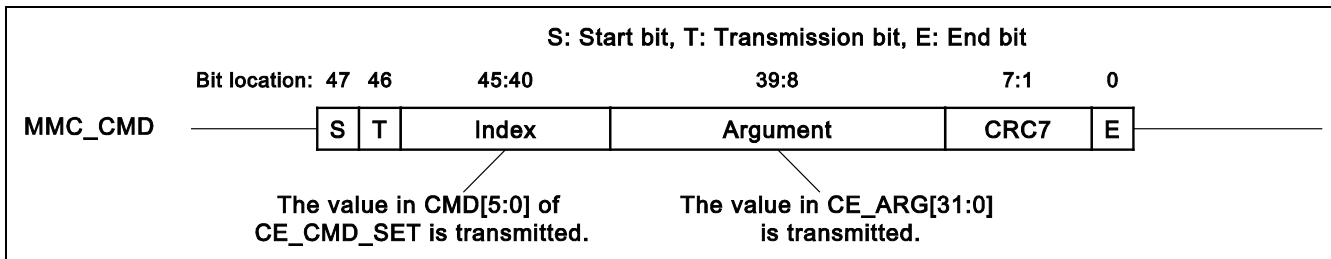

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE\_BLOCK\_SET) ´ BLKCNT (the number of blocks for transfer set in CE\_BLOCK\_SET), and negated after the last block has been transferred. Note that the BUFREN bit in CE\_INT will not be asserted during DMA transfer.

If an error has occurred during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

**49.3.3 Operations**

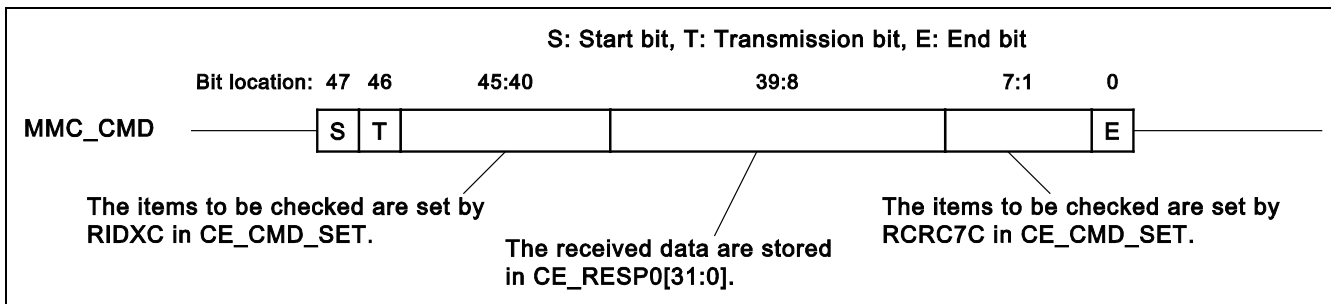

**(1) Command/response formats**

Figure 60.3 shows the format of the command to be transferred. The command index that is set in the CMD[5:0] bits in CE\_CMD\_SET and the argument set in the ARG[31:0] bits in CE\_ARG are reflected in the command.

**Figure 49.3 Command Format**

Figures 60.4 and figure 60.5 show the formats when a 6-byte response and 17-byte response (R2) are received, respectively. The received response is stored in CE\_RESP0 or CE\_RESP3 to CE\_RESP0. The items to be checked are set by the RIDXC bits and the RCRC7C bits in CE\_CMD\_SET.

**Figure 49.4 Format of 6-Byte Response**

**Figure 49.5 Format of 17-Byte Response (R2)**

(2) Data block format

Figure 60.6 shows the format of data blocks. For D0 to D3 in the figure, see section 60.3.3 (3), Buffer structure and buffer access. When data are written to the card, the data stored in the buffer are transmitted. When data are read from the card, the received data are stored in the buffer.

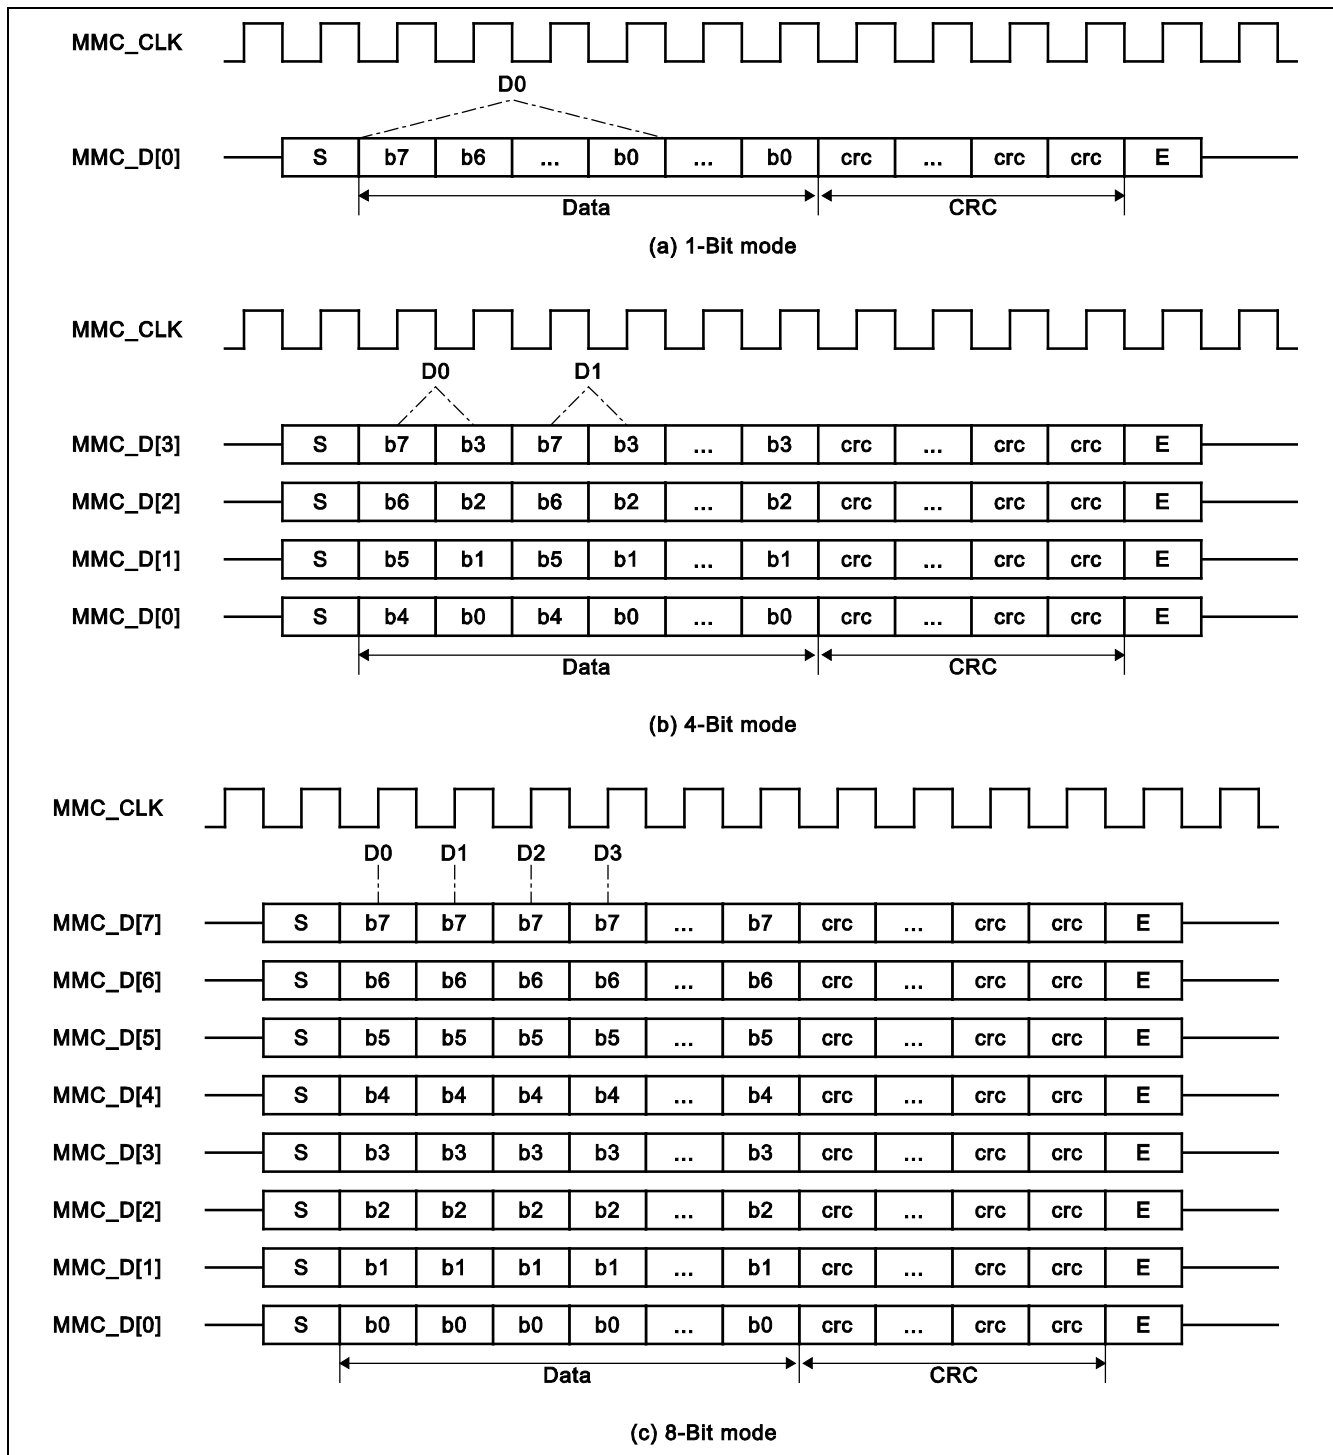

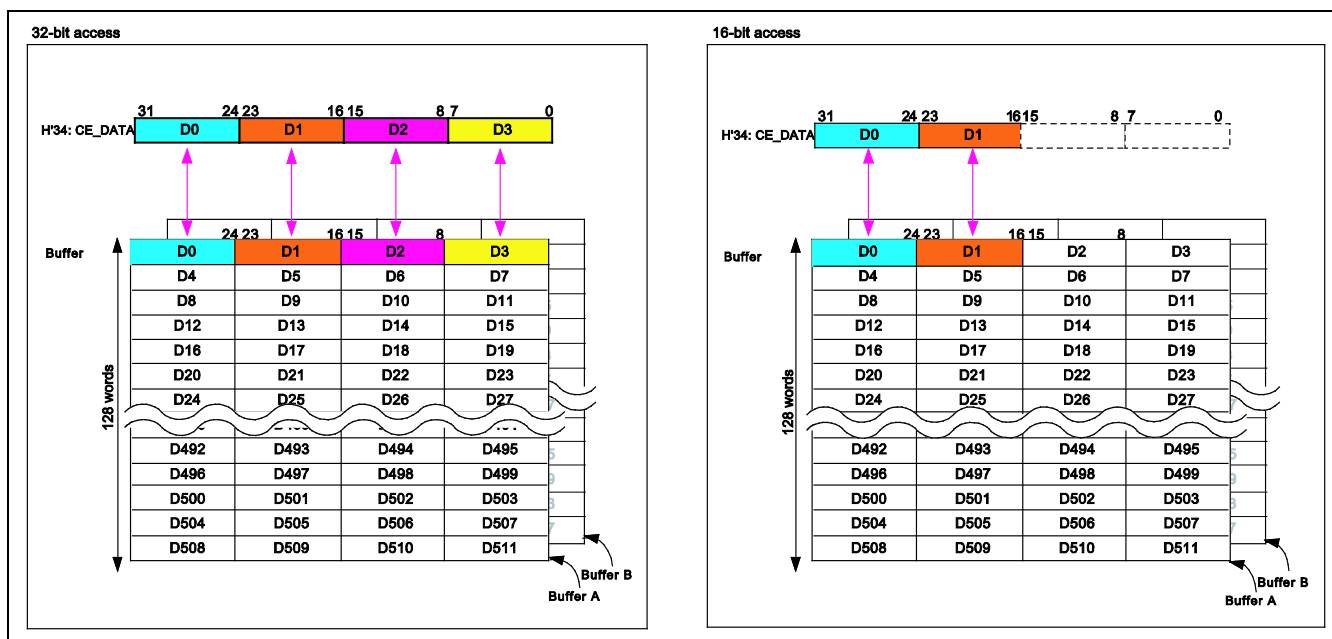

Figure 49.6 Data Block Format

**(3) Buffer structure and buffer access**

As shown in figure 60.7, this module has two 512-byte RAM units for double buffering. If a block of data (512 bytes) stored in one buffer is transmitted during multi-block writing, the next block of data can be transmitted as soon as the other buffer is full. If a block of received data (512 bytes) is stored in one buffer during multi-block reading, the next block of received data can be stored in the other buffer once it is empty.

If neither buffer is empty during multi-block reading, the MMC clock is stopped, which in turn temporarily stops reception. Once either of the buffers becomes empty, supply of the MMC clock signal is re-started and data reception is resumed.

The buffers are accessed by CE\_DATA. If the transfer block size is set to  $4 \cdot n + 1$  or  $4 \cdot n + 3$ , access should be made for  $4 \cdot (n + 2)$  bytes or  $4 \cdot (n + 1)$  bytes in 16-bit access, and for  $4 \cdot (n + 1)$  bytes in 32-bit access. ( $n = 0, 1, 2, \dots, 127$ )

**Figure 49.7 Double Buffer Structure**

This module has the buffer access select function that allows byte-wise swapping of data when the buffer is accessed by writing to or reading from CE\_DATA. This function is enabled by the setting of CE\_BUFF\_ACC. Figure 60.8 shows the specification of 32-bit and 16-bit accesses.

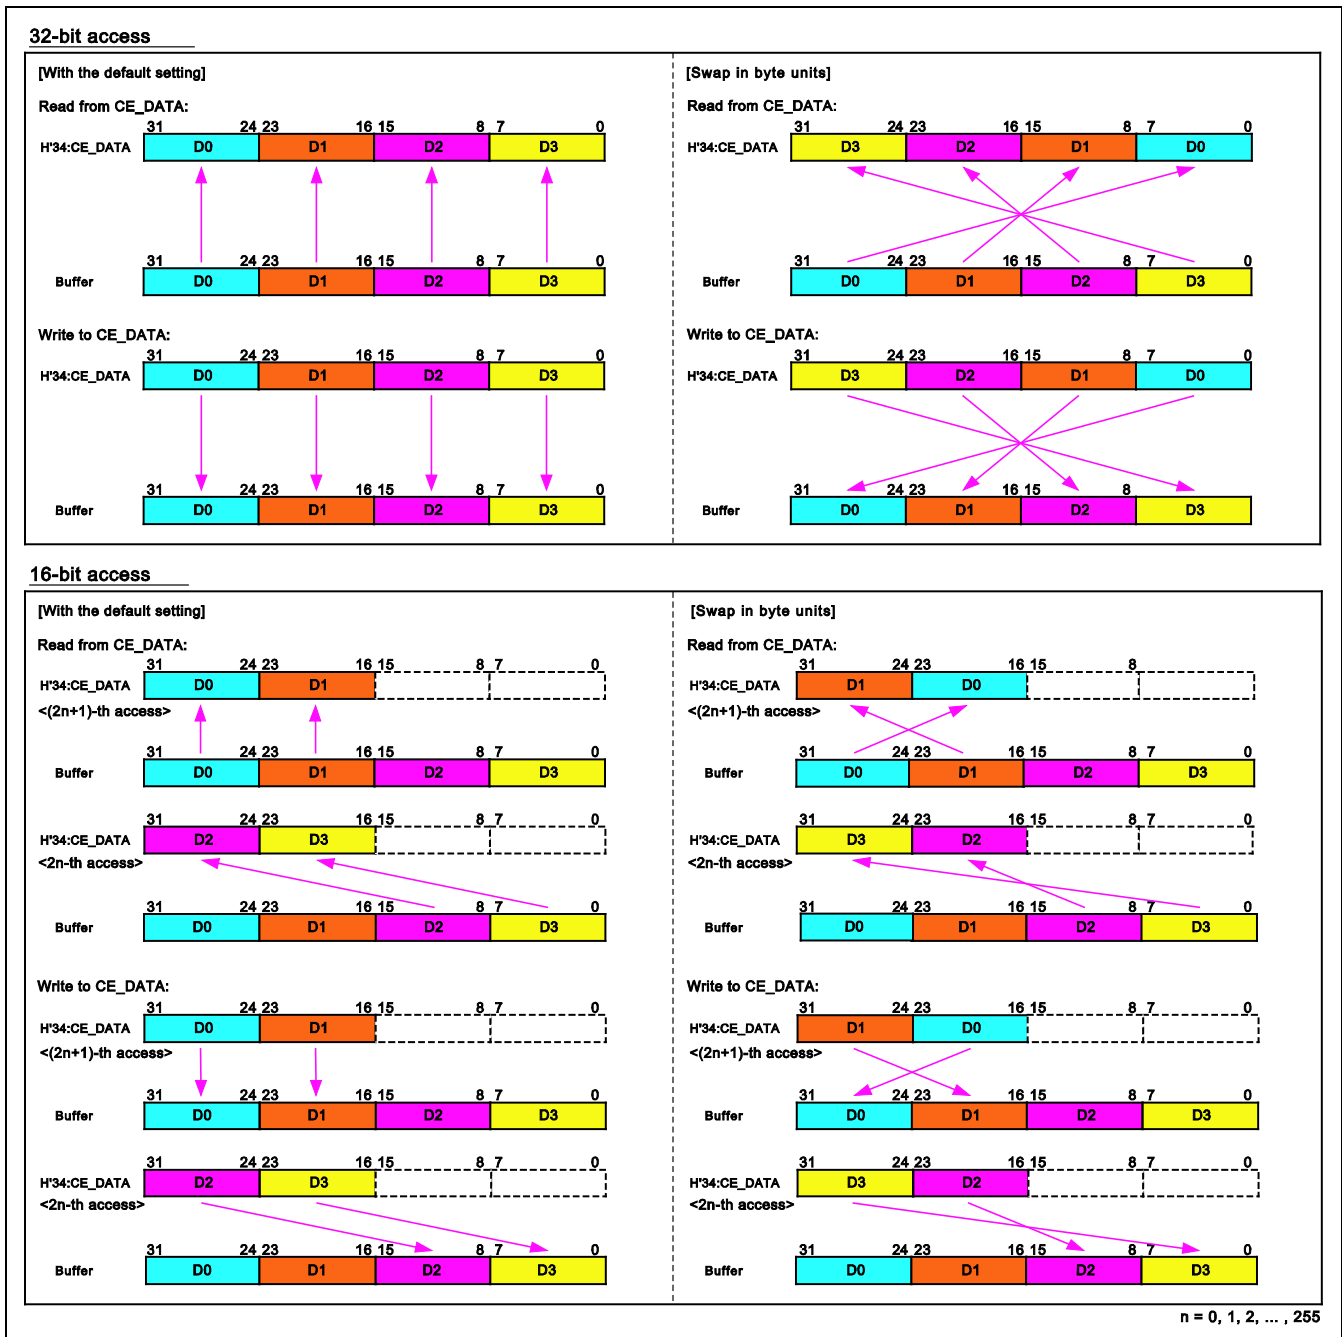

Figure 49.8 Specification of Byte-Swapping in 32-/16-Bit Accesses

**(4) Automatic CMD12 issuance**

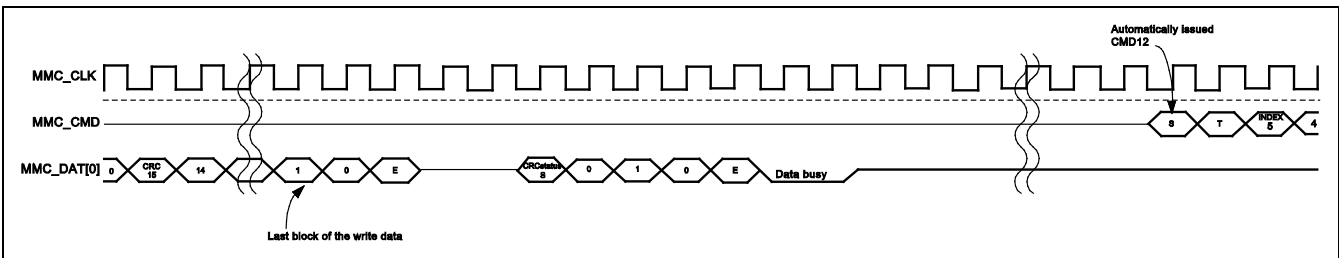

This module has the function that automatically issues CMD12 when multi-block transfer is performed with the CMD12EN bit in CE\_CMD\_SET set to 1.

Figure 60.9 shows the timing of automatic CMD12 issuance in multi-block read. CMD12 is issued such that the end bit of the command is sent two bits before the end bit of the data during reception of the last block.

**Figure 49.9 Timing of Automatically-Issued CMD12 in Multi-Block Read (1-Bit Mode)**

Figure 60.10 shows the timing of automatic CMD12 issuance in multi-block write. CMD12 is issued after the data busy after transmission of the last block has ended.

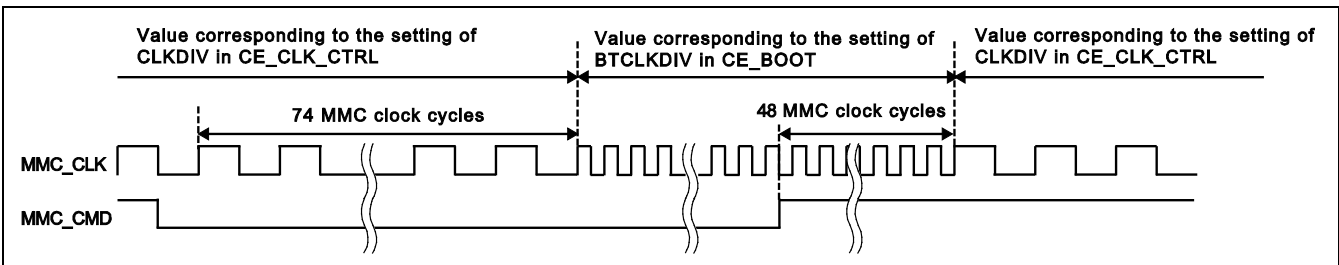

**Figure 49.10 Timing of Automatically-Issued CMD12 in Multi-Block Write (1-Bit Mode)**

The argument for the automatically-issued CMD12 is set in CE\_ARG\_CMD12. Bits [39:8] of the response to the CMD12 is stored in CE\_RESP\_CMD12. "Busy" is involved in response reception.

**(5) MMC clock frequency in boot operations**

Figure 60.11 shows the timing for changing the MMC clock frequency in boot operations. In boot operations, the MMC clock frequency can be switched to the value corresponding to the setting of the BTCLKDIV bits of CE\_BOOT 74 MMC clock cycles after MMCCMD is modified from 1 to 0. Alternatively, it can be switched to the value corresponding to the setting of the CLKDIV bits of CE\_CLK\_CTRL 48 MMC clock cycles after MMC\_CMD is modified from 0 to 1.

**Figure 49.11 MMC Clock Frequency in Boot Operations**

## (6) High priority interrupt (HPI)

The HPI should be processed according to the following procedure. Refer to section 60.2, Register Description, and section 60.3.4, Examples of Setting.

### (a) To execute the HPI during a write to the device

- Terminate the command sequence forcibly.
- Wait until the CMDSEQ bit in CE\_HOST\_STS1 becomes 1.
- Issue CMD12 (R1) to cause a device state transition from rcv to prg. If the device is already in the prg state here, the device does not output a response.
- Issue CMD13 (R1).
- Issue the HPI command.\*

### (b) To execute the HPI in the response busy state not during a write to the device

- Terminate the command sequence forcibly.
- Wait until the CMDSEQ bit in CE\_HOST\_STS1 turns 0.
- Issue CMD13 (R1).
- Issue the HPI command.\*

HPIs in the sequence of CMD6, CMD24, CMD25 (pre-defined), and CMD38 are supported.

Note: \* CMD12 (R1b) or CMD13 (R1b) differs depending on the e-MMC connected.

## (7) Background operation

The background operation should be processed according to the following procedure. Refer to section 60.2, Register Description, and section 60.3.4, Examples of Setting.

To execute background operation, issue CMD6 (R1) to write to the BKOPS\_START byte in the EXT\_CSD register of the device.

To confirm that background operation has been completed, issue CMD6 (R1) and then CMD13 (R1) to check the device state, or poll the MMCDAT[0]. If the device state is trans after issuing CMD13 (R1) or MMCDAT[0] is high, background operation has been completed.

To suspend background operation, use the HPI (see section 60.3.3 (6), High priority interrupt (HPI)).

## (8) Handling of this module in the case of error/timeout

This module may not be stopped when an error has occurred. If an error has occurred and the CMDSEQ bit in CE\_HOST\_STS1 is still indicating that the command sequence is in progress, terminate the sequence forcibly and execute software reset. Note that the data for transmission or received data that had been stored in the buffers at the time of error occurrence are not guaranteed.

This module is not stopped when a timeout has occurred. Before issuing the next command after the timeout has occurred, terminate the sequence forcibly and execute software reset.

### 49.3.4 Examples of Setting

This section shows the procedures for executing typical command sequences.

#### (1) Legends

Figure 60.12 shows the legends for the symbols used in the figures in the following subsections.

## 49.4 Usage Note

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 49.4.1 Multi-Block Transfer

It is recommended to use the pre-defined multi-block transfer for a higher data transfer rate.

## 50. Serial-ATA Interface

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 50.1 Overview

The serial-ATA interface provides a serial ATA physical interface which complies with the serial-ATA standard.

Note: References to the SH-Navi2G in this section refer to a previous product from Renesas. The serial-ATA interface of the RZ/G1H and M/N has backward compatibility with that of the SH-Navi2 series.

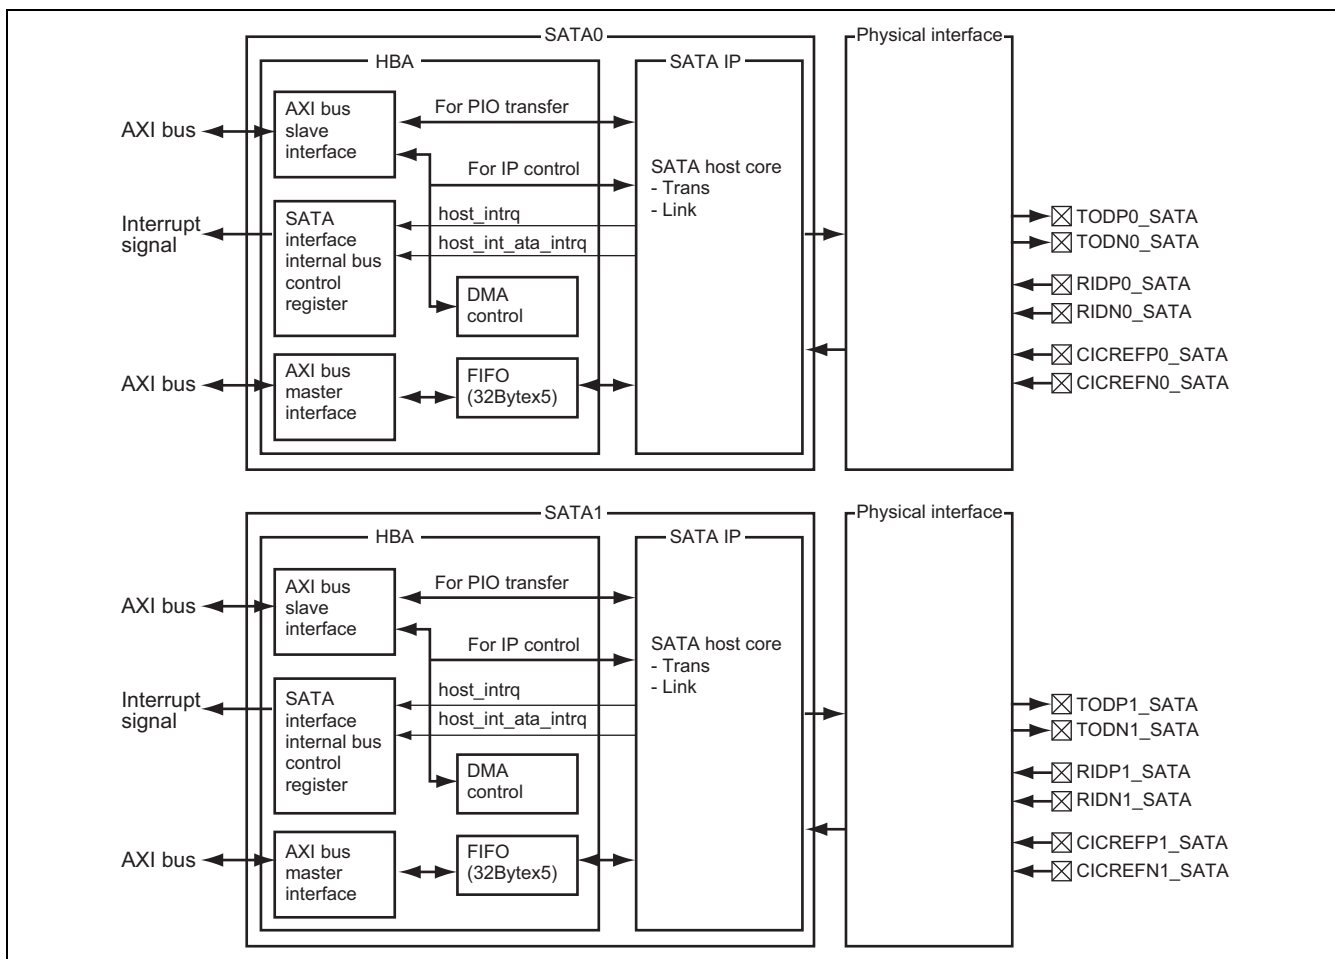

#### 50.1.1 Features

- Supports 3.0 Gbps (second generation) and 1.5 Gbps (first generation) transfer rate.
- Two interfaces in master mode
- Supports the emulation and descriptor modes of the SH-Navi2 parallel-ATAPI (host controller).
- Parallel-ATA emulation
- Packet protocol transfer
- Supports SATA standard 8b/10b encoding, cyclic redundancy check (CRC), and scrambling modes.
- Supports the SATA power management mode (partial mode/slumber mode).
- Does not support reset speed negotiation (RSN).

#### 50.1.2 Block Diagram

Figure 50.1 shows the block diagram of the SATA interfaces.

**Figure 50.1 Block Diagram of SATA Interfaces**

host\_intrq and host\_int\_ata\_intrq are internal interrupt request signals. For the interrupt sources of these signals, refer to the description of the SATA INT status register.

For a physical interface, the SATA function must be selected by the M23 or M24 pin.

### 50.1.3 Input/Output Pins

Table 50.1 shows the external pins of the SATA interface.

**Table 50.1 External Pins**

Name	Pin Name	SATA Symbol	I/O	Description	RZ/G Series Products			
					RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Reference clock	CICREFP0_SATA	—	Input	Reference clock input to the PLL circuit in the Serial-ATA module (differential input). Apply a 100-MHz clock.	√	√	√	—
	CICREFN0_SATA							
	CICREFP1_SATA							
	CICREFN1_SATA							
Transmit data	TODP0_SATA	TX+	Output	Pins for data transmission pins. A 3.0-GHz (second generation) signal or 1.5-GHz (first generation) signal is transmitted through these pins.  The pins with names ending in P and N are combined to provide a differential signal.	√	√	√	—
	TODN0_SATA	TX-						
	TODP1_SATA							
	TODN1_SATA							
Receive data	RIDP0_SATA	RX+	Input	Pins for data reception. A 1.5-GHz (first generation) or 3.0-GHz (second generation) signal is received through these pins.  The pins with names ending in P and N are combined to provide a differential signal.	√	√	√	—
	RIDN0_SATA	RX-						
	RIDP1_SATA							
	RIDN1_SATA							

### 50.1.4 Register Configuration

Table 50.2 shows the register configuration of the SATA interface. The set of registers shown below are allocated to the register map space.

The area allocated for the SATA0 interface is from H'EE30 0000 to H'EE4F FFFF (2-Mbyte space).

The area allocated for the SATA1 interface is from H'EE50 0000 to H'EE6F FFFF (2-Mbyte space).

These registers must not be accessed in any access sizes other than those listed in the table.

Addresses other than those listed below must not be write-accessed to. If written to, operation is not guaranteed. If read, an undefined value is read.

**Table 50.2 Register Configuration**

Add the offsets under “address” below to H'EE30 0000 for SATA0 and to H'EE50 0000 for SATA1.

Name	Symbol	R/W	Address	Access Size (Available Bit Size)	RZ/G Series Products

Notes: See the descriptions of individual registers for the R/W attributes of the valid bits.

1. Bits 15 to 0 of the data bus are used.
2. Bits 7 to 0 of the data bus are used.

## 50.2 Register Descriptions

- Legend:
  - Address: Address of the register
  - Bit map: Bit configuration of the entire register. The initial value and R/W of the individual bits are also indicated.
  - Bit: Bit number and range
  - Bit name: Bit name or field name
  - Initial value: Register value after a reset
  - : Undefined value
  - R/W: Readable/writable. The written value can be read.
  - R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.
  - R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.
  - R: Read-only. The write value should always be 0. (If a read/write value is specified in the bit description, however, it must be observed.)
  - /W: Write-only. The read value is undefined.
  - RC: Read-only. The bit is cleared to 0 after it has been read.

### 50.2.1 Note on the Access to the Registers Allocated to H'1018 to H'10A8

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

No normal access can basically be made to the registers that are allocated to H'1018 to H'10A8 unless the PHYRDY state is established. The PHYRDY state here refers to the state in which the rate of transfer between the host and device is established and they are ready for data transfer. In this state, bits 3-0 of the SCR SStatus register described in section 50.2.26, SCR SStatus Register (SCRSSSTS), is set to B'0011\*. The integrity of the value of a register that is accessed in the non-PHYRDY state is not guaranteed.

### 50.2.2 ATAPI Control Register (ATAPI\_CONTROL1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISM
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DTA32 M	—	—	—	RESET	—	—	—	DESE	R/W	STOP	START
Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	—	R	Reserved The write value should always be 0.
16	ISM	0	R/W	Interrupt Status mode 0: IP compatible mode Normal operating mode of the SATA INT status register (SATAINTSTAT). 1: CIS interrupt mode A valid interrupt source specified by the SATA INT mask register is set in the SATA INT status register (SATAINTSTAT). No interrupts are generated by valid sources specified in the SATA INT mask register (SATAINTMASK). Read access to the SATA INT status register (SATAINTSTAT) will not negate the ATA-sourced DEVINT interrupt signal. Note: For details, refer to section 50.3.6, Interrupt Modes. Set ISM to 1 while the SATA-IP host core block is being reset (bit 7 (RESET) is 1). Do not change the value of ISM after the SATA-IP host core block has been released from the reset state (bit 7 (RESET) is 0).
15 to 12	—	All 0	R	This bit is fixed to 0 and cannot be set to 1.
11	DTA32M	0	R/W	DTA32M enables bits 31 to 29 of the descriptor DMA start address in descriptor table operation mode. This causes the termination flag to be changed from bit 31 to bit 0. 0: SH-Navi1-compatible mode 1: Enabled bits of the descriptor DMA start address are bits 31 to 2.
10 to 8	—	All 0	R	These bits are fixed to 0 and cannot be set to 1.
7	RESET	0	R/W	RESET controls the SATA-IP host core block. Setting this bit to 1 resets the SATA-IP host core block.
6 to 4	—	All 1	R	These bits are fixed to 1. Attempting to set these bits to 0 is ignored and not reflected in the value of the bits.

Bit	Bit Name	Initial Value	R/W	Description
3	DESE	0	R/W	DESE controls the descriptor table operation mode. 0: Descriptor functions disabled 1: Descriptor functions enabled
2	R/W	0	R/W	R/W controls FIFO read/write. 0: FIFO write (data-out operation at DMA transfer) 1: FIFO read (data-in operation at DMA transfer) Set this bit to 1 when reading data from the SATA device. Clear it to 0 when writing data to the SATA device.
1	STOP	0	R/W	This bit forces termination of DMA transfer. When writing 0: Ignored 1: Forcibly terminates data transfer When reading 0: Forced termination command is not issued. 1: Forced termination of data transfer command is issued. This bit is cleared to 0 when the next DMA starts. To power down (SATA internal clock turns off) while DMA is active (ACT = 1), DMA transfer should be forcibly terminated. Note: Transfer cannot always be resumed from the address at which DMA transfer has been forcibly terminated.
0	START	0	R/W	This bit initiates DMA transfer. If this bit set to 1 then the DMA transfer is started. When cleared to 0, this bit is ignored. When writing 0: Ignored 1: Starts DMA transfer When reading 0: DMA transfer is not active 1: DMA transfer is in busy state Note: Access to the task file register is prohibited while DMA is active.

### 50.2.3 ATAPI Status Register (ATAPI\_STATUS)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSBSY	SSDRDY	—	—	SSDRQ	—	—	SSERR	—	—	—	—	—	—	—	—
Initial value:	0	0	—	—	0	—	—	0	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SATAINT	—	—	SWERR	—	DNEND	DEVTRM	DEVINT	—	ERR	NEND	ACT
Initial value:	—	—	—	—	0	—	—	0	—	0	0	0	—	0	0	0
R/W:	R	R	R	R	R	R	R	R/WC0	R	R/WC0	R/WC0	R	R	R/WC0	R/WC0	R

Bit	Bit Name	Initial Value	R/W	Description
31	SSBSY	0	R	SSBSY corresponds to INTBSY of the SATA INT status register (SATAINTSTAT), the BSY bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
30	SSDRDY	0	R	SSDRDY corresponds to INTDRDY of the SATA INT status register (SATAINTSTAT), the DRDY bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
29, 28	—	—	R	Reserved The write value should always be 0.
27	SSDRQ	0	R	SSDRQ corresponds to INTDRQ of the SATA INT status register (SATAINTSTAT), the DRQ bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
26, 25	—	—	R	Reserved The write value should always be 0.
24	SSERR	0	R	SSERR corresponds to INTERR of the SATA INT status register (SATAINTSTAT), the ERR bit value of the shadow status register (SSTATUS). This bit is enabled when ISM = 1 and disabled (0) when ISM = 0. The write value should always be 0.
23 to 12	—	—	R	Reserved The write value should always be 0.
11	SATAINT	0	R	SATAINT indicates the status of host-intrq of the SATA-IP block. This bit is read-only. host_intrq is the internal interrupt request signal. For the interrupt source of this signal, refer to the description of the SATA INT Status register. The write value should always be 0.
10, 9	—	—	R	Reserved The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	SWERR	0	R/WC0	Software error bit. 1 in this bit indicates that the task file register is accessed when the DMA is active. Access to the SH-Navi2G/ATAPI-ATA-compatible task register is prohibited while DMA is active. This bit is set to 1 when a PIO transfer is performed during DMA transfer. In this case, no output is directed to the SATA-IP block and the access is ignored. Writing 0 resets this bit.
7	—	—	R	Reserved The write value should always be 0.
6	DNEND	0	R/WC0	DNEND indicates that all DMAs have successfully ended in the descriptor mode. Writing 0 resets this bit.
5	DEVTRM	0	R/WC0	DEVTRM is set to 1 when the DMA mode for the SATA_IP block is terminated before the number of DMA transfer bytes defined in the DMA transfer count register (ATAPI_DMA_TRANS_CNT) is reached (corresponds to P-ATA device's device termination operation). Writing 0 resets this bit.
4	DEVINT	0	R	DEVINT indicates the status of host_int_ata_intrq in the SATA-IP block (host_int_ata_intrq signal corresponds to the IDEINT signal of the P-ATA device and ATA of the SATA INT status register (SATAINTSTAT)). This bit is read-only. Since this LSI chip preserves no status, this bit is cleared to 0 when host_int_ata_intrq is set to 0. The SATA_HBA block regards any interrupt signal from the SATA-IP block as a level trigger input. host_int_ata_intrq is negated by the SATA device to clear the interrupt pending state after the shadow status register (SSTATUS) is read out. There is no time specification. The write value should always be 0.
3	—	—	R	Reserved The write value should always be 0.
2	ERR	0	R/WC0	ERR is set to 1 when the host forcibly terminated the DMA transfer. Writing 0 resets this bit.
1	NEND	0	R/WC0	NEND indicates that DMA has been successfully terminated. Writing 0 resets this bit.
0	ACT	0	R	ACT indicates that DMA is active. To power down (SATA internal clock turns off) while DMA is active (ACT = 1), DMA transfer should be forcibly terminated (STOP = 1). The write value should always be 0.

### 50.2.4 Interrupt Enable Register (ATAPI\_INT\_ENABLE)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

When 1 is written to a bit, the interrupt signal corresponding to the bit in the ATAPI status register (ATAPI\_STATUS) is enabled.

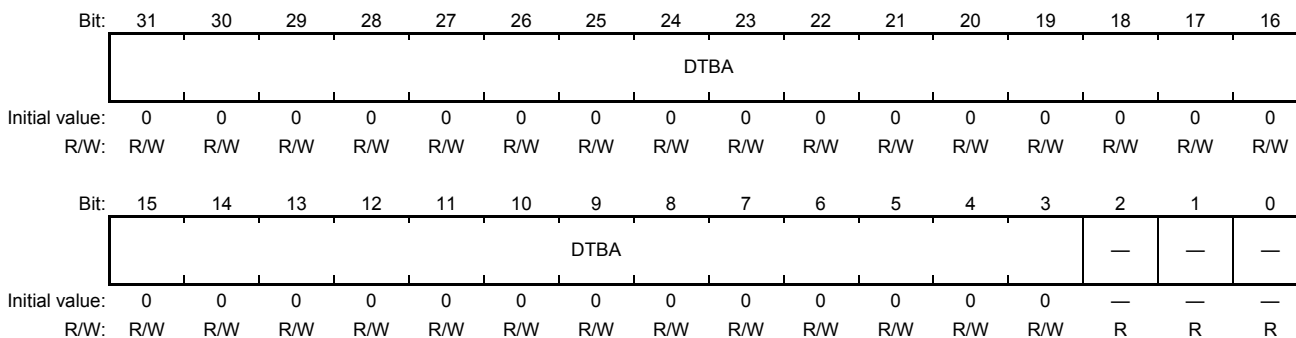

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	iSATAI NT	—	—	iSWER R	—	iDNEN D	iDEV TRM	iDEVIN T	—	iERR	iNEND	iACT
Initial value:	—	—	—	—	0	—	—	0	—	0	0	0	—	0	0	0
R/W:	R	R	R	R	R/W	R	R	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	—	R	Reserved The write value should always be 0.
11	iSATAINT	0	R/W	SATAINT interrupt enable
10, 9	—	—	R	Reserved The write value should always be 0.
8	iSWERR	0	R/W	SWERR interrupt enable
7	—	—	R	Reserved The write value should always be 0.
6	iDNEND	0	R/W	DNEND interrupt enable
5	iDEVTRM	0	R/W	DEVTRM interrupt enable
4	iDEVINT	0	R/W	DEVINT interrupt enable
3	—	—	R	Reserved The write value should always be 0.
2	iERR	0	R/W	ERR interrupt enable
1	iNEND	0	R/W	NEND interrupt enable
0	iACT	0	R/W	ACT interrupt enable bit. Since ACT is cleared automatically when a DMA transfer is completed, interrupt processing should be completed during assertion.

Note: Writing 1 to a bit enables the interrupt signal corresponding to the bit in the ATAPI status register. Do not clear the interrupt mask of the INTC while the SATA module is being reset. For resetting of the SATA module, refer to the descriptions of SRCR8 register and SRSTCLR8 register of the RESET module. For the interrupt mask of INTC, refer to the description of IMR4S3 register in the section on the INTC module.

### 50.2.5 Descriptor Table Base Address Register (ATAPI\_DTBA\_ADR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DTBA	0	R/W	These bits indicate the descriptor table base address. Bits 31 to 0 are used to set the descriptor table base address.
2 to 0	—	—	R	Reserved The write value should always be 0.

Note: This address does not change and the set value is retained even after the DMA becomes active.

#### (1) Descriptor Table

The descriptor table consists of the termination flag, the descriptor DMA start address (DDSTA), and the descriptor DMA transfer count (DDTRC).

##### (a) For SH-Navi1-compatible (DTA32M = 0, Initial value)

Table 50.3 Descriptor Table Map in Memory

Address	Data Description
DTBA	The first termination flag (bit 31 = 0) and DDSTA
DTBA + 4	The first DDTRC
DTBA + 8	The second termination flag (bit 31 = 0) and DDSTA
DTBA + 12	The second DDTRC
...	...
DTBA+8* (n - 1)	The n-th termination flag (bit 31 = 1) and DDSTA
DTBA+8* (n - 1) + 4	The n-th DDTRC

• Termination Flag and Descriptor DMA Start Address

Bit	Bit Name	Description
31	DTEND	DTEND controls the termination of a descriptor DMA operation 0: Validating the descriptor table When DTEND is 0, the system reads the DMA transfer count, transfers the DMA, and reads the next descriptor table. 1: Terminating the descriptor DMA operation When DTEND is 1, the system recognizes that the descriptor table is the last one.
30, 29	—	Reserved The write value should always be 0.
28 to 2	DDSTA	DDSTA shows the DMA start address in descriptor operation. Bits 28 to 0 are used to set the descriptor table start address on a byte basis. Bits 1 and 0 are ignored because it is necessary to secure the boundary of 32-bit addresses in the DMA start address.
1, 0	—	Reserved The write value should always be 0.

The valid flag and descriptor DMA start address should be set in the descriptor table base address + "m" in the memory, where m is multiple of 2 (such as 0, 2, 4, ...).

**(b) When Bits 31 to 29 of Descriptor DMA Start Address are Valid (DTA32M = 1)**

**Table 50.4 Descriptor Table Map in Memory**

Address	Data Description
DTBA	The first termination flag (bit 0 = 0) and DDSTA
DTBA + 4	The first DDTRC
DTBA + 8	The second termination flag (bit 0 = 0) and DDSTA
DTBA + 12	The second DDTRC
...	...
DTBA + 8* (n - 1)	The n-th termination flag (bit 0 = 1) and DDSTA
DTBA + 8* (n - 1) + 4	The n-th DDTRC

• Termination Flag and Descriptor DMA Start Address

Bit	Bit Name	Description
31 to 2	DDSTA	DDSTA shows the DMA start address in descriptor operation. Bits 31 to 0 are used to set the descriptor table start address on a byte basis. Bits 1 and 0 are ignored because it is necessary to secure the boundary of 32-bit addresses in the DMA start address.
1	—	Reserved The write value should always be 0.
0	DTEND	DTEND controls the termination of a descriptor DMA operation. 0: Validates the descriptor table When DTEND is 0, the DMA transfer count is read, DMA transfer is performed, and the next descriptor table is read. 1: Terminates the descriptor DMA operation When DTEND is 1, the last descriptor table is detected.

The valid flag and descriptor DMA start address should be set in the descriptor table base address + "m" in the memory, where m is multiple of 2 (such as 0, 2, 4, ...).

• Descriptor DMA Transfer Count

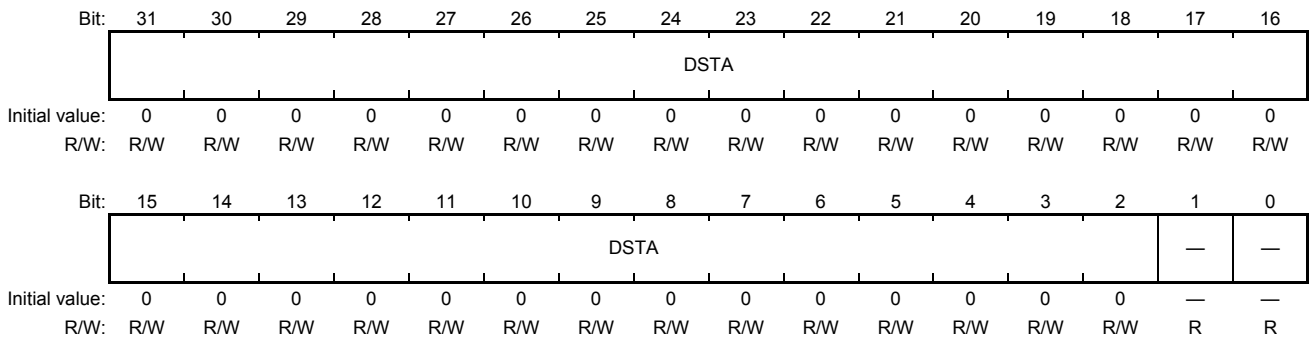

Bit	Bit Name	R/W	Description
31 to 29	—	R	Reserved The write value should always be 0.
28 to 1	DDTRC	R/W	These bits set the DMA transfer count during descriptor operation. Bits 28 to 0 are used to set the DMA transfer count on a byte basis. Bit 0 is ignored because the SATA data bus is handled on a 16-bit basis (on a word basis).
0	—	R	Reserved The write value should always be 0.

The descriptor DMA transfer count should be set in the descriptor table base address + "m" in the memory, where the value of m is any multiple number of 2 plus 1 (such as 1, 3, 5, ...).

**50.2.6 DMA Start Address Register (ATAPI\_DMA\_START\_ADR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	DSTA	All 0	R/W	DSTA sets a DMA start address that indicates the data transfer start address in the memory. Bits 31 to 0 are used to set the DMA start address on a byte basis.  Bits 1 and 0 are ignored because it is necessary to secure the boundary of 32-bit addresses in the DMA start address.
1, 0	—	—	R	Reserved  The write value should always be 0.

Note: This address does not change and the set value is retained even after the DMA becomes active.

**50.2.7 DMA Transfer Count Register (ATAPI\_DMA\_TRANS\_CNT)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	—	R	Reserved The write value should always be 0.
28 to 1	DTRC	All 0	R/W	DTRC sets the DMA transfer count. Bits 28 to 0 are used to set the DMA transfer count on a byte basis. Bit 0 is ignored because the ATAPI data bus is handled on a 16-bit basis (on a word basis).
0	—	—	R	Reserved The write value should always be 0.

Note: This count value does not change and the set value is retained even after the DMA becomes active.

**50.2.8 ATAPI Control 2 Register (ATAPI\_CONTROL2)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	LWORD SWAP	WORD SWAP	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	—	R	Reserved The write value should always be 0.
2	LWORDSWAP	0	R/W	LWORDSWAP controls the swapping of the upper 32-bit data and the lower 32-bit data on a 2-longword basis (64-bit data) on the AXI bus. 0: Longword swap is not executed. The 64-bit data on the AXI bus appears in a big endian format. 1: Longword swap is executed between the SATA interface and the AXI bus interface. Note that longword swap is only available on data transfer when bit 0 (START) in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.
1	WORDSWAP	0	R/W	WORDSWAP controls the swapping of the upper 16-bit data and the lower 16-bit data on a longword basis when the 64-bit data bus is enabled in the AXI bus. 0: Word swap is not executed. 1: Word swap is executed between the SATA interface and the AXI bus interface. Note that word swap is only available on data transfer when bit 0 (START) in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.
0	—	—	R	Reserved The write value should always be 0.

**50.2.9 ATAPI Signal Status Register (ATAPI\_SIG\_ST)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPIOR DY	DMAR Q
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	—	R	Reserved The write value should always be 0.
1	DPIORDY	—	R	DPIORDY indicates the state of the IF signal for PIO transfer in the SATA_IP block.
0	DMARQ	—	R	DMARQ indicates ATAPIDMARQ (IDEDREQ) signal state.

**Note:** Since the SATA interface has separate PIO and DMA interfaces, the DDMARDY signal of conventional ATAPI cannot be monitored.  
 The IORDY signal is not emulated. DPIORDY monitors the PIO-transfer interface signal only. Monitoring of the DMA-transfer interface signals is not possible.  
 The DPIORDY bit actually monitors the HREADY signal, i.e. the AHB for the internal PIO bus.

**50.2.10 Byte Swap Register (ATAPI\_BYTE\_SWAP)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BYTE SWAP
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	—	R	Reserved The write value should always be 0.
0	BYTESWAP	0	R/W	BYTESWAP controls the swapping of the upper 8-bit data and the lower 8-bit data in the SATA interface. 0: Byte swap is not executed between the SATA interface and the AXI bus. 1: Byte swap is executed between the SATA interface and the AXI bus. Note that byte swap is only available on data transfer when START in the ATAPI control register (ATAPI_CONTROL1) = 1: DMA mode start.

**50.2.11 BIST Config Register (BISTCONF)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The BISTCONF register is used to configure the operation to be performed in BIST mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOOPB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

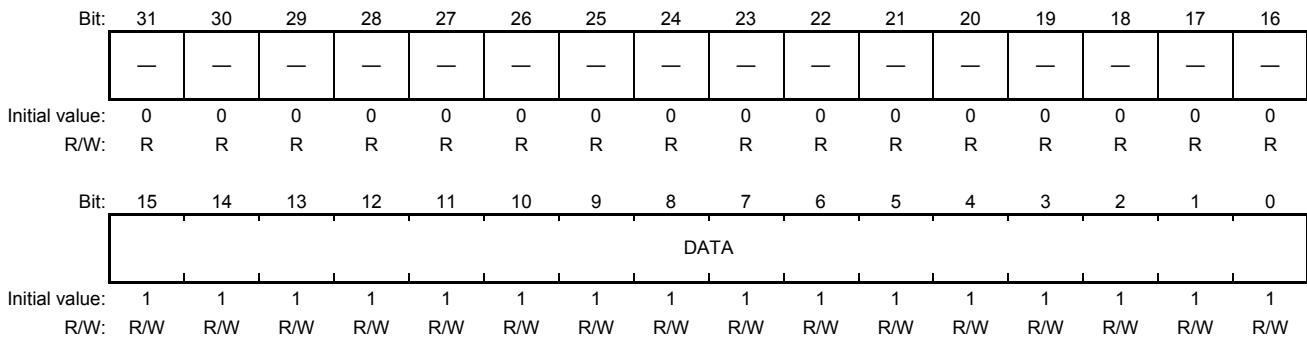

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	LOOPB	0	R/W	Loopback mode bit (Loopback Mode) 0: Loopback (for far-end retimed loopback mode) is not formed in the link layer of the host. 1: Loopback (for far-end retimed loopback mode) is formed in the link layer of the host.

- Notes:
1. No read access can be made to this register and no correct data can be read from this register until the PHYRDY state is established. (See section 50.2.1, Note on the Access to the Registers Allocated to H'1018 to H'10A8.)
  2. BIST mode is not operational unless the SATA interface is in PHYRDY state.

**50.2.12 Shadow Data Register (DATA) (SDATA)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Shadow Data Register corresponds to the ATA standard's Data Register/Port. This is a data register that is read and written in PIO transfer mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	DATA	All 1	R/W	Transmit/receive data (SHADOW_DATA)

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. In PIO transfer mode, that is, except when the host\_shdw\_stat\_DRQ signal is being asserted, both of R/W operations are canceled, and therefore the initial value H'FFFF is not read out but H'0000 is read out. When a read attempt is made after the PIO mode read transfer, the last read value is read out.
  3. Access to the data register is prohibited while DMA is active. The SDATA register is accessible.

**50.2.13 Shadow Error Register (SERR[Read Mode]) (SSERR[Read Mode])**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow error register corresponds to the ATA standard's error register. (The actual register is on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	—	—	—	—	SERR								—	—
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7 to 0	SERR	All 1	R	Error monitor bit (SHADOW_ERROR) The bit definitions except that for bit 2 vary with the commands. Bit 2: ABRT bit. Set to 1 when the command that is issued is Abort.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a write to the address of this register essentially causes the shadow features register (SFEATURES[Write Mode]) (SSFEATURES[Write Mode]) to be accessed.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. Access to the SERR register is prohibited while DMA is active. The SSERR register is accessible.

**50.2.14 Shadow Features Register (SFEATURES[Write Mode]) (SSFEATURES[Write Mode])**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow features register corresponds to the ATA standard's features register. (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	—	—	—	—	SFEATURES								—	—
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1		
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W		

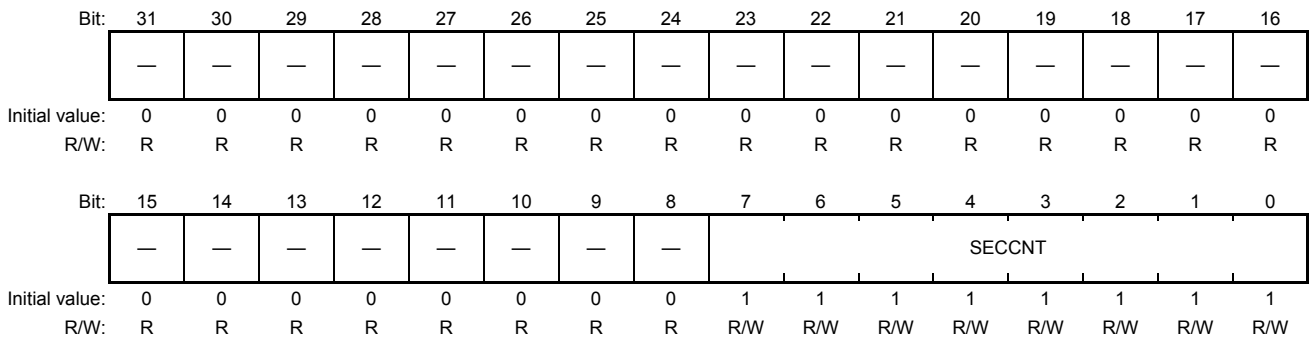

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	SFEATURES	All 1	W	Subcommand setup bits (SHADOW_FEATURES) The bit definitions vary with the commands.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a read from the address of this register essentially causes the shadow error register (SERR[Read Mode]) (SSERR[Read Mode]) to be accessed.
  2. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 50.4.2, Extended ATA Registers.
  3. Access to the SFEATURES register is prohibited while DMA is active. The SSFEATURES register is accessible.

**50.2.15 Shadow Sector CNT Register (SECCNT) (SSECCNT)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow sector CNT register corresponds to the ATA standard's sector count register.  
 (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	SECCNT	All 1	R/W	Sector count bits (SHADOW_SECTOR_CNT) The bit definitions vary with the commands.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 50.4.2, Extended ATA Registers.
  4. Access to the SECCNT register is prohibited while DMA is active. The SSECCNT register is accessible.

### 50.2.16 Shadow LBA Low Register (LBALOW) (SLBALOW)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow LBA low register corresponds to the ATA standard's LBA low (sector number) register.  
 (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LBALOW							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBALOW	All 1	R/W	LBA_low address bits (SHADOW_LBA_LOW) The bit definitions vary with the commands.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 50.4.2, Extended ATA Registers.
  4. Access to the LBALOW register is prohibited while DMA is active. The SLBALOW register is accessible.

### 50.2.17 Shadow LBA Mid Register (LBAMID) (SLBAMID)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow LBA mid register corresponds to the ATA standard's LBA mid (cylinder low) register. (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBAMID	All 1	R/W	LBA_MID address bits (SHADOW_LBA_MID) The bit definitions vary with the commands.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 50.4.2, Extended ATA Registers.
  4. Access to the LBAMID register is prohibited while DMA is active. The SLBAMID register is accessible.

**50.2.18 Shadow LBA High Register (LBAHIGH) (SLBAHIGH)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow LBA high register corresponds to the ATA standard's LBA high (cylinder high) register. (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	—	—	—	—	LBAHIGH								—	—
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1		
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W		

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	LBAHIGH	All 1	R/W	LBA_high address bits (SHADOW_LBA_HIGH) The bit definitions vary with the commands.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. This register functions in a 2-stage FIFO configuration when a device that is compatible with the 48-bit Address features set is connected. For details, see section 50.4.2, Extended ATA Registers.
  4. Access to the LBAHIGH register is prohibited while DMA is active. The SLBAHIGH register is accessible.

**50.2.19 Shadow Device/Head Register (DEVHEAD) (SDEVHEAD)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow device/head register corresponds to the ATA standard's device/head register.  
 (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DEVHEAD							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DEVHEAD	All 1	R/W	Device function select bits (SHADOW_DEVHEAD) The bit definitions except those for bits 7, 5, and 4 vary with the commands. Bits 7 and 5: Obsolete Bit 4: DEV bit. Selects either the Master or Slave. This bit must always be set to 0.

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. Access to the DEVHEAD register is prohibited while DMA is active. The SDEVHEAD register is accessible.

### 50.2.20 Shadow Status Register (SSTATUS[Read Mode]) (SSSTATUS[Read Mode])

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The SSTATUS or SSSTATUS register corresponds to the ATA standard's status register. Its value can be read out correctly only when the DEV bit (bit 4) of the shadow device/head register (DEVHEAD) (SDEVHEAD) is set to 0. Its read value is always H'0000\_0000 when the DEV bit is set to 1.

Accessing this register for read causes the ATA-sourced host\_intrq interrupt signal to be negated. (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	BSY	DRDY	DFSE	SSTATUS	DRQ	—	—	ERR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7	BSY	0	R	BSY bit
6	DRDY	1	R	DRDY bit
5	DFSE	1	R	DF/SE bit
4	SSTATUS	1	R	Definition varies with the command.
3	DRQ	1	R	DRQ bit
2, 1	—	11	R	Reserved This bit is always read as 1.
0	ERR	1	R	ERR/CHK bit

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a write to the address of this register essentially causes the shadow command register (SCOM[Write Mode]) (SSCOM[Write Mode]) to be accessed.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. Access to the SSTATUS register is prohibited while DMA is active. The SSSTATUS register is accessible.

**50.2.21 Shadow Command Register (SCOM[Write Mode]) (SSCOM[Write Mode])**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow command register corresponds to the ATA standard's command register. The ATA command code is set by this register.

Accessing this register for write causes the command to be issued to the device (sending command register FIS). (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	—	—	—	—	SCOM								—	—
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1		
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W		

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	SCOM	All 1	W	Transmit command setup bits (SHADOW_COMMAND)

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a read from the address of this register essentially causes the shadow status register (SSTATUS[Read Mode]) (SSSTATUS[Read Mode]) to be accessed.
  2. Access to the SCOM register is prohibited while DMA is active. The SSCOM register is accessible.

### 50.2.22 Shadow Alternates Status Register (SALTSTS[Read Mode]) (SSALTSTS[Read Mode])

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The SALTSTS or SSALTSTS register is the ATA standard's alternate status register. Its value can be read out correctly only when the DEV bit (bit 4) of the shadow device/head register (DEVHEAD) (SDEVHEAD) is set to 0. Its read value is always H'0000\_0000 when the DEV bit is set to 1.

The bits of this register always have the same bit value as the corresponding bits of the shadow status register. Any attempt to access this register for read, however, does not cause the ATA-sourced host\_intrq interrupt signal to be negated.

(\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

control register (SDEVCON[Write Mode])

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	ABSY	ADRDY	ADFSE	SALTSTS	ADRQ	—	—	AERR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7	ABSY	0	R	BSY bit
6	ADRDY	1	R	DRDY bit
5	ADFSE	1	R	DF/SE bit
4	SALTSTS	1	R	Definition varies with the command.
3	ADRQ	1	R	DRQ bit
2, 1	—	11	R	Reserved These bits are always read as 1.
0	AERR	1	R	ERR/CHK bit

- Notes:
1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a write to the address of this register essentially causes the shadow device control register (SDEVCON[Write Mode]) (SSDEVCON[Write Mode]) to be accessed.
  2. The initial value of this register cannot be read out since the value of this register is normally rewritten by the device immediately after the interface gets ready for communication following a power-on reset. See section 50.4.3, Signature of the Shadow Register (INFORMATIVE).
  3. Access to the SALTSTS register is prohibited while DMA is active. The SSALTSTS register is accessible.

**50.2.23 Shadow Device Control Register (SDEVCON[Write Mode]) (SSDEVCON[Write Mode])**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The shadow device control register is the ATA standard's device control register.

(\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HOB	—	—	—	—	SRST	NIEN	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	R	R	R	R	W	W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7	HOB	0	W	HOB bit
6 to 3	—	All 0	R	Reserved The write value should always be 0.
2	SRST	0	W	SRST bit
1	NIEN	0	W	nIEN bit
0	—	0	R	Reserved The write value should always be 0.

- Notes: 1. Refer to the ATA/ATAPI-7 and Serial-ATA specification for further information about this register. Note that a read from the address of this register essentially causes the shadow alternates status register (SALTSTS[Read Mode]) (SSALTSTS[Read Mode]) to be accessed.
2. Access to the SDEVCON register is prohibited while DMA is active. The SSDEVCON register is accessible.

**50.2.24 SATA Extend ICC Register**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	ICC	All 0	R	ICC stands for Isochronous Command Completion

Note: Refer to the Serial-ATA specification for further information about this register.

**50.2.25 SATA Extend Auxiliary Register**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Auxiliary	All 0	R	Auxiliary Contains parameter values specified on per command basis

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.26 SCR SStatus Register (SCRSSTS)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	IPM			SPD				DET				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0.
11 to 8	IPM	0000	R	Interface power manager state monitor bits These bits indicate the interface's Power Management mode or state. 0000: No device is connected or the device is not ready for communication. 0001: Active mode 0010: Partial mode 0110: Slumber mode Other: Setting prohibited. After a transition to the slumber mode from the partial mode by automatic partial to slumber, IPM is set to B'0110 to indicate the slumber mode.
7 to 4	SPD	0000	R	Communication speed monitor bits These bits indicate the speed at which the interface communicates with the device. 0000: No device is connected or the device is not ready for communication. 0001: First generation (1.5 Gbps) 0010: Second generation (3.0 Gbps) Other: Setting prohibited.
3 to 0	DET	0000	R	Device communication state monitor bits These bits indicate the PHY state with respect to device detection. 0000: No device is detected or the device is not ready for communication. 0001: A device is detected but the device is not ready for communication. 0011: A device is detected and the device is ready for communication. 0100: Offline mode or loopback mode Other: Setting prohibited.

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.27 SCR SError Register (SCRSERR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	DIAGA	DIAGX	DIAGF	DIAGT	DIAGS	DIAGH	DIAGC	DIAGD	DIAGB	DIAGW	DIAGI	DIAGN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	ERRE	ERRP	ERRC	ERRT	—	—	—	—	—	—	ERRM	ERRI
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R	R	R	R	R	R	R/WC1	R/WC1

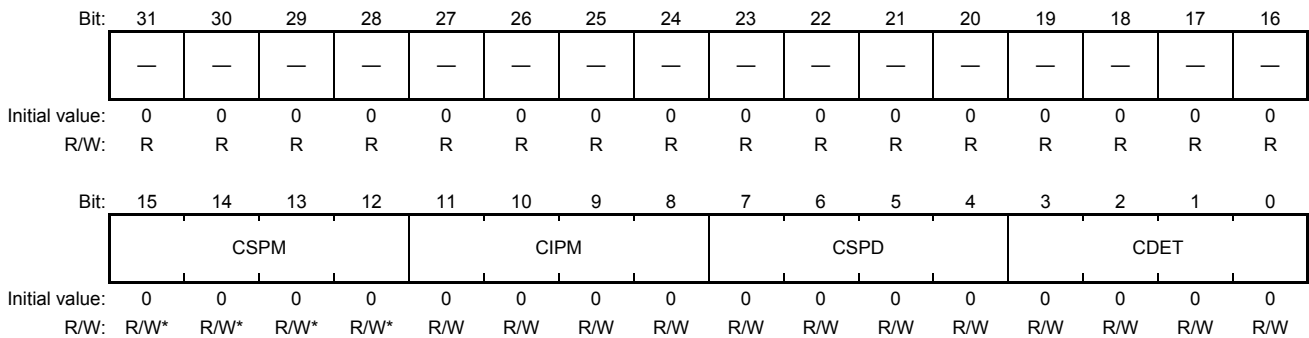

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	DIAGA	0	R/WC1	DIAGA is used to sense COMWAKE before detecting a device. Port Selector Presence Detect (set when COMWAKE is detected before the Phy layer detects a device)
26	DIAGX	0	R/WC1	DIAGX is used to sense the change in device connection state. Exchanged (Set when the Phy layer detects a device connection or disconnection)
25	DIAGF	0	R/WC1	FIS type error bit Unrecognized FIS Type
24	DIAGT	0	R/WC1	Abnormal timing transfer result reception bit Transport state transition error (Set when transfer result notification is received at an invalid timing)
23	DIAGS	0	R/WC1	Abnormal state transition bit Link Sequence Error (Set when an illegal state transition occurs in the Link layer)
22	DIAGH	0	R/WC1	Handshake error bit
21	DIAGC	0	R/WC1	CRC error bit
20	DIAGD	0	R/WC1	Disparity error bit
19	DIAGB	0	R/WC1	10b/8b decode error bit
18	DIAGW	0	R/WC1	COMWAKE detect bit COMWAKE Detect (Set when COMWAKE is detected at any timing)
17	DIAGI	0	R/WC1	Error state bit Phy Internal Error (Set when an error occurs in the Phy layer)
16	DIAGN	0	R/WC1	Transfer Ready state change bit PHYRDY change (Set when the PhyRdy signal indicating the Phy layer's transfer ready state is toggled)
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11	ERRE	0	R/WC1	Internal FIFO flow error bit Internal Error (Set when a flow error occurs in the internal FIFO. Perform a software reset whenever this bit is set.)
10	ERRP	0	R/WC1	Protocol error bit Protocol Error (Set when either one of the following conditions occurs): An illegal state transition occurs in the Link layer (same as the DIAGS bit) An unsupported FIS is received (same as the DIAGF bit). The size of the received FIS is found invalid. A transfer result notification is received at an invalid timing (same as the DIAGT bit).
9	ERRC	0	R/WC1	FIS transmission PhyRdy signal negated bit Non-recovered persistent communication or data integrity error (Set when the PhyRdy signal is negated during transmission of a FIS except Data FIS (including retries))
8	ERRT	0	R/WC1	Data FIS transfer error bit Non-recovered transient data integrity error (Set when an error occurs during Data FIS transfer. Be sure to check this bit during PIO reads.)
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ERRM	0	R/WC1	Communication error recovery monitor bit Recovered communications error (The PhyRdy signal indicating the Phy layer's transfer ready state is negated but asserted again within approximately 200 $\mu$ s.)
0	ERRI	0	R/WC1	Retransmission result bit Recovered data integrity error (Set when retransmission of an FIS is successful)

- Notes:
1. Refer to the Serial-ATA specification for further information about this register.
  2. There are cases in which the DIAGW and DIAGN bits of this register are already set before a first access is made since the initial data is automatically set in the register when it is provided with a clock signal after a power-on reset. Consequently, it is recommended that all bits of this register be cleared (writing H'FFFF\_FFFF) at the beginning of the startup sequence.
  3. The operation of this register is irrelevant to the settings of the SATA INT status register (SATAINTSTAT) and SATA INT mask register (SATAINTMASK). The way in which the SCR SError register behaves remain unchanged even when bits b1, b2, and b3 of the SATA INT mask register are set (that is, interrupt sources are masked as the result of the update of the SCR SError result).

**50.2.28 SCR SControl Register (SCRSCON)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 12	CSPM	0000	R/W*	Power Management Mode transition request bits (SPM) CSPM is a set of bits that request for the state of the Power Management mode. Set as follows to have Power Management to transit to the required state: 0000: No request 0001: Request transition to the Partial Mode. 0010: Request transition to the Slumber Mode. 0100: Request to restoration to the Active Mode. Other: Setting prohibited. (* The transition request to the Partial/Slumber Mode is not retried. When using this field, unmask the SLUMMSK and PARTIMSK bits (bits 6 and 5) of the SATA INT mask register (SATAINTMASK) and enable "device rejects transition to Slumber Mode" and "device rejects transition to Partial Mode" interrupts.)
11 to 8	CIPM	0000	R/W	Interface Power Management Mode enable bit (IPM) CIPM enables or disables the interface's Power Management mode. 0000: No limitation. 0001: Partial Mode Disable 0010: Slumber Mode Disable 0011: Partial/Slumber Mode Disable Other: Setting prohibited.
7 to 4	CSPD	0000	R/W	Communication speed bits (SPD) The CSPD bits define the limiting speed at which communication with the device is to be made. 0000: No limitation (same as B'0010) 0001: First generation (1.5 Gbps) 0010: Second generation (3.0Gbps) or less Other: Setting prohibited. (This field is not initialized by a hardware reset. It is initialized at power-on reset time.)

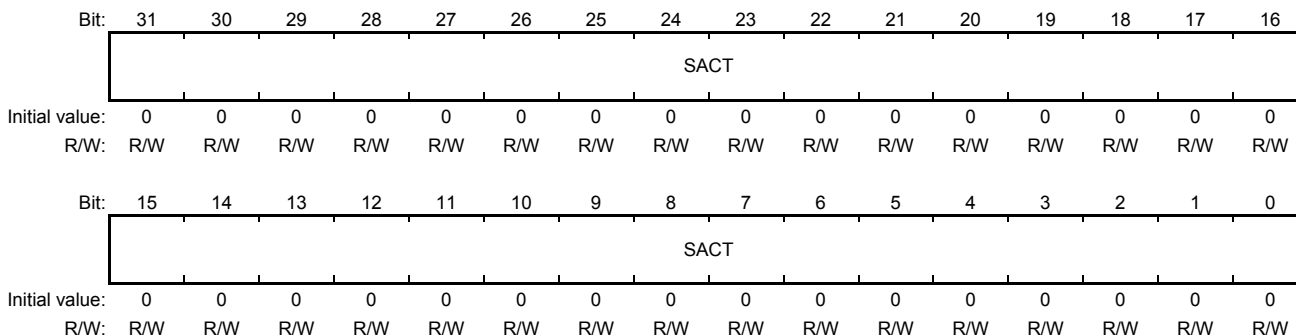

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CDET	0000	R/W	RESET/Offline mode bits (DET) The CDET bits specify the RESET/Offline mode. 0000: No request 0001: RESET. Handled as a hardware reset. 0100: Places the PHY in offline mode. Other: Setting prohibited. (The SCR SControl register is initialized after the switching of the CDET field value from B'0001 to B'0000 is detected. Consequently, the values of the CSPM, CIPM, and CSPD fields are invalid when a write access such that the CDET field is set to B'0000 is made to this register.)

- Notes:
1. Refer to the Serial-ATA specification for further information about this register.
  2. It is impossible to check the value of this field since the field is reset to B'0000 as soon as setting of the value is internally detected.

**50.2.29 SCR SActive Register (SCRSACT)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The SCR SActive register is used to set up the TAG value to be used for Native Command Queuing.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SACT	All 0	R/W	b31: Corresponds to a TAG value of B'11111. b30: Corresponds to a TAG value of B'11110. b29: Corresponds to a TAG value of B'11101. b28: Corresponds to a TAG value of B'11100. b27: Corresponds to a TAG value of B'11011. b26: Corresponds to a TAG value of B'11010. b25: Corresponds to a TAG value of B'11001. b24: Corresponds to a TAG value of B'11000. b23: Corresponds to a TAG value of B'10111. b22: Corresponds to a TAG value of B'10110. b21: Corresponds to a TAG value of B'10101. b20: Corresponds to a TAG value of B'10100. b19: Corresponds to a TAG value of B'10011. b18: Corresponds to a TAG value of B'10010. b17: Corresponds to a TAG value of B'10001. b16: Corresponds to a TAG value of B'10000. b15: Corresponds to a TAG value of B'01111. b14: Corresponds to a TAG value of B'01110. b13: Corresponds to a TAG value of B'01101. b12: Corresponds to a TAG value of B'01100. b11: Corresponds to a TAG value of B'01011. b10: Corresponds to a TAG value of B'01010. b9: Corresponds to a TAG value of B'01001. b8: Corresponds to a TAG value of B'01000. b7: Corresponds to a TAG value of B'00111. b6: Corresponds to a TAG value of B'00110. b5: Corresponds to a TAG value of B'00101. b4: Corresponds to a TAG value of B'00100. b3: Corresponds to a TAG value of B'00011. b2: Corresponds to a TAG value of B'00010. b1: Corresponds to a TAG value of B'00001. b0: Corresponds to a TAG value of B'00000.

- Notes:
1. Refer to the Serial-ATA specification for further information about this register.
  2. This register is write-only. To reset this register, it is necessary to reset the device (Software Reset will do).

### 50.2.30 SATA INT Status Register (SATAINTSTAT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bits 31 to 24 of the SATA INT status register are Shadow Status bits and mirror the value of the shadow status register. As with the shadow status register, accessing this register for read causes the ATA-sourced host\_int\_ata\_intrq interrupt signal to be negated. (\* The real entity of the register lies on the device side; the host side value is handled as a mirror value.)

Bits 11 to 0 of this register identify the interrupt source of the host\_intrq signal. The bits that are masked by the SATA INT mask register (SATAINTMASK) do not cause the host\_intrq signal to be asserted when the corresponding interrupt source event occurs. In this case, the pertinent bit is not set either.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INT BSY	INT DRDY	INT DFSE	INTSST ATUS	INT DRQ	—	—	INT ERR	—	—	—	—	—	—	—	—
Initial value:	0	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SDBF	SLUMR	PARTI R	VEND	BIST	SLUM	PARTI	DMAST	SERR	ERR	ERR CRT	ATA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC	RC

Bit	Bit Name	Initial Value	R/W	Description
31	INTBSY	0	R	BSY bit
30	INTDRDY	1	R	DRDY bit
29	INTDFSE	1	R	DF/SE bit
28	INTSSTATUS	1	R	Definition varies with the command.
27	INTDRQ	1	R	DRQ bit.
26, 25	—	11	R	Reserved These bits are always read as 1.
24	INTERR	1	R	ERR/CHK bit
23 to 12	—	All 0	R	Reserved These bits are always read as 0.
11	SDBF	0	RC	Set Device Bits FIS reception Refer to notes 3 and 4.
10	SLUMR	0	RC	A request for transition to the Slumber state has been received (for device-initiated power management, i.e. DIPM). Refer to notes 3 and 4
9	PARTIR	0	RC	A request for transition to the Partial state has been received (for device-initiated power management, i.e. DIPM). Refer to notes 3 and 4.
8	VEND	0	RC	Vendor Specific FIS reception Refer to notes 3 and 4.
7	BIST	0	RC	BIST Active FIS reception Refer to notes 3 and 4.

Bit	Bit Name	Initial Value	R/W	Description
6	SLUM	0	RC	Device rejects transition to Slumber Mode. Refer to notes 2, 3, and 4.
5	PARTI	0	RC	Device rejects transition to Partial Mode. Refer to notes 2, 3, and 4
4	DMAST	0	RC	Same meaning as DMA Setup FIS reception (fpdma_req signal asserted) Refer to notes 3 and 4.
3	SERR	0	RC	SCR SERROR register update Refer to notes 3 and 4.
2	ERR	0	RC	SCR SERROR register (SCRSERR) ERRE, ERRP, ERRC, ERRT, ERM, and ERRI bits update Refer to notes 3 and 4.
1	ERRCRT	0	RC	SCR SERROR register (SCRSERR) ERRE, ERRP, and ERRT bits update Refer to notes 1, 3, and 4.
0	ATA	0	RC	ATA source (equivalent to P-ATA's INTRQ) Refer to notes 3 and 4.

Notes: 1. When the "SCR SError register ERRE, ERRP, and ERRT bits update" interrupt bit is set, it indicates that the condition cannot be recovered by this host controller module. In such a case, take appropriate actions according to the operating state established before the error occurred and the value of the SCR SError register (SCRSERR).

Example:

- 1) When the ERRT bit of the SCR SError register (SCRSERR) is set on completion of a PIO Read (data-in) transfer:  
The read data contains an error bit. Restart processing at the issuance of the command.
  - 2) When the ERRE bit of the SCR SError register (SCRSERR) is set during DMA transfer:  
The data that is being transferred contains an error but since it cannot be detected by the device, it is necessary to perform a software reset and restart processing at the issuance of the command.
  - 3) When the ERRP bit of the SCR SError register (SCRSERR) is set:  
Perform a hardware reset and re-execute the preceding operation.
2. When a "device rejects transition to Slumber Mode" or "device rejects transition to Partial Mode" interrupt occurs, no request is reissued (retried) to the device. If requests should be made again, reset the SCR SControl register with a correct value.
  3. Table 50.5 lists the combinations of twelve interrupt source bits (bit 11 to bit 0) that are likely to be set at the same timing.

**Table 50.5 Interrupt Source Bits That are Likely to be Set at the Same Time**  
(√: Possible, —: Impossible)

	Bit11	Bit10	bit9	bit8	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
Bit11	—	—	—	—	—	—	—	—	√	√	√	—
bit10	—	—	—	—	—	—	—	—	√	√	√	—
bit9	—	—	—	—	—	—	—	—	√	√	√	—
bit8	—	—	—	—	—	—	—	—	√	√	√	—
bit7	—	—	—	—	—	—	—	—	√	√	√	—
bit6	—	—	—	—	—	—	—	—	√	√	√	—
bit5	—	—	—	—	—	—	—	—	√	√	√	—
bit4	√	—	—	—	—	—	—	—	√	√	√	—
bit3	√	√	√	√	√	√	√	√	√	√	√	√
bit2	√	√	√	√	√	√	√	√	√	√	√	√
bit1	—	√	√	√	√	√	√	√	√	√	√	√
bit0	—	—	—	—	—	—	—	—	√	√	√	√

4. Examples of operations that are performed when the SATA INT status register (SATAINTSTAT) interrupt sources are masked by the SATA INT mask register (SATAINTMASK)

Example 1): The SATA INT mask register (SATAINTMASK) is not set up for an interrupt source before the pertinent interrupt source occurs.

If BIST Activate FIS which is the interrupt source for bit7 is received when SATAINTMASK[11:0] = B'1111\_0111\_1111,

the results are:

SATAINTSTAT[11:0] = B'0000\_1000\_0000;

host\_intrq: High (asserted)

Example 2): The SATA INT mask register (SATAINTMASK) is set up for an interrupt source before the pertinent interrupt source occurs.

If Vendor Specific FIS which is the interrupt source for bit8 is received when

SATAINTMASK[11:0] = B'1111\_0111\_1111;

the results are:

SATAINTSTAT[11:0] = B'0000\_0000\_0000;

host\_intrq: Low (not asserted)

Example 3): Another interrupt source occurs after an interrupt occurs.

If BIST Activate FIS which is the interrupt source for bit7 is received when SATAINTMASK[11:0] = B'1111\_0111\_1110,

SATAINTSTAT[11:0] = B'0000\_0000\_0001, and host\_intrq: High (asserted),

the results are:

SATAINTSTAT[11:0] = B'0000\_1000\_0001;

host\_intrq: High (remains asserted)

Example 4): Another interrupt source (but the interrupt source is masked on) occurs after an interrupt occurs.

If Vendor Specific FIS which is the interrupt source for bit8 is received when

SATAINTMASK[11:0] = B'1111\_0111\_1110, SATAINTSTAT[11:0] = B'0000\_0000\_0001, and

host\_intrq: High (asserted),

the results are:

SATAINTSTAT[11:0] = B'0000\_0000\_0001;

host\_intrq: High (remains asserted)

### 50.2.31 SATA INT Mask Register (SATAINTMASK)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The SATA INT mask register is used to mask the interrupt sources configured in the SATA INT status register (SATAINTSTAT). Interrupt sources corresponding to bits for which 1s have been specified are masked.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SDBF MSK	SLUMR MSK	PARTIT MSK	VEND MSK	BIST MSK	SLUM MSK	PARTI MSK	DMAST MSK	SERR MSK	ERR MSK	ERR CRT MSK	ATA MSK
Initial value:	0	0	0	0	1	0	0	1	1	1	1	1	1	1	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	SDBFMSK	1	R/W	Masks the "Set Device Bits FIS received" interrupt.
10	SLUMRMSK	0	R/W	Mask for the "request for transition to Slumber mode" interrupt (for DIPM).
9	PARTITMSK	0	R/W	Mask for the "request for transition to Partial mode" interrupt (for DIPM).
8	VENDMSK	1	R/W	Masks the "Vendor Specific FIS received" interrupt.
7	BISTMSK	1	R/W	Masks the "BIST Activate FIS received" interrupt.
6	SLUMMSK	1	R/W	Masks the "device reject transition to Slumber mode" interrupt.
5	PARTIMSK	1	R/W	Masks the "device reject transition to Partial mode" interrupt.
4	DMASTMSK	1	R/W	Masks the "DMA Setup FIS received" interrupt.
3	SERRMSK	1	R/W	Masks the "SCR SError register (SCRSERR) update" interrupt.
2	ERRMSK	1	R/W	Masks the "SCR SError register (SCRSERR) ERRE, ERRP, ERRC, ERRT, ERRM, and ERRI bits update" interrupt.
1	ERRCRTMSK	0	R/W	Masks the "SCR SError register (SCRSERR) ERRE, ERRP, and ERRT bits update" interrupt.
0	ATAMSK	0	R/W	Masks the "ATA source (equivalent to P-ATA's INTRQ)" interrupt. The NIEN bit of the shadow device control register (SDEVCON) provides the same effect.

**50.2.32 PHY STOP Register (PHYSTOP)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PHY STOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
0	PHY STOP	0	R/W	0: Normal 1: PHY STOP

Note: PHY STOP mode is used to stop the AFE. Apply a power-on reset to return the AFE from the PHY STOP mode (a software reset will not do this).

### 50.2.33 Rx DMA Setup FIS Dword0 Register (DMADW0)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword0 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AUTO ACT	DMA INT	DMA DIR	—	PMPORT				FISTYPE							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

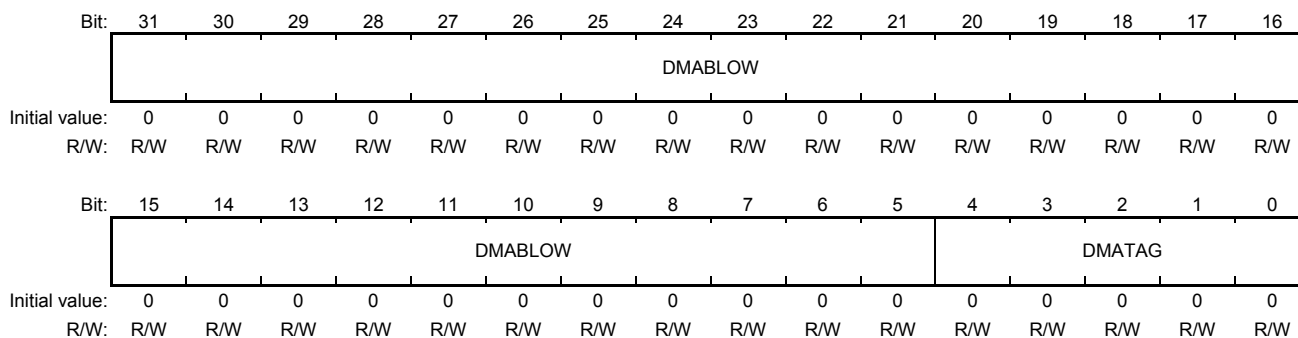

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	AUTOACT	0	R/W	Auto-Activation bit 1 indicates Auto-Activation.
14	DMAINT	0	R/W	Interrupt bit
13	DMADIR	0	R/W	Data transfer direction bit The direction of the next data transfer. 0: Host -> device 1: Device -> host
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
11 to 8	PMPORT	All 0	R/W	Source device ID Always set to B'0000 in NCQ mode.
7 to 0	FISTYPE	All 0	R/W	FIS type bits FISTYPE indicates the type of a received FIS. The value is "41" when a DMA setup FIS is received.

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.34 Rx DMA Setup FIS Dword1 Register (DMADW1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword1 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

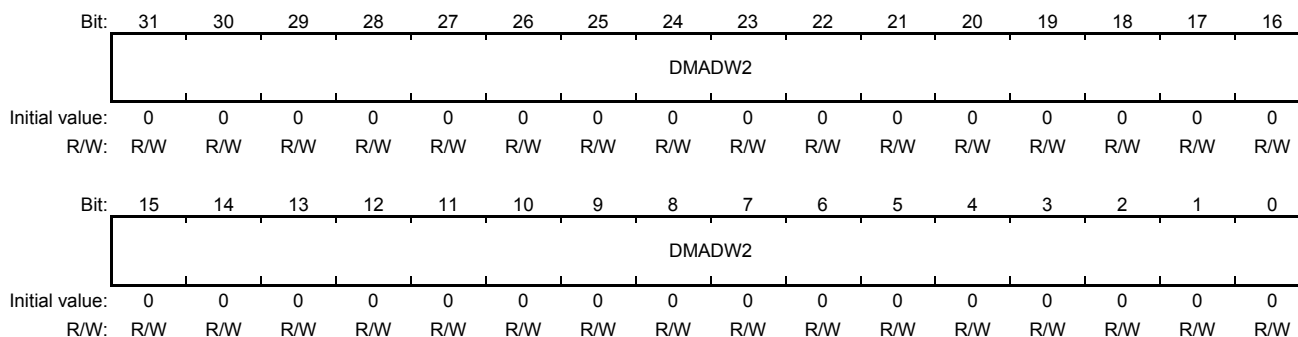

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	DMABLOW	All 0	R/W	DMA Buffer Identifier Low field value in the DMA Setup FIS (set to H'0000_0000 in NCQ mode)
4 to 0	DMATAG	All 0	R/W	TAG field for NCQ

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.35 Rx DMA Setup FIS Dword2 Register (DMADW2)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword2 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

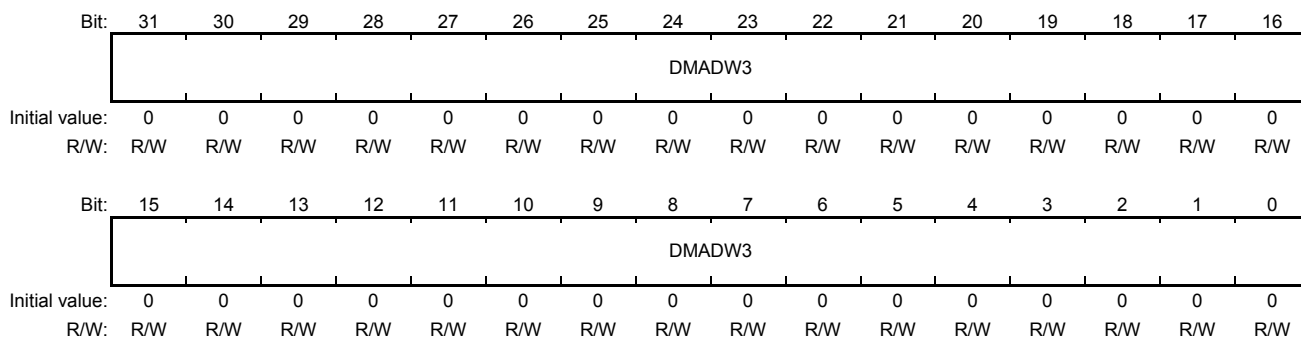

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW2	All 0	R/W	DMA Buffer Identifier High field value (Set to H'0000_0000 in NCQ mode)

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.36 Rx DMA Setup FIS Dword3 Register (DMADW3)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword3 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

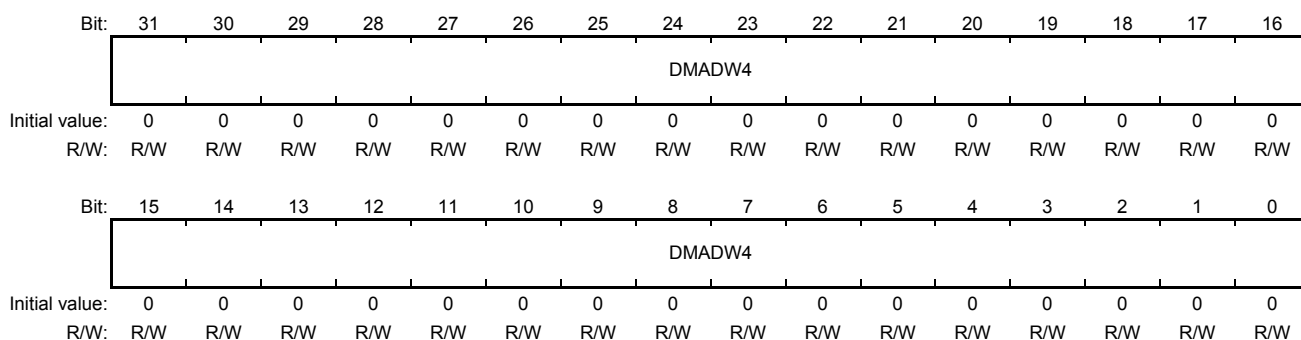

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW3	All 0	R/W	Dword3 value in the DMA Setup FIS (Normally set to H'0000_0000 as DMADW3 is handled as Reserved)

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.37 Rx DMA Setup FIS Dword4 Register (DMADW4)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword4 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

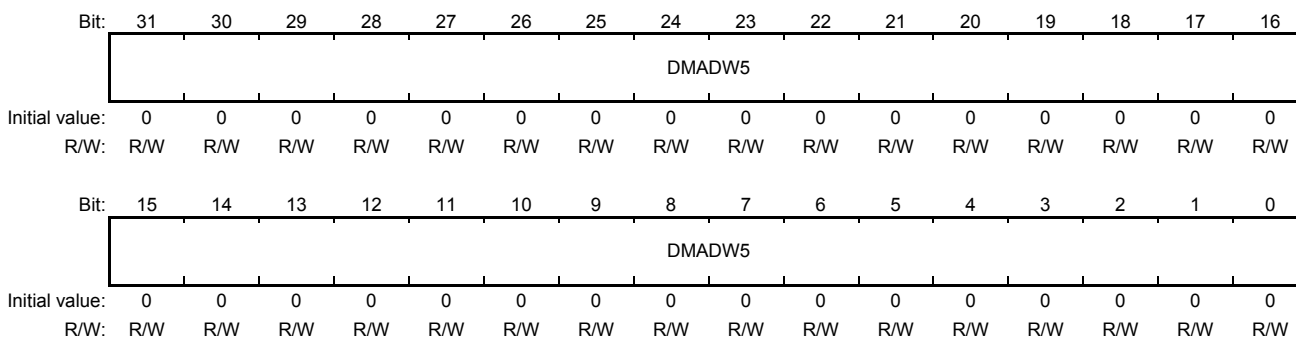

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW4	All 0	R/W	DMA Buffer Offset value in the DMA Setup FIS

Note: Refer to the Serial-ATA specification for further information about this register.

### 50.2.38 Rx DMA Setup FIS Dword5 Register (DMADW5)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword5 Register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

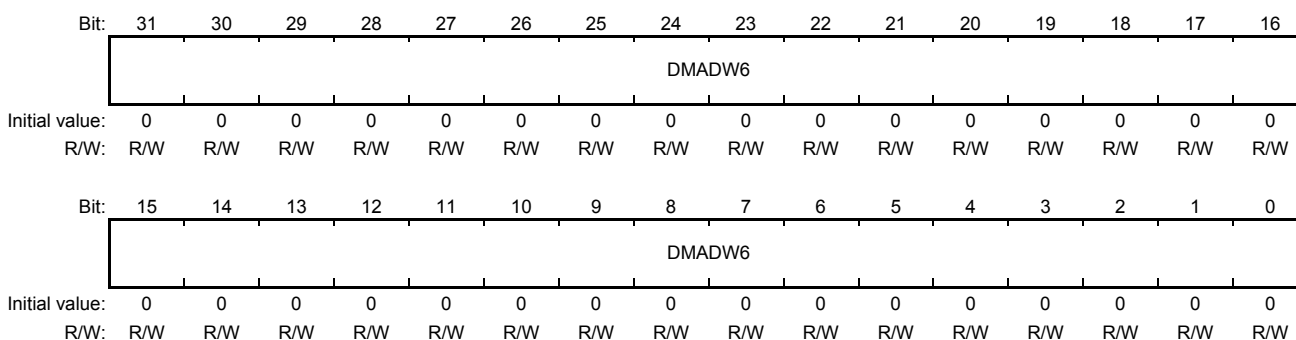

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW5	All 0	R/W	DMA Transfer Count value in the DMA Setup FIS

Note: Refer to the Serial-ATA Specification for further information about this register.

### 50.2.39 Rx DMA Setup FIS Dword6 Register (DMADW6)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

The Rx DMA setup FIS Dword6 register contains the most recently received DMA Setup FIS information. It should be referenced when a DMA Setup FIS received interrupt occurs as indicated in the SATA INT status register (SATAINTSTAT).

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DMADW6	All 0	R/W	Dword6 value in the DMA Setup FIS (Normally set to H'0000_0000 as DMADW6 is handled as Reserved)

Note: Refer to the Serial-ATA specification for further information about this register.

## 50.3 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 50.3.1 Power Management Mode

The SATA interface can be switched into Partial, Slumber, or Active mode by setting up the CSPM field of the SCR SControl register (SCRSCON) for the required mode.

Note: Whenever restoring the SATA interface from Partial or Slumber mode to Active mode, be sure to verify with the SCR SStatus register (SCRSSTS) that the SATA interface is in Partial or Slumber mode. Any request issued to the device to switch into Power Management Mode with this register setting is not retried when it is rejected. To reissue the request, it is necessary to set up the SCR SControl register (SCRSCON) again.

### 50.3.2 Initialization

To perform communication using this module, it is necessary to set up the bridge function and establish an SATA connection.

Follow the procedure shown below to initialize the SATA.

#### (1) Release the Module from Standby

After resetting, release the module from the standby state. Refer to section 7, Clock Pulse Generator (CPG), for details on module standby. The module enters the module standby state after release from the power-on reset state.

#### (2) Initializing the Physical Layer

Access the physical layer control register, and, please perform the nerdy initialization that assumes a physical layer an operation state.

For the method of accessing the physical layer control registers, see section 50.3.3, Access to the Physical Layer Control Registers.

#### (3) Establishing OOB and Speed Negotiation

Start OOB and speed negotiation at the resetting of the standby state.

### 50.3.3 Access to the Physical Layer Control Registers

Before using this module, set the parameter values to the address fields as shown in the table below to initialize the physical layer.

**Table 50.6 Access to the Physical Layer**

Address	Parameter	Access size
H'1704	SSCG OFF: H'3418_0002 SSCG ON: H'3418_C182	32
H'170C	H'0000_2303	32
H'171C	H'000B_0194	32
H'1724	H'0003_0994	32
H'1740	Reference clock setting is AC connection, termination resistor OFF: H'0300_4001	32
	Reference clock setting is DC connection, termination resistor OFF: H'0300_4003	
	Reference clock setting is AC connection, termination resistor ON: H'0300_4005	
	Reference clock setting is DC connection, termination resistor ON: H'0300_4007	

### 50.3.4 SH-Navi2G Compatibilities

The compatibility items of the SH-Navi2G/ATAPI (P-ATA host controller) include the internal bus related DMA transfer functions and PATA task register access functions.

### 50.3.5 SH-Navi2G Compatible Descriptor Function

SATA allows two or more non-overlapping contiguous memory spaces to be specified in the memory space for DMA data transfer. The DMA start address and DMA transfer count of the individual memory spaces must be specified in the descriptor table.

### 50.3.6 Interrupt Modes

The Link block supports two operating modes in addition to the ATA compliant registers.

This section describes the interrupt source masks and the specifications with respect to the clearing of the interrupt sources.

Figure 50.2 illustrates interrupt functions.

#### (1) IP Compatible Mode (Initial Value, when ISM = 0)

##### (a) Interrupt Source Mask

When an interrupt is masked, the corresponding interrupt flag is not set in the status register.

##### (b) Clearing Interrupt Sources

Interrupt sources are cleared by reading the SATA INT status register (SATAINTSTAT).

As with the shadow status register (SSTATUS), a read access causes the ATA-sourced (corresponding to INTRQ of P-ATA) host\_intrq interrupt signal to be negated.

The ATA-specified interrupt source, SCR SError register (SCRSERR), is cleared by writing 1.

**(2) CIS Interrupt Mode (when ISM = 1)**

**(a) Interrupt Source Mask**

Interrupts are masked but corresponding flags are still set in the status register.

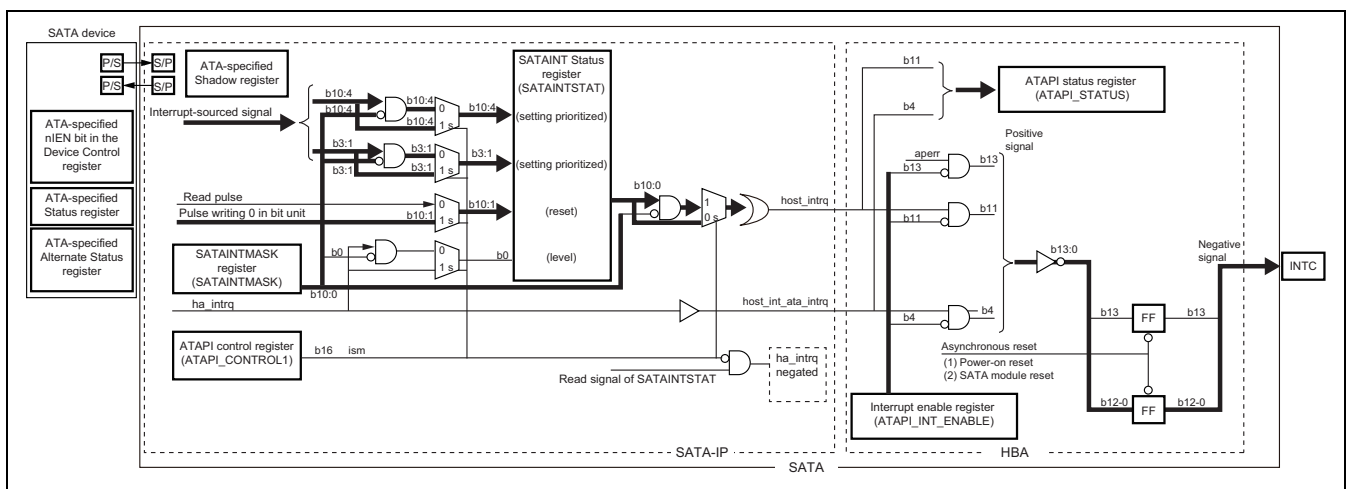

During negotiation, bit 3 in the Interrupt Status register is set. After negotiation ends, all bits in the Interrupt Status register must be cleared to 0.

**(b) Clearing Interrupt Sources**

Interrupt sources are cleared by writing 0.

A read access does not cause the ATA-sourced (corresponding to INTRQ of P-ATA) host\_intrq interrupt signal to be negated.

The ATA-specified interrupt source, SCR Error register (SCRERR), is cleared by writing 1; there is no change with this respect.

**Figure 50.2 Interrupt Functions**

### 50.3.7 Interrupt Processing Flow

The end of host device transfer interrupt and the ERR interrupt need to be considered.

The use of a timer in the wait processing is recommended to detect abnormal operations.

The device and host sources conflict. Figures 50.3 to 50.10 show the flow diagrams of interrupt processing.

The meanings of the words in the flow diagrams are given below.

CMD:	The CPU requests data transfer by writing to the SATA host and device registers.
Data ready:	Data for writing to (DATA-OUT) the SATA device by the CPU are prepared in memory.
DATA:	Data to be transferred (data to be transferred by DMA)
Data reference:	The CPU refers to data to be read from (DATA-IN) the SATA device in memory.
DMA request:	Request for DMA transfer from the SATA device
DEVINT, SERR, SATAINT:	Interrupt request originating in the device, such as the request corresponding to DEVINT (bit 4) in the ATAPI status register (ATAPI_STATUS)
NEND:	Interrupt request for the end of normal transfer of the SATA host, such as the requests corresponding to NEND (bit 1) in the ATAPI status register (ATAPI_STATUS)
response:	Response to completion of writing to memory of data read from the SATA device
'Order may be reversed.':	The order of the error interrupt or the interrupt at the end of normal transfer to or from the device may be reversed before or after the end of normal transfer.
End of normal transfer:	The time of generation of the interrupt request corresponding to NEND (bit 1) or DNEND (bit 6) in the ATAPI status register (ATAPI_STATUS) as the source

One of the two sets of events listed below will occur according to the response time of the device and the internal response time.

States (1) to (3) occur at the end of normal transfer of DATA-OUT:

- (1) Errors originating in the SATA device overlap.
- (2) Errors due to SATA communications and the host overlap.
- (3) The device's end interrupts will overlap if the device response is fast.

States (4) to (6) occur at the end of normal transfer of DATA-IN:

- (4) Errors originating in the SATA device overlap.
- (5) Errors due to SATA communications or the host overlap.
- (6) The device's end interrupts will overlap if the internal response is fast.

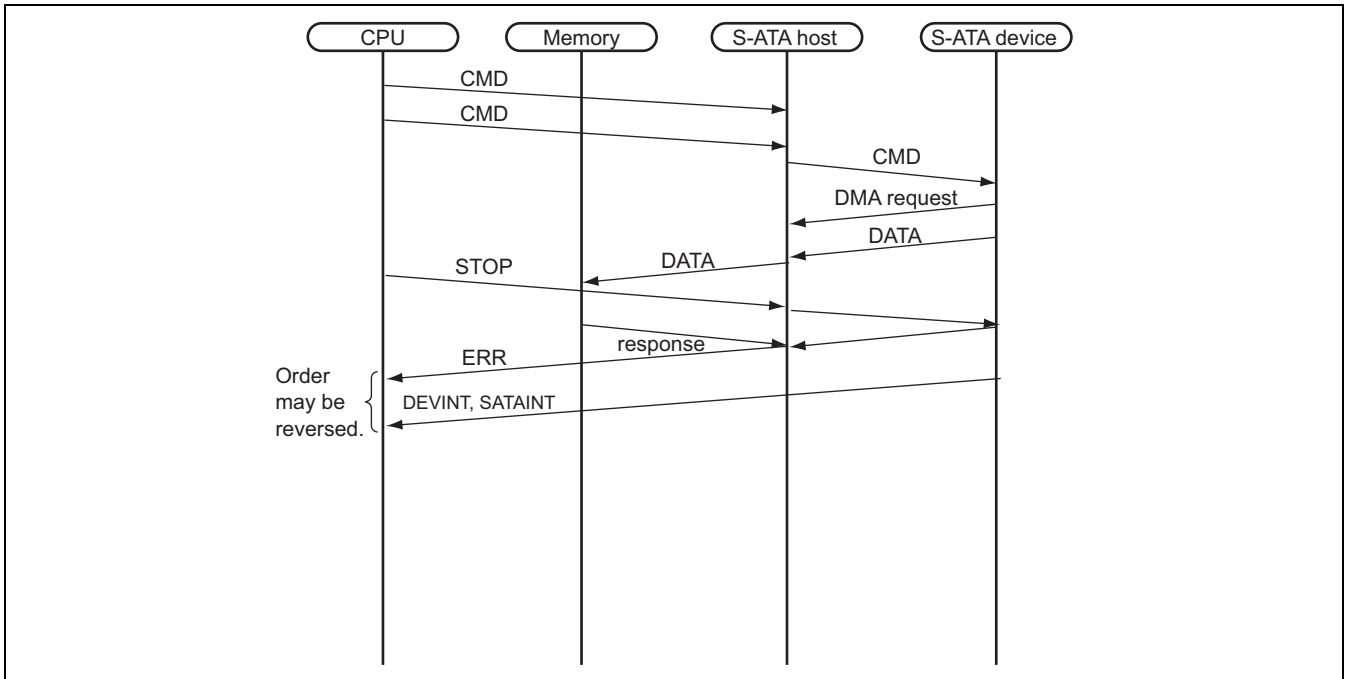

Figure 50.9 DATA-IN (Internal Bus or CPU Sources)

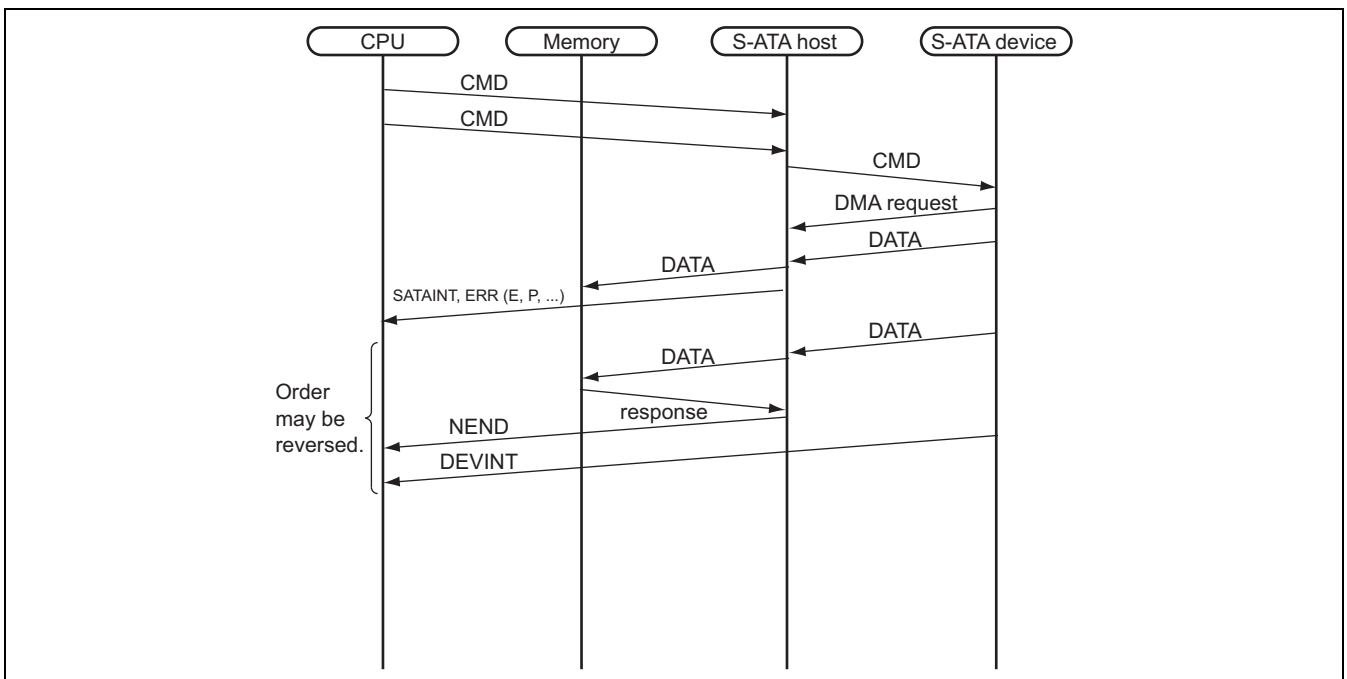

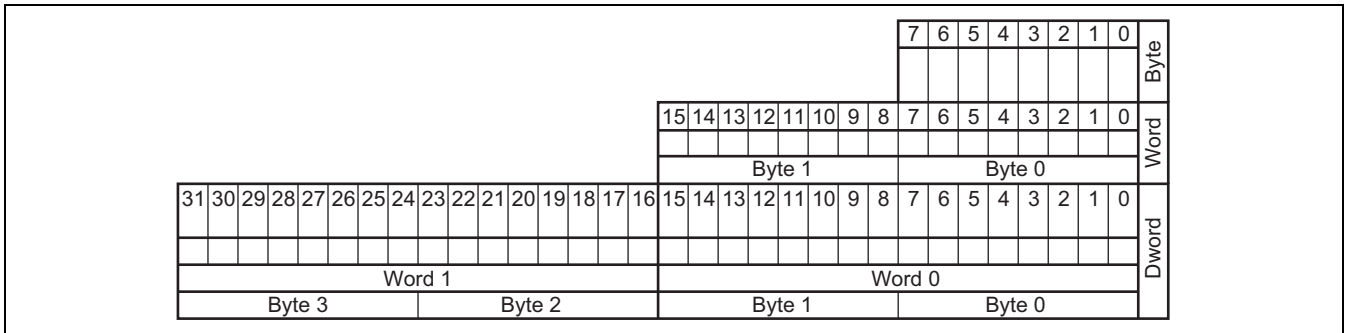

Figure 50.10 DATA-IN (SATA Communication/Host-Sourced Error)

**50.3.8 Endian**

This module adopts little endian. Consequently, data is represented in the same way as specified in the ATA/ATAPI-7 Specification and Serial-ATA Specification.

The bits of the registers are assigned in the order shown in Figure 50.11.

**Figure 50.11 Endian and Bit Order**

### 50.3.9 SATA BIST Modes

This module supports the Far-end Retimed Loopback and Far-end Analog Loopback modes that are stipulated in the Serial-ATA standard. The SATA BIST mode is the Loopback mode in which Loopback is formed on the host side. This mode can be configured and controlled for operation using the BIST config register (BISTCONF).

No match is performed between the transmit data from this module and the receive data from the device.

#### (1) Loopback Mode

In this mode, the data characters that are received are looped back to the sending side. The processing passes through the steps of input for reception → 10b/8b conversion → (Loopback) → 8b/10b conversion → output for transmission. This corresponds to the Serial-ATA Specification's Far-end Retimed Loopback (Figure 50.12).

There are cases in which some action is requested by the device side in this mode. More specifically, the device side will request the module to transmit the BIST Activate FIS. The module, however, can reject the request.

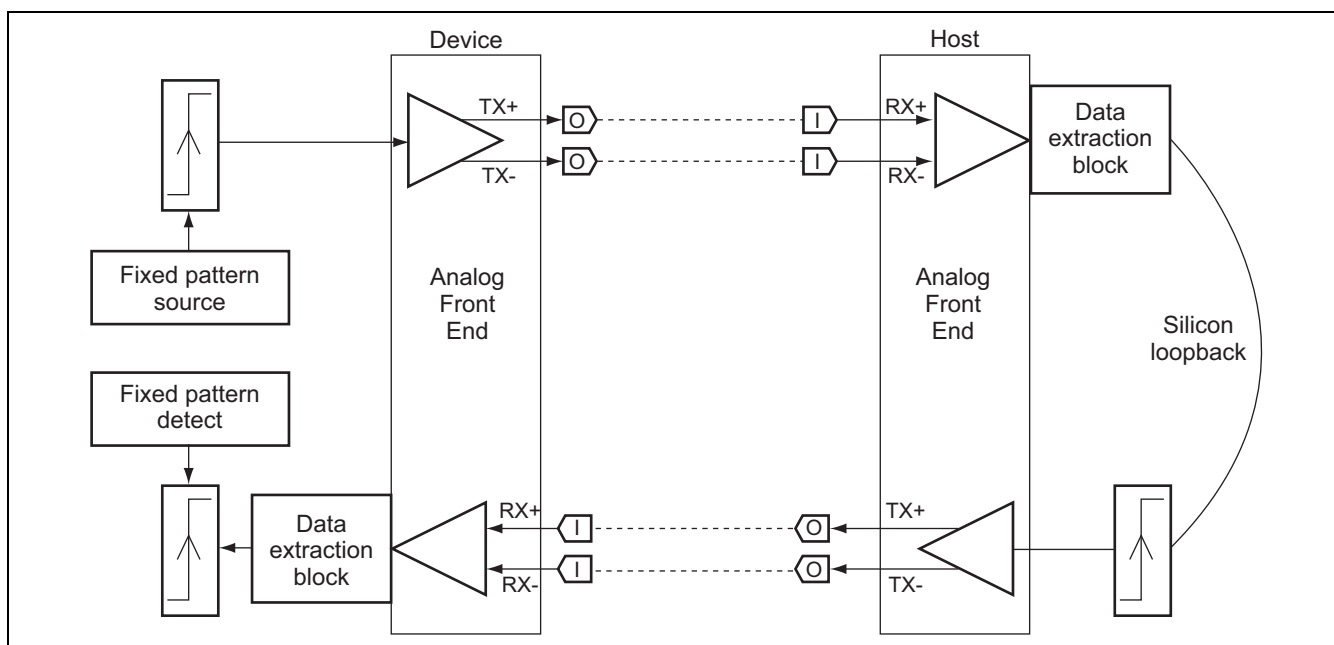

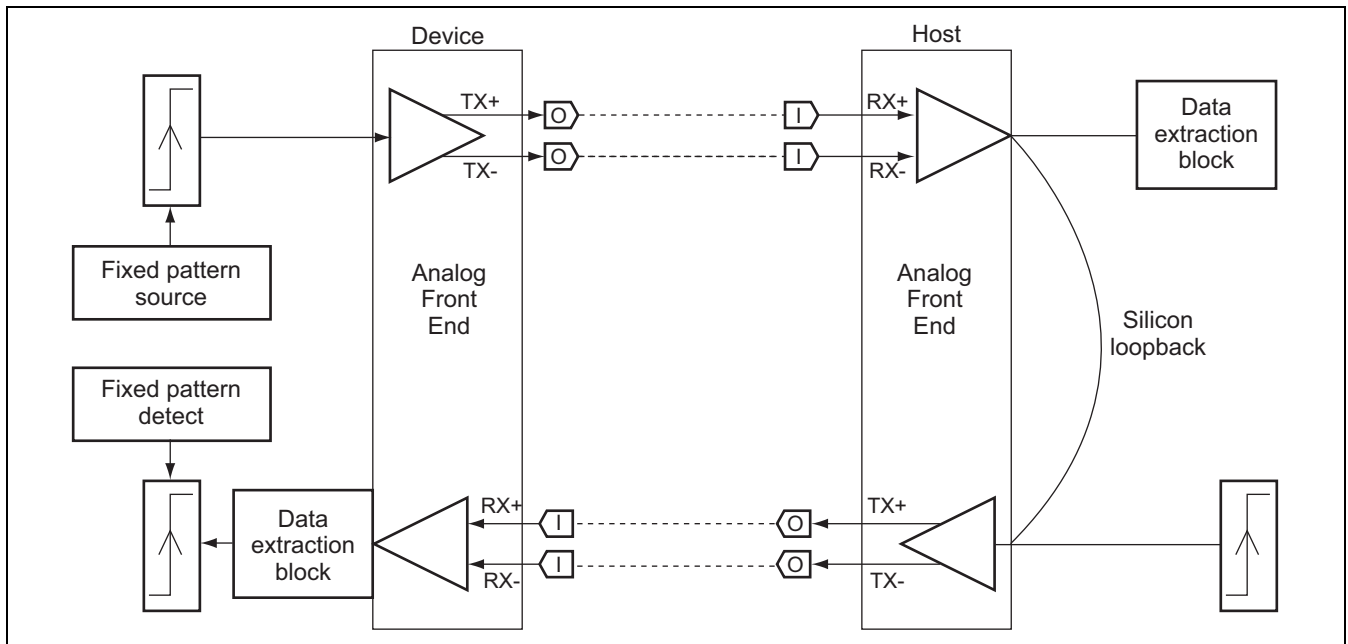

Figure 50.12 Far-End Retimed Loopback

**(2) Analog Loopback Mode**

This module does not support the Far-End Analog Loopback Mode (Figure 50.13) that is stipulated in the Serial-ATA Specification. In this mode, the received signal loops back through the AFE and output without modification as the result of which none of the Link and Transport layers get activated.

There are cases in which some action is requested by the device side in this mode. More specifically, the device side will request the module to transmit the BIST Activate FIS. The module, however, can reject the request.

**Figure 50.13 Far-End Analog Loopback**

### 50.3.10 Operation Flow

Figure 50.14 shows the flow of operations for turning on the power, setting the interrupt mode, and initializing the PHY layer.

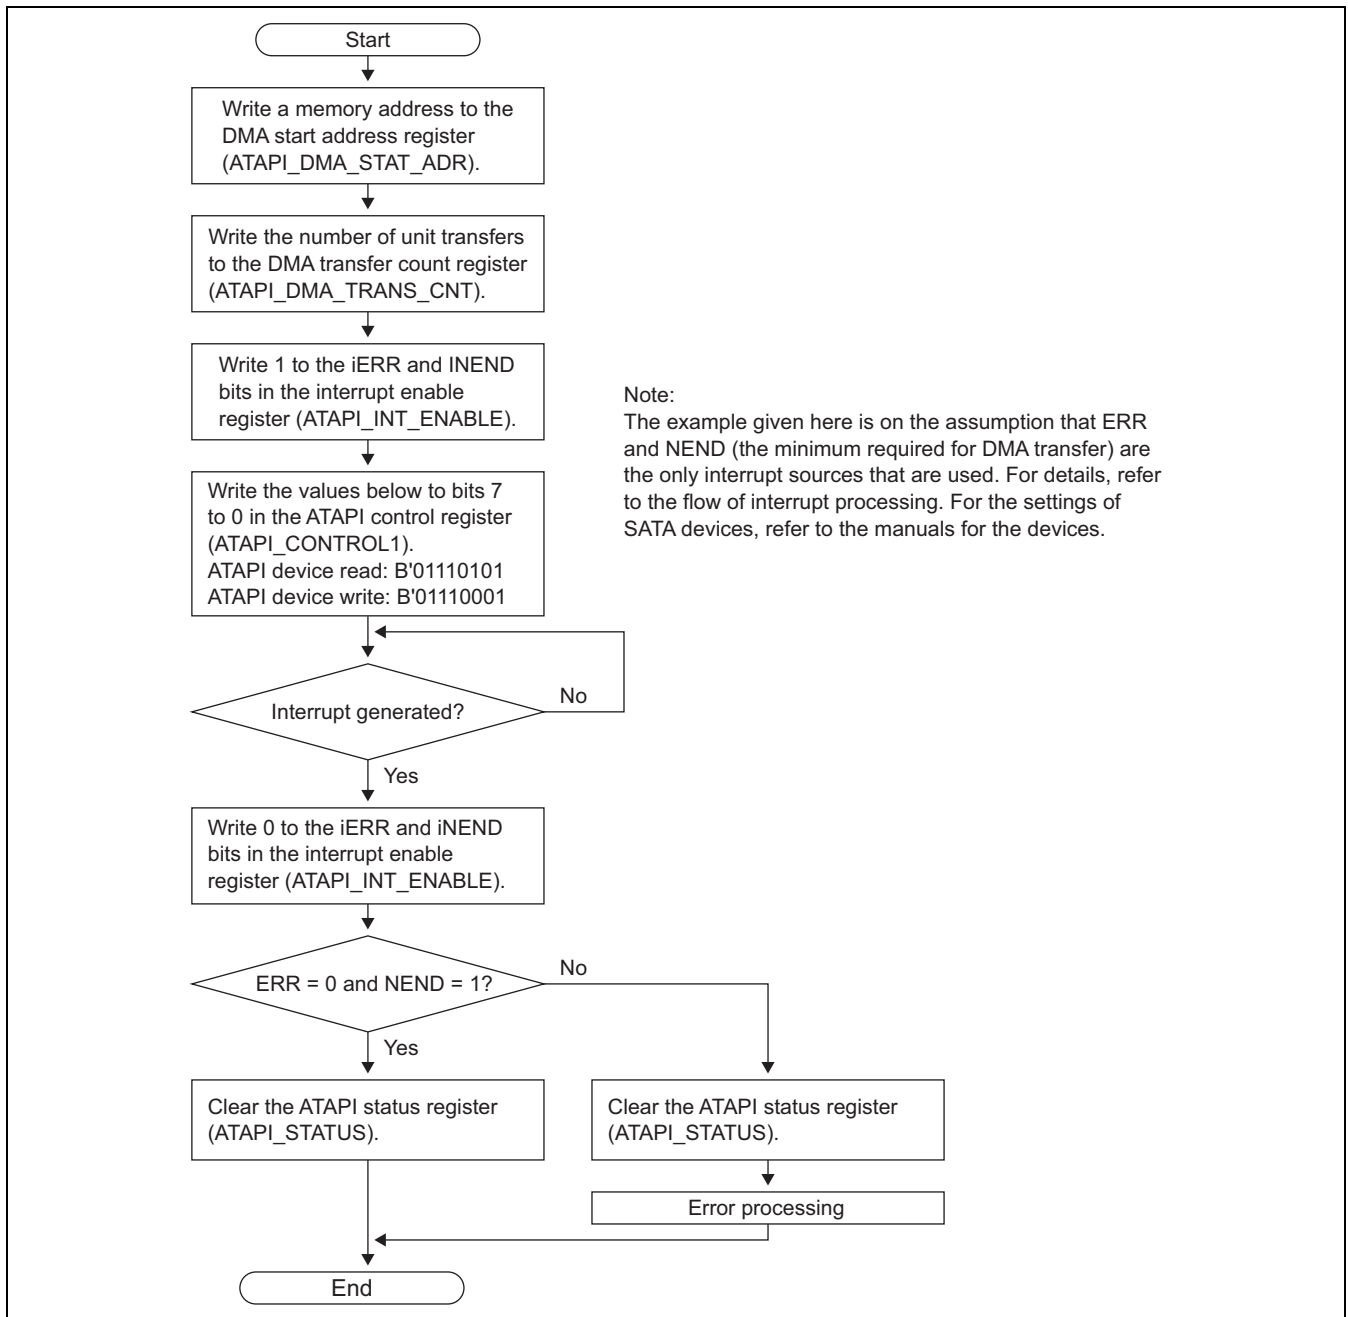

Figure 50.15 Flow of Data Transfer

## 50.4 Notes on Use

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 50.4.1 Resets

#### (1) Power-on Reset

It is possible to reset this module into the initial state that is entered when the module is started by performing a power-on reset. Set and hold this line low for 25  $\mu$ s or longer before releasing the signal. When the reset sequence subsequently gets completed, the BSY bit of the shadow status register (SSTATUS) is set to 0 (the same sequence as in a hardware reset is carried out after the SATA interface is stabilized).

#### (2) Resetting the SATA Module

The RESET module has reset functions equivalent to those of a power-on reset. Refer to the descriptions of SATA\_0 (bit 15) and SATA\_1 (bit 14) in the SRCR8 register and SRSTCLR8 register of the RESET module.

#### (3) SH-Navi2G-Compatible P-ATA Interface Reset

This module supports a reset function that is compatible with the reset function for the SH-Navi2G's parallel ATA interface. Refer to the description of RESET (bit 7) in the ATAPI control register (ATAPI\_CONTROL1).

This function resets the SATA Link and PHY blocks, as well as the SATA devices.

Release from the reset state should be after retention at the low level for at least 25  $\mu$ s. On completion of the reset sequence, the BSY bit of the shadow status register (SSTATUS) is set to 0 (after the SATA interface has become stable, the same sequence as for a hardware reset is executed).

#### (4) Hardware Reset

Changing the value of the CDET field of the SCR SControl register (SCRSCON) from B'0001 to B'0000 resets the device and the Phy, Link, and Transport layers' state machines. This handling corresponds to the Hardware Reset stipulated in the ATA standard. Reset the CDET field to B'0001 and, after the lapse of 25  $\mu$ s or longer, reset it to B'0000. When the reset sequence subsequently is completed, the BSY bit of the shadow status register (SSTATUS) is set to 0.

The hardware reset causes all of the shadow task registers (shadow data (DATA), shadow error (SERR), shadow features (SFEATURES), shadow sector CNT (SECCNT), shadow LBA low (LBALOW), shadow LBA mid (LBAMID), shadow LBA high (LBAHIGH), shadow device/head (DEVHEAD), shadow status (SSTATUS), shadow command (SCOM), shadow alternates status (SALTSTS), and shadow device control (SDEVCON) registers), SATA extend register and SCR registers (SCR SStatus (SCRSSSTS), SCR SError (SCRSEERR), SCR SControl (SCRSCON), and SCR SActive (SCRSACT) registers) to be reset.

Note: Refer also to the ATA/ATAPI-7 specification and Serial-ATA specification for further information about register update and hardware reset.

#### (5) Software Reset

The ATA specified software reset can be carried out by setting and resetting the SRST bit of the shadow device control register (DEVHEAD). Set the SRST bit to 1 and, after the lapse of 5  $\mu$ s or longer, reset the bit to 0. When the reset sequence subsequently is completed, the BSY bit of the shadow status register (SSTATUS) is set to 0.

Note: Refer also to the ATA/ATAPI-7 specification and Serial-ATA specification for further information about register update and software reset.

### 50.4.2 Extended ATA Registers

The five ATA stipulated registers, i.e., Features, sector count, LBA low, LBA mid, and LBA high registers, are provided with an 8-bit extended (exp) register. This register is used by the 48-bit Address feature set commands, WRITE FPDMA QUEUED, and READ FPDMA QUEUED commands.

This host controller module implements the exp registers for the above registers according to the ATA standard.

The following steps are required when writing data into the exp register of, for example, the Sector Count register:

- 1) Write a desired value to be set in sector count exp register to the sector count register.
- 2) Write a desired value to be set in sector count register to the sector count register.

Consequently, the value that is written in step 1) is pushed into the exp register by the access that is made in step 2).

This host controller module transmits the data corresponding to the exp register as contents of the (H2D) Register FIS irrespective of the command code specified. Whether the data corresponding to the exp register is used or not is at the discretion of the command interpreter on the device side and the host side makes no intervention.

### 50.4.3 Signature of the Shadow Register (INFORMATIVE)

The Serial-ATA Specification stipulates that the device shall transmit a Register FIS\*<sup>1</sup> immediately after a power-on reset, hardware reset, or software reset\*<sup>2</sup> for the purpose of loading a shadow register with a value called the signature. This is also stipulated in the ATA/ATAPI-7 standard in the same way. Even when this SATA module reads out the shadow register for the purpose of receiving this register FIS and having its value reflected in the shadow register, for example, following the completion of OOB processing at power-on time, it cannot read the original initial value of the register because its value has already been modified.

For details on the signature, refer to the section on "Device command layer protocol" in the Serial-ATA Specification.

- Notes:
1. There are commands such as EXECUTE DEVICE DIAGNOSTIC which take the signature as their return value. Their detailed description is omitted here. For details, refer to the Serial-ATA Specification.
  2. This refers to the PHYRDY state, that is, immediately after bits 3-0 of the SCR SStatus register (SCRSSSTS) are set to B'0011 for power-on reset and hardware reset, and to the time immediately after the reset processing is completed on the device side for software reset.

### 50.4.4 Host Termination

#### (1) Restriction

Immediately after host termination is executed in this IP, conduct a power-on reset or reset the hardware immediately.  
Fractional Data in DOUT Transfer

For host termination in DOUT transfer, the last DWORD is copied, including the end of the data management unit for the device. Zero padding is applied where data do not take up 16 bits.

### 50.4.5 SH-Navi2G Compatible Registers

#### (1) Parallel-ATA Compatible Task Registers (SATA-IP Task Registers)

**Table 50.7 Parallel-ATA Compatible Task Register (SATA-IP Task Register) Map**

(The registers listed below are allocated to the SATA device and their mirror values are retained in this module.)

Address	Read Register	Write Register	Access Size*1 (Possible Bit Size)	Register Location	Register Abbreviation	
					Read	Write
H'0100	Data	Data	32 (16)*2	Drive	DATA	DATA
H'0104	Error	Function	32 (8)*3	Drive	SERR	SFEATURES
H'0108	Sector count	Sector count	32 (8)*3	Drive	SECCNT	SECCNT
H'010C	Sector number	Sector number	32 (8)*3	Drive	LBALOW	LBALOW
H'0110	Cylinder low	Cylinder low	32 (8)*3	Drive	LBAMID	LBAMID
H'0114	Cylinder high	Cylinder high	32 (8)*3	Drive	LBAHIGH	LBAHIGH
H'0118	Device/head	Device/head	32 (8)*3	Drive	DEVHEAD	DEVHEAD
H'011C	Status	Command	32 (8)*3	Drive	SSTATUS	SCOM
H'0120	Obsolete	Obsolete	32 (8)*2		—	—
H'0124	Obsolete	Obsolete	32 (8)*2		—	—
H'0128	Obsolete	Obsolete	32 (8)*2		—	—
H'012C	Obsolete	Obsolete	32 (8)*2		—	—
H'0130	Obsolete	Obsolete	32 (8)*2		—	—
H'0134	Obsolete	Obsolete	32 (8)*2		—	—
H'0138	Alternate status	Device control	32 (8)*3	Drive	SALTSTS	SDEVCON
H'013C	Obsolete	Obsolete	32 (8)*3		—	—

Notes: 1. The CPU must access the above listed registers in longword (32-bit) units. Accesses in byte or word units are not allowed.

2. Bits 15 to 0 of the data bus are used.

3. Bits 7 to 0 of the data bus are used.

"Enable external accesses when ATAPI control register, RADRE = 1" has been made obsolete.

The real value of the mirror value of this task register is held in the SATAIP unit and doubly decoded.

While the PATA registers use a 32-bit APB bus, the SATA registers use a 64-bit AXI Bus. The registers hold addresses in their 32 bits and map them onto the 64-bit bus.

**(2) Parallel-ATA Compatible ATAPI Packet Command Task File Registers (SATA-IP Task Registers)****Table 50.8 Parallel-ATA Compatible ATAPI Packet Command Task File Register Map**

(The registers listed below are allocated to the SATA device and their mirror values are retained in this module.)

Address	Read Register	Write Register	Access Size*1 (Possible Bit Size)	Register Location	Register Abbreviation	
					Read	Write
H'0100	Data	Data	32 (16)*2	Drive	DATA	DATA
H'0104	Error	Function	32 (8)*3	Drive	SERR	SFEATURES
H'0108	Interrupt source	—	32 (8)*3	Drive	SECCNT	SECCNT
H'010C	—	—	32 (8)*3	Drive	LBALOW	LBALOW
H'0110	Byte count low	Byte count low	32 (8)*3	Drive	LBAMID	LBAMID
H'0114	Byte count high	Byte count high	32 (8)*3	Drive	LBAHIGH	LBAHIGH
H'0118	Device select	Device select	32 (8)*3	Drive	DEVHEAD	DEVHEAD
H'011C	Status	Command	32 (8)*3	Drive	SSTATUS	SCOM
H'0120	Obsolete	Obsolete	32 (8)*2		—	—
H'0124	Obsolete	Obsolete	32 (8)*2		—	—
H'0128	Obsolete	Obsolete	32 (8)*2		—	—
H'012C	Obsolete	Obsolete	32 (8)*2		—	—
H'0130	Obsolete	Obsolete	32 (8)*2		—	—
H'0134	Obsolete	Obsolete	32 (8)*2		—	—
H'0138	Alternate status	Device control	32 (8)*2	Drive	SALTSTS	SDEVCON
H'013C	Obsolete	Obsolete	32 (8)*3		—	—

Notes: 1. The above listed registers must be accessed in longword (32-bit) units. Accesses in byte or word units are not allowed.

2. Bits 15 to 0 of the data bus are used.

3. Bits 7 to 0 of the data bus are used.

The above listed registers must be accessed in longword (32-bit) units. Accesses in byte or word units are not allowed.

"Enable external accesses when ATAPI control register, RADRE = 1" has been made obsolete.

The real value of the mirror value of this task register is held in the SATAIP unit and doubly decoded.

While the PATA registers use a 32-bit APB bus, the SATA registers use a 64-bit AXI Bus. The registers hold addresses in their 32 bits and map them onto the 64-bit bus.

**(3) SH-Navi2G/ATAPI Module Compatible Control Register (Parallel-ATA) Map****Table 50.9 ATAPI Interface Control Register Map**

(The registers listed below are allocated to the internal bus bridge block of this LSI SATA module.)

Address	Register Name	Symbol	Access Type	Register Access Size*1

Reserved	—	Ultra DMA timing	ATAPI_ULTRA_TIMING	

Table 50.11 Differences in Flags

- ATAPI control register (ATAPI\_CONTROL)

RZ/G1H/M/N Flag Name				SH-Navi2G Flag Name		Description
Bit	Bit Name	Initial Value	R/W	Bit Name	Initial Value	
16	ISM	0	R/W	—	—	An interrupt mode was added. The initial setting and interrupt handling differ from those for SH-Navi2G.
12	—	0	R	RADRE	0	This bit is allocated to IP-specific debugging functions such as monitoring. Setting this bit to 1 is prohibited.
9	—	0	R	DTCD	0	When device termination occurs, completion of DMA transfer is not possible.
7	RESET	0	R/W	RESET	0	The SATAIP module and SATA devices are reset. In parallel ATA, only the devices were reset.
6	—	1	R	M/S	0	Only the master setting is available. In the SH-Navi2G, the slave setting was the initial value.
5	—	1	R	—	1	In the SH-Navi2G, setting this bit to 0 was prohibited. In the SH-Navi3, setting this bit to 0 is ignored.
4	—	1	R	UDMAEN	0	SATA is set to emulate the ultra DMA mode. In the SH-Navi2G, the setting for the multi-word DMA mode was the initial value.

- ATAPI status register (ATAPI\_STATUS)

RZ/G1H/M/N Flag Name				SH-Navi2G Flag Name		Description
Bit	Bit Name	Initial Value	R/W	Bit Name	Initial Value	
31	SSBSY	0	R	—	—	This function was added for SATA.
30	SDDRQ	0	R	—	—	This function was added to SATA.
27	SDDRQ	0	R	—	—	This function was added to SATA.
24	SSERR	0	R	—	—	This function was added to SATA.
11	SATAINT	0	R	—	—	This function was added to SATA.
8	SWERR	0	R/WC0	SWERR	0	The shadow task registers are mapped to the Serial-ATA HOST control registers and are accessible during DMA transfer.
7	—	—	R	IFERR	0	SATA has functions to suit the IP module. Refer to the SCR Error register (SCRSEERR) to check the values of flags such as that for protocol errors.
3	—	—	R	TOUT	0	SATA has functions to suit the IP module. Refer to the SCR Error register (SCRSEERR) to check the values of flags such as that for protocol errors.
2	ERR	0	R/WC0	ERR	0	Since DTCD is fixed to 0, 'DTCD = 1 and ACT = 0 because of device termination' was deleted.

- ATAPI signal status register (ATAPI\_SIG\_ST)

RZ/G1H Flag Name				SH-Navi2G Flag Name		Description
Bit	Bit Name	Initial Value	R/W	Bit Name	Initial Value	
1	DPIORDY	—	R	DDMARDY	—	IORDY cannot be monitored during DMA transfer.

**50.4.6 Clock Input in the Partial and Slumber States**

Do not stop input of the reference clock signal while the interface is in the Partial or Slumber state.

## 51. USB2.0 Host (EHCI/OHCI)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 51.1 Overview

Complies with Universal Serial Bus Specification Revision 2.0

Complies with Open Host Controller Interface (OHCI) Specification for USB Rev 1.0a

Complies with Enhanced Host Controller Interface (EHCI) Specification for USB Rev 1.0

Supports USB2.0 High-Speed (480 Mbps)/Full-Speed (12 Mbps)/Low-Speed (1.5 Mbps) transfer

Supports USB2.0 compliance test function.

USB reference clock fixed 48 MHz.

Required address size: 128 Kbytes (Align on a 128-Kbyte boundary.)

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

## 51.2 Register Mapping

There are following three register areas:

1. OHCI/EHCI Operational Registers area
2. PCI Configuration Space
3. AHB-PCI Bridge PCI Communication area

To access each area in the PCI Configuration Space, the AHB-PCI Bridge register AHBPCI\_WIN1\_CTR should be set. Addresses should be correctly allocated for the areas such as OHCI/EHCI Operational Registers and PCI Communication Space in the PCI space in the USB in addition to mapping registers in the AHB space. For details on the register accesses and address mapping, refer to section 51.7, Register Accesses.

Offset address from each channel base address [Ch.0: H'EE080000, Ch.1: H'EE0A0000, Ch.2: H'EE0C0000]. [RZ/G1H]

Offset address from each channel base address [Ch.0: H'EE080000, Ch.1: H'EE0C0000]. [RZ/G1M/N/E]

Note: Do not access registers in the reserved area.

## 51.6 Register Descriptions

This section describes the register functions. The following shows the legends for the register bit maps.

Bit: Bit position in 32-bit space

R/W: R indicates readable space and W indicates writable space.

Reset: Read value after a reset

Note: A blank in the bit name space indicates a reserved bit.

### 51.6.1 OHCI Operational Registers

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Please refer to the OHCI standard for the details of the OHCI register. The meaning follows the OHCI standard.

#### 51.6.1.1 HcRevision Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	Revision[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved (Don't care)
7 to 0	Revision[7:0]	H'10	R	These bits indicate the HCI standard version implemented by the host logic. The set value H'10 indicates that this host logic complies with OHCI Standard 1.0a.

## 51.6.1.2 HcControl Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RWE	RWC	IR	HCFS[1:0]	BLE	CLE	IE	PLE	CBSR[1:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved The write value should be 0.
10	RWE	0	R/W	Remote Wakeup Enable Controls PME assertion. When this bit is 1, PME is asserted when the RD (bit 3) in HcInterruptStatus is set to 1. 0: PME is not asserted when Resume is detected (PME disabled). 1: PME is asserted when Resume is detected (PME enabled).
9	RWC	0	R/W	Remote Wakeup Connect Selects whether or not the host logic supports the remote wakeup function or not. To support the remote wakeup by the system, set this bit during initialization. 0: Remote wakeup is not supported. 1: Remote wakeup is supported.
8	IR	0	R/W	Interrupt Routing Sets the host logic interrupt output route. Specifies the interrupt source notification method of interrupt source indicated in HcInterruptStatus to the system. This bit should not be changed from the initial value since SMI is not used in this module. 0: Interrupt generated through INTA 1: Interrupt generated through SMI
7, 6	HCFS[1:0]	00	R/W	Host Controller Functional State Sets the host logic operation state. A transition to USB operational state begins management of frames divided into 1 ms. The operation state is always controlled by the software except when transition to USB resume is caused during USB suspend state by the remote wakeup. These bits are set to the USB reset after a hardware reset, and set to USB suspend after a software reset. 00: USB reset 01: USB resume 10: USB operational 11: USB suspend

Bit	Bit Name	Initial Value	R/W	Description										
5	BLE	0	R/W	<p>Bulk List Enable</p> <p>Sets whether to perform Bulk list processing or not. This bit setting becomes effective from the next frame. To modify the Bulk list, this bit should be 0.</p> <p>0: Blk list processing is not performed. 1: Blk list processing is performed.</p>										
4	CLE	0	R/W	<p>Control List Enable</p> <p>Sets whether to perform Control list processing or not. This bit setting becomes effective from the next frame. To modify the Control list, this bit should be 0.</p> <p>0: Control list processing is not performed. 1: Control list processing is performed.</p>										
3	IE	0	R/W	<p>Isochronous Enable</p> <p>Sets whether or not to perform Isochronous ED processing. This bit setting becomes effective from the next frame. When the Isochronous ED is detected during list processing, this bit status is checked to determine whether or not to perform the Isochronous ED processing or not.</p> <p>0: Isochronous transfer is not performed 1: Isochronous transfer is performed</p>										
2	PLE	0	R/W	<p>Periodic List Enable</p> <p>Sets whether or not to perform Periodic list processing. This bit setting becomes effective from the next frame.</p> <p>0: Periodic list processing is not performed 1: Periodic list processing is performed</p>										
1, 0	CBSR[1:0]	00	R/W	<p>Control Bulk Service Ratio</p> <p>Sets the service ratio between the Bulk transfer and Control transfer.</p> <p>During the Periodic list processing, transfer is performed keeping the service ratio specified by these bits.</p> <table border="0"> <tr> <td>CBSR</td> <td>Service Ratio (BulkED:Control ED)</td> </tr> <tr> <td>00:</td> <td>1:1</td> </tr> <tr> <td>01:</td> <td>2:1</td> </tr> <tr> <td>10:</td> <td>3:1</td> </tr> <tr> <td>11:</td> <td>4:1</td> </tr> </table>	CBSR	Service Ratio (BulkED:Control ED)	00:	1:1	01:	2:1	10:	3:1	11:	4:1
CBSR	Service Ratio (BulkED:Control ED)													
00:	1:1													
01:	2:1													
10:	3:1													
11:	4:1													

### 51.6.1.3 HcCommandStatus Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	OCR	BLF	CLF	HCR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	W	R/W	R/W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved The write value should be 0.
17, 16	SOC[1:0]	00	R	Scheduling Overrun Count Indicates the number of schedule overruns. These bits are incremented on each schedule overruns. When the value reaches B'11, it returns to B'00. Increment is continued even if the SO (bit 0) in HcInterruptStatus is set.
15 to 4	—	All 0	R	Reserved The write value should be 0.
3	OCR	0	W	Ownership Change Request Changes the control right of the host logic.
2	BLF	0	R/W	Bulk List Filled Indicates whether there are any TDs on the Bulk list or not. The host logic checks this bit status to start the first ED processing on the Bulk list. When this bit is 0, the host logic does not start the list processing. When 1, the host logic starts the Bulk list processing and sets this bit to 0. If the host logic finds a TD on the Bulk list, this bit is set to 1 and the Bulk list processing is continued. When the host logic completes the list processing, this bit is cleared to 0. If a TD is not detected in the list or the software does not set this bit to 1, this bit remains to be 0 and the list processing is stopped. To re-configure the list and start the processing, set the BLE (bit 5) in HcCommand and set this bit before starting the list processing.

Bit	Bit Name	Initial Value	R/W	Description
1	CLF	0	R/W	<p>Control List Filled</p> <p>Indicates whether there are any TDs on the Control list or not.</p> <p>The host logic checks this bit status to start the first ED processing on the Control list.</p> <p>When this bit is 0, the host logic does not start the list processing. When 1, the host logic starts the Control list processing and sets this bit to 0. If the host logic finds a TD on the Control list, this bit is set to 1 and the Control list processing is continued.</p> <p>When the host logic completes the list processing, this bit is cleared to 0. If a TD is not detected in the list or the software does not set this bit to 1, this bit remains to be 0 and the list processing is stopped.</p> <p>To re-configure the list and start the processing, set the CLE (bit 4) in HcCommand and set this bit before starting the list processing.</p>
0	HCR	0	W	<p>Host Controller Reset</p> <p>Initiates the host logic software reset.</p> <p>When this bit is set, a transition to the USB suspend state is made regardless of the functional state of the host logic.</p>

## 51.6.1.4 HcInterruptStatus Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RHSC	FNO	UE	RD	SF	WDH	SO
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R/W	Reserved The write value should be 0.
6	RHSC	0	R/W	Root Hub Status Change This is an interrupt bit that indicates that the HcRhStatus or HcRhPortStatus register status has changed. This bit is set when HcRhStatus or HcRhPortStatus changes by a hardware source. Writing 1 to this bit clears the interrupt. 0: RHSC interrupt has not been generated. 1: RHSC interrupt has been generated.
5	FNO	0	R/W	Frame Number Overflow This is an interrupt bit that indicates that MSB of bits 15 to 0 (FrameNumber) in HcFmNumber has changed. This bit is set after HccaFrameNumber has been updated in the frame where the MSB of the FrameNumber bits changes from 0 to 1 or 1 to 0, Writing 1 to this bit clears the interrupt. 0: FNO interrupt has not been generated. 1: FNO interrupt has been generated.
4	UE	0	R/W	Unrecoverable Error This is an interrupt bit that indicates that a system error not related to the USB has been detected in the PCI bus. Writing 1 to this bit clears the interrupt. 0: UE interrupt has not been generated. 1: UE interrupt has been generated.
3	RD	0	R/W	Resume Detected This is an interrupt bit that indicates that Resume has been detected. This bit is set when it is detected that the device on the USB is asserting the Resume signal. This bit is not set when the USB Resume has been detected by the software. Writing 1 to this bit clears the interrupt. 0: RD interrupt has not been generated. 1: RD interrupt has been generated.

Bit	Bit Name	Initial Value	R/W	Description
2	SF	0	R/W	<p>Start of Frame</p> <p>This is an interrupt bit that indicates that HccaFrameNumber has been updated at the start of each frame.</p> <p>The host logic updates HccaFrameNumber on transmission of SOF packet and sets this bit.</p> <p>Writing 1 to this bit clears the interrupt.</p> <p>0: SF interrupt has not been generated.</p> <p>1: SF interrupt has been generated.</p>
1	WDH	0	R/W	<p>Writeback Done Head</p> <p>This is an interrupt bit that indicates that the host logic has updated the HccaDoneHead contents.</p> <p>The host logic sets this bit immediately after updating the HccaDoneHead, and does not update HccaDoneHead until this bit is cleared.</p> <p>Writing 1 to this bit clears the interrupt.</p> <p>0: WDH interrupt has not been generated.</p> <p>1: WDH interrupt has been generated.</p>
0	SO	0	R/W	<p>Scheduling Overrun</p> <p>This is an interrupt bit that indicates that USB schedule has overrun in the frame. This bit is set after HccaFrameNumber in the next frame has been updated.</p> <p>When this bit is set, the SOC (bits 17 and 16) in HcCommandStatus is also incremented</p> <p>Writing 1 to this bit clears the interrupt.</p> <p>0: SO interrupt has not been generated.</p> <p>1: SO interrupt has been generated.</p>

### 51.6.1.5 HcInterruptEnable Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MIE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RHSCE	FNOE	UEE	RDE	SFE	WDHE	SOE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	MIE	0	R/W	<p>Master Interrupt Enable</p> <p>Enables interrupt source settings of bits 6 to 0 in this register.</p> <p>When this bit is 0, all the interrupts are masked.</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored</p> <p>1: Interrupt generation settings are enabled</p>
30 to 7	—	All 0	R	<p>Reserved</p> <p>The write value should be 0.</p>
6	RHSCE	0	R/W	<p>Root Hub Status Change Enable</p> <p>Enables interrupt generation by RHSC.</p> <p>Writing 1 to this bit enables the RHSC interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: RHSC interrupt enabled.</p>
5	FNOE	0	R/W	<p>Frame Number Overflow Enable</p> <p>Enables interrupt generation by FNO.</p> <p>Writing 1 to this bit enables the FNO interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: FNO interrupt enabled.</p>
4	UEE	0	R/W	<p>Unrecoverable Error Enable</p> <p>Enables interrupt generation by UE.</p> <p>Writing 1 to this bit enables the UE interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: UE interrupt enabled.</p>
3	RDE	0	R/W	<p>Resume Detected Enable</p> <p>Enables interrupt generation by RD.</p> <p>Writing 1 to this bit enables the RD interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: RD interrupt enabled.</p>

Bit	Bit Name	Initial Value	R/W	Description
2	SFE	0	R/W	<p>Start of Frame Enable</p> <p>Enables interrupt generation by SF.</p> <p>Writing 1 to this bit enables the SF interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: SF interrupt enabled.</p>
1	WDHE	0	R/W	<p>Writeback Done Head Enable</p> <p>Enables interrupt generation by WDH.</p> <p>Writing 1 to this bit enables the WDH interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: WDH interrupt enabled.</p>
0	SOE	0	R/W	<p>Scheduling Overrun Enable</p> <p>Enables interrupt generation by SO.</p> <p>Writing 1 to this bit enables the SO interrupt</p> <p>To clear this bit, write 1 in the pertinent bit in HcInterruptDisable.</p> <p>0: Ignored.</p> <p>1: SO interrupt enabled.</p>

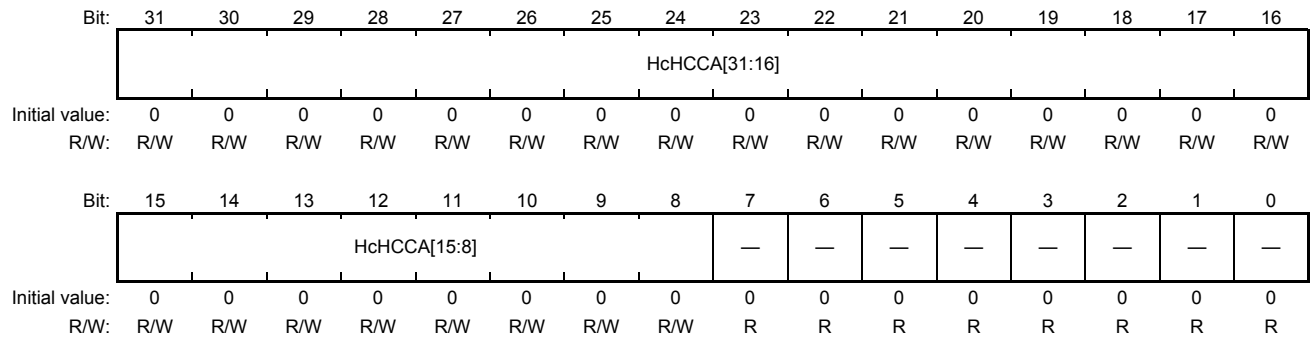

## 51.6.1.6 HcInterruptDisable Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MID	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

0	SOD	0	R/W	<p>Scheduling Overrun Disable</p> <p>Removes SO from interrupt sources.</p> <p>Writing 1 to this bit clears the SO interrupt setting.</p> <p>To set SO as an interrupt source, write 1 in the pertinent bit in HcInterruptEnable.</p> <p>0: Ignored</p> <p>1: SO is removed from interrupt sources.</p>

### 51.6.1.7 HcHCCA Register

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	HcHCCA[31:8]	H'00 0000	R/W	Sets the base address of RAM allocated as the Host Controller Communication Area.  Set these bits during initialization. The host logic requires 256 bytes of area for HCCA from this base address.
7 to 0	—	All 0	R	Reserved  The write value should be 0.

### 51.6.1.8 HcPeriodicCurrentED Register

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	PeriodicCurrent ED[31:4]	H'000 0000	R	Indicates the physical address of the ED currently processed in the Periodic list.  The host logic updates these bits on completion of the list processing of the ED.
3 to 0	—	All 0	R	Reserved  The write value should be 0.

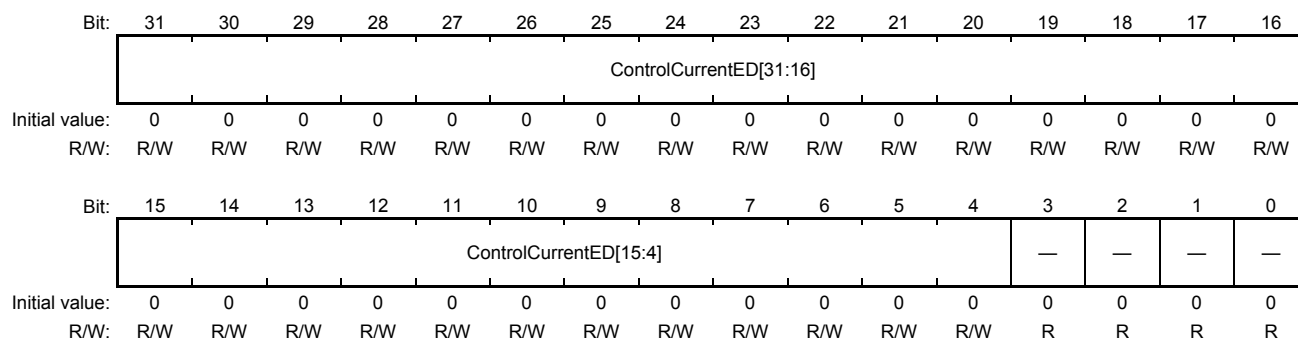

### 51.6.1.9 HcControlHeadED Register

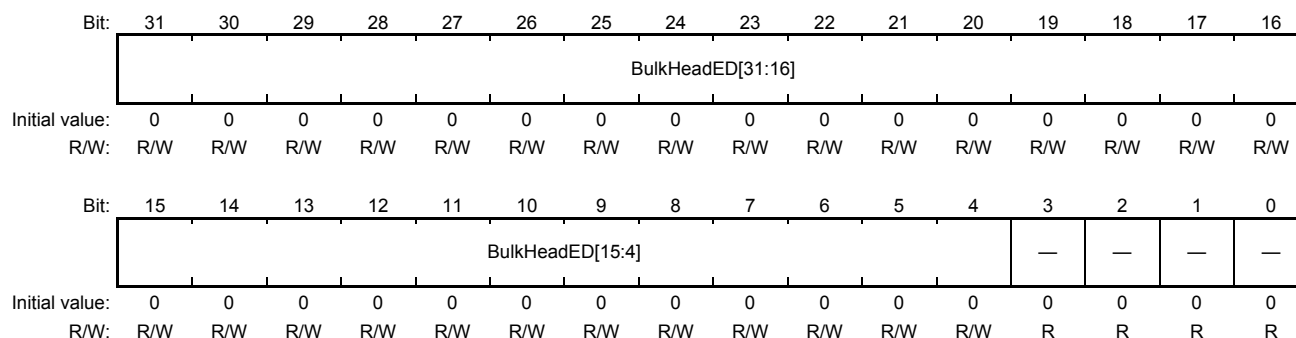

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	ControlHeadED [31:4]	H'000 0000	R/W	Sets the physical address of the first ED in the Control list. To perform Control transfer, set these bits before setting the CLE (bit 4) in HcControl.
3 to 0	—	All 0	R	Reserved The write value should be 0.

### 51.6.1.10 HcControlCurrentED Register

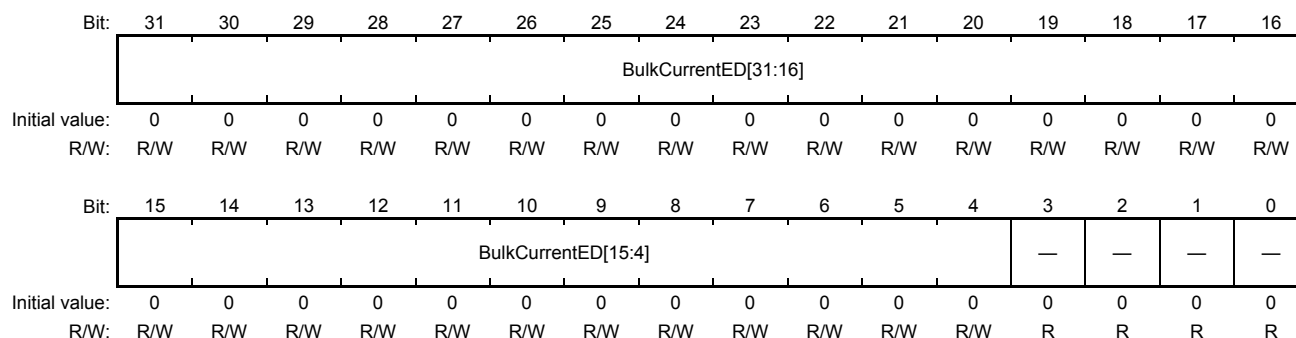

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	ControlCurrent ED[31:4]	H'000 0000	R/W	Indicates the physical address of the ED currently processed in the Control list. The host logic updates these bits on each completion of the Control ED processing. To newly configure the list, set these bits to H'00000000 that indicates the list end. To stop the transfer and restart it, check to see that the ED indicated by the ControlCurrentED link pointer exists.
3 to 0	—	All 0	R	Reserved The write value should be 0.

### 51.6.1.11 HcBulkHeadED Register

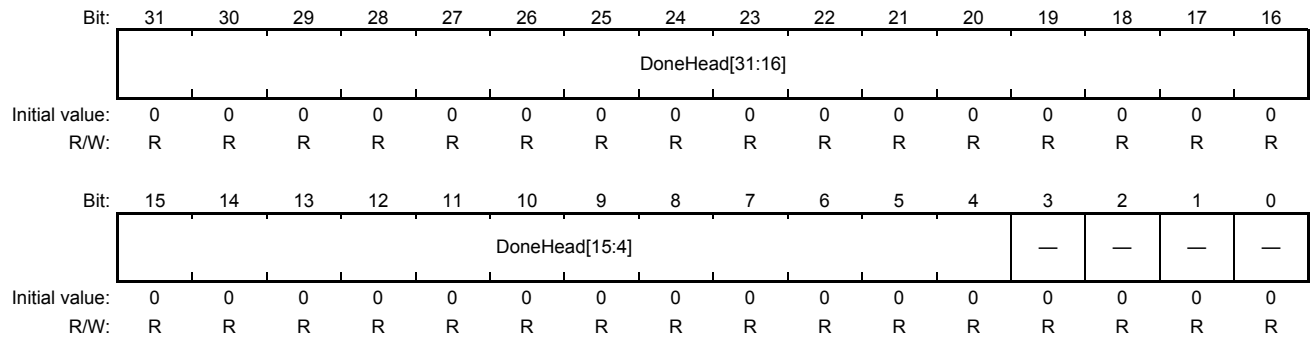

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	BulkHeadED [31:4]	H'000 0000	R/W	Sets the physical address of the first ED in the Bulk list. To perform Bulk transfer, set these bits before setting the BLE (bit 5) in HcControl.
3 to 0	—	All 0	R	Reserved The write value should be 0.

### 51.6.1.12 HcBulkCurrentED Register

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	BulkCurrentED [31:4]	H'000 0000	R/W	Indicates the physical address of the ED currently processed in the Bulk list. The host logic updates these bits on each completion of the Bulk ED processing. To newly configure the list, set these bits to H'00000000 that indicates the list end. To stop the transfer and restart it, check to see that the ED indicated by the BulkCurrentED link pointer exists.
3 to 0	—	All 0	R	Reserved The write value should be 0.

**51.6.1.13 HcDoneHead Register**

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	DoneHead [31:4]	H'000 0000	R	Indicates the physical address of HcDoneHead of the host logic. The physical address of the last completed TD that was added to the Done queue is indicated.
3 to 0	—	All 0	R	Reserved The write value should be 0.

## 51.6.1.14 HcFmInterval Register

Bit	Bit Name	Initial Value	R/W	Description
31	FIT	0	R/W	<p>Frame Interval Toggle</p> <p>This bit is used for synchronization of the frame settings between the software and host logic.</p> <p>This bit should be toggled by the software when the FI bit is updated.</p> <p>The host logic sets this bit value to the FRT (bit 31) in HcFmRemaining when the FI bit is loaded. By comparing this bit value that is set on the write of the FI bit with the read FRT bit value, whether or not a new FI bit is reflected can be checked by the software.</p>
30 to 16	FSMPS[14:0]	H'0000	R/W	<p>FS Largest Data Packet</p> <p>Sets the largest amount data to be transmitted or received without causing a schedule overrun. By comparing the current frame position with the setting value, to which frame the transfer can be performed is determined. Since the data amount differs depending on system bus capability, these bits are set by the driver.</p>
15, 14	—	All 0	R	<p>Reserved</p> <p>The write value should be 0.</p>
13 to 0	FI[13:0]	H'2EDF	R/W	<p>Frame Interval</p> <p>Sets the frame length (bit time) used in a FS transfer.</p> <p>Set H'2EDF to satisfy one frame (= 1ms) defined by the USB standard.</p>

**51.6.1.15 HcFmRemaining Register**

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FRT	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	FR[13:0]													
Initial value:	0	0	1	0	1	1	1	0	1	1	0	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

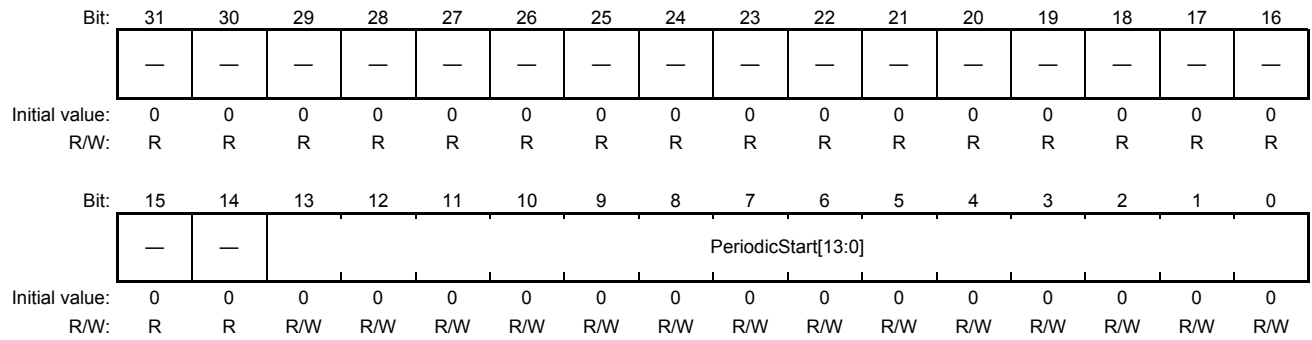

Bit	Bit Name	Initial Value	R/W	Description
31	FRT	0	R	<p>Frame Remaining Toggle</p> <p>This bit is used for synchronization of the frame settings between the software and host logic.</p> <p>When the FR bit reaches H'0000, the host logic copies the FI value (bits 13 to 0) in HcFmInterval into the FR bit, and also copies the FIT value (bit 31) in HcFmInterval into this bit.</p> <p>By comparing the FIT bit value with this bit value, whether the new FI value is set in the FR bit can be checked by the software.</p>
30 to 14	—	All 0	R	Reserved (Don't care)
13 to 0	FR[13:0]	H'2EDF	R	<p>Frame Remaining</p> <p>Indicates the current frame value in the 14-bit down counter.</p> <p>This bit is decremented as the time elapses.</p> <p>When these bits reach H'0000, the value of the FI (bits 13 to 0) in HcFmInterval is copied into these bits to re-load the frame value, and counting is restarted.</p>

**51.6.1.16 HcFmNumber Register**

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FrameNumber[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

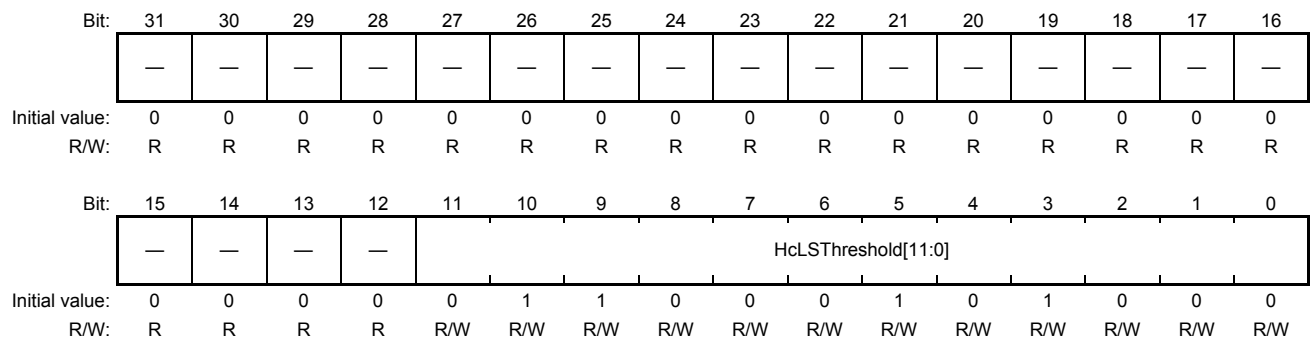

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved (Don't care)
15 to 0	FrameNumber [15:0]	H'0000	R	<p>Indicates the number of frames elapsed.</p> <p>When the FR (bits 13 to 0) in HcFmRemaining reaches H'0000, these bits are incremented.</p>

**51.6.1.17 HcPeriodicStart Register**

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved The write value should be 0.
13 to 0	PeriodicStart [13:0]	H'0000	R/W	Indicates the time when the host logic should start periodic list processing in the frame.  This bit value should be set in the host logic initialization by the software. If the value of the FR (bits 13 to 0) in HcFmRemaining is larger than the set value, NonPeriodic list takes priority over Periodic list.  These bits are recommended to be set to the value approximately 90% of the FI (bits 13 to 0) in HcFmInterval by the OHCI standard. Thus, the recommended value is H'2A2F.

**51.6.1.18 HcLSThreshold Register**

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved The write value should be 0.
11 to 0	HcLSThreshold [11:0]	H'628	R/W	These bits are used to determine whether or not the transfer can be performed in the remaining frame time during LS transfer.  If the FmRemaining value is larger than this value, LS transfer can be started.

## 51.6.1.19 HcRhDescriptorA Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	POTPGT[7:0]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	NOCP	OCPM	DT	NPS	PSM	NDP[7:0]							
Initial value:	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1
R/W:	R	R	R	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	POTPGT[7:0]	H'0F	R/W	Power On To Power Good Time Sets the wait time from power supply to the root-hub port to access by the software. The time unit is 2ms. Thus, the wait time is calculated as POTPGT × 2ms.
23 to 13	—	All 0	R	Reserved The write value should be 0.
12	NOCP	0	R/W	No Over Current Protection Module Specifies whether to support the root-hub overcurrent function. 0: Overcurrent status supported. 1: Overcurrent status not supported.
11	OCPM	1	R/W	Over Current Protection Mode Specifies how to notify the root-hub overcurrent status. This bit should indicate the same mode as the PSM bit. This bit is only valid when the NOCP bit is cleared. 0: Overcurrent status is notified collectively for all the ports. 1: Overcurrent status is notified for each port.
10	DT	0	R	Device Type Indicates that the root-hub is not a composite device. This bit is always read as 0 since the root-hub is not permitted to be a composite device.
9	NPS	0	R/W	No Power Switching Specifies the port power supply control method. 0: Port power can be switched on or off. 1: Port power is always on during host logic operation.
8	PSM	1	R/W	Power Switching Mode Specifies how to control the power switching of each root-hub port. The port responds only to the Set/ClearPortPower when the PPCM (bits 31 to 16) in HcRhDescriptorB is set. When PPCM is cleared, the power switching is controlled by Set/ClearGlobalPower. This bit is only valid when the NPS bit is cleared. 0: All the ports are powered on or off at the same time. 1: Ports are powered on or off individually.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	NDP[7:0]	H'00	R	Number Downstream Port Specifies the number of down-stream ports supported by the host logic root-hub.

**51.6.1.20 HcRhDescriptorB Register**

Bit	Bit Name	Initial Value	R/W	Description															
31 to 16	PPCM[15:0]	H'0002	R/W	Port Power Control Mask Sets the power supply control command for each port. These bits are valid when the PSM (bit 8) in HcRhDescriptorA is set. Each bit is dedicated to a port. Only port 1 is available in this module. <table border="1"> <thead> <tr> <th>Bit</th> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>—</td> <td>Reserved</td> </tr> <tr> <td>1</td> <td>0:</td> <td>All the ports are collectively controlled (Set/ClearGlobalPower).</td> </tr> <tr> <td></td> <td>1:</td> <td>Port 1 is individually controlled (Set/ClearPortPower).</td> </tr> <tr> <td>[15:2]</td> <td>—</td> <td>Reserved</td> </tr> </tbody> </table>	Bit	Value	Description	0	—	Reserved	1	0:	All the ports are collectively controlled (Set/ClearGlobalPower).		1:	Port 1 is individually controlled (Set/ClearPortPower).	[15:2]	—	Reserved
Bit	Value	Description																	
0	—	Reserved																	
1	0:	All the ports are collectively controlled (Set/ClearGlobalPower).																	
	1:	Port 1 is individually controlled (Set/ClearPortPower).																	
[15:2]	—	Reserved																	
15 to 0	DR[15:0]	H'0000	R/W	Device Removable Sets whether each root-hub port is removable or not. Each bit is dedicated to a port. Only port 1 is available in this module. <table border="1"> <thead> <tr> <th>Bit</th> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>—</td> <td>Reserved</td> </tr> <tr> <td>1</td> <td>0:</td> <td>A device connected to port 1 is not removable.</td> </tr> <tr> <td></td> <td>1:</td> <td>A device connected to port 1 is removable.</td> </tr> <tr> <td>[15:2]</td> <td>—</td> <td>Reserved</td> </tr> </tbody> </table>	Bit	Value	Description	0	—	Reserved	1	0:	A device connected to port 1 is not removable.		1:	A device connected to port 1 is removable.	[15:2]	—	Reserved
Bit	Value	Description																	
0	—	Reserved																	
1	0:	A device connected to port 1 is not removable.																	
	1:	A device connected to port 1 is removable.																	
[15:2]	—	Reserved																	

**51.6.1.21 HcRhDescriptorA Register**

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCIC	LPSC/SGP

## 51.6.1.22 HcRhPortStatus1 Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	PRSC	OCIC	PSSC	PESC	CSC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	LSDA/ CPP	PPS/ SPP	—	—	—	PRS/ SPR	POCI/ CSS	PSS/ SPS	PES/ SPE	CCS/ CPE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved The write value should be 0.
20	PRSC	0	R/W	Port Reset Status Change Indicates that a port reset is completed. This bit is set to 1 on completion of the 10-ms hardware reset by the host logic. Writing 1 by the software clears this bit. 0: Port reset not completed or PRS not changed 1: Port reset completed
19	OCIC	0	R/W	Over Current Indicate Change This bit is set when the port overcurrent status has been detected. This bit is only valid when the overcurrent status notification for individual port is set (OCPM in HcRhDescriptorA = 1). Writing 1 by the software clears this bit. 0: Overcurrent status not changed 1: Overcurrent status changed
18	PSSC	0	R/W	Port Suspend Status Change Indicates that RESUME sequence is completed. This bit is set to 1 on completion of all of the RESUME processings by the hardware. Writing 1 by the software clears this bit. This bit is cleared when the PRSC bit is set. 0: RESUME processing not completed 1: RESUME processing completed
17	PESC	0	R/W	Port Enable Status Change Indicates that the PES bit has changed. This bit is set when the port status has changed due to a hardware event such as an overcurrent status, disconnection, power-off, and babble error. Writing 1 by the software clears this bit. 0: PES status not changed 1: PES status changed

Bit	Bit Name	Initial Value	R/W	Description
16	CSC	0	R/W	<p>Connect Status Change</p> <p>Indicates that the CCS bit has changed.</p> <p>This bit is set by the host logic when the CCS bit has changed by the device connection or disconnection.</p> <p>When a port reset, port suspend, or port enable is requested during disconnection, this bit is also set to re-evaluate the device connection status by the software.</p> <p>Writing 1 by the software clears this bit.</p> <p>0: CCS status not changed 1: CCS status changed</p>
15 to 10	—	All 0	R	<p>Reserved</p> <p>The write value should be 0.</p>
9	LSDA	0	R/W	<p>Low Speed Device Attached</p> <p>Indicates the speed of the device connected to the port.</p> <p>This status bit is only valid when the CCS bit is set.</p> <p>0: FS device is connected. 1: LS device is connected.</p>
	CPP	0	R/W	<p>Clear Port Power</p> <p>This bit is used to turn off power to the port when power control for individual port is set.</p> <p>Writing 1 turns off power to the port. Writing 0 has no effect.</p>
8	PPS	0	R/W	<p>Port Power Status</p> <p>Indicates the port power supply status.</p> <p>This bit is cleared when an overcurrent status has been detected.</p> <p>0: Port power off 1: Port power on</p>
	SPP	0	R/W	<p>Set Port Power</p> <p>This bit is used to turn on power to the port when power control for individual port is set.</p> <p>Writing 1 turns on power to the port. Writing 0 has no effect.</p>
7 to 5	—	All 0	R	<p>Reserved</p> <p>The write value should be 0.</p>
4	PRS	0	R/W	<p>Port Reset Status</p> <p>Indicates the port reset status.</p> <p>This bit is cleared when the PRSC bit is set on completion of a 10-ms port reset.</p> <p>When the CCS bit is cleared (device disconnected), this bit cannot be set.</p> <p>0: Port reset not performed 1: Port reset in progress</p>
	SPR	0	R/W	<p>Set Power Reset</p> <p>Issues the port reset to the down-stream port.</p> <p>Writing 1 to this bit initiates the 10-ms port reset. If this bit is written to when the CCS bit is cleared, the PRS bit cannot be written to. At this time, the CSC bit is set to notify the software of the attempt of resetting the port to which no device is connected.</p> <p>Writing 0 has no effect.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	POCI	0	R/W	<p>Port Over Current Indicator</p> <p>Indicates that the down-stream port is in the overcurrent status.</p> <p>This bit is only valid when the overcurrent status notification for individual port is set (OCPM in HcRhDescriptorA is 1). When the collective overcurrent status notification for all the ports is set, this bit is set to 0.</p> <p>0: Normal status 1: Overcurrent status</p>
	CSS	0	R/W	<p>Clear Suspend Status</p> <p>Terminates the Suspend status and activates the Resume sequence.</p> <p>Writing 1 activates the Resume sequence. Writing 0 has no effect. The Resume sequence is activated only when the PSS bit is set.</p>
2	PSS	0	R/W	<p>Port Suspend Status</p> <p>Indicates that the port is in the Suspend status or in the Resume sequence.</p> <p>This bit is set by writing to the SPS bit.</p> <p>This bit cannot be set when the CCS bit is 0 (device disconnected).</p> <p>This bit is cleared when:</p> <ul style="list-style-type: none"> <li>the Resume sequence is completed and PSSC bit is set.</li> <li>the port reset is completed and the PRSC bit is set.</li> <li>the port is in USB RESUME state.</li> </ul> <p>0: Normal transfer state 1: Suspend state</p>
	SPS	0	R/W	<p>Set Port Suspend</p> <p>Causes the port state transition to the Suspend state.</p> <p>When 1 is written to this bit, the port state is transitioned to the Suspend state. Writing 0 has no effect.</p> <p>If this bit is written to when the CCS bit is cleared, the CSC bit is set to notify the driver of the attempt of suspending a disconnected port.</p>
1	PES ( )	0	R/W	<p>Port Enable Status</p> <p>Indicates whether the port is enabled or disabled.</p> <p>When the overcurrent state, disconnection, power-off, babble error is detected, this bit is automatically cleared by the host logic and the PES bit is set.</p> <p>This bit cannot be set when the CCS bit is 0 (device disconnected).</p> <p>The host logic sets this bit on completion of a port reset or a suspend state.</p> <p>0: Disabled 1: Enabled</p>
	SPE	0	R/W	<p>Set Port Enable</p> <p>Sets the PES bit.</p> <p>Writing 1 sets the port to be enabled. Writing 0 has no effect.</p> <p>Note: The port state transition should be made using the SPR (bit 4) in HcRhPortStatus1. Port state transition to Enable by the SPE bit is supported by the OHCI standard, but not supported by the USB standard.</p>

---

Bit	Bit Name	Initial Value	R/W	Description
0	CCS	0	R/W	Current Connect Status Indicates the current connection state of the down-stream port. 0: Device not connected 1: Device connected
	CPE	0	R/W	Clear Port Enable Clears the PES bit. Writing 1 makes the port transition to Disable. Writing 0 has no effect.

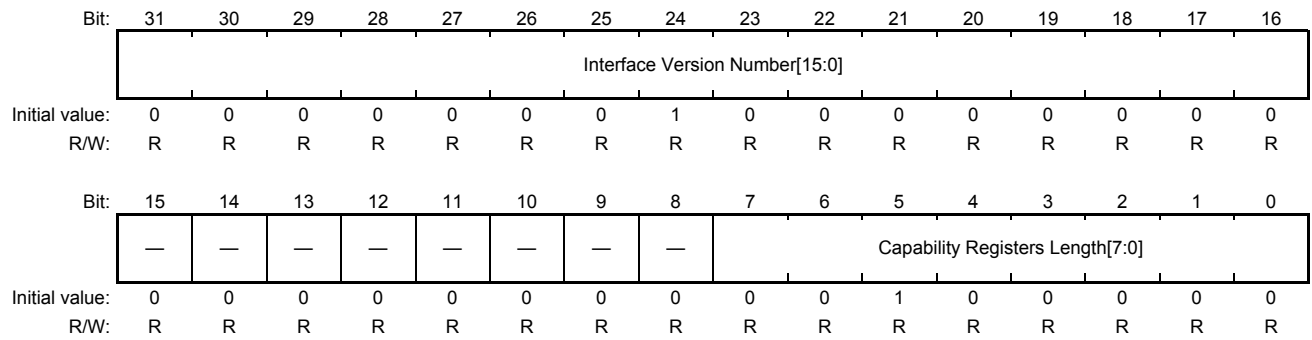

---

### 51.6.2 EHCI Operational Registers

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Please refer to the EHCI standard for the details of the EHCI register. The meaning follows the EHCI standard.

#### 51.6.2.1 HCIVERSION/CAPLENGTH Register

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Interface Version Number[15:0]	H'0100	R	Indicates the EHCI standard version supported by the host logic. The set value H'0100 indicates that the host logic complies with EHCI Rev.1.0.
15 to 8	—	All 0	R	Reserved (Don't care)
7 to 0	Capability Registers Length[7:0]	H'20	R	Indicates the start address of the operational register area. The set value H'20 indicates that the operational register area is started at H'20.

## 51.6.2.2 HCSPARAMS Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	1	0	0	0	1	1	0	0	1	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved (Don't care)
23 to 20	DPN[3:0]	0000	R	Debug Port Number Indicates a debugging port. The set value is B'0000 since the host logic does not support a debugging port.
19 to 17	—	All 0	R	Reserved (Don't care)
16	P_INDICATOR	0	R	Indicates whether or not the host logic supports the port indicator control function. The set value is 0 since the host logic does not support the port indicator control function.
15 to 12	N_CC[3:0]	H'1	R	Number of Companion Controller Indicates the number of OHCI host logics related to the EHCI host logic. The set value is H'1 since one OHCI host logic is incorporated.
11 to 8	N_PCC[3:0]	H'1	R	Number of Ports per Companion Controller Indicates the number of ports supported by one OHCI host logic. These bits are set according to the Port_no (bits 1 and 0) setting in PCI Configuration EXT1. The set value is H'1 since one port is supported.
7	PRR	1	R	Port Routing Rules Indicates how the ports are mapped by the OHCI host logic. The set value is H'1 since the ports are mapped according to the HCSP_PORTROUTE register setting.
6, 5	—	All 0	R	Reserved (Don't care)
4	PPC	1	R	Port Power Control Indicates how the port power is controlled. This bit is set according to the Ppcnt (bit 2) setting in PCI Configuration EXT1. The set value is 1 since the power supply control is supported by this module.

---

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	N_PORTS [3:0]	H'1	R	<p>Number of ports</p> <p>Indicates the number of down-stream ports. The set value is 1h since one port is supported.</p> <p>The number of physical down-stream ports used by the host logic is indicated.</p> <p>These bits change according to the Port_no (bits 1 and 0) setting in PCI Configuration EXT1.</p> <p>The set value is H'1 since one port is supported.</p>

---

## 51.6.2.3 HCCPARAMS Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EECP[7:0]							IST[3:0]				—	ASPC	PFLF	64AC	
Initial value:	1	1	1	0	1	0	0	0	0	0	0	0	0	1	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved (Don't care)
15 to 8	EECP[7:0]	H'E8	R	EHCI Extend Capabilities Pointer Indicates the offset address for the EHCI extend capabilities registers. These bits indicate that an extend register exists on H'E8 in the EHCI configuration space. The read value is invalid since the legacy function is not supported by the host logic.
7 to 4	IST[3:0]	H'0	R	Isochronous Scheduling Threshold The set value is H'0 since the host logic does not support the cache mode for isochronous schedule data for the whole frame.
3	—	0	R	Reserved (Don't care)
2	ASPC	1	R	Asynchronous Schedule Park Capability Indicates whether or not the park mode function is supported for high-speed queue heads in asynchronous schedules. The set value is 1 since the park mode function is supported by the host logic.
1	PFLF	1	R	Programming Frame List Flag Indicates how the size of the frame list to be used by the software is set. The set value is 1. When this bit is 1, the frame list size can be set with the FLS (bits 3 and 2) in the USBCMD register, which allows the setting of 4-kbyte or less frame list size.
0	64AC	0	R	64-bit Addressing Capability Indicates whether the data structure uses the 32-bit or 64-bit address memory pointer. The set value is 0 since the 32-bit address memory pointer is used in this host logic data structure. The 64-bit address memory pointer is not supported by this host logic.

### 51.6.2.4 HCSP\_PORTROUTE Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Companion Port Route[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Companion Port Route[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Companion Port Route [31:0]	All 0	R	Indicates the correspondence between the ports and OHCI host logics. The set value is all 0 since one OHCI host logic is incorporated in this host logic.

### 51.6.2.5 USBCMD Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	ITC[7:0]								—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W		
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	ASPME	—	ASPMC[1:0]	LHCR	IAAD	ASE	PSE	FLS[1:0]	HC RESET	RS	—	—		
Initial value:	0	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R/W	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W		

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved The write value should be 0.
23 to 16	ITC[7:0]	H'08	R/W	Interrupt Threshold Control Specifies the maximum rate for interrupts generated by the host logic. If a value other than below is set, the operation cannot be guaranteed. H'00: Reserved H'01: 1 microframe H'02: 2 microframes H'04: 4 microframes H'08: 8 microframes (1 ms) H'10: 16 microframes (2 ms) H'20: 32 microframes (4 ms) H'40: 64 microframes (8 ms)
15 to 12	—	All 0	R	Reserved The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
11	ASPME	1	R/W	Asynchronous Schedule Park Mode Enable Enables or disables park mode. 0: Park mode is disabled. 1: Park mode is enabled
10	—	All 0	R	Reserved The write value should be 0.
9, 8	ASPMC[1:0]	11	R/W	Asynchronous Schedule Park Mode Count Specifies the number of transactions that can be executed continuously from one QH. The settable range is from H'1 to H'3. These bits are valid when the ASPME (bit 11) is 1.
7	LHCR	0	R/W	Light Host Controller Reset Indicates the execution status of the Light Host Controller Reset command. This bit is fixed to 0 since Light Host Controller Reset is not supported by this host logic.
6	IAAD	0	R/W	Interrupt on Async Advance Doorbell This bit is used as a doorbell by the software. The software sets this bit to 1 to generate an interrupt on a transition to the next QH processing. When the IAAE (bit 5) in USBINTR is 1, the interrupt is generated in the next interrupt timing after this bit is set to 1. If this bit is set when IAAE bit is 0, the operation cannot be guaranteed. This bit is cleared by the host logic. The host logic clears this bit to 0 on completion of one QH processing and sets the IAA (bit 5) in USBSTS to 1.
5	ASE	0	R/W	Asynchronous Schedule Enable Specifies that the host logic executes or skips asynchronous list processing. 0: Asynchronous list processing is not executed (skipped). 1: Asynchronous list processing is executed using the ASYNCLISTADDR register.
4	PSE	0	R/W	Periodic Schedule Enable Specifies that the host logic executes or skips periodic list processing. 0: Periodic list processing is not executed (skipped). 1: Periodic list processing is executed using the PERIODICLISTBASE register.
3, 2	FLS[1:0]	00	R/W	Frame List Size Specifies the frame list size. The size of Frame List Current index of FRINDEX is determined depending on the frame list size specified with this field. 00: 1024 elements (4096 bytes) 01: 512 elements (2048 bytes) 10: 256 elements (1024 bytes) 11: Reserved

Bit	Bit Name	Initial Value	R/W	Description
1	HCRESET	0	R/W	<p>Host Controller Reset</p> <p>Resets the host logic.</p> <p>When this bit is set to 1, the host logic resets the internal pipeline and state machine and sets the initial value. In addition, the host logic immediately terminates communication on the USB. At this time, the USB reset is not issued to the down-stream port.</p> <p>Although the resetting does not initialize the PCI configuration registers, the EHCI operation registers are reset to their initial value. The ownership of the port is returned to the OHCI.</p> <p>This bit is automatically cleared to 0 by the host logic upon completion of the resetting operation. During the resetting process, software cannot clear this bit and interrupt the resetting process.</p> <p>This bit should be set when the HCH (bit 12) in USBSTS is 1.</p>
0	RS	0	R/W	<p>Run/Stop</p> <p>Controls the ON/OFF action of the EHCI host logic.</p> <p>Setting this bit to 1 starts the host logic operation.</p> <p>While the bit is 1, the host logic continues execution.</p> <p>This bit should be set to 1 while the host logic is in the halt state.</p> <p>The HCH (bit 12) in USBSTS indicates that the host logic has terminated the transaction and transitioned into the Stop state</p> <p>0: Stopped (The host logic has terminated the transaction and halted the operation.)</p> <p>1: Executed (The host logic executes the schedule.)</p>

## 51.6.2.6 USBSTS Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ASS	PSS	REC	HCH	—	—	—	—	—	—	IAA	HSE	FLR	PCD	USBER RINT	USBIN T
Initial value:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be 0.
15	ASS	0	R	Asynchronous Schedule Status Indicates the current status of asynchronous schedules. Asynchronous schedules are enabled (1) or disabled (0) when this bit matches the ASE (bit 5) in USBCMD. 0: Asynchronous schedules are disabled. 1: Asynchronous schedules are enabled.
14	PSS	0	R	Periodic Schedule Status Indicates the current status of periodic schedules. Periodic schedules are enabled (1) or disabled (0) when this bit matches the PSE (bit 4) in USBCMD. 0: Periodic schedules are disabled. 1: Periodic schedules are enabled.
13	REC	0	R	Reclamation This bit is used to detect empty asynchronous schedule state. The host logic clears this bit to 0 after a reset or a QH fetch with H = 1. The host logic also sets this bit when executing an asynchronous transaction or having detected a start event. The host logic transitions to Async Schedule Sleeping mode when a QH with H = 1 is fetched while this bit is 0.
12	HCH	1	R	This bit is cleared to 0 when the RS (bit 0) in USBCMD is 1. When the RS bit is set to 0 by the host logic or software, the EHCI host logic stops the execution and the host logic sets this bit to 0. 0: EHCI host logic execution in progress 1: EHCI host logic execution stopped
11 to 6	—	All 0	R	Reserved The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
5	IAA	0	R/W	<p>Interrupt on Async Advance</p> <p>Indicates the Async Advance interrupt status.</p> <p>Fetching a QH, the host logic checks the Interrupt on Async Advance Doorbell (IAAD) bit status in USBCMD. If the IAAD bit is 1, the host logic clears the IAAD bit on the successful completion of the QH processing and sets this bit.</p> <p>When the IAAE bit (bit 5) in USBINTR is 1, the Async Advance interrupt is generated on the next timing after this bit is set to 1.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>0: Async Advance interrupt has not been generated. 1: Async Advance interrupt generation has been detected.</p>
4	HSE	0	R/W	<p>Host System Error</p> <p>This bit is set to 1 if a severe error, such as a parity error on the PCI system, has occurred in the host logic.</p> <p>When a severe error has occurred, the host logic clears the RS (bit 0) in USBCMD to 0 to prevent any TD from being executed.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>0: A system error has not occurred. 1: A system error has occurred.</p>
3	FLR	0	R/W	<p>Frame List Rollover</p> <p>The host logic sets this bit to 1 if the Frame Index bit in FRINDEX rolls over from its maximum value to H'0000.</p> <p>The maximum value (at what value a Rollover occurs) depends on the FLS (bits 3 and 2) of USBCMD.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>0: Rollover to H'000 has not occurred in frame list. 1: Rollover to H'000 has occurred in frame list.</p>
2	PCD	0	R/W	<p>Port Change Detect</p> <p>Indicates that port status has changed.</p> <p>The host logic sets this bit when any of the following conditions is satisfied in a port with the Port Owner (bit 13) of PORTSC1 being 0:</p> <ul style="list-style-type: none"> <li>• The CSC (bit 1) of PORTSC1 changes from 0 to 1 (device connection/disconnection detected)</li> <li>• The PEDC (bit 3) of PORTSC1 changes from 0 to 1 (port enable state changed)</li> <li>• The OC (bit 5) of PORTSC1 changes from 0 to 1 (overcurrent state detected)</li> <li>• The FPR (bit 6) of PORTSC1 changes from 0 to 1 (a transition from J to K detected in a suspended port)</li> </ul> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p>

Bit	Bit Name	Initial Value	R/W	Description
1	USBERRINT	0	R/W	<p>USB Error Interrupt</p> <p>Indicates that a USB transaction has ended with an error.</p> <p>The host logic sets this bit when a USB transaction ends with an error, such as an error counter underflow.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>0: Normal USB transaction 1: USB transaction has ended with an error</p>
0	USBINT	0	R/W	<p>USB Interrupt</p> <p>Indicates that the USB transfer has ended.</p> <p>The host logic sets this bit when:</p> <ul style="list-style-type: none"> <li>• USB transfer is completed, or</li> <li>• A short packet is received</li> </ul> <p>If the IOC (Interrupt on Complete) of the TD is 1, this bit is also set even if the USB transfer ends with an error.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>0: USB transfer has not ended 1: USB transfer has ended</p>

## 51.6.2.7 USBINTR Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	IAAE	HSEE	FLRE	PCIE	USBEI E	USBIE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

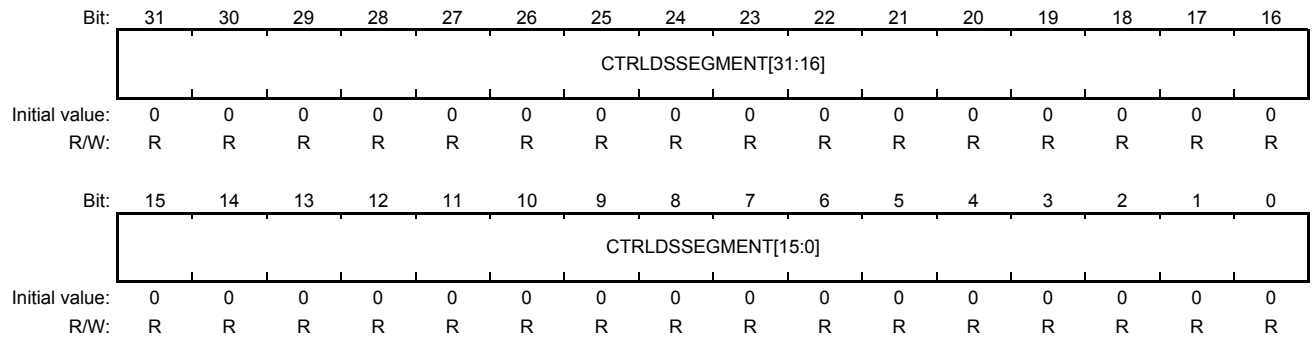

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved The write value should be 0.
5	IAAE	0	R/W	Interrupt on Async Advance Enable Enables or disables the IAA bit (bit 5) in USBSTS. The interrupt can be cleared with the IAA bit. 0: Disable 1: Enable
4	HSEE	0	R/W	Host System Error Enable Enables or disables the HSE bit (bit 4) in USBSTS. The interrupt can be cleared with the HSE bit. 0: Disable 1: Enable
3	FLRE	0	R/W	Frame List Rollover Enable Enables or disables the FLR bit (bit 3) in USBSTS. The interrupt can be cleared with the FLR bit. 0: Disable 1: Enable
2	PCIE	0	R/W	Port Change Interrupt Enable Enables or disables the PCD bit (bit 2) in USBSTS. The interrupt can be cleared with the PCD bit. 0: Disable 1: Enable
1	USBEIE	0	R/W	USB Error Interrupt Enable Enables or disables the USBERRINT bit (bit 1) in USBSTS. The interrupt can be cleared with the USBERRINT bit. 0: Disable 1: Enable
0	USBIE	0	R/W	USB Interrupt Enable Enables or disables the USBINT bit (bit 0) in USBSTS. The interrupt can be cleared with the USBINT bit. 0: Disable 1: Enable

**51.6.2.8 FRINDEX Register**

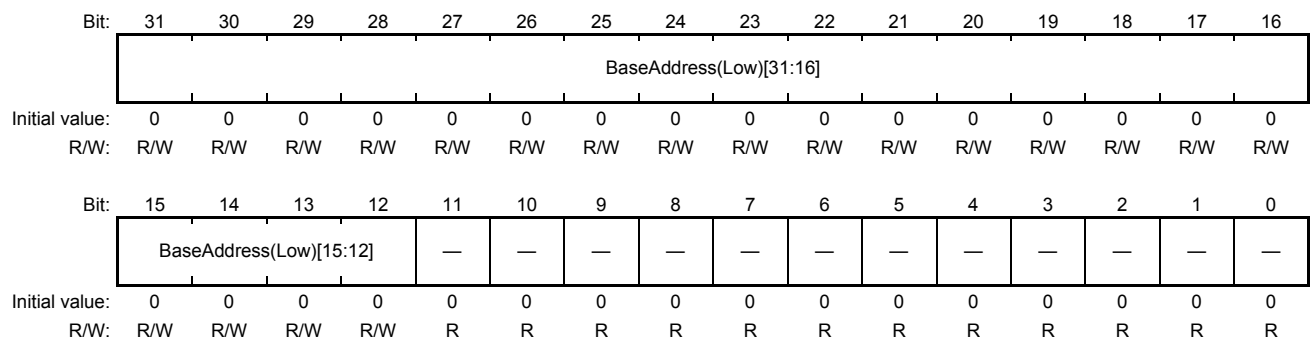

Bit	Bit Name	Initial Value	R/W	Description															
31 to 14	—	All 0	R	Reserved The write value should be 0.															
13 to 0	Frame Index [13:0]	H'0000	R/W	<p>This bit is used to attach an index to a periodic frame list by the host logic.</p> <p>This value is incremented at every end of microframe.</p> <p>Bits[N:3] are used for the Current Index of the frame list. In other words, the current frame list is accessed eight times before a transition is made to the next index. N depends on the FLS bits (bits 3 and 2) in USBCMD as follows:</p> <table border="1"> <thead> <tr> <th>Frame List Size</th> <th>Number of Elements</th> <th>N</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>1024</td> <td>12</td> </tr> <tr> <td>01</td> <td>512</td> <td>11</td> </tr> <tr> <td>10</td> <td>256</td> <td>10</td> </tr> <tr> <td>11</td> <td>Reserved</td> <td></td> </tr> </tbody> </table> <p>This register should be accessed only when the host logic is stopped (HCH bit (bit 12) in USBSTS = 1)</p> <p>The value of this register is used as the SOF frame number of an SOF token.</p>	Frame List Size	Number of Elements	N	00	1024	12	01	512	11	10	256	10	11	Reserved	
Frame List Size	Number of Elements	N																	
00	1024	12																	
01	512	11																	
10	256	10																	
11	Reserved																		

**51.6.2.9 CTRLDSSEGMENT Register**

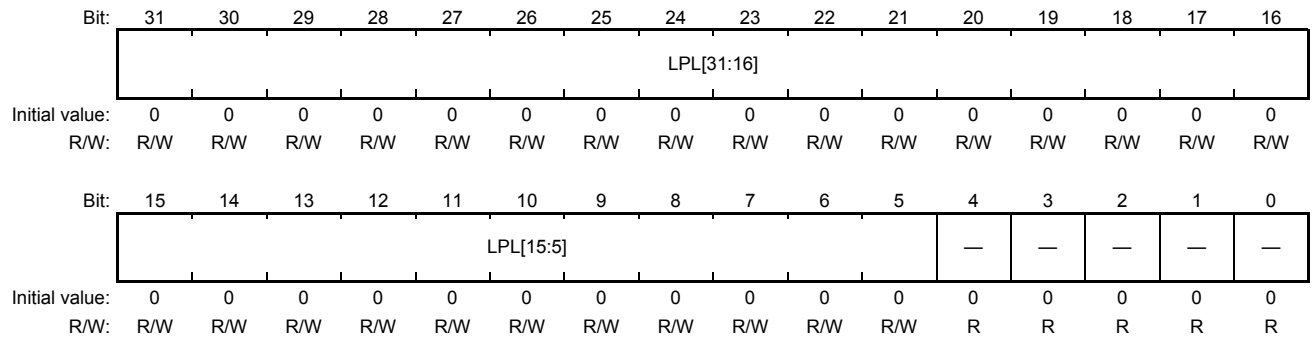

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CTRLDSSEGM ENT[31:0]	All 0	R	This register is not used since the host logic does not support the 64-bit addressing. Do not access this register.

**51.6.2.10 PERIODICLISTBASE Register**

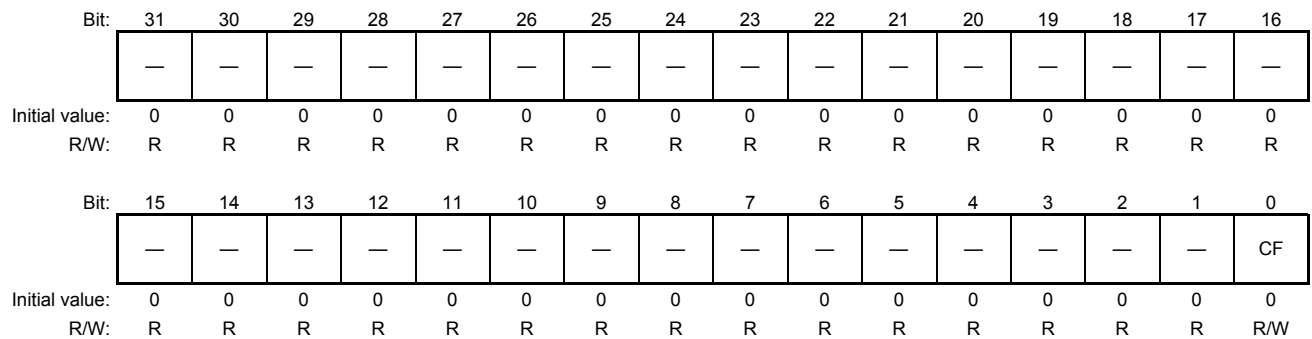

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	BaseAddress (Low)[31:12]	All 0	R/W	Specifies the start address of the periodic frame list placed on the system memory. This register value is loaded by software before the list processing is executed by the host logic. The host logic determines the frame list to be executed using these bits and the Frame Index (bits 13 to 0) in FRINDEX. A periodic frame list address should be allocated on the 4-Kbyte boundary. If these bits are changed during operation, the operation cannot be guaranteed.
11 to 0	—	All 0	R	Reserved The write value should be 0.

**51.6.2.11 ASYNCLISTADDR Register**

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	LPL[31:5]	All 0	R/W	Link Pointer Low Specifies the asynchronous queue head for the next execution in the system memory. An asynchronous queue head address should be allocated on the 32-byte boundary.
4 to 0	—	All 0	R	Reserved The write value should be 0.

**51.6.2.12 CONFIGFLAG Register**

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved The write value should be 0.
0	CF	0	R/W	Configure Flag Specifies whether the OHCI or EHCI is routed by the port routing control circuit by default. This bit is set to 1 by the software at the end of the host logic configuration process. 0: Each port is routed to the OHCI host logic by default. 1: Each port is routed to the EHCI host logic by default.

## 51.6.2.13 PORTSC1 Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	WKOC _E	WKDSC NNT_E	WKCNT E	PTC[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIC[1:0]		PO	PP	LS[1:0]		—	PR	SUS	FPR	OC	OCA	PEDC	PED	CSC	CCS
Initial value:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved The write value should be 0.
22	WKOC_E	0	R/W	Wake on Over-current Enable Setting this bit to 1 enables detecting overcurrent for ports as a wakeup event. The host logic operation is not affected by this bit. When the PP bit is 0, this bit is 0.
21	WKDSCNNT_E	0	R/W	Wake on Disconnect Enable Setting this bit to 1 enables detecting device disconnection as a wakeup event. The host logic operation is not affected by this bit. When the PP bit is 0, this bit is 0.
20	WKCNTNT_E	0	R/W	Wake on Connect Enable Setting this bit to 1 enables detecting device connection as a wakeup event. The host logic operation is not affected by this bit. When the PP bit is 0, this bit is 0.
19 to 16	PTC[3:0]	0000	R/W	Port Test Control Controls test mode. For details of the test mode, see section 7 in the USB2.0 Specifications. 0000: Normal 0001: Test J_STATE 0010: Test K_STATE 0011: Test SE0_NAK 0100: Test Packet 0101: Test FORCE_ENABLE Other: Reserved
15, 14	PIC[1:0]	00	R/W	Port Indicator Control Since the host logic does not support the port indicator control function, these bits are set to B'00. Writing these bits has no effect.

Bit	Bit Name	Initial Value	R/W	Description																				
13	PO	1	R/W	<p>Port Owner</p> <p>Specifies whether the OHCI or EHCI has the port ownership.</p> <p>0: The EHCI has the port ownership.</p> <p>1: The OHCI has the port ownership.</p> <p>This bit is cleared to 0 when the CF (bit 0) in CONFIGFLAG changes from 0 to 1. When the CF bit is 0, this bit is 1.</p> <p>When the connected device is not a high-speed device, this bit is set to 1 and the ownership is passed to the OHCI.</p>																				
12	PP	0	R/W	<p>Port Power</p> <p>Controls the port power.</p> <p>When this bit is 0 or the port power is turned off, the port does not function and connection/disconnection is not detected.</p> <p>If overcurrent is detected with this bit being 1, the host logic clears this bit and turns off the power to the port.</p> <p>0: The port power is turned off.</p> <p>1: The port power is turned on.</p> <p>The function of this bit differs depending on the PPC bit (bit 4) in HCSPARAMS.</p> <table border="1"> <thead> <tr> <th>PPC</th> <th>PP</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>1</td> <td>This bit is always 1 and the port power is always turned on.</td> </tr> <tr> <td>1</td> <td>0 or 1</td> <td>The port power can be switched on and off depending on this bit.</td> </tr> </tbody> </table>	PPC	PP	Function	0	1	This bit is always 1 and the port power is always turned on.	1	0 or 1	The port power can be switched on and off depending on this bit.											
PPC	PP	Function																						
0	1	This bit is always 1 and the port power is always turned on.																						
1	0 or 1	The port power can be switched on and off depending on this bit.																						
11, 10	LS[1:0]	00	R	<p>Line Status</p> <p>These bits indicate the current D+/D- logic level of the current USB port. Bit	Bit Name	Initial Value	R/W	Description												
8	PR	0	R/W	<p><b>Port Reset</b></p> <p>Controls the port resetting processing.</p> <p>The setting of this bit by software commences the bus resetting operation that is defined in the USB 2.0 specifications. To complete the bus resetting operation, the software must write a 0 to this bit. The software must keep this bit at 1 until such time as the reset time defined in the USB 2.0 specifications has elapsed.</p> <p>When HCH (bit 12) in USBSTS is 1, the software must not set this bit.</p> <p>This bit is 0 when either of the following conditions are satisfied:</p> <ul style="list-style-type: none"> <li>• PP bit = 0</li> <li>• Port Owner bit = 1</li> <li>• Current Connect Status = 0</li> </ul> <p>1: The port being reset 0: The port not being reset</p>												
7	SUS	0	R/W	<p><b>Suspend</b></p> <p>Indicates the suspend state of the port.</p> <p>1: The port is in the Suspend state. 0: The port is not in the Suspend state.</p> <p>Depending on the setting of this bit and PED (bit 2), the port assumes the following condition:</p> <table border="1"> <thead> <tr> <th>PED</th> <th>Suspend</th> <th>Port State</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>X</td> <td>Disable</td> </tr> <tr> <td>1</td> <td>0</td> <td>Enable</td> </tr> <tr> <td>1</td> <td>1</td> <td>Suspend</td> </tr> </tbody> </table> <p>In the Suspend state, any data transfer from this port to the downstream port is blocked, except that Port Reset is conveyed. If this bit is set to 1 during data transfer, the status is updated and the data is blocked after the current transfer operation is completed.</p> <p>This bit is set to 1 by the software. This bit can be set to 1 only when the PP bit = 1, PO bit = 0, and CCS bit = 1.</p> <p>This bit is unconditionally cleared to 0 when:</p> <ul style="list-style-type: none"> <li>• the software clears the Force PR bit to 0 or</li> <li>• the software sets the PR bit to 1.</li> </ul> <p>This bit is 0 when the PP bit is 0.</p>	PED	Suspend	Port State	0	X	Disable	1	0	Enable	1	1	Suspend
PED	Suspend	Port State														
0	X	Disable														
1	0	Enable														
1	1	Suspend														

Bit	Bit Name	Initial Value	R/W	Description
6	FPR	0	R/W	<p>Force Port Resume</p> <p>Indicates that the Resume operation of the port has been detected.</p> <p>The host logic sets this bit and PCD (bit 2) in USBSTS to 1 when a transition from J to K (RemoteWakeUp) is detected when the ports is in the Suspend state. In addition, the software sets this bit to output the Resume signal. At this time, Port Change Detect bit must not be set.</p> <p>As long as this bit is 1, the Resume signal (Full-Speed K) continues to be driven. The software must clear this bit after an appropriate length of time. By changing this bit from 1 to 0, the port returns to the HS idle state. The bit remains 1 until the port returns to the HS idle state.</p> <p>This bit is 0 when the PP bit is 0.</p> <p>0: Resume (K-state) has not been detected/output 1: Resume (K-state) has been detected/output</p>
5	OC	0	R/W	<p>Over-current Change</p> <p>Indicates that the OCA (bit 4) status has changed.</p> <p>This bit can be cleared by writing 1 by software. Writing 0 has no effect.</p> <p>0: Indicates that the Over-Current Active bit has not changed. 1: Indicates that the Over-Current Active bit has changed.</p>
4	OCA	0	R	<p>Over-current Active</p> <p>Indicates the port overcurrent status.</p> <p>Detecting the overcurrent status, the host logic clears the PP (bit 12) and related bits to 0 and sets this bit to 1.</p> <p>This bit is automatically cleared to 0 when the over-current state is cancelled.</p> <p>0: Indicates that the port is not in the overcurrent state. 1: Indicates that the port is in the overcurrent state.</p>
3	PEDC	0	R/W	<p>Port Enable/Disable Change</p> <p>Indicates that the port enable/disable status has changed.</p> <p>Detecting the Frame Babble, the host logic disables the port and sets this bit to 1.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>This bit is 0 when the PP bit is 0.</p> <p>0: Indicates that the port state has not changed. 1: Indicates that the port state has changed from enable to disable status.</p>

Bit	Bit Name	Initial Value	R/W	Description
2	PED	0	R/W	<p>Port Enabled/Disabled</p> <p>Indicates that the port is enabled or disabled.</p> <p>The host logic enables the port and sets this bit to 1 when it resets the port and verifies that the connected device is a HS device. This bit cannot be set by the software.</p> <p>The host logic disables the port and clears this bit to 0 when it detects a disconnection of a device or other errors. The port is also disabled by writing 0 by the software. The status of this bit does not change until the port status actually changes.</p> <p>If the port is disabled, data does not propagate to the down-stream port; the port reset, however, is conveyed.</p> <p>This bit is 0 when the PP bit is 0.</p> <p>When the PTC (bits 3 to 0) is B'0101 (Test FORCE_ENABLE), the port is unconditionally enabled and this bit is set to 1.</p> <p>0: The port is disabled. 1: The port is enabled.</p>
1	CSC	0	R/W	<p>Connect Status Change</p> <p>Indicates that the CCS (bit 0) has changed.</p> <p>This bit can be cleared by writing 1 by the software. Writing 0 has no effect.</p> <p>This bit is 0 when the PP bit is 0.</p> <p>0: Status has not changed. 1: The Current Connect Status bit has changed.</p>
0	CCS	0	R/W	<p>Current Connect Status</p> <p>Indicates the port connection status.</p> <p>Detecting a connection of a device, the host logic sets this bit to 1.</p> <p>When the PTC (bits 3 to 0) is B'0101 (Test FORCE_ENABLE), this bit is set to 1 even if a device is not connected.</p> <p>Detecting a disconnection of a device clears this bit to 0.</p> <p>This bit is 0 when the PP or PO bit is 0.</p> <p>0: No device has been connected to the port. 1: A device has been connected to the port.</p>

**51.6.3 PCI Configuration Registers for OHCI**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

**51.6.3.1 Offset H'00 (Vendor ID, Device ID)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Device ID[15:0]	H'0035	R	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.
15 to 0	Vendor ID[15:0]	H'1033	R	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.

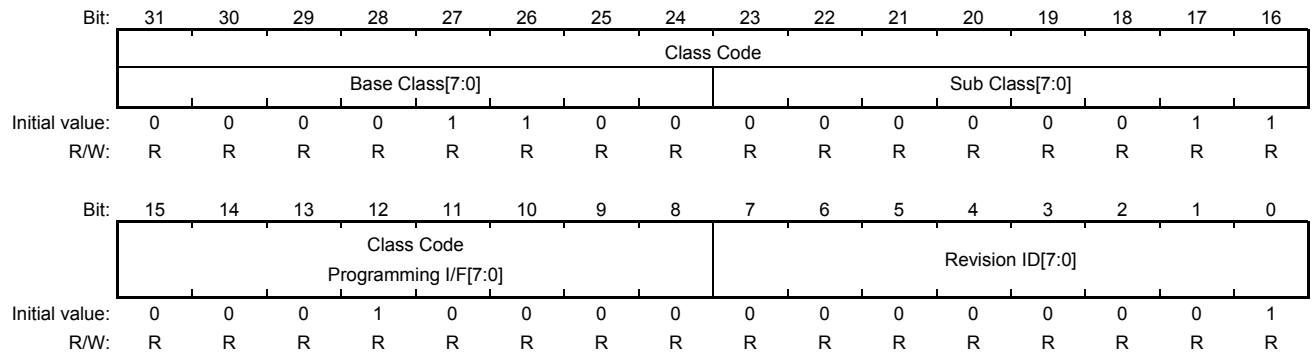

## 51.6.3.2 Offset H'04 (Command, Status)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	Fast Back to Back Enable	SERR Enable	Wait Cycle Control	Parity Error Response	VGA Palette Snoop	Memory Write and Invalidate	Special Cycle	Bus Master	Memory Space	I/O Space
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31	Detected Parity Error	0	R/W	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 from the PCI bus clears this bit.
30	Signaled System Error	0	R/W	This is a status bit for SERR. This bit is set to 1 when a system error occurs. Writing 1 from the PCI bus clears this bit.
29	Received Master Abort	0	R/W	This is a status bit for Master/Master Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Master Abort. Writing 1 from the PCI bus clears this bit.
28	Received Target Abort	0	R/W	This is a status bit for Master/Target Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Target Abort. Writing 1 from the PCI bus clears this bit.
27	Signaled Target Abort	0	R/W	This is a status bit for Slave/Target Abort. This bit is set to 1 in slave operation when the host logic has terminated, through Target Abort, the bus cycle in which the host logic is accessed. Writing 1 from the PCI bus clears this bit.
26, 25	Devsel Timing[1:0]	01	R	These bits indicate the DEVSEL response speed. The value is fixed to B'01 (medium-speed response).
24	Data Parity Error Detected	0	R/W	This bit is set when a parity error is detected in master operation. Writing 1 from the PCI bus clears this bit. The value is fixed to 0 while the Parity Error Response bit is set as disabled.
23	Fast Back to Back Capable	0	R	This bit indicates whether Fast Back to Back transactions are supported. As the host logic does not support Fast Back to Back transactions, this value is fixed to 0.
22, 21	—	0	R	Reserved The write value should be 0.
20	Capabilities List	1	R	This value is fixed to 1, which indicates that the power management mode is supported.
19 to 10	—	All 0	R	Reserved The write value should be 0.
9	Fast Back to Back Enable	0	R	This bit enables Fast Back to Back transactions. As the host logic does not support Fast Back to Back transactions, this value is always 0.

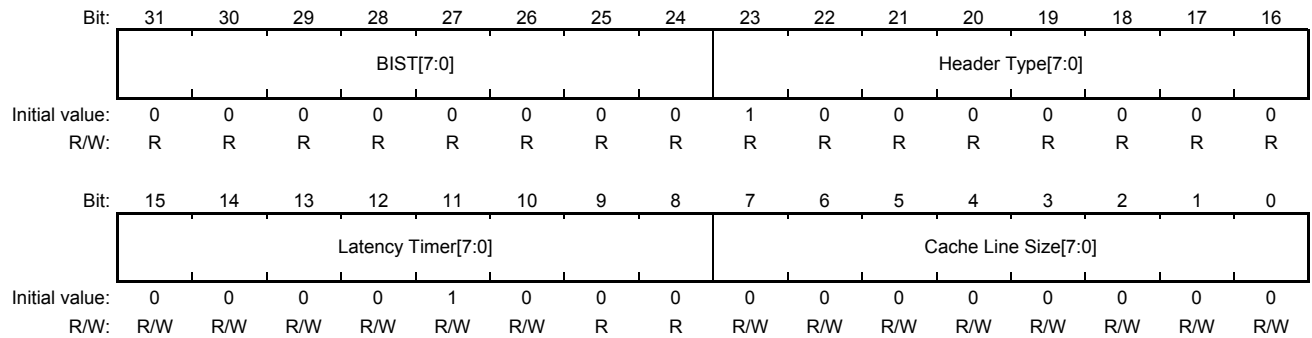

Bit	Bit Name	Initial Value	R/W	Description
8	SERR Enable	0	R/W	This bit enables system error response. 0: SERR0 is not asserted. 1: SERR0 is asserted. To notify of a system error through the SERR signal, set this bit to 1.
7	Wait Cycle Control	0	R	This bit enables wait cycle control. As the host logic does not support address/data stepping, this value is always 0.
6	Parity Error Response	0	R/W	This bit enables parity error response. 0: PERR0 is not asserted. 1: PERR0 is asserted. When a parity error is detected, the Detected Parity Error bit is set to 1 even if this bit is cleared to 0.
5	VGA Palette Snoop	0	R	This bit enables VGA palette snooping. As the host logic does not support VGA palette snooping, this value is always 0.
4	Memory Write and Invalidate Enable	0	R/W	This bit enables the Memory Write and Invalidate command. In this module, do not change this from the initial value (0). 0: Memory write and invalidate command is disabled. 1: Memory write and invalidate command is enabled.
3	Special Cycle	0	R	This bit enables Special Cycle operation. As the host logic does not support the Special Cycle operation, this value is always 0.
2	Bus Master	0	R/W	This bit enables bus master operation. This is an enable signal for master access to the PCI bus. Set to 1 when accessing the SRAM on the system bus. Set this bit to 1 during initial setting of the host logic.
1	Memory Space	0	R/W	This bit enables access to the memory space. This is an enable signal for memory access specified in the PCI standard. Set to 1 when accessing registers. Set this bit to 1 during initial setting of the host logic.
0	I/O Space	0	R	This bit enables access to the I/O space. As the host logic does not accept I/O access, this value is always 0.

**51.6.3.3 Offset H'08 (Revision ID, Class Code)**

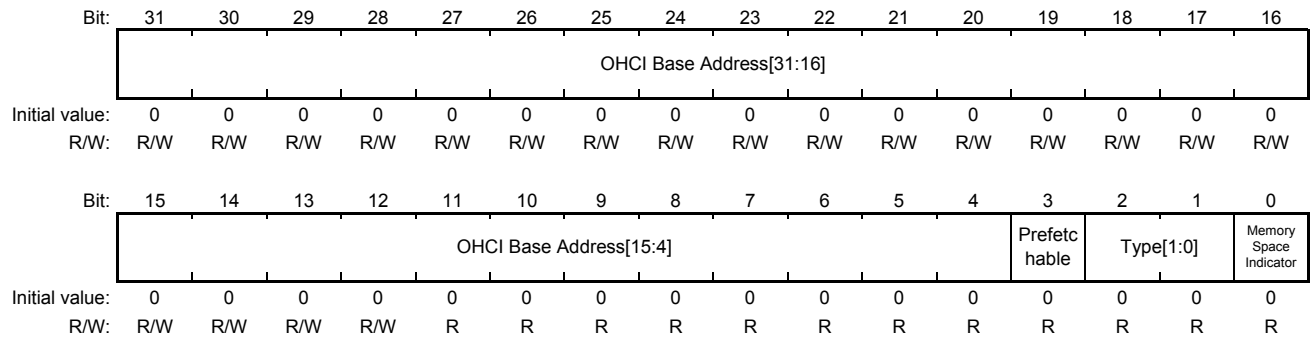

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Base Class[7:0]	H'0C	R	These bits indicate the base class specified in the PCI standard. The value is H'0C, which indicates a serial peripheral bus controller.
23 to 16	Sub Class[7:0]	H'03	R	These bits indicate the subclass specified in the PCI standard. The value is H'03, which indicates a USB device.
15 to 8	Programming I/F[7:0]	H'10	R	These bits indicate the program interface specified in the PCI standard. The value is H'10, which indicates OHCI.
7 to 0	Revision ID[7:0]	H'01	R	These bits indicate the revision of the host logic. The value is fixed to H'01.

**51.6.3.4 Offset H'0C (Cache Line Size, Latency Timer, Header Type, BIST)**

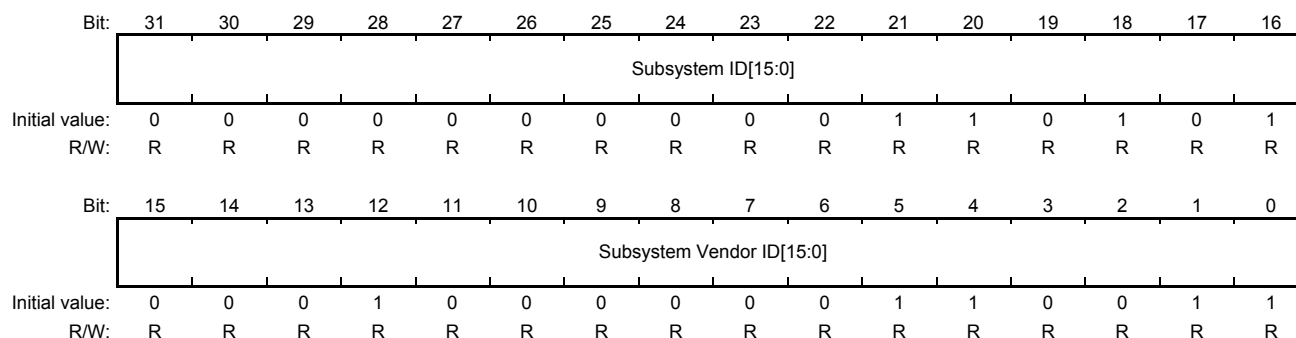

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	BIST[7:0]	H'00	R	These bits are used for self testing. As the host logic does not support the self test function, this value is always H'00.
23 to 16	Header Type[7:0]	H'80	R	These bits notify the system of the header type. As the header type is Type 0, bits [22:16] are fixed to H'00. As this is a multifunction device, bit 23 is fixed to 1.
15 to 8	Latency Timer[7:0]	H'08	R/W	These bits notify the system of the latency timer. The lowest two bits are fixed to B'00.
7 to 0	Cache Line Size[7:0]	H'00	R/W	These bits notify the system of the cache line size.

**51.6.3.5 Offset H'10 (OHCI Base Address)**

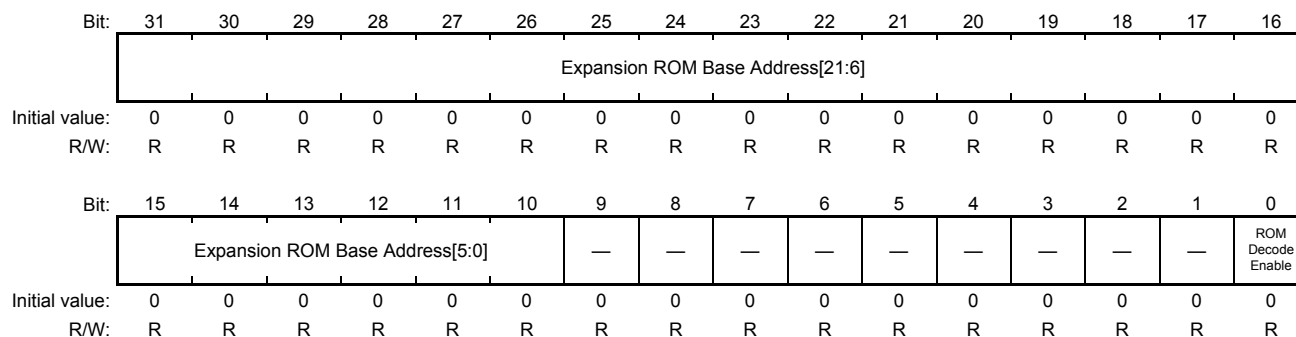

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	OHCI Base Address[31:12]	H'0000 0	R/W	Bits [31:12] specify the base address of the operational registers. Specify the base address of the operational registers determined by the system during initialization. Bits [11:4] are fixed to H'00, which indicates that the operational registers are allocated to a 4-Kbyte address space.
	OHCI Base Address[11:4]	H'00	R	
3	Prefetchable	0	R	As the host logic does not support prefetching in memory read cycles, this bit is fixed to 0.
2, 1	Type[1:0]	00	R	These bits are fixed to B'00, which indicates that the base address of the OHCI operational registers has a 32-bit width and can be allocated to any location in a 32-bit memory space.
0	Memory Space Indicator	0	R	This bit is fixed to 0, which indicates that the OHCI operational registers are mapped to the system memory space.

### 51.6.3.6 Offset H'2C (Subsystem Vendor ID, Subsystem ID)

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Subsystem ID[15:0]	H'0035	R	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.
15 to 0	Subsystem Vendor ID [15:0]	H'1033	R	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.

### 51.6.3.7 Offset H'30 (Expansion ROM Base Address)

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	Expansion ROM Base Address[21:0]	H'000000	R	As decoding of expansion ROM is prohibited, these bits are always read as H'000000. These bits cannot be written to.
9 to 1	—	All 0	R	Reserved (Don't care)
0	ROM Decode Enable	0	R	As decoding of expansion ROM is prohibited, this bit is always read as 0. This bit cannot be written to.

**51.6.3.8 Offset H'34 (Capability Pointer)**

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	Capability Pointer[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved (Don't care)
7 to 0	Capability Pointer[7:0]	H'40	R	These bits hold the pointer to the capability identifier. As the pointer is set to H'40 in the host logic, this value is set to H'40.

**51.6.3.9 Offset H'3C (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)**

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Max Latency[7:0]								Min Gnt[7:0]							
Initial value:	0	0	1	0	1	0	1	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Interrupt Pin[7:0]								Interrupt Line[7:0]							
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Max Latency[7:0]	H'2A	R	These bits indicate the maximum frequency of PCI bus acquisition. As the maximum frequency is set to H'2A in the host logic, this value is set to H'2A.
23 to 16	Min Gnt[7:0]	H'01	R	These bits indicate the minimum burst transfer time. As the minimum time is set to H'01 in the host logic, this value is set to H'01.
15 to 8	Interrupt Pin[7:0]	H'01	R	These bits indicate the pin for outputting interrupts. As INTA is used, this value is fixed to H'01.
7 to 0	Interrupt Line[7:0]	H'00	R/W	These bits indicate the interrupt line. In this module, do not change this from the initial value (H'00).

### 51.6.3.10 Offset H'40 (Capability Identifier, Next Item Pointer, Power Management Capabilities)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Power Management Capabilities															
	PME Support[4:0]				D2 Support	D1 Support	AUX Current[2:0]			DSI	—	PME CLK	Version[2:0]			
Initial value:	0	1	1	1	1	1	1	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Next Item Pointer[7:0]							Capability Identifier[7:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	PME Support[4:0]	0	R	This bit indicates whether the D3 cold state is supported. As the D3 cold state is not supported, this value is fixed to 0.
30 to 27		1111	R	These bits are fixed to B'1111, which indicates that PME interrupt generation is supported in all PCI power states (D0 to D3).
26	D2 Support	1	R	This bit is fixed to 1, which indicates that PCI power state D2 is supported.
25	D1 Support	1	R	This bit is fixed to 1, which indicates that PCI power state D1 is supported.
24 to 22	AUX Current[2:0]	000	R	These bits indicate the necessary current for 3.3-V auxiliary power supply. As PME interrupt generation from the D3 cold state is not supported, this value is fixed to B'000.
21	DSI	0	R	This bit is fixed to 0, which indicates that special initialization is not necessary for power management.
20	—	0	R	Reserved (Don't care)
19	PMECLK	0	R	This bit is fixed to 0, which indicates that PCLK is not necessary for PME interrupt generation.
18 to 16	Version[2:0]	010	R	These bits are fixed to B'010, which indicates that the host logic conforms to "PCI power management interface specification release 1.1".
15 to 8	Next Item Pointer[7:0]	H'00	R	These bits are fixed to H'00, which indicates that the next item does not exist.
7 to 0	Capability Identifier[7:0]	H'01	R	These bits indicate the PCI power management register ID. The value is fixed to H'01.

### 51.6.3.11 Offset H'44 (Power Management Control/Status, PMCSR Bridge Support Extensions)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Data								PMCSR Bridge Support Extensions							
	Data[7:0]								BPCC Enable	B2_B3	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Power Management Control/Status															
	PME Status	Data Scale[1:0]	Data Select[3:0]			PME Enable	—	—	—	—	—	—	—	—	Power State[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Data[7:0]	H'00	R/W	The value of these bits is H'00. This is an optional field in the PCI standard, and the host logic does not support it.
23	BPCC Enable	0	R	The value of this bit is 0. This is a bit for the bridge, and the host logic does not support it.
22	B2_B3	0	R	The value of this bit is 0. This is a bit for the bridge, and the host logic does not support it.
21 to 16	—	All 0	R	Reserved The write value should always be 0.
15	PME Status	0	R/W	This bit indicates the PME interrupt state. It is set to 1 when the following condition for PME generation is satisfied. [PME generation condition] Bit 3 (RD) in the HcInterruptStatus register is set to 1 while bit 10 (RWE) in the HcControl register is 1. Writing 1 from the PCI bus clears this bit to 0.
14, 13	Data Scale[1:0]	00	R	The value of these bits is B'00. This is an optional field in the PCI standard, and the host logic does not support it.
12 to 9	Data Select[3:0]	H'0	R	The value of these bits is H'0. This is an optional field in the PCI standard, and the host logic does not support it.
8	PME Enable	0	R/W	This bit specifies whether to use PME. Setting this bit to 1 generates a PME interrupt when operation returns from the power management state.
7 to 2	—	All 0	R	Reserved The write value should always be 0.
1, 0	Power State[1:0]	00	R/W	These bits indicate the power state of the PCI as follows. 00: D0 state 01: D1 state 10: D2 state 11: D3 hot state

### 51.6.3.12 Offset H'E0 (EXT1)

This register is the same as the EXT1 register located in the EHCI configuration space.

Therefore, this register can be accessed also by using the offset address on the EHCI configuration register side.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Potpgt								Hyper Speed transfer Control #2				—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	Hyper Speed transfer Control #1	—	—	—	—	—	ID_Write	—	—	—	—	Ppcnt	Port_no	
Initial value:	0	0	1	1	0	0	1	1	0	0	0	1	1	1	0	1
R/W:	R	R	R/W	R	R	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Potpgt[7:0]	H'0F	R/W	These bits specify the value for bits [31:24] (PPOTPGT) in the OHCI HcRhDescriptorA register. POTPGT is the time that software should wait before accessing a root hub port after power supply to the port is started.
23 to 19	Hyper Speed transfer Control #2	H'02	R/W	Do not specify any value other than H'02 (HS asynchronous FIFO threshold = 64 bytes).
18 to 14	—	10000	R	Reserved Do not change this from the initial value.
13	Hyper Speed transfer Control #1 (HS Async OUT advance Mode)	1	R/W	This bit specifies the hyper-speed transfer mode for asynchronous OUT transfer. Setting to 1 enables this function (transfer rate improvement).
12 to 8	—	10011	R	Reserved Do not change this from the initial value.
7	ID_Write_Enable	0	R/W	This bit write-protects the Subsystem ID, Subsystem Vendor ID, Max Latency, and Min Gnt bits. 0: Write-protected. 1: Can be written to.
6 to 3	—	0011	R	Reserved Do not change this from the initial value.
2	Ppcnt	1	R/W	This bit specifies a value for bit 4 (PPC) in the EHCI HCSPARAMS register. 0: The PPC bit is cleared to 0. This indicates that the system incorporating this host logic does not provide a port power control switch and the port power is always active. 1: The PPC bit is set to 1. This indicates that the system incorporating this host logic provides a port power control switch. When the port power is always active, set this bit to 0 and bit 9 (NPS) in the OHCI HcRhDescriptor A register to 1.

---

Bit	Bit Name	Initial Value	R/W	Description
1, 0	Port_no	01	R/W	<p>These bits specify the number of valid USB downstream ports.</p> <p>Setting   Valid Ports</p> <p>01:       Port1</p> <p>10:       Port1 and Port2</p> <p>Others:   Reserved</p> <p>In this module, do not change this from the initial value (B'01).</p>

---

### 51.6.3.13 Offset H'E4 (EXT2)

This register is the same as the EXT2 register located in the EHCI configuration space. Therefore, this register can be accessed also by using the offset address on the EHCI configuration register side. However, note that bit 0 (EHCI\_mask) can be written to only on the OHCI side.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	PLL Unlock Register Access Mode	—	—	—	—	—	RAM Connect Check Result	RAM Connect Check END Flag	RUN RAM Connect Check
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	Hyper Speed transfer Control #3	EHCI_mask
Initial value:	0	1	1	0	1	1	0	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved Do not change this from the initial value.
24	PLL Unlock Register Access Mode	1	R/W	This bit specifies how to respond to register access in the PLL unlocked state. 0: If a register access request is received in the PLL unlocked state, a correct access response is not returned. Access is delayed until the PLL is locked. 1: If a register access request is received in the PLL unlocked state, a correct access response is returned but the read or written data is not guaranteed.
23 to 19	—	All 0	R	Reserved Do not change this from the initial value.
18	RAM Connect Check Result	0	R	This bit indicates the result of RAM connection check. 0: Connection check result is NG. 1: Connection check result is OK. This value is valid when the RAM Connect Check END Flag bit is 1. Once the connection check is done, this value is not cleared until the RUN RAM Connect Check bit changes from 0 to 1.
17	RAM Connect Check END Flag	0	R	This bit indicates the end of RAM connection check. 0: Connection check has not been done or ended. 1: Connection check has ended. This bit is set when a specified time (about 2 μs) has passed after the RAM connection check is started by modifying the RUN RAM check bit from 0 to 1.
16	RUN RAM Connect Check	0	R/W	This bit activates the RAM connection check circuit. Set this bit to 1 to start the RAM connection check. This bit is not cleared even after the check is completed. To check again, write 0 to this bit to clear it, and then write 1 again to start the check. When this bit changes from 0 to 1, the connection check circuit is reset and the RAM Connect Check END Flag bit and RAM Connect Check Result bit are cleared.
15 to 2	—	All 0	R	Reserved Do not change this from the initial value.

Bit	Bit Name	Initial Value	R/W	Description
1	Hyper Speed transfer Control #3	1	R/W	This bit specifies the hyper-speed transfer mode for asynchronous IN/OUT transfer. Setting to 1 enables this function (transfer rate improvement).
0	EHCI_mask	0	R/W	This bit enables or disables the EHCI host logic. 0: EHCI host logic is enabled. 1: EHCI host logic is disabled. When this bit is set to 1, register access in the EHCI PCI configuration space and memory space is disabled and the EHCI host logic does not operate.

**51.6.4 PCI Configuration Registers for EHCI**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

**51.6.4.1 Offset H'00 (Vendor ID, Device ID)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Device ID [15:0]	H'00E0	R	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.
15 to 0	Vendor ID [15:0]	H'1033	R	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.

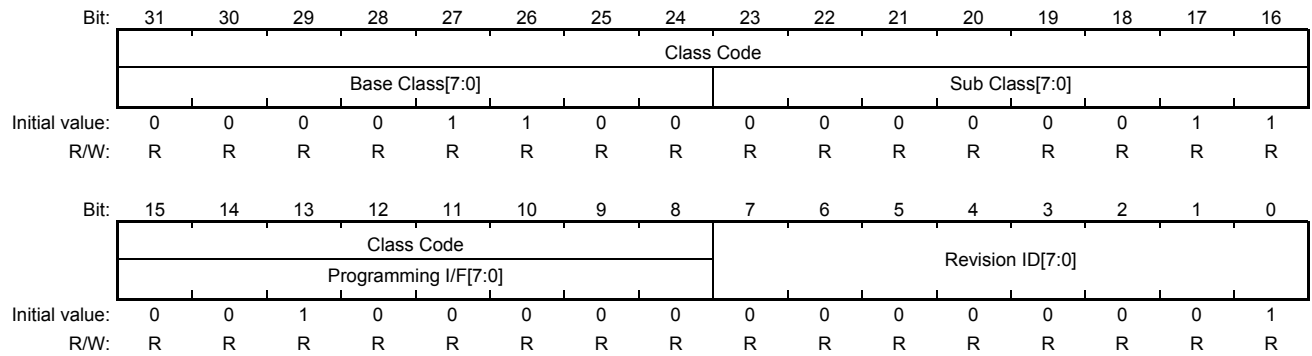

## 51.6.4.2 Offset H'04 (Command, Status)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Detected Parity Error	Signaled System Error	Received Master Abort	Received Target Abort	Signaled Target Abort	Devsel Timing[1:0]	Data Parity Error Detected	Fast Back to Back Capable	—	66 MHz Capable	Capabilities List	—	—	—	—

	—	—	—	—	—	—	Fast Back to Back Enable	SERR Enable	Wait Cycle Control	Parity Error Response	VGA Palette Snoop	Memory Write and Invalidate Enable	Special Cycle	Bus Master	Memory Space	I/O Space
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31	Detected Parity Error	0	R/W	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 from the PCI bus clears this bit.
30	Signaled System Error	0	R/W	This is a status bit for SERR. This bit is set when a system error occurs. Writing 1 from the PCI bus clears this bit.
29	Received Master Abort	0	R/W	This is a status bit for Master/Master Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Master Abort. Writing 1 from the PCI bus clears this bit.
28	Received Target Abort	0	R/W	This is a status bit for Master/Target Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Target Abort. Writing 1 from the PCI bus clears this bit.
27	Signaled Target Abort	0	R	This is a status bit for Slave/Target Abort. This bit is set to 1 in slave operation when the host logic has terminated, through Target Abort, the bus cycle in which the host logic is accessed. Writing 1 from the PCI bus clears this bit.
26, 25	Devsel Timing[1:0]	01	R	These bits indicate the DEVSEL response speed. The value is fixed to B'01 (medium-speed response).
24	Data Parity Error Detected	0	R/W	This bit is set when a parity error is detected in master operation. Writing 1 from the PCI bus clears this bit. The value is fixed to 0 when the Parity Error Response bit is set as disabled.
23	Fast Back to Back Capable	0	R	This bit indicates whether Fast Back to Back transactions are supported. As the host logic does not support Fast Back to Back transactions, this value is fixed to 0.
22	—	0	R	Reserved The write value should always be 0.
21	66 MHz Capable	0	R	This bit indicates whether 66-MHz operation is available. As the host logic operates only at 33-MHz, this value is fixed to 0.
20	Capabilities List	1	R	This value is fixed to 1, which indicates that the power management mode is supported.
19 to 10	—	All 0	R	Reserved The write value should always be 0.
9	Fast Back to Back Enable	0	R	This bit enables Fast Back to Back transactions. As the host logic does not support Fast Back to Back transactions, this value is always 0.

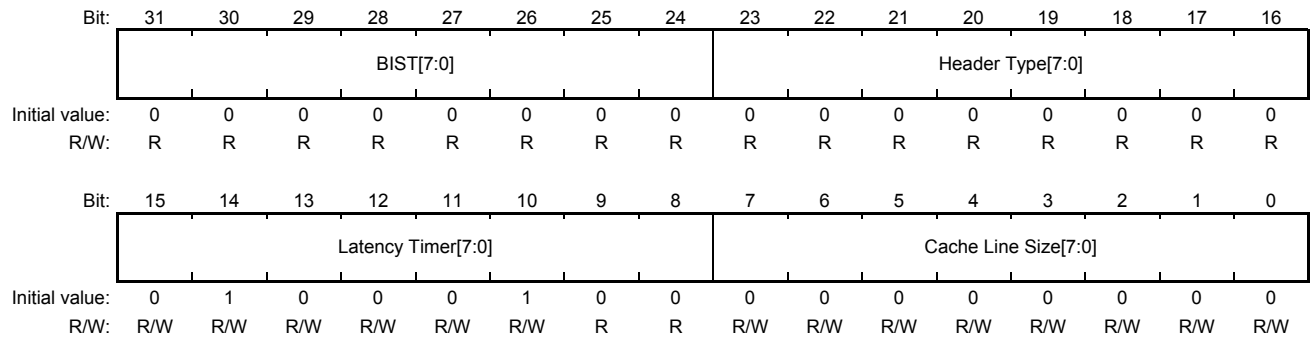

Bit	Bit Name	Initial Value	R/W	Description
8	SERR Enable	0	R/W	This bit enables system error response. 0: SERR0 is not asserted. 1: SERR0 is asserted. To notify of a system error through the SERR signal, set this bit to 1.
7	Wait Cycle Control	0	R	This bit enables wait cycle control. As the host logic does not support address/data stepping, this value is always 0.
6	Parity Error Response	0	R/W	This bit enables parity error response. 0: PERR0 is not asserted. 1: PERR0 is asserted. When a parity error is detected, the Detected Parity Error bit is set to 1 even if this bit is cleared to 0.
5	VGA Palette Snoop	0	R	This bit enables VGA palette snooping. As the host logic does not support VGA palette snooping, this value is always 0.
4	Memory Write and Invalidate Enable	0	R/W	This bit enables the Memory Write and Invalidate command. In this module, do not change this from the initial value (0). 0: Memory write and invalidate command is disabled. 1: Memory write and invalidate command is enabled.
3	Special Cycle	0	R	This bit enables Special Cycle operation. As the host logic does not support the Special Cycle operation, this value is always 0.
2	Bus Master	0	R/W	This bit enables bus master operation. This is an enable signal for master access to the PCI bus. Set to 1 when accessing the SRAM on the system bus. Set this bit to 1 during initial setting of the host logic.
1	Memory Space	0	R/W	This bit enables access to the memory space. This is an enable signal for memory access specified in the PCI standard. Set to 1 when accessing registers. Set this bit to 1 during initial setting of the host logic.
0	I/O Space	0	R	This bit enables access to the I/O space. As the host logic does not accept I/O access, this value is always 0.

**51.6.4.3 Offset H'08 (Revision ID, Class Code)**

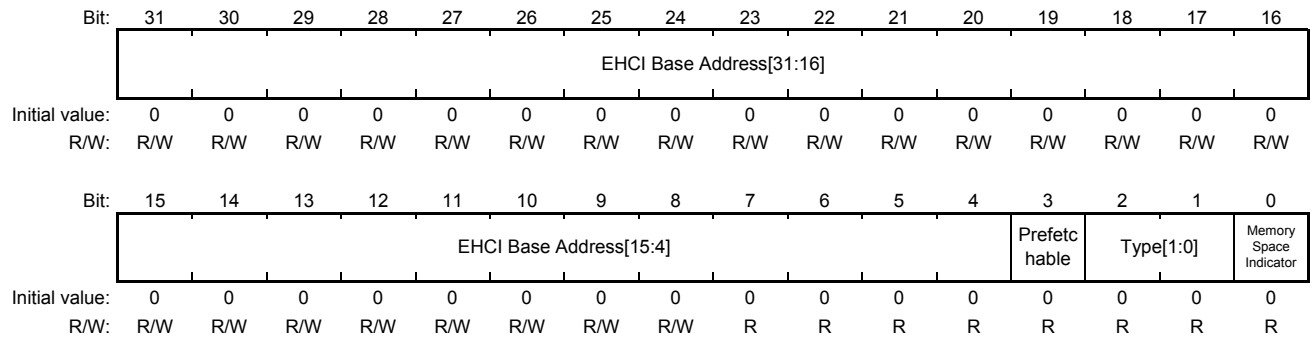

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Base Class [7:0]	H'0C	R	These bits indicate the base class specified in the PCI standard. The value is H'0C, which indicates a serial peripheral bus controller.
23 to 16	Sub Class [7:0]	H'03	R	These bits indicate the subclass specified in the PCI standard. The value is H'03, which indicates a USB device.
15 to 8	Programming I/F [7:0]	H'20	R	These bits indicate the program interface specified in the PCI standard. The value is H'20, which indicates EHCI.
7 to 0	Revision ID [7:0]	H'01	R	These bits indicate the revision of the host logic. The value is fixed to H'01.

#### 51.6.4.4 Offset H'0C (Cache Line Size, Latency Timer, Header Type, BIST)

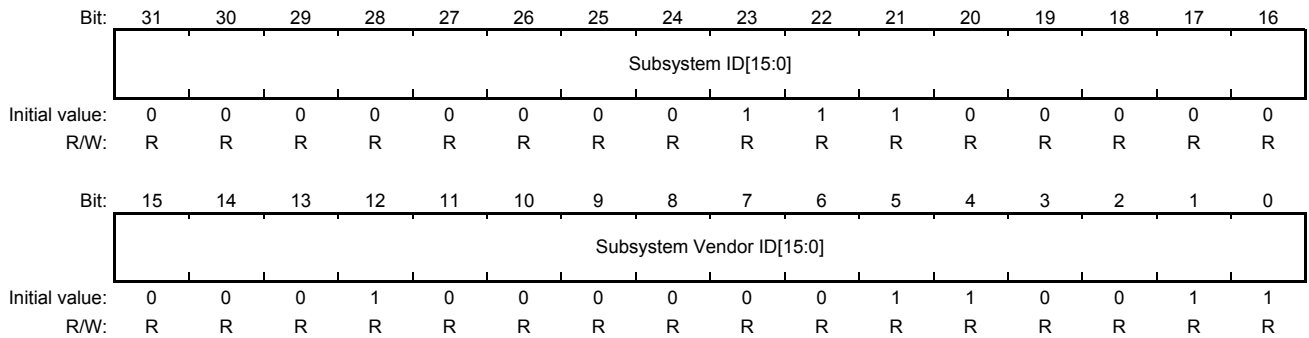

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	BIST[7:0]	H'00	R	These bits are used for self testing. As the host logic does not support the self test function, this value is always H'00.
23 to 16	Header Type [7:0]	H'00	R	These bits notify the system of the header type. As the header type is Type 0, bits [22:16] are fixed to H'00. As the multifunction capability is not supported, bit 23 is fixed to 0.
15 to 8	Latency Timer [7:0]	H'44	R/W[7:2] R[1:0]	These bits notify the system of the latency timer. The lowest two bits are fixed to B'00.
7 to 0	Cache Line Size [7:0]	H'00	R/W	These bits notify the system of the cache line size.

**51.6.4.5 Offset H'10 (EHCI Base Address)**

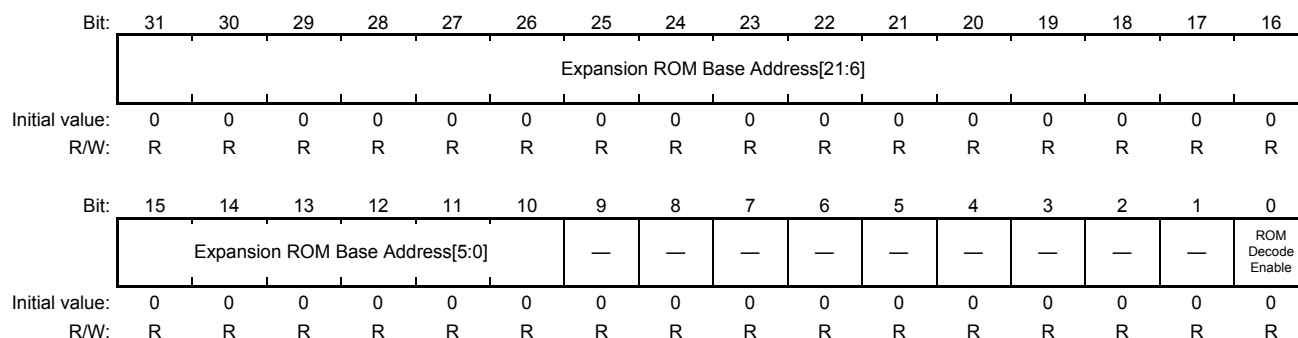

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	EHCI Base Address[31:4]	H'000 000	R/W[31:8] R[7:4]	Bits [31:8] specify the base address of the operational registers. Specify the base address of the operational registers determined by the system during initialization. Bits [7:4] are fixed to H'0, which indicates that the operational registers are allocated to a 256-byte address space.
3	Prefetchable	0	R	As the host logic does not support prefetching in memory read cycles, this bit is fixed to 0.
2, 1	Type[1:0]	00	R	These bits are fixed to B'00, which indicates that the base address of the EHCI operational registers has a 32-bit width and can be allocated to any location in a 32-bit memory space.
0	Memory Space Indicator	0	R	This bit is fixed to 0, which indicates that the EHCI operational registers are mapped to the system memory space.

**51.6.4.6 Offset H'2C (Subsystem Vendor ID, Subsystem ID)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Subsystem ID [15:0]	H'00C0	R	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.
15 to 0	Subsystem Vendor ID [15:0]	H'1033	R	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.

**51.6.4.7 Offset H'30 (Expansion ROM Base Address)**

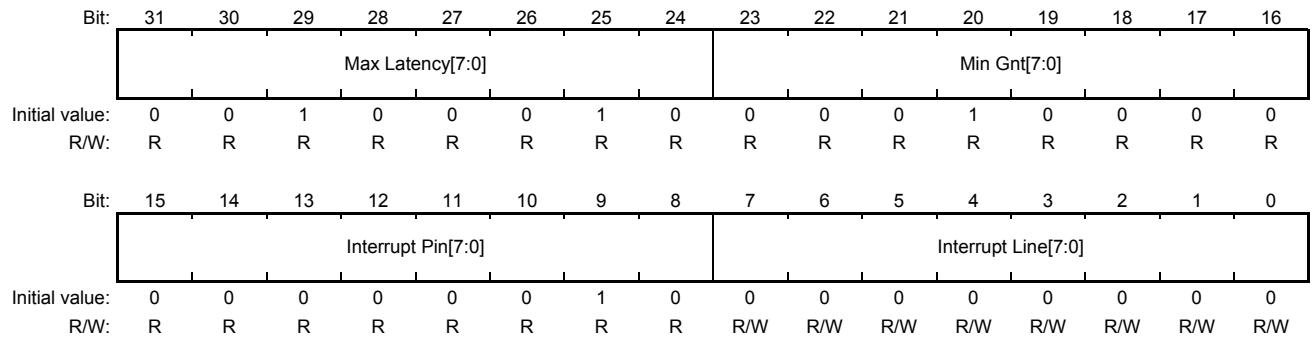

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	Expansion ROM Base Address[21:0]	H'000000	R	As decoding of expansion ROM is prohibited, these bits are always read as H'000000. These bits cannot be written to.
9 to 1	—	All 0	R	Reserved (Don't care)
0	ROM Decode Enable	0	R	As decoding of expansion ROM is prohibited, this bit is always read as 0. This bit cannot be written to.

**51.6.4.8 Offset H'34 (Capability Pointer)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved (Don't care)
7 to 0	Capability Pointer[7:0]	H'40	R	These bits hold the pointer to the capability identifier. As the pointer is set to H'40 in the host logic, this value is set to H'40.

**51.6.4.9 Offset H'3C (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Max Latency [7:0]	H'22	R	These bits indicate the maximum frequency of PCI bus acquisition. As the maximum frequency is set to H'22 in the host logic, this value is set to H'22.
23 to 16	Min Gnt[7:0]	H'10	R	These bits indicate the minimum burst transfer time. As the minimum time is set to H'10 in the host logic, this value is H'10.
15 to 8	Interrupt Pin [7:0]	H'02	R	These bits indicate the pin for outputting interrupts. As INTB is used, this value is fixed to H'02.
7 to 0	Interrupt Line [7:0]	H'00	R/W	These bits indicate the interrupt line. In this module, do not change this from the initial value (H'00).

### 51.6.4.10 Offset H'40 (Capability Identifier, Next Item Pointer, Power Management Capabilities)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Power Management Capabilities															
	PME Support[4:0]				D2 Support	D1 Support	AUX Current[2:0]		DSI	—	PME CLK	Version[2:0]				
Initial value:	0	1	1	1	1	1	1	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Next Item Pointer[7:0]							Capability Identifier[7:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	PME Support[4:0]	0	R	This bit indicates whether the D3 cold state is supported. As the D3 cold state is not supported, this value is fixed to 0.
30 to 27		1111	R	These bits are fixed to B'1111, which indicates that PME interrupt generation is supported in all PCI power states (D0 to D3).
26	D2 Support	1	R	This bit is fixed to 1, which indicates that PCI power state D2 is supported.
25	D1 Support	1	R	This bit is fixed to 1, which indicates that PCI power state D1 is supported.
24 to 22	AUX Current[2:0]	000	R	These bits indicate the necessary current for 3.3-V auxiliary power supply. As PME interrupt generation from the D3 cold state is not supported, this value is fixed to B'000.
21	DSI	0	R	This bit is fixed to 0, which indicates that special initialization is not necessary for power management.
20	—	0	R	Reserved
19	PME CLK	0	R	This bit is fixed to 0, which indicates that PCLK is not necessary for PME interrupt generation.
18 to 16	Version[2:0]	010	R	These bits are fixed to B'010, which indicates that the host logic conforms to "PCI power management interface specification release 1.1".
15 to 8	Next Item Pointer[7:0]	H'00	R	These bits are fixed to H'00, which indicates that the next item does not exist.
7 to 0	Capability Identifier[7:0]	H'01	R	These bits indicate the power management register ID. The value is fixed to H'01.

### 51.6.4.11 Offset H'44 (Power Management Control/Status, PMCSR Bridge Support Extensions)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	PME Status	Data Scale[1:0]	Data Select[3:0]			PME Enable	—	—	—	—	—	—	—	Power State[1:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Data[7:0]	H'00	R	The value of these bits is H'00. This is an optional field in the PCI standard, and the host logic does not support it.
23	BPCC Enable	0	R	The value of this bit is 0. This is a bit for the bridge and the host logic does not support it.
22	B2_B3	0	R	The value of this bit is 0. This is a bit for the bridge and the host logic does not support it.
21 to 16	—	All 0	R	Reserved The write value should always be 0.
15	PME Status	0	R/W	This bit indicates the PME interrupt state. It is set to 1 when the PME generation condition is satisfied. Writing 1 from the PCI bus clears this bit to 0.
14, 13	Data Scale[1:0]	00	R	The value of these bits is B'00. This is an optional field in the PCI standard, and the host logic does not support it.
12 to 9	DSEL[3:0]	H'0	R	Data Select The value of these bits is H'0. This is an optional field in the PCI standard, and the host logic does not support it.
8	PME Enable	0	R/W	This bit specifies whether to use external pin PME. Setting this bit to 1 generates a PME interrupt when operation returns from the power management state.
7 to 2	—	All 0	R	Reserved The write value should always be 0.
1, 0	Power State[1:0]	00	R/W	These bits indicate the power state of the PCI as follows. 00: D0 state 01: D1 state 10: D2 state 11: D3 hot state

**51.6.4.12 Offset H'60 (SBRN, FLADJ, PORTWAKECAP)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PORTWAKECAP[15:0]	H'003F	R/W	These bits specify a mask to select from the connected devices the port to be used for a wakeup event. This setting does not affect the actual operation of the host logic. This module has only one port and this register does not need to be used.
15 to 8	FLADJ[7:0]	H'20	R[7:6] R/W[5:0]	These bits adjust the length of a micro-frame in 16-HS bit time units. The initial value is H'20 (60000d HS bit time).
7 to 0	SBRN[7:0]	H'20	R	These bits indicate the serial bus release number. The value is fixed to H'20.

**51.6.4.13 Offset H'E0 (EXT1)**

This register is the same as the EXT1 register located in the OHCI configuration space. Refer to the description of the OHCI configuration register.

**51.6.4.14 Offset H'E4 (EXT2)**

This register is the same as the EXT2 register located in the OHCI configuration space. Refer to the description of the OHCI configuration register.

Note that bit 0 (EHCI\_mask) cannot be accessed from the EHCI side.

### 51.6.5 PCI Configuration Registers for AHB-PCI Bridge

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

#### 51.6.5.1 Offset H'00 (Vendor ID, Device ID)

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DEVICE_ID [15:0]	H'0000	R	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.
15 to 0	VENDOR_ID [15:0]	H'1033	R	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host. It is always read as H'1033.

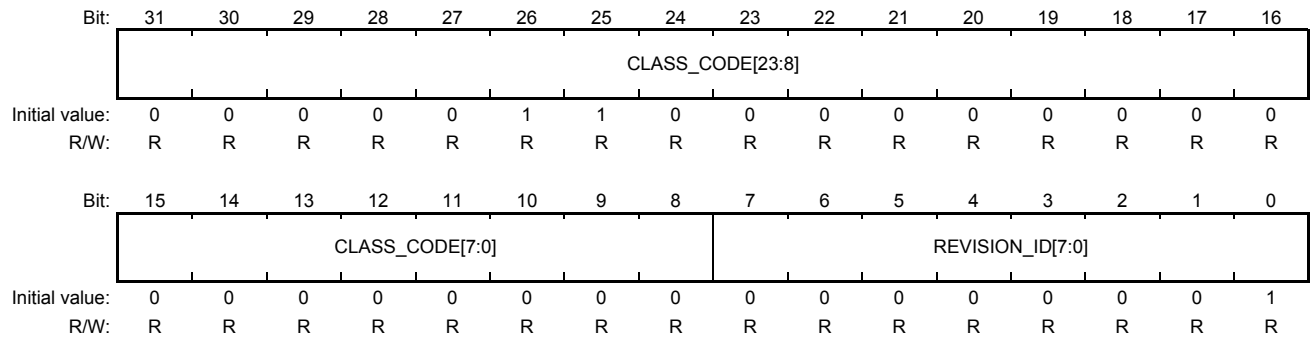

## 51.6.5.2 Offset H'04 (Command, Status)

Bit	Bit Name	Initial Value	R/W	Description
31	DETPERR	0	R/W	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 clears this bit. 0: Parity error has not been detected. 1: Parity error has been detected.
30	SIGSERR	0	R/W	This is a status bit for SERR. This bit is set when a system error occurs. Writing 1 clears this bit. 0: SERR# has not been asserted. 1: SERR# has been asserted.
29	REMAPORT	0	R/W	This is a status bit for Master Abort. This bit is set when Master Abort is received. Writing 1 clears this bit. 0: Master Abort has not been received. 1: Master Abort has been received.
28	RETABORT	0	R/W	This is a status bit for Master Target Abort. This bit is set when Target Abort is received. Writing 1 clears this bit. 0: Target Abort has not been received. 1: Target Abort has been received.
27	SIGTABORT	0	R/W	This is a status bit for Slave Target Abort. This bit is set when Target Abort is transmitted. Writing 1 clears this bit. 0: Target Abort has not been transmitted. 1: Target Abort has been transmitted.
26, 25	DEVTIM[1:0]	01	R	These bits indicate the DEVSEL response speed. The value is fixed to B'01 (Medium Mode).
24	MDPERR	0	R/W	This bit is set when a parity error is detected in master operation. Writing 1 clears this bit. 0: Parity error has not been detected. 1: Parity error has been detected.

Bit	Bit Name	Initial Value	R/W	Description
23	FBTBCAP	0	R	This bit indicates whether Fast Back to Back transactions are supported. The value is fixed to 0. (Fast Back to Back transactions are not supported.)
22	—	0	R	Reserved The write value should always be 0.
21	66MCAP	0	R	This bit indicates whether 66-MHz operation is supported. The value is fixed to 0. (66-MHz operation is not supported.)
20	CAPLIST	0	R	This bit indicates whether the capabilities list is supported. The value is fixed to 0. (The capabilities list is not supported.)
19 to 10	—	All 0	R	Reserved The write value should always be 0.
9	FBTBEN	0	R	This bit enables Fast Back to Back transactions. The value is fixed to 0.
8	SERREN	0	R/W	This bit specifies the operation when a system error is detected. In this module, set to 1 during initial setting. 0: Ignored (initial value) 1: SERR# is asserted.
7	STEPCTR	0	R	This bit controls address stepping. The value is fixed to 0. (Address stepping is not done.)
6	PERREN	0	R/W	This bit specifies the operation when a parity error is detected. In this module, set to 1 during initial setting. 0: Ignored (initial value) 1: PERR# is asserted.
5	VGAPSNP	0	R	This bit enables VGA palette snooping. The value is fixed to 0.
4	MWINVEN	0	R	This bit enables the Memory Write and Invalidate command. The value is fixed to 0.
3	SPECIALC	0	R	This bit enables the Special Cycle operation. The value is fixed to 0.
2	MASTEREN	0	R/W	This bit specifies the PCI master operation. In this module, set to 1 during initial setting. 0: Master operation is disabled (initial value). 1: Master operation is enabled.
1	MEMEN	0	R/W	This bit specifies the PCI slave operation. In this module, set to 1 during initial setting. 0: Memory cycles cannot be accepted (initial value) 1: Memory cycles can be accepted.
0	IOEN	0	R	This bit enables access to the I/O space. The value is fixed to 0.

**51.6.5.3 Offset H'08 (Revision ID, Class Code)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	CLASS_CODE [23:0]	H'060000	R	The value of these bits is H'060000.
7 to 0	REVISION_ID [7:0]	H'01	R	The value of these bits is H'01.

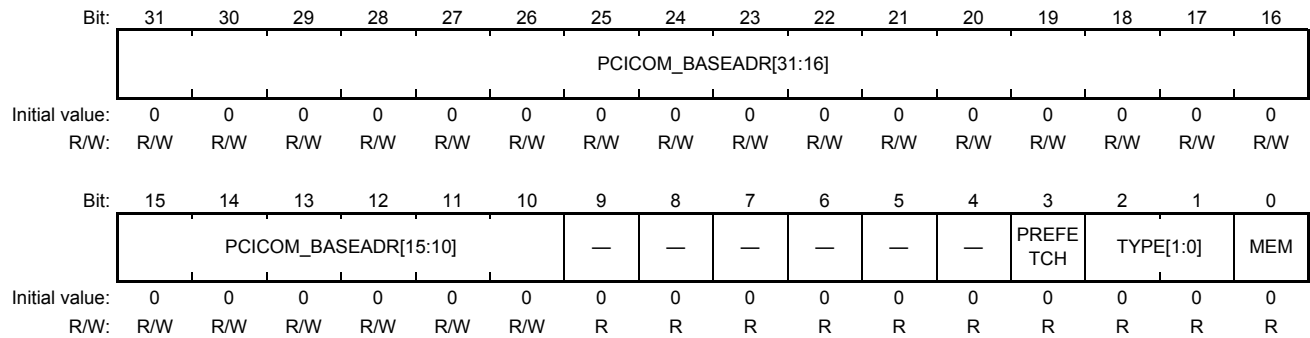

#### 51.6.5.4 Offset H'0C (Cache Line Size, Latency Timer, Header Type, BIST)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	BIST[7:0]	H'00	R	The value of these bits is H'00 (BIST is not implemented).
23 to 16	HEADER_TYPER[7:0]	H'00	R	The value of these bits is H'00 (single function device).
15 to 8	LATENCY_TIMER[7:0]	H'00	R/W	These bits notify the system of the latency timer. This module does not use the latency timer; do not change this from the initial value (H'00).
7 to 0	CACHE_LINE_SIZE[7:0]	H'00	R	The value of these bits is H'00 (cache is not supported).

### 51.6.5.5 Offset H'10 (AHB-PCI Bridge Base Address)

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	PCICOM_BA SEADR [31:10]	All 0	R/W	These bits specify the base address of the AHB-PCI bridge PCI communication register area. A 1-Kbyte area is necessary and the upper 24 bits specify the base address.
9 to 4	—	All 0	R	Reserved The write value should always be 0.
3	PREFETCH	0	R	This bit indicates whether data can be prefetched. The value is fixed to 0. (Data cannot be prefetched.)
2, 1	TYPE[1:0]	00	R	These bits indicate the base address type. The value is B'00. (The base address can be allocated to any location in a 4-Gbyte space.)
0	MEM	0	R	This bit indicates that the bits specified by the base address are in the memory space. The value is fixed to 0.

## 51.6.5.6 Offset H'14 (PCI-AHB WIN1 Base Address)

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PCI_WIN2_B ASEADR [31:28]	H'0	R/W	These bits specify the base address of PCI-AHB Window 2. In this module, a 256-Mbyte area is necessary, and the upper four bits specify the base address.
27 to 4	—	All 0	R	Reserved The write value should always be 0.
3	PREFETCH	0	R	This bit indicates whether data can be prefetched.
2, 1	TYPE[1:0]	00	R	These bits indicate the base address type. The value is B'00. (The base address can be allocated to any location in a 4-Gbyte space.)
0	MEM	0	R	This bit indicates that the bits specified by the base address are in the memory space. The value is fixed to 0.

**51.6.5.8 Offset H'2C (Subsystem Vendor ID, Subsystem ID)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	SUBSYS_ID [15:0]	H'00	R	The value of these bits is H'0000.
15 to 0	SUBSYS_VENDOR_ID [15:0]	H'1033	R	The value of these bits is H'1033.

**51.6.5.9 Offset H'3C (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MAX_LAT[7:0]	H'00	R	The value of these bits is H'00. (No value is specified for the bus use frequency.)
23 to 16	MIN_GNT[7:0]	H'02	R	The value of these bits is H'02. (Requested latency timer: 16 burst).
15 to 8	INT_PIN[7:0]	H'01	R	The value of these bits is H'01. (INTA# is used).
7 to 0	INT_LINE[7:0]	H'00	R/W	These bits specify the interrupt line. In this module, do not change this from the initial value (H'00).

### 51.6.6 AHB-PCI Bridge PCI Communication Registers

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

#### 51.6.6.1 PCIAHB\_WIN1\_CTR Register

This register is used to make settings for access from the host logic to AHB.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 51.6.6.3 AHBPCI\_WIN1\_CTR Register

This register is used to make necessary settings for access to the PCI configuration space.

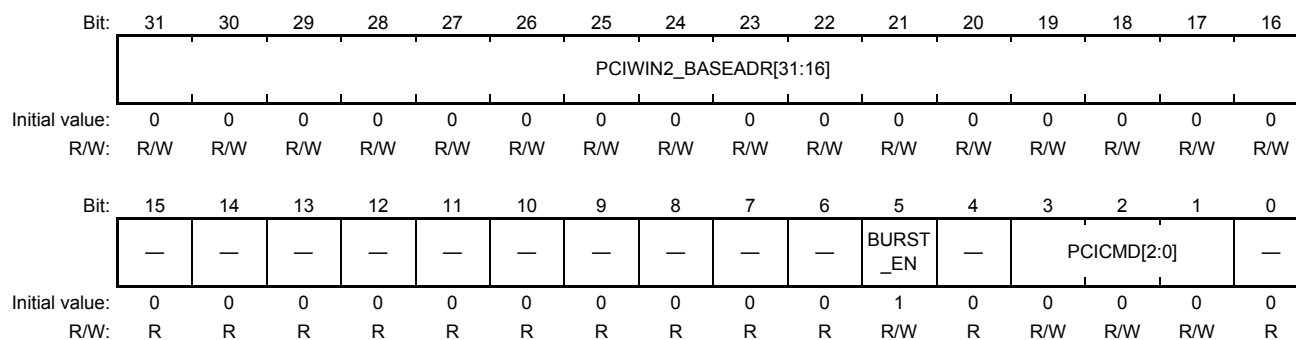

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	PCIWIN1_BA SEADR [31:11]	All 0	R/W	These bits specify the base address of the PCI bus for access from AHB to AHB-PCI Window 1.  This register should be set when the PCI configuration space for the host logic or for the AHB-PCI bridge is accessed. For details of settings, refer to section 51.7, Register Accesses.
10 to 4	—	All 0	R	Reserved  The write value should always be 0.
3 to 1	PCICMD[2:0]	000	R/W	These bits specify the type of PCI bus cycle.  In this module, set to B'101 during initial setting and do not modify this value.  000: Interrupt Acknowledge or Special Cycle 001: I/O Read or I/O Write 011: Memory Read or Memory Write 101: Configuration Read or Configuration Write 110: Memory Read Multiple or Memory Write 111: Memory Read Line or Memory Write Others: Setting prohibited
0	—	0	R	Reserved  The write value should always be 0.

### 51.6.6.4 AHBPCI\_WIN2\_CTR Register

This register is used to make necessary settings for access to the OHCI operational register area.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PCIWIN2_BA SEADR [31:16]	H'0000	R/W	These bits specify the base address of the PCI bus for access from AHB to AHB-PCI Window 2.  This register is used for access to the OHCI operational register area. For details of settings, refer to section 51.7, Register Accesses.
15 to 6	—	All 0	R	Reserved  The write value should always be 0.
5	BURST_EN	1	R/W	This bit enables burst transfer to the PCI bus  In this module, clear to 0 during initial setting and do not modify this value.  0: Burst transfer is disabled. 1: Burst transfer is enabled.
4	—	0	R	Reserved  The write value should always be 0.
3 to 1	PCICMD[2:0]	000	R/W	These bits specify the type of PCI bus cycle.  In this module, set to B'011 during initial setting and do not modify this value.  001: I/O Read or I/O Write 011: Memory Read or Memory Write 110: Memory Read Multiple or Memory Write 111: Memory Read Line or Memory Write Others: Setting prohibited
0	—	0	R	Reserved  The write value should always be 0.

### 51.6.6.5 PCI\_INT\_ENABLE Register

This register enables or disables each interrupt source indicated in the PCI\_INT\_STATUS register. When an interrupt source is disabled, the interrupt signal is not asserted even when the interrupt source is generated and the corresponding bit in the PCI\_INT\_STATUS register is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	USBH_P MEEN	—	USBH_I NTBEN	USBH_I NTAEN

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should always be 0.
19	USBH_PMEEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 19 (USBH_PME) in PCI_INT_STATUS. 0: Disabled 1: Enabled
18	—	0	R	Reserved The write value should always be 0.
17	USBH_INTBEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 17 (USBH_INTB) in PCI_INT_STATUS. 0: Disabled 1: Enabled
16	USBH_INTAEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 16 (USBH_INTA) in PCI_INT_STATUS. 0: Disabled 1: Enabled
15, 14	—	All 0	R	Reserved The write value should always be 0.
13	PCIAHB_WIN2_INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 13 (PCIAHB_WIN2_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
12	PCIAHB_WIN1_INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 12 (PCIAHB_WIN1_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
11 to 6	—	All 0	R	Reserved The write value should always be 0.
5	RESERR_INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 5 (RESERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
4	SIGSERR_IN TEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 4 (SIGSERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
3	PERR_INTE N	0	R/W	This bit enables or disables the interrupt source indicated in bit 3 (PERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
2	REMARBOR T_INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 2 (REMABOOT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
1	RETARBORT _INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 1 (RETABORT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled
0	SIGTARBOR T_INTEN	0	R/W	This bit enables or disables the interrupt source indicated in bit 0 (SIGTABORT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled

**51.6.6.6 PCI\_INT\_STATUS Register**

This register indicates the state of interrupt sources in the AHB-PCI bridge and the state of interrupt signals from the host logic.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	USBH_PME	—	USBH_INTB	USBH_INTA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	PCIAHB_WIN2_INT	PCIAHB_WIN1_INT	—	—	—	—	—	—	RESER_R_INT	SIGSER_R_INT	PERR_INT	REMAORT_INT	RETAORT_INT	SIGTABORT_INT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should always be 0.
19	USBH_PME	0	R	This bit indicates the state of the PME# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: PME interrupt has not occurred. 1: PME interrupt has occurred.
18	—	0	R	Reserved The write value should always be 0.
17	USBH_INTB	0	R	This bit indicates the state of the INTB# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: INTB interrupt has not occurred. 1: INTB interrupt has occurred.
16	USBH_INTA	0	R	This bit indicates the state of the INTA# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: INTA interrupt has not occurred. 1: INTA interrupt has occurred.
15, 14	—	All 0	R	Reserved The write value should always be 0.
13	PCIAHB_WIN2_INT	0	R/W	This bit indicates that an AHB bus error has occurred in PCIAHB Window 2. Writing 1 clears this bit. 0: AHB bus error has not occurred. 1: AHB bus error has occurred.
12	PCIAHB_WIN1_INT	0	R/W	This bit indicates that an AHB bus error has occurred in PCIAHB Window 1. Writing 1 clears this bit. 0: AHB bus error has not occurred. 1: AHB bus error has occurred.

Bit	Bit Name	Initial Value	R/W	Description
11 to 6	—	All 0	R	Reserved The write value should always be 0.
5	RESERR_IN T	0	R/W	This bit indicates the state of the interrupt source caused by SERR# input. Writing 1 clears this bit. 0: SERR# assertion has not been detected. 1: SERR# assertion has been detected.
4	SIGSERR_IN T	0	R/W	This bit indicates the state of the interrupt source caused by SERR# output. Writing 1 clears this bit. 0: SERR# has not been asserted. 1: SERR# has been asserted.
3	PERR_INT	0	R/W	This bit indicates the state of the interrupt source caused by PERR# input/output. Writing 1 clears this bit. 0: PERR# has not been asserted. 1: PERR# has been asserted.
2	REMABORT_ INT	0	R/W	This bit indicates that Master Abort has been received in PCI master operation. Writing 1 clears this bit. 0: Master Abort has not been received. 1: Master Abort has been received.
1	RETABORT_ INT	0	R/W	This bit indicates that Target Abort has been received in PCI master operation. Writing 1 clears this bit. 0: Target Abort has not been received. 1: Target Abort has been received.
0	SIGTABORT_ INT	0	R/W	This bit indicates that Target Abort has been sent in PCI target operation. Writing 1 clears this bit. 0: Target Abort has not been sent. 1: Target Abort has been sent.

### 51.6.6.7 AHB\_BUS\_CTR Register

This register specifies the AHB master and slave functions of the host logic.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SMODE_READY_CTR	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MMODE_HBUSREQ	—	—	—	—	MMODE_WR_INCR	MMODE_BYTEBURST	MMODE_HTRANS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved The write value should always be 0.
17	SMODE_READY_CTR	1	R/W	This bit controls the wait operation in AHB slave operation. Set this bit to 0 in a system that uses RETRY or SPLIT. Do not modify this value except for initial setting. 0: Wait is controlled with HRESP = RETRY. 1: Wait is controlled with HREADY = 0.
16 to 8	—	All 0	R	Reserved The write value should always be 0.
7	MMODE_HBUSREQ	0	R/W	This bit specifies the timing of HBUSREQ deassertion in AHB master operation. In this module, set to 1 during initial setting and do not modify this value. 0: Deasserted in the last address phase of the cycle. 1: Deasserted with the first timing of HGRANT = 1 and HREADY = 1.
6 to 3	—	0	R	Reserved The write value should always be 0.
2	MMODE_WR_INCR	0	R/W	This bit specifies the condition of using an undefined-length burst for write transfer in AHB master operation. In this module, set to 1 during initial setting and do not modify this value. 0: INCR is always used except when the transfer count is 4, 8, or 16. 1: INCR4, INCR8, and INCR16 are generally used, and INCR is used only when the remaining data is two to three beats.
1	MMODE_BYTEBURST	0	R/W	This bit controls burst transfer for 16-bit or 8-bit transfer in AHB master operation. In this module, set to 1 during initial setting and do not modify this value. 0: Burst transfer is enabled for 16-bit or 8-bit transfer. 1: Burst transfer is disabled for 16-bit or 8-bit transfer.

---

Bit	Bit Name	Initial Value	R/W	Description
0	MMODE_HTRANS	0	R/W	<p>This bit specifies the operating mode for the HTRANS signal in AHB master operation.</p> <p>In this module, set to 1 during initial setting and do not modify this value.</p> <p>0: For divided cycles, NONSEQ is output continuously.</p> <p>1: For divided cycles, IDLE is inserted and the bus is requested again through HBUSREQ.</p>

---

### 51.6.6.8 USBCTR Register

This register is used to make settings of the host logic.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	PCI_AHB_WIN1_SIZE[1:0]	PCI_AHB_WIN2_EN	DIRPD	—	—	—	—	—	—	PLL_RST	PCICLK_MASK	USBH_RST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved The write value should always be 0.
11, 10	PCI_AHB_WIN1_SIZE[1:0]	0	R/W	These bits control the PCI-AHB Window 1 area. For details, refer to section 51.7, Register Accesses. Do not modify this value except for initial setting. 00: 256 Mbytes 01: 512 Mbytes 10: 1 Gbyte 11: 2 Gbytes
9	PCI_AHB_WIN2_EN	0	R/W	This bit enables operation of PCI-AHB Window 2. For details, refer to section 51.7, Register Accesses. Do not modify this value except for initial setting. In this module, the PCI-AHB Window 2 area is fixed to 256 Mbytes. 0: PCI-AHB Window 2 is not available. 1: PCI-AHB Window 2 is available.
8	DIRPD	0	R/W	When this bit is set to 1, the host logic enters the direct power-down state. When 0 is written while this bit is 1, the host logic returns from the direct power-down state. For the setting of and return from the direct power-down state, refer to section 51.10.3, Direct Power-Down.  As well as this register, bit 12 (DIRPD) in the EPCTR register and the DIRPD input pin can be used to control the direct power-down state. 0: Normal operation 1: Direct power-down state
7 to 3	—	0	R	Reserved The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2	PLL_RST	1	R/W	<p>This bit controls the reset signal supplied to the PLL.</p> <p>The PLL is used in common for the host logic and the UTMI+ logic. To stop the PLL operation, set this bit to 1.</p> <p>When both this bit and the PLL_RESET pin in the host logic are 1, a reset signal is issued to the PLL.</p> <p>Clearing (0) for either this bit or the PLL_RESET pin in the host logic cancels the reset signal for the PLL.</p> <p>0: PLL reset is canceled. 1: PLL reset is issued.</p>
1	PCICLK_MAS K	1	R/W	<p>This bit stops the PCI clock supply in the host logic.</p> <p>Note that the host logic cannot be accessed when this bit is set to 1.</p> <p>0: PCI clock is supplied. 1: PCI clock is stopped.</p>
0	USBH_RST	1	R/W	<p>This bit controls the reset signal supplied to the host logic.</p> <p>The host logic can be accessed a maximum of three PCLK clock cycles after the reset is canceled.</p> <p>0: Host logic reset is canceled. 1: Host logic reset is issued.</p>

### 51.6.6.9 PCI\_ARBITER\_CTR Register

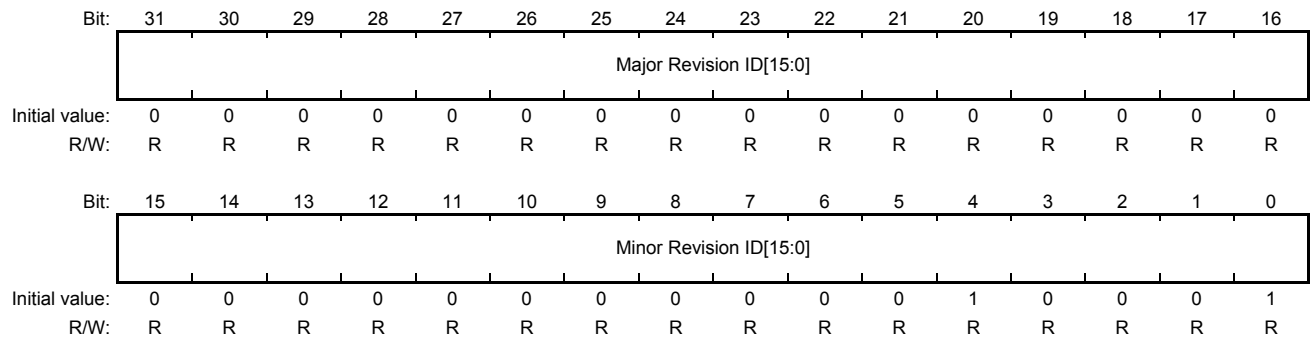

This register is used to make settings of the PCI bus arbitration function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	—	—	—	PCIBP_MODE	—	—	—	—	—	—	—	—	—	—	PCIREQ1	PCIREQ0	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	—	R	Reserved Do not change this from the initial value.
12	PCIBP_MODE	0	R/W	This bit specifies the master while the PCI bus is in the parking state. In this module, set to 1 during initial setting and do not modify this value. 0: This unit is the master in the bus parking state. 1: The master that made the last access is the master in the bus parking state.
11 to 2	—	All 0	R	Reserved The write value should always be 0.
1	PCIREQ1	0	R/W	This bit enables or disables the PCI bus request signal from the host logic. In this module, set to 1 during initial setting and do not modify this value. 0: Request signal is disabled. 1: Request signal is enabled.
0	PCIREQ0	0	R/W	This bit enables or disables the PCI bus request signal from this unit. In this module, set to 1 during initial setting and do not modify this value. 0: Request signal is disabled. 1: Request signal is enabled.

**51.6.6.10 PCI\_UNIT\_REV Register**

This register indicates the version of the AHB-PCI bridge macro.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	Major Revision ID [15:0]	H'0000	R	These bits indicate the major revision ID of this unit.
15 to 0	Minor Revision ID [15:0]	H'0011	R	These bits indicate the minor revision ID of this unit.

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

### 51.7 Register Accesses

The registers are accessed through the internal PCI bus. Thus, to provide accesses correctly through the AHB bus, the AHB bus memory space and PCI bus memory space in the USB should be mapped correctly. The PCI has two spaces: PCI configuration space to set the PCI bus transfer settings and base address settings in the PCI memory space and the PCI memory space to perform actual data transfers.

The accesses from the AHB to the host logic or master accesses from the host logic to the AHB are performed through the window area included in the AHB-PCI bridge. Figure 51.2 and Table 51.5 show the relationship between the register areas and window areas.

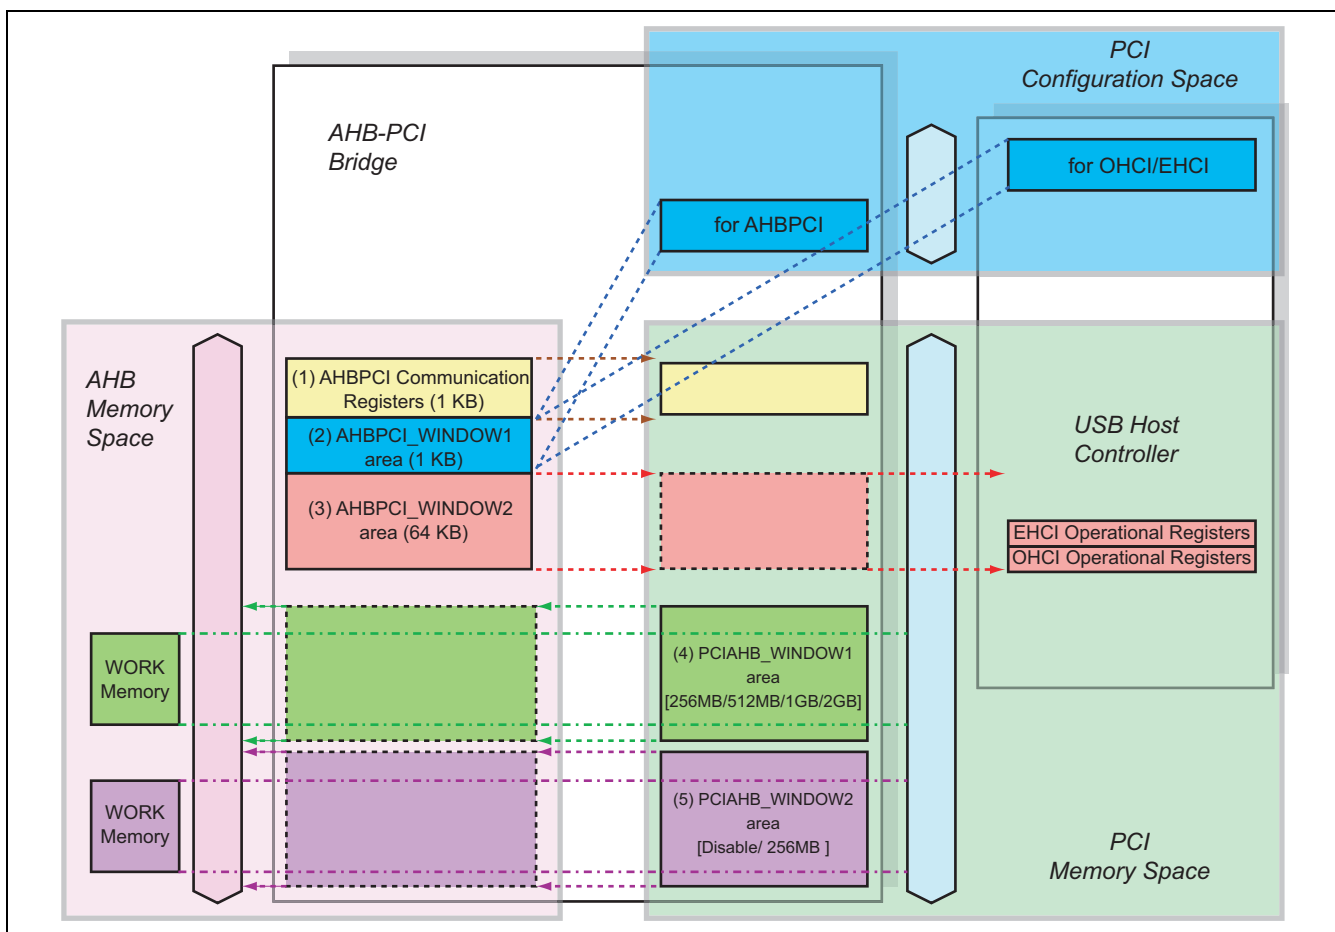

Figure 51.2 Mapping in AHB and PCI Spaces

**Table 51.5 Description of Each Area**

<b>AHB Areas</b>	<b>Size</b>	<b>Description</b>
(1) AHBPCI Communication Registers area	1 KB	Used for various AHB settings and base address settings for WINDOW areas. Since this area is also allocated in the PCI memory space, map this area so that it should not overlap with the other areas.
(2) AHBPCI WINDOW1 area	1 KB	The PCI configuration registers are accessed through this area. Whether to access the OHCI/EHCI configuration registers or AHBPCI bridge registers is switched using the AHBPCI_WIN1_CTR register.
(3) AHBPCI WINDOW2 area	64 KB	The OHCI/EHCI operational registers are accessed through this area.
(4) PCIAHB WINDOW1 area	256 MB, 512 MB, 1 GB and 2 GB	The host logic accesses the work memory on the AHB bus through this area. The size of this area can be changed using the USBCTR register.
(5) PCIAHB WINDOW2 area	Disable, 256 MB	The host logic accesses the work memory on the AHB bus through this area. Whether to use this area or not can be selected using the USBCTR register.

The AHBPCI Communication Registers and AHBPCI WINDOW2 (OHCI/EHCI operational registers) areas and the PCIAHB WINDOW1 and PCIAHB WINDOW2 areas must not overlap each other.

Usually, the AHB memory space and PCI memory space can be allocated in the same address. However, if an overlap occurs between the above areas by the AHB bus memory mapping, set the base addresses so that they should not overlap with the PCIAHB WINDOW1/2 areas using the PCI configuration register (OHCI/EHCI/AHBPCI Base Address). This is shown in Figure 51.3.

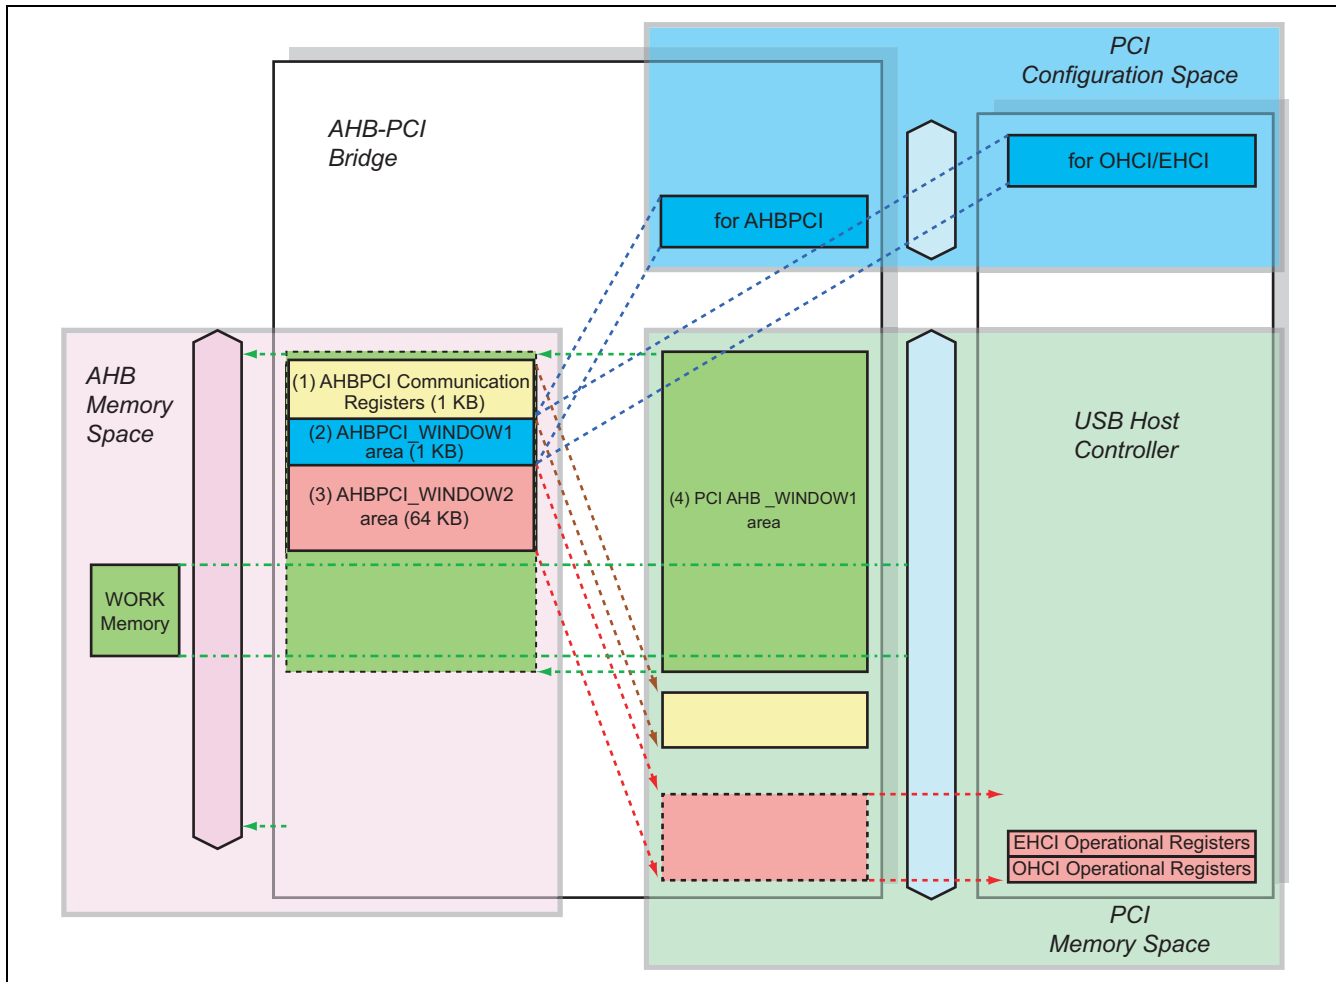

Figure 51.3 Mapping AHB and PCI Spaces (Spaces Overlapped)

Figure 51.4 shows the registers for AHB and PCI space mapping and Table 51.6 shows the relationship between the registers and the settings. In addition, the base address of Figure 51.4 AHB Memory Space is Ch.0. Please refer to a right note address for Ch.0/Ch.1/Ch.2. "Ch.0: H'EE08 / Ch.1: H'EE0A / Ch.2: H'EE0C"

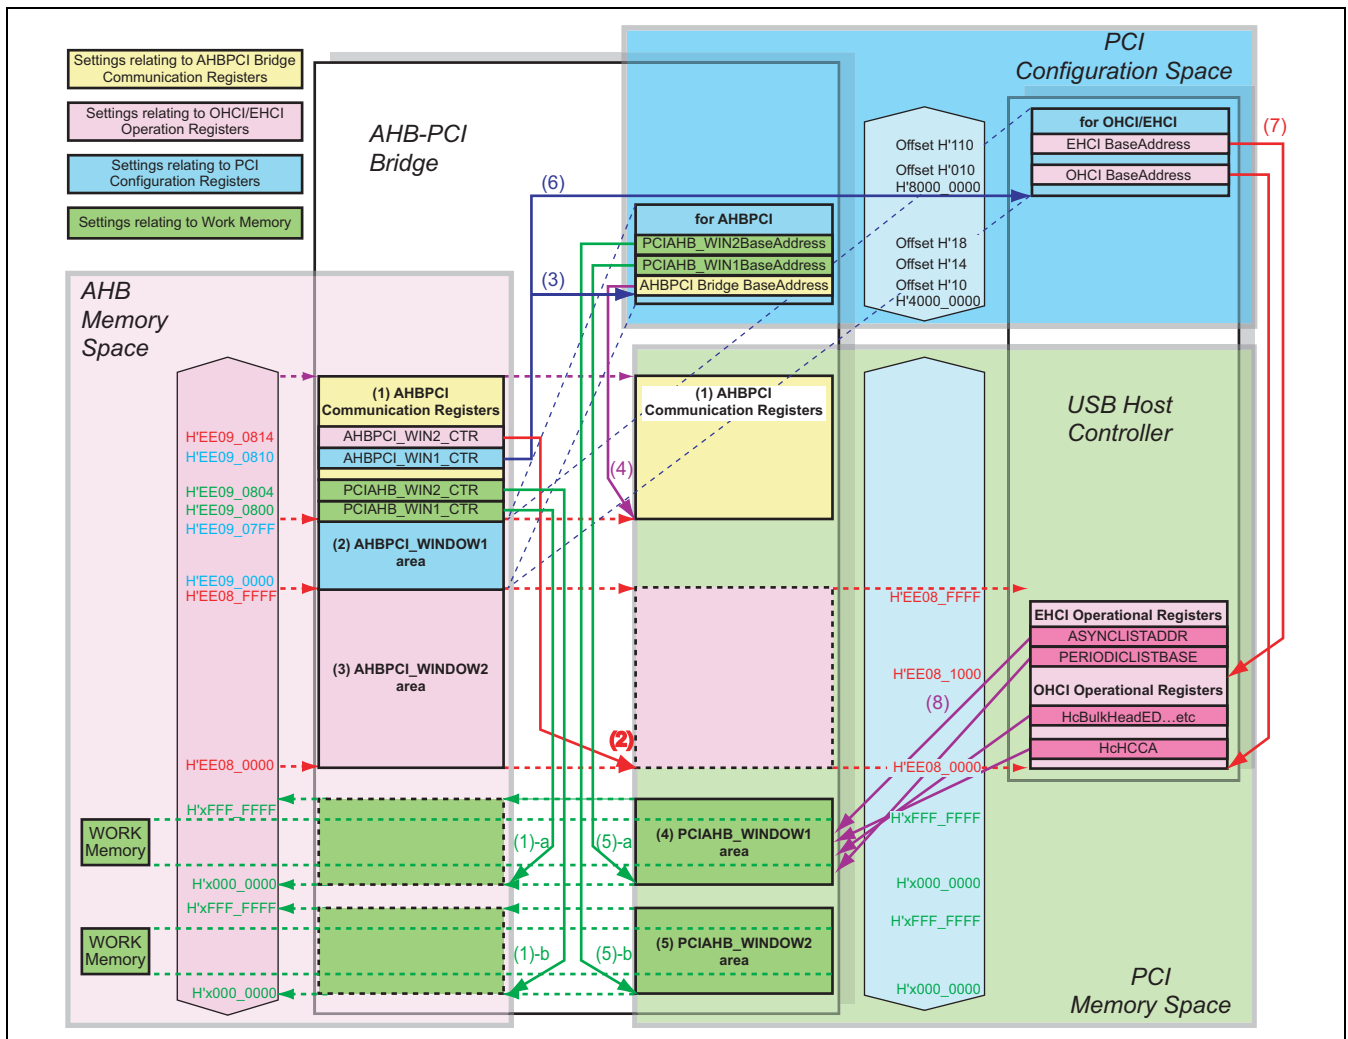

Figure 51.4 Address Setting Registers and AHB and PCI Space Mapping

**Table 51.6 Descriptions of Address Setting Register Values**

Register	Description
(1)-a PCIAHB_WIN1_CTR	When the host logic performs master-access to the ACIPHB WINDOW1 area, the AHB bus address is translated to the base address set in this register. Usually, set the area including the work memory to be used.
(1)-b PCIAHB_WIN2_CTR	When the host logic performs master-access to ACIPHB WINDOW2 area, the AHB bus address is translated to the base address set in this register. Usually, set the area including the work memory to be used.
(2) AHBPCI_WIN2_CTR	When the AHBPCI WINDOW2 area is accessed, the PCI bus address is translated to the base address set in this register. Although the same value as the AHBPCI WINDOW2 area can be set usually, if an overlap occurs with the area including the work memory set in (1), set the address so that it can prevent overlapping.
(3) AHBPCI_WIN1_CTR	When the base address is set to H'4000 0000 in this register, the PCI Configuration Registers area for AHBPCI is accessed.
(4) AHBPCI Bridge base address	Specifies a base address for the AHB-PCI bridge in the PCI space. Set this register so that it should not overlap with the other areas though this register is not accessed from the PCI bus,
(5)-a PCIAHB_WIN1 base address	Specifies a base address for the PCIAHB WINDOW1 area in the PCI space. Usually, the same base address as (1)-a should be set. Areas (5)-a and (5)-b must not overlap each other.
(5)-b	Specifies a base address for the PCIAHB WINDOW2 area in the PCI space. Usually, the same base address as (1)-b should be set. Areas (5)-a and (5)-b must not overlap with each other.
(6)	When the base address is set to H'8000 0000 in this register, the PCI Configuration Registers area for OHCI/EHCI Operational Registers is accessed.
(7)	Specifies a base address for the OHCI/EHCI Operational Registers in the PCI space. Usually, the OHCI base address should be set as the same base address set in (2). The EHCI base address is calculated by adding the base address set in (2) and offset H'1000.
(8) OHCI/EHCI operational registers	On completion of settings (1) to (7), the host logic can access data, such as a descriptor, expanded on the AHB work RAM through the PCI. The following registers are used to specify addresses for data in the work RAM: OHCI/EHCI operational registers HcHCCA HcPeriodicCurrentED HcControlHeadED HcControlCurrentED HcBulkHeadED HcBulkCurrentED HcDoneHead EHCI operational registers PERIODICLISTBASE ASYNCLISTADDR

### 51.7.1 PCI Configuration Register Accesses

The registers in the PCI Configuration Space can be accessed through the AHB-PCI WINDOW1 area (addresses H'10000 to H'107FF: 2-Kbytes). For the access, the AHBPCI\_WIN1\_CTR register should be set correctly. Table 51.7 shows the AHBPCI\_WIN1\_CTR settings to access the PCI Configuration Space areas for the OHCI/EHCI and AHB-PCI Bridge.

**Table 51.7 AHBPCI WIN1 CTR Register Settings**

Access to	AHBPCI_WIN1_CTR Setting	
	PCIWIN1_BASEADR[31:11]	PCICMD[2:0]
OHCI/EHCI PCI Configuration Space	Only set bit 31 to 1.	B'101
AHB-PCI Bridge PCI Configuration Space	Only set bit 30 to 1.	

### 51.7.2 OHCI/EHCI Operational Register Accesses

To access the OHCI/EHCI Operational Registers area, set the PCI space addresses and also set the OHCI/EHCI PCI Configuration Space and AHBPCI\_WIN2\_CTR register. Table 51.8 shows the required settings.

**Table 51.8 Settings Required for Accessing OHCI/EHCI Operational Registers Area**

Bit	Setting
OHCI/EHCI PCI Configuration Space offset H'04 (Command Status) Memory Space (bit 1)	1 (access to memory space enabled)
PCICMD (bits 3 to 1) in AHBPCI WIN2 CTR register	B'011 (memory read/memory write)

## 51.8 Reset System

### 51.8.1 Reset Configuration

This USB host controller is reset by the HRESET signal. When the HRESET signal is asserted, all the circuits within the USB host controller are reset. The HRESET is a power-on reset, and assumes that the HRESET signal of the AHB is connected. The reset signal of this USB host controller is an asynchronous reset that is directly connected to the F/F reset signal. The table lists the reset signals of this USB host controller.

Table 51.9 lists the reset signals for the USB host controller.

**Table 51.9 Reset Signals**

Reset Signal	Supplied From	Description
HRESETn	CPG	Power-on Reset Signal of the USB host controller. Resets the entire USB host controller. HRESETn is controlled from CPB as software reset.
PLL_RST	Internal	PLL in Transceiver Reset signal. This signal reset the Transceiver circuit too. Do not assert this signal when USB Host controller or Function Controller is active.
USBH_RST	Internal	USB Host Controller Reset Signal

When the HRESET is asserted, the USBH\_RST is also asserted. The internal reset can be operated from the AHB-PCI Bridge register. After the HRESET assertion, use the same register to cancel the reset state. For the reset sequence, refer to section 51.11.1, Reset Sequence.

### 51.8.2 Reset System Diagram

Figure 51.5 shows the reset system in the USB host controller.

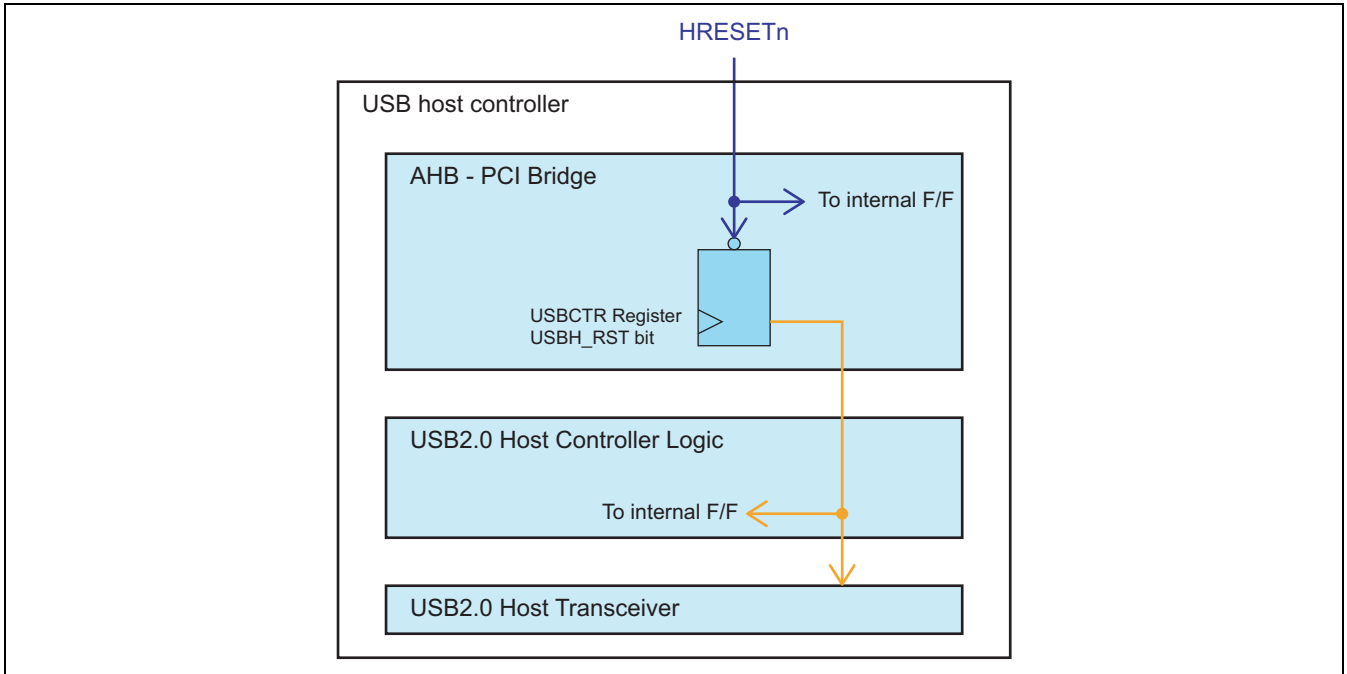

Figure 51.5 Reset System Diagram

## 51.9 Interrupts

### 51.9.1 Interrupt Signals

This USB host controller has the interrupt signals listed below. These signals are used as level-triggered interrupts. The interrupt lines can be reduced by the U2H\_BIND\_INT register if required (e.g., due to insufficient system resources). The U2H\_BIND\_INT register is not used when these interrupts are used individually.

**Table 51.10 Interrupt Signals**

Interrupt Signals	Synchronization Clock	Active Level	Description
USB_INTH	HCLK	High	Interrupt signal generated from the AHB-PCI Bridge
U2H_OHCI_INT	HCLK	High	INTA interrupt signal generated from the host controller
U2H_EHCI_INT	HCLK	High	INTB interrupt signal generated from the host controller
U2H_PME_INT	PMCLK	High	PME interrupt signal generated from the host controller
U2H_BIND_INT	HCLK/PMCLK	High	OR of the interrupt signals (Bridge + OHCI + EHCI + PME)

### 51.9.2 Interrupt Control Registers

#### (1) USB\_INTH Control Register

USB\_INTH is an interrupt that is generated by the AHB-PCI Bridge. The status check, interrupt clear, and interrupt enable are performed by the AHB-PCI Bridge registers.

**Table 51.11 USB\_INTH Control Register**

Function	Register
Interrupt status check and clear	PCI_INT_STATUS Register
Interrupt enable	PCI_INT_ENABLE Register

#### (2) U2H\_OHCI\_INT Control Register

U2H\_OHCI\_INT is an INTA interrupt that is generated by the host controller. This interrupt is controlled by the host controller registers; however, for this interrupt signal assertion, the interrupt enable bit of the AHB-PCI Bridge must be set to Enabled.

**Table 51.12 U2H\_OHCI\_INT Control Register**

Function	Register
Interrupt status check and clear	HcInterruptStatus Register
Interrupt enable	HcInterruptEnable Register
	HcInterruptDisable Register
	PCI_INT_ENABLE Register (bit[16] USBH_INTAEN)

**(3) U2H\_EHCI\_INT Control Register**

U2H\_EHCI\_INT is an INTB interrupt that is generated by the host controller. This interrupt is controlled by the host controller register. To assert this interrupt signal, the interrupt enable bit of the AHB-PCI Bridge must be valid.

**Table 51.13 U2H\_EHCI\_INT Control Register**

Function	Register
Interrupt status check and clear	USBSTS Register
Interrupt enable	USBINTR Register PCI_INT_ENABLE Register (bit[17] USBH_INTBEN)

**(4) U2H\_PME\_INT Control Register**

U2H\_PME\_INT is a PME interrupt that is generated by the host controller. This interrupt is controlled by the host controller register. To assert this interrupt signal, the interrupt enable bit of the AHB-PCI Bridge must be valid.

**Table 51.14 U2H\_PME\_INT Control Register**

Function	Register
Interrupt status check and clear	PCI Configuration Register for OHCI/EHCI offset H'44
Interrupt enable	PCI Configuration Register for OHCI/EHCI offset H'44 PCI_INT_ENABLE Register (bit[19] USBH_PMEEN)

### 51.9.3 U2H\_BIND\_INT

The U2H\_BIND\_INT interrupt signal is generated by an OR of the interrupt source signals (USB\_INTH, U2H\_OHCI\_INT, U2H\_EHCI\_INT, and U2H\_PME\_INT). The signal states of the U2H\_PME\_INT, U2H\_OHCI\_INT and U2H\_EHCI\_INT are reflected to the PCI\_INT\_STATUS register. Reading the PCI\_INT\_STATUS register enables the user to check the interrupt source.

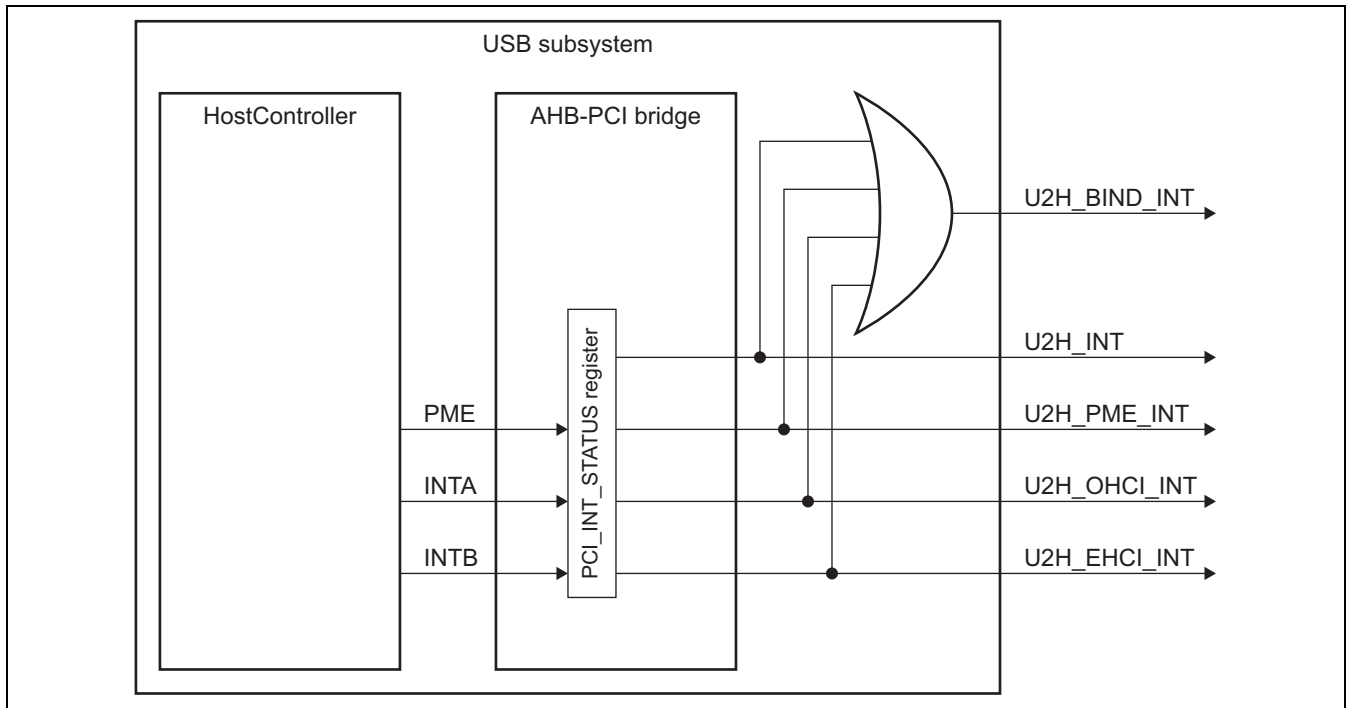

Figure 51.6 Interrupt Signals Aggregation Image

### 51.9.4 Interrupt Signal Clear Time

The AHB-PCI Bridge implements a posted write; therefore, an interrupt generated by the host controller may not be cleared soon after setting the clear register and same interrupt state may be recognized many times. (See the Figure 51.7) The user must take a countermeasure to avoid such false recognition.

For example; access to the host controller register (2) after accessing to an Interrupt Clear Register (1). The operation of (2) is waited (SHREADY = 0 or Retry response) until the operation of (1) is completed. As the result, the interrupt is cleared without fail at the completion of the access of (2).

The U2H\_OHCI\_INT, U2H\_EHCI\_INT, and U2H\_PME\_INT may not be cleared soon after setting the clear register. When HCLK = 150 MHz and PCICLK = 25 MHz, the interrupt is cleared in about 300 ns after setting the clear register. When the host controller is executing a transfer as a master on the internal PCI-bus, it takes about 1.6 μs (35CLK@PCICLK + 3CLK@HCLK + 2CLK@12 MHz) at worst to clear the interrupt.

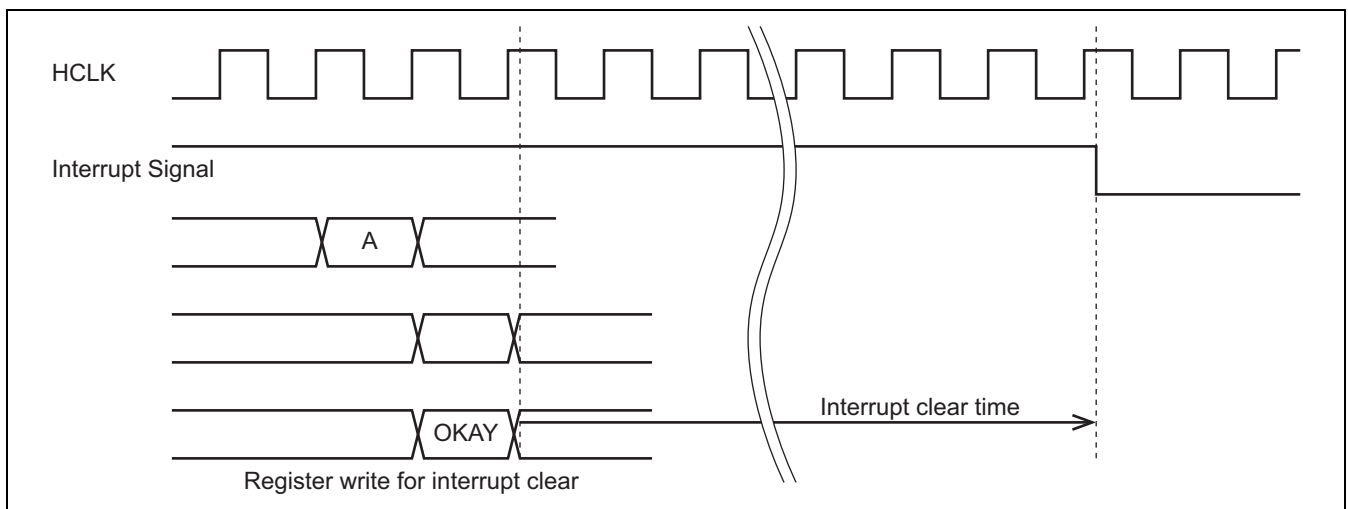

Figure 51.7 Interrupt Clear Time

## 51.10 Power Management

This chapter describes the power management function of the USB Host controller V1 Type-H2.

When the USB is not used, hold the power state in a reset state after cancellation of the AHB bus reset (USBCTR Register, USBH\_RST = 1). The subsequent sections describe a power-off operation that temporarily powers down (suspend) the USB host.

### 51.10.1 Power-Off Sequence

When the USB Host function is temporarily stopped, the power consumption can be reduced by powering down the host controller and stopping the internal PCI bus clock (PCICLK) of the USB host controller.

The USB host controller has a gating circuit for the PCICLK, and the circuit can be controlled from the AHB-PCI Bridge register. The following figure shows the power-off sequence.

#### 51.10.1.1 OHCI Mode

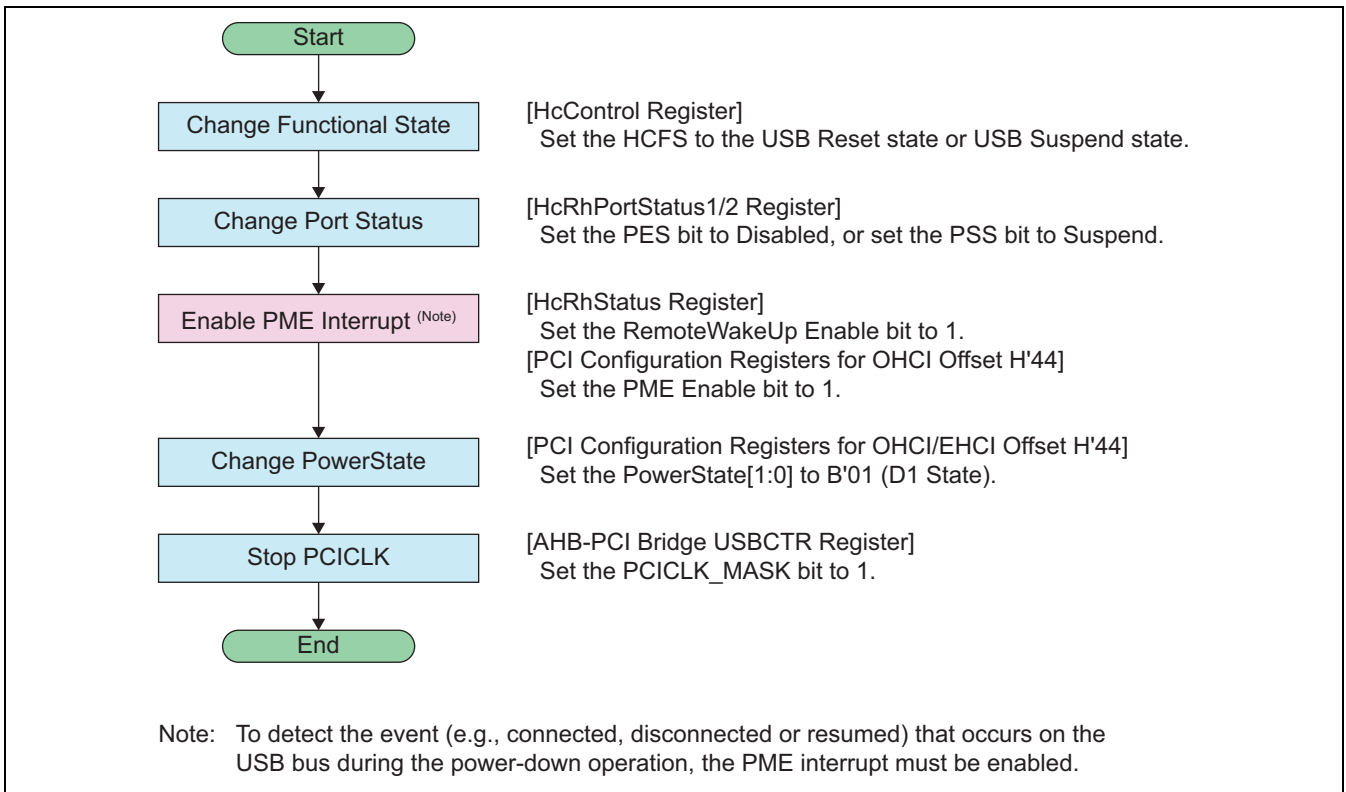

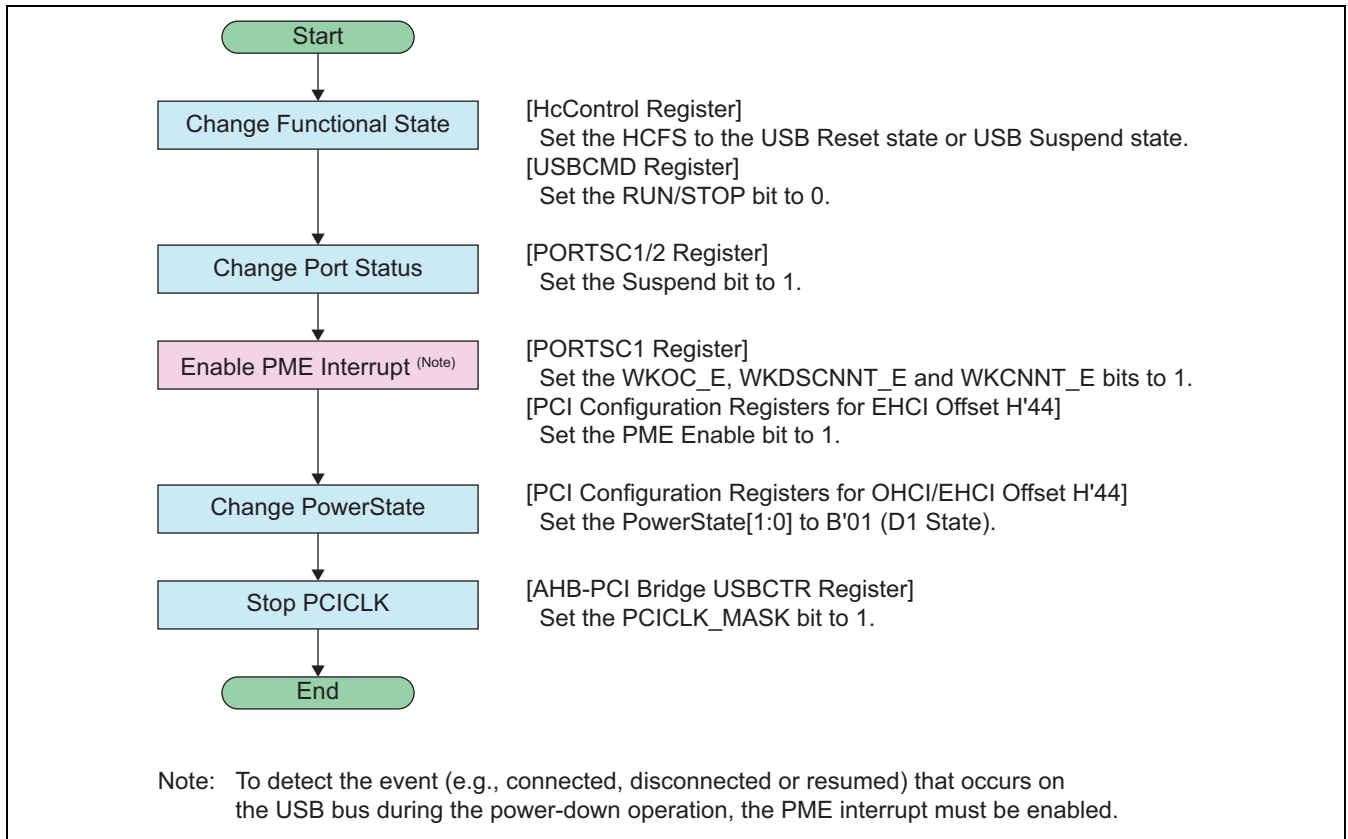

Figure 51.8 Power-Off Sequence

**51.10.1.2 EHCI Mode**

**Figure 51.9 Power-Off Sequence**

### 51.10.2 Power On Sequence

The recovery from the power-down state is performed in the opposite procedure of the power-down operation.

#### 51.10.2.1 OHCI Mode

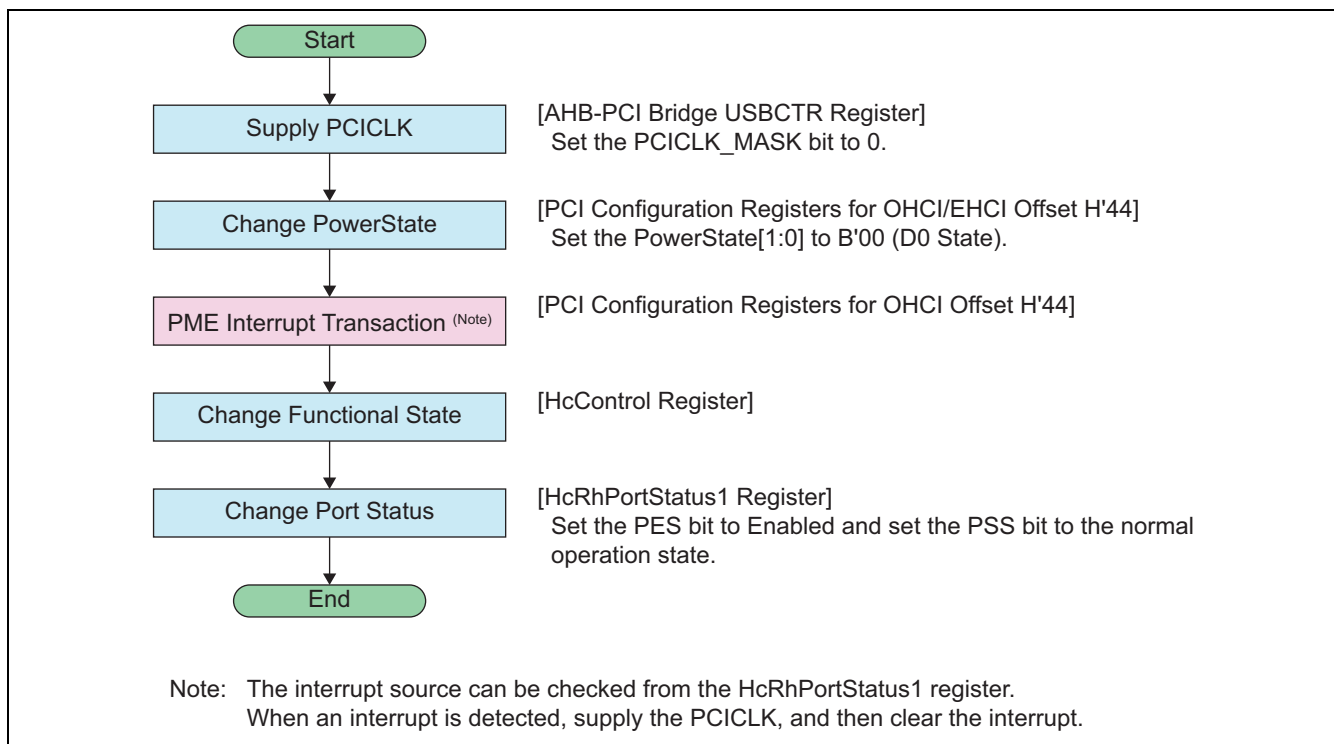

Figure 51.10 Power-On Sequence

#### 51.10.2.2 EHCI Mode

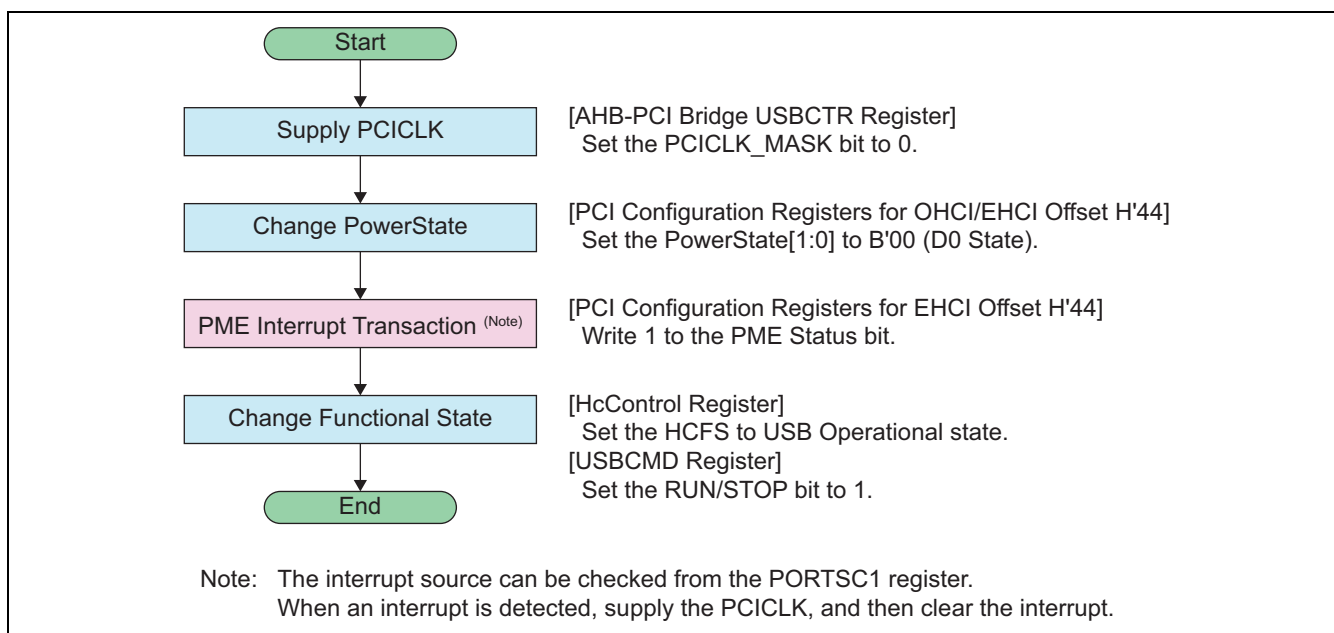

Figure 51.11 Power-On Sequence

### 51.10.3 Direct Power-Down Feature

When the whole USB host controller is not used, power consumption of the USB host controller can be reduced using the direct power-down function. Recovery from the direct power-down state is not performed in this USB host controller.

#### 51.10.3.1 Direct Power-Down Setting

The figure below shows how to set the direct power-down mode. It is recommended that the PCICLK be masked from the PCICLK\_MASK register to minimize power consumption.

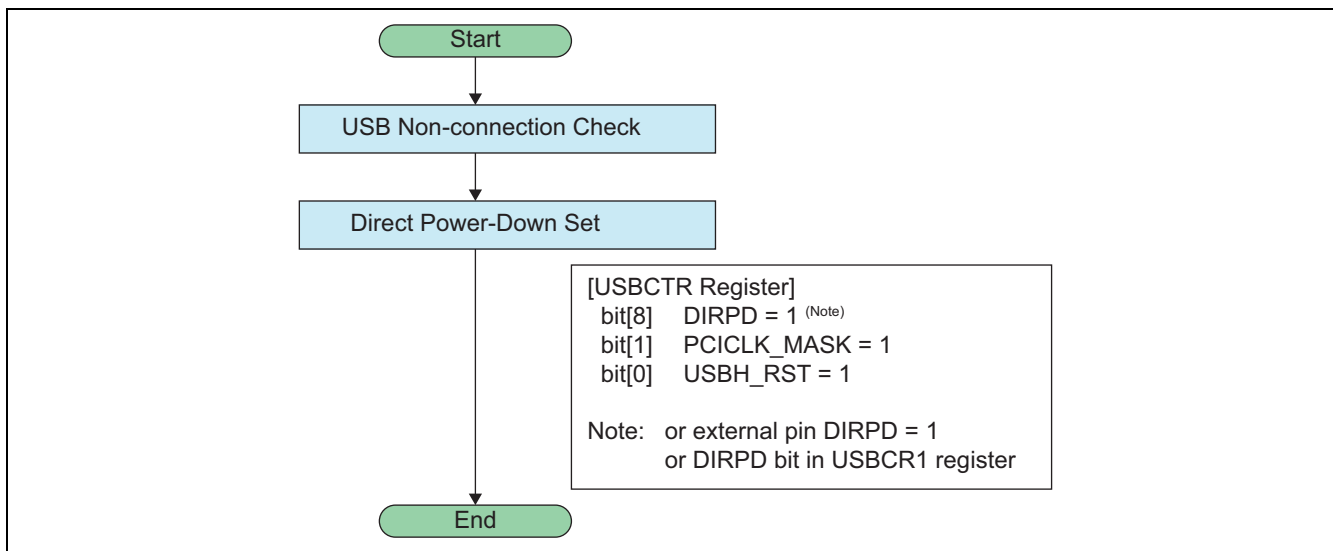

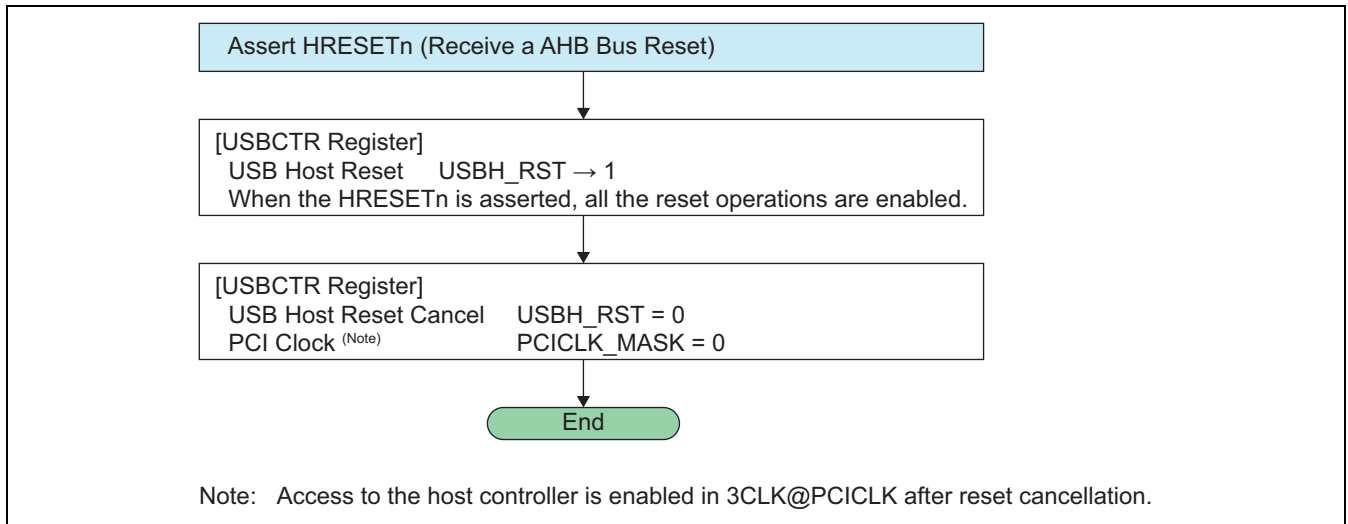

Figure 51.12 Direct Power-Down Setting

## 51.11 Operating Procedures

### 51.11.1 Reset Sequence

**Figure 51.13 Reset Sequence**

51.11.2 Initial Setup Sequence

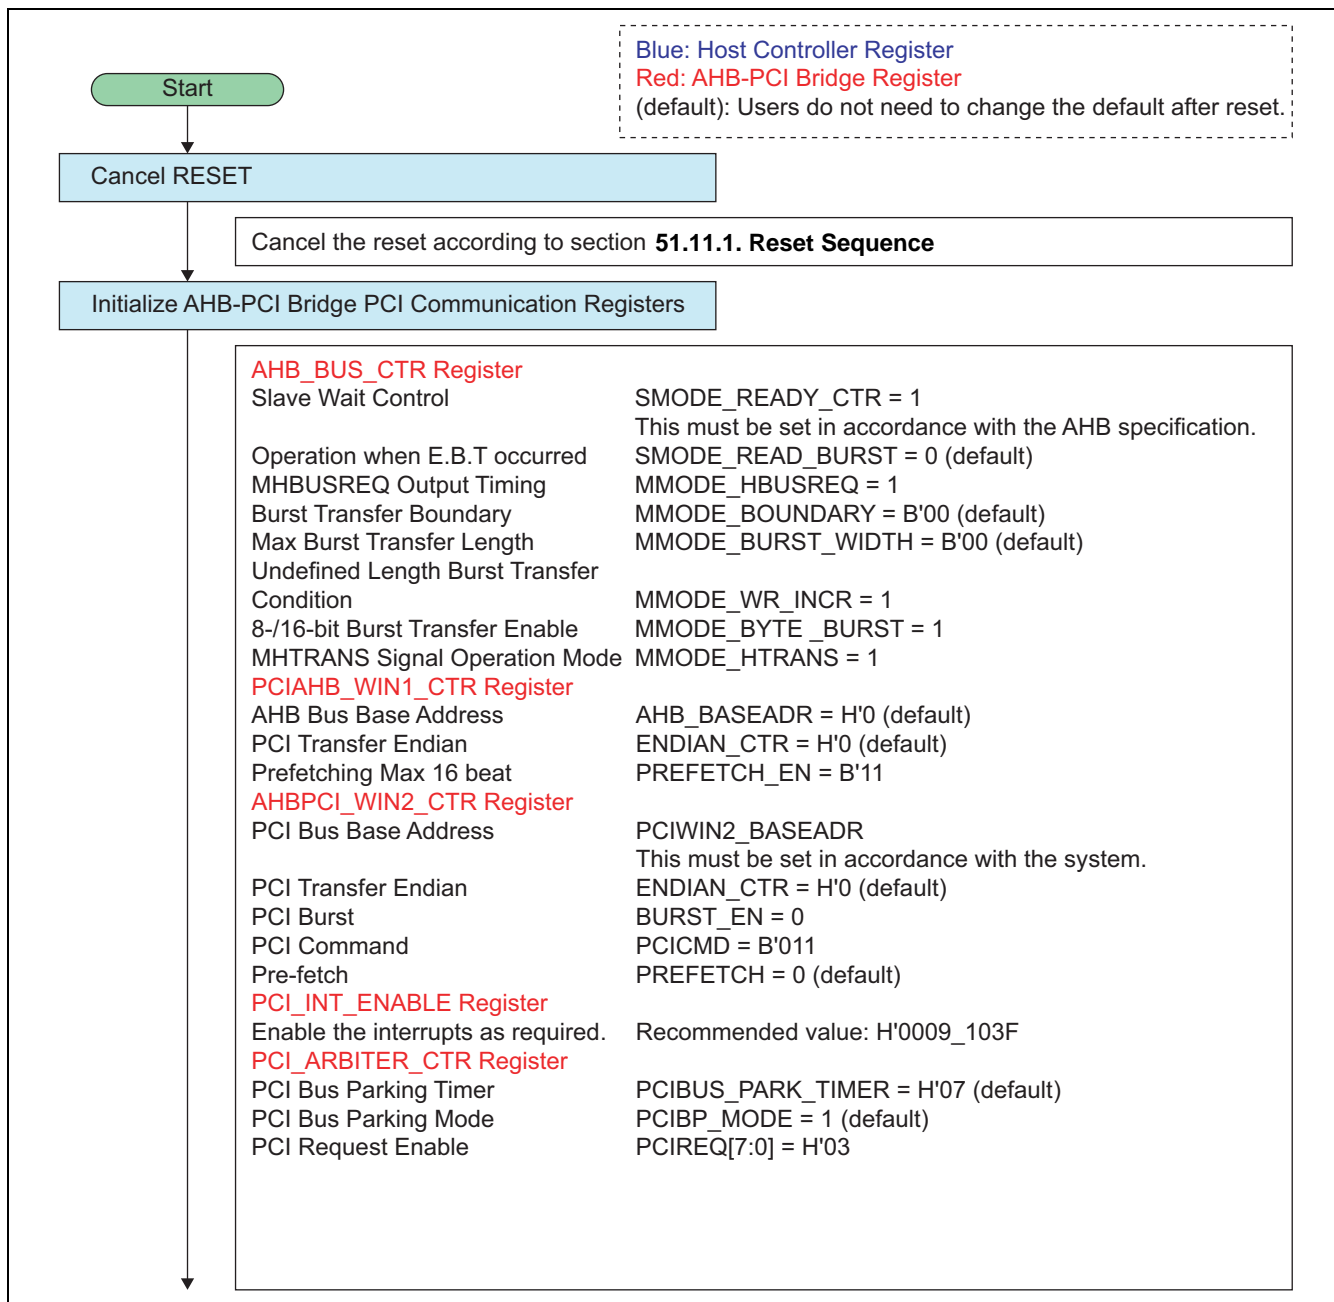

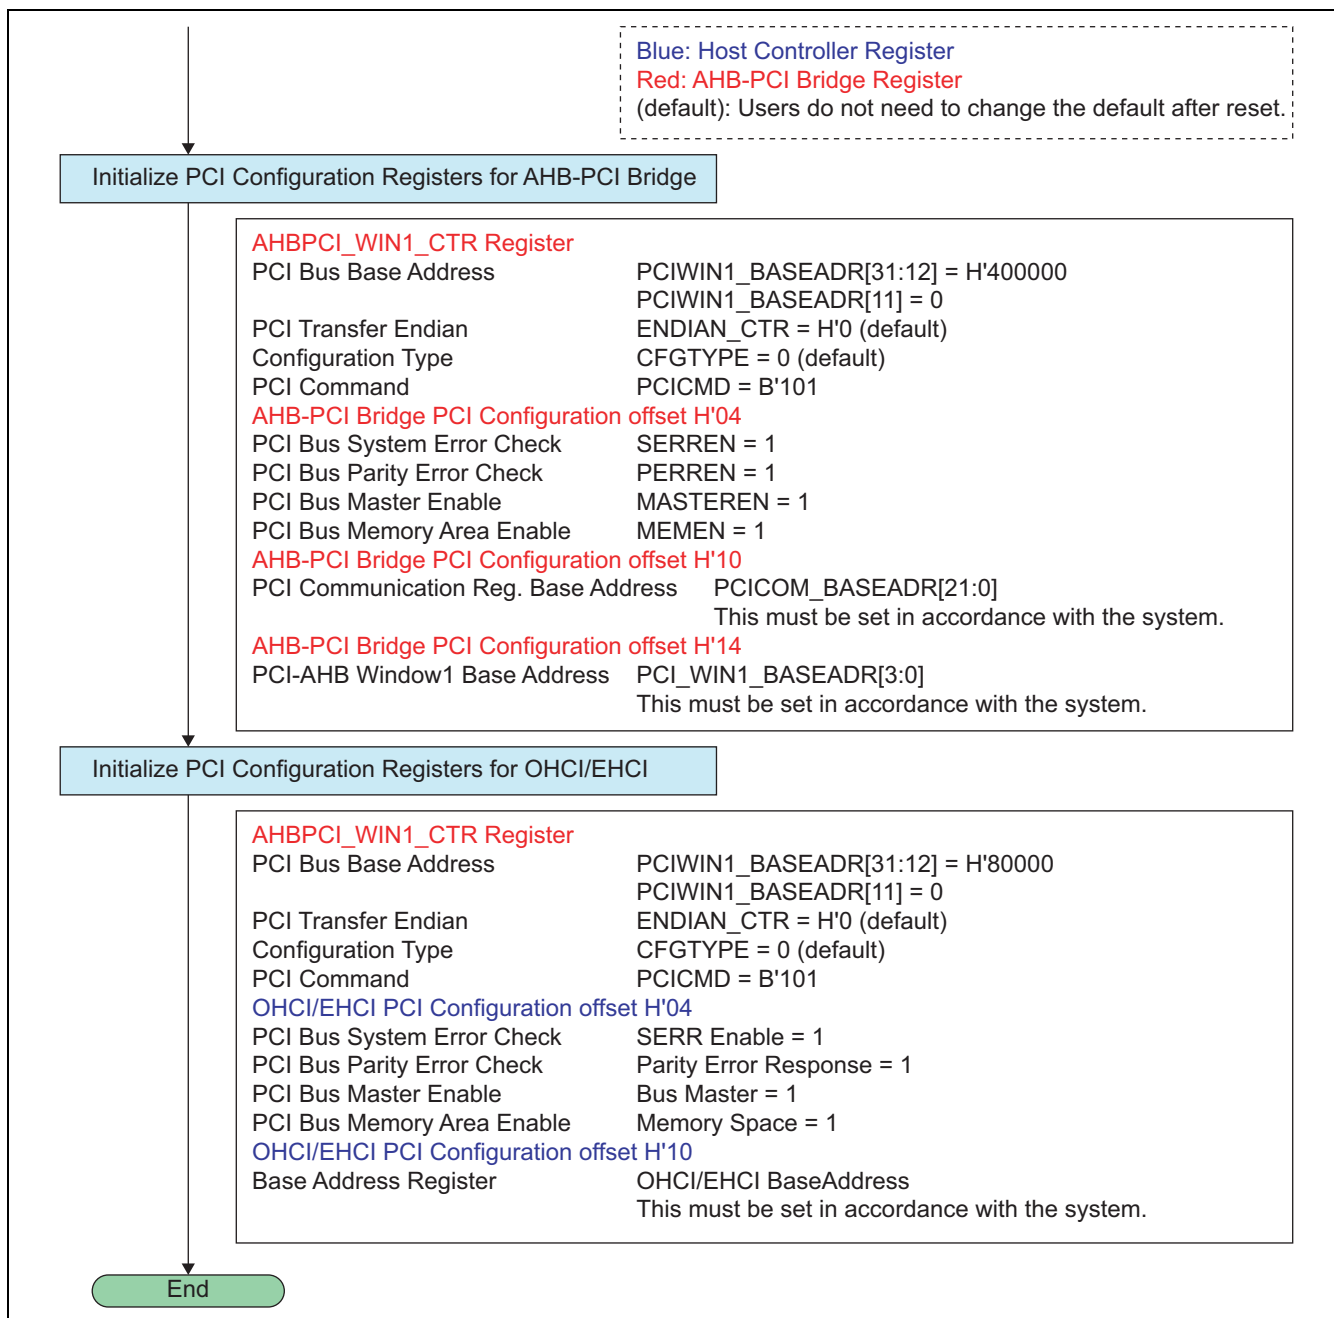

Figure 51.14 USB Host Initial Setup Sequence (1)

**Figure 51.15 USB Host Initial Setup Sequence (2)**

The above settings enable the following operations.

- Access to the OHCI and EHCI Operation Registers via the AHB-PCI Window2 register
- Data transfer to the AHB from the host controller

### 51.11.3 Transfer Overview

Transfer by the host controller must be performed in compliance with the following OHCI and EHCI specifications.

Open Host Controller Interface Specification for USB Rev 1.0a

Enhanced Host Controller Interface Specification for Universal Serial Bus Revision 1.0

This section provides supplementary note about the DMA stop.

#### 51.11.3.1 DMA Transfer Stop

The AHB-PCI Bridge does not have a control bit that turns on or off DMA mode. When the host controller initiates a PCI bus cycle as a master, the AHB-PCI Bridge performs DMA transfer to the AHB. DMA transfer of the host controller is performed: (1) to write the current frame number into memory; and (2) to write or read the descriptor and data loaded into memory to perform a list transaction.

Writing of the frame number (1) is performed per frame cycle when the USB is in the Operational state; therefore, the USB must be put into the Suspend or Reset state before stopping the DMA transfer. In this case, the list transaction of (2) is stopped at the same time.

The list transaction of (2) is stopped when the enable bit (HcControl Register, BLE bit, CLE bit, IE bit, PLE bit) of the list transaction is cleared. The transaction is stopped from the next frame when the bit is cleared. In this case, a writing of the frame number of (1) is not stopped.

## 51.12 Over Current and Vbus Control

### 51.12.1 Over Current Control

This chapter describes the over current detection of USB port and OCI/PPON operation which controls VBUS. OCI is connected to external input pin USB\*\_OVC, PPON is connected to external output pin USB\*\_PWEN.

#### 51.12.1.1 Description of OCI/PPON

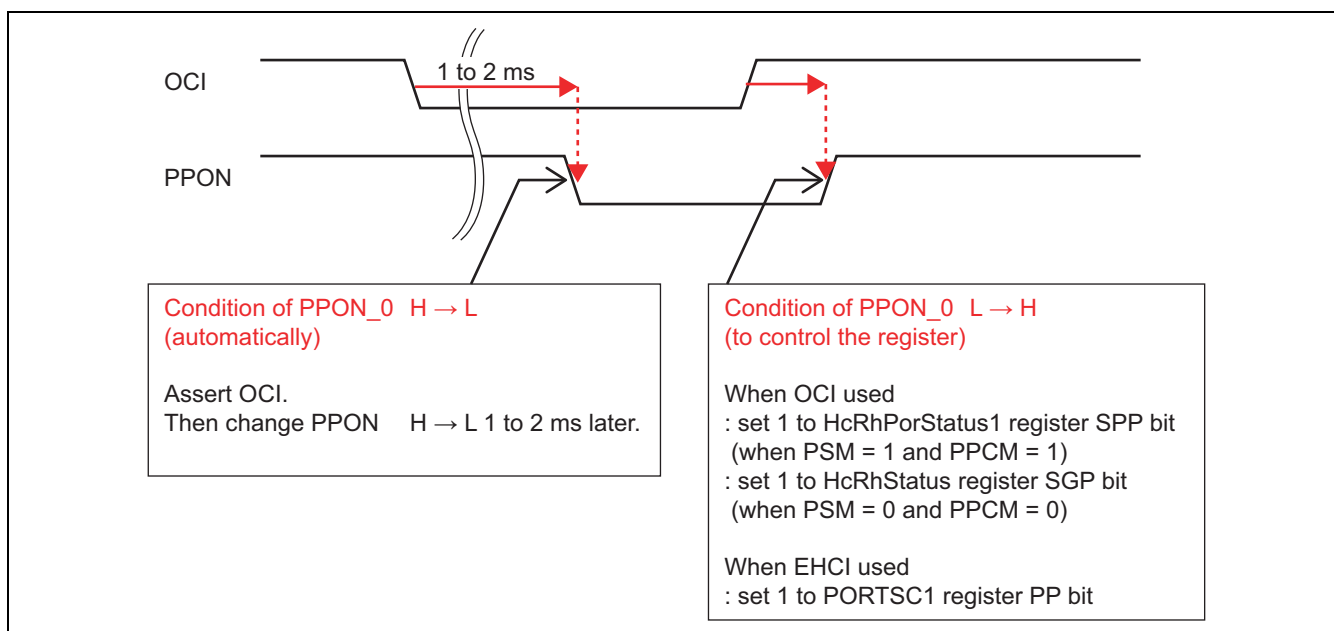

The function of OCI/PPON is described in the following table.

**Table 51.15 OCI/PPON**

Pin	IO	Level	Description
OCI	IN	1	Not detect over current
		0	Detect over current
PPON	OUT	1	Power supply to VBUS ON
		0	Power supply to VBUS OFF

#### 51.12.1.2 Condition of PPON Assertion

The timing chart of OCI / PPON assertion is described following figure.

**Figure 51.16 Timing chart of OCI / PPON assertion and deassertion**

PPON are not asserted automatically when OCI is changed from L to H. Assert PPON by setting the port power bit from software after OCI are changed L → H.

### 51.12.2 VBUS Control

Power supply to VBUS can be stopped by connecting OCI and PPON to highside switch when USB port is not used. It can reduce power consumption.

Note : It depends on the external circuit attached to RZ/G.

The configuration of this operation is described in the following table.

**Table 51.16 PPON setting for VBUS control**

PPON setting	State of VBUS
PPON = 0	VBUS stopped
PPON = 1	VBUS is supplied

The operation of PPON for OCI assertion is changed by the setting of PCI configuration register and OHCI Operation register. The description of this operation is described in following table.

**Table 51.17 PPON operation**

PCI Configuration Register		OHCI Operation Register				PPON operation
EXT1 register	HcRhDescitporA register	HcRhDescriptorB register		PPCM	PPON	
Ppcnt bit	NOCP bit	NPS bit	PSM bit	Bit 1		
0	—	—	—	—	—	Fixed 1
—	1	—	—	—	—	Fixed 1
—	—	1	—	—	—	Fixed 1
1	0	0	0	—	PPON is changed H → L by asserting OCI to 0.	
			1	0		
				1		

Note: If NPS is 1, Host controller detects the over current, but it not change PPON H → L.

51.12.3 Over current detection flow

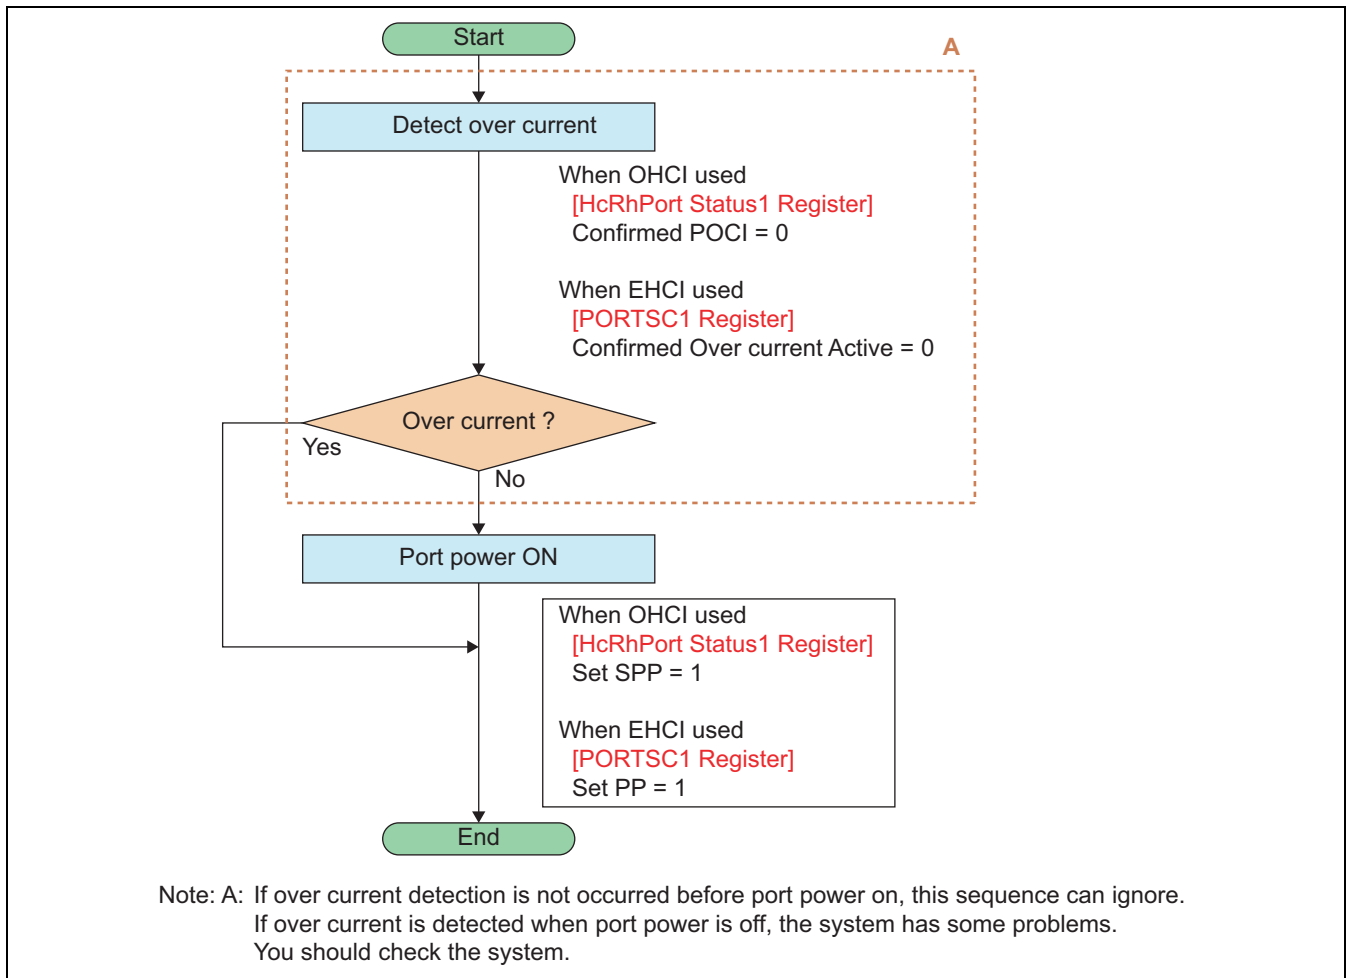

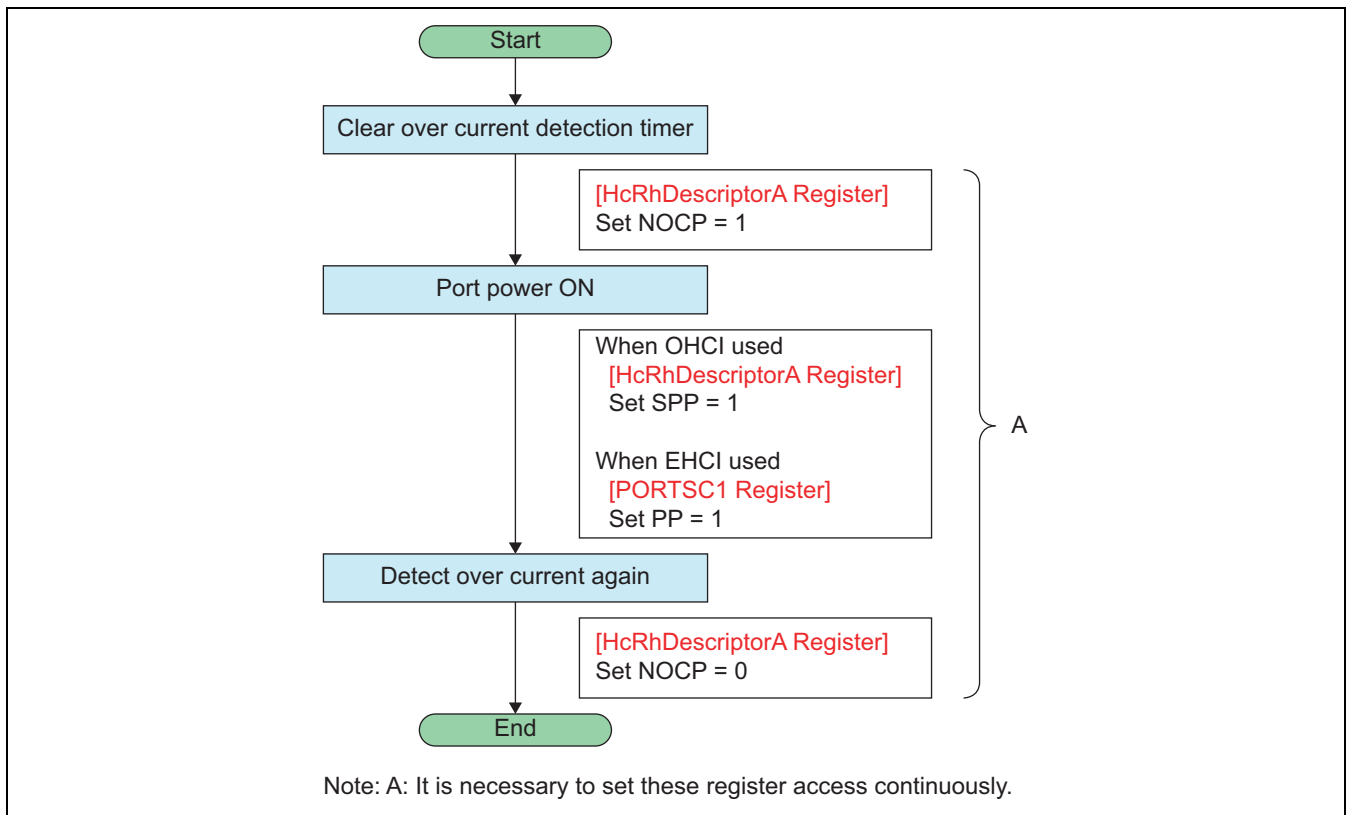

Figure 51.17 Over current detection flow

**51.12.4 PPON setting flow**

PPON setting flow that the case of OCI is active (B'0) when the system is started is described the following figure.

**Figure 51.18 PPON Setting Flow**

If OCI is active when system is started, you should set that OCI detect function is OFF before setting PPON.

OCI detect timer becomes OFF when the OCI detect function is disabled.

If the OCI detect function is set ON after PPON setting, OCI detection value that detected when system is started is cleared.

## 51.13 Usage Note

### 51.13.1 EXT1 register bit 12 (current: reserved bit) should be specified as 0 (default: 1) under some conditions

Problem: The size of the short packet may become the maximum size with the undefined padding data when all of the following conditions are satisfied.

- 1) The transfer type is Control or Bulk Out and transfer is at high speed mode.
- 2) Asynchronous schedule park mode is enabled (USBCMD.ASPME =1).
- 3) Periodic list processing is disabled (USBCMD.PSE = 0).
- 4) Bit 12 of EXT1 register is 1 (this bit is reserved and its initial value is 1).
- 5) Time taken to transfer a fetched QH exceeds the uFrame limit.
- 6) The amount of data remaining to be transferred once the uFrame boundary is exceeded is "maximum packet size  $\times$  n + short packet". n represents a positive integer more than 1.

Note 1. It is most likely harmless for the typical use case. The following cases are some example not to occur this problem.

- Only HS asynchronous out transfer, such as BULK out write transaction to a USB memory from a navigation system cause this issue. The issue does not occur for read operations. Isochronous transfer to transmit audio data or interrupt transfer can avoid this issue even if it is OUT transaction because these are not asynchronous transfer.
- The recent Linux device driver set the asynchronous schedule park mode to disabled by default though it prevent the host controller from achieving the maximum transfer performance. The asynchronous schedule park mode is possibly disabled if the system is based on Linux. In this case the issue does not occur.
- The periodic schedule enable bit is set as enabled for the system which use periodic transfer, isochronous or interrupt transfer. For example a HUB require interrupt transfer so that the USB ports through hubs does not show this issue.
- If the data length does not match with the condition, MAX packet size  $\times$  N + short packet, then the issue does not occur. The file systems for HDD or USB memory use the transfer size multiple of 512-byte. In this case the issue does not occur.

Note 2. The condition 5) is controlled by the host controller hardware therefore it is uncontrollable from user. Linux BSP driver enable or disable the periodic schedule depends on the USB device connected but the park mode is disabled by default. The issue does not occur by default because of condition 2). Applying the workaround is recommended if the park mode is enabled by user and condition 6) are met.

## [Workaround]

The recommended workaround for this problem is the following, which prevent the condition 4).

1. Write 0 to bit 12 in the EXT1 register\*<sup>1</sup> during the initialization sequence.

Notes: \*1. See section 51.6.3.12, Offset H'E0 (EXT1).

## Function of the bit 12 in EXT1

This bit enables or disables fetching of QH at the beginning of the next uFrame once processing for packet transfer exceeds the uFrame time limit; this bit is initially set to 1, but clearing it to 0 (workaround 1) disables the fetching.

Disabling of this function does not cause any problems during packet transfer.

## 52. USB High-Speed Module (HS-USB)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

This module is a USB controller provided with the function controller function, and high-speed transfer and full-speed transfer are available. Provided with an on-chip USB transceiver, this module also supports all transfer types defined by the USB Specification.

This module can use up to 16 pipes. Furthermore, for pipes 1 to F, arbitrary endpoint numbers can be allocated according to peripheral devices to be communicated and user systems.

### 52.1 Features

#### (1) On-chip USB transceiver

#### (2) Achieves space-saving mount with less external elements

- On-chip D+ pull-up resistor (function operation mode)
- On-chip D+/D- terminating resistors (high-speed operation mode)
- On-chip D+/D- output resistors (full-speed operation mode)

#### (3) All Types of USB Transfers Supported

- Control transfer
- Bulk transfer
- Interrupt transfer (except for high bandwidth)
- Isochronous transfer (except for high bandwidth)

#### (4) Dedicated DMA interface

- On-chip 4-channel DMA interface

#### (5) Pipe configuration

- Up to 16 pipes are selectable (including the default control pipe)
- Programmable pipe configuration
- Arbitrary endpoint numbers can be allocated to pipes 1 to F.
- Settable transfer conditions for each pipe are as follows:

Pipe 0: A pipe only for control transfer with a 64-byte (fixed) single buffer

Pipes 1 and 2: Bulk transfers/isochronous transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)

Pipes 3 to 5 and B to F: Bulk transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)

Pipes 6 to 8: Interrupt transfer, 64-byte fixed single buffer

Pipes 9 to A: Interrupt transfer, Bulk transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)

#### (6) Other functions

- Transfer ending function using transaction count
- SOF pulse output function
- BRDY interrupt event notification timing change function (BFRE)
- Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0 to 3) port has been read (DCLRM)

- NAK setting function (SHTNAK) for the response PID due to the transfer end
- The suspend and resume of whole LSI can be done by using USBHS.

### (7) Embedded USB PHY

The embedded USB PHY consists of the following features.

- Contains the USB functions drivers and receivers for D+ and D- signaling

The embedded USB PHY does not support ID pin detection and VBUS detection. This function is exported to the external device (for example, MAX3355E). This product support only OVC signals for vbus detection.

This USB subsystem support external device interface for external device control. These signals inform the vbus status, vbus valid and the OTG SRP.

#### 52.1.1 Input/Output Pins

Table 52.1 lists the input and output pins of the USB.

**Table 52.1 Pin Configuration of USB**

Classification	Pin Name	Name	I/O	Description
USB bus interface	DP	USB D+ data	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus.
	DM	USB D- data	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus.
Reference resistance	RREF	Reference input	Input	Reference resistance connecting pin Connect this pin to the ground through a 1.8 kΩ ±1% resistor.

## 52.2 Register Descriptions

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

Table 52.2 lists the registers used in this module. Table 52.3 lists the register states in each processing mode.

### 52.2.1 System Configuration Control Register (SYSCFG)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SYSCFG enables or disables high-speed operation, controls DP\_0 and DM\_0 pins, and enables or disables the operation of this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HSE	—	—	DPRPU	—	—	—	USBE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R	R	R/W	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	—	0	R/W	Reserved This bit is always read as 0. Writes have no effect.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	HSE	0	R/W	High-Speed Operation Enable 0: High-speed operation is disabled. When the function controller function is selected: Full-speed operation only 1: High-speed operation is enabled. (This module detects the transmission rate.) When HSE is 0, this module performs full-speed operation. When HSE is 1, this module executes the reset handshake protocol, and according to the result, this module automatically performs high-speed or full-speed operation. Change this bit while the DPRPU bit is 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DPRPU	0	R/W	D+ Line Resistance Control Enables or disables pull-up of the D+ line when the function controller function is selected. 0: Pull-up is disabled. 1: Pull-up is enabled. When this bit is set to 1 with the function controller function selected, this module pulls up the D+ line at 3.3V, and informs the USB host of ATTACH. Clearing this bit to 0 cancels the pull-up of the D+ line, and informs the USB host of DETACH. Set this bit to 1 before using this module.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	USBE	0	R/W	<p>USB Module Operation Enable</p> <p>Enables or disables the USB module operation.</p> <p>0: The USB module operation is disabled.</p> <p>1: The USB module operation is enabled.</p> <p>Table 52.4 lists the registers and bit names initialized when this bit is cleared to 0.</p>

**Table 52.4 Registers Initialized by Writing 0 in the USBE Bit**

Register Name	Bit Name
SYSSTS	LNST
DVSTCTR	RHST
INTSTS0	DVSQ
USBADDR	USBADDR
USEREQ	BRequest, bmRequestType
USBVAL	wValue
USBINDX	wIndex
USBLENG	wLength

### 52.2.2 CPU Bus Wait Register (BUSWAIT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

BUSWAIT specifies the number of access waits from the CPU to this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	BWAIT[3:0]	1111	R/W	<p>CPU Bus Wait</p> <p>Specify the number of access waits to this module.</p> <p>0000: 0 waits (2 access cycles)</p> <p>0001: 1 wait (3 access cycles)</p> <p>0010 to 1110: 2 to 14 waits (4 to 16 access cycles)</p> <p>1111: 15 waits (17 access cycles) initial value</p> <p>The following restriction is provided for access cycles to the registers of addresses beginning with H'04 of this controller.</p> <p>Restriction for wait: The cycle of continuous accesses to the registers of this controller must be 80 ns or more.</p> <p>To satisfy this restriction, control waits using the frequency of system clock HP<math>\phi</math>. Choose the best value within the initial value of 17 clock cycles (maximum).</p> <p>This setting is the same as the waits in accesses to the FIFO port register. The maximum speed of accesses to the FIFO port is as follows:</p> <p>MBW = B'10 (32-bit width) : Max. 48 Mbytes/s</p> <p>MBW = B'01 (16-bit width) : Max. 24 Mbytes/s</p> <p>MBW = B'00 (8-bit width) : Max. 12 Mbytes/s</p>

### 52.2.3 System Configuration Status Register (SYSSTS)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SYSSTS monitors the USB data bus line status (D+ and D- lines).

This register is initialized by a power-on reset or a USB reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LINE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	LNST[1:0]	Undefined*	R	USB Data Line Status Monitor Indicate the USB data bus line (D+ and D- lines) status. Table 52.5 shows the USB data bus line status. Read these bits after the attach processing (DPRPU = 1).

Note: \* These bits depend on the state of the DP, DM, OVC, and IDIN pins.

**Table 52.5 USB Data Bus Line Status**

LNST[1]	LNST[0]	Full-Speed Operation	High-Speed Operation	Chirp Operation
0	0	SE0	Squelch	Squelch
0	1	J-State	UnSquelch	Chirp J
1	0	K-State	Invalid	Chirp K
1	1	SE1	Invalid	Invalid

Legend:

Chirp:	The reset handshake protocol (RHSP) is being executed with high-speed operation is enabled (HSE = 1 in SYSCFG).
Squelch:	SE0 or idle state
UnSquelch:	High-speed J-State or high-speed K-State
Chirp J:	Chirp J-State
Chirp K:	Chirp K-State
Invalid:	Invalid

### 52.2.4 Device State Control Register (DVSTCTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

DVSTCTR controls and monitors the USB data bus state.

This register is initialized by a power-on reset. The WKUP bit is initialized and the RESUME bit becomes undefined by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	WKUP	—	—	—	—	—	RHST[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	WKUP	0	R/W*	Wakeup Output Enables or disables the remote wakeup (resume signal output) to the USB bus when the function controller function is selected. 0: The remote wakeup signal is not output. 1: The remote wakeup signal is output. This module controls the remote wakeup signal output time. When this bit is set to 1, this module outputs 10 ms K-State and then clears this bit. The USB Specification requires the USB bus idle state to be maintained for at least 5 ms before transmitting the remote wakeup signal. For this reason, this module outputs K-State after waiting for 2 ms even if 1 is written in this bit immediately after the suspended state is detected. Write 1 in this bit only when the device is in the suspended state (DVSQ = 1xx in INTSTS0) and remote wakeup is enabled by the USB host. When setting this bit to 1, do not stop the internal clock even in the suspended state.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	RHST[2:0]	000	R	Reset Handshake Indicate the reset handshake state. 000: Transmission rate is undefined. 100: The reset handshake processing is in progress. 010: Full-speed connection 011: High-speed connection When this module detects a USB bus reset with the HSE bit set to 1 for the port, these bits become B'100. After that, when this module outputs ChirpK and detects ChirpJK from the USB host three times, these bits become B'011. Unless high-speed mode is fixed within 2.5 ms after the ChirpK output, these bits become B'010. When this module detects a USB bus reset with the HSE bit set to 0 for the port, these bits become B'010. When the RHST bits are fixed to B'010 or B'011 after this module detected a USB bus reset, the DVST interrupt occurs.

### 52.2.5 Test Mode Register (TESTMODE)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TESTMODE controls the USB test signal output in high-speed operation mode.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	UTST[3:0]	0000	R/W	Test Mode Table 52.6 shows the test mode operation of this module. Control the USB test signal output in high-speed operation mode. These bits are valid only in high-speed operation mode. Use this test mode when the RHST bits in DVSTCTR are B'011. After the test with these bits, cancel this test mode by a power-on reset. Set these bits according to the SetFeature request from the USB host during high-speed communication. While these bits are B'0001 to B'0100, this module does not enter the suspended state.

**Table 52.6 Test Mode Operation**

Test Mode	UTST Bits Setting
Normal operation	B'0000
Test_J	B'0001
Test_K	B'0010
Test_SE0_NAK	B'0011
Test_Packet	B'0100
Test_Force_Enable	—
Reserved	B'0101 to B'0111

### 52.2.6 CFIFO Port Register

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CFIFO is a port register to read data from or write data to the FIFO buffer memory.

Each FIFO port consists of this register (CFIFO) for data read/write from/to the FIFO buffer memory, the select registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL) to select pipes to be allocated to a FIFO port, and the control registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR).

Each FIFO port provides the following features.

- Make accesses to the FIFO buffer for DCP through the CFIFO port.
- Make accesses to the FIFO buffer with DMA transfers through the DMAC module for USB high-speed only.
- When using a function specific to FIFO ports (DMA transfer function, etc.), the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed.
- Register groups of a FIFO port do not affect other FIFO ports.
- Do not allocate the same pipe number to different FIFO ports.
- There are two FIFO buffer states where the access mastership is on the CPU side and on the SIE side. When the FIFO buffer access mastership is on the SIE side, the CPU cannot make an access to the FIFO buffer.

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFOPORT [31:0]	All 0	R/W	<p>FIFO Port</p> <p>Read receive data from the FIFO buffer or write transmit data to the FIFO buffer using these bits.</p> <p>Access to this register is enabled only when the FRDY bit in each control register (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR) is set to 1.</p> <p>Valid bits in this register vary with the value of the MBW bits. Table 52.7 shows the valid bits in this register.</p>

**Table 52.7 Operation of This Register when Accessed**

Access Size	Bits 31 to 24	Bits 23 to 16	Bits 15 to 8	Bits 7 to 0
32 bits	N + 3 address	N + 2 address	N + 1 address	N + 0 address
16 bits	Write: Invalid, Read: Prohibited*		N + 1 address	N + 0 address
8 bits	Write: Invalid, Read: Prohibited*			N + 0 address

Note: \* Reading an invalid register with word access or byte access is prohibited.

### 52.2.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL, D3FIFOSEL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL select pipes to be allocated to FIFO ports and control accesses to each FIFO port.

Do not specify the same pipe number for the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL. When the CURPIPE bits in D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL are set to B'000, no pipe is specified.

Do not change any pipe number when DMA transfer is enabled.

This register is initialized by a power-on reset.

#### (1) CFIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Note: \* Only reading 0 is enabled.

### 52.2.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR, D3FIFOCTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CFIFOCTR and D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR specify buffer memory write end and CPU buffer clear, as well as indicate whether the FIFO port is accessible or not. These registers correspond to each FIFO port.

These registers are initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	BVAL	0	R/W*1	<p><b>Buffer Memory Enable Flag</b></p> <p>This flag is set to 1 upon completion of data write in the FIFO buffer of the CPU of the pipe selected by the CURPIPE bits.</p> <p>0: Invalid 1: Write end</p> <p>When the selected pipe is in the transmit direction, set this bit to 1 in the following cases. This module sets the FIFO buffer of the CPU to the SIE side to enable data transmission.</p> <p>To send a short packet, set this bit to 1 upon completion of data write.</p> <p>To send a Zero-Length packet, set this bit to 1 before writing data to the FIFO buffer.</p> <p>For pipes of continuous transfer mode, set this bit to 1 after writing data that is a positive integer multiple of MaxPacketSize and less than the BufferSize value.</p> <p>When data with the size specified by MaxPacketSize is written to a pipe of continuous transfer mode, this module writes 1 in this bit and sets the FIFO buffer of the CPU to the SIE side to enable data transmission.</p> <p>Set this bit to 1 when this module shows FRDY = 1.</p> <p>When the selected pipe is in the receive direction, do not set this bit to 1.</p>

Bit	Bit Name	Initial Value	R/W	Description
14	BCLR	0	R/W*2	<p>CPU buffer clear</p> <p>Clears the CPU side FIFO buffer of the selected pipe.</p> <p>0: Invalid</p> <p>1: Clears the CPU side FIFO buffer.</p> <p>When the FIFO buffer assigned to the selected pipe is set to a double buffer, and even when both sides of the buffer are readable, this module clears only one side of the FIFO buffer.</p> <p>When the selected pipe is DCP, this module clears the FIFO buffer when this bit is set to 1 irrespective of whether the FIFO buffer is on the CPU side or SIE side. When clearing the SIE side FIFO buffer, be sure to set the PID bits in DCP to NAK and then set the BCLR bit to 1.</p> <p>When the selected pipe is in the transmit direction, and if 1 is written in the BVAL and BCLR bits at the same time, this module clears the previously written data, and makes a Zero-Length packet transmittable.</p> <p>When the selected pipe is not DCP, write 1 in this bit while the FRDY flag indicates 1.</p>
13	FRDY	0	R	<p>FIFO Port Ready</p> <p>Indicates whether the CPU (DMAC) can access the FIFO port.</p> <p>0: The FIFO port is not accessible.</p> <p>1: The FIFO port is accessible.</p> <p>This module indicates FRDY = 1 in the following cases. However, since there is no data to read, no data can be read from the FIFO port. In these cases, set the BCLR bit to 1 to clear the FIFO buffer to make transmission/reception of the next data available.</p> <p>When a Zero-Length packet is received with the FIFO buffer assigned to the selected pipe empty</p> <p>When a short packet is received with BFRE set to 1 and the packet data is completely read</p>
12	—	0	R	<p>Reserved</p> <p>This bit is always read as 0. The write value should always be 0.</p>
11 to 0	DTLN[11:0]	H'000	R	<p>Receive Data Length</p> <p>Indicate the receive data length.</p> <p>The value of these bits during FIFO buffer reading varies as follows depending on the setting of the RCNT bit.</p> <p>When RCNT = 0:</p> <p>This module indicates the receive data length with these bits until the CPU (DMAC) finishes reading one side of the FIFO buffer.</p> <p>When BFRE is 1, this module retains the receive data length until the BCLR bit is set to 1 after the FIFO buffer read is completed.</p> <p>When RCNT = 1:</p> <p>This module decrements the value of the DTLN bits in each read cycle (-1 when MBW = 0, and -2 when MBW = 1)</p> <p>When reading out from a single FIFO buffer is complete, DTLN = 0 for this module. However, the behavior is different when double-buffering has been specified. If reading out of data from one side is not finished before the other side is full of received data, when all data have been read out from the first side, the DTLN bits reflect the amount of data received in the other side.</p> <p>When reading these bits during FIFO buffer reading while the RCNT bit is 1, note that this module updates the value in these bits within 150 ns after each FIFO port read cycle.</p>

- Notes:
1. Only writing 1 is enabled.
  2. Only reading 0 and writing 1 are enabled.

### 52.2.9 Interrupt Enable Register 0 (INTENB0)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

INTENB0 specifies masking of each interrupt when selection for function controller. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS0.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS0 is set to 1, this module generates a USB interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBSE	0	R/W	VBUS_0 and VBUSIN_0 Interrupt Enable Enables or disables USB interrupt outputs when the VBINT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	RSME	0	R/W	Resume Interrupt Enable Enables or disables USB interrupt outputs when the RESM interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	SOFE	0	R/W	Frame Number Update Interrupt Enable Enables or disables USB interrupt outputs when the SOFR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	DVSE	0	R/W	Device State Transition Interrupt Enable* Enables or disables USB interrupt outputs when the DVST interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	CTRE	0	R/W	Control Transfer Stage Transition Interrupt Enable* Enables or disables USB interrupt outputs when the CTRT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
10	BEMPE	0	R/W	<b>Buffer Empty Interrupt Enable</b> Enables or disables USB interrupt outputs when the BEMP interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	NRDYE	0	R/W	<b>Buffer Not Ready Response Interrupt Enable</b> Enables or disables USB interrupt outputs when the NRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	BRDYE	0	R/W	<b>Buffer Ready Interrupt Enable</b> Enables or disables USB interrupt outputs when the BRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	<b>Reserved</b> These bits are always read as 0. The write value should always be 0.

**52.2.10 BRDY Interrupt Enable Register (BRDYENB)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

BRDYENB enables or disables the BRDY bit to be set to 1 when the BRDY interrupt of a pipe is detected.

When this module detects the BRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBRDY bit of the pipe in BRDYSTS and also sets the BRDY bit in INTSTS0 and generates the BRDY interrupt.

When one or more PIPEBRDY bits in BRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BRDY interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**52.2.11 NRDY Interrupt Enable Register (NRDYENB)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

NRDYENB enables or disables the NRDY bit to be set to 1 when the NRDY interrupt of a pipe is detected.

When this module detects the NRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPENRDY bit of the pipe in NRDYSTS and also sets the NRDY bit in INTSTS0 and generates an NRDY interrupt.

When one or more PIPENRDY bits in NRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates an NRDY interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**52.2.12 BEMP Interrupt Enable Register (BEMPENB)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

BEMPENB enables or disables the BEMP bit to be set to 1 when the BEMP interrupt of a pipe is detected.

When this module detects the BEMP interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBEMP bit of the pipe in BEMPSTS and the BEMP bit in INTSTS0 and generates the BEMP interrupt.

When one or more PIPEBEMP bits in BEMPSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BEMP interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BEMPE	PIPEE BEMPE	PIPED BEMPE	PIPEC BEMPE	PIPEB BEMPE	PIPEA BEMPE	PIPE9 BEMPE	PIPE8 BEMPE	PIPE7 BEMPE	PIPE6 BEMPE	PIPE5 BEMPE	PIPE4 BEMPE	PIPE3 BEMPE	PIPE2 BEMPE	PIPE1 BEMPE	PIPE0 BEMPE

### 52.2.13 SOF Output Configuration Register (SOFCFG)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

SOFCFG specifies an effective period of transactions, the BRDY interrupt status clear timing, and others.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BRDY M	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	BRDYM	0	R/W	Status Clear Timing of Each Pipe BRDY Interrupt Specifies the timing to clear the BRDY interrupt status of each pipe. 0: The software clears the status. 1: This module clears the status by reading or writing the FIFO buffer.
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

### 52.2.14 Interrupt Status Register 0 (INTSTS0)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

INTSTS0 can know the interrupt generation by referring to the register when the function controller is selected.

Please permit interrupt by the status change that each bit of this register shows only when you select the function.

This register is initialized by a power-on reset. The DVSQ2 to DVSQ0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBINT	RESM	SOFR	DVST	CTRTR	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Initial value:	0	0	0	0/1	0	0	0	0	0/1	0	0	0/1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBINT	0	R/W*6	<p>VBUS_0 and VBUSIN_0 Interrupt Status*4*5</p> <p>0: No VBUS_0 and VBUSIN_0 interrupt is generated. 1: A VBUS_0 and VBUSIN_0 interrupt is generated.</p> <p>This bit indicates 1 when this module detects a change in the VBUS_0 and VBUSIN_0 pin input level (high to low or low to high level). This module indicates the VBUS_0 and VBUSIN_0 pin input value using the VBSTS bit. When a VBINT interrupt occurs, read the VBSTS bit several times by the software and confirm that the read value is equal each time to eliminate chattering.</p>
14	RESM	0	R/W*6	<p>Resume Interrupt Status*4*5</p> <p>0: No resume interrupt is generated. 1: A resume interrupt is generated.</p> <p>This bit indicates 1 when this module detects a falling of the DP_0 pin level in the suspended state (DVSQ = 1XX) with the function controller function selected.</p>
13	SOFR	0	R/W*6	<p>Frame Number Update Interrupt Status*4</p> <p>0: No SOF interrupt is generated. 1: An SOF interrupt is generated.</p> <p>This module indicates SOFR = 1 at the frame number update timing (This interrupt is detected every millisecond).</p> <p>Even when an SOF packet from the USB host is corrupted, this module detects an SOFR interrupt using the internal interpolation.</p>
12	DVST	0/1*1	R/W*6	<p>Device State Transition Interrupt Status*4</p> <p>0: No device state transition interrupt is generated. 1: A device state transition interrupt is generated.</p> <p>When this module detects a change in device state, this module updates the DVSQ value and set this bit to 1.</p> <p>When this interrupt occurred, clear the status before this module detects the next device state transition.</p>

Bit	Bit Name	Initial Value	R/W	Description
11	CTRT	0	R/W*6	<p>Control Transfer Stage Transition Interrupt Status*4</p> <p>0: No control transfer stage transition interrupt is generated. 1: A control transfer stage transition interrupt is generated.</p> <p>When this module detects a control transfer stage transition, this module updates the CTSQ value and set this bit to 1.</p> <p>When this interrupt occurred, clear the status before this module detects the next stage transition in control transfers.</p>
10	BEMP	0	R	<p>Buffer Empty Interrupt Status</p> <p>0: No BEMP interrupt is generated. 1: A BEMP interrupt is generated.</p> <p>This module indicates BEMP = 1 when at least one of the PIPEBEMP bits in BEMPSTS corresponding to the pipes for which 1 is set in the PIPEBEMPE bits in BEMPENB is set to 1 (when this module detects a BEMP interrupt of one or more pipes for which BEMP interrupts are enabled by the software).</p> <p>For PIPEBEMP status assertion conditions, see section 52.3.2 (3), BEMP Interrupt.</p> <p>When the software writes 0 to all PIPEBEMP bits corresponding to the pipes for which interrupts are enabled by the PIPEBEMPE bits, this module clears this bit to 0.</p> <p>This bit cannot be cleared to 0 by writing 0 by the software.</p>
9	NRDY	0	R	<p>Buffer Not Ready Interrupt Status</p> <p>0: No NRDY interrupt is generated. 1: An NRDY interrupt is generated.</p> <p>This module indicates NRDY = 1 when at least one of the PIPENRDY bits in NRDYSTS corresponding to the pipes for which 1 is set in the PIPENRDYE bits in NRDYENB is set to 1 (when this module detects an NRDY interrupt of one or more pipes for which NRDY interrupts are enabled by the software).</p> <p>For PIPENRDY status assertion conditions, see section 52.3.2 (2), NRDY Interrupt.</p> <p>When the software writes 0 to all PIPENRDY bits corresponding to the pipes for which interrupts are enabled by the PIPENRDYE bits, this module clears this bit to 0.</p> <p>This bit cannot be cleared to 0 by writing 0 by the software.</p>
8	BRDY	0	R	<p>Buffer Ready Interrupt Status</p> <p>Indicates the BRDY interrupt status.</p> <p>0: No BRDY interrupt is generated. 1: A BRDY interrupt is generated.</p> <p>This module indicates BRDY = 1 when at least one of the PIPEBRDY bits in BRDYSTS corresponding to the pipes for which 1 is set in the PIPEBRDYE bits in BRDYENB is set to 1 (when this module detects a BRDY interrupt of one or more pipes for which BRDY interrupts are enabled by the software).</p> <p>For PIPEBRDY status assertion conditions, see section 52.3.2 (1), BRDY Interrupt.</p> <p>When the software writes 0 to all PIPEBRDY bits corresponding to the pipes for which interrupts are enabled by the PIPEBRDYE bits, this module clears this bit to 0.</p> <p>This bit cannot be cleared to 0 by writing 0 by the software.</p>

Bit	Bit Name	Initial Value	R/W	Description
7	VBSTS	0/1* <sup>3</sup>	R	VBUS Input Status 0: The VBUS pin is low level. 1: The VBUS pin is high level.
6 to 4	DVSQ[2:0]	000/001* <sup>2</sup>	R	Device State 000: Powered state 001: Default state 010: Address state 011: Configuration state 1xx: Suspended state
3	VALID	0	R/W* <sup>6</sup>	USB Request Receive 0: Not detected 1: A setup packet is received.
2 to 0	CTSQ[2:0]	000	R	Control Transfer Stage 000: Idle stage or setup stage 001: Control read data stage 010: Control read status stage 011: Control write data stage 100: Control write status stage 101: Control write (NoData) status stage 110: Control transfer sequence error 111: Setting prohibited

- Notes:
1. The initial value is B'0 after a power-on reset, and B'1 after a USB bus reset.
  2. The initial value is B'000 after a power-on reset, and B'001 after a USB bus reset.
  3. The initial value is 1 when the VBUS pin is high level, and is 0 when the VBUS pin is low level.
  4. To clear the VBINT, RESM, SOFR, DVST, or CTRT bit, write 0 only to bits to be cleared and write 1 to the other bits. Do not write 0 to status bits that indicate 0.
  5. Only writing 0 is enabled.

**52.2.15 BRDY Interrupt Status Register (BRDYSTS)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

BRDYSTS indicates the BRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BRDY	PIPEE BRDY	PIPED BRDY	PIPEC BRDY	PIPEB BRDY	PIPEA BRDY	PIPE9 BRDY	PIPE8 BRDY	PIPE7 BRDY	PIPE6 BRDY	PIPE5 BRDY	PIPE4 BRDY	PIPE3 BRDY	PIPE2 BRDY	PIPE1 BRDY	PIPE0 BRDY

15	PIPEFNDRDY	0	R/W*	Pipe F NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEENRDY	0	R/W*	Pipe E NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDNRDY	0	R/W*	Pipe D NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECNRDY	0	R/W*	Pipe C NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBNRDY	0	R/W*	Pipe B NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEANRDY	0	R/W*	Pipe A NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9NRDY	0	R/W*	Pipe 9 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8NRDY	0	R/W*	Pipe 8 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7NRDY	0	R/W*	Pipe 7 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6NRDY	0	R/W*	Pipe 6 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
5	PIPE5NRDY	0	R/W*	Pipe 5 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4NRDY	0	R/W*	Pipe 4 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3NRDY	0	R/W*	Pipe 3 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2NRDY	0	R/W*	Pipe 2 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1NRDY	0	R/W*	Pipe 1 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0NRDY	0	R/W*	Pipe 0 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: \* To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

### 52.2.17 BEMP Interrupt Status Register (BEMPSTS)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

BEMPSTS indicates the BEMP interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BEMP	PIPEE BEMP	PIPED BEMP	PIPEC BEMP	PIPEB BEMP	PIPEA BEMP	PIPE9 BEMP	PIPE8 BEMP	PIPE7 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBEMP	0	R/W*	Pipe F BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBEMP	0	R/W*	Pipe E BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBEMP	0	R/W*	Pipe D BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBEMP	0	R/W*	Pipe C BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBEMP	0	R/W*	Pipe B BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABEMP	0	R/W*	Pipe A BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BEMP	0	R/W*	Pipe 9 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BEMP	0	R/W*	Pipe 8 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BEMP	0	R/W*	Pipe 7 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BEMP	0	R/W*	Pipe 6 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
5	PIPE5BEMP	0	R/W*	Pipe 5 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4BEMP	0	R/W*	Pipe 4 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BEMP	0	R/W*	Pipe 3 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BEMP	0	R/W*	Pipe 2 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BEMP	0	R/W*	Pipe 1 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BEMP	0	R/W*	Pipe 0 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: \* To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

### 52.2.18 Frame Number Register (FRMNUM)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

FRMNUM indicates the sources of isochronous errors and a frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRN	0	R/W*	<p>Overrun/Underrun Detect Status</p> <p>Indicates whether an overrun or underrun error is detected or not in a pipe that is performing isochronous transfer.</p> <p>0: No error is detected.</p> <p>1: An error is detected.</p> <p>Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register.</p> <p>This module indicates OVRN =1 in any of the following cases.</p> <p>When the IN token is received when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type</p> <p>When the OUT token is received with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type</p>
14	CRCE	0	R/W*	<p>Receive Data Error</p> <p>Indicates whether a CRC error or bit stuffing error is detected or not in a pipe that is performing isochronous transfer.</p> <p>0: No error is detected.</p> <p>1: An error is detected.</p> <p>Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register.</p> <p>When a CRC error is detected, this module does not generate an internal NRDY interrupt request.</p>
13 to 11	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
10 to 0	FRNM [10:0]	H'000	R	<p>Frame Number</p> <p>This module modifies this bit when an SOF is received and indicates the latest frame number.</p> <p>Read these bits twice and confirm that the read value is equal each time.</p>

Note: \* Only writing 0 is enabled.

**52.2.19  $\mu$  Frame Number Register (UFRMNUM)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

UFRMNUM indicates a  $\mu$  frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	UFRNM[2:0]	000	R	$\mu$ Frame Indicate a $\mu$ frame number. In high-speed operating mode, these bits indicate a $\mu$ frame number. In other operating modes, these bits indicate B'000. Read these bits twice and confirm that the read value is equal each time.

**52.2.20 USB Address Register (USBADDR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

USBADDR indicates a USB address.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	USBADDR[6:0]	H'00	R	USB Address Indicate the USB address allocated by the host when the SET_ADDRESS request is successfully processed. When this module detects a USB reset, these bits indicate H'00.

### 52.2.21 USB Request Type Register (USBREQ)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

USBREQ stores the setup request for control transfers.

USBREQ stores the values of received bRequest and bmRequestType.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	BREQUEST [7:0]	H'00	R	Request Store the value of USB request bRequest. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.
7 to 0	BMREQUEST TYPE[7:0]	H'00	R	Request Type Store the value of USB request bmRequestType. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.

### 52.2.22 USB Request Value Register (USBVAL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

USBVAL stores the value of received wValue.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WVALUE [15:0]	H'0000	R	Value Store the value of USB request wValue. Indicate the value of USB request wValue received in the SETUP transaction. These bits cannot be modified.

### 52.2.23 USB Request Index Register (USBINDX)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

USBINDX stores the setup request for control transfers.

USBINDX stores the value of received wIndex.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WINDEX [15:0]	H'0000	R	Index Store the value of USB request wIndex. Indicate the value of USB request wIndex received in the SETUP transaction. These bits cannot be modified.

### 52.2.24 USB Request Length Register (USBLENG)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

USBLENG stores the setup request of control transfers.

USBLENG stores the value of received wLength.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WLENGTH [15:0]	H'0000	R	Length Store the value of USB request wLength. Indicate the value of USB request wLength received in the SETUP transaction. These bits cannot be modified.

**52.2.25 DCP Maximum Packet Size Register (DCPMAXP)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

DCPMAXP specifies the maximum packet size of the DCP.

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	MXPS [6:0]	H'40	R/W	Maximum Packet Size Set the payload of DCP data (maximum DCP packet size) in these bits. The initial value of these bits is H'40 (64 bytes). Set a value in the MXPS bits based on the USB Specification. Set the MXPS bits when PID = NAK, and the CURPIPE bits are not set. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS bits are 0 or set the PID bits to BUF.

### 52.2.26 DCP Control Register (DCPCTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

DCPCTR is used to monitor the buffer memory status, change/check the data PID sequence bit, and set the response PID for a DCP.

This register is initialized by a power-on reset. The PID2 to PID0 bits in CCPL are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	—	—	—	—	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	<p>Buffer Status</p> <p>Indicates whether the DCP FIFO buffer is accessible or not.</p> <p>0: The buffer is not accessible.</p> <p>1: The buffer is accessible.</p> <p>This bit indicates as follows depending on the ISEL value.</p> <p>When ISEL = 0, this bit indicates whether the buffer is ready to read receive data.</p> <p>When ISEL = 1, this bit indicates whether the buffer is ready to write transmit data.</p>
14 to 9	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
8	SQCLR	0	R/W*	<p>Toggle Bit Clear</p> <p>The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA0.</p> <p>0: Invalid</p> <p>1: The expected value is set in DATA0.</p> <p>This bit always indicates 0.</p> <p>Do not set the SQCLR and SQSET bits to 1 at the same time.</p> <p>Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set.</p> <p>When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*	<p>Toggle Bit Set</p> <p>The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA1.</p> <p>0: Invalid</p> <p>1: The expected value is set in DATA1.</p> <p>Do not set the SQCLR and SQSET bits to 1 at the same time.</p> <p>Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set.</p> <p>When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>
6	SQMON	1	R	<p>Sequence Toggle Bit Monitor</p> <p>Indicates the expected value of the sequence toggle bit for the next transaction in DCP transfer.</p> <p>0: DATA0</p> <p>1: DATA1</p> <p>When the transaction is successfully completed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.</p> <p>When the function controller function is selected, this module sets this bit to 1 (sets the expected value in DATA1) when the setup packet is successfully received.</p> <p>When the function controller function is selected, this module does not read this bit in IN transactions or OUT transactions in the status stage.</p>
5	PBUSY	0	R	<p>Pipe Busy</p> <p>Indicates whether the DCP communication state is shifted to the NAK state or not when the DCP changed the PID bits from BUF to NAK.</p> <p>0: Transition to the NAC state is not completed.</p> <p>1: Transition to the NAC state is completed.</p> <p>When this module starts the USB transaction for the corresponding pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction.</p> <p>After the software sets PID = NAK, read this bit to check whether changing the pipe setting is enabled or not.</p>
4, 3	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
2	CCPL	0	R/W*	<p>Control Transfer End Enable</p> <p>0: Invalid</p> <p>1: The control transfer end is enabled.</p> <p>When the software sets this bit to 1 while the corresponding PID bits are set to BUF, this module finishes the control transfer stage.</p> <p>That is, this module sends an ACK handshake in response to OUT transactions from the USB host in the control read transfer, and sends a Zero-Length packet in response to IN transactions from the USB host in control write and no-data control transfers. However, a SET_ADDRESS request is detected, this module automatically sends responses from the SETUP stage until the end of the status stage irrespective of the setting of this bit.</p> <p>When this module receives the next setup packet, this module clears this bit to 0.</p> <p>When VALID = 1, the software cannot write 1 to this bit.</p>
1, 0	PID[1:0]	00	R/W	<p>Response PID</p> <p>Control responses of this module in control transfers.</p> <p>00: NAK response</p> <p>01: BUF response (depending on buffer state)</p> <p>10: STALL response</p> <p>11: STALL response</p> <p>This module modifies these bits in the following cases.</p> <p>This module changes these bits to NAK upon receiving a SETUP packet. At this time, this module indicates VALID = 1. The software cannot modify these bits until the software sets VALID = 0.</p> <p>When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11).</p> <p>When this module detects a control transfer sequence error, this module indicates PID = STALL (1x).</p> <p>When this module detects a USB bus reset, this module indicates PID = NAK.</p> <p>This module does not read the value of these bits during the SET_ADDRESS request processing (auto processing).</p>

Notes: \* These bits are always read as 0. Only writing 1 is enabled.

**52.2.27 Pipe Window Select Register (PIPESEL)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Make settings for pipes 1 to F using PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

Specify a pipe to be used with PIPESEL, and then make function settings for each pipe in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. The PIPEnCTR, PIPEnTRE, and PIPEnTRN registers can be set independently from pipe selection using PIPESEL.

Not only the selected pipe but also the corresponding bits in registers for all pipes are initialized by a power-on reset or USB bus reset.

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PIPESEL [3:0]	0000	R/W	Pipe Window Select Specify a pipe number corresponding to PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI to be read or written. 0000: No pipe is selected. 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A 1011: Pipe B 1100: Pipe C 1101: Pipe D 1110: Pipe E 1111: Pipe F PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI corresponding to the pipe number specified by these bits can be read and written. When these bits are set to B'0000, all bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI are read as 0 and cannot be modified.

### 52.2.28 Pipe Configuration Register (PIPECFG)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPECFG specifies the transfer type, buffer memory access direction, and endpoint number for pipes 1 to F, selects continuous transfer mode or discontinuous transfer mode, and single buffer or double buffer, and also specifies whether to disable the operation of each pipe when data transfer finishes.

This register is initialized by a power-on reset. The TYPE1 and TYPE0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TYPE[1:0]		—	—	—	BFRE	DBLB	CNTM D	SHTNA K	—	—	DIR	EPNUM[3:0]

### 52.2.29 Pipe Buffer Register (PIPEBUF)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPEBUF specifies the buffer size and buffer number for pipes 1 to F.

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 10	BUFSIZE [4:0]	H'00	R/W	<p>Buffer Size</p> <p>Specify the buffer size of the pipe specified by the PIPESEL bits (selected pipe) in units of blocks. One block is 64 bytes.</p> <p>00000 (H'00): 64 bytes</p> <p>00001 (H'01): 128 bytes</p> <p>:</p> <p>11111 (H'1F): 2 Kbytes</p> <p>When DBLB = 1 is set by the software, this module allocates the FIFO buffer size specified by these bits to the selected pipe for two sides.</p> <p>Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows:</p> $(BUFSIZE + 1) \times 64 \times (DBLB + 1) \text{ [bytes]}$ <p>A value that can be set in these bits varies depending on pipes selected.</p> <p>For pipes 1 to 5, 9 to F: Set BUFSIZE to H'00 to H'1F.</p> <p>For pipes 6 to 8: Set BUFSIZE to H'00.</p> <p>When using the buffer with CNTMD = 1, set a value in multiples of MaxPacketSize in these bits.</p> <p>Modify these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits.</p> <p>When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	BUFNMB [7:0]	H'00	R/W	<p>Buffer Number</p> <p>Specify the FIFO buffer number of the selected pipe with a value from H'04 to H'FF.</p> <p>When the selected pipe is either of pipes 1 to 5, 9 to F, these bits can be set to a value according to user systems. Set BUFNMB to H'06 to H'4F.</p> <p>BUFNMB = 0 to 3 are for DCP only.</p> <p>BUFNMB = 4 is for pipe 6 only.</p> <p>However, when pipe 6 is not used, this is available for other pipes.</p> <p>When pipe 6 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 4.</p> <p>BUFNMB = 5 is for pipe 7 only.</p> <p>However, when pipe 7 is not used, this is available for other pipes.</p> <p>When pipe 7 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 5.</p> <p>BUFNMB = 6 is for pipe 8 only.</p> <p>However, when pipe 8 is not used, this is available for other pipes.</p> <p>When pipe 8 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 6.</p> <p>Modify these bits when PID = NAK, and no pipe number is set in the CURPIPE bits.</p> <p>When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>

### 52.2.30 Pipe Maximum Packet Size Register (PIPEMAXP)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPEMAXP specifies the maximum packet size for pipes 1 to F.

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	MXPS[10:0]	*	R/W	Maximum Packet Size Specify the payload of data (maximum packet size) of the selected pipe. The settable value range for each pipe is as follows: Pipes 1 and 2: 1 byte (H'001) to 1024 bytes (H'400) Pipes 3 to 5, 9 to F: 8 (H'008), 16 (H'010), 32 (H'020), 64 (H'040), or 512 bytes (H'200) (MXPS2 to MXPS0 bits are not provided.) Pipes 6 to 8: 1 byte (H'001) to 64 bytes (H'040) Set a value in the MXPS bits based on the USB Specification for each transfer type. To transmit an isochronous pipe in split transactions, set a value of 188 bytes or less in the MXPS bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS = 0 or set the PID bits to BUF.

Note: \* The initial value is H'000 (when no pipe is selected by the PIPESEL bits in PIPESEL) or H'040 (when a pipe is selected).

### 52.2.31 Pipe Cycle Control Register (PIPEPERI)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPEPERI specifies whether to activate the buffer flush function or not at the time of an interval error during the isochronous IN transfer, and also specifies the interval error detection interval for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	IFIS	0	R/W	<p>Isochronous IN Buffer Flush</p> <p>Specifies whether to flush the FIFO buffer when the pipe specified by the PIPESEL bits (selected pipe) is isochronous IN transfer type.</p> <p>0: The FIFO buffer is not flushed. 1: The FIFO buffer is flushed.</p> <p>Buffer flush is a function that this module automatically clears the FIFO buffer when this module does not receive IN-Token from the USB host in a (<math>\mu</math>) frame for each interval specified in the IITV bits when the function controller function is selected and the selected pipe is isochronous IN transfer type.</p> <p>When double buffer is selected (DBLB = 1), this module clears data of only the older side.</p> <p>The FIFO buffer is cleared when an SOF packet is received immediately after the (<math>\mu</math>) frame where IN-Token is to be received. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time when the SOF packet is to be received using the internal interpolation.</p> <p>When the selected pipe is not isochronous transfer type, set this bit to 0.</p>
11 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	IITV[2:0]	000	R/W	<p>Interval Error Detection Interval</p> <p>Specify the interval error detection interval of the selected pipe with a value of 2's n-th power of the frame timing.</p> <p>Set these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits.</p> <p>When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p> <p>To change the setting of these bits after USB communication, set PID = NAK and then set ACLRM = 1 to initialize the interval timer.</p> <p>These bits are not provided for pipes 3 to F. Set B'000 in the position of these bits corresponding to pipes 3 to F.</p>

### 52.2.32 Pipe n Control Register (PIPEnCTR) (n = 1 to F)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPEnCTR monitors the buffer memory status, changes/checks the data PID sequence bits, selects whether to use auto-response mode and buffer auto-clear mode, and specifies a response PID for pipes 1 to F. This register can be set independently of the pipe selection using PIPESEL.

This register is initialized by a power-on reset. The PID1 and PID0 bits are also initialized by a USB bus reset.

#### (1) PIPEnCTR (n = 1 to 5, 9 to F)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	<b>Buffer Status</b> Indicates the FIFO buffer status of the pipe. 0: The buffer is not accessible from the CPU. 1: The buffer is accessible from the CPU. The meaning of this bit differs depending on the settings of the DIR, BFRE, and DCLRM bits as shown in Table 52.8.
14	INBUFM	0	R	<b>Transmit Buffer Monitor</b> Indicates the FIFO buffer status of the selected pipe in the transmit direction. 0: The buffer memory contains no transmittable data. 1: The buffer memory contains transmittable data. When transmit direction (DIR = 1) is set for the pipe, this module sets this bit to 1 when the software (or DMAC) finishes writing data to the FIFO buffer for at least one register set. When this module finishes sending all data on the register set (writing is completed) of the FIFO buffer, this bit indicates 0. In the case of a double buffer (DBLB = 1), when this module finishes sending all data on both register sets and the software (or DMAC) has not completed writing of data for one register set, this bit indicates 0. When receive direction (DIR = 0) is set for the selected pipe, this bit indicates the same value as the BSTS bit.
13 to 11	—	All 0	R	<b>Reserved</b> These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ATREPM	0	R/W	<p><b>Auto-Response Mode</b></p> <p>Enables or disables auto-response for the selected pipe.</p> <p>0: Auto-response is disabled.</p> <p>1: Auto-response is enabled.</p> <p>When the transfer type of the selected pipe is set to bulk transfer, this bit can be set to 1.</p> <p>When this bit is 1, this module sends responses to tokens from the USB host as follows:</p> <p>(1) When the selected pipe is set for Bulk-IN transfer (TYPE = B'01 and DIR = 1)</p> <p>When ATREPM = 1 and PID = BUF, this module sends a Zero-Length packet in response to the IN-Token.</p> <p>Each time this module receives ACK from the USB host (flow of one transaction: receiving IN-Token -&gt; sending Zero Length packet -&gt; receiving ACK), this module updates the sequence toggle bit (DATA-PID) by toggling it.</p> <p>No BRDY interrupt or BEMP interrupt is generated.</p> <p>(2) When the selected pipe is set for Bulk-OUT transfer (TYPE = B'01 and DIR = 0)</p> <p>When ATREPM = 1 and PID = BUF, this module sends NAK in response to the OUT-Token (or PING-Token) and generates an NRDY interrupt.</p> <p>Modify this bit when PID = NAK.</p> <p>When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p> <p>Be sure to set this bit to 1 for USB communication when the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1.</p> <p>When the selected pipe is set for isochronous transfer, be sure to set this bit to 0.</p>
9	ACLRM	0	R/W	<p><b>Buffer Auto-Clear Mode</b></p> <p>Enables or disables buffer auto-clear mode for the selected pipe.</p> <p>0: Buffer auto-clear mode is disabled.</p> <p>1: Buffer auto-clear mode is enabled. (All buffers are initialized.)</p> <p>To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit.</p> <p>Table 52.9 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared.</p> <p>Modify this bit when PID = NAK.</p> <p>When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>

Bit	Bit Name	Initial Value	R/W	Description
8	SQCLR	0	R/W*	<p>Toggle Bit Clear</p> <p>Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe.</p> <p>0: Invalid</p> <p>1: The expected value is cleared in DATA0.</p> <p>When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0.</p> <p>Set the SQCLR bit to 1 when PID = NAK.</p> <p>When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>
7	SQSET	0	R/W*	<p>Toggle Bit Set</p> <p>Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe.</p> <p>0: Invalid</p> <p>1: The expected value is set in DATA1.</p> <p>When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA1. This module always indicates SQSET = 0.</p> <p>Set the SQSET bit to 1 when PID = NAK.</p> <p>When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>
6	SQMON	0	R	<p>Toggle Bit Check</p> <p>Indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.</p> <p>0: DATA0</p> <p>1: DATA1</p> <p>If the pipe is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.</p>
5	PBUSY	0	R	<p>Pipe Busy</p> <p>Indicates whether the pipe is currently used in the USB bus or not.</p> <p>0: The selected pipe is not used in the USB bus.</p> <p>1: The selected pipe is being used in the USB bus.</p> <p>When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction.</p> <p>After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.</p>
4 to 2	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	<p>Response PID</p> <p>Specify a response used in the next transaction for the selected pipe.</p> <p>00: NAK response</p> <p>01: BUF response (depending on buffer state)</p> <p>10: STALL response</p> <p>11: STALL response</p> <p>These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Table 52.10 shows the basic operation (with no error in packets) of this module in each setting of the PID bits.</p> <p>When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the pipe entered the NAK state. However, when this module changed these bits to NAK, the software does not have to check the PBUSY bit.</p> <p>This module modifies these bits in the following cases.</p> <ul style="list-style-type: none"> <li>When the pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end.</li> <li>When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11).</li> <li>When this module detects a USB bus reset, this module indicates PID = NAK.</li> </ul> <p>Set these bits as follows:</p> <ul style="list-style-type: none"> <li>To change the state from NAK (00) to STALL, write B'10.</li> <li>To change the state from BUF (01) to STALL, write B'11.</li> <li>To change the state from STALL (11) to NAK, write B'10 then B'00.</li> <li>To change the state from STALL to BUF, set these bits to NAK and then to BUF.</li> </ul>

Notes: \* Only reading 0 and writing 1 are enabled.

**Table 52.8 Operations of BSTS Bit**

DIR Bit	BFRE Bit	DCLRM Bit	Meaning of BSTS Bit
0	0	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
		1	Setting prohibited
	1	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 when the software sets BCLR = 1 after the buffer data read.
		1	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
1	0	0	Indicates 1 when the FIFO buffer becomes ready to write transmit data to the buffer, and indicates 0 upon completion of the data write.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

**Table 52.9 Data Cleared by This Module when ACLRM = 1**

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer (both sides for double FIFO buffer) allocated to the pipe	
2	Interval count value when the pipe is isochronous transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	FIFO buffer toggle control	When changing the DBLB setting
5	Internal flags related to the transaction count	When forcibly terminating the transaction count function

**Table 52.10 Operations of This Module in Each Setting of PID Bits**

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
B'00 (NAK)	Bulk or interrupt	Independent of the setting	Sends a NAK response to a token from the USB host.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.
B'01 (BUF)	Bulk	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response.  Sends an ACK response to the PING token from the USB host when the FIFO buffer for the selected pipe is ready to receive. Otherwise, sends a NYET response.
		Interrupt	Receive direction (DIR = 0)
	Bulk or interrupt	Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a NAK response.
		Isochronous	Receive direction (DIR = 0)
	Transmit direction (DIR = 1)		Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a Zero-Length packet.
B'10 (STALL) or	Bulk or interrupt	Independent of the setting	Sends a STALL response to a token from the USB host.
B'11 (STALL)	Isochronous	Independent of the setting	Sends no response to a token from the USB host.

However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*1	<p>Toggle Bit Set*2*3</p> <p>Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe.</p> <p>0: Invalid</p> <p>1: The expected value is set in DATA1.</p> <p>When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the selected pipe in DATA1. This module always indicates SQSET = 0.</p> <p>Set the SQSET bit to 1 when PID = NAK.</p> <p>When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.</p>
6	SQMON	0	R	<p>Toggle Bit Check</p> <p>Indicates the expected value of the sequence toggle bit for the next transaction of the pipe.</p> <p>0: DATA0</p> <p>1: DATA1</p> <p>If the selected pipe that is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.</p>
5	PBUSY	0	R	<p>Pipe Busy</p> <p>Indicates whether the selected pipe is currently used in the USB bus or not.</p> <p>0: The selected pipe is not used in the USB bus.</p> <p>1: The selected pipe is being used in the USB bus.</p> <p>When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction.</p> <p>After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.</p>
4 to 2	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	<p>Response PID</p> <p>Specify a response used in the next transaction for the selected pipe.</p> <p>00: NAK response</p> <p>01: BUF response (depending on buffer state)</p> <p>10: STALL response</p> <p>11: STALL response</p> <p>These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Table 52.10 shows the basic operation (with no error in packets) of this module in each setting of the PID bits.</p> <p>When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the selected pipe entered the NAK state. However, when this module changed these bits to NAK, the software needs not check the PBUSY bit.</p> <p>This module modifies these bits in the following cases.</p> <ul style="list-style-type: none"> <li>• When the selected pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end.</li> <li>• When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11).</li> <li>• When this module detects a USB bus reset, this module indicates PID = NAK.</li> </ul> <p>Set these bits as follows:</p> <ul style="list-style-type: none"> <li>• To change the state from NAK (00) to STALL, write B'10.</li> <li>• To change the state from BUF (01) to STALL, write B'11.</li> <li>• To change the state from STALL (11) to NAK, write B'10 then B'00.</li> <li>• To change the state from STALL to BUF, set these bits to NAK and then to BUF.</li> </ul>

- Notes:
1. Only reading 0 and writing 1 are enabled.
  2. Set the ACLRM, SQCLR, or SQSET bit when PID = NAK, and the selected pipe is not set in the CURPIPE bits.
  3. When setting the ACLRM, SQCLR, or SQSET bit after changing the PID bits from BUF to NAK, check that PBUSY = 0 for the pipe. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

**Table 52.11 Data Cleared by This Module when ACLRM = 1**

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer allocated to the selected pipe	
2	Not Support	
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	Internal flags related to the transaction count	When forcibly terminating the transaction count function

### 52.2.33 Pipe n Transaction Counter Enable Register (PIPnTRE) (n = 1 to 5, 9 to F)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPnTRE enables or disables the transaction counter function and clears the counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	TRENB	0	R/W	Transaction Counter Enable Enables or disables the transaction counter function. 0: The transaction counter function is disabled. 1: The transaction counter function is enabled. When the software sets the number of total packets in the TRNCNT bits in PIPEnTRN for the receive pipe and then sets this bit to 1, this module controls the following when it received the same number of packets as the setting of the TRNCNT bits. When continuous communication mode is used (CNTMD = 1), this module toggles the received data to the CPU even if the FIFO buffer is not full at the end of reception. When SHTNAK = 1, this module changes the PID bits for the corresponding pipe to NAK when this module received the same number of packets as the setting of the TRNCNT bits. When BFRE = 1, this module asserts the BRDY interrupt when this module received the same number of packets as the setting of the TRNCNT bits and read the receive data completely. For transmit pipes, set this bit to 0. When the transaction counter function is not used, set this bit to 0. When using the transaction counter function, set the TRNCNT bits and then set this bit to 1. Furthermore, set this bit to 1 before receiving the first packet that is included in the transaction count range.
8	TRCLR	0	R/W	Transaction Counter Clear Clears the current count value of the transaction counter for the pipe and indicates TRCLR = 0. 0: Invalid 1: The current count value is cleared.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Change the bits in this register when CSSTS = 0 and PID = NAK.

When changing the bits in this register after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

### 52.2.34 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5, 9 to F)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

PIPEnTRE is a transaction counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset, but the setting of this register is retained through a USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description

## 52.3 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 52.3.1 System Control and Oscillation Control

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

#### (1) Power control and Initialization

The following is the initialize power on procedure of USB subsystem.

1. Turn on the power domain of HS-USB
2. Supply 1.8 V (VD181)
3. Supply 3.3 V (VD331) (Note: Do not supply 3.3 V when 1.8 V is not supplied.)
4. Wait 100  $\mu$ s for USB PHY power stable.
5. Power Isolation control disable
6. HS-USB and EHCI module stop release and module reset assert.
7. PLLRESET release
8. LPSTS.SUSPM set to normal mode.
9. Check PLL Lock status by USB General status register
10. Starting normal operation after PLL Lock status enabled.
11. UGCTRL.CONNECT bit set to 1

The following is the power off procedure of USB subsystem

1. Normal operation finished
2. UGCTRL.CONNECT bit set to 0
3. PLL disable by PLLRESET assert
4. Power Isolation control enable
5. Shut off 3.3V (VD331)
6. Shut off 1.8V (VD181) (Note: Do not shut off 1.8 V while 3.3 V is being supplied.)
7. Module stop enable and shut off power domain of HS-USB if needed.

#### (2) Enabling High-Speed Operation

This module can set the USB transmission rate (communication bit rate) by the software.

When the function controller function is selected, high-speed operation or full-speed operation is selectable. To enable high-speed operation with this module, set the HSE bit in SYSCFG to 1. When high-speed operation is enabled, this module executes the reset handshake protocol and automatically sets the USB transmission rate. The reset handshake result can be checked by the RHST bits in DVSTCTR.

When high-speed operation is disabled, this module operates only in full speed when the function controller function is selected.

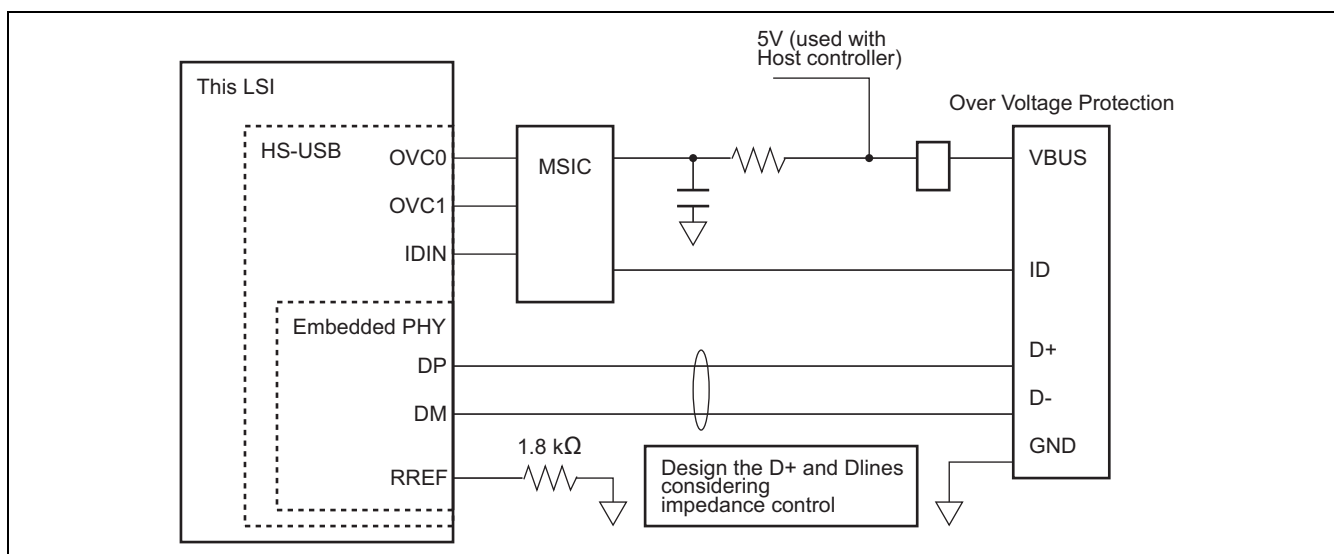

### (3) USB Data Bus Resistor Control

Figure 52.1 shows the connection between this module and the USB connector.

This module incorporates a pull-up resistor of the D+ signal. Specify pull-up using the DPRPU bits in SYSCFG.

Furthermore, this module controls the terminating resistors of the D+ and D- signals in high-speed operation, and the output resistors in full-speed operation. This module automatically switches the on-chip resistors after connection to the host controller detecting a reset handshake, suspended state, or resume.

When the DPRPU bit in SYSCFG is set to 0 during communication with the host controller, this module disables the pull-up resistors (or terminating resistors) of the USB data line. Therefore, the USB host can be notified of a disconnection from the device.

**Figure 52.1 Connection to the USB Connector**

### (4) Software reset when the USB disconnection is detected

Issue a software reset of the USBHS module when the USB disconnection is detected. If the DMA interface is being used, issue a software reset of the USB-DMAC module as well. A software reset can be issued via a register in the CPG

Whether or not the USB disconnection is detected can be determined by the VBSTS in the INTSTS0 register when the function controller function is selected.

Note: USB-PHY might become inoperable to use by the instantaneous interruption of VBUS. As a result S/W on the LSI side (driver) becomes a state of the connection, and USB-PHY becomes a state of power cutoff. It's possible to cancel this state by putting the next way into effect by software.

- 1) When detecting a bus reset or cutoff of VBUS, please refer to the state bit of USB - PHY (USB\_OFF bit of USB\_CR2 register in GPIO) and in case of USB\_OFF=1, set USB\_START bit.
- 2) When 1) is performed and USB - PHY is started, USB\_PHY\_ON interrupt occurs, so please perform a soft reset to USBHS,USB-DMAC and do the setting by which USBHS,USB-DMAC is initialization and DP pull up --, etc. by this timing.

### 52.3.2 Interrupt Function

Table 52.12 lists the interrupt generating conditions of this module.

When any of the following interrupt generating conditions are satisfied and the interrupt output is enabled by the corresponding interrupt enable register, this module outputs a USB interrupt request to the interrupt controller (INTC).

**Table 52.12 Interrupt Generating Conditions**

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
VBINT	VBUS interrupt	When VBUS input pin state change is detected (both L to H and H to L)		VBSTS
RESM	Resume interrupt	When a USB bus state change is detected in the suspended state (J-State to K-State or J-State to SE0)		—
SOFR	Frame number update interrupt	SOFRM = 0: When an SOF packet with a different frame number is received SOFRM = 1: When an SOF packet with a $\mu$ frame number of 0 cannot be received due to damage, etc.		—
DVST	Device state transition interrupt	When a device state transition is detected USB bus reset detected Suspended state detected SET_ADDRESS request received SET_CONFIGURATION request received		DVSQ
CTRT	Control transfer stage transition interrupt	When a control transfer stage transition is detected Setup stage completed Control write transfer status stage shifted Control read transfer status stage shifted Control transfer completed Control transfer sequence error occurred		CTSQ
BEMP	Buffer empty interrupt	When the buffer becomes empty after sending all buffer memory data When a packet with a size exceeding the maximum packet size is received		BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	When NAK is sent in response to IN token, OUT token, or PING token When a CRC error or bit stuffing error occurred during data reception in isochronous transfer When an overrun or underrun error occurred during data reception in isochronous transfer		NRDYSTS.PIPENRDY
BRDY	Buffer ready interrupt	When the buffer becomes ready for reading or writing		BRDYSTS.PIPEBRDY
OVRRCR	OVRRCR interrupt	When an OVC input pin state change is detected		OVCMON

Note: These bits in this table are those of INTSTS0 if any register's name is not indicated.

Figure 52.2 shows a block diagram of the interrupt circuit of this module.

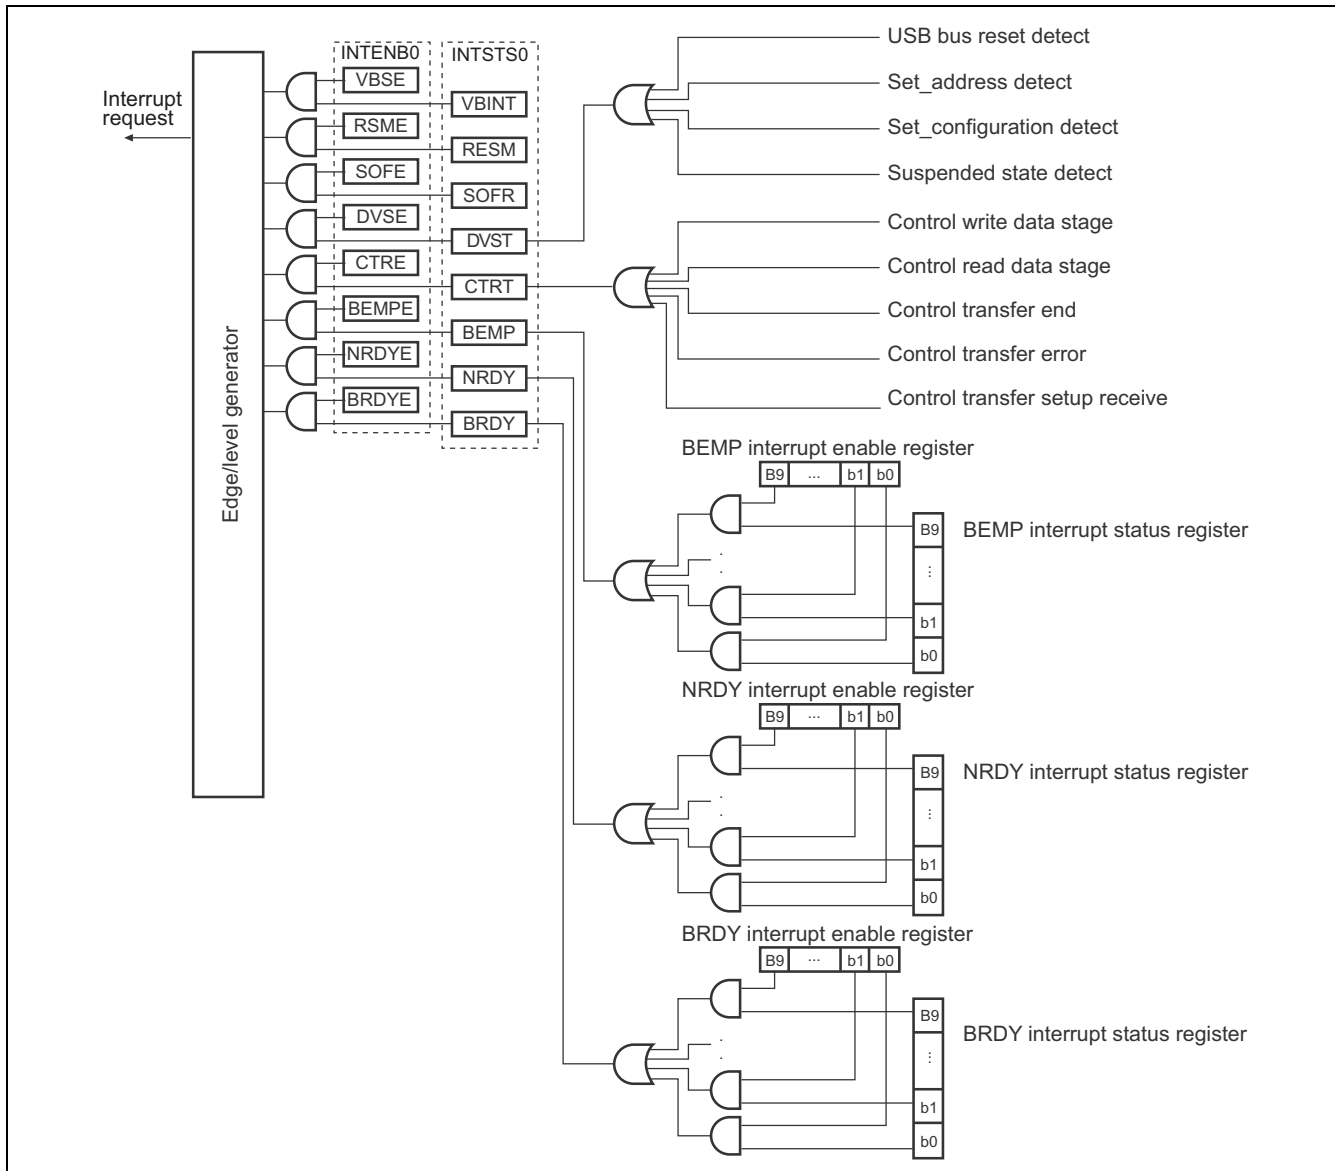

Figure 52.2 Block Diagram of Interrupt Circuit

**(1) BRDY Interrupt**

A BRDY interrupt can be generated when the following conditions in each pipe are satisfied, this module sets the corresponding bit in BRDYSTS to 1. At this time, when the PIPEBRDYE bit for the pipe in BRDYENB is set to 1 and the BRDYE bit in INTENB0 is set to 1 by the software, this module generates a BRDY interrupt.

BRDY interrupt generating conditions and clearing method depend on the settings of the BRDYM bit and the BFRE bit for each pipe.

**(a) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified**

With this setting, a BRDY interrupt indicates that the FIFO port is accessible.

This module generates an internal BRDY interrupt request trigger when the following conditions are satisfied, and sets the PIPEBRDY bit corresponding to the request trigger pipe to 1.

## 1. Pipes set for the transmit direction

- When the software changes the DIR bit from 0 to 1
- When this module finishes sending a packet of the pipe while data write from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
- When continuous communication mode is selected, this module generates a BRDY interrupt request trigger upon completion of sending data for one side of the FIFO buffer.
- When a double FIFO buffer is specified and one side of the FIFO buffer is empty when data write to the other side of the FIFO buffer is completed.  
Even if one side of the FIFO buffer becomes empty while the other side is in data write processing, no BRDY interrupt is generated until the ongoing data write finishes.
- When this module generates a buffer flush for a pipe of isochronous transfer type
- When the FIFO buffer becomes write enable state by writing 1 to the ACLRM bit

No BRDY interrupt request trigger is generated for the DCP (in data transmission of control transfer).

## 2. Pipes set for the receive direction

- When this module receives a packet successfully and the FIFO buffer becomes ready for reading while data read access from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
- No BRDY interrupt request trigger is generated in transactions with incorrect data PID.
- When continuous communication mode is selected, no BRDY interrupt request trigger is generated for packets with a MaxPacketSize data size and when the FIFO buffer still has available space.
- When this module receives a short packet, this module generates a BRDY interrupt request trigger even if the buffer has available space.
- When a transaction counter is used, this module generates a BRDY interrupt request trigger when this module receives a packet with a size of the set value even if the FIFO buffer still has available space.
- When a double FIFO buffer is specified and one side of the FIFO buffer is ready for reading when data read from the other side of the FIFO buffer is completed  
Even if data read for one side of the FIFO buffer is completed while the other side is undergoing data read, no BRDY interrupt request trigger is generated until the ongoing data read finishes.

This interrupt is not generated in communication in the control transfer status stage.

The software can clear the PIPEBRDY interrupt status of the pipe by writing 0 to the PIPEBRDY bit for the pipe in BRDYSTS. At this time, write 1 to the bits corresponding to other pipes.

Be sure to clear the BRDY interrupt status before accessing the FIFO buffer.

**(b) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 1) at the end of data read are specified**

With this setting, this module determines that a BRDY interrupt is generated upon completion of reading all data of one transfer in a receive pipe, and sets the bit for the pipe in this register to 1.

This module determines that the last data of a transfer was received in either of the following cases.

- A Zero-Length packet or another short packet is received.
- A transaction counter (TRNCNT bits) is used and a packet with a size of the value of the TRNCNT bits is received.

When either of these conditions is satisfied and the data read is completed, this module determines that reading all data for one transfer is completed.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module determines that reading all data for one transfer is completed when the Zero-Length packet data is toggled to the CPU. In this case, write 1 to the BCLR bit in the corresponding FIFOCTR register by the software to start the next transfer.

With this setting, this module generates no BRDY interrupt for transmit pipes.

The software can clear the PIPEBRDY interrupt status of the pipe to 0 by writing 0 to the PIPEBRDY bit for the pipe. At this time, write 1 to the bits corresponding to other pipes.

When using this mode, do not change the BFRE setting until the processing for one transfer is completed.

To change the BFRE bit during processing, clear all FIFO buffers for the pipe by the ACLRM bit.

**(c) When BRDY interrupt enable (BRDYM = 1) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified**

With this setting, the value of the PIPEBRDY bit varies with the value of the BSTS bit for each pipe. That is, this module indicates 1 or 0 of the BRDY interrupt status according to the FIFO buffer status.

1. Pipes set for the transmit direction

When the FIFO port is ready to write data, the PIPEBRDY bit indicates 1. When the FIFO port is not ready to write data, the PIPEBRDY bit indicates 0.

However, even if the transmit pipe of the DCP is ready to write data, no BRDY interrupt is asserted.

2. Pipes set for the receive direction

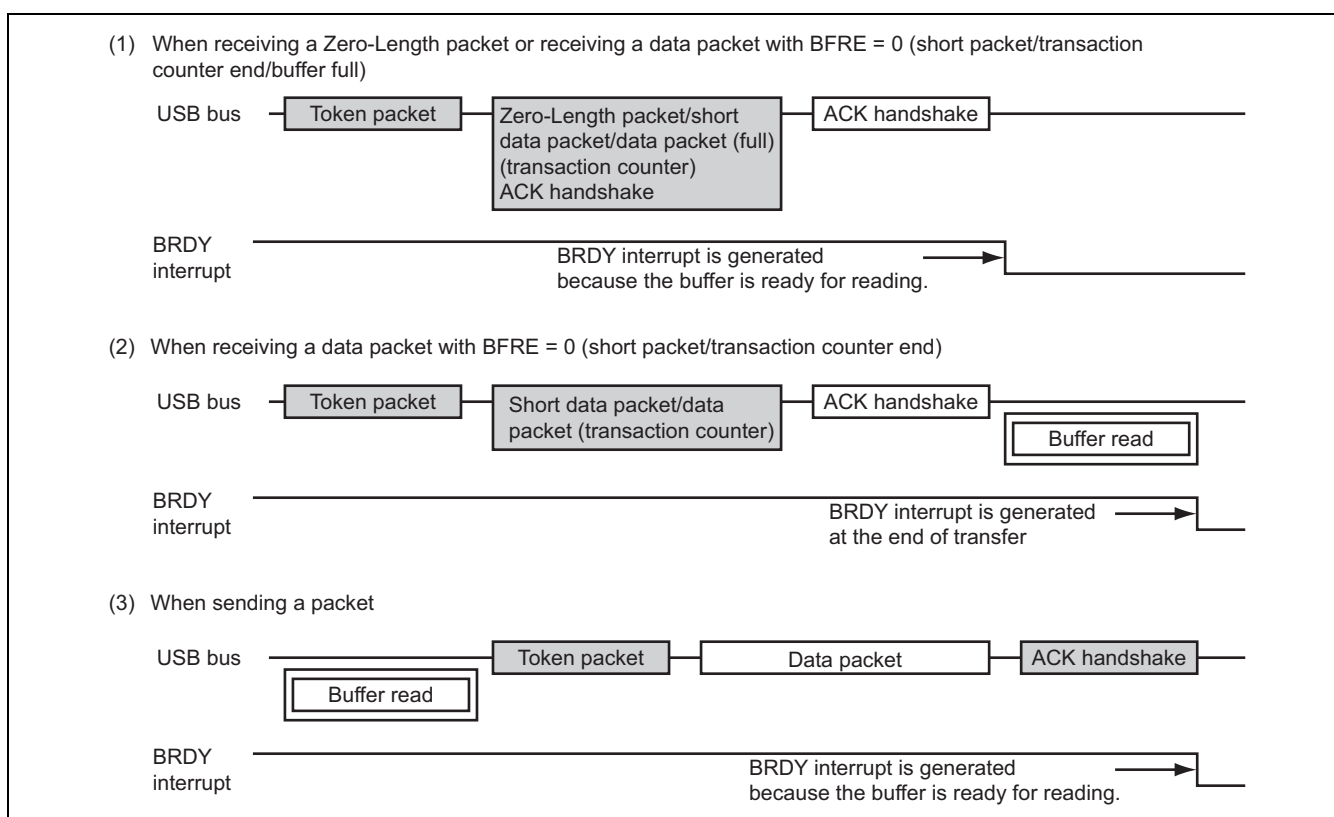

When the FIFO port is ready to read data, the PIPEBRDY bit indicates 1. When all data is read from the FIFO port (reading disabled), the PIPEBRDY bit indicates 0.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module indicates 1 with the corresponding bit until 1 is written to BCLR by the software, and continues to assert the BRDY interrupt.

With this setting, the software cannot clear the PIPEBRDY bit to 0.

When BRDYM = 1, set the BFRE bit to 0 for all pipes.

Figure 52.3 shows the BRDY interrupt generation timing.

**Figure 52.3 BRDY Interrupt Generation Timing**

## (2) NRDY Interrupt

When this module generates an internal NRDY interrupt request for the pipe in which PID = BUF is set by the software, this module indicates PIPENRDY = 1 for the pipe in NRDYSTS. At this time, when 1 is set in the corresponding bit in NRDYENB by the software, this module indicates NRDY = 1 in INTSTS0 and generates a USB interrupt.

The following shows the conditions for this module to generate an internal NRDY interrupt request for a pipe.

Furthermore, when executing the control transfer status stage, this module generates no interrupt request.

### 1. Pipes in the transmit direction

— When this module receives an IN token with no transmit data in the FIFO buffer

This module generates an NRDY interrupt request and indicates PIPENRDY = 1.

— When the pipe in which the interrupt is generated is isochronous transfer type, this module sends a Zero-Length packet and indicates OVRN = 1.

### 2. Pipes in the receive direction pipe

— When this module receives an OUT token with the FIFO buffer occupied

— When the pipe in which the interrupt is generated is isochronous transfer type, this module generates an NRDY interrupt request when this module receives an OUT token, and indicates PIPENRDY = 1 and OVRN = 1.

— When the pipe in which the interrupt is generated is not isochronous transfer type, this module generates an NRDY interrupt request when this module sends an NAK handshake response after receiving data following the OUT token, and indicates PIPENRDY = 1.

However, this module generates no NRDY interrupt when resending data (in the case of DATA-PID mismatch) or when an error occurs in a data packet.

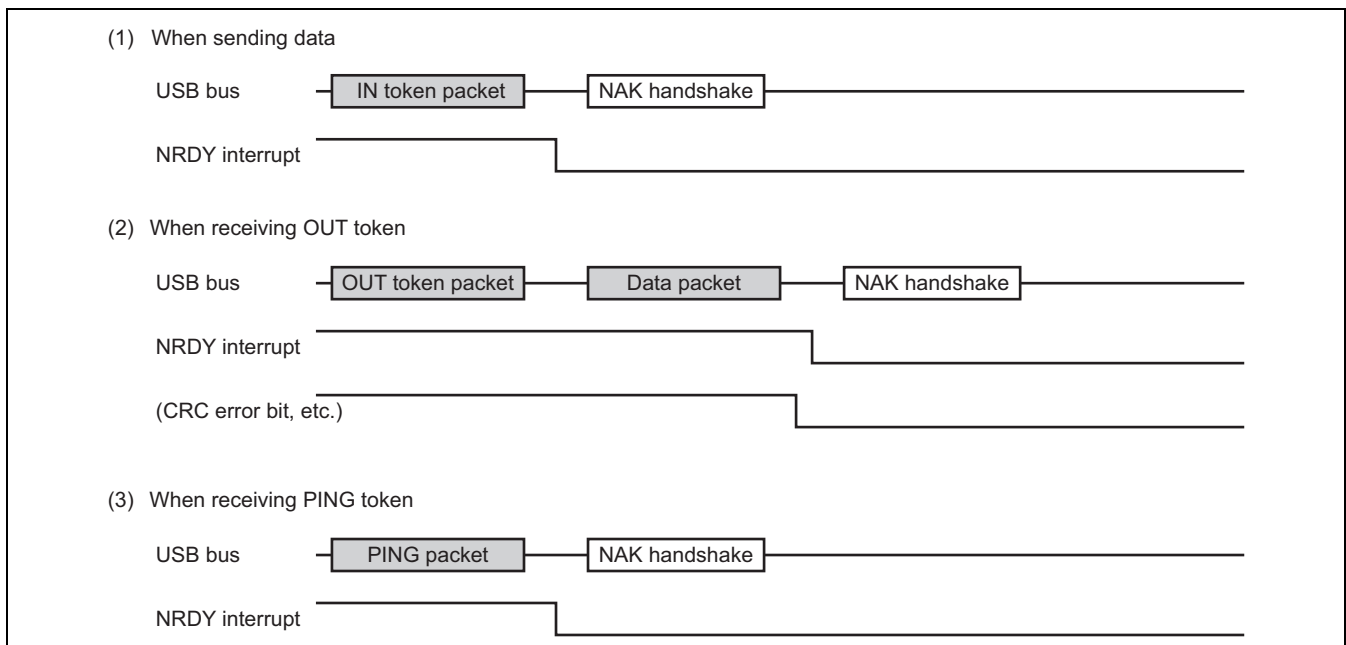

— When this module receives a PING token with the FIFO buffer occupied

This module generates an NRDY interrupt request when this module receives a PING token and indicates PIPENRDY = 1.

— When a packet is not received correctly within the interval frame in an isochronous transfer-type pipe

This module generates an NRDY interrupt request when this module receives SOF and indicates PIPENRDY = 1.

Figure 52.4 shows the NRDY interrupt generation timing when the function controller function is selected.

**Figure 52.4 NRDY Interrupt Generation Timing when the Function Controller Function is Selected**

### (3) BEMP Interrupt

When this module detects a BEMP interrupt for the pipe in which PID = BUF is set by the software, this module indicates PIPEBEMP = 1 for the pipe in BEMPSTS. At this time, when 1 is set in the corresponding bit in BEMPENB by the software, this module indicates BEMP = 1 in INTSTS0 and generates a USB interrupt.

This module generates an internal BEMP interrupt request in the following cases.

#### 1. Transmit direction pipes

- When the FIFO buffer for the pipe is empty at the end of transmission (including transmission of a Zero-Length packet)
- When single buffer is set for the FIFO buffer, this module generates an internal BEMP interrupt request concurrently with a BRDY interrupt for pipes other than DCP.

However, this module generates no internal BEMP interrupt request in the following cases.

- In the case of double buffer, when the software (DMAC) already started writing data to the FIFO buffer of the CPU at the end of transmission for one-side data
- When the buffer is cleared (empty) by writing 1 to the ACLRM or BCLR bit.
- When sending a Zero-Length packet (IN transfer) of the control transfer status stage

#### 2. Receive direction pipes

- When this module receives a packet with a data size exceeding the MaxPacketSize value
- In this case, this module generates a BEMP interrupt request and indicates the PIPEBEMP = 1 for the pipe, ignores the received data, and changes the PID bits for the pipe to STALL (11).

At this time, this module sends a STALL response.

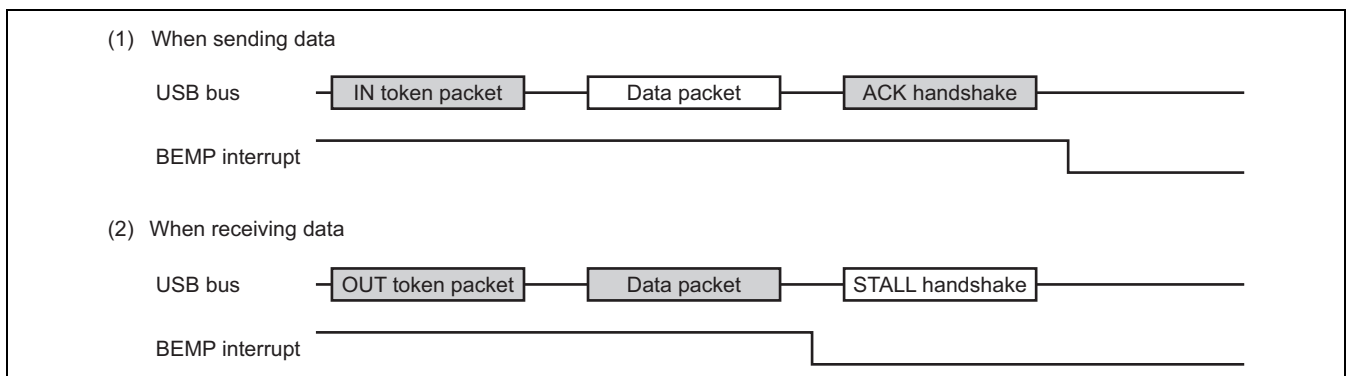

However, this module generates no BEMP interrupt request in the following cases.

- When this module detects a CRC error or bit stuffing error in the receive data
- When executing the SETUP transaction

Writing 0 to the PIPEBEMP bits clears the status.

Writing 0 to the PIPEBEMP bits has no effect on the operation of this module.

Figure 52.5 shows the BEMP interrupt generation timing when the function controller function is selected.

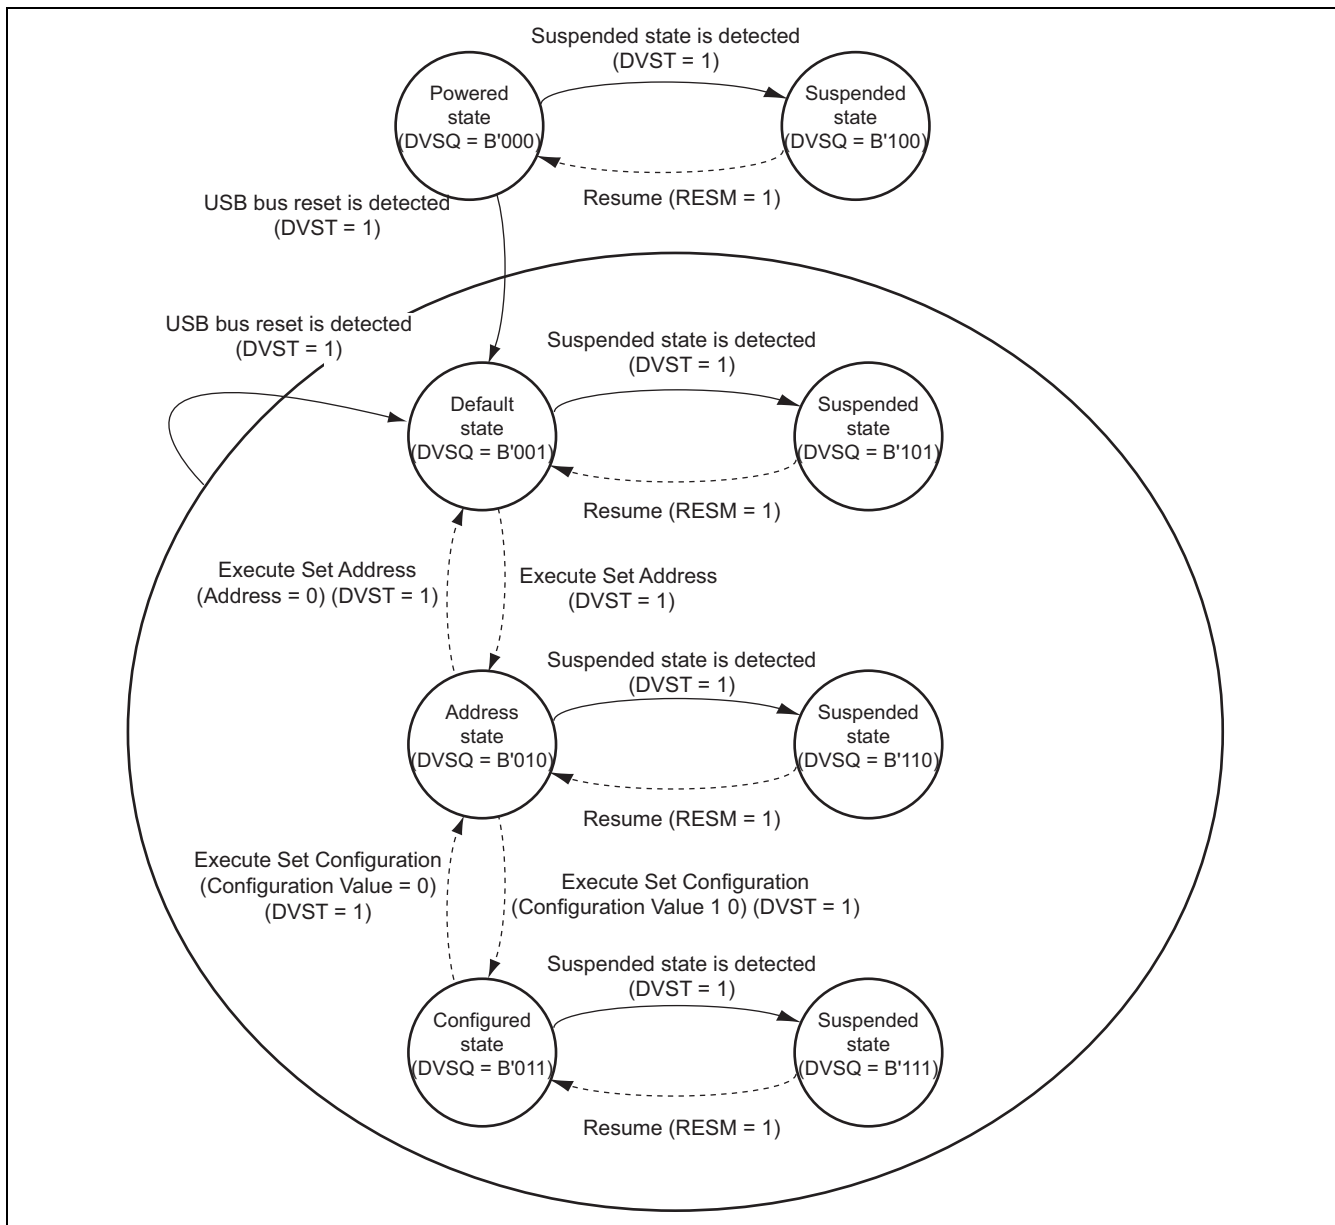

**Figure 52.5 BEMP Interrupt Generation Timing when the Function Controller Function is Selected**

**(4) Device State Transition Interrupt**

Figure 52.6 shows the device state transitions of this module. This module controls device states and generates device state transition interrupts. However, when returning from the suspended state (detecting the resume signal), this module detects the transition with a resume interrupt. The device state transition interrupt is enabled or disabled by setting INTENB0. The current device state can be monitored using the DVSQ bits in INTSTS0.

When this module shifts to the default state, a device state transition interrupt occurs after executing the reset handshake protocol.

**Figure 52.6 Device State Transitions**

**(5) Control Transfer Stage Transition Interrupt**

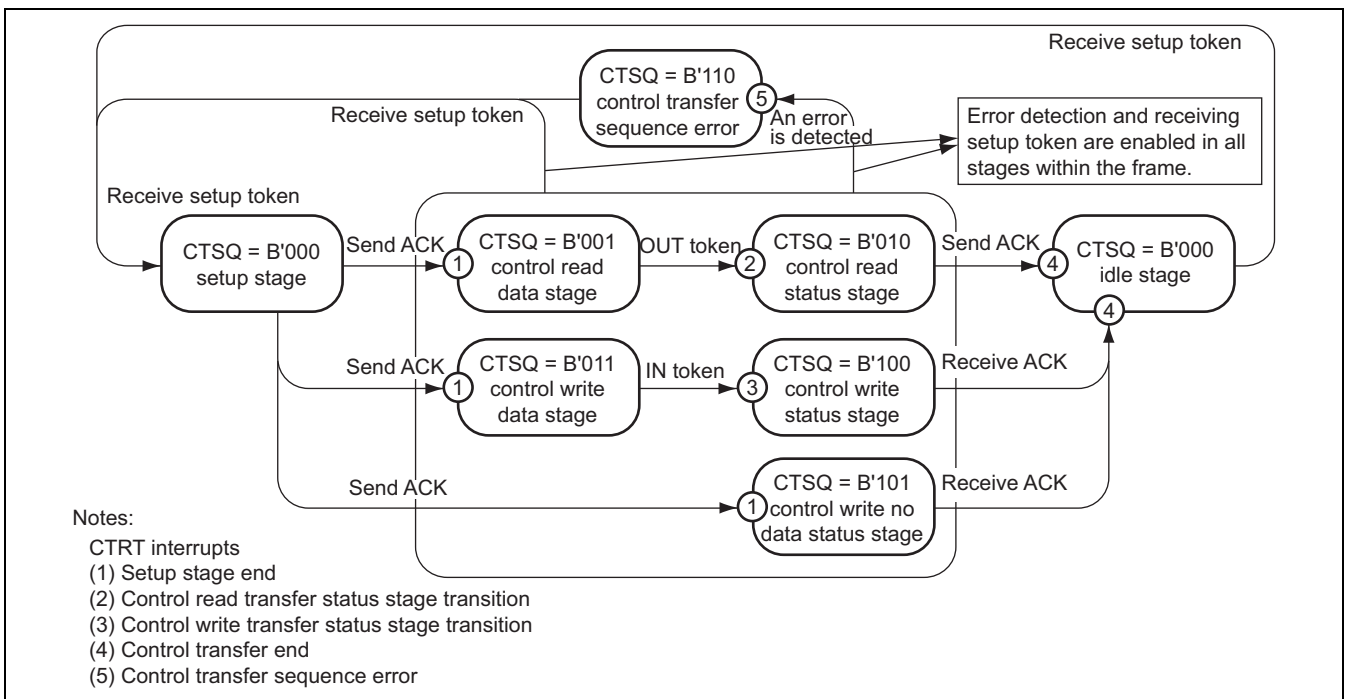

Figure 52.7 shows control transfer stage transitions of this module. This module manages the sequence of control transfers and generates control transfer stage transition interrupts. Enabling or disabling each control transfer stage transition interrupt can be set by INTENB0. The current transfer stage after transition can be checked by the CTSQ bits in INTSTS0.

The following describes control transfer sequence errors. When an error occurs, the PID bits in DCPCTR indicate B'1x (STALL response).

1. Control read transfer
  - This module receives an OUT or PING token in response to the IN token in the data stage before starting data transfer.
  - This module receives an IN token in the status stage.
  - This module receives a packet with a data packet of DATAPID = DATA0 in the status stage.
2. Control write transfer
  - This module receives an IN token in response to the OUT token in the data stage before sending an ACK response.
  - This module receives a packet with the first data packet of DATAPID = DATA0.
  - This module receives an OUT or PING token in the status stage.
3. Control write no-data control transfer
  - This module receives an OUT or PING token in the status stage.

If the size of the receive data exceeds the wLength value of the USB request in the control write transfer data stage, this is not treated as a control transfer sequence error. This module sends ACK for normal end in response to a packet other than Zero-Length packet in the control read transfer status stage.

When a CTRT interrupt is generated (SERR = 1) due to a sequence error, CTSQ = B'110 is retained until the interrupt status is cleared (CTRT = 0) by the system. For this reason, while CTSQ = B'110, even if a new USB request is received, a CTRT interrupt at the end of the setup stage is not generated. (This module retains the setup stage end status and generates a setup stage end interrupt after the interrupt status is cleared by the software.)

**Figure 52.7 Control Transfer Stage Transitions**

### (6) Frame Update Interrupt

Figure 52.8 shows an example of the SOFR interrupt output timing of this module.

An SOFR interrupt is generated immediately after the frame number is updated.

When this module detects a new SOF packet during the full-speed operation, this module updates the frame number and generates an SOFR interrupt. In the high-speed operation, however, the frame number is not updated or no SOFR interrupt is generated unless the module enters the  $\mu$  SOF lock state. Furthermore, the SOF interpolation function is not activated. The  $\mu$  SOF lock state occurs when this module receives a  $\mu$  SOF packet twice in a row with different frame numbers without an error.

The  $\mu$  SOF lock monitoring start and stop conditions are as follows:

1.  $\mu$  SOF lock monitoring start conditions  
USBE = 1
2.  $\mu$  SOF lock monitoring stop conditions  
USBE = 0, receiving USB bus reset, or detection of suspended state

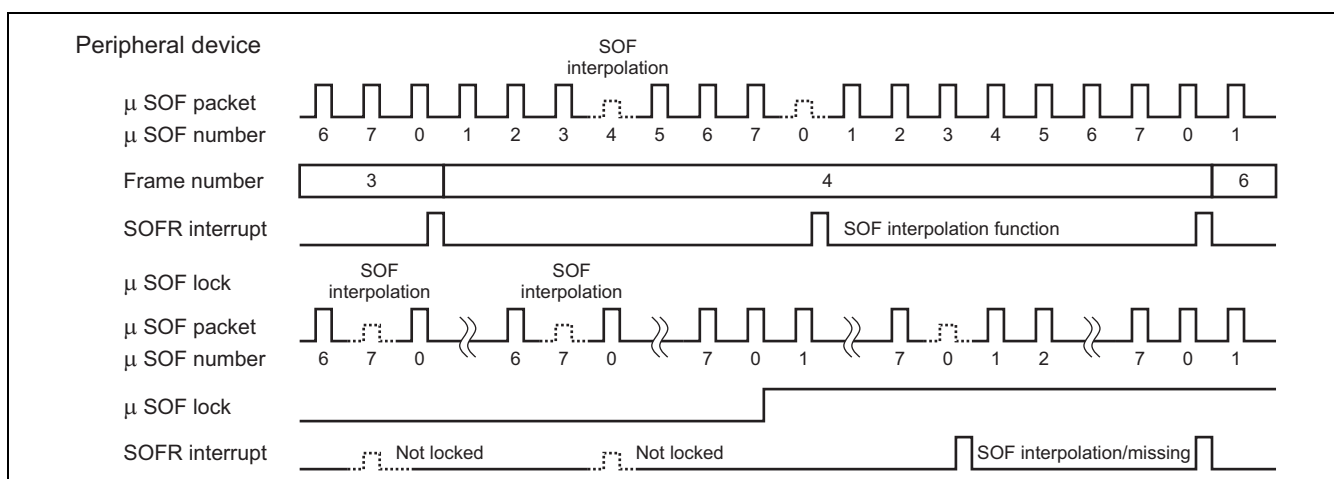

Figure 52.8 Example of SOFR Interrupt Output Timing

### (7) VBUS Interrupt

When the VBUSIN\_0 pin state changes, a VBUS interrupt is generated. The VBUSIN\_0 pin level can be checked by the VBSTS bit in INTSTS0. The VBUS interrupt is used to check connection or disconnection to the host controller.

However, when the system starts up with the host controller connected, the VBUSIN\_0 pin state remains unchanged, and therefore the first VBUS interrupt is not generated.

### (8) Resume Interrupt

When the function controller function is selected and the USB bus state changes (J-State to K-State or J-State to SE0) with the device state suspended, a resume interrupt is generated. The resume interrupt is used to detect the return from the suspended state.

### 52.3.3 Pipe Control

Table 52.13 lists the pipe settings of this module. In the USB data transfer, data must be transmitted or received using virtual pipes called “endpoint.” This module is provided with ten pipes for data transfer. Set each pipe according to system specifications.

**Table 52.13 Pipe Settings**

Register Name	Bit Name	Setting	Remarks
DCPCFG	TYPE	Transfer type	Pipes 1 to F: Setting allowed
PIPECFG	BFRE	BRDY interrupt mode	Pipes 1 to 5, 9 to F: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5, 9 to F: Setting allowed
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1, 2, 9, A: Setting allowed only when bulk transfer is selected
			Pipes 3 to 5, B to F: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to F: Setting allowed Set a value other than 0000 when using pipes
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed)
			Pipes 1 to 5, 9 to F: Setting allowed (up to 2 Kbytes) Pipes 6 to 8: Setting disallowed (64 bytes fixed)
PIPEBUF	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed)
			Pipes 1 to 5, 9 to F: Setting allowed (H'8 to H'7F) Pipes 6 to 8: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	MXPS	Maximum packet size	Setting conforming to the USB Specification
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected
			Pipes 3 to F: Setting disallowed
PIPEPERI	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected
			Pipes 3 to F: Setting disallowed
DCPCTR PIPECTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5, 9 to F.
	ATREPM	Auto-response mode	Pipes 1 to 5, 9 to F Setting allowed only when the function controller function is selected.
	ACLRM	Buffer auto-clear	Pipes 1 to F Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear

Register Name	Bit Name	Setting	Remarks
DCPCTR	SQSET	Sequence setting	Data toggle bit setting
PIPEnCTR	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 52.3.3 (6), Response PID.
	TRENB	Transaction count enable	Pipes 1 to 5, 9 to F: Setting allowed
PIPEnTRE	TRCLR	Current transaction counter clear	Pipes 1 to 5, 9 to F: Setting allowed
	TRNCNT	Transaction counter	Pipes 1 to 5, 9 to F: Setting allowed

### (1) Pipe Control Registers Switching Procedure

The following bits in the pipe control registers can be modified only when USB communication is set to disabled (PID = NAK).

Bits/registers that cannot be modified when USB communication is set to enabled (PID = BUF)

- Each bit in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEXCTR
- Each bit in PIPEXTRE and PIPEXTRN

When changing these bits from the state where USB communication is enabled (PID = BUF), follow the steps below.

1. Generate a pipe control register bit change request.
2. Change the PID bits for the pipe to NAK.
3. Wait until the PBUSY bit for the pipe is cleared to 0.
4. Change the bits in the pipe control registers.

The following bits in the pipe control registers can be modified only for pipe information that is not set in any of the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL.

Bits/registers that cannot be modified while the CURPIPE bits in FIFO-PORT are being set

- Each bit in DCPCFG and DCPMAXP
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI

Before changing the pipe information, set the CURPIPE bits to a pipe other than that to be changed. For the DCP, clear the buffer by the BCLR bit after modifying the pipe information.

### (2) Transfer Type

Specify the transfer type of each pipe by the TYPE bits in PIPECFG as follows:

- DCP: Setting is not required (fixed to control transfer).
- Pipes 1, 2: Set bulk transfer or isochronous transfer.
- Pipes 3 to 5, B to F: Set bulk transfer.
- Pipes 6 to 8 Set interrupt transfer.
- Pipes 9 to A: Set bulk transfer or interrupt transfer.

### (3) Endpoint Number

Specify the endpoint number of each pipe by the EPNUM bits in PIPEPCFG. The endpoint number of the DCP is always 0. For other pipes, endpoint 1 to endpoint 15 are selectable.

- DCP: Setting is not required (fixed to endpoint 0).
- Pipes 1 to F Set an endpoint number by selecting a number 1 to 15.  
However, set an endpoint number so that combinations of the DIR bit and the EPNUM bits do not overlap.

### (4) Maximum Packet Size

Specify the maximum packet size of each pipe by the MXPS bits in DCPMAXP and PIPEMAXP. For the DCP and pipes 1 to 5, 9 to F, any of the maximum packet sizes defined in the USB Specification can be set. For pipes 6 to 8a maximum packet size up to 64 bytes can be set. Specify a maximum packet size as follows before starting transfer (PID = BUF):

- DCP: Set 64 for high-speed operation.
- DCP: Set 8, 16, 32, or 64 for full-speed operation.
- Pipes 1 to 5, 9 to F: Set 512 for high-speed bulk transfer.
- Pipes 1 to 5, 9 to F: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 8 Set a value from 1 to 64.
- Pipes 9 to A: Set a value from 1 to 64 for interrupt transfer.

High Bandwidth in interrupt and isochronous transfers is not supported.

### (5) Transaction Counter (Pipes 1 to 5, 9 to F: Read Direction)

When the specified number of transactions with data packet in the receive direction are completed, this module recognizes this as a transfer end. The transaction counter works when the pipe selected for the D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL ports is set for the data read (from the buffer memory) direction. The transaction counter is provided with the TRNCNT register to specify the number of transactions and the current counter to count transactions internally. When the current counter reaches the specified value, the buffer memory becomes ready for reading. The current counter of the transaction counter function can be initialized by the TRCLR bit to count transactions again from the beginning. The TRNCNT read data varies depending on the TRENb setting.

- TRENb = 0: The set transaction counter value is read.
- TRENb = 1: The internally counted current counter value is read.
- Change the CURPIPE bits according to the following.
- Do not change the CURPIPE bits until the transaction for the specified pipe finishes.
- Change the CURPIPE bits when the current counter is cleared.
- Control the TRCLR bit according to the following.
- Do not clear the current counter during transaction count and PID = BUF.
- Do not clear the current counter while data is remaining in the buffer.

## (6) Response PID

Specify the response PID for each pipe by the PID bits in DCPCTR and PIPEnCTR.

This module operates as follows according to the response PID setting.

The response PID specifies a response to transactions from the host.

- NAK setting: NAK is always sent in response to a transaction.
- BUF setting: A response is sent to a transaction according to the buffer memory status.
- STALL setting: STALL is always sent in response to a transaction.

Note: This module always sends ACK in response to a setup transaction irrespective of the PID setting, and stores a USB request in the register.

This module modifies the PID bits in the following cases depending on transaction results.

- When the response PID is set by the hardware
  - NAK setting: This module sets PID to NAK in the following cases and always sends NAK in response to a transaction.
- When a SETUP token is successfully received (DCP only)
- When the SHTNAK bit in PIPECFG is set to 1 in a bulk transfer and the transaction counter stops counting or this module receives a short packet
  - BUF setting: This module does not set the PID bits to BUF.
  - STALL setting: This module sets PID to STALL in the following cases and always sends STALL in response to a transaction.
- When a maximum packet size exceeded error is detected in a receive data packet
- When a control transfer sequence error is detected (DCP only)

## (7) Data PID Sequence Bit

When data is successfully transferred in the control transfer data stage, bulk transfer, or interrupt transfer, this module automatically toggles the data PID sequence bit. The sequence bit of the data PID transmitted next can be monitored by the SQMON bit in DCPCTR and PIPEnCTR. In a data transmission period, the sequence bit switches at the ACK handshake receive timing. In a data reception period, the sequence bit switches at the ACK handshake transmit timing. The data PID sequence bit can also be changed by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.

In control transfers when the function controller function is selected, this module automatically sets the sequence bit during a stage transition. DATA0 is indicated at the end of the setup stage, and DATA1 is used for responses in the status stage. This does not require the setting of the sequence bit by the software.

Note that, the software must also set the data PID sequence bit when sending or receiving a ClearFeature request.

The sequence bit cannot be modified by the SQSET bit for isochronous transfer pipes.

### (8) Response PID = NAK Function

This module has a function to disable the pipe operation (Response PID = NAK) at the last data packet receive timing in a transfer (this module automatically identifies the last data packet receive timing at the short packet receive timing or using the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

This function allows reception of data packets in transfer units when the buffer memory is used as a double buffer. Furthermore, when the pipe operation is disabled, the software must set the response PID to BUF to enable the pipe operation.

This function is available only for bulk transfers.

### (9) Auto-Response Mode

When the ATREPM bit in PIPEnCTR is set to 1 in a bulk transfer pipe (pipes 1 to 5, 9 to F), this module enters auto-response mode: OUT-NAK mode in OUT transfers (DIR = 0) or null auto-response mode in IN transfers (DIR = 1).

#### 1. OUT-NAK mode

When the ATREPM bit is set to 1 in a bulk OUT transfer pipe, this module sends NAK in response to an OUT token or PING token and outputs an NRDY interrupt. To change response mode from normal mode to OUT-NAK mode, specify OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, OUT-NAK mode is enabled. However, if an OUT token is received immediately before the pipe operation is disabled, this module receives the data of the token correctly and sends ACK to the host.

To change response mode from OUT-NAK mode to normal mode, reset OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). In normal mode, this module can receive OUT data and sends ACK in response to a PING token when the buffer is ready for receiving.

#### 2. Null auto-response mode

When the ATREPM bit is set to 1 in a bulk IN transfer pipe, this module continues to send Zero-Length packets. To change response mode from normal mode to null auto-response mode, specify null auto-response mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, null auto-response mode is enabled. However, specify null auto-response mode while the buffer is empty. Verify this by checking INBUFM = 0. Since INBUFM = 1 indicates that the buffer contains data, clear the buffer by setting the ACLRM bit. Do not write data to the buffer from the FIFO port during setting to null auto-response mode.

To change response mode from null auto-response mode to normal mode, delay the pipe operation disabled state (Response PID = NAK) for a time period for sending a Zero-Length packet (full-speed: 10  $\mu$ s, high-speed: 3  $\mu$ s), and then reset null auto-response mode. Normal mode allows writing from the FIFO port, and also allows sending packets to the host by enabling the pipe operation (Response PID = BUF).

### 52.3.4 FIFO Buffer Memory

#### (1) Allocating FIFO Buffer Memory

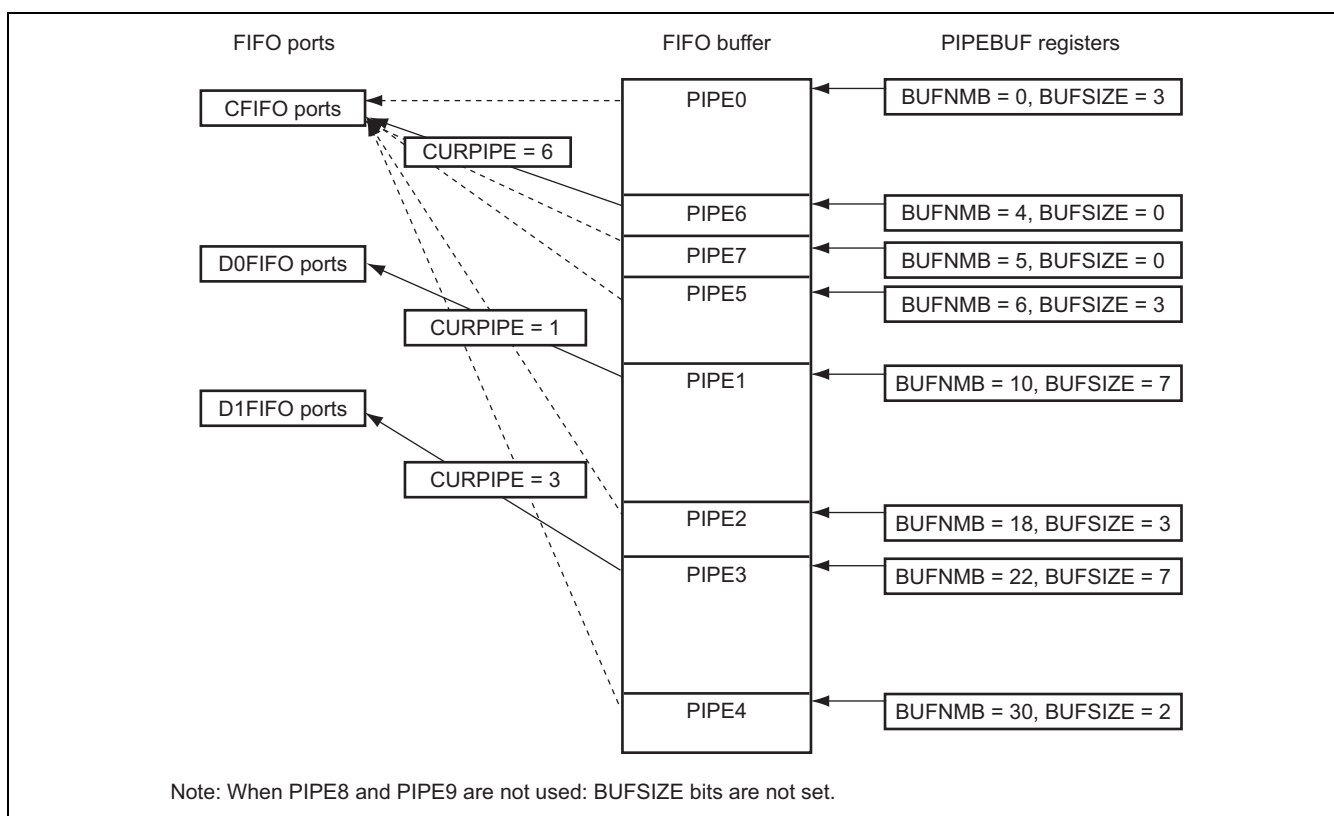

Figure 52.9 shows an example of the FIFO buffer memory map of this module. The FIFO buffer memory is an area shared by the CPU and this module. There are two FIFO buffer memory states where the access right is given to the system (CPU) or to this module (SIE).

The FIFO buffer memory provides independent areas for each pipe. A memory area is set with the block start number and the number of blocks (BUFNMB and BUFSIZE bits in PIPEBUF) in 64-byte units as one block.

When continuous transfer mode is selected by the CNTMD bit in PIPECFG, be sure to set the BUFSIZE bits to a value in integral multiples of the maximum packet size. When double buffer is selected by the DBLB bit in PIPECFG, two sides of the memory area specified by the BUFSIZE bits in PIPEBUF are provided for the same pipe.

Furthermore, three FIFO ports are used for accesses (data read/write) to the buffer memory. The number of a pipe to be allocated to the FIFO ports is specified by the CURPIPE bits in CFIFOSEL and DnFIFOSEL.

The buffer status of each pipe can be monitored by the BSTS and INBUFM bits in DCPCTR and PIPECTR. The access right to the FIFO ports can be checked by the FRDY bit in CFIFOCTR and DnFIFOCTR.

**Figure 52.9 Example of Buffer Memory Map**

- Buffer status

Tables 52.14 and 52.15 show the buffer memory status of this module. The buffer memory status can be monitored by the BSTS bit in DCPCTR and the INBUFM bit in PIPECTR. The buffer memory access direction is specified by the DIR bit in PIPECFG or the ISEL bit in CFIFOSEL (when DCP is selected).

The INBUFM bit is valid only for pipes 1 to 5, 9 to F in the transmit direction.

When a transfer pipe in the transmit direction is set to double buffer, the BSTS bit is used to monitor the buffer status on the CPU side, and the INBUFM bit is used to monitor the buffer status on the SIE side. When data write to the FIFO port by the CPU (DMAC) takes time and buffer empty cannot be checked by the BEMP interrupt, the INBUFM bit is available to check completion of transmission.

**Table 52.14 Buffer Memory Status That Varies Depending on the BSTS Bit**

ISEL or DIR	BSTS	Buffer Memory Status
0 (receive direction)	0	No receive data in the buffer memory or data is being received. Data cannot be read from the FIFO port.
0 (receive direction)	1	Receive data in the buffer memory or a Zero-Length packet is received. Data can be read from the FIFO port. However, the buffer must be cleared because the FIFO port cannot be read when this module receives a Zero-Length packet.
1 (transmit direction)	0	Transmission of data is not completed. Data cannot be written to the FIFO port.
1 (transmit direction)	1	Transmission of data is completed. The CPU can write data to the buffer memory.

**Table 52.15 Buffer Memory Status That Varies Depending on the INBUFM Bit**

DIR	INBUFM	Buffer Memory Status
0 (receive direction)	Invalid	Invalid
1 (transmit direction)	0	Transmittable data is completely sent. No transmittable data is in the buffer memory.
1 (transmit direction)	1	Transmittable data is written from the FIFO port. The buffer memory contains transmittable data.

- FIFO buffer clear

Table 52.16 shows clearing of the FIFO buffer memory of this module. The buffer memory can be cleared by the BCLR, DCLRM, and ACLRM bits.

**Table 52.16 Buffer Clear**

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Function	Clears the buffer memory of the CPU.	Automatically clears the buffer memory after reading data of the specified pipe.	Automatically clears the buffer memory by ignoring all received packets.
Clearing method	Writing 1 to this bit clears the buffer memory.	1: This mode is enabled. 0: This mode is disabled.	1: This mode is enabled. 0: This mode is disabled.

- Buffer area

Table 52.17 shows a buffer memory map of this module. The buffer memory includes a dedicated areas reserved beforehand for pipes and user areas provided for user settings.

The buffer for DCP is a dedicated area commonly used in control read transfers and control write transfers.

Areas for pipes 6 to 8 are allocated respectively in advance. However, when none of pipes 6 to 9 is used, the areas are available for pipes 1 to 5, 9 to F as user areas.

Allocate different areas of the buffer memory to each pipe. Note that, when double buffer is specified, the size of an area is twice of the set value.

Do not set the buffer size to a value smaller than the maximum packet size.

**Table 52.17 Buffer Memory Map**

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'0	64 bytes	Fixed only for DCP	Single buffer
H'1 to H'3	—	Unavailable	—
H'4	64 bytes	Fixed only for pipe 6	Single buffer
H'5	64 bytes	Fixed only for pipe 7	Single buffer
H'6	64 bytes	Fixed only for pipe 8	Single buffer
H'7 to H'7F	Max. 7616 bytes	User area for pipes 1 to 5, 9 to F	Double buffer and continuous transfer can be set

- Buffer auto-clear mode function

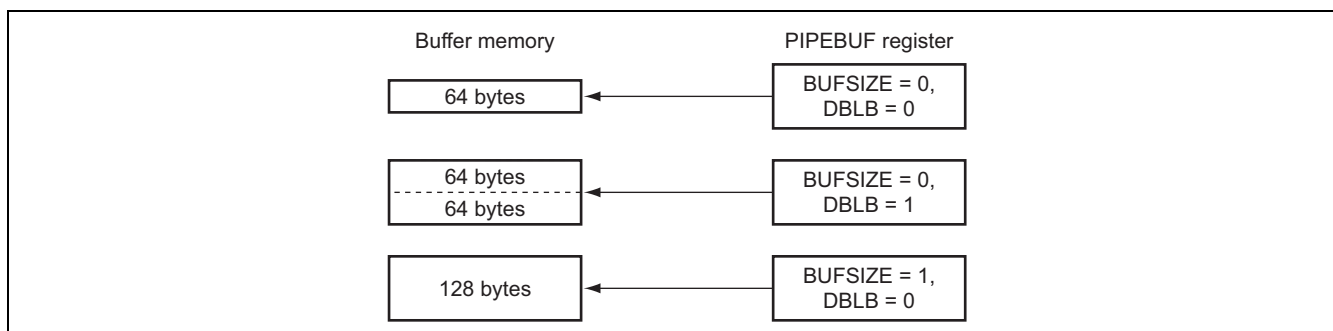

When the ACLRM bit PIPEnCTR is set to 1, this module discards all data packets received. However, when this module receives a data packet successfully, it sends ACK to the host controller. This function is available only for the buffer memory read direction.

Writing 1 and then 0 continuously to the ACLRM bit clears the buffer memory of the selected pipe irrespective of the access direction.

Take at least 100 ns between writing 1 and writing 0 for the sequence execution time of the hardware.

- Buffer memory specifications (single buffer/double buffer setting)

Single buffer or double buffer is selectable for pipes 1 to 5, 9 to F with the DBLB bit in PIPEnCFG. Double buffer is a function to provide two sides of the memory area specified by the BUFSIZE bits in PIPEBUF for the same pipe. Figure 52.10 shows an example of setting for the buffer memory of this module.

**Figure 52.10 Example of Buffer Memory Setting**

- Buffer memory operation (continuous transfer setting)

Continuous transfer mode or discontinuous transfer mode is selectable with the CNTMD bit in PIPEnCFG. This selection is enabled for pipes 1 to 5, 9 to F.

The continuous transfer mode function allows continuous transmission/reception of multiple transactions. When continuous transfer mode is selected, data up to the buffer size allocated to each pipe can be transferred without outputting an interrupt to the CPU.

In continuous transmission mode, data in the buffer is divided by the maximum packet size and is then transmitted. To send data less than the buffer size (a short packet or a packet with a size of integral multiples of the maximum packet size and less than the buffer size), set BVAL = 1 after writing transmit data to the buffer.

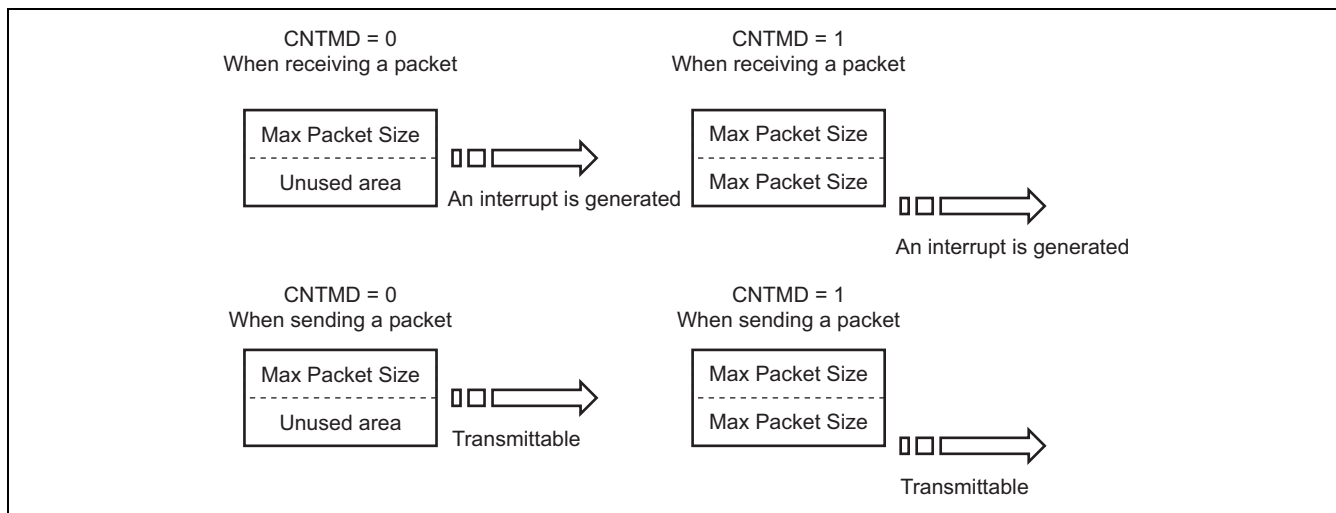

In continuous reception mode, no interrupt is generated until this module receives packets to the buffer size, the transaction count ends, or this module receives a short packet.

Table 52.18 shows the relationship between the CNTMD setting and determination of transmission/reception end of the FIFO buffer.

**Table 52.18 Relationship between CNTMD Setting and Determination of Transmission/Reception End of FIFO Buffer**

Transfer Mode	Determination of Buffer Readable State and Data Transmittable State
Discontinuous transfer (CNTMD = 0)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When this module receives one packet
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The software (or DMAC) writes data of the maximum packet size to the FIFO buffer. The software (or DMAC) writes data of a short packet (including 0 bytes) to the FIFO buffer, and then sets BVAL = 1.
Continuous transfer (CNTMD = 1)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When the bytes of data received in the FIFO buffer for the selected pipe equals the allocated bytes ((BUFSIZE + 1) × 64) When this module receives a short packet other than a Zero-Length packet When this module receives a Zero-Length packet when data is already stored in the FIFO buffer for the selected pipe When this module receives packets as large as the transaction counter value specified for the selected pipe by the software
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The volume of data written by the software (or DMAC) equals the size of one side of the FIFO buffer for the selected pipe. The software (or DMAC) writes data less than the size of one side of the FIFO buffer for the selected pipe to the FIFO buffer, and then sets BVAL = 1.

Figure 52.11 shows an example of buffer memory operation of this module.

**Figure 52.11 Example of Buffer Memory Operation**

## (2) FIFO Port Function

Table 52.19 lists the settings for the FIFO port functions of this module. During a data write access, when data up to buffer full (or up to the maximum packet size in discontinuous transfer) is written, the FIFO port automatically enters the data transmittable state. To make data less than buffer full (or the maximum packet size in discontinuous transfer) transmittable, set the BVAL bit in CFIFOCTR and DnFIFOCTR to 1 to set write end. For transmission of a Zero-Length packet, clear the buffer using the BCLR bit in these registers and then set the BVAL bit to 1.

During a data read access, when all data is read, the FIFO port automatically enters the new packet receivable state. However, when receiving a Zero-Length packet (DTLN = 0), no data can be read. Therefore, clear the buffer using the BCLR bit in these registers. The receive data length can be checked by the DTLN bits in CFIFOCTR and DnFIFOCTR.

**Table 52.19 FIFO Port Function Settings**

Register Name	Bit Name	Function	Remarks
CFIFOSEL	RCNT	Selects DTLN read mode.	
DnFIFOSEL	REW	Rewinds the buffer memory (reread/rewrite).	
	DCLRM	Reads and clears receive data of the specified pipe.	DnFIFO only
	DREQE	Enables DMA transfer.	DnFIFO only
	MBW	Specify FIFO port access bit width.	
	BIGEND	Selects FIFO port endian.	
	ISEL	Selects FIFO port access direction.	DCP only
	CURPIPE	Select the current pipe.	
CFIFOCTR	BVAL	Specifies buffer memory write end.	
DnFIFOCTR	BCLR	Clears the buffer memory of the CPU.	
	DTLN	Check receive data length.	

### (a) FIFO Port Selection

Table 52.20 shows pipes that can be selected in each FIFO port. Select a pipe to be accessed by the CURPIPE bits in CFIFOSEL and DnFIFOSEL. After selecting a pipe, confirm that the set CURPIPE value is read correctly, check FRDY = 1, and then make an access to the FIFO port. (If the previous pipe number is read, this controller is changing a pipe.)

Also select the bus width to be accessed by the MBW bits. The buffer memory access direction is specified by the DIR bit in PIPECFG. However, only the access direction of DCP is determined by the ISEL bit.

**Table 52.20 FIFO Port Access**

Pipe	Access	Available port
DCP	CPU access	CFIFO port register
Pipes 1 to F	CPU access	CFIFO port register
	DMA access	D0FIFO and D1FIFO port

### (b) REW Bit

The current access to a pipe can be suspended temporarily, and it is also possible to make an access to another pipe to continue the ongoing pipe processing. This processing is allowed by using the REW bit in CFIFOSEL and DnFIFOSEL.

When the REW bit is set to 1 together with the CURPIPE bits in CFIFOSEL and DnFIFOSEL and a pipe is selected, the reading or writing pointer of the buffer memory is reset, which allows reading or writing data from the first byte. Furthermore, when a pipe is selected with the REW bit set to 0, data can be read or written following the data at the previous selection without resetting the reading or writing pointer of the buffer memory.

To make accesses to the FIFO port, select a pipe and check  $FRDY = 1$ .

### (3) DMA Transfer (Dedicated DMA Interface)

#### (a) Overview of DMA Transfer

The FIFO port can be accessed by the DMAC for pipes 1 to F. When the buffer of a pipe specified for DMA transfer becomes accessible, this module outputs a DMA transfer request.

Specify the data transfer unit to the FIFO port by the MBW bits in  $DnFIFOSEL$ , and select a pipe used for DMA transfer by the CURPIPE bits in  $DnFIFOSEL$ . Do not change the selected pipe during a DMA transfer.

#### (b) DMA Transfer End Auto-Recognition

This module can terminate writing of data by DMA transfer to the FIFO buffer by controlling the DMA transfer end signal input. After sampling the transfer end signal, this module drives the buffer memory into the transmittable state (same state as  $BVAL = 1$ ).

#### (c) DnFIFO Auto-Clear Mode (D0FIFO, D1FIFO, D2FIFO and D3FIFO Port Read Direction)

By setting the DCLRM bit in  $DnFIFOSEL$  to 1, this module automatically clears the buffer memory for the selected pipe upon completion of data read from the buffer memory.

Table 52.21 shows the relationship between packet reception and buffer memory clear by the software. As shown in the table, buffer clearing conditions vary with the BFRE setting. However, in any state that needs clearing, using the DCLRM bit makes buffer clearing by the software unnecessary. Thus DMA transfer is enabled without requiring any software control.

- This function is available only for the buffer memory read direction.

**Table 52.21 Relationship between Packet Reception and Buffer Memory Clear by the Software**

Buffer Status When Receiving a Packet	Register Setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-Length packet reception	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet reception	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

### 52.3.5 Control Transfer (DCP)

The default control pipe (DCP) is used for data transfer in the control transfer data stage. The buffer memory for the DCP is a 256-byte single buffer of a fixed area used for both control read and control write. The buffer memory can be accessed only by the CFIFO ports.

#### (1) Setup Stage

1. This module always sends ACK in response to a normal setup packet to this module. The following describes the operation of this module in the setup stage.

When this module receives a new setup packet, this module sets the following bits.

- The VALID bit in INTSTS0 to 1
  - The PID bits in DCPCTR to NAK
  - The CCPL bit in DCPCTR to 0
2. When this module receives a data packet following a setup packet, this module stores the USB request parameters in USBREQ, USBVAL, USBINDEX, and USBLENG.

Be sure to process responses to control transfers while VALID = 0. The PID bits cannot be set to BUF when VALID = 1, and therefore the data stage cannot be completed.

With the VALID bit function, this module can suspend the ongoing request processing if this module receives a new USB request during a control transfer, and send a response to the latest request.

This module also determines the direction bit (bit 8 of bmRequestType) of the received USB request and the request data length (wLength), identifies a control read transfer, control write transfer, and control write no-data transfer, and controls stage transitions. For an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and the error is reported to the software. For the stage control of this module, see Figure 52.7.

#### (2) Data Stage

Transfer data in response to the received USB request using the DCP. Before making an access to the DCP buffer memory, specify the access direction by the ISEL bit in CFIFOSEL.

When the transfer data size is larger than the DCP buffer memory size, use a BRDY interrupt for control write transfers and a BEMP interrupt for control read transfers.

In the high-speed control write transfer, this module sends responses using the NYET handshake according to the buffer memory status.

#### (3) Status Stage

Setting the CCPL bit to 1 with the PID bits in DCPCTR set to BUF finishes a control transfer.

After these settings, this module executes the status stage as follows according to the data transfer direction determined in the setup stage:

- Control read transfer  
This module sends a Zero-Length packet and receives an ACK response from the USB host.
- Control write transfer, no-data control transfer  
This module receives a Zero-Length packet from the USB host and sends an ACK response.

#### (4) Control Transfer Auto-Response Function

This module automatically responds to a correct SET\_ADDRESS request. If any of the following errors occurs in the SET\_ADDRESS request, the software must respond to the error.

- Other than control read transfer: bmRequestType ≠ H'00
- Request errors: wIndex ≠ H'00
- Other than no-data control transfer: wLength ≠ H'00
- Request errors: wValue > H'7F
- Control transfer of device state errors: DVSQ = B'011 (configured)

All requests other than SET\_ADDRESS require a response made by the software.

#### 52.3.6 Bulk Transfer (Pipes 1 to 5, 9 to F)

The buffer memory usage (single buffer/double buffer setting or continuous/discontinuous transfer mode setting) can be selected for bulk transfers. The buffer memory size can be set to up to 2 Kbytes. This module manages the buffer memory status and automatically responds to a PING packet and an NYET handshake.

##### (1) NYET Handshake Control

Table 52.22 lists NYET handshake responses of this module. This module sends a NYET response under the following conditions. However, when this module receives a short packet, this module sends ACK instead of NYET. The same is true of the control write transfer data stage.

**Table 52.22 NYET Handshake Responses**

Setting of PID Bits in DCPCTR	Buffer Memory Status	Token	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY1	OUT/PING	ACK	Receives a data packet when receiving an OUT token.
	RCV-BRDY2	OUT	NYET	Receives a data packet. Sends a “reception disable” response.
	RCV-BRDY2	OUT (Short)	ACK	Receives a data packet. Sends a “reception enable” response.
	RCV-BRDY2	PING	ACK	Sends a “reception enable” response.
	RCV-NRDY	OUT/PING	NAK	Sends a “reception disable” response.
	TRN-BRDY	IN	DATA0/1	Sends a data packet.
TRN-NRDY	IN	NAK	TRN-NRDY	

[Legend]

RCV-BRDY1: The buffer memory has available space for two packets or more when receiving an OUT or PING token.

RCV-BRDY2: The buffer memory has available space for only one packet when receiving an OUT token.

RCV-NRDY: The buffer memory is occupied when receiving an PING token.

TRN-BRDY: The buffer memory contains transmit data when receiving an IN token.

TRN-NRDY: The buffer memory contains no transmit data when receiving an IN token.

### 52.3.7 Interrupt Transfer (Pipes 6 to A)

This module performs interrupt transfer following the cycles controlled by the host controller. In interrupt transfers, this module ignores PING packets (no response), sends no NYET handshake, and sends ACK, NAK, and STALL responses.

This module does not support the High-Bandwidth interrupt transfer.

### 52.3.8 Isochronous Transfer (Pipes 1, 2)

This module is provided with the following functions for isochronous transfers.

- Reporting isochronous transfer error information
- Interval counter (IITV bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (IFIS bit)

This module does not support the isochronous High-Bandwidth transfer.

#### (1) Isochronous Transfer Error Detection

This module is provided with a function to detect the following error information so that the software can manage isochronous transfer errors. Tables 52.23 and 52.24 show the error detection priority of this module and interrupts generated as a result of error detection.

1. PID error
  - When the PID in a receive packet is invalid
2. CRC error, bit stuffing error
  - When a CRC error is found in a receive packet or bit stuffing is invalid
3. Maximum packet size exceeded error
  - When the data size of a receive packet is over the maximum packet size setting
4. Overrun/underrun error
  - When the buffer memory contains no data when this module receives an IN token in the IN direction (transmission) transfer
  - When the buffer memory is occupied when this module receives an OUT token in the OUT direction (reception) transfer
5. Interval error
  - This module generates an interval error in the following cases.
  - When no IN token can be received in interval frames in the isochronous IN transfer
  - When this module receives an OUT token other than interval frames in the isochronous OUT transfer

**Table 52.23 Error Detection when Receiving Tokens**

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates no interrupt (ignores as a damaged packet).
3	Overrun error, underrun error	This module generates an NRDY interrupt and sets the OVRN bit. This module sends a Zero-Length packet in response to the IN token. This module receives no data packet in response to the OUT token.
4	Interval error	This module generates an NRDY interrupt.

**Table 52.24 Error Detection when Receiving Data Packets**

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates an NRDY interrupt and sets the CRCE bit.
3	Maximum packet size exceeded error	This module generates a BEMP interrupt and sets the PID bits to STALL.

**(2) DATA-PID**

This module does not support the High-Bandwidth transfer. The following lists responses to received PIDs when the function controller function is selected.

1. IN direction
  - DATA0: Sent correctly as the PID of data packet.
  - DATA1: Not sent
  - DATA2: Not sent
  - mData: Not sent
2. OUT direction (full-speed operation)
  - DATA0: Received correctly as the PID of a data packet.
  - DATA1: Received correctly as the PID of a data packet.
  - DATA2: The packet is ignored.
  - mData: The packet is ignored.
3. OUT direction (high-speed operation)
  - DATA0: Received correctly as the PID of a data packet.
  - DATA1: Received correctly as the PID of a data packet.
  - DATA2: Received correctly as the PID of a data packet.
  - mData: Received correctly as the PID of a data packet.

### (3) Interval Counter

Intervals for isochronous transfers can be set by the IITV bits in PIPEPERI. The functions shown in Table 52.25 are made available with the interval counter.

**Table 52.25 Interval Counter Functions**

Transfer Direction	Function	Detection Conditions
IN	Transmit buffer flush	No IN token can be successfully received in the interval frame during the isochronous IN transfer.
OUT	Reporting reception of no token	No OUT token can be successfully received in the interval frame during the isochronous OUT transfer.

Since the interval counter is counted upon receiving an SOF or using the interpolated SOF, the isochronism can be maintained even if the SOF is damaged. The specifiable frame interval is  $2^{\text{IITV}}$  frames or  $2^{\text{IITV}}$   $\mu$  frames.

#### (a) Counter initialization

This module initializes the interval counter as follows:

- Power-on reset  
The IITV bits are initialized.
- Initializing buffer memory by ACLRM  
The IITV bits are not initialized but the interval counter is initialized. Clearing the ACLRM bit to 0 causes the counter to start counting from the set IITV value.

After the interval counter is initialized, the interval counter starts counting in either of the following cases after a packet is correctly transferred.

1. When this module receives an SOF after sending data in response to the IN token with PID = BUF
2. When this module receives an SOF after receiving the OUT token data with PID = BUF

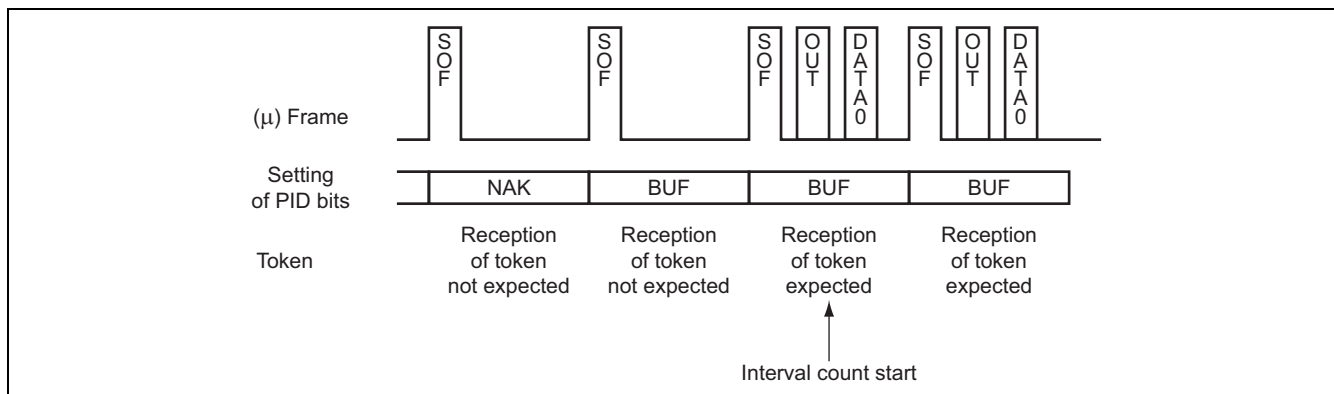

The interval counter is not initialized under the following conditions.

1. When PID = NAK or STALL  
The interval timer does not stop. Try to execute the transaction in the next interval.
2. USB bus reset and USB suspended  
The IITV bits are not initialized. When this module receives an SOF, the interval counter starts counting from the value before receiving the SOF.

#### (b) Interval count and transfer control

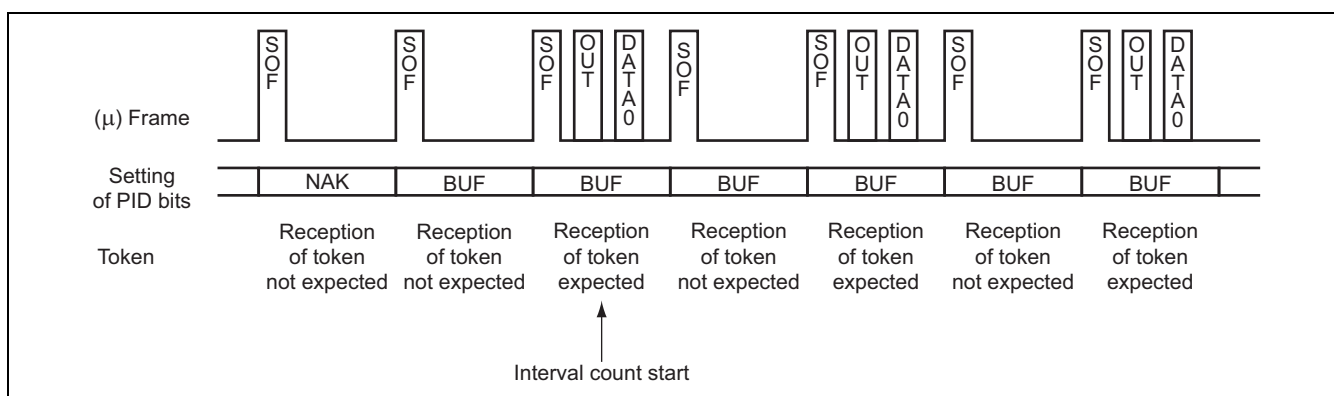

1. When the selected pipe is Isochronous-OUT transfer pipe  
When this module receives no data packet in ( $\mu$ ) frames at the intervals specified by the IITV bits, this controller generates an NRDY interrupt.  
When this module cannot receive data due to a CRC error in the data packet, FIFO buffer full, or other reasons, this module also generates an NRDY interrupt.  
An NRDY interrupt is generated at the SOF packet receive timing. Even if the SOF packet is damaged, this module generates an NRDY interrupt at the SOF packet receive timing using the internal interpolation function.  
When  $\text{IITV} \neq 0$ , however, this module generates an NRDY interrupt at the SOF packet receive timing in each interval after the interval count starts.  
When PID = NAK is set by the software after the interval timer is activated, this module generates no NRDY interrupt even when this module receives an SOF packet.  
The interval count start conditions vary with the set IITV value.

— When IITV = 0: The interval count starts from the next ( $\mu$ ) frame where the PID bits for the selected pipe is changed to BUF.

**Figure 52.12 ( $\mu$ ) Frames and Expectation of Receiving a Token when IITV = 0**

— When IITV  $\neq$  0: The interval count starts from the time when this module successfully receives the first data packet after the PID bits for the selected pipe is changed to BUF.

**Figure 52.13 ( $\mu$ ) Frames and Expectation of Receiving a Token when IITV  $\neq$  0**

2. When the selected pipe is Isochronous-IN transfer pipe

Use the selected pipe by combining with the setting of IFIS = 1. When IFIS = 0, this module sends data packets in response to received tokens irrespective of the IITV value.

When this module receives no IN-Token in ( $\mu$ ) frames at the intervals specified by the IITV bits with transmittable data stored in the FIFO buffer with IFIS = 1, this module clears the FIFO buffer.

When this module cannot receive data due to a CRC error or another bus error in the IN-Token, this module also clears the FIFO buffer.

The FIFO buffer is cleared at the SOF packet receive timing. Even if the SOF packet is damaged, this module clears the FIFO buffer at the SOF packet receive timing using the internal interpolation function.

The interval count start conditions vary with the set IITV value (same as Isochronous-OUT transfer).

When the function controller function is selected, the interval count start conditions are as follows:

- When this module is reset by the hardware (The set IITV value is also cleared to 0.)
- When ACLRM is set to 1 by the software
- When this module detects a USB reset

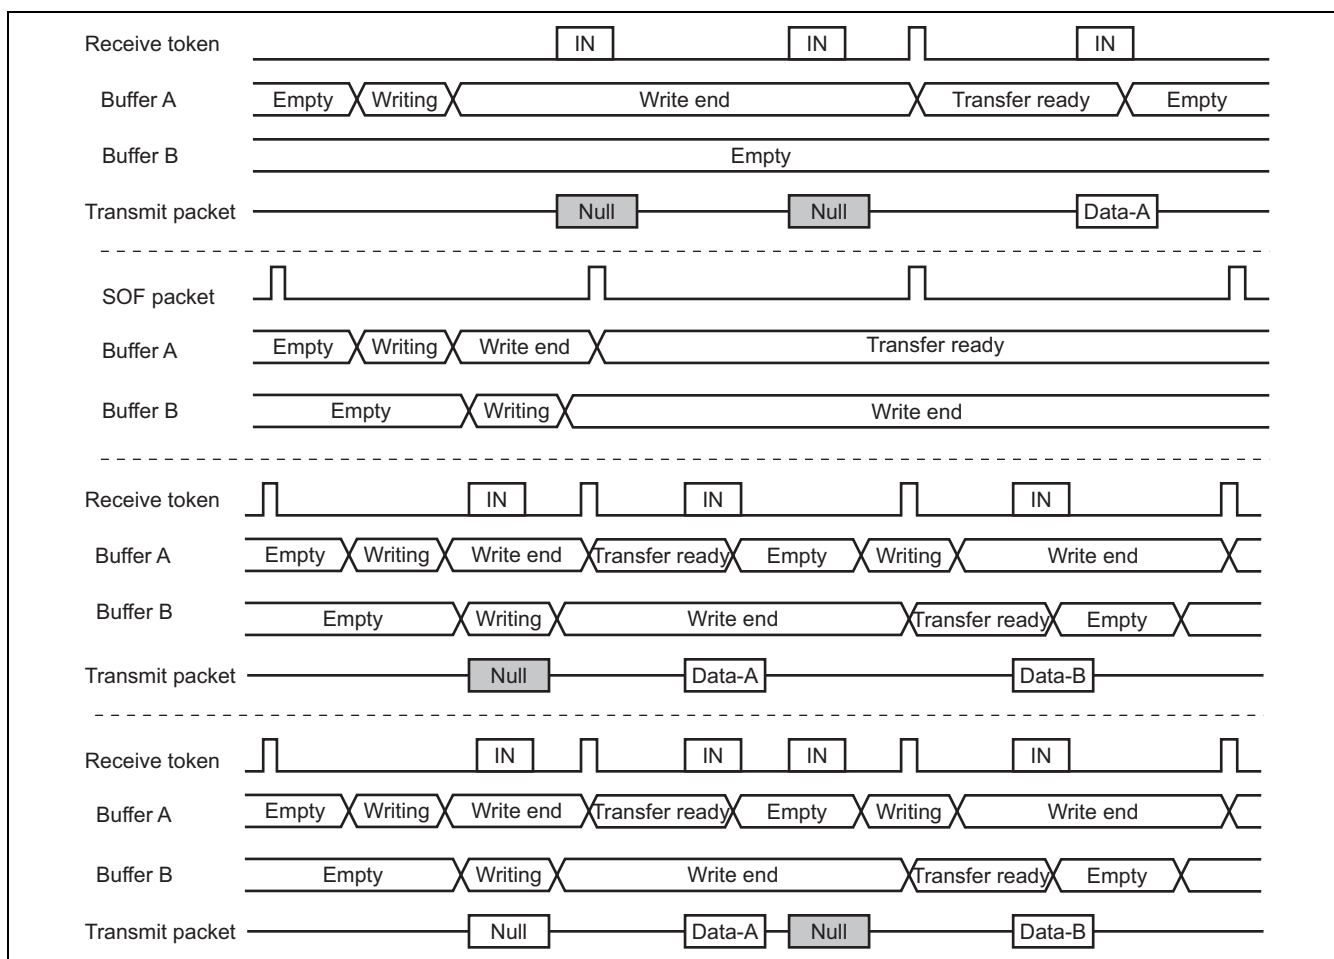

**(4) Transmit Data Setup in Isochronous Transfer**

In isochronous data transmission is selected, this module can send a data packet in the next frame after this module detects an SOF packet after writing data to the buffer. This function is referred to as the isochronous transfer transmit data setup function. With this function, the frame that started data transmission can be identified.

When the buffer memory is used as a double buffer, even if writing data to both buffers is completed, only one side that finished writing earlier becomes transferable. For this reason, even if multiple IN tokens are received in the same frame, only one packet of the buffer memory is sent.

When the buffer memory is ready for transmission in the IN token reception cycle, this module sends data and an ACK response. However, when the buffer memory is not ready for transmission, this module sends a Zero-Length packet and generates an underrun error.

Figure 52.14 shows an example of transmission using the isochronous transfer transmit data setup function of this module when IITV = 0 (each frame). Transmission of a Zero-Length packet is indicated as hatched “Null” in the figure.

**Figure 52.14 Example of Transmit Data Setup Function**

### (5) Transmit Buffer Flush in Isochronous Transfer

In isochronous data transmission is selected, this module receives no IN token in the interval frame. When this module receives the SOF or  $\mu$  SOF packet of the next frame, this module regards the IN token as damaged and clears the buffer that is ready for transmission to make it writable.

At this time, when the buffer memory is used as a double buffer and writing data to both buffers is completed, this module regards the discarded buffer memory data as transmitted in the same interval frame, and drives the buffer memory that is not discarded due to the reception of an SOF or  $\mu$  SOF packet into the transmission ready state.

The buffer flush function activation timing varies depending on the IITV value.

- When IITV = 0  
This module activates the buffer flush function from the next frame after the pipe is enabled.
- When IITV  $\neq$  0  
This module activates the buffer flush function from the first normal transaction.

Figure 52.15 shows an example of the buffer flush function of this module. For tokens before the interval frame (outside the specified interval), however, this module sends the data stored in the buffer according to the data setup state or sends a Zero-Length packet as an underrun error.

**Figure 52.15 Example of Buffer Flush Function**

Figure 52.16 shows an example of an interval error of this module. Interval errors are the following five. An interval error occurs at timing [1] in the figure, and the buffer flush function is activated.

When an interval error occurs, the buffer flush function is activated in the IN transfer and an NRDY interrupt occurs in the OUT transfer. Discriminate an NRDY interrupt (including a receive packet error) from an overrun error with the OVRN bit.

This module sends a response to the hatched tokens in the figure according to the buffer memory status.

1. IN direction
  - When the buffer is ready to transmit data, this module sends the data and an ACK response.
  - When the buffer is not ready to transmit data, this module sends a Zero-Length packet and generates an underrun error.
2. OUT direction
  - When the buffer is ready to receive data, this module receives data and sends an ACK response.
  - When the buffer is not ready to receive data, this module discards the data and generates an overrun error.

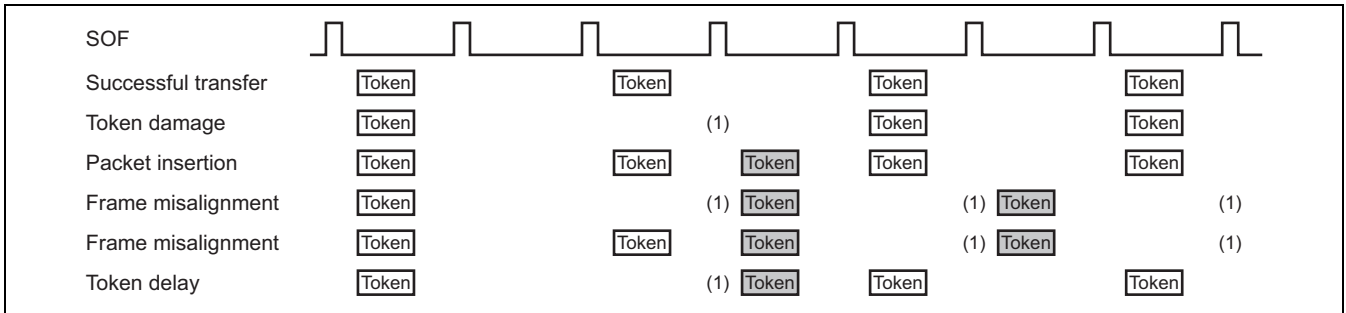

Figure 52.16 Example of Interval Error when IITV = 1

### 52.3.9 SOF Interpolation Function

In case this module cannot receive SOF packets at intervals of 1 ms (full-speed operation) or 125  $\mu$ s (high-speed operation) due to damage or missing of SOF packets, this module interpolates the SOF. The SOF interpolation starts functioning when SYSCFG.USBE = 1 and at the SOF packet receive timing. Furthermore, the interpolation function is initialized in the following cases.

- Power-on reset
- USB bus reset
- When the suspended state is detected

The SOF interpolation functions with the following specifications.

- The frame intervals (125  $\mu$ s or 1 ms) conform to the result of the reset handshake protocol.
- The SOF interpolation does not function until this module receives an SOF packet.
- After receiving the first SOF packet, 125  $\mu$ s or 1 ms is counted by the internal 48-MHz clock to interpolate the SOF.
- After receiving the second SOF packet or a following packet, the SOF is interpolated using the previous receive intervals.
- The SOF interpolation does not function in the suspended state and during a USB bus reset.  
(When this module enters the suspended state in high-speed operation, the SOF interpolation continues for 3 ms from the final packet.)

This module activates the following functions based on the reception of SOF packets. When one or more SOF packets are lost, normal operation can be continued to perform the SOF interpolation.

- Updating frame numbers and  $\mu$  frame numbers
- SOFR interrupt timing and  $\mu$  SOF lock
- Isochronous transfer interval count

When one or more SOF packets are lost in full-speed operation, the FRNM bits in FRMNUM are not updated. When one or more  $\mu$  SOF packets are lost in high-speed operation, the FRNM bits are updated. However, when a  $\mu$  SOF packet with UFRNM = B'000 is lost, the FRNM bits are not updated even if following  $\mu$  SOF packets with UFRNM  $\neq$  B'000 are successfully received.

## 52.4 Guidelines for Designing USB2.0 Hi-Speed Boards

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 52.4.1 USB Transmission Line

The USB transmission line indicates the pattern that connects the USB connector and the USB transceiver with built-in this LSI.

The USB2.0 has three communication modes: Hi-Speed, Full-Speed and Low-Speed modes. The transmission speed in the Hi-Speed mode is 480 Mbps. Therefore, the USB transmission line must be designed as a high-frequency circuit. Impedance control is required for the USB transmission line.

- The characteristic impedance required for the USB Hi-Speed transmission line is differential impedance  $90\ \Omega$  ( $\pm 15\%$ ).
- The pattern width and pattern pitch for impedance control vary depending on the board thickness, material and layer configuration. For details, consult the board manufacturer.
- A maximum delay of 1 ns is allowed from the USB connector to this LSI. Therefore it is recommended that the pattern length from the USB device to the USB connector is less than 50 mm and the difference between the pattern lengths for D+ and D- is less than 2.5 mm for a generic PCB.
- The lower layer of the USB transmission line must be a solid ground plane. The ground must be wider than the USB transmission line by 2 mm or more. The power supply for a solid ground plane is DG33.
- Do not allocate other signal lines near to the USB transmission line. In particular, lines carrying widely fluctuating signals, such as clock and data bus lines, must be assigned far from the USB transmission line. Furthermore, layout of the USB transmission lines must be such that they do not cross with other signal lines.
- Locate the USB transmission line on the same layer without passing it through a through-hole. Do not create stubs.
- Place the USB transmission lines so that they are equally spaced from each other.
- Locate the USB transmission line as far as possible from the oscillator, power supply circuit, and other I/O connectors.
- Try to avoid bending the USB transmission line as far as possible. If it is absolutely necessary to bend it, do not bend it at acute or right angles. Bend it moderately, at not more than 45 degrees, or bend it into an arc.
- It is recommended to guard ring the clock, reset, read, write and chip select signals with grounds.

When a resistance is connected to the USB transmission line, locate it near to the USB transmission line. The connecting wire must be as short as possible.

### 52.4.2 Power Supply and Ground Pattern

Analog power supply: AVDD (1.8 V)

Digital power supply: DV181 (1.8 V), DV331 (3.3 V)

Analog ground: PVSS, AVSS

Digital ground: GND1, GND2

- It is recommended to separate power supplies and ground patterns into digital and analog.
- Connect the power supplies and grounds firmly on wide areas.
- Tantalum solid electrolytic capacitors or ceramic capacitors having excellent high-frequency characteristics are recommended as capacitors for power supplies.
- Aluminum electrolytic capacitors affect the jitter value during measurement of EYE diagram. Use the capacitors after adequately designing and testing them.
- It is recommended to place decoupling capacitors with values of 0.1  $\mu\text{F}$ , 0.01  $\mu\text{F}$ , and 0.001  $\mu\text{F}$  as close as possible to the USB power supply.

### 52.4.3 Oscillation

- USB clock is supplied by the internal PLL.
- Provide an oscillation circuit near the clock input pin for USB (EXTAL). It is recommended to guard ring EXTAL with a ground.
- When using a crystal resonator, consult its manufacturer to determine the circuit constant.

### 52.4.4 VBUS

- This HS-USB subsystem cannot connect 5 V signals so that vbus status is informed by ovc0 and ovc1 status.

### 52.4.5 RREF Pin

- Provide a resistor (hereafter called reference resistor) of  $1.8\text{ k}\Omega \pm 1\%$ , between the RREF pin and AVSS, PVSS.
- Locate the reference resistor as close as possible to this LSI.
- The RREF pin, the reference resistor, PVSS and AVSS should be wired on wide areas and the shortest length.
- Use a wiring pattern for and only for the reference resistor, PVSS and AVSS. The pattern should be connected to the analog ground. The pattern should be designed avoiding the possibility for common impedance between RREF and other signals.
- To prevent cross talk, very-frequently switched signals such as DP, DM, clocks, and control signals for addresses and data, should not be placed near to the reference resistor, and their patterns should neither get across nor go parallel to the wiring pattern between the reference resistor and the RREF pin.

It is recommended to guard ring the reference resistor and its wiring pattern with ground.

## 53. USB High-Speed DMAC (USB-DMAC)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 53.1 Features

- Three types of clock: ZS $\phi$ , HP $\phi$  and HS-USB local bus clock (48 MHz), which are asynchronously absorbed in the local bus bridge and AXI bus bridge.
- The AXI bus interface functions are implemented.  
The AXI bus interface handles data transfer with the memory and register settings.
- Data communication is performed using the local DMA protocol.
- Supports two channels that can work concurrently.
- Interrupts
  - Setting count end interrupt
  - USB-DMAC is composed of USB-DMAC0 and USB-DMAC1. There are 2 channels in USB-DMAC0 and 2 channels in USB-DMAC1.
  - Transfer end interrupt upon receiving a short packet from the USB-IP  
This function allows generation of an interrupt even in the case where DMA transfer ends after receiving data less than the transfer size set in the DMAC.
  - Timeout interrupt  
A timeout interrupt can be generated after the specified cycles after the last HS-USB transfer request. (This interrupt is used for the timeout when the final packet received is Max packet.)
  - Interrupts can also be generated when a NULL packet is received or an address error is detected.

**Table 53.1 Main Functions of This Module**

Item	Description
Application	Transfer between USB-IP (FIFO) and AXI bus (4-Gbyte arbitrary space)
Purpose of DMA transfer	High-speed data transfer between USB-IP and AXI bus
DMA transfer end notification to the software	Interrupt signals (transfer count end, USB-IP short packet reception, timeout, etc.)
Transfer space/transfer address direction	4-Gbyte arbitrary space (forward direction) to 4-Gbyte arbitrary space (forward direction)
Maximum transfer count	16,777,216
Transfer unit	8, 16, or 32 bytes
Control signals generated	Address/data read/data write conforming to the USB-IP local bus interface and AXI bus protocols
Number of channels	2 (parallel operation enabled)
Bus specification	AXI bus, local bus (USB-IP local bus)
Clock	AXI bus clock (ZS $\phi$ : 260 MHz), HPB bus clock (HP $\phi$ : 130 MHz) USB local bus clock (48 MHz) Note: The restrictions of ratio of the clock $ZS\phi \geq HP\phi \geq 48 \text{ MHz}$ Please don't change the clock frequency during USB-DMAC0 or USB-DMAC1 transferring.
Maximum transfer rate	IN transfer: About 350 Mbps (USB-DMAC0) OUT transfer: About 340 Mbps (USB-DMAC0) IN transfer: About 175 Mbps (USB-DMAC1) OUT transfer: About 170 Mbps (USB-DMAC1)

**Table 53.2 Bus Access Type**

	Supported Access Type
AXI bus access (USB-DMAC master)	8-byte read/write 16-byte read/write 32-byte read/write
USB-DMAC register setting	4-byte read/write 8-byte read/write

The configuration of this module is shown below.

This module is provided with buffers and bus bridges and controls transfers between the AXI bus and USB High-Speed module (HS-USB).

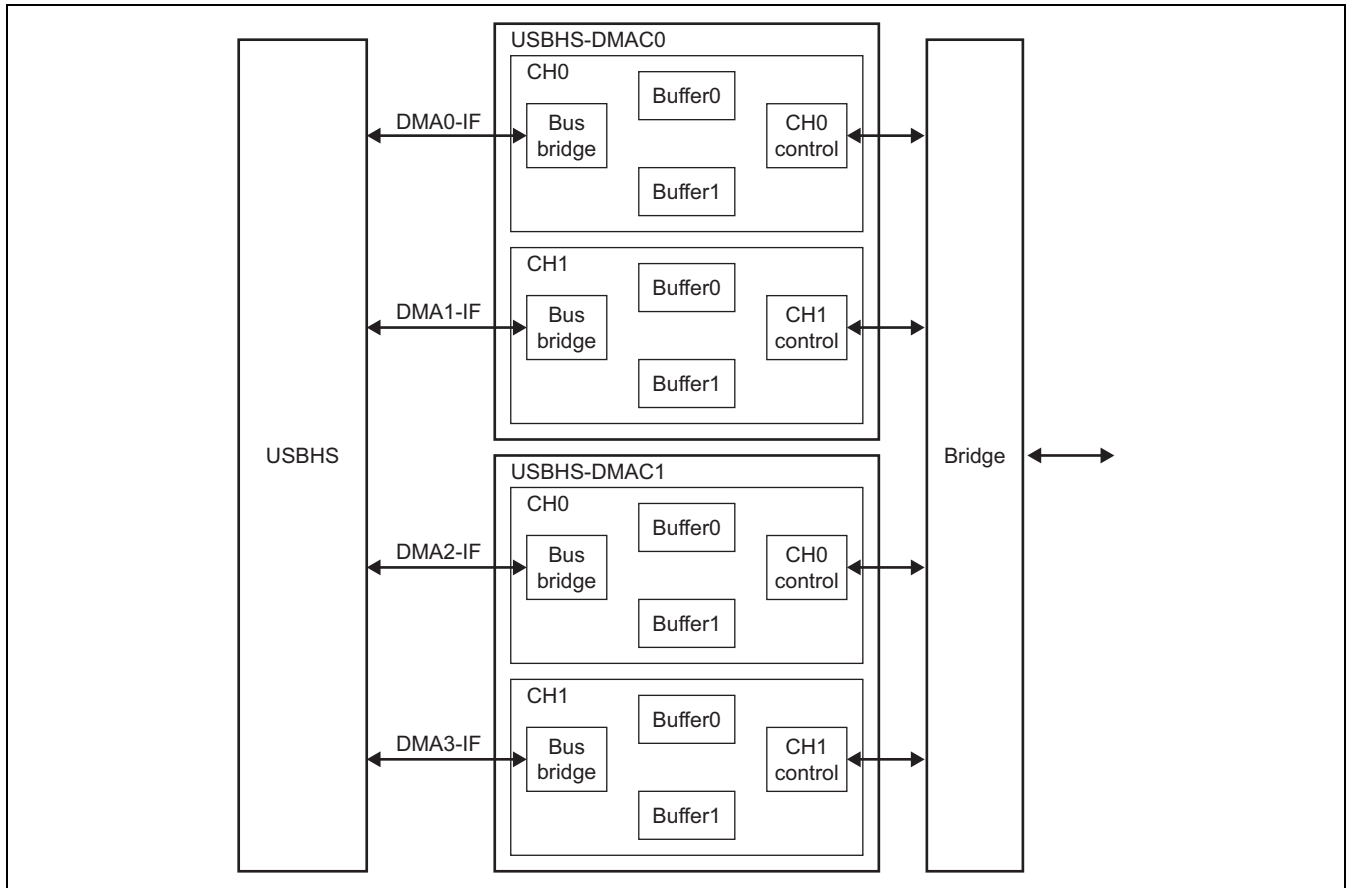

Figure 53.1 USB-DMAC Configuration

## 53.2 Register Descriptions

Table 53.3 shows the register configuration. Table 53.4 shows the register states in each processing mode.

**Table 53.3 Register Configuration**

Register Name	Abbreviation	R/W	Address	Access Size	RZ/G Series Products			
					RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
DMA0 VCR register	USBDMA0_VCR	R/W	H'E65A 0000	32	√	√	√	√
DMA0 Software reset register	USBDMA0_SWR	R/W	H'E65A 0008	32	√	√	√	√
DMA0 interrupt source register	USBDMA0_DMICR	R	H'E65A 0010	32	√	√	√	√

8	TE1	0	R	CH1 Transfer End Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TE in the channel 1 control register is reflected.)
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	TR0	0	R	CH0 Transaction End Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TR in the channel 0 control register is reflected.)
5	BUF0	0	R	CH0 Buffer End Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (BUF in the channel 0 control register is reflected.)
4	RW0	0	R	CH0 RWEND Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (RW in the channel 0 control register is reflected.)
3	NULL0	0	R	CH0 NULL Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (NULL in the channel 0 control register is reflected.)
2	TO0	0	R	CH0 Timeout Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TO in the channel 0 control register is reflected.)
1	SP0	0	R	CH0 Short Packet Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (SP in the channel 0 control register is reflected.)
0	TE0	0	R	CH0 Transfer End Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TE in the channel 0 control register is reflected.)

**53.2.4 DMA0/1 Source Address Registers 0 and 1 (USBDMA0\_SAR\_0/USBDMA1\_SAR\_1)**

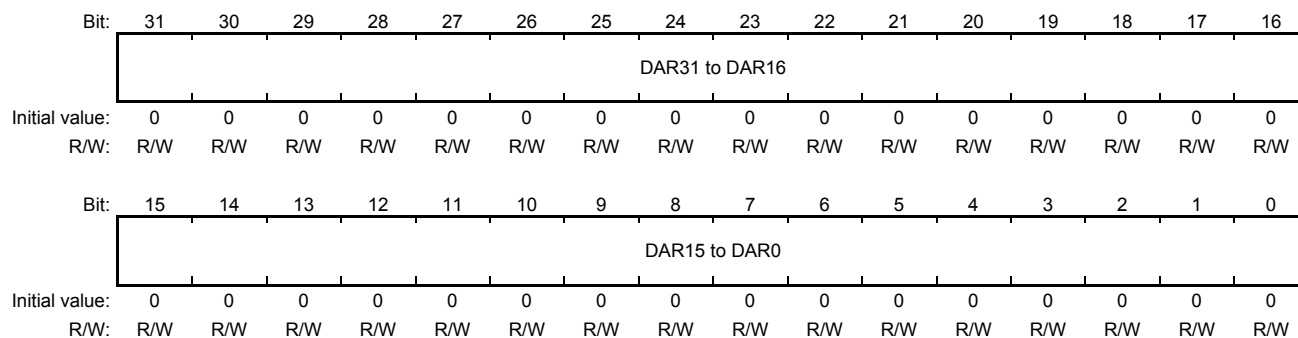

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR31 to SAR0	H'0000 0000	R/W	Source Address (H'00000000 to H'FFFFFFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer source address during a DMA transfer.

**53.2.5 DMA0/1 Destination Address Registers 0 and 1 (USBDMA0\_DAR\_0/USBDMA1\_DAR\_1)**

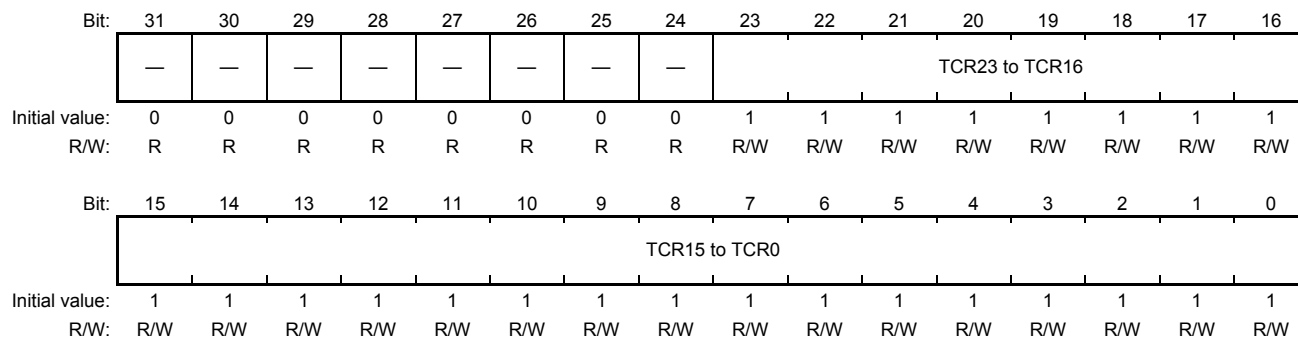

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR31 to DAR0	H'0000 0000	R/W	Destination Address (H'00000000 to H'FFFFFFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer destination address during a DMA transfer.

**53.2.6 DMA0/1 Transfer Count Registers 0 and 1 (USBDMA0\_TCR\_0/USBDMA1\_TCR\_1)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

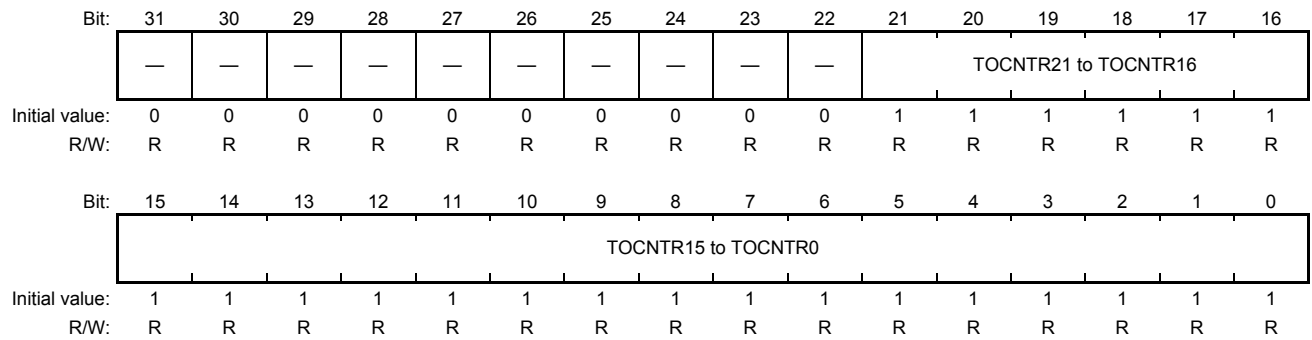

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	TCR23 to TCR0	H'FF FFFF*	R/W	Transfer Count <ul style="list-style-type: none"> <li>When H'000001 is set, total transfer volume is as follows: Transfer size = 32 bytes: 32 × 1 bytes Transfer size = 16 bytes: 16 × 1 bytes Transfer size = 8 bytes: 8 × 1 bytes</li> <li>When H'FFFFFF is set, 16,777,215 times</li> <li>When H'000000 is set, 16,777,216 times (maximum)</li> <li>Indicate 0 when a DMA transfer completes successfully.</li> </ul>

Note: \* To read this register, read the internal transfer counter value (the TCR counter value) directly. This register is read as all 1 after a reset is cleared because the initial value of the TCR counter is all 1 (H'FFFFFF). When DMA is enabled (DE in USBDMA0/1\_CHCR is asserted), the TCR counter is loaded with the value set in this register and decrements during DMA transfers. This means that the remaining transfer count is read back. Note that the read value may be different from the one set in this register due to this reason.

**53.2.7 DMA0/1 Timeout Count Registers 0 and 1 (USBDMA0\_TOCNTR\_0/USBDMA1\_TOCNTR\_1)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

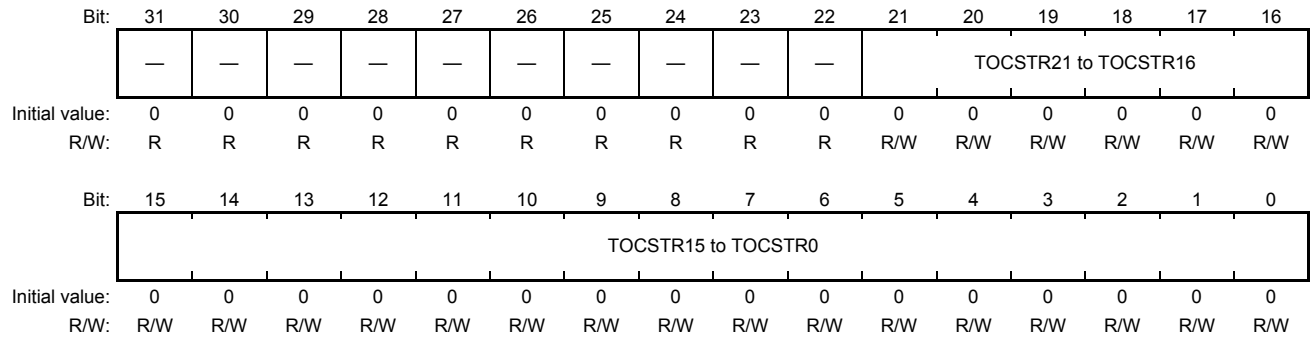

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCNTR21 to TOCNTR0	H'3F FFFF	R	Timeout Counter Value (H'000000 to H'27AC40) Indicate the remaining timeout count during timeout counting. (Countable up to H'3FFFFFF (approximately 21 ms) by the hardware. See the descriptions of the USBDMA0/1_TOCSTR register.)

**53.2.8 DMA0/1 Timeout Constant Registers 0 and 1  
(USBDMA0\_TOCSTR\_0/USBDMA1\_TOCSTR\_1)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCSTR21 to TOCSTR0	H'00 0000	R/W	Timeout Constant Value (H'000000 to H'27AC40) Set a timeout value (at 200 MHz cycle). The maximum timeout time is approximately 13ms. (Setting up to H'3FFFFFF (approximately 21 ms) is allowed by the hardware.)

## 53.2.9 DMA0/1 Channel Control Registers 0 and 1 (USBDMA0\_CHCR\_0/USBDMA1\_CHCR\_1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TR	BUF	RW	NULL	—	—	—	—	TS1	TS0	IE	TOE	TO	SP	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FTE	0	(R)/W	Forced TE Set Register When a NULL packet is received, the TE bit is forced to 1 to terminate the transfer by setting 1 in this register. (The DREQE bit of the USB-IP should also be controlled accordingly. For details on the control procedure and restrictions, see section 53.3.2 (3), DMA transfer flow.) This bit is always read as 0. 0: No effect (nothing happens). 1: Forces the TE bit to 1.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SPIM	0	R/W	Short Packet Receive Interrupt Mask Enables or disables the reflection of the short packet (SP) receive flag in the interrupt signal. If this bit is set to 1, no interrupts are generated when an SP is received. However, the SP receive flag (the SP bit) is set regardless of this register setting. 0: The short packet receive interrupt is enabled (default). 1: The short packet receive interrupt is disabled.
19	TRE	0	R/W	Transaction End Detect Interrupt Flag Enable Enables or disables the reflection of TR in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the TR bit is always 0.) 0: The TR flag is disabled. 1: The TR flag is enabled.
18	BUFE	0	R/W	Buffer End Detect Interrupt Flag Enable Enables or disables the reflection of BUF in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the BUF bit is always 0.) 0: The BUF flag is disabled. 1: The BUF flag is enabled.

Bit	Bit Name	Initial Value	R/W	Description
17	RWE	0	R/W	<p>Final Buffer Access Detect Interrupt Flag Enable</p> <p>Enables or disables the reflection of RW in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the RW bit is always 0.)</p> <p>0: The RW flag is disabled. 1: The RW flag is enabled.</p>
16	NULLE	0	R/W	<p>NULL Receive Interrupt Flag Enable</p> <p>Enables or disables the reflection of the NULL receive interrupt flag (NULL) in the interrupt signal.</p> <p>0: The NULL receive interrupt flag is disabled. 1: The NULL receive interrupt flag is enabled.</p>
15	TR	0	R/W*	<p>Transaction End Detect Interrupt Flag</p> <p>When the transaction end is detected, an interrupt is generated.</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A transaction end receive interrupt is generated.</p>
14	BUF	0	R/W*	<p>Buffer End Detect Interrupt Flag</p> <p>When the end of the buffer is detected, an interrupt is generated.</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A buffer end detect interrupt is generated.</p>
13	RW	0	R/W*	<p>Final Buffer Access Detect Interrupt Flag</p> <p>When the final access to the buffer is detected, an interrupt is generated.</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A final buffer access detect interrupt is generated.</p>
12	NULL	0	R/W*	<p>NULL Receive Interrupt Flag</p> <p>When NULL packet is received, an interrupt is generated.</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A NULL packet receive interrupt is generated.</p>
11 to 8	—	All 0	R	<p>Reserved</p> <p>The bits should always be written as 0.</p>

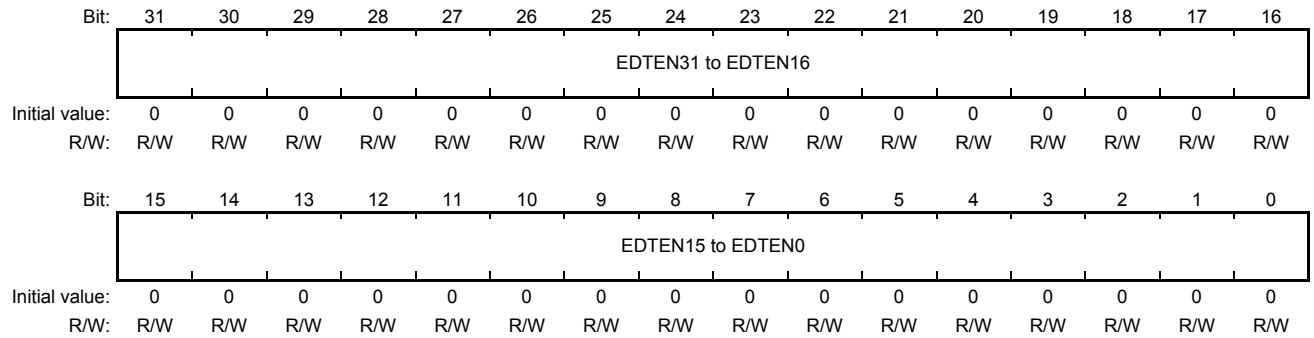

Bit	Bit Name	Initial Value	R/W	Description
7, 6	TS1 to TS0	00	R/W	<p>DMA Transfer Size</p> <p>00: 8 bytes 01: 16 bytes 10: 32 bytes 11: Setting prohibited</p> <p>Specify the same transfer size and address boundary when setting addresses in USBDMA0/1_SAR and USBDMA0/1_DAR as a transfer source and transfer destination.</p> <p>If TS = 11 is set, an address error is generated and DMA transfer is disabled.</p>
5	IE	0	R/W	<p>Interrupt Enable</p> <p>Enables or disables an interrupt request to the CPU when DMA transfer ends. When AE, TE, SP, TO, NULL, RW, BUF, or TR bit is set with this bit set to 1, an interrupt request is output to the CPU.</p> <p>However, when the TRE, BUFE, RWE, NULLE, or TOE bit is set to disabled, no interrupt due to TR, BUF, RW, NULL, or TO is generated.</p> <p>0: An interrupt request is disabled. 1: An interrupt request is enabled.</p>
4	TOE	0	R/W	<p>Timeout Enable</p> <p>Enables or disables the reflection of the timeout flag (TO) in the interrupt.</p> <p>0: Timeout flag is disabled. 1: Timeout flag is enabled.</p>
3	TO	0	R/W*	<p>Timeout Flag</p> <p>After a transfer request REQ is negated, a timeout interrupt is generated after the specified cycles. (Used for timeout when the final packet is Max packet.)</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: Timeout is generated.</p>
2	SP	0	R/W*	<p>Short Packet Receive Flag</p> <p>A transfer end interrupt is generated upon receiving a short packet from the USB-IP. For example, if DMA transfer size is set to 1 MB but actual data transfer is 900 KB, this interrupt is generated when transfer of 900 KB finishes.</p> <p>0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A short packet is received.</p>

Bit	Bit Name	Initial Value	R/W	Description
1	TE	0	R/W*	<p>Transfer End Flag</p> <p>When a DMA transfer ends with USBDMA0/1_TCR = 0, the TE bit is set to 1. When a DMA address error occurs before USBDMA0/1_TCR is cleared to 0 and the transfer is suspended by clearing the DE bit and the DME bit in USBDMA0/1_DMAOR, the TE bit is not set to 1. To clear the TE bit, write 0 after reading 1. When TE = 1, DMA transfer is disabled even if the DE bit is set to 1.</p> <p>0: DMA transfer is in progress or suspended.            [Clearing condition]            Writing 0 after reading 1.</p> <p>1: DMA transfer end (TCR = 0)</p>
0	DE	0	R/W	<p>DMA Enable</p> <p>Enables or disables DMA transfer. Setting the DME bit in USBDMA0/1_DMAOR and the DE bit for the corresponding channel to 1 starts a DMA transfer, provided that all interrupt flags are 0. Clearing the DE bit to 0 suspends the ongoing transfer after the transfer of one transaction is completed.</p> <p>0: DMA transfer is disabled.            1: DMA transfer is enabled.</p>

Note: \* Only writing 0 to clear the flag is enabled.

**53.2.10 DMA0/1 Final Transaction Valid Data Transfer Enable Registers 0 and 1 (USBDMA0\_TEND\_0/USBDMA1\_TEND\_1)**

### 53.3.1 Interrupt/Error Detection Function

This section describes the interrupt/error detection function that is implemented in this module.

Table 53.5 lists the mask, source, and flag registers for each interrupt type.

**Table 53.5 Registers by Interrupts/Errors**

	Interrupt Generation	Interrupt Mask Register	Interrupt Mask Register (Individual Mask)	Source Register	Flag Register
Transfer count end	√	X*1_CHCR_x.IE	—	X*1_DMICR.TEx	X*1_CHCR_x.TE
Short packet receive	√	X*1_CHCR_x.IE	X*1_CHCR_x.SPIM	X*1_DMICR.SPx	X*1_CHCR_x.SP
NULL packet receive	√	X*1_CHCR_x.IE	X*1_CHCR_x.NULLE	X*1_DMICR.NULLx	X*1_CHCR_x.NULL
Timeout	√	X*1_CHCR_x.IE	X*1_CHCR_x.TOE	X*1_DMICR.TOx	X*1_CHCR_x.TO
Transaction end detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.TRE*	X*1_DMICR.TRx	X*1_CHCR_x.TR
Buffer end detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.BUFE*	X*1_DMICR.BUFx	X*1_CHCR_x.BUF
Final buffer access detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.RWE*	X*1_DMICR.RWx	X*1_CHCR_x.RW
Address error	√	X*1_CHCR_x.IE	—	X*1_DMICR.AE	X*1_DMAOR.AE
Response packet error	—	—	—	—	X*1_VCR.ERR_SNT X*1_VCR.ERR_RCV

Legend: X\*1: USBDMA0/USBDMA1

Note: These registers not only mask interrupt generation but also disable error processing (flag sources and flag clearing).

Table 53.6 shows the processing to be executed when different interrupts occur. DMA transfer control is not affected when the NULL packet receive, timeout, or response packet error interrupt occurs. When the transfer count end interrupt occurs, processing is restarted. Processing can be resumed or restarted after interrupts occur from other sources.

**Table 53.6 Processing to be Executed When Interrupts Occur (Suspend/Resume/Restart)**

	Suspend/Resume	Terminate/Restart	Suspend/Resume/Restart Control Mask Register
Transfer count end	—	√	—
Short packet receive	√	√	—
NULL packet receive	—	√*	—
Timeout	—	√	—
Transaction end detect	√	√	USBDMA0/1_CHCR_x.TRE
Buffer end detect	√	√	USBDMA0/1_CHCR_x.BUFE
Final buffer access detect	√	√	USBDMA0/1_CHCR_x.RWE
Address error	√	√	—
Response packet error	—	—	—

Note: \* When a NULL packet is received, processing is forced to be terminated and restarted by the FTE bit (see section 53.3.2 (3), DMA transfer flow.).

The internal circuit is reloaded register values when restarted, but not when resumed.

Table 53.7 lists the interrupt generating conditions.

**Table 53.7 Interrupt Generating Conditions**

<b>Interrupt Name</b>	<b>Interrupt Conditions</b>
Transfer count end interrupt	When the final data transfer of the specified transfer count (in the USBDMA0/1_TCR register) completes IN transfer: When the final access to USB-IP completes OUT transfer: When the data transmission to the AXI completes
Short packet receive interrupt	When the data transfer at the time the end of a transaction is detected completes
NULL packet receive interrupt	When a NULL packet is detected or the forced TE register is set
Timeout interrupt	When the specified time elapses after the last transfer request
Transaction end detect interrupt	When the end of a transaction is detected
Buffer end detect interrupt	When the end of the buffer is detected
Final buffer access detect interrupt	When the final access to the buffer is detected
Address error interrupt	When invalid access to the DMAC register is attempted (With invalid USBDMA0/1_SAR/USBDMA0/1_DAR values or invalid transfer size (TS) specified)
Response packet error	Error Transmission (ERR_SNT) When accessed by a transaction that is not supported Error Reception (ERR_RCV) When received a response packet error from the system

Figure 53.2 shows a block diagram of the interrupt circuit.

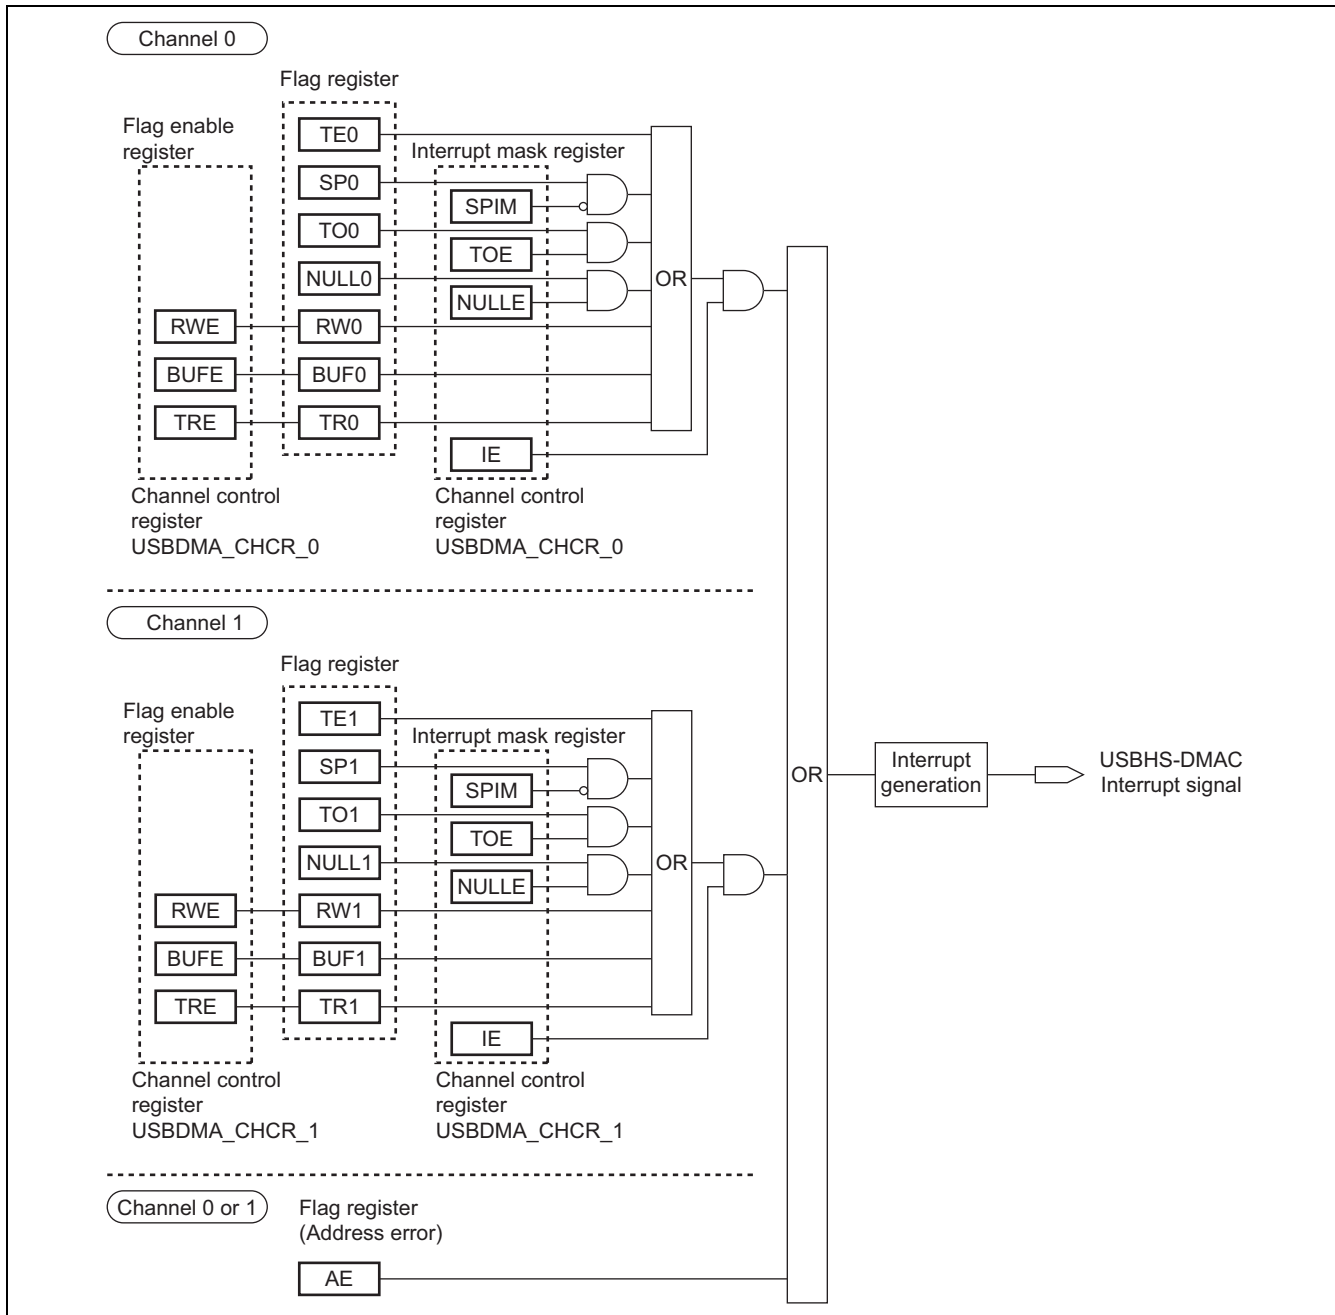

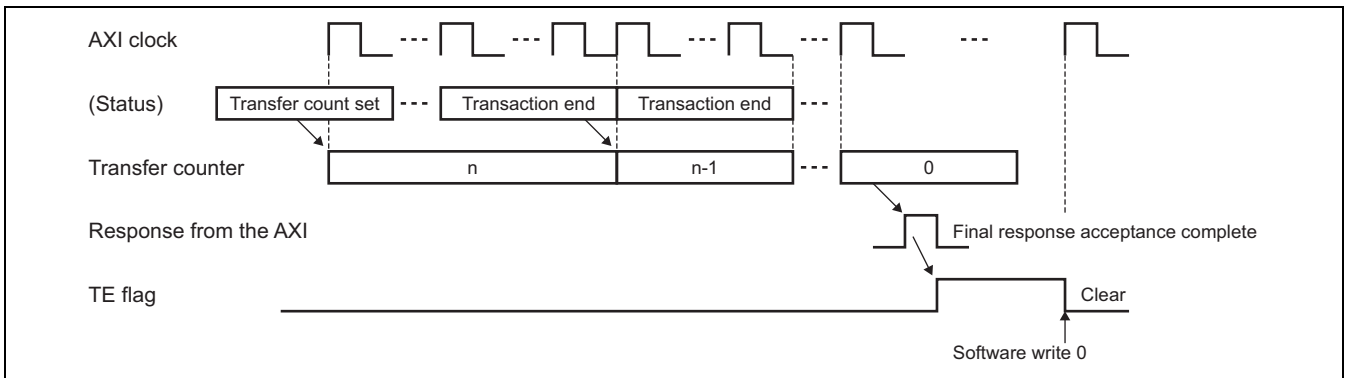

Figure 53.2 Block Diagram of Interrupt Circuit

**(1) Transfer count end interrupt (TE flag)**

Can be generated when the specified number of transfers complete or the FTE bit in the channel control register (USBDMAC0/1\_CHCR\_0 to USBDMAC0/1\_CHCR\_1) is set to 1. When the IE bit in the USBDMAC0/1\_CHCR\_0 to USBDMAC0/1\_CHCR\_1 is set to 0, no interrupts are generated. However, the TE bit in USBDMAC0/1\_CHCR\_0 to USBDMAC0/1\_CHCR\_1 and the TE0 or TE1 bit in the interrupt source register (USBDMAC0/1\_DMICR) are set to 1 regardless of the IE bit setting.

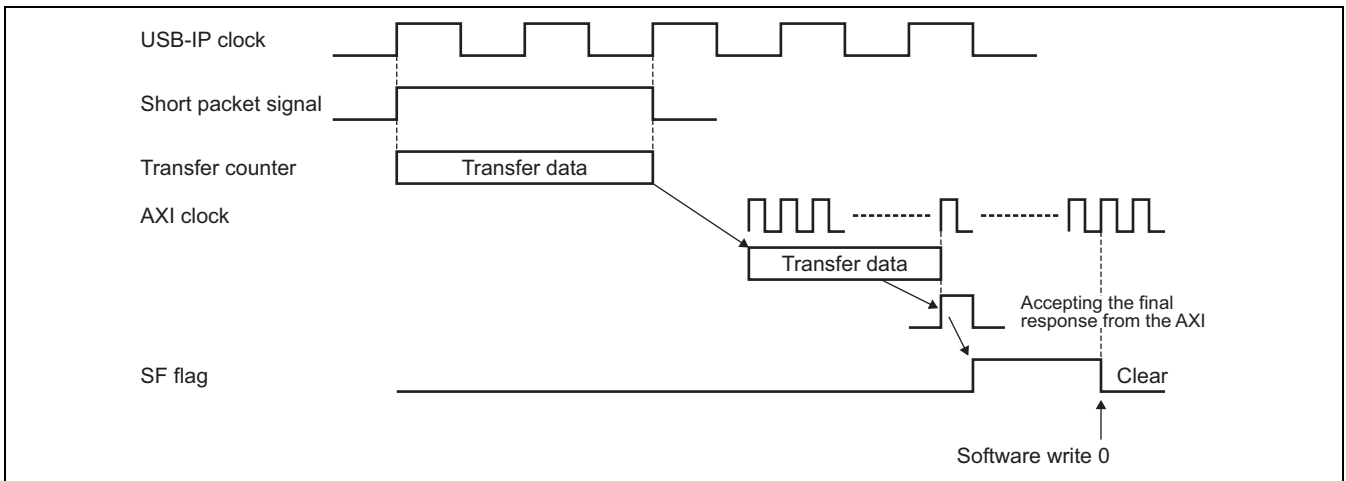

The internal transfer counter is loaded with the value set in the USBDMAC0/1\_TCR\_x register and decrements based on the AXI clock every time one transaction (8-/16-/32-byte) completes. When the transfer count value reaches 0 (the end of a transfer count), the counter sets the TE (transfer end) flag from 0 to 1 (when the FTE bit is set, it is reflected on the TE flag immediately). The TE bit is cleared by writing 0 to it after reading it as 1 by software.

**Figure 53.3 Transfer Count End Interrupt (TE) Generation Timing**

**(2) Short packet receive interrupt (SP flag)**

Can be generated when a short packet is detected. When the SPIM bit in the USBDMAC0/1\_CHCR\_x register is set to 1, no interrupts are generated. However, the SP bit (SP flag) in the USBDMAC0/1\_CHCR\_x register and the SP0 or SP1 bit in the USBDMAC0/1\_DMICR register are set to 1, regardless of the SPIM bit setting. The SP bit is cleared by writing 0 to it after reading it as 1 by software.

**Figure 53.4 Short Packet Receive Interrupt (SP) Generation Timing**

**(3) NULL packet receive interrupt (NULL flag)**

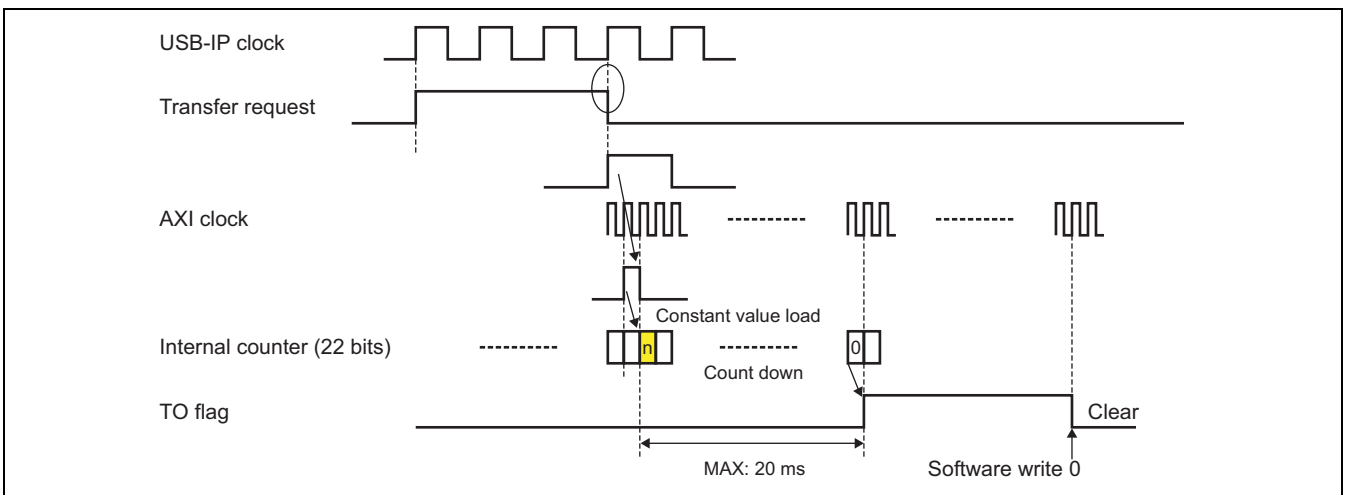

Can be generated when a NULL packet is detected. When the NULLE bit in the USBDMA0/1\_CHCR\_x register is set to 0, no interrupts are generated. However, the NULL bit (NULL flag) in the USBDMA0/1\_CHCR\_x register and the NULL0 or NULL1 bit in the USBDMA0/1\_DMICR register are set to 1, regardless of the NULLE bit setting. Note also that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a NULL packet is received. The software is responsible for implementing special processing if necessary since in this module this interrupt is designed only to signal the software that a NULL packet is received.

**Figure 53.5 NULL Packet Receive Interrupt (NULL) Generation Timing**

**(4) Timeout interrupt (TO flag)**

Can be generated when the time period that is specified in the timeout constant register (USBDMA0/1\_TOCSR\_0 or USBDMA0/1\_TOCSR\_1) elapses after the final transfer request is received from the USB-IP. On detecting the final transfer request, the internal counter is loaded with the value set in the USBDMA0/1\_TOCSR\_x register and starts counting down. When the counter reaches 0, it generates a timeout interrupt. Note that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a timeout interrupt occurs. The TO bit is cleared by writing 0 to it after reading it as 1 by software. Figures 53.6 and 53.7 show the timeout interrupt generation timing.

**Figure 53.6 Timeout Interrupt (TO) Generation Timing**

**Figure 53.7 Timeout Interrupt Timing**

The functions described in section 53.3.1 (5) to 53.3.1 (9) are added to detect and notify the transitions on an individual signal line to the software, but no use is defined. They can be used as required.

**(5) Transaction end detect interrupt (TR flag)**

Can be generated when the end of a transaction is detected within the USB-IP. Note that the TR bit in the USBDMA0/1\_CHCR\_x register and the TR0 or TR1 bit in the USBDMA0/1\_DMICR register are not reflected in the interrupt signal when the TRE bit in the USBDMA0/1\_CHCR\_x register is set to 0.

**Figure 53.8 Transaction End Detect Interrupt Timing**

**(6) Buffer end detect interrupt (BUF flag)**

Can be generated when the end of the buffer in the USB-IP is detected. Note that the BUF bit in the USBDMA0/1\_CHCR\_x register and the BUF0 or BUF1 bit in the USBDMA0/1\_DMICR register are not reflected in the interrupt signal when the BUFE bit in the USBDMA0/1\_CHCR\_x register is set to 0.

**Figure 53.9 Buffer End Detect Interrupt Timing**

**(7) Final buffer access detect interrupt (RW flag)**

Can be generated when the final access to the buffer in the USB-IP is detected. Note that the RW bit in the USBDMA0/1\_CHCR\_x register and the RW0 or RW1 bit in the USBDMA0/1\_DMICR register are not reflected in the interrupt signal when the RWE bit in the USBDMA0/1\_CHCR\_x register is set to 0.

**Figure 53.10 Final Buffer Access Detect Interrupt Timing**

**(8) Address error detection**

This is a flag that indicates an address error interrupts has occurred when setting the source address register (USBDMA0/1\_SAR0 to USBDMA0/1\_SAR1) and the destination address register (USBDMA0/1\_DAR0 to USBDMA0/1\_DAR1). When the value written to the USBDMA0/1\_SAR or USBDMA0/1\_DAR register differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited), the AE bit in the USBDMA0/1\_DMAOR register is set to 1. There is no distinction between CH0 and CH1 for an address error (the AE bit is set to 1 when an address error occurs on CH0 or CH1).

While the AE is set, no DMA transfer is allowed even if the DE bit in the USBDMA0/1\_CHCR\_x register and the DME bit in the USBDMA0/1\_DMAOR register are set to 1. The address error interrupt is cleared by setting correct addresses in USBDMA0/1\_SAR\_x and USBDMA0/1\_DAR\_x.

**Table 53.8 Address Error Detection Conditions When Setting Transfer Sizes**

Transfer Size	Address Error Detection Conditions
TS = B'00 (8-byte transfer)	When data that is not aligned to 8-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
TS = B'01 (16-byte transfer)	When data that is not aligned to 16-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
TS = B'10 (32-byte transfer)	When data that is not aligned to 32-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
—	When B'11 (setting prohibited) is written to the TS bit (Writes to the TS bit are valid.)

**(9) Response packet error detection**

This function reports response packet errors when the interface between the AXI and this module is accessed in ways that are not listed in Table 53.2.

**(a) Transmitting response packet errors**

When a response packet error occurs during accessing from the AXI to this module, the ERR\_SNT bit in the USBDMA0/1\_VCR register is set to 1.\* The error signal is also sent to the AXI bus if the RM bit in the USBDMA0/1\_DMAOR register is 0. If the RM bit is set to 1, the error signal is masked (0 is signaled).

Note: \* When a response packet error occurs, the ERR\_SNT bit is set to 1 regardless of the RM bit setting. The ERR\_SNT bit is cleared by writing 0 after reading 1.

**Table 53.9 Response Packet Error Generation**

USBDMA0_DMAOR		
(RM bit) Setting	1 (Mask Mode)	0 (Normal Mode)
Response packet error signal notification to AXI	Signals the fixed value (0) to the AXI bus without determining if there is a response packet error.	Reports a response packet error to the AXI bus when it is accessed with a transfer size other than those supported in this module (4-byte read/write and 8-byte read).

**(b) Receiving response packet errors**

When a response packet error occurs during accessing from this module to the AXI, the ERR\_RCV bit in the USBDMA0/1\_VCR register is set to 1. The TID bit in the USBDMA0/1\_DMAOR register indicates on which channel of this module the error has occurred (TID[1]=1 means it has occurred on CH1 and TID[0]=1 on CH0).

The ERR\_RCV bit is cleared by writing 0 after reading 1.

### 53.3.2 DMA Transfer Function

#### (1) Operating mode

The following operating modes (a) to (b) are supported according to the setting of the PR bit in the DMA operation register (USBDMA0/1\_DMAOR).

##### (a) CH0 first control

Forces CH1 to wait to start a DMA transfer until a DMA transfer completes on CH0.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, CH0 takes precedence over CH1. If a DMA transfer is in progress on CH1 when CH0 tries to start a DMA transfer, CH0 waits to start it until the ongoing DMA transfer completes on CH1.

##### (b) CH1 first control

Forces CH0 to wait to start a DMA transfer until a DMA transfer completes on CH1.

When there is a timing conflict in starting a DMA transfer between CH1 and CH0, CH1 takes precedence over CH0. If a DMA transfer is in progress on CH0 when CH1 tries to start a DMA transfer, CH1 waits to start it until the ongoing DMA transfer completes on CH0.

Figure 53.11 shows an overview of the processing of the AXI bridge in each operating mode.

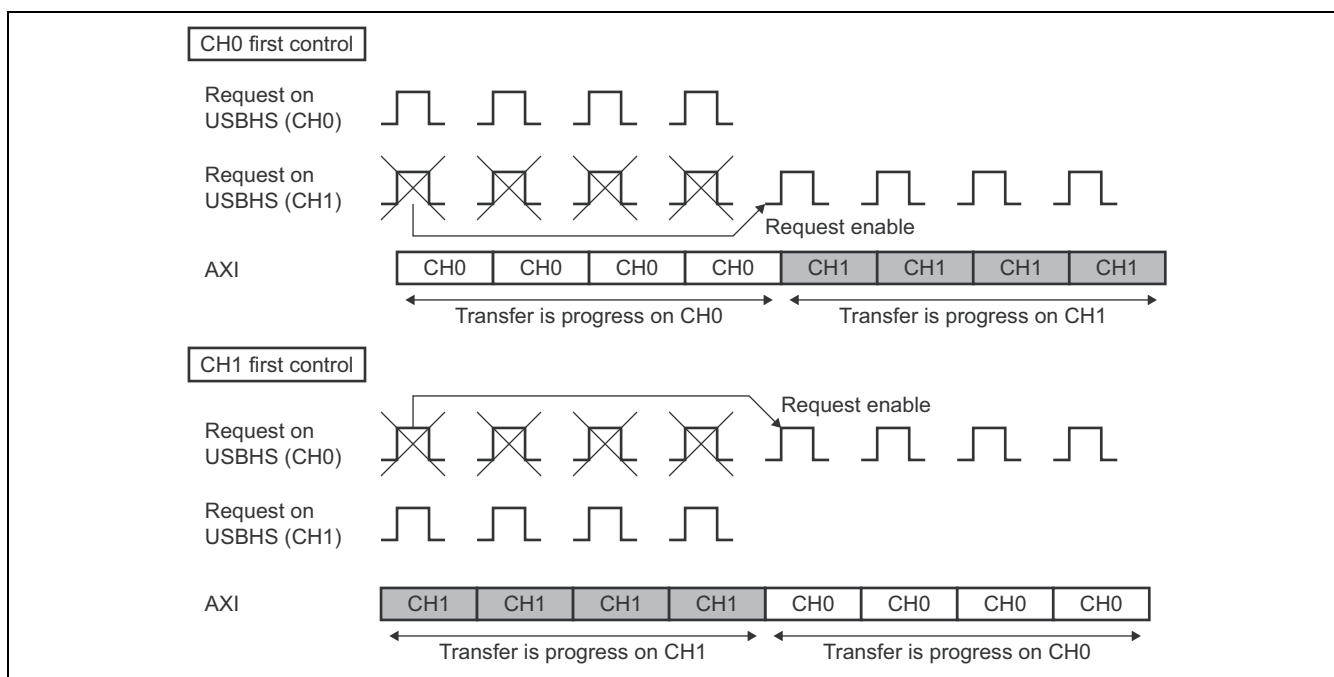

Figure 53.11 Overview of AXI Bridge Processing in Each Mode

**(2) Transfer size**

The transfer size on the AXI can be selected by setting the channel control register (the TS bit).

8-, 16-, and 32-byte can be set for each channel independently.

The following consideration should be observed during IN transfers.

The minimum transfer size that can be set to the TS bit is 8 bytes while the USB-IP can control transfers in 1-byte units. For example, if valid transfer data that is  $8 \times (n - 1) + \alpha$  ( $\alpha$  is less than 7 bytes) in size is to be transferred to the USB-IP with the transfer size set to 8 bytes and the transfer count set to  $n$ ,  $\alpha$  is transferred as a valid transfer unit by controlling byte enables according to the DMA final transaction valid data transfer enable register (the EDTEN bits) setting. Likewise, data is transferred in "transfer size x transfer count" (the final transaction is controlled by EDTEN) for 16- and 32-byte transfer sizes. The EDTEN setting is valid only for IN transfer and is don't care for OUT transfer.

Figure 53.12 shows an example of EDTEN setting. When only EDTEN31 in EDTEN31 to EDTEN0 is 1, one byte is enabled. When only EDTEN31 and EDTEN30 in EDTEN31 to EDTEN0 are 1, two bytes are enabled. Therefore, the total transfer volumes in the example shown above are calculated as "(32 bytes x (n - 1)) bytes + 10 bytes" for 32-byte transfer, "(16 bytes x (n - 1)) bytes + 7 bytes" for 16-byte transfer, and "(8 bytes x (n - 1)) bytes + 2 bytes" for 8-byte transfer. EDTEN15 to EDTEN0 in 16-byte transfer, EDTEN23 to EDTEN0 in 8-byte transfer are invalid (their values are ignored).

**Figure 53.12 Example of Final Transaction Valid Data Transfer Enable (EDTEN) Setting**

### (3) DMA transfer flow

After the DMA source address register (USBDMA0/1\_SAR), DMA destination address register (USBDMA0/1\_DAR), DMA transfer count register (USBDMA0/1\_TCR), DMA channel control register (USBDMA0/1\_CHCR), final valid data transfer enable register (USBDMA0/1\_TEND), and DMA operation register (USBDMA0/1\_DMAOR) are set appropriately, the DMAC starts data transfer in the following sequence. The DMA timeout constant register (USBDMA0/1\_TOCSTR) may also need to be set.

If the transfer enabling conditions are set as DE = 1, DME = 1, TE = 0, AE = 0, SP = 0, and (TR = 0, BUF = 0, RW = 0), transfers are performed according to the transfer request enables and transfer requests from the USB-IP. The transfer direction (IN/OUT transfer) is determined by the direction signal from the USB-IP. The transfer size is determined by the setting of TS1 to TS0.

Every time one AXI transaction (in the transfer size specified in the TS bit) completes, the internal counter of this module decrements the USBDMA0/1\_TCR value by one. When the specified transfer count ends (the USBDMA0/1\_TCR value reaches 0), it means all transfers complete. At this time, an USB-DMAC interrupt is generated if the IE bit in the USBDMA0/1\_CHCR register is set to 1.

When a NULL packet is received, transfer can be stopped or restarted by setting FTE = 1 after negating the DREQE bit of the HS-USB module. Follow the steps described later in "Control when a NULL packet is received".

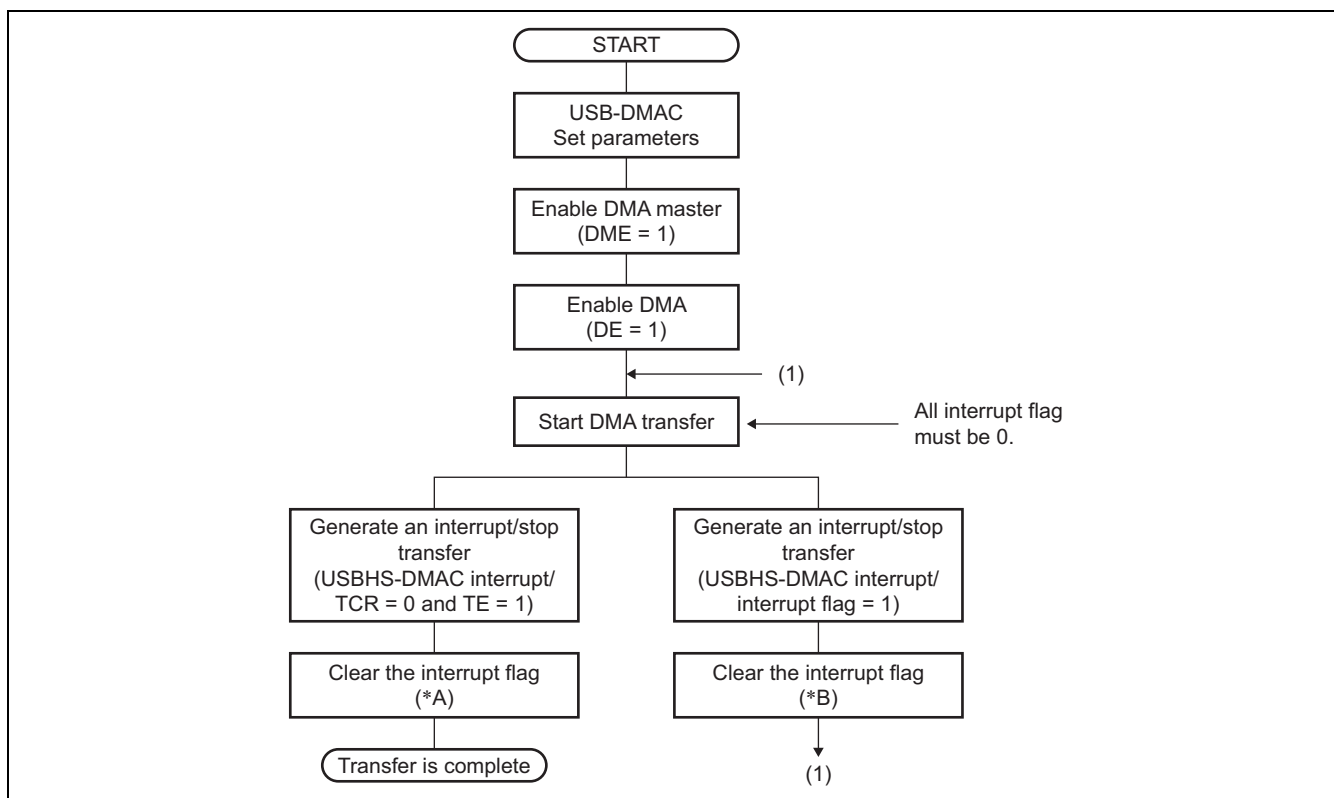

Table 53.10 shows the conditions for each DMA transfer.

**Table 53.10 DMA Transfer Conditions**

Transfer enabling condition	TE = 0, SP = 0, (*TR = 0, BUF = 0, RW = 0)
Transfer (starting) condition	When a transfer request is enabled by the USB-IP When a transfer request is issued by the USB-IP
Transfer completing (then restarting) condition	When the transfer count ends (the TE flag is set to 1), (can be restarted by setting DE and DME to 1.) When FTE = 1 (when DREQE = 1 in the HS-USB module is also set), and the steps described later should be followed. When reset (can enter into standby state by releasing the reset.)
Transfer suspending (then resuming) condition	When DE = 0 or DME = 0 (can be resumed by setting DE = 1 or DME = 1.) When SP = 1 (can be resumed by clearing the SP flag.) When RW = 1, BUF = 1, and TR = 1 (can be resumed by clearing the RW, BUF, and TR flag.)* When the module stops (can be resumed by resuming the module.)

Note: \* Can be ignored when the RWE, BUFE, and TRE bits are disabled (set to 0).

Figure 53.13 illustrates the high-level DMA transfer flow.

**Figure 53.13 DMA Transfer Flow Overview**

Where A and B apply to the following flags:

(Note that RW, BUF, and TR are not set when RWE, BUFE, and TRE are disabled, respectively.)

\* A: TE flag

\* B: SP, (RW, BUF, TR) flags

#### **When to change USBDMAC parameters**

USB-DMAC parameters (such as destination address or transfer count) should be changed while all interrupt flags are cleared and DE = 0 and DME = 0 are set (a transfer is started with the latest parameters when DME = 1 and DE = 1 are set). Furthermore, USB-DMAC parameters should not be changed while the DMA is enabled (DME = 1 and DE = 1).

#### **What to do if freeze**

If a transfer should freeze during operation, issue a software reset after setting DE = 0 and DME = 0 and clearing all interrupt flags. All hardware except configuration registers is initialized. Restart by setting DME and DE to 1 after updating USB-DMAC parameters if necessary.

#### **Control when a timeout occurs**

Since this module assumes bus access in the transfer units listed in Table 53.2, it cannot be restarted when a timeout occurs in an irregular case where it is being accessed with any size that are not in the table. This irregular case should be handled by software, such as by issuing a software reset (to both CH0 and CH1).

**Control when a NULL packet is received**

When a NULL packet is received during a DMA transfer, the DMA transfer can be suspended and resumed on each channel independently by controlling the FTE bit of this module and the DREQE bit of the HS-USB module in the following sequence.

[Control sequence]

During a DMA transfer (A)

- (1) A NULL packet is received (an interrupt is generated and the NULL flag is detected).
- (2) The DREQE bit of the HS-USB module is negated (= 0).
- (3) Wait for the internal bus to be stabilized.
- (4) Perform three actions at the same time; setting the FTE bit, clearing the NULL bit and negating the DE bit.

An interrupt is generated due to TE.

- (5) Clear the interrupt caused by TE.
- (6) Set the parameters (such as TCR or DAR) for the next transfer.
- (7) Assert the DE bit (= 1). The DMA is restarted.
- (8) Assert the DREQE bit (= 1).

Start a DMA transfer (B).

[Restrictions]

1) FTE bit set timing

If this module is accessing the AXI (SHBSYx bit = 1) when setting the FTE bit, you need to wait to set the FTE bit until this module's internal buffer is empty and the AXI bus access is complete (SHBSYx bit = 0). Note that if you accidentally set the FTE bit while an AXI bus access is in progress, the transfer fails and transfer data may be lost or the transfer may be unable to be restarted.

2) DREQE bit assert (negate clear) timing

It is necessary to allow at least  $20\text{clk}@ZS\phi$  after the DE bit is asserted and before the DREQE is asserted. This is because DREQE needs to be asserted after transfers enabled by the DE bit are ready internally to be started. Asserting DREQE immediately after DE may cause malfunction such as initiating unnecessary bus access.

3) Fractional byte and NULL packet reception

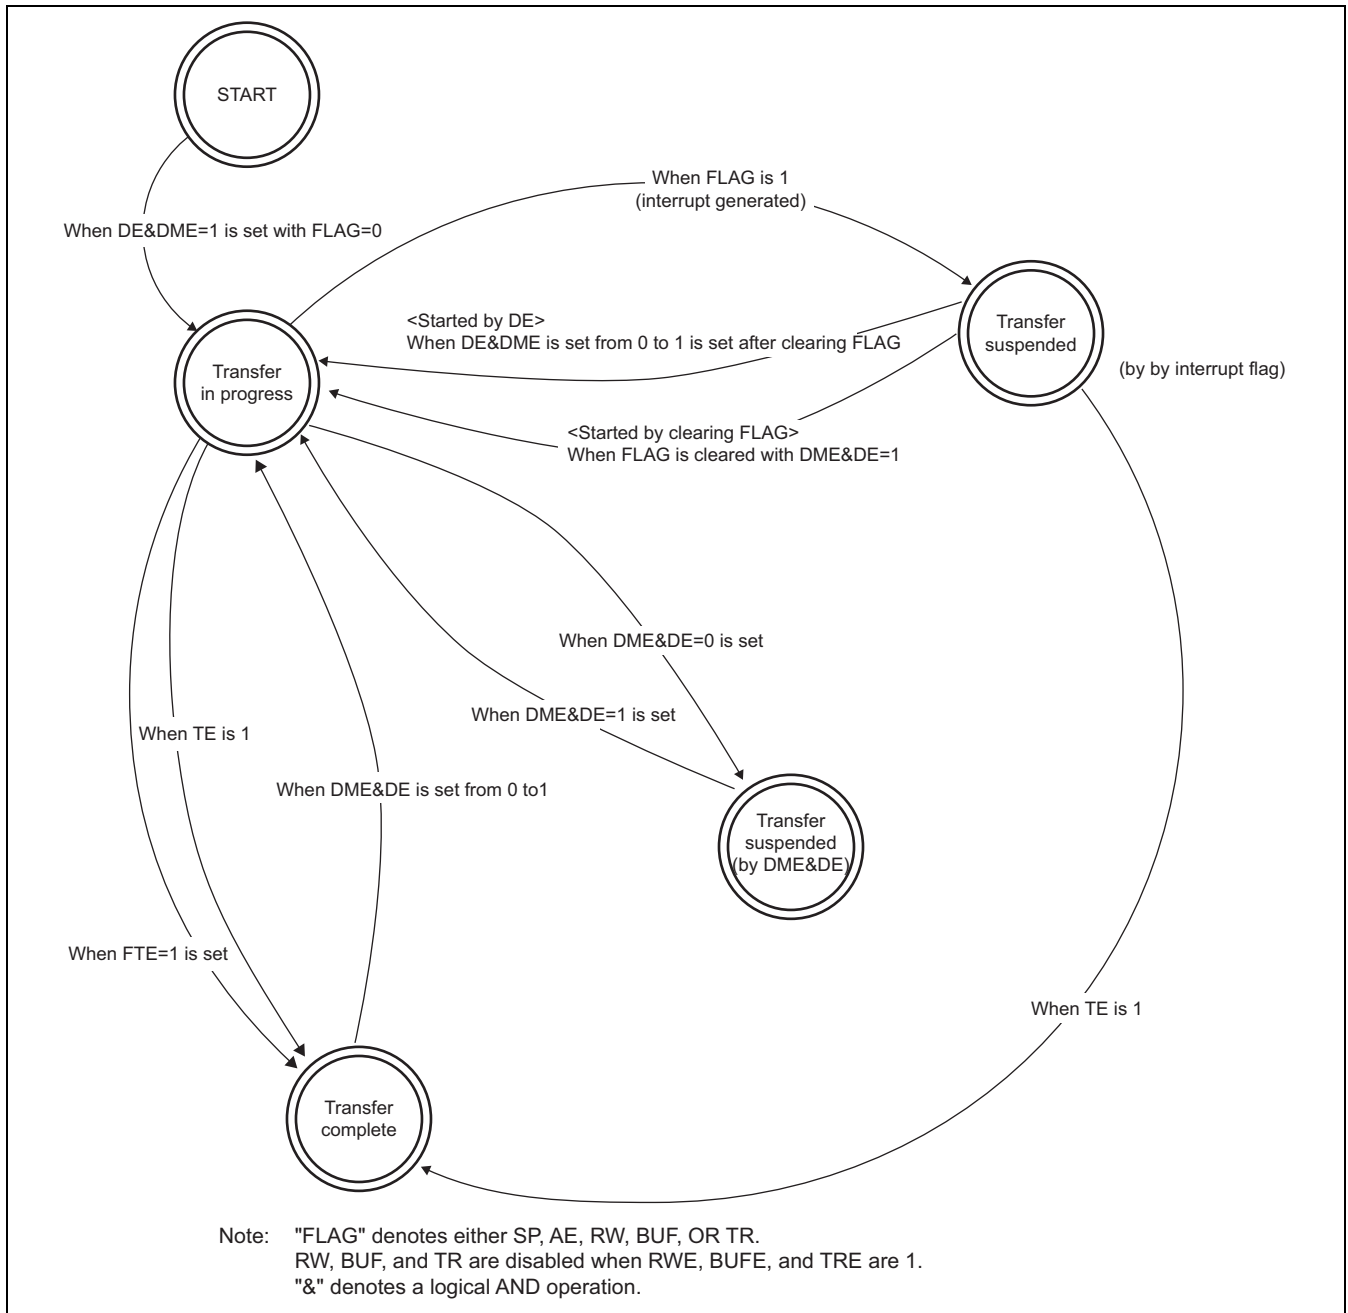

This module assumes bus access in the transfer units listed in Table 53.2 and goes out of control when it receives a NULL packet in an unsupported transfer unit. Therefore, data transfer in any transfer unit that is not in the table is prohibited.

4) IN/OUT switching after NULL packet reception

After a NULL is received, transfers cannot be restarted with the transfer direction switched from OUT to IN. This is because this module still considers the terminated transfer as an OUT transfer until the transfer count reaches its end. Note that if you switch the transfer direction to IN transfer accidentally after a NULL packet is received, a conflict occurs between an IN and an OUT transfers, which may cause illegal bus access.

Use CH0 and CH1 with their transfer direction fixed, or if the transfer direction needs to be switched on the same channel, make sure to do it every time a transfer completes successfully due to the end of transfer count or is terminated by software reset.

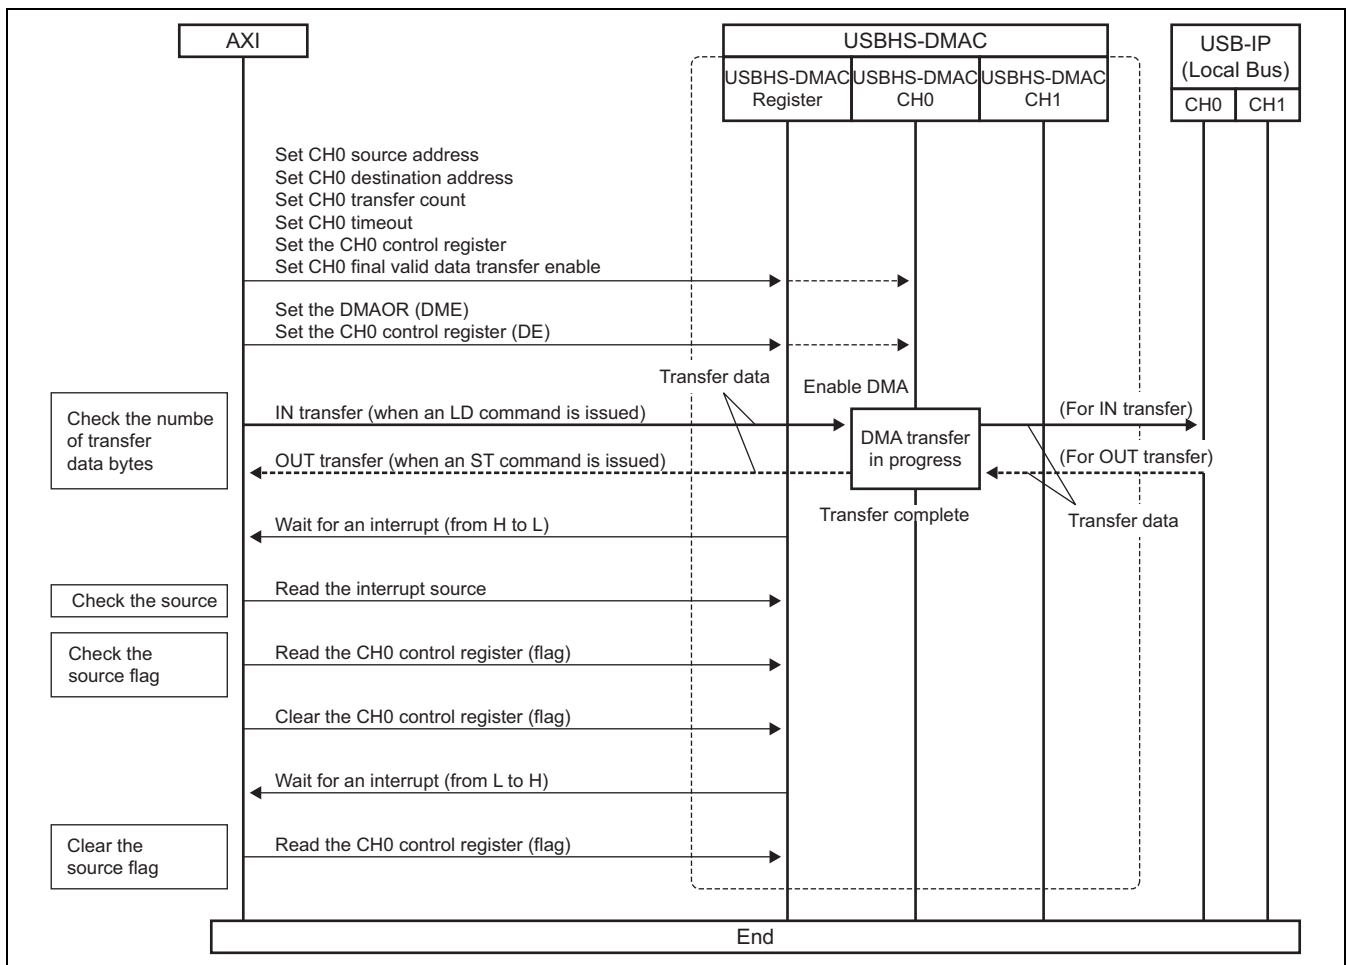

Figure 53.14 shows the state transitions for DMA transfers.

**Figure 53.14 State Transitions for DMA Transfer**

**(4) Control sequence**

Figure 53.15 shows an outline of the control sequence of this module.

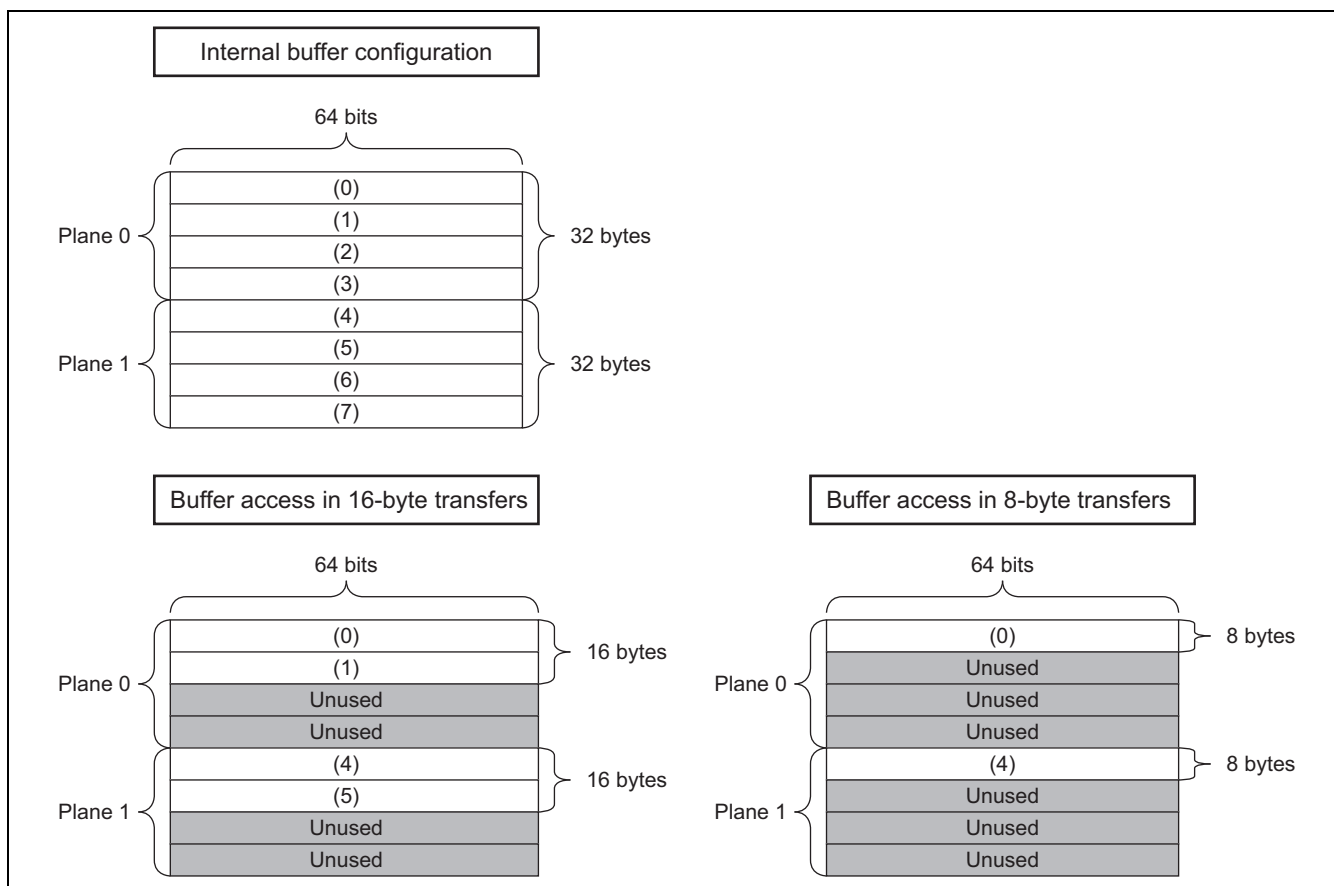

**Figure 53.15 Control Sequence Overview**

**(5) Internal buffer configuration**

This module has 64 bytes (64 bits × 8 words) of internal buffer for each of two channels. Thus, the total capacity of this module's internal buffers is 128 bytes (1,024 bits).

The internal buffers are composed of two planes each of which is organized as 64 bits × 4 words and are readable /writable on per-plane basis from the USB-IP local bus or AXI bus (plane 1 is writable when plane 0 is readable or vice versa). For 16-byte transfers, only 2 words in plane 0 and 2 words in plane 1 are used. For 8-byte transfers, only 1 word in plane 0 and 1 word in plane 1 are used.

Note that these internal buffers cannot be accessed directly by software.

**Figure 53.16 Internal Buffer Configuration and Used Area for Each Transfer Size**

**(6) Internal buffer control (hardware control, for reference)**

**(a) IN transfer (from AXI to USB)**

Retrieves transfer data from a source on the AXI bus and writes it to this module's internal buffer. Reads the written data from the internal buffer and writes it to the USB-IP.

Figure 53.17 shows how the planes of this module's internal buffers are controlled during an IN transfer. In this figure, "read" and "write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words\* and 1 word\* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 and a transfer the read data to the USB-IP are complete, the readable plane flag is toggled (every time 2 words\* and 1 word\* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set on the same plane as a read/write access conflict may occur.

Note: \* 1 word = 64 bits

**Figure 53.17 Read/Write Control for Internal Buffer: From AXI to USB (IN Transfer)**

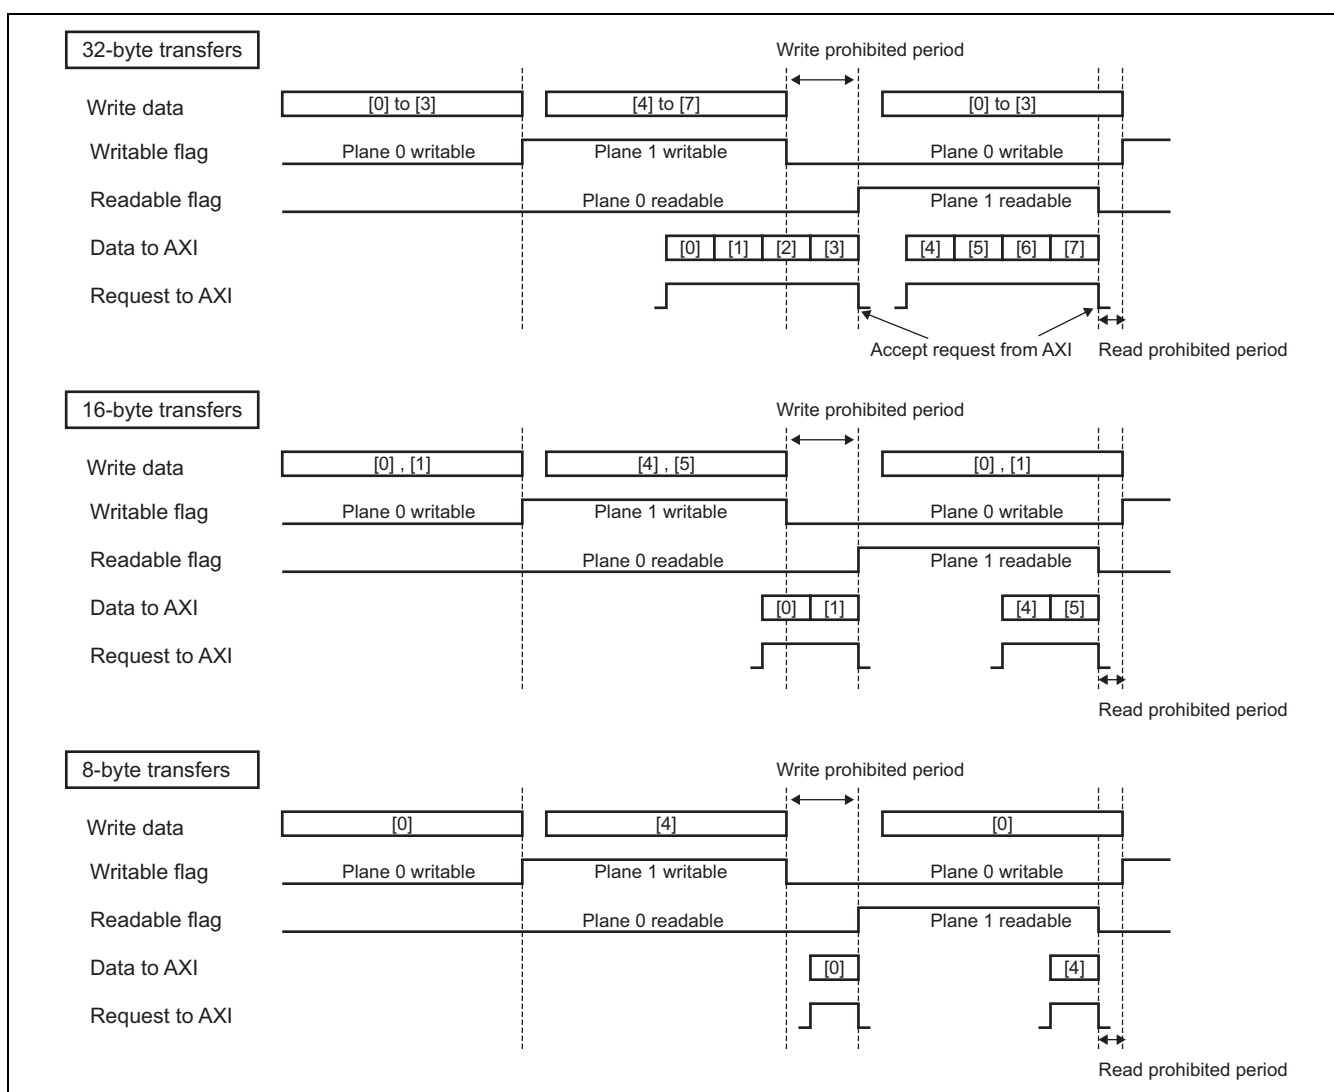

**(b) OUT transfer (from USB to AXI)**

Writes data read from the USB-IP to the internal buffers. Reads the written data from this module's internal buffers and writes it to the destination on the AXI bus (OUT transfer).

Figure 53.18 shows how the planes of this module's internal buffers are controlled during an OUT transfer. In this figure, "read" and "write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words\* and 1 word\* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 is complete, the readable plane flag is toggled (every time 2 words\* and 1 word\* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set the same plane as a read/write access conflict may occur.

Note: \* 1 word = 64 bits

**Figure 53.18 Read/Write Control for Internal Buffer: From USB to AXI (OUT Transfer)**

### 53.4 DDM (Descriptor DMAC)

The DDM is a module that reconfigures the DMAC and USBDMAC. The OS on the main CPU is highly sophisticated and the overhead from interrupt notification to reconfiguration increases. To solve this problem, the DDM reconfigures the DMAC and USBDMAC in a fast response time on behalf of the CPU.

Figure 53.19 shows the relationship diagram of DDM DMAC USBDMAC connection.

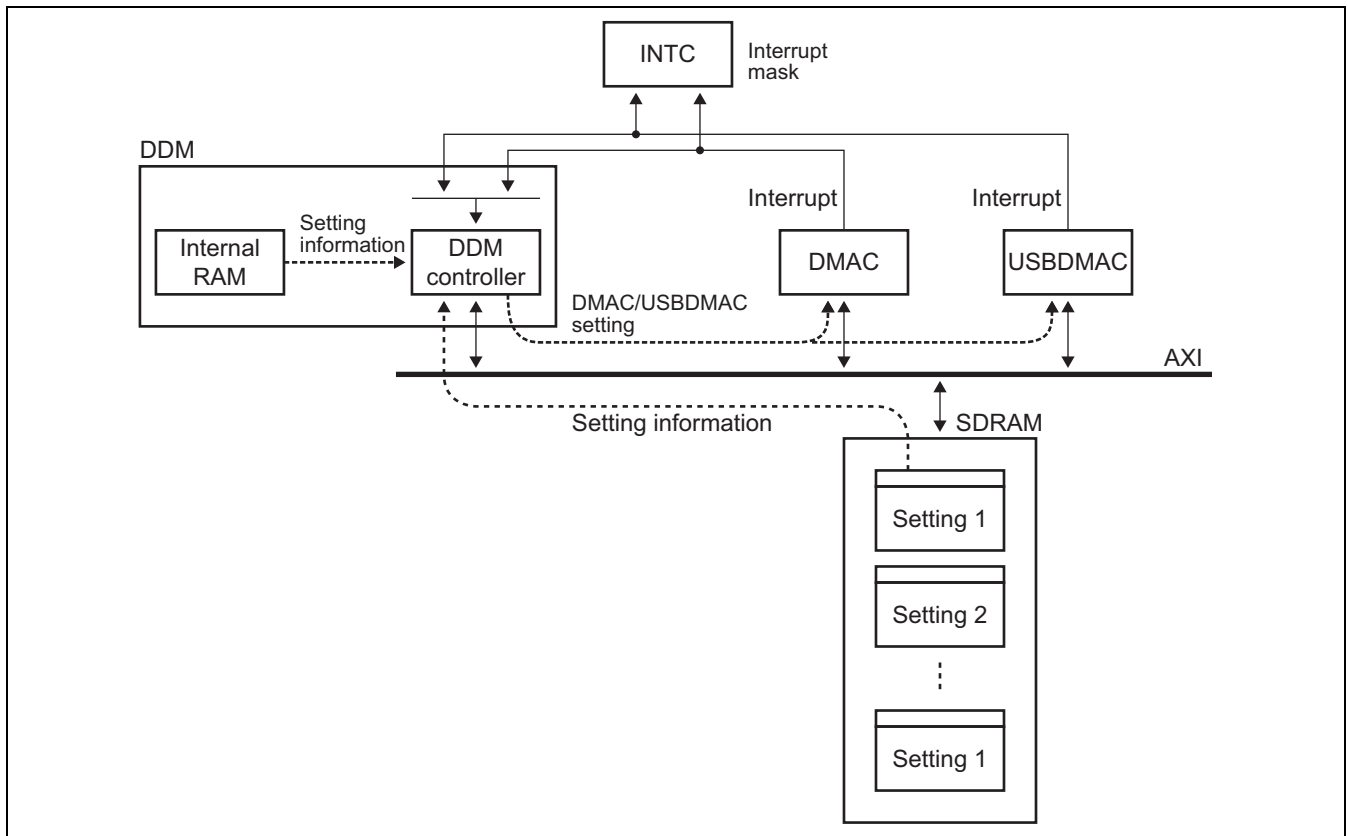

Figure 53.19 Relationship Diagram of DDM Connection

### 53.4.1 DDM Register Descriptions

Table 53.11 shows the DDM register configuration. Table 53.12 shows the register states in each operating mode.

**Table 53.11 DDM Control Registers**

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)	RZ/G Series Products			
						RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E

0	END1	0	R/W	Interrupt Output by CH1 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.

### 53.4.3 DDM Interrupt Source Register (DDIREQSTA)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

The DDM Interrupt Source Register indicates the currently output interrupt source. This register is read-only. You cannot clear the interrupt source in this register. Clear the interrupt source by using the control register of each channel.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CM8	CM7	CM6	CM5	CM4	CM3	CM2	CM1

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR8	END8	ERR7	END7	ERR6	END6	ERR5	END5	ERR4	END4	ERR3	END3	ERR2	END2	ERR1	ENS1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 24	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	CM8	0	R	Interrupt output by CH8 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
22	CM7	0	R	Interrupt output by CH7 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
21	CM6	0	R	Interrupt output by CH6 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
20	CM5	0	R	Interrupt output by CH5 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
19	CM4	0	R	Interrupt output by CH4 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
18	CM3	0	R	Interrupt output by CH3 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
17	CM2	0	R	Interrupt output by CH2 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.
16	CM1	0	R	Interrupt output by CH1 Counter consistent 0: The interrupt is not output. 1: The interrupt is output.

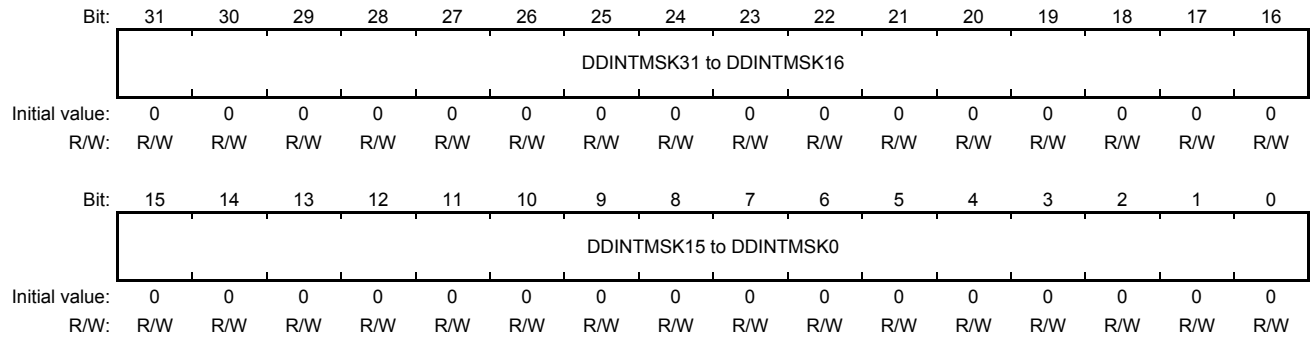

Bit	Bit Name	Initial Value	R/W	Descriptions
15	ERR8	0	R	Interrupt output by CH8 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
14	END8	0	R	Interrupt output by CH8 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
13	ERR7	0	R	Interrupt output by CH7 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
12	END7	0	R	Interrupt output by CH7 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
11	ERR6	0	R	Interrupt output by CH6 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
10	END6	0	R	Interrupt output by CH6 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
9	ERR5	0	R	Interrupt output by CH5 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
8	END5	0	R	Interrupt output by CH5 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
7	ERR4	0	R	Interrupt output by CH4 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
6	END4	0	R	Interrupt output by CH4 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
5	ERR3	0	R	Interrupt output by CH3 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
4	END3	0	R	Interrupt output by CH3 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
3	ERR2	0	R	Interrupt output by CH2 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
2	END2	0	R	Interrupt output by CH2 DDM_END 0: The interrupt is not output. 1: The interrupt is output.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	ERR1	0	R	Interrupt output by CH1 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
0	END1	0	R	Interrupt output by CH1 DDM_END 0: The interrupt is not output. 1: The interrupt is output.

**53.4.4 DDM CHn Start Source Mask Registers 1 to 2**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

DDM CHn Start Source Mask Registers 1 to 2 mask DDM start sources.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDINTMSK31 to DDINTMSK0	H'0000 0000	R/W	Start Source Mask 0: Does not mask the start source. 1: Masks the start source.

The current source assignment is as follows:

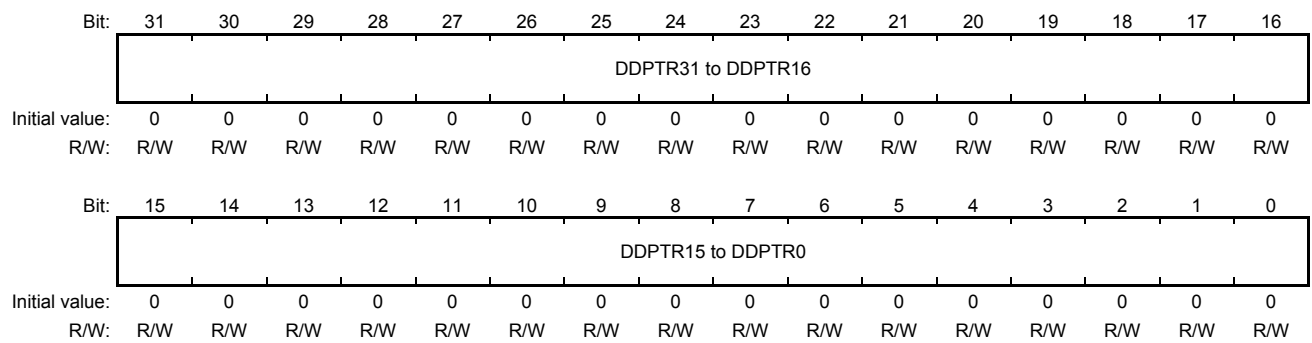

Bit Name	Bit	Assigned Start Source
DDINTMSKn	31 to 20	Reserved
(n=1,2)	19	DMACHCR19 TE bit
	18	DMACHCR18 TE bit
	17	DMACHCR17 TE bit
	16	DMACHCR16 TE bit
	15	DMACHCR15 TE bit
	14	DMACHCR14 TE bit
	13	DMACHCR13 TE bit
	12	DMACHCR12 TE bit
	11	DMACHCR11 TE bit
	10	DMACHCR10 TE bit
	9	DMACHCR9 TE bit
	8	DMACHCR8 TE bit
	7	DMACHCR7 TE bit
	6	DMACHCR6 TE bit
	5	DMACHCR5 TE bit
	4	DMACHCR4 TE bit
	3	DMACHCR3 TE bit
	2	DMACHCR2 TE bit
	1	DMACHCR1 TE bit
	0	DMACHCR0 TE bit

Bit Name	Bit	Assigned Start Source
DDINTMSKn	31 to 2	Reserved
(n=1,2)	1	USBDMAC1 Interrupt
	0	USBDMAC0 Interrupt

**53.4.5 DDM CHn Descriptor Pointer (DDPTRn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

The DDM CHn Descriptor Pointer indicates the start address of setting code allocated onto memory.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDPTR31 to DDPTR0	H'0000 0000	R/W	Descriptor pointer.

### 53.4.6 DDM CHn Control Register (DDCTRLn)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

The DDM CHn Control Register controls start and stop of DDM.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRI3 to PRI0				—	—	ENDC M	ENDC MMSK	END_NUM							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	END_CNT							—	—	—	STOP	KICK	DDM_ ERR	DDM_ END	DDE	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PRI3 to PRI0	H'0	R/W	PRI value on the AXI bus.
27, 26	—	00	R	Reserved
25	ENDCM	0	R/W	Descriptor end Counter Consistent Detection Writing 0 is possible to clear the flag. 0: Counter consistent is not detected. 1: Counter consistent is detected.
24	ENDCMMSK	0	R/W	Descriptor end Counter Consistent Detection Mask 0: Masks the ENDCM. (END_CNT is cleared to 0) 1: Does not mask the ENDCM.
23 to 16	END_NUM	All 0	R/W	Number of descriptor ends
15 to 8	END_CNT	All 0	R/W	Descriptor end Counter
7 to 5	—	000	R	Reserved
4	STOP	0	R/W	Forced Stop Function 0: Does not perform forced stop. 1: Performs forced stop.
3	KICK	0	R/W	Forced Start Function without Start Source 0: Does not perform forced start. 1: Performs forced start. This bit is automatically cleared to 0 after 1 is written.
2	DDM_ERR	0	R	Error Occurrence. The error is cleared by setting the DDE bit to 0. 0: No error occurred. 1: An error occurred.
1	DDM_END	0	R	DDM End. DDM end is cleared by setting the DDE bit to 0. 0: The DDM did not end. 1: The DDM ended.
0	DDE	0	R/W	Start Enable 0: Does not enable DDM start. 1: Enables DDM start according to the start source.

### 53.4.7 Internal RAM

Address	Area
H'FE08 0000	Register_area
H'FE08 8000	Code RAM 1 KB
H'FE08 C000	Data RAM 1.5 KB

**Figure 53.20 Internal RAM**

DDM builds in RAM. It is the 2nd page composition of Code RAM and Data RAM. DDM can access without AXI. Access size is arbitrary. In addition, a functional difference is not in both depending on the way of calling depending on which Code RAM and Data RAM were conscious of the use.

### 53.4.8 Principles of Operation

To reconfigure the DMAC by using the DDM, use the following procedure:

1. Describing setting codes
2. Starting and ending the DDM

#### (1) Describing setting codes

##### (a) Data structure

A setting code is fixed-length data consisting of four longwords.

Setting code data consists of the following fields, starting from the beginning:

Field	bit
Operation field	32 bits
Address field	32 bits
Data field	32 bits
Bit mask field	32 bits

Note: Arrange a setting code in 16 bytes boundary.

The following describes the operation field.

### (b) Operation field

The structure of the operation field is as follows:

Bit	Bit Name	Descriptions
31 to 16	HEADER	Indicates DDM setting data. H'DDDD: Normal DDM setting code Usually, set this value. H'EEEE: DDM end code Set this value when ending the channel without starting the DDM the next time. If the HEADER bits have other values, a DDM_ERR interrupt occurs. The channel of the DDM stops immediately.
15 to 8	OPERAND	Operand attribute B'00xyyzz 00: immediately 01: register 10: pointer 11: pointer (Register value) xx: Bit mask field yy: Data field zz: Address field
7 to 4	SIZE	Specify the data access size to be set. 0000: Bytes 0001: Words 0010: Longwords
3	ENDFLG	End Flag of Setting Processing Based on This Start Source 0: Continuation 1: Setting end. The DDM waits for the next start source.
2 to 0	OPC	Operation Code 000: read (cmp/eq) (read) 001: write (write) 010: rmodw (read modify write) 011: add (addition) 100: jmp/eq (branch) 101:ror (rotate right) Others: DDM_ERR interrupt occurs

The address field, data field, and bit mask field each consist of 32 bits. The data field and bit mask field use the LSB side for word- and byte-size access.

Four of register R0-R3 of longword size can be used for every Ch.

**(c) read (cmp/eq)**

The read (cmp/eq) code reads the target address and compares the address with the expected values written in the data field and bit mask field.

When the comparison result becomes true, the TFLG internal variable is set to 1. TFLG is cleared to 0 when jmp/eq is executed or operation with ENDFLG is performed.

Description example1:

The read (cmp/eq) code in this example reads the H'FE00 802C address in longwords and checks if bit 1 is set to 1.

```
H'DDDD 0020
H'FE00 802C
H'0000 0002
H'0000 0002
```

Description example2:

The read (cmp/eq) code in this example reads the R1 in longwords and checks if bit 1 is set to 1.

```
H'DDDD 0120
H'0000 0001
H'0000 0002
H'00000002
```

**(d) write**

The write code writes data to the target address.

Description example1:

The write code in this example accesses the H'FE00 802C address in longwords and writes H'0010 5400.

```
H'DDDD 0021
H'FE00 802C
H'0010 5400
H'FFFF FFFF (don't care)
```

Description example2:

The write code in this example accesses the H'FE00802C address in longwords and writes the value of H'00000001 address to H'FE00802C address.

```
H'DDDD 0821
H'FE00 802C
H'0000 0001
H'FFFF FFFF (don't care)
```

**(2) Description example3:**

The write code in this example accesses the H'FE00 802C address in longwords and writes the value of pointer of R1 to the H'FE00 802C address.

```
H'DDDD 0C21
H'FE00 802C
H'0000 0001
H'FFFF FFFF (don't care)
```

**(a) rmodw**

The rmodw code reads the target address and performs modify-write according to the values of the bit mask field.

Description example:

The rmodw code in this example reads the H'FE00 802C address in longwords and applies H'54 modify-write to bits 11 to 4.

```
H'DDDD 0022
H'FE00 802C
H'0000 0540
H'0000 0FF0
```

**(b) add**

The add code reads the target address and performs add-modify-write according to the values of the bit mask field.

Description example:

The add code in this example reads the H'FE00 802C address in longwords and applies H'200 add-modify-write to bits 11 to 0.

```
H'DDDD 0023
H'FE00 802C
H'0000 0200
H'0000 0FFF
```

Use 0 as the addition data corresponding to the area where the bit mask is 0.

**(c) jmp/eq**

If TFLG is set to 1 by the cmp/eq code, jmp/eq changes the descriptor pointer to the values of the data field. Descriptor pointer change by jmp/eq is not reflected in execution based on the next start source. Changing the descriptor pointer for the next start requires that the CHn descriptor pointer be reconfigured.

Description example:

The jmp/eq code in this example changes the descriptor pointer when TFLG is 1 to H'E558 000E.

```
H'DDDD 0024
H'0000 0000 (don't care)
H'E558 000E
H'0000 0000 (don't care)
```

**(d) ror**

The ror code reads the target address and performs rotate-right-write according to the values of the bit mask field. The shifted lower bits are rotated to higher bits. The ror command shifts according to the value of the data field.

Description example:

The ror code in this example reads the H'FE00 802C address in longwords and applies 8-bits right-shift.

```
H'DDDD 0025
H'FE00 802C
H'0000 0008
H'00FF FFFF
```

**(e) Settings description order**

Describe settings in the following order:

- (1) Clearing the start source (source output side, not the DDM start source mask register)
- (2) Changing the DDM source mask setting as required
- (3) Reconfiguring registers such as DMAC
- (4) Reconfiguring the next descriptor pointer

If several start sources are set, the last write may be unable to catch up with the next start. In such a case, end next descriptor pointer setting in (4) in read after write (do not end it in write).

**(f) Example of setting DMAC restart**

Use DDM CH1. The following shows an example of describing setting codes for reconfiguration when the TE bit of the DMAC1 CH0 channel control register is HI.

```
//TE bit read
H'DDDD 0020
H'FE00 802C
H'0000 0002
H'0000 0002
//TE bit clear
H'DDDD 0021
H'FE00 802C
H'0010 5400
H'FFFF FFFF
//SAR setting
H'DDDD 0021
H'FE00 8020
H'5800 0000
H'FFFF FFFF
//DAR setting
H'DDDD 0021
H'FE00 8024
H'0000 0000
H'FFFF FFFF
//TCR setting
H'DDDD 0021
```

```

H'FE00 8028
H'0000 0010
H'FFFF FFFF
//DE bit write. DMA start
H'DDDD 0021
H'FE00 802C
H'0010 5401
H'FFFF FFFF
//Next descriptor pointer write.
H'DDDD 0021
H'E65C 0050
H'5800 02D0
H'FFFF FFFF
// Setting end by this start. (dummy read)
H'DDDD 0028
H'E65C 0050
H'0000 0000
H'0000 0000

```

### (3) Start and end

#### (a) Starting the DDM

Make necessary settings in the DDM.

- Enabling interrupt output as required
  - Setting a DDM start source
    - Setting a descriptor pointer

After setting the above, set the DDM Enable bit of the DDM control register to 1 to enable DDM start.

Setting example:

```

Enable the interrupt by DDM CH1 end.
  Address: H'E65C 0008 Write data: H'0000 0001
Enable DDM CH1 start when the DMAC1 TE bit is changed.
  Address: H'E65C 0030 Write data: H'0000 1000
Set the DDM CH1 descriptor pointer to H'5800 0210.
  Address: H'E65C 0050 Write data: H'5800 0210
Enable DDM CH1 start.
  Address: H'E65C 0054 Write data: H'0000 0001

```

Set the KICK bit to forced start after setting the DDM Enable bit to 1. Do not set these bits at the same time.

#### (b) Ending the DDM

When the DDM ends, the DDM\_END bit is set to 1. DDM end is cleared by setting the DDE bit to 0. To restart the DDM, you must clear the DDM\_END bit by setting the DDE bit to 0.

Procedure for stopping the DDM by the STOP bit

```

Set the STOP bit to 1. Keep the DDE bit at 1.
Check that the DDM_END bit is 1.
Set the DDE bit to 0.

```

## 54. USB3.0 Host Controller

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 54.1 Introduction

The USB3.0 host controller is compliant with the Universal Serial Bus (USB) 3.0 Specifications.

It uses AXI interconnection, which is a system interface that is based on the AMBA® AXI Protocol v1.0 Specification.

The USB3.0 host controller supports super speed (5 Gbps), high speed (480 Mbps), full speed (12 Mbps) and low speed (1.5 Mbps).

**Table 54.1 Supported Speed Type**

Speed Type	High Speed	Full Speed	Low Speed
Super Speed	√	√	√

Also, the USB3.0 host controller is compliant with battery charging.

It is based on the eXtensible Host Controller Interface for the Universal Serial Bus (xHCI) Specification as a host controller interface.

The USB3.0 host controller requires to download FW to operate as a host (see section 54.4.1, FW Download). Contact Renesas to obtain the FW.

#### 54.1.1 Features

The functions of the USB3.0 host controller are listed below.

The USB3.0 host controller has one USB port, one AXI master, and one AXI slave.

##### (1) USB3.0 Host Controller Function

###### [USB Function]

###### Compliant with Universal Serial Bus 3.0 Specification Revision 1.0

- Supports one downstream port. USB2.0 port implements a 50-ohm resistance.
- Supports control, bulk, interrupt, and isochronous transfers.
- Supports all USB bus speeds, USB 3.0 super speed (5 Gbps), high speed (480 Mbps), full speed (12 Mbps) and low speed (1.5 Mbps).
- Supports power control and overcurrent detection
- Supports BIOS USB.
  - Pre-OS and OS hand-off
  - xHCI legacy support control
- Implements the USB2.0ECN USB 2.0 Link Power Management Addendum and LPM function that is compliant with the xHCI specification.
- Supports polarity inversion of USB3.0 SS differential data pin pair.

**Has the following capabilities that are compliant with the eXtensible host controller interface for Universal Serial Bus Specification Revision 1.0.**

- 64-bit addressing capability
- BW negotiation capability
- Port power control
- Latency tolerance message capability
- xHCI host capability
  - Number of device slots (MaxSlots): 32
  - Number of total endpoints: 128
  - Number of stream IDs (MaxPSASize): 32 per endpoint (1 EP for reserved bit)
  - Number of event ring segment tables: 2 (max. 512 events/ring) (ERST Max = 1)
  - Supported page size: 4 Kbytes
  - Context size: 64 bytes
- Debug Port
  - Supports debug port compliant with xHCI debug capability

**[Battery Charging]**

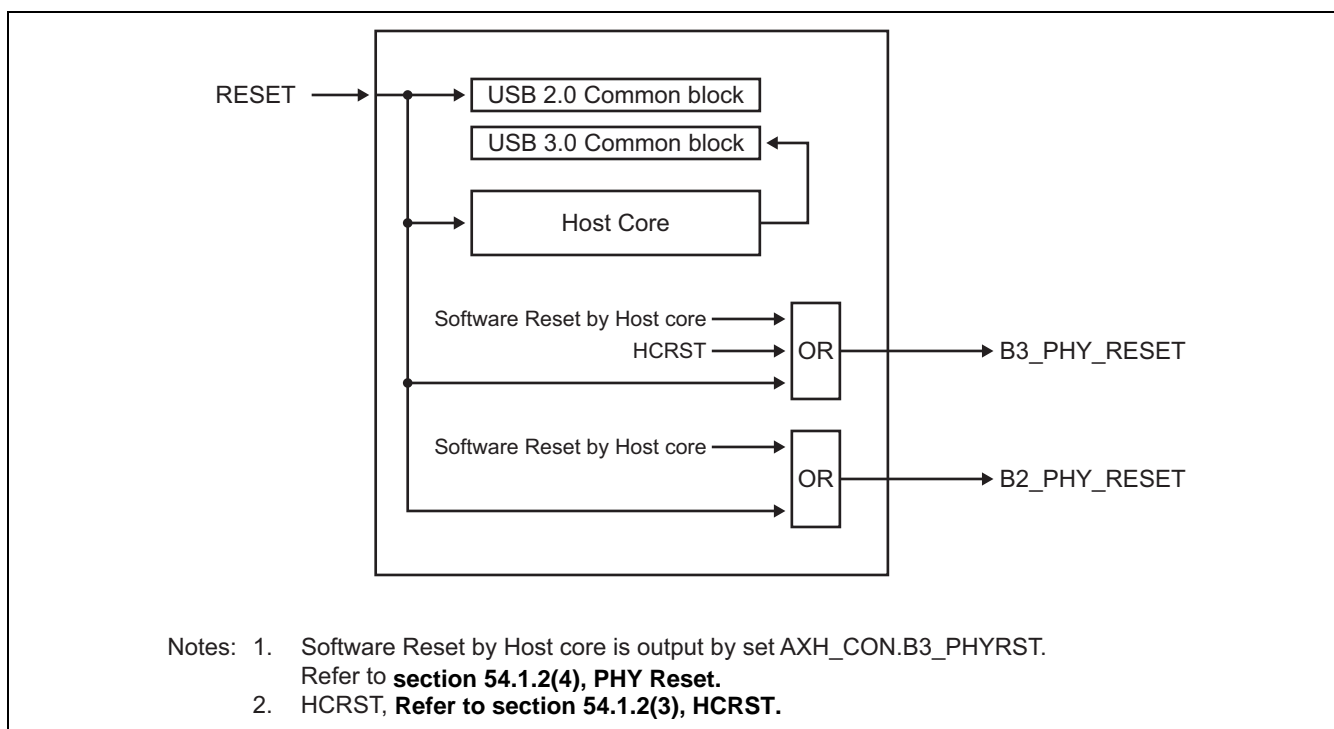

Supports the following modes that are compliant with Battery Charging Specification Revision 1.2

**Charging port device**

- Standard downstream port mode (SDP)
- Charging downstream port mode (CDP)
- Dedicated charging port mode (DCP)

### 54.1.2 Reset

The USB3.0 host controller reset diagram is provided below.

**Figure 54.1 Reset Diagram**

#### (1) Reset Operation

- When the power is on or host core is reset, RESET is asserted.
- The reset is deasserted when USB2.0PLL becomes stable because reset synchronization is cleared.

#### (2) Reset in Cold Boot

- During cold boot and when the power is on, RESET is asserted.
- The reset is deasserted when USB2.0 PLL becomes stable because reset synchronization is cleared.

#### (3) HCRST

- The host controller reset (HCRST) is operated when the USBCMD.HCRST bit is set to 1 by Driver, after which the USBSTS.HCH bit (HCHalted bit) will be 0.
- When HCRST is set, Host core is reset by FW, and initialized.

#### (4) PHY Reset

The B3\_PHY\_RESET is used for a reset of USB3.0 PHY, and the B2\_PHY\_RESET is used for a reset of USB2.0 PHY. Each PHY reset signal is generated by reset signals from the host core.

When Host role, if the bit [16] B3\_PHYRST/ [0] B2\_PHYRST of AXI host control register [H'100 to H'104] is set, B3\_PHY\_RESET/ B2\_PHY\_RESET is output to USB3.0PHY/ USB2.0PHY.

**Table 54.2 B3\_PHY\_RESET and B2\_PHY\_RESET**

USB3.0 Host Controller	Register Setting	Reset Signal Behavior
Host core	AXH_CON.B3_PHYRST = 1	The value of B3_PHYRST is output to B3_PHY_RESET signal.
	AXH_CON.B2_PHYRST = 1	The value of B2_PHYRST is output to B2_PHY_RESET signal.

**Table 54.3 Resources of B3\_PHY\_RESET and B2\_PHY\_RESET**

	(1) Software Reset	(2) HCRST	RESET
B3_PHY_RESET	√	√	√
B2_PHY_RESET	√	—	√

### 54.1.3 Shared Port Configuration

USB3.0 host controller share HS/FS/LS transceiver with USB2.0 Ch.2. Set USB2SEL bit in UGCTRL2 register to enable USB3.0. Refer to section 52.2.38, USB General Control Register 2 (UGCTRL2).

USB 3.0's external pins shares SATA0's ones. When mode pin is selected the following value, USB 3.0 is enabled.

- In the case of RZ/G1H or RZ/G1M, MD23 = 1.
- In the case of RZ/G1N, MD23 =1, MD24 = 0

**Table 54.4 External Pins**

Pin Name	I/O	Description	RZ/G Series Products

## 54.2 Register Specification

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 54.2.1 Register Attributes

**Table 54.5 Register Bit-field types**

Register Attribute	Description
R/W	Register bits can be read and written.
RW1C	Register bits can be read. A clear bit may be set by writing "1"; writing 0 to RW1C bits has no effect.
RWT	Register bits can be read. An inversion bit may be set by writing "1"; writing 0 to RWT bits has no effect.
RW1S	Register bits can be read and written. A bit may be set to 1 by writing "1"; writing 0 to RW1S bits has no effect.
R	Register bits can only be read.
W	Register bits can only be written.
Reserved	Reserved bits are Read Only field.

### 54.2.2 Register Overview

Register groups in host cores are consisted of following registers.

- AXI Register
- xHCI Register

CLK60 shall be supplied to host core when user reads or writes valid value at host register.

### 54.2.3 USB3.0 Address Mapping

#### 54.2.3.1 Address Mapping

Base address is H'EE00 0000. Following sections describe only offset address from the base address.

31 to 17	—	All 0	R	Reserved
16	B3_PHYRST	0	R/W	Bit for reset USB3.0 PHY. 0: Normal condition 1: Reset condition
15 to 9	—	All 0	R	Reserved
8	SYS_SUSPEND	0	R/W	Bit for setting Suspend USB2.0 PHY (PLL stops) by system. 0: Normal condition 1: Suspend condition (USB2PHY PLL stops)
7 to 1	—	All 0	R	Reserved
0	B2_PHYRST	0	R/W	Bit for reset USB2.0 PHY. 0: Normal condition 1: Reset condition

### 54.3.1.2 AXI Host Control Status Register

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	SS_DISABLE	—	—	—	—	—	—	—	B3_PLL_ACTIVE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	B2_PLL_ACTIVE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	SS_DISABLE	0	R	Bit for showing SuperSpeed (SS) Port is disabled. The USB3.0 host controller core doesn't support SS port when this bit is 1.
23 to 17	—	All 0	R	Reserved
16	B3_PLL_ACTIVE	0	R	Bit for showing that USB3PHY PLL is locked or not. When this bit is 0, it means USB3.0 function is not able to use because valid clock is not output from USB3.0 PHY during USB3PHY PLL is unlocked. 0: PLL Unlock (USB3PHY Clock is invalid) 1: PLL Lock (USB3PHY Clock is valid)
15 to 1	—	All 0	R	Reserved
0	B2_PLL_ACTIVE	0	R	Bit for showing that USB2PHY PLL is locked or not. When this bit is 0, it means USB2.0 function is not able to use because valid clock is not output from USB2.0 PHY during USB2PHY PLL is unlocked. 0: PLL Unlock (USB2PHY Clock is invalid) 1: PLL Lock (USB2PHY Clock is valid)

### 54.3.1.3 Revision ID

Register displaying Revision ID.

Bit:	7	6	5	4	3	2	1	0
	Revision ID							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	Revision ID	—	R	Renesas management number

#### 54.3.1.4 Pseudo PCI Class Code

Pseudo register corresponding to PCI class code. This register's value doesn't influence the performance of the AXH block or USB3.0 host controller core.

Bit	Bit Name	Initial Value	R/W	Description
23 to 0	Class Code	H'0C 0330	R	Device Type and Function Base Class: Serial Bus Controller (H'0C) Sub Class: Universal Serial Bus Host Controller (H'03) Program Interface: USB3.0 Host Controller (H'30)

#### 54.3.1.5 Serial Bus Release Number

Register corresponding to the Serial Bus Release Number Register specified in the xHCI specification.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SBRN	H'30	R	Serial Bus Release Number Version of universal serial bus specification that is compliant with host controller. H'30: Release 3.0

### 54.3.1.6 Frame Length Adjustment

Register corresponding to the frame length adjustment register specified in the xHCI specification.

This register is used for adjustment of the frame length in USB3.0 host controller core. Only in the HC halted state, write is valid.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved
5 to 0	FLADJTV	H'20	SRW	Frame Length Adjustment Register (FLADJ) Timing Value Adjust SOF counter Clock. H'20: Frame Length 60,000 $SOF\ cycle\ time = 59,488 + (Register\ setting\ value \times 16\ high\ speed\ bit)$

54.3.1.7 Host Interrupt

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	SMI_S TA	LTM_S TA	HSE_S TA	PME_S TA	XHC_S TA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	RWC	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved
4	SMI_STA	0	R	SMI Interrupt Status bit. When an SMI interrupt occurs, this bit is set to 1.
3	LTM_STA	0	RWC	LTM Interrupt status bit. When an LTM interrupt occurs, this bit is set to 1 by FW. AXI sets 1 to clear the bit.
2	HSE_STA	0	R	HSE Interrupt Status bit. When USBSTS.HSE = 1 & USBCMD.HSEE = 1, this bit is set to 1. AXI sets 1 to clear the bit.
1	PME_STA	0	R	PME Interrupt Status bit. When PME_STA = 1 & PME_ENA = 1, this bit is set to 1.
0	XHC_STA	0	R	xHCI Interrupt Status bit. When EventRing is updated and then the INT signal, which indicates asserting of the interrupt in the core, is detected, this bit is set to 1.  When the INT signal, which indicates deasserting of the interrupt in the core, is detected, this bit is set to 0 and cleared.

## 54.3.1.8 Host Interrupt Enable

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	SMI_E NA	LTM_E NA	HSE_E NA	PME_E NA	XHC_E NA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved
4	SMI_ENA	0	R/W	When this bit is set to 1, SMI_STA interrupt is valid.
3	LTM_ENA	0	R/W	When this bit is set to 1, LTM_STA interrupt is valid.
2	HSE_ENA	0	R/W	When this bit is set to 1, HSE_STA interrupt is valid.
1	PME_ENA	0	R/W	When this bit is set to 1, PME_STA interrupt is valid.
0	XHC_ENA	0	R/W	When this bit is set to 1, XHC_STA interrupt is valid.

## 54.3.1.9 LTR

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Requirement	—	—	Latency Scale			Maximum No-Snoop Latency Value									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Requirement	—	—	Latency Scale			Maximum Snoop Latency Value									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	Requirement	0	R	Requirement (No-Snoop)
30, 29	—	All 0	R	Reserved
28 to 26	Latency Scale	000	R	Latency Scale (No-Snoop)
25 to 16	Maximum No-Snoop Latency Value	H'000	R	Latency Value (No-Snoop)
15	Requirement	0	R	Requirement (No-Snoop)
14, 13	—	All 0	R	Reserved
12 to 10	Latency Scale	000	R	Latency Scale (No-Snoop)
9 to 0	Maximum Snoop Latency Value	H'000	R	Latency Value (No-Snoop)

### 54.3.1.10 Battery

Register for setting Battery Charging operational Mode.

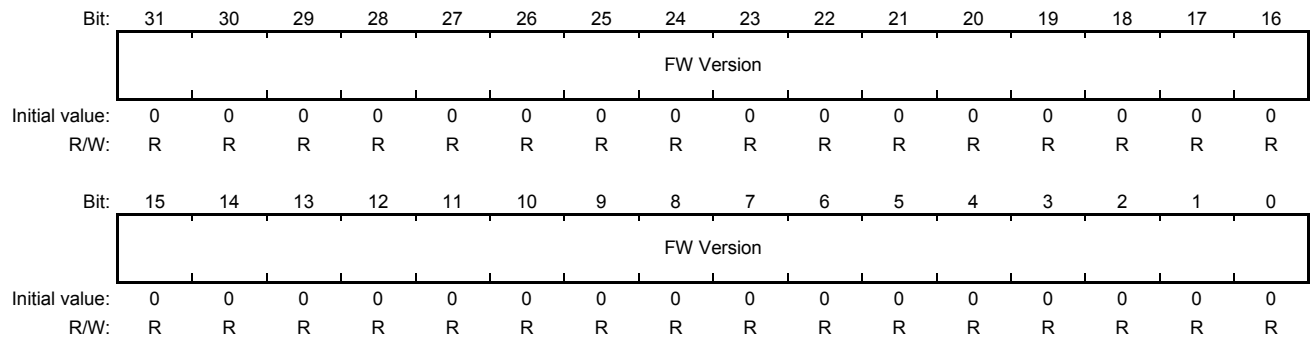

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	PTPWE R_CTRL	—	—	—	—	—	—	Renesas Private field	
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	LCLK_NONSTOP_FREQ		—	—	—	—	BC_MODE				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	PTPWER_CTL	1	R/W	Set value of PortPowerControl (PPC) at HCCPARAMS in xHCI register.  The bit is set to 1 when there is an external Power Switch for control VBUS.
23 to 18	—	All 0	R	Reserved
17, 16	Renesas Private field	00	R/W	Renesas Private bit.  This bit can be written only "0". Don't write "1".
15 to 11	—	All 0	R	Reserved
10 to 8	LCLK_NONSTOP_FREQ	000	R/W	Showing a frequency of NONSTOP_CLK entered in USB3.0 host controller core.  000: Default value. Following users shall set this value to 000. <ul style="list-style-type: none"> <li>User who can supply clock (12, 24, 30, 48-MHz) as NONSTOP_CLK to core but don't want to use low-power function.</li> <li>User who can't supply clock (12, 24, 30, 48-MHz) as NONSTOP_CLK to core.</li> </ul> 001: User can supply LCLK_NOSTOP:12 MHz (+/-10%), and uses the function. 010: User can supply LCLK_NOSTOP:24 MHz (+/-10%), and uses the function. 011: User can supply LCLK_NOSTOP:30 MHz (+/-10%), and uses the function. 100: User can supply LCLK_NOSTOP:48 MHz (+/-10%), and uses the function.
7 to 4	—	All 0	R	Reserved
3 to 0	BC_MODE	0000	R/W	Set mode of Battery Charge function.

**54.3.1.11 FW Version**

Register displaying FW Version.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FW Version	H'0000_0000	R	FW Version is showed here. After FW downloading, FW Version can be read. Before FW download: H'0020 0000 After FW download: H'0020 XX00

### 54.3.1.12 FW Download Control & Status

Register displaying Status and Control for writing FW via AXI Bus.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	Set_Data1	Set_Data0	—	Result_Code			—	—	BIOS Download Lock	BIOS Download Enable
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	RW1S	RW1S	R	R	R	R	R	R	RW1S	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved
9	Set_Data1	0	RW1S	When this bit is 1, the value of AXICNF05C register is set by the system.
8	Set_Data0	0	RW1S	When this bit is 1, the value of AXICNF058 register is set by the system.
7	—	0	R	Reserved
6 to 4	Result_Code	000	R	This field presents the results of BIOS Download. 000: Invalid 001: Success 010: Error Others: Reserved
3, 2	—	All 0	R	Reserved
1	BIOS Download Lock	0	RW1S	When this bit is 1, the BIOS download function is locked.
0	BIOS Download Enable	0	R/W	When this bit is 1, the BIOS download function is enabled.

**54.3.1.13 FW Data0**

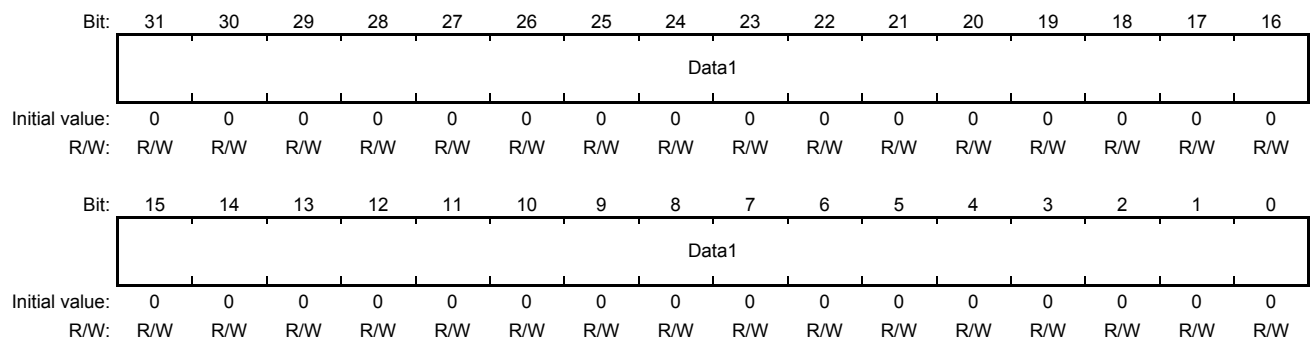

Data Register for writing FW via AXI Bus.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Data0	H'0000_0000	R/W	Data register 0 for writing FW

**54.3.1.14 FW Data1**

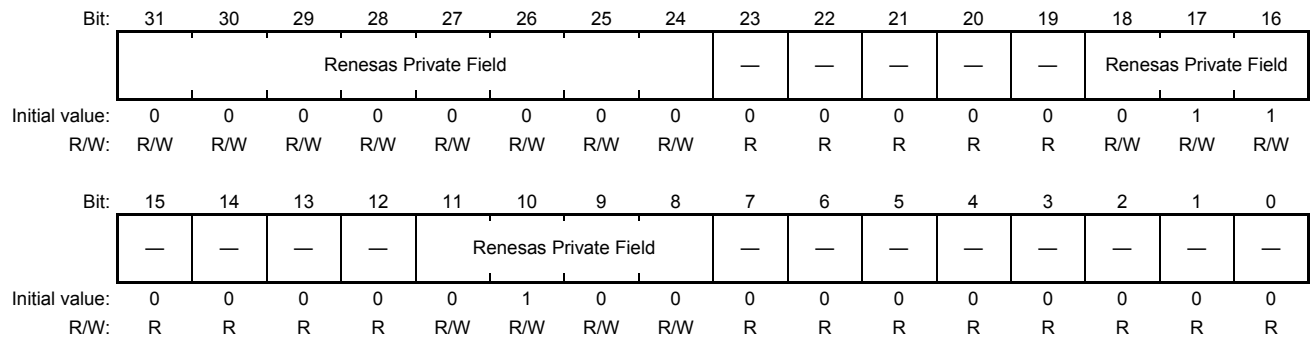

Data Register for writing FW via AXI Bus.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Data1	H'0000_0000	R/W	Data register 1 for writing FW

### 54.3.1.15 Renesas Private Register

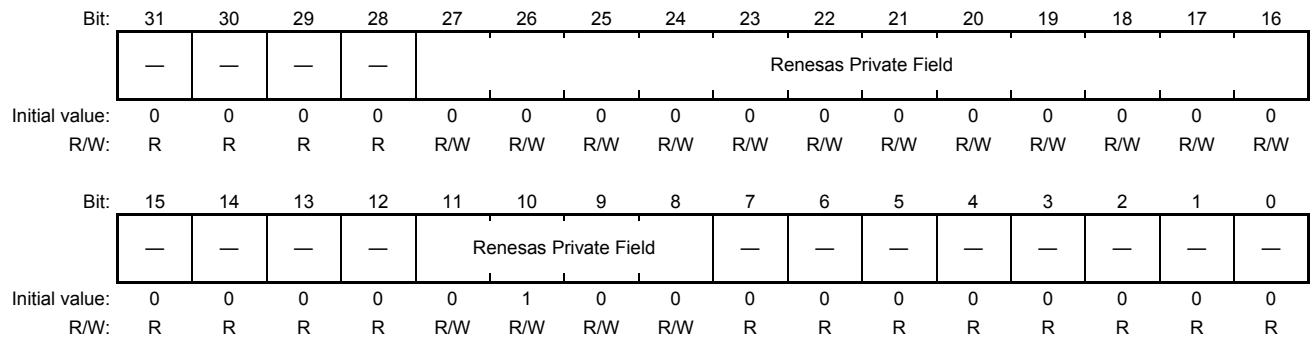

This register is Write inhibit.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Renesas Private field	H'00	R/W	Renesas Private field. This is write inhibit field.
23 to 19	—	All 0	R	Reserved
18 to 16	Renesas Private field	011	R/W	Renesas Private field. This is write inhibit field.
15 to 12	—	All 0	R	Reserved
11 to 8	Renesas Private field	H'4	R/W	Renesas Private field. This is write inhibit field.
7 to 0	—	All 0	R	Reserved

### 54.3.1.16 Renesas Private Register

This register is Write inhibit.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved
27 to 16	Renesas Private Field	H'000	R/W	Renesas Private field. This is write inhibit field.
15 to 12	—	All 0	R	Reserved
11 to 8	Renesas Private field	H'4	R/W	Renesas Private field. This is write inhibit field.
7 to 0	—	All 0	R	Reserved

## 54.3.1.17 Core Control 3

Register for other setting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	Renesas Private bit	—	—	—	—	—	—	—	Renesas Private bit
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PMC_MODE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	Renesas Private bit	1	R/W	Renesas Private bit. Do not write 0 to this bit.
23 to 17	—	All 0	R	Reserved
16	Renesas Private bit	1	R	Renesas Private bit This is write inhibit bit.
15 to 2	—	All 0	R	Reserved
1, 0	PMC_MODE	00	R/W	Sets control of HO_CACTIVE at Low Power Interface. When Bit[0] is 0, it is kept HO_CACTIVE at 1 even if system requests to stop ACLK_H. When Bit[1] is 0, it is kept HO_CACTIVE at 1 and is not to be 0 voluntarily. Bit[0] 1: 0 Control of HO_CACTIVE is valid when HI_CSYSREQ/HI_CSYSACK handshake 0: 0 Control of HO_CACTIVE is invalid when HI_CSYSREQ/HI_CSYSACK handshake Bit[1] 1: 0 Control of HO_CACTIVE is valid when not HI_CSYSREQ/HI_CSYSACK handshake 0: 0 Control of HO_CACTIVE is invalid when not HI_CSYSREQ/HI_CSYSACK handshake

### 54.3.1.18 Renesas Private Register

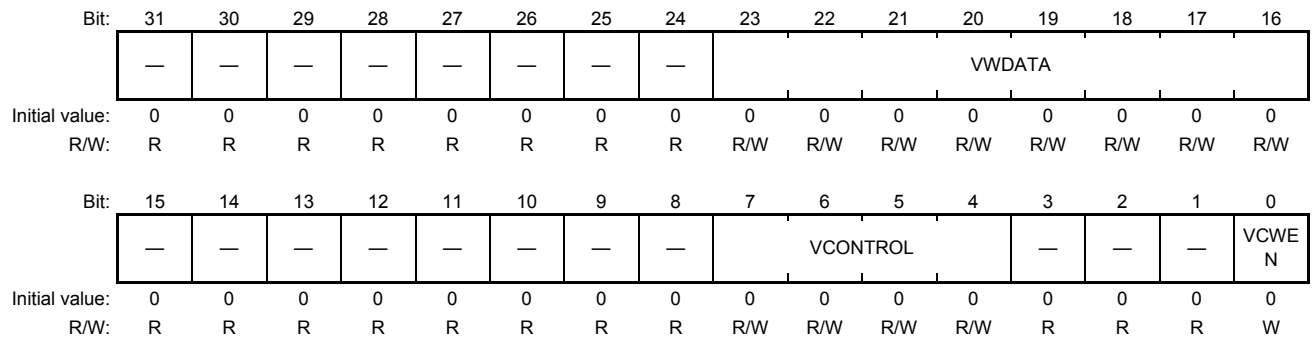

This is write inhibit register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Renesas Private field	H'FFFF FFFF	R/W	Renesas Private field. This is write inhibit field.

### 54.3.1.19 UTMI Plus Vendor Control Interface Set Register (VENDOR\_CON\_SET)

The register for Vendor Control Interface signal setting.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved
23 to 16	VWDATA	H'00	R/W	Signal for Vendor Write Data. It is write data signal to vendor control register write field.
15 to 8	—	All 0	R	Reserved
7 to 4	VCONTROL	H'0	R/W	Signal for Vendor Control. It is able to select vendor control register that user wants to use.
3 to 1	—	All 0	R	Reserved
0	VCWEN	0	W	Signal for enabling write VWDATA for Vendor Control Address. If this bit is set to 1, it is enabled to write the value of VWDATA for vendor control address.

### 54.3.1.20 UTMI Plus Vendor Control Interface Status Register (VENDOR\_CON\_STA)

The register for status of Vendor Control Interface signal.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	—	—	—	—	—	—	—	—	VSTATUS								—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R		

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved
7 to 0	VSTATUS	H'00	R	Signal for Vendor Status. It is read data signal from vendor control register read field.

### 54.3.1.21 LCLK Select Register (LCLKSEL)

The register configure LCLK. Write H'0103\_0001 to enable LCLK operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	LSEL	—	—
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	H'0020	R/W	Reserved This field should be set to H'0020.
18	LSEL	1	R/W	LCLK selection This bit control LCLK selection. This bit should be set to 0 when this IP operating. 0: LCLK enabled 1: LCLK disabled
17 to 0	—	H'3 0001	R/W	Reserved This field should be set to H'3 0001.

### 54.3.1.22 USB3.0 Configuration1

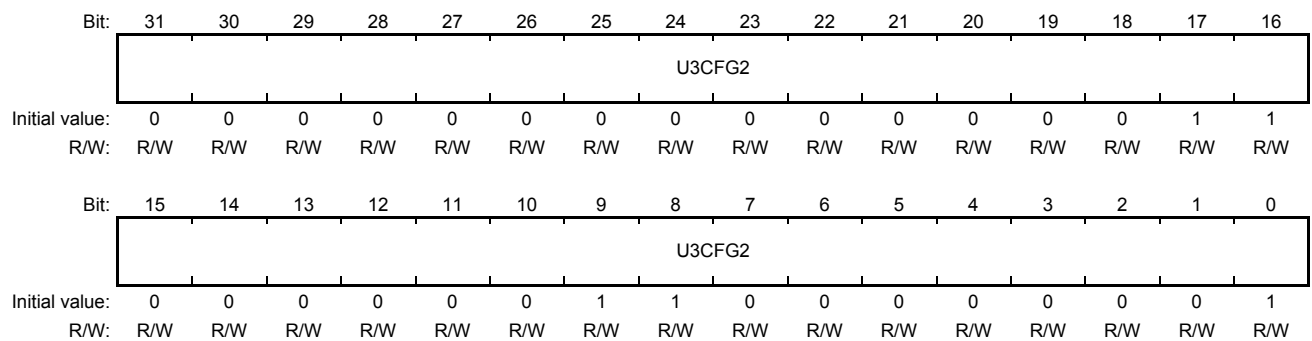

The register controls initial configuration of USB3.0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	U3CFG1	H'0007 0204	R/W	Must be set to H'0003 0204.

### 54.3.1.23 USB3.0 Configuration2

The register controls initial configuration of USB3.0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	U3CFG2	H'0003 0301	R/W	Must be set to H'0003 0300.

### 54.3.1.24 USB3.0 Configuration3

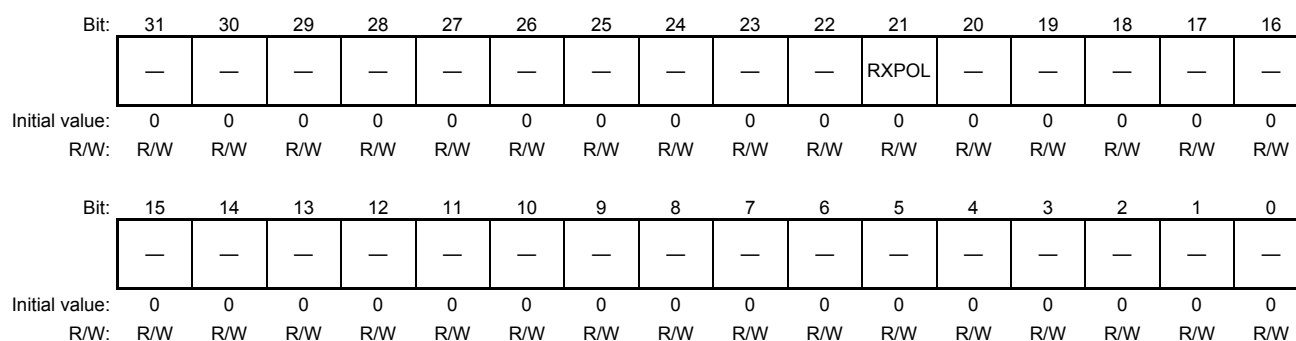

The register controls initial configuration of USB3.0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	U3CFG3_HI	H'1380 200	R/W	Must be set to H'1380 200.
3	COMTERM	1	R/W	Internal reference clock terminator control. 0: OFF 1: ON
2 to 0	U3CFG3_LO	111	R/W	Must be set to 111

### 54.3.1.25 USB3.0 RX Polarity

The register controls polarity inversion of SS USB3.0 RX.

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R/W	Reserved The write value should be 0.
21	RXPOL	0	R/W	Polarity inversion setting of RX. 0: Normal operation 1: Polarity Inversion enable
20 to 0	—	All 0	R/W	Reserved The write value should be 0.

### 54.3.1.26 USB3.0 TX Polarity

The register controls polarity inversion of SS USB3.0 TX.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TXPOL	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R/W	Reserved The write value should be 0.
4	TXPOL	0	R/W	Polarity inversion setting of TX. 0: Normal operation 1: Polarity Inversion enable
3 to 0	—	All 0	R/W	Reserved The write value should be 0.

### 54.3.2 xHCI Register

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

#### 54.3.2.1 Host Controller Capability Registers

Host controller capability registers constitute a register group indicating capability information that shows the host controller interface component.

No.	Offset	Base Offset	Register	Default Value (H)	Function
1	H'00	H'000	CAPLENGTH	H'20	Capability register length
2	H'01	H'001	—	H'00	Reserved
3	H'02	H'002	HCIVERSION	H'0100	Host controller interface version number
4	H'04	H'004	HCSPARAMS1	H'0200 0120	Structural parameters 1
5	H'08	H'008	HCSPARAMS2	H'2400 0011	Structural parameters 2
6	H'0C	H'00C	HCSPARAMS3	H'0000 0000	Structural parameters 3
7	H'10	H'010	HCCPARAMS	H'0140 51CF	Capability parameters
8	H'14	H'014	DBOFF	H'0000 0800	Doorbell offset
9	H'18	H'018	RTSOFF	H'0000 0600	Runtime register space offset
CAPLENGTH-H'01C					Reserved

#### (1) CAPLENGTH

Register specifying capability register size

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	CAPLENGTH	H'20	R	Displays Capability Register Size

#### (2) HCIVERSION

Register storing revision of xHCI Specification supported by the host controller.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	Major Version	H'01	R	Displays Major version of xHCI Specification
7 to 0	Minor Version	H'00	R	Displays Minor version of xHCI Specification

**(3) HCSPARAMS1**

Register storing basic architectural parameters supported by the host controller core.

For MaxPorts, the total number of ports for USB3 port and USB2 port is set. The host core has 1 port for each of USB3 and USB2, so the maxports value is 2. For MaxInters, the total number of Interrupters supported by the host controller is set. The host core has 1 interrupter, so bit is set to 1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MaxPorts	H'02	R	Number of Ports Total number of downstream ports implemented by host controller
23 to 18	—	All 0	R	Reserved
17 to 8	Max Inters	H'001	R	Number of Interrupters Total number of Interrupters implemented by host controller
7 to 0	MaxSlots	H'20	R	Number of Device Slots Maximum number of device context structures and doorbell array entries that can be supported

**(4) HCSPARAMS2**

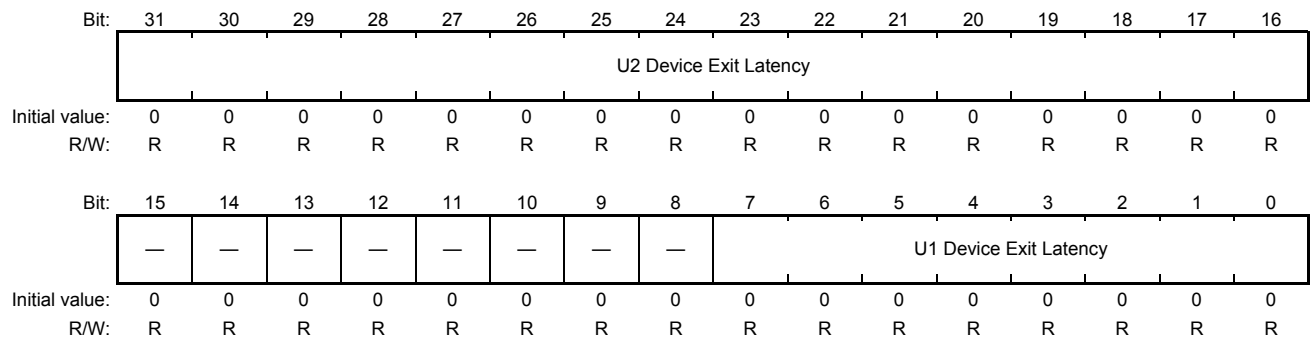

Register storing basic architectural parameters supported by the host controller core.

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	Max Scratchpad Buffers	H'04	R	Displays the number of scratchpad buffers that the system software reserves for xHC. Valid: 0 to 31
26	SPR	1	R	Scratchpad Restore Indicates whether xHC uses a scratchpad buffer or not to save the state when max scratchpad buffers > 0 and save and restore operations are performed. If Max Scratchpad Buffer = 0, this bit is set to 0.
25 to 8	—	All 0	R	Reserved
7 to 4	ERST Max	H'1	R	Event Ring Segment Table Max Determines the maximum supported value for the event ring segment table base size register. The maximum number of event ring segment table entries = $2^{ERST\ Max}$
3 to 0	IST	H'1	R	Isochronous Scheduling Threshold Specifies the number of frames/microframes. Until bit[3] 0: IST[2:0] microframes, TRB can be added. Until bit[3] 1: IST[2:0] frames, TRB can be added.

**(5) HCSPARAMS3**

Register specifying link exit latency.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	U2 Device Exit Latency	H'0000	R	Worst case latency during transition from U2 to U0. H'0000: zero H'0001: less than 1 $\mu$ s. H'0002: less than 2 $\mu$ s ... H'07FF: less than 2,047 $\mu$ s. H'0800 to H'FFFF: reserved
15 to 8	—	All 0	R	Reserved
7 to 0	U1 Device Exit Latency	H'00	R	Worst case latency during transition from U1 to U0. H'00: zero H'01: less than 1 $\mu$ s. H'02: less than 2 $\mu$ s ... H'0A: less than 10 $\mu$ s. H'0B to H'FF: reserved

**(6) HCCPARAMS**

Register specifying optional capability supported by xHCI.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	xECP															
Initial value:	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MaxPSASize				—	—	—	PAE	NSS	LTC	LHRC	PIND	PPC	CSZ	BNC	AC64
Initial value:	0	1	0	1	0	0	0	1	1	1	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

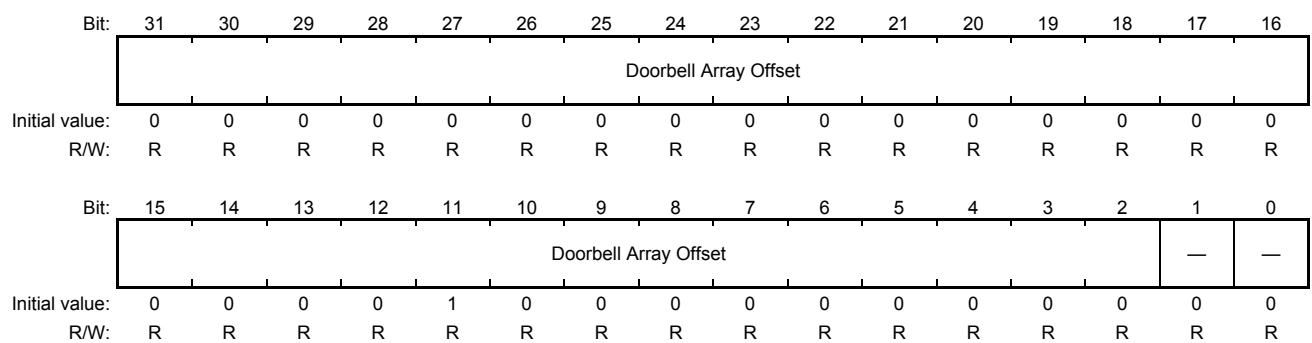

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	xECP	H'0140	R	xHCI Extended Capabilities Pointer Presence or absence of capabilities list H'0000: No extended capabilities Other: Indicates offset from BASE to extended capability. USB Legacy Supported Protocol Capability is at offset H'500.
15 to 12	MaxPSASize	H'5	R	Maximum Primary Stream Array Size Maximum size of primary stream array supported by host. Primary Stream Array size = $2^{\text{MaxPSASize}+1}$ Valid: 1 to 15 Default value is 5 as stream number HSP supports 63.
11 to 9	—	All 0	R	Reserved
8	PAE	1	R	Parse All Event Data Indicates whether host controller parses event data TRB that is found while skipping next TD after receiving short packet in aTD. 0: Just parse first 1: Parse all
7	NSS	1	R	No Secondary SID Support Indicates whether host controller supports secondary stream IDs. 0: Supported 1: Not supported
6	LTC	1	R	Latency Tolerance Messaging Capability Indicates whether host controller supports latency tolerance messaging. 0: Not supported 1: Supported
5	LHRC	0	R	Light HC Reset Capability Indicates whether host controller supports light host controller reset. 0: Not supported 1: Supported

Bit	Bit Name	Initial Value	R/W	Description
4	PIND	0	R	Port Indicators Indicates whether xHCI root hub port supports port indicator control. 0: Not contained 1: Port status/control register contains a field that can be read and written to control port indicator condition.
3	PPC	1	R	Port Power Control Indicates whether host controller contains port power control. 0: Port doesn't contain port power switch. 1: Port contains port power switch
2	CSZ	1	R	Context Size 0: xHC uses 32-byte Context data structure 1: xHC uses 64-byte Context data structure
1	BNC	1	R	BW Negotiation Capability Indicates whether xHC supports bandwidth negotiation 0: Does not support BW negotiation 1: Supports BW negotiation
0	AC64	1	R	64-bit Addressing Capability Addressing range 0: 32-bit address memory pointers 1: 64-bit address memory pointers

**(7) DBOFF**

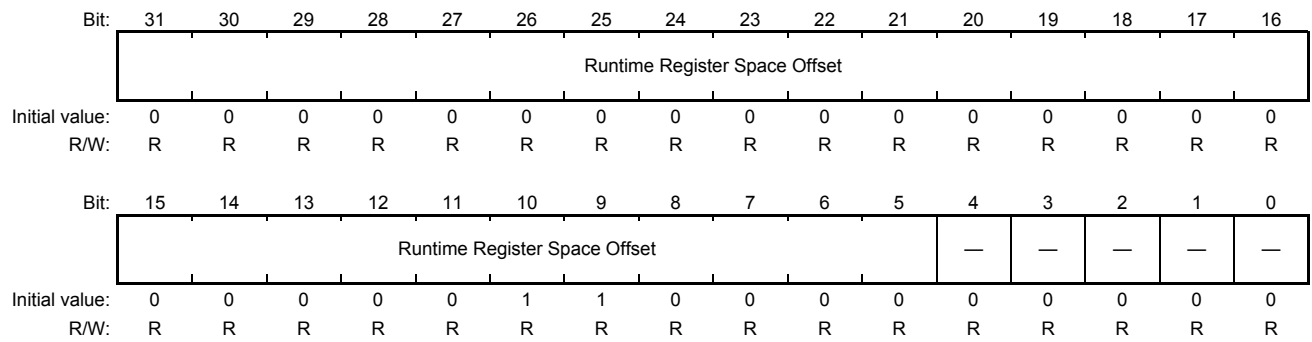

Register specifying Offset from Base Address of Doorbell Array.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	Doorbell Array Offset	H'0000 0200	R	Dword Offset from Base of Doorbell Array base address. Doorbell array's offset is H'800
1, 0	—	All 0	R	Reserved

**(8) RSTOFF**

Register specifying Offset from Base Address of Runtime Register Space.

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	Runtime Register Space Offset	H'000 0030	R	64-byte offset from Base, for xHCI Runtime Register. Address = Base + runtime register set offset runtime register's offset is H'600
4 to 0	—	All 0	R	Reserved

### 54.3.2.2 Host Controller Operational Registers

Host controller operational registers constitute a register group for monitoring and controlling the operational state of the host controller. The beginning address (Operational BASE) of the host controller operational registers is specified as follows;

Base address = Capability base address + CAPLENTH

No.	Offset	Base Offset	Register	Default Value (H)	Function
1	H'00	H'020	USBCMD	H'0000_0000	USB command
2	H'04	H'024	USBSTS	H'0000_0801	USB status
3	H'08	H'028	PAGESIZE	H'0000_0001	Page size
4	H'10 to H'0C	H'030 to H'02C	—		Reserved
5	H'14	H'034	DNCTRL	H'0000_0000	Device notification control
6	H'18	H'038	CRCRL	H'0000_0000	Command ring control lo
7	H'1C	H'03C	CRCRH	H'0000_0000	Command ring control hi
8	H'2C to H'20	H'04C to H'040	—		Reserved
9	H'30	H'050	DCBAAPL	H'0000_0000	Device context bass address array pointer lo
10	H'34	H'054	DCBAAPH	H'0000_0000	Device context bass address array pointer hi
11	H'38	H'058	CONFIG	H'0000_0000	Configure

Host Controller Port Register Set

Beginning Address is Operational Base + CAPLENTH + (H'400 + H'10 × (n - 1))

“n” indicates Port Number of Host Controller and the maximum value is the value of MaxPorts.

This Host Control Core's MaxPorts is 2. The Register group is as follows.

No.	Offset	Base Offset	Register	Default Value (H)	Function
1	H'00	H'420	PORTSC1	H'0000 02A0	Port Status and Control 1 (USB3)
2	H'04	H'424	PORTPMSC1	H'0000 0000	Port PM Status and Control 1 (USB3)
3	H'08	H'428	PORTLI1	H'0000 0000	Port Link Info 1 (USB3)
—	H'0C	H'40C	—		Reserved
4	H'10	H'430	PORTSC2	H'0000 02A0	Port Status and Control 2 (USB2)
5	H'14	H'434	PORTPMSC2	H'0000 0000	Port PM Status and Control 2 (USB2)
—	H'18	H'438	—		Reserved
—	H'1C	H'43C	—		Reserved

**(1) USBCMD**

Register indicating command to be executed by host controller. The host controller writes the register after which the Command is executed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	EU3S	EWE	CRS	CSS	LHCRST	—	—	—	HSEE	INTE	HCRST	R/S
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved
11	EU3S	0	R/W	Enable U3 MFINDEX stop 0: If all root hub ports are in the disconnected, disabled, or powered-off state, xHC can stop count of MFINDEX. 1: If all root hub ports are in the U3, disconnected, disabled, or powered-off state, xHC can stop count of MFINDEX.
10	EWE	0	R/W	Enable Wrap Event 0: Do not generate MFINDEX wrap event 1: Every time MFINDEX register changes from H'03FFF to H'0, xHC generates MFINDEX wrap event.
9	CRS	0	R/W	Controller Restore State <ul style="list-style-type: none"> <li>CRS bit = 1, Run/Stop bit = 0 and Save State bit = 1: xHC executes restore state operation to restore the internal state.</li> <li>CRS bit = 0: Restore state operation not executed</li> <li>CRS bit = 1, Run/Stop bit = 1 or Save State bit = 0: Restore state operation not executed read value from AXI is 0. If this bit is set to 1 by AXI, H/W sets USBSTS bit 9 to 1, bit 10 to 0 clear.</li> </ul>
8	CSS	0	R/W	Controller Save State <ul style="list-style-type: none"> <li>CSS bit = 1, Run/Stop bit = 0: xHC saves internal state that is restored at next restore state operation</li> <li>CSS bit = 1, Run/Stop bit = 1: Save state operation is not executed. read value from AXI is 0. If this bit is set to 1 by AXI, H/W sets USBSTS bit 8 to 1, bit 10 to 0 clear.</li> </ul>
7	LHCRST	0	R	Light Host Controller Reset If Light HC Reset Capability bit of HCCPARAMS register is 1, this bit is enabled. Read 0: Reset completed Read 1: Reset not completed
6 to 4	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
3	HSEE	0	R/W	Host System Error Enable HSEE bit = 1, HSE bit = 1: xHC asserts out-of-band error signal to host. Software clears HSE bit, after which its notice signal is received.
2	INTE	0	R/W	Interrupt Enable If this bit is 1, host system interrupt is enabled.
1	HCRST	0	R/W	Host Controller Reset Used to reset host controller. Write 1: Reset Does not influence AXI register. Host controller sets 0, then resetting process completes. Software continues resetting process until this bit changes to 0. Software shall not set 1 when HCHalted bit = 0.
0	R/S	0	R/W	Run/Stop 0: Stop 1: Run During 1, scheduling is being continued. During 0, completes USB transaction and transits to halted state. xHC shall goes to halted state during the 16 microframes after bit clearing. Software shall not set 1 except when xHC is in halted state.

**(2) USBSTS**

Register displaying condition of host controller. If a bit is set to 1, the bit is cleared to 0. If a bit is set 0, the set value is ignored.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	HCE	CNR	SRE	RSS	SSS	—	—	—	PCD	EINT	HSE	—	HCH
Initial value:	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	RW1C	R	R	R	R	R	RW1C	RW1C	RW1C	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved
12	HCE	0	R	Host Controller Error 0: No internal xHC error condition exists 1: Internal xHC error condition
11	CNR	1	R	Controller Not Ready 0: Ready 1: Not ready Software shall not set any doorbell and xHC operational registers except USBSTS until CNR = 0. This flag is set by Chip HW reset and cleared when writing is enabled. This flag remains set to 0 until next HW reset.
10	SRE	0	RW1C	Save/Restore Error When error occurs in save or restore operation, this bit is set to 1. This bit is cleared when save or restore operation starts or when the bit is written with 1.
9	RSS	0	R	Restore State Status When controller restore state flag in USBCMD is set to 1, this bit is set to 1. During restoring, this bit remains set to 1. When restore state operation finishes, this bit is set to 0.
8	SSS	0	R	Save State Status This bit is set to 1 when controller save state flag bit in USBCMD is set to 1. Maintains a value of 1 during saving. This bit is set to 0 when save state operation finishes.
7 to 5	—	All 0	R	Reserved
4	PCD	0	RW1C	Port Change Detect This bit is set to 1 when port change bit changes from 0 to 1 and Force Port Resume bit changes from 0 to 1. 1: Detects resuming of suspended port
3	EINT	0	RW1C	Event interrupt xHC sets 1 when interrupt pending bit is set. 1 write clear

Bit	Bit Name	Initial Value	R/W	Description
2	HSE	0	RW1C	Host System Error 1: Fatal error occurs when xHC accesses host system. And also DMA transfer error. When these errors occur xHC sets Run/Stop bit to 0 and stops command and event after errors.
1	—	0	R	Reserved
0	HCH	1	R	HCHalted If Run/Stop bit is 1, this bit is set to 0. If Run/Stop bit is set to 0 to stop operation, Software or xHC hardware sets this bit to 1.

**(3) PAGESIZE**

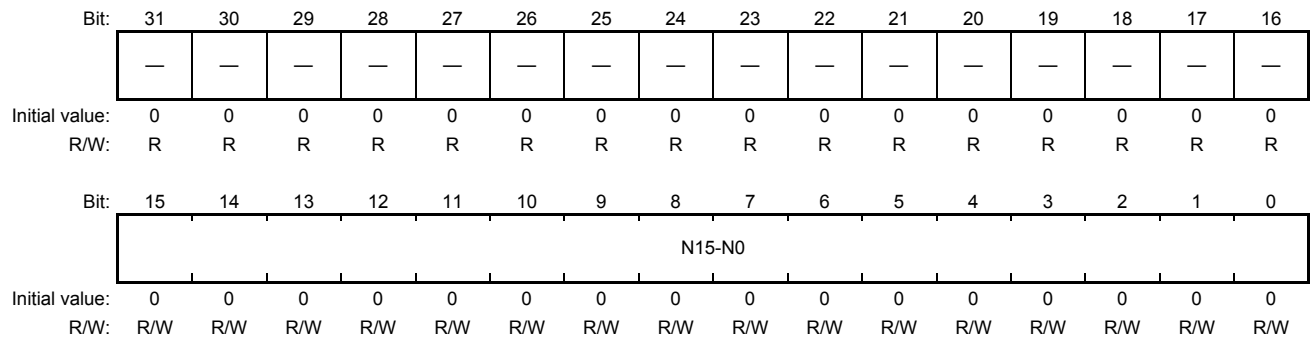

Page size that is supported by xHC implementation is defined.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	Page Size	H'0001	R	xHC's system page size. 4 KB page size

**(4) DNCTRL**

This register is used by host controller to set notification of whether USB device notification Transaction Packet in DNCTRL register is enabled or disabled. Device notification event is permitted by bit setting. It is presupposed that bits are written in units of one word (4 bytes).

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	N15-N0	H'0000	R/W	<p>Notification Enable</p> <p>When the Notification Enable bit is set, and the device notification transaction packet has the same value in the notification type field, a device notification event occurs.</p> <p>EX) When N3 is set, and the device notification TP with its notification type field set to 3 (FUNCTION_WAKE) is received, a device notification event occurs.</p>

**(5) CRCR**

Register indicating base address of first segment of command ring.

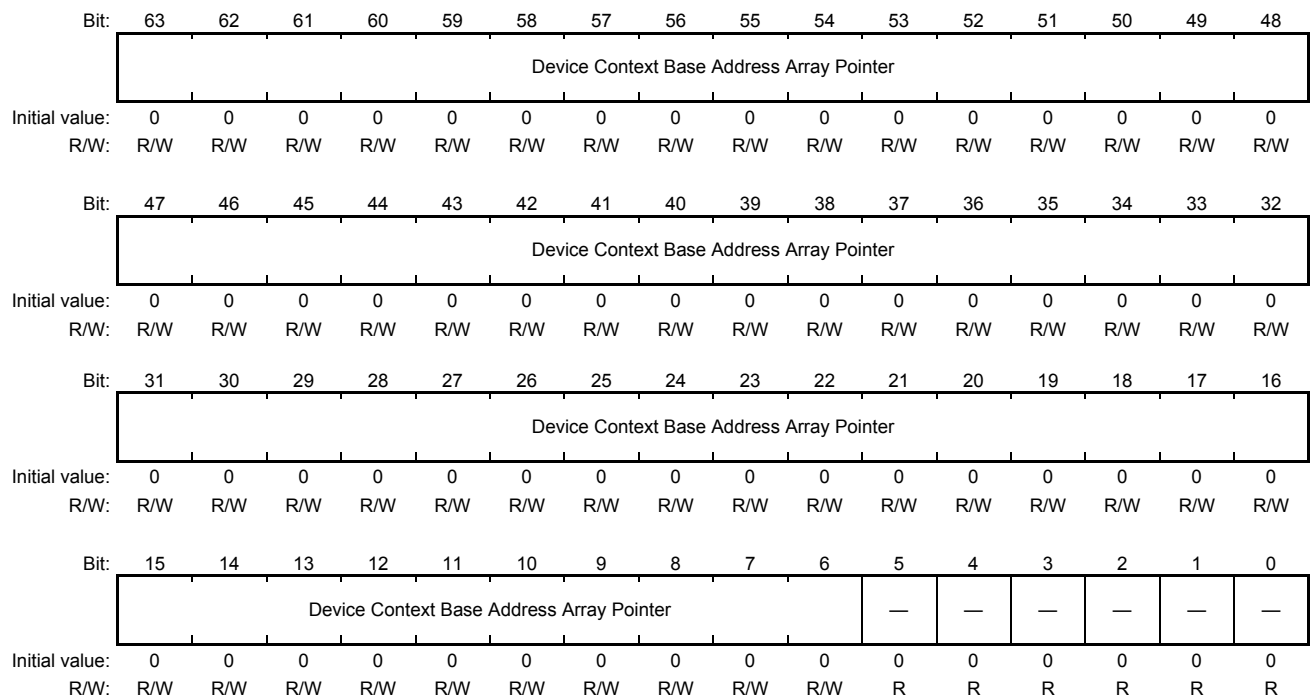

Bit	Bit Name	Initial Value	R/W	Description
63 to 6	Command Ring Pointer	H'0000 0000 0000 000	R/W	Defines a 64-bit Command Ring Dequeue Pointer default value. When Command Ring Running (CRR) is 1, any writing to this bit is ignored. The read value from AXI is 0.
5, 4	—	All 0	R	Reserved
3	CRR	0	R	Command Ring Running This bit is set when the Run/Stop bit is 1 and the DB reason field in the host controller doorbell register is set to 1 by the host controller command. This bit is cleared to 0 when the command ring stops after command stop or command abort is set to 1, or when Run/Stop bit is cleared to 0.
2	CA	0	R/W	Command Abort When this bit is set to 1, stops all commands and stops command ring, changes completion code to “Command Ring Stop”, and sends command completion with the completion code set to current command ring dequeue pointer value. When Command Ring Running (CRR) is 0, xHC ignores any writing to this field. The read value is 0.
1	CS	0	R/W	Command Stop Writing 1 causes command ring operation to be stopped after the command’s completion, then the completion code is changed to command ring stop. Command completion with the command TRB pointer set to the current command ring dequeue pointer value is sent. When Command Ring Running (CRR) is 0, xHC ignores any writing to this field. The read value is 0.

Bit	Bit Name	Initial Value	R/W	Description
0	RCS	0	R/W	Ring Cycle State Defines the xHC Consumer Cycle State (CCS) referred to by the command ring pointer. When Command Ring Running (CRR) is 1, any writing to this field is ignored. The read value is 0.

**(6) DCBAPP**

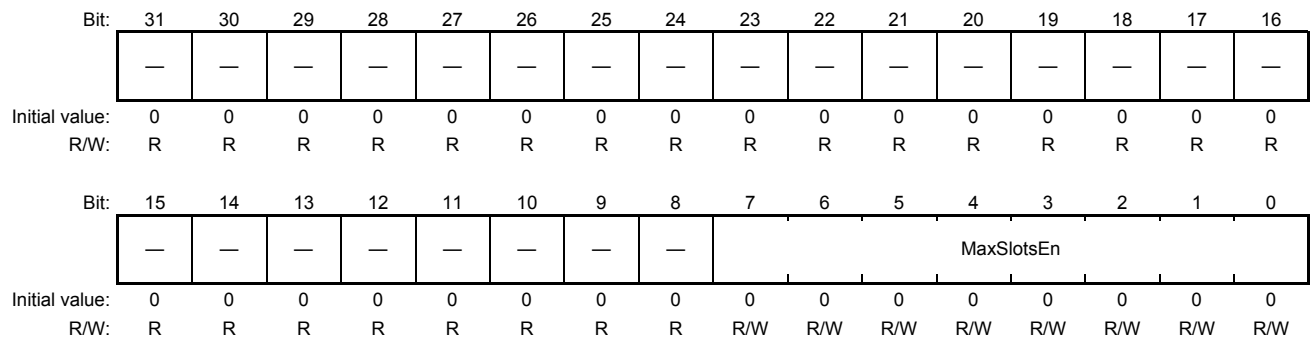

Registers indicating base address of device context bass address array.

Bit	Bit Name	Initial Value	R/W	Description
63 to 6	Device Context Base Address Array Pointer	H'0000 0000 0000 000	R/W	Defines 64-bit base address of device context pointer array table.
5 to 0	—	All 0	R	Reserved

**(7) CONFIG**

Register defining numeric xHC configuration parameters.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved
7 to 0	MaxSlotsEn	H'00	R/W	<p>Max Device Slots Enable</p> <p>Indicates maximum number of enabled device slots. The valid range is 0 to MaxSlots.</p> <p>Enabled device slots are allocated continuously.</p> <p>EX) When 16 is defined, Device Slots 1-16 constitute the active range.</p> <p>0: Disable Device slots</p> <p>While xHC is running, (Run/Stop bit = 1), it is not possible to write to this field.</p>

**(8) PORTSC1**

This register controls port status of USB3.0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WPR	DR	—	—	WOE	WDE	WCE	CAS	CEC	PLC	PRC	OCC	WRC	PEC	CSC	LWS

Initial value:	0	0	0	0	0	0	1	0	1	0	1	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	RW1C	R

Bit	Bit Name	Initial Value	R/W	Description
31	WPR	0	RW1S	Warm Port Reset Write 1: Starts warm reset sequence, and sets PR bit to 1. Conformity with the warm reset sequence, is reflected in the PR bit setting of PR, PRC, and WRC.
30	DR	0	R	Device Removable 0: Device connected to this Port is removable 1: Device connected to this Port is non-removable
29, 28	—	All 0	R	Reserved
27	WOE	0	R/W	Wake on Over-current Enable Write 1: Enables over-current condition as system wake-up event. If Port Power is 0, this bit is set to 0.
26	WDE	0	R/W	Wake on Disconnect Enable Write 1: Enables device disconnect as system wake-up event. If Port Power is 0, this bit is set to 0.
25	WCE	0	R/W	Wake on Connect Enable Write 1: Enables device connect as system wake-up event If Port Power is 0, this bit is set to 0.
24	CAS	0	R	Cold Attach Status 1: Far-end receiver Termination is detected but port status cannot transition to enabled state. If PP is 0 or at USB2.0 Port, this bit is set to 0.
23	CEC	0	RW1C	Port Config Error Change This bit is set when configuration with link partner fails.
22	PLC	0	RW1C	Port Link State Change This bit is set when link transitions from U3 to U0 state. 0: No Change 1: Link state Changed If a port status change event occurs, this bit is cleared to 0 automatically. Software writes 1 and then the bit is cleared.

Bit	Bit Name	Initial Value	R/W	Description
21	PRC	0	RW1C	<p>Port Reset Change</p> <p>This bit is set when port reset process completes. (Port Reset Change from 1 to 0 )</p> <p>0: No change 1: Reset complete</p> <p>If a port status change event occurs, this bit is cleared to 0 automatically. Software writes 1 and then the bit is cleared.</p>
20	OCC	0	RW1C	<p>Over-current Change</p> <p>When over-current active changes, this bit is set to 1. If a port status change event occurs, this bit is cleared to 0 automatically. Software writes 1 and then the bit is cleared.</p>
19	WRC	0	RW1C	<p>Warm Port Reset Change</p> <p>This bit is set to 1 when a warm reset is completed.</p>
18	PEC	0	RW1C	<p>Port Enable/Disable Change</p> <p>0: No change 1: Port enabled/disabled status has changed</p> <p>This bit is set when USB2 protocol port is disabled due to exiting from appropriate conditions at EO2 point. If a port status change event occurs, this bit is cleared to 0 automatically. Software writes 1 and then this bit is cleared. If Port Reset is 0, this bit is set to 0.</p>
17	CSC	0	RW1C	<p>Connect Status Change</p> <p>0: No change 1: Change in current connect status</p> <p>xHC sets this bit to 1 at change of port device connect status. If a port status change event occurs, this bit is cleared to 0 automatically. Software writes 1 and then this bit is cleared. If Port Reset is 0, this bit is set to 0.</p>
16	LWS	0	R/W	<p>Port Link State Write Strobe</p> <p>Write 0: Writing to PLS field is ignored. 1: Writing to PLS field is enabled.</p> <p>The read value is 0</p>
15, 14	PIC	00	R/W	<p>Port Indicator Control</p> <p>If Port Indicator (PIND) bit in HCCPRAMS register is 0, writing to this field has no effect. If Port Indicator (PIND) bit is 1;</p> <p>00: Port indicators are off 01: Amber 10: Green 11: Undefined</p> <p>If Port Reset is 0, this field is set to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
13 to 10	Port Speed	H'0	R	<p>Speed type of USB device connected to the port.</p> <p>This is enabled only when a device is connected to the port. (Current Connect Status is 1)</p> <p>After a port reset, this field indicates the speed of the device connected to the port. If the reset or speed detection fails, this field indicates Unknown Speed. When the Current Connect Status changes from 0 to 1, this field indicates Undefined Speed.</p> <p>H'0: Undefined Speed (Before Speed detection)</p> <p>H'1: Full-speed device attached</p> <p>H'2: Low-speed device attached</p> <p>H'3: High-speed device attached</p> <p>H'4: SuperSpeed device attached</p> <p>H'5 to H'E: Reserved</p> <p>H'F: Unknown Speed</p> <p>(Error detected during speed detection or Port Reset.)</p>
9	PP	1	R/W	<p>Port Power</p> <p>This field reflects a port's logical power state.</p> <p>0: This port is in the Powered-off state.</p> <p>1: This port is not in the Powered-off state.</p> <p>When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 1, xHC has a port power control switch and this bit shows the current state of the switch. (0:off, 1:on)</p> <p>When the Port Power Control (PPC) bit in the HCSPATAMS1 register is 0, xHC has no port power control switch and each port is hard wired to power and not affected by this bit.</p> <p>If an over-current condition is detected at a powered port, the PP bit of each port is changed from 1 to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
8 to 5	PLS	H'5	R/W	<p>Port Link State</p> <p>This field is used for port power management and shows the Current Link state. When PED is 1, System software sets this bit then sets Link U state.</p> <p>Port Link State is not set to Disabled, RxDetect, or Inactive State.</p> <p>H'0: The link shall transition to the U0 state from any of the U states.</p> <p>H'1: The link should transition to the U1 State.</p> <p>H'2: The link should transition to the U2 State.</p> <p>H'3: The link shall transition to the U3 state from any of the U states.</p> <p>H'4 to H'F: Ignored.</p> <p>To write to this field, the Port Link State Write strobe should be 1.</p> <p>For USB2 Protocol port, writing 2 requests LPM.</p> <p>Software reads this field to determine success/failure of transition to U2 state.</p> <p>Write 0: Deasserts L1 signal</p> <p>Write 1: No influence</p> <p>Read Value Meaning</p> <p>H'0: Link is in the U0 State</p> <p>H'1: Link is in the U1 State</p> <p>H'2: Link is in the U2 State</p> <p>H'3: Link is in the U3 State (Device Suspended)</p> <p>H'4: Link is in the Disabled State</p> <p>H'5: Link is in the RxDetect State</p> <p>H'6: Link is in the Inactive State</p> <p>H'7: Link is in the Polling State</p> <p>H'8: Link is in the Recovery State</p> <p>H'9: Link is in the Hot Reset State</p> <p>H'A: Link is in the Compliance Mode State</p> <p>H'B: Link is in the Loopback State</p> <p>H'C to H'F: Reserved</p> <p>If Port Reset is 0, this field is ambiguous.</p>
4	PR	0	R/W	<p>Port Reset</p> <p>0: port is not in reset</p> <p>1: port reset assert</p> <p>When software sets this bit from 0 to 1, the bus reset sequence is started.</p> <p>Port Enable/Disable bit is 0.</p> <p>Port Enable bit is 0.</p> <p>This bit remains set to 1 until reset by root hub is completed.</p> <p>When error is detected during resetting, Port Speed bits indicate Unknown Speed.</p> <p>If Port Power is 0, this field is set to 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
3	OCA	0	R	Over-current Active 0: Over-current condition 1: Not over-current condition When an over-current condition is removed, this bit changes from 1 to 0 automatically.
2	—	0	R	Reserved
1	PED	0	RW1C	Port Enable/Disable 0: Disable 1: Enable After detecting a connection at a port, if SS port initialization or reset by the system software is successful, this bit is automatically enabled by xHC. Port is disabled by fault condition (disconnect event or other fault condition), or USB System Software. Bit status doesn't change until port status changes. If Port Power is 0, this field is set to 0.
0	CCS	0	R	Current Connect Status 0: No device is present 1: Device is present on port Reflects current port status. If Port Power is 0, this field is set to 0.

**(9) PORTSC2**

Register controlling Port Status of USB2.0.

Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved
24	HC OS Owned Semaphore	0	R/W	System Software sets this bit to request xHC ownership. When this bit is 1 and the HC BIOS Owned Semaphore bit is 0, then the OS gets ownership.
23 to 17	—	All 0	R	Reserved
16	HC BIOS Owned Semaphore	0	R/W	BIOS sets this bit to establish xHC ownership. If there is an ownership request from the System Software, the BIOS sets this bit to 0.
15 to 8	Next Capability Pointer	H'04	R	Location of next Capability
7 to 0	Capability ID	H'01	R	Extended Capability This field is fixed to H'01 due to the Legacy Support Capability.

**(2) USBLEGCTLSTS**

Register for enabling System Management Interrupts (SMIs).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SMI on BAR	SMI on PCI Command	SMI on OS Ownership Change	—	—	—	—	—	—	—	—	SMI on Host System Error	—	—	—	SMI on Event Interrupt
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	RW1C	RW1C	RW1C	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SMI on BAR Enable	SMI on PCI Command Enable	SMI on OS Ownership Change Enable	—	—	—	—	—	—	—	—	SMI on Host System Error	—	—	—	USB SMI Enable
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SMI on BAR	0	RW1C	This bit is set to 1 when the Bass Address Register is written.
30	SMI on PCI Command	0	RW1C	This bit is set to 1 when the PCI Command Register is written.
29	SMI on OS Ownership Change	0	RW1C	This Bit is set to 1 when the HC OS Owned Semaphore bit in the USBLEGSUP register changes from 1 to 0, or from 0 to 1.
28 to 21	—	All 0	R	Reserved
20	SMI on Host System Error	0	R	Shadow bit of the Host System Error Interrupt bit in the USBSTS register. If this bit is set to 0, the System Software shall set the Host System Error Interrupt bit in the USBSTS register to 1.
19 to 17	—	All 0	R	Reserved
16	SMI on Event Interrupt	0	R	Shadow bit of the Event Interrupt (EINT) bit in USBSTS register. If EINT is set, this bit is also set. If EINT is cleared, this bit is also cleared.
15	SMI on BAR Enable	0	R/W	If this bit is 1 and SMI on the BAR bit is 1, the Host controller issues SMI.
14	SMI on PCI Command Enable	0	R/W	If this bit is 1 and SMI of the PCI Command bit is 1, the Host controller issues SMI.
13	SMI on OS Ownership Change Enable	0	R/W	If this bit is 1 and SMI of the OS Ownership Change bit is 1, the Host controller issues SMI.
12 to 5	—	All 0	R	Reserved
4	SMI on Host System Error Enable	0	R/W	If this bit is 1 and SMI of the Host System Error bit is 1, the Host controller issues SMI immediately.
3 to 1	—	All 0	R	Reserved
0	USB SMI Enable	0	R/W	If this bit is 1 and SMI of the SMI Event Interrupt bit is 1, the Host controller issues SMI immediately.

### 54.3.2.4 xHCI Supported Protocol Capability Register

The xHCI Supported Protocol Capability is defined in the xHCI specification.

The beginning address of the xHCI Supported Protocol Capability Register is;

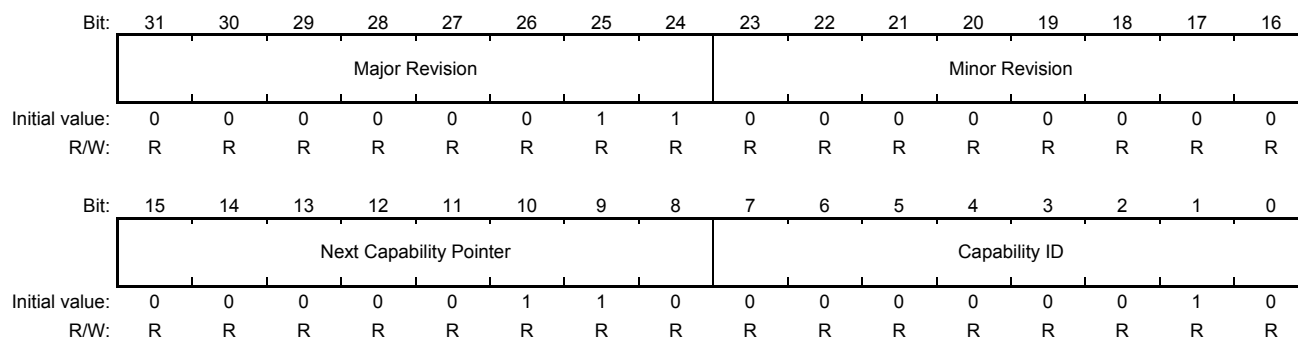

The beginning address of the USB Legacy Support Capability Register + USB Legacy Support Capability

Register's Next Item Pointer (relative DW Offset)

No.	Offset	Base Offset	Default Value (H)	Function
1	H'00	H'510	H'0300 0602	xHCI Supported Protocol Capability
2	H'04	H'514	H'2042 5355	(USB3.0)
3	H'08	H'518	H'0000 0101	
4	H'10	H'520	H'0000 0000	PSI (SuperSpeed)
5	H'18	H'528	H'0200 0802	xHCI Supported Protocol Capability
6	H'1C	H'52C	H'2042 5355	(USB2.0)
7	H'20	H'530	H'0000 0102	
8	H'28	H'538	H'0000 0000	PSI (Full-Speed)
9	H'2C	H'53C	H'0000 0000	PSI (Low-Speed)
10	H'30	H'540	H'0000 0000	PSI (High-Speed)

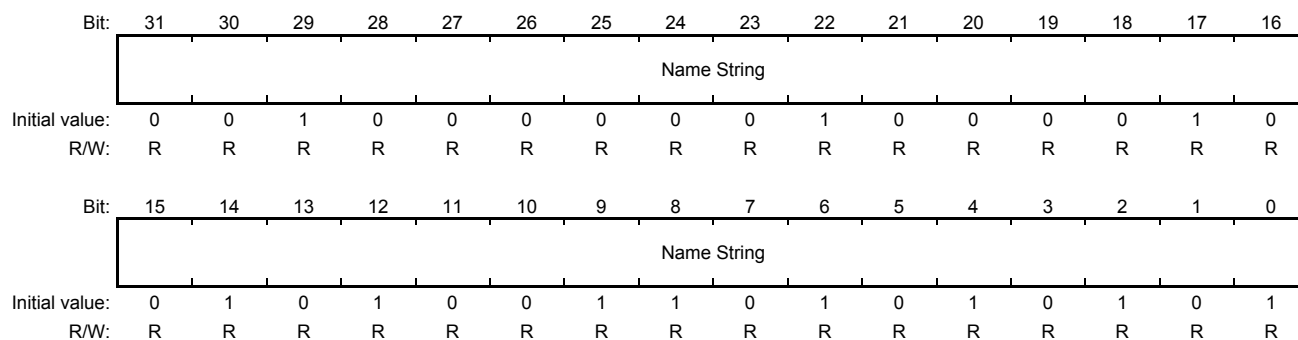

#### (1) xHCI Supported Protocol Capability (USB3.0)

##### (a) AXI Offset H'00

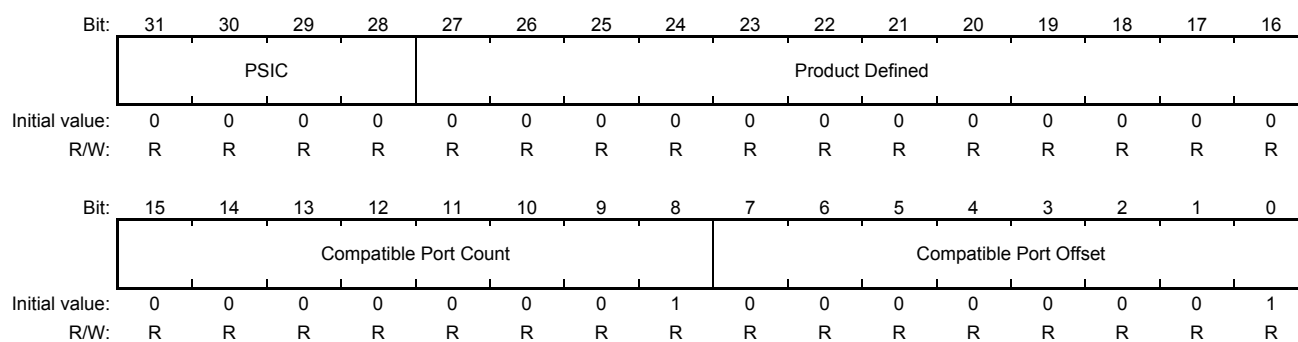

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Major Revision	H'03	R	Major release number compliant with xHC specification.
23 to 16	Minor Revision	H'00	R	Minor release number compliant with xHC specification.
15 to 8	Next Capability Pointer	H'06	R	Next Capability Location
7 to 0	Capability ID	H'02	R	Extended Capability Fixed to H'02 due to xHCI Supported Protocol Capability

**(b) AXI Offset H'04**

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Name String	H'2042 5355	R	Mnemonic name string compliant with xHC specification

**(c) AXI Offset H'08**

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PSIC	H'0	R	Product Speed ID Count Number of the Product Speed IDs that this protocol supports.
27 to 16	Product Defined	H'000	R	Reserved
15 to 8	Compatible Port Count	H'01	R	Number of the Root Hub Ports that this protocol supports.
7 to 0	Compatible Port Offset	H'01	R	Starting Port Number of the Root Hubs that this protocol supports.

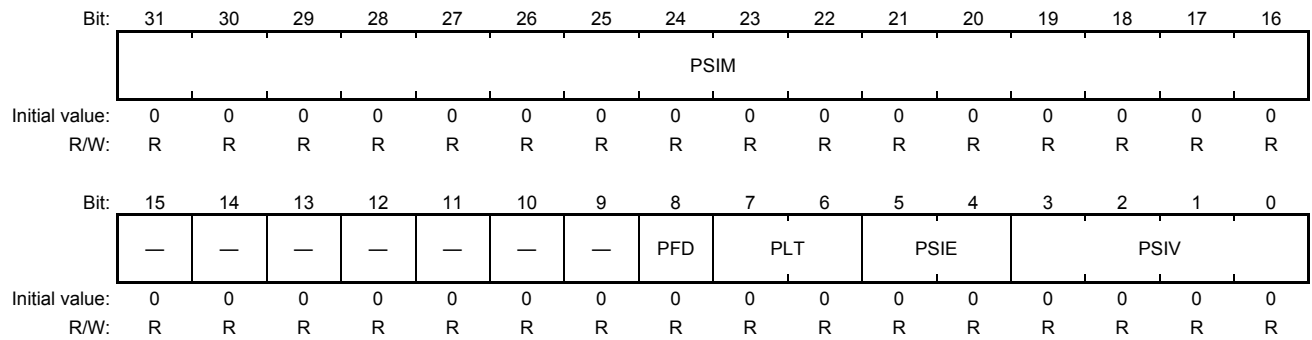

Compatible Port Offset is the starting port number of the ports that this protocol supports.

Compatible Port Count is the number of ports that this protocol supports.

In the case of the Host Core, the number of the USB3.0 (Super Speed) Port starts from 1, and the port number is indicated as 1.

PSIC (31:28) is the PSI number that the protocol supports.

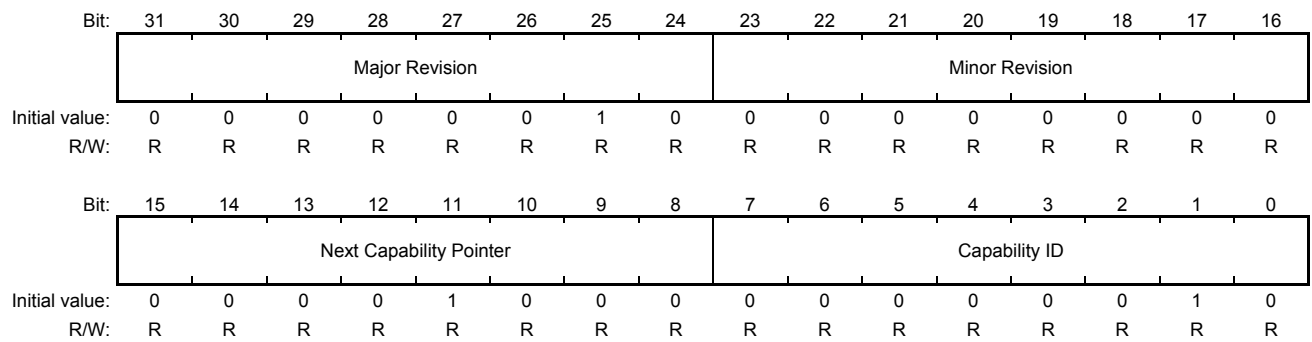

**(d) AXI Offset H'10 (PSI: SuperSpeed)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PSIM	H'0000	R	Product Speed ID Mantissa Maximum bit rate defined in this PSI register. Used with the PSIE field.
15 to 9	—	All 0	R	Reserved
8	PFD	0	R	PSI Full-duplex 0: Link is half-duplex. 1: Link is full-duplex.
7, 6	PLT	00	R	PSI Type Shows whether Symmetric or Asymmetric bit rate is defined for this PSI Register. 00: Symmetric 01: Reserved 10: Asymmetric Rx (Used with Tx PSI Dword) 11: Asymmetric Tx
5, 4	PSIE	00	R	Protocol Speed ID Exponent Unit indicated in PSIM. Value Bit Rate 00: Bits per second 01: Kb/s 10: Mb/s 11: Gb/s
3 to 0	PSIV	0000	R	Protocol Speed ID Value Used for reporting the Bit rate defined in the PSI register of the Port Speed bits in PORTSC.

**(2) xHCI Supported Protocol Capability (USB2.0)**

**(a) AXI Offset H'00**

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Major Revision	H'02	R	Major release number compliant with xHC specification.
23 to 16	Minor Revision	H'00	R	Minor release number compliant with xHC specification.
15 to 8	Next Capability Pointer	H'08	R	Next Capability Location
7 to 0	Capability ID	H'02	R	Extended Capability Fixed to H'02 due to xHCI Supported Protocol Capability

**(b) AXI Offset H'04**

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	Name String	H'2042 5355	R	Mnemonic name string compliant with xHC specification

(c) AXI Offset H'08

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PSIC	H'0	R	Product Speed ID Count Number of Product Speed IDs that this protocol supports.
27 to 20	—	All 0	R	Reserved
19	HLC	0	R	Hardware LPM Capability 1: Indicates whether hardware controlled LPM is supported
18	IHI	0	R	Integrated Hub Implemented 1: Root Hub and Port mapping of External xHC port are not compliant with default mapping specified in 4.24.2.1 in xHCI Spec.
17	HSO	0	R	High-speed Only 1: USB2 Port indicated with this Capability is HS Only
16	—	0	R	Reserved
15 to 8	Compatible Port Count	H'01	R	Number of Root Hub Ports that this protocol supports.
7 to 0	Compatible Port Offset	H'02	R	Starting Port Number of Root Hubs that this protocol supports.

Compatible Port Offset is the starting port number of the ports that this protocol supports.

Compatible Port Count is the number of ports that this protocol supports.

In the case of the Host Core, the number of the USB2.0 Port starts from 2, and the port number is indicated as 1.

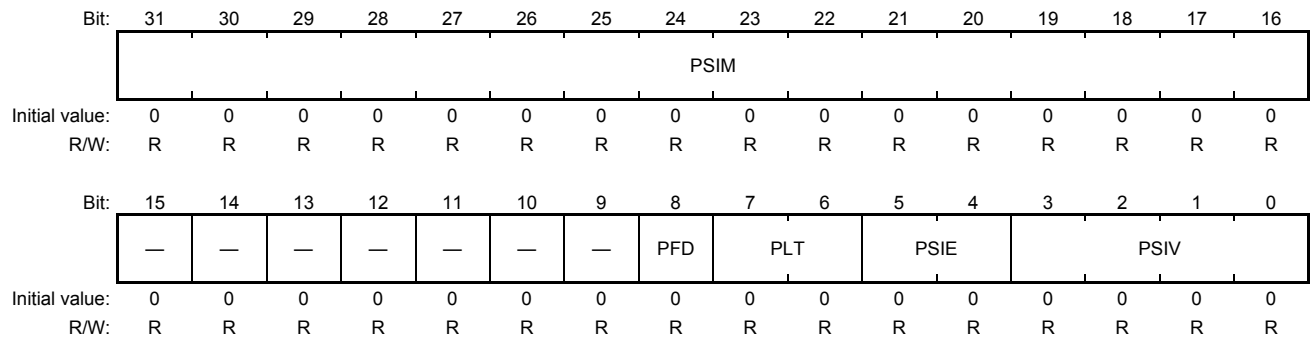

PSIC (31:28) is the PSI number that the protocol supports.

**(d) AXI Offset H'10 (PSI: Full-Speed)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PSIM	H'0000	R	Product Speed ID Mantissa Maximum bit rate defined in this PSI register. Used with the PSIE field.
15 to 9	—	All 0	R	Reserved
8	PFD	0	R	PSI Full-duplex 0: Link is half-duplex. 1: Link is full-duplex.
7, 6	PLT	00	R	PSI Type Shows whether Symmetric or Asymmetric bit rate is defined for this PSI Register. 00: Symmetric 01: Reserved 10: Asymmetric Rx (Used with Tx PSI Dword) 11: Asymmetric Tx
5, 4	PSIE	00	R	Protocol Speed ID Exponent Unit indicated in PSIM. Value Bit Rate 00: Bits per second 01: Kb/s 10: Mb/s 11: Gb/s
3 to 0	PSIV	0000	R	Protocol Speed ID Value Used for reporting the Bit rate defined in the PSI Register of the Port Speed field in PORTSC.

**(e) AXI Offset H'14 (PSI: Low-Speed)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PSIM	H'0000	R	Product Speed ID Mantissa Maximum bit rate defined in this PSI register. Used with the PSIE field.
15 to 9	—	All 0	R	Reserved
8	PFD	0	R	PSI Full-duplex 0: Link is half-duplex. 1: Link is full-duplex.
7, 6	PLT	00	R	PSI Type Shows whether Symmetric or Asymmetric bit rate is defined for this PSI Registers. 00: Symmetric 01: Reserved 10: Asymmetric Rx (Used with Tx PSI Dword) 11: Asymmetric Tx
5, 4	PSIE	00	R	Protocol Speed ID Exponent Unit indicated in PSIM. Value    Bit Rate 00:     Bits per second 01:     Kb/s 10:     Mb/s 11:     Gb/s
3 to 0	PSIV	0000	R	Protocol Speed ID Value Used for reporting the Bit rate defined in the PSI Register of the Port Speed field in PORTSC.

**(f) AXI Offset H'18 (PSI: High-Speed)**

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PSIM	H'0000	R	Product Speed ID Mantissa Maximum bit rate defined in this PSI register. It is used with PSIE field.
15 to 9	—	All 0	R	Reserved
8	PFD	0	R	PSI Full-duplex 0: Link is half-duplex. 1: Link is full-duplex.
7, 6	PLT	00	R	PSI Type Shows Symmetric or Asymmetric bit rate is defined for this PSI Register. 00: Symmetric 01: Reserved 10: Asymmetric Rx (Used with Tx PSI Dword) 11: Asymmetric Tx
5, 4	PSIE	00	R	Protocol Speed ID Exponent Unit indicated in PSIM. Value Bit Rate 00: Bits per second 01: Kb/s 10: Mb/s 11: Gb/s
3 to 0	PSIV	0000	R	Protocol Speed ID Value Used for reporting the Bit rate defined in the PSI Register of the Port Speed field in PORTSC.

If PSIC is 0 in both the USB2.0 and USB3.0 protocol, the following are used as default values.

Default Speed ID Value	Definition	Bit Rate	Protocol	Equivalent PSI Dword value			
				PLT	PFD	PSIE	PSIM
1	Full-Speed	12 Mb/s	USB2.0	0	0	2	12
2	Low-Speed	1.5 Mb/s	USB2.0	0	0	1	1500
3	High-Speed	480 Mb/s	USB2.0	0	0	2	480
4	Super-Speed	5 Gb/s	USB3.0	0	1	3	5

### 54.3.2.5 xHCI Extended Power Management Capability Register

This Capability is equivalent to the PCI Power Management Capability in AXI Configuration.

This Capability is needed when the xHC System Interface is other than PCI.

However the value set for the Next Capability Pointer is compliant with the xHCI specification.

#### (a) AXI Offset H'00

**54.3.2.6 xHCI Vender Defined Capability Register**

According to the xHCI specification, when using and defining the Vender Defined Command, the following conditions are specified. This capability is prepared for them.

- Create xHCI Extended Capability Register(Vender Defined)
- Permit enable/disable setting for Vender Defined function by Driver with Create xHCI Extended Capability Register.
- Do not use this function until validation.

No.	Offset	Base Offset	Default Value (H)	Function
1	H'00	H'550	H'0000 04C0	xHCI Vender Defined Capability
2	H'04	H'554	H'0000 0000	Command Enable

3, 2	—	All 0	R	Reserved
1	PED	0	R/W	Port Enable/Disable 0: Disabled 1: Enabled When DCE is 0 or CCS is 0, this bit is set to 0.

Bit	Bit Name	Initial Value	R/W	Description
0	CC	0	R	Current Connect Status If Debug Port Number is other than 0, this bit is 1.

(i) AXI Offset H'30 (DCCP)

Bit	Bit Name	Initial Value	R/W	Description
63 to 4	Debug Capability Context Pointer Register	H'000 0000 0000 0000	R/W	Beginning address of Debug Capability Context Pointer When define AXI_MASTER_ADDRESS_WIDTH_64 is not set, address Hi is fixed to 0.
3 to 0	—	All 0	R	Reserved

### 54.3.2.8 Host Controller Runtime Register

Register group for using Runtime during Host Controller operation.

The beginning Address of the Host Controller Runtime Registers is defined as the Runtime Register Space Offset field in the RTSOFF Register and Capability Base Address.

Base Address = Capability Base Address + Runtime Register Space Offset

No.	Offset	Base Offset	Register	Default Value (H)	Function
1	H'00	H'600	MFINDEX	H'0000 0000	Runtime Microframe Index
—	H'1C to H'04	H'604 to H'61F	—	—	Reserved
—	H'20	H'620	IR #0	H'0000 0000	Interrupter Register Set #0

#### (1) MFINDEX

Indicates the current periodic frame.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

#### (2) Interrupter Register Set #0

Register controlling Interrupter #0.

No.	Offset	Register	Default Value (H)	Function
—	H'00	IMAN	H'0000 0000	Interrupter Management
—	H'04	IMOD	H'0000 0FA0	Interrupter Moderation
—	H'08	ERSTSZ	H'0000 0000	Event Ring Segment Table Size
—	H'0C	—	H'0000 0000	Reserved
—	H'10	ERSTBA	H'0000 0000 0000 0000	Event Ring Segment Table Base Address
—	H'18	ERDP	H'0000 0000 0000 0000	Event Ring Dequeue Pointer

**(a) AXI Offset H'00 (IMAN)**

This register shows the status of an interrupt and controls enable/disable of Interrupter.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IE	IP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	RWC

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved
1	IE	0	R/W	Interrupt Enable Indicates whether Interrupter can generate an interrupt or not. 0: Does not generate an Interrupt. 1: IP bit is 1, Interrupter Moderation Counter changes to 0 then Interrupter generates an interrupt.
0	IP	0	RWC	Interrupt Pending Current status of Interrupter. 0: Event Ring for Interrupter is empty. There is no pending interrupt. 1: Event Ring for Interrupter is not empty. For interrupter 0, interrupt is pending.

**(b) AXI Offset H'04 (IMOD)**

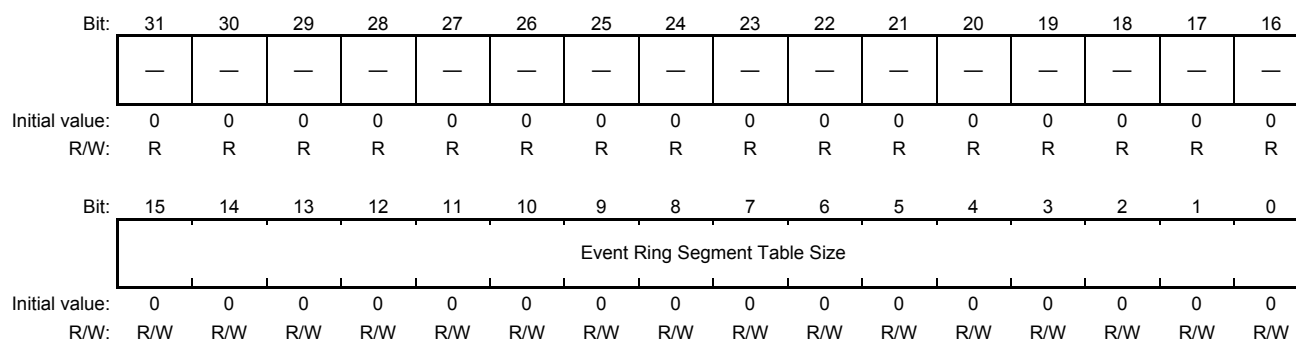

Register for controlling cycle of Moderation of Interrupter.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	IMODC	undefined	R/W	Down Counter: If IP is cleared to 0, the interval value is loaded and then counted down until 0, at which point the 0 counter will stop. An interrupt is generated when the counter is 0 but Event Ring is not empty and IM and IP bits are 1. Anytime Software can write this counter to change the interrupt rate.
15 to 0	IMODI	H'0FA0	R/W	Minimum value for the inter-interrupt interval. This interval can be set in increments of 250 ns. 0 is not permitted.

**(c) AXI Offset H'08 (ERSTSZ)**

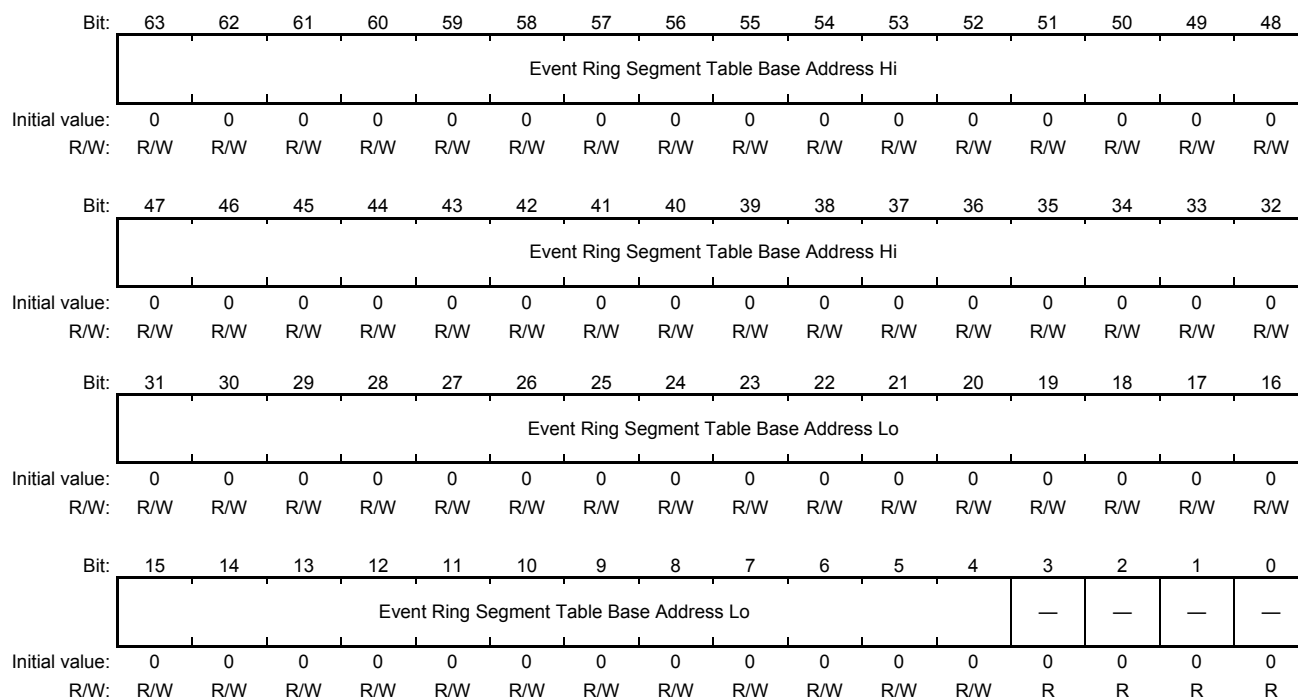

Register for setting number of Event Ring Segment Table entries.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	Event Ring Segment Table Size	H'0000	R/W	Defines the number of valid Event Ring Segment Table entries in the Event Ring Segment Table indicated by Event Ring Segment Table Base Address register. The maximum value supported by xHC is defined by ERST Max field in HSCPARAMS2 Register. xHC ignores bit writing when the Run/Stop bit is set to 1.

**(d) AXI Offset H'10 (ERSTBA)**

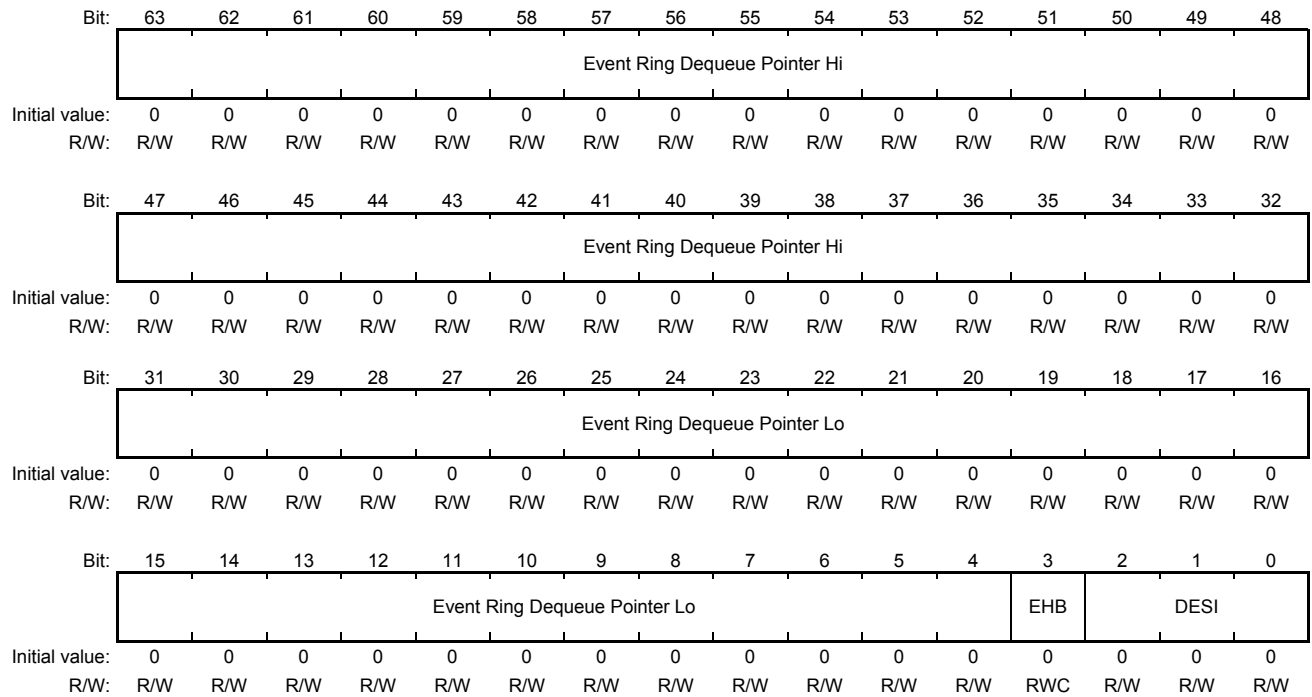

Register for setting the Base Address of the Event Ring Segment Table.

Bit	Bit Name	Initial Value	R/W	Description
63 to 32	Event Ring Segment Table Base Address Hi	H'0000 0000	R/W	Defines the Start Address (Hi) of the Event Ring Segment Table. Upon a write to this Register, the Event Ring State Machine transitions to the Start State. When define AXI_MASTER_ADDRESS_WIDTH_64 is not set, address Hi is fixed to 0.
31 to 4	Event Ring Segment Table Base Address Lo	H'000 0000	R/W	Defines the Start Address (Lo) of the Event Ring Segment Table. Upon a write to this Register, the Event Ring State Machine transitions to the Start State.
3 to 0	—	All 0	R	Reserved

**(e) AXI Offset H'18 (ERDP)**

Register for notification of Event Ring Dequeue Pointer by software

Bit	Bit Name	Initial Value	R/W	Description
63 to 32	Event Ring Dequeue Pointer Hi	H'0000 0000	R/W	Defines the Address (Hi) of Current Dequeue Pointer. Software initializes this Register before the Run/Stop bit is set to 1. When define AXI_MASTER_ADDRESS_WIDTH_64 is not set, address Hi is fixed to 0.
31 to 4	Event Ring Dequeue Pointer Lo	H'000 0000	R/W	Defines the Address (Lo) of the Current Dequeue Pointer. Software initializes the Register before the Run/Stop bit is set to 1.
3	EHB	0	RWC	Event Handler Busy This flag shall be set to '1' when the IP bit is set to '1' and cleared to '0' by software when the Dequeue Pointer register is written.
2 to 0	DESI	000	R/W	Dequeue ERST Segment Index This field is used for confirmation of the Event Ring full condition by xHC.

### 54.3.2.9 Doorbell Register

The Doorbell Register is used for notification of a Device Slot in processing execution on the Host Controller by System Software.

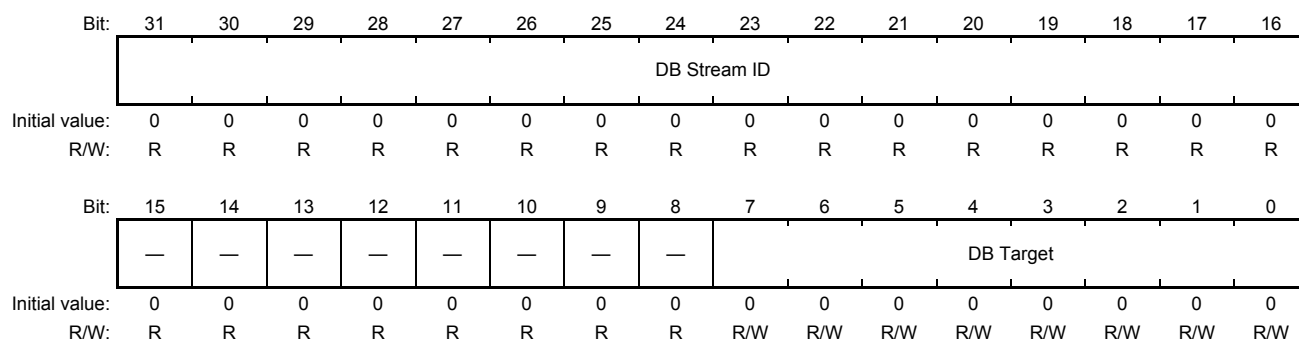

This Register is configured from 33 registers: 1 Host Controller Doorbell and 32 Device Context Doorbells.

The Doorbell Base Address is Dword Align, and provides the Doorbell Array Offset in the Doorbell Offset Register and the Base Address in the xHCI operational register address.

Base Address = Operational Base address + Doorbell Array Offset

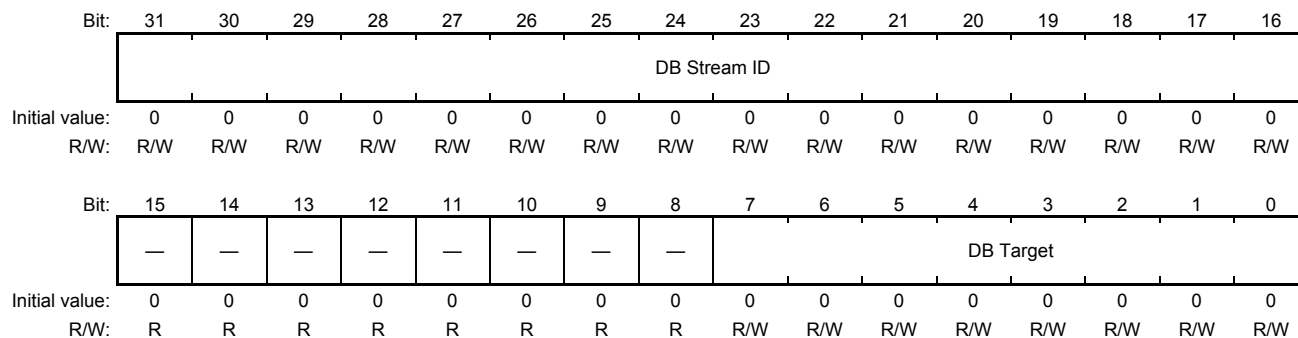

No.	Offset	Base Offset	Register	Default Value (H)	Function
1	H'00	H'800	DOORBELL0	H'0000 0000	Host Controller Doorbell
2	H'80 to H'04	H'880 to H'804	DOORBELL1 to 32	H'0000 0000	Device Context Doorbell (#1 to #32)

#### (1) Doorbell 0

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DB Stream ID	H'0000	R	Fixed to H'0000
15 to 8	—	All 0	R	Reserved
7 to 0	DB Target	H'00	R/W	Doorbell Target. For Device Context. Command Ring Host Controller Doorbell (0) Value Definition H'00: Host Controller Command H'01 to H'F7: Reserved H'F8 to H'FF: Vendor Defined If the set value is other than 0, it is ignored. The read Value is 0. When the Host Controller Doorbell (0) is set, DB Stream ID field is set to 0.

(2) Doorbell 1-32

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DB Stream ID	H'0000	R/W	Indicates targeted Endpoint's Stream when Endpoint defines Stream. If Endpoint doesn't define Stream (Max PStream = 0), but this bit is not set to 0, then this setting is ignored. The read Value is 0.
15 to 8	—	All 0	R	Reserved
7 to 0	DB Target	H'00	R/W	Doorbell Target. For Device Context Device Context Doorbells (1 to 255) Value            Definition H'00:            Reserved H'01:            Control EP 0 Enqueue Pointer Update H'02:            EP 1 OUT Enqueue Pointer Update H'03:            EP 1 IN Enqueue Pointer Update H'04:            EP 2 OUT Enqueue Pointer Update H'05:            EP 2 IN Enqueue Pointer Update ...                ... H'1E:            EP 15 OUT Enqueue Pointer Update H'1F:            EP 15 IN Enqueue Pointer Update H'20 to H'F7: Reserved H'F8 to H'FF: Vendor Defined The read Value is 0.

## 54.4 Description of Functions

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 54.4.1 FW Download

The USB3.0 host controller requires to download FW via AXI to operate as a host.

FW Download is realized by writing FW image data to a specific area in the AXI Register space. Upon the completion of FW Download, there is no need to write or reload FW.

#### 54.4.1.1 Download Data Format

The following format is used for FW Download.

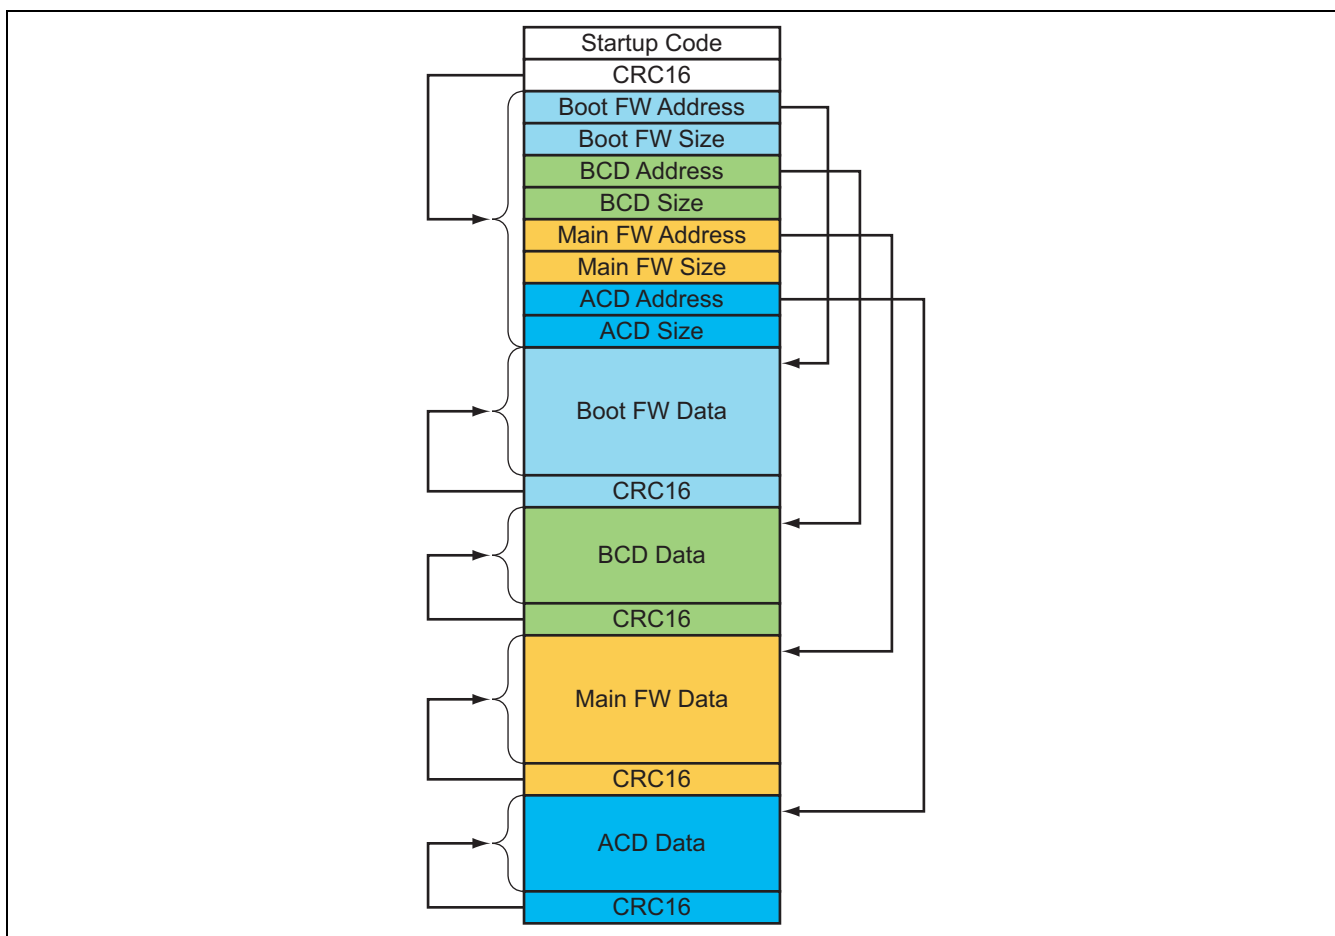

Figure 54.5 The Format of FW Download

Offset (Byte)	Size (Byte)	Field	Field Explanation
H'0000	2	Startup Code	Flag bit to show the storing of ROM Data. H'55AA is set.
H'0002	2	Header CRC16	CRC16 value from BCD Address to ACD size.
H'0004	2	Boot FW Address	Offset from the beginning of ROM Data in Boot FW Data field.
H'0006	2	Boot FW Size	Size of Boot FW field. (L)
H'0008	2	BCD Address	Offset from the beginning of Start Code in BCD Data field.
H'000A	2	BCD Size	Size of BCD Data field. (M)
H'000C	2	Main FW Address	Offset from the beginning of Startup Code in Main FW Data field. (N)
H'000E	2	Main FW Size	Size of Main FW field.
H'0010	2	ACD Address	Offset from the beginning of Startup Code in ACD Data field. (P)
H'0012	2	ACD Size	Size of ACD Data field.
H'0014	L	Boot FW Data	Bootstrap Code
(H'0014+L)	l	Boot FW CRC16	CRC16 of Boot FW Data field. If Boot FW Size field value is 0, it doesn't exist.
(H'0014+L+l)	pl	Padding	Padding to assign the beginning of BCD Data to 2-byte boundary.
(H'0014+L+l+pl)	M	BCD Data	BCD Data (Boot conf)
(H'0014+L+M+l+pl)	m	BCD CRC16	CRC16 of BCD Data field. If BCD Size field value is 0, it doesn't exist.
(H'0014+L+M+l+m+pl)	pm	Padding	Padding to assign the beginning of Main FW Data to 2-byte boundary.
(H'0014+L+M+l+m+pl+pm)	N	Main FW Data	Main FW
(H'0014+L+M+N+l+m+pl+pm)	n	Main FW CRC16	CRC16 of Main FW Data field. If Main FW Size field value is 0, it doesn't exist.
(H'0014+L+M+N+l+m+n+pl+pm)	pn	Padding	Padding to assign the beginning of ACD to 2-byte boundary.
(H'0014+L+M+N+l+m+n+pl+pm+pn)	P	ACD Data	ACD Data (Application conf)
(H'0014+L+M+N+P+l+m+n+pl+pm+pn)	p	ACD CRC16	CRC16 of ACD Data field. If ACD Size field value is 0, it doesn't exist.

Note: If "l", "m", "n", and "p" exist in each CRC16 field then the value is 2.  
If they do not exist, then the value is 0.

### 54.4.1.2 System Interface

The USB3.0 host controller delivers data through the AXI Register.

A register for delivering FW data has no specified data length, so data is always delivered at a 4-byte rate.

If delivered data cannot be allocated to a 4-byte boundary, Host calculates a length of necessary data and discards extra data.

Register	Bit	Field	Default	Attributes	Explanation										
AXICNF050	0	FW Download Enable	0	R/W	Flag bit to show that BIOS indicates execution of FW Download.  The System sets this bit to 1 when FW writing starts, and 0 when the last data is set to FW Data0/1.										
	1	FW Download Lock	0	RW1S	Flag for lock of FW Download.  When this bit is 1, FW Download is not done even when FW Download Enable is 1.										
	6 to 4	Result Code	0	RO	Execution result of BIOS Download.  <table border="1"> <thead> <tr> <th>Value</th> <th>Meaning</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Invalid</td> </tr> <tr> <td>1</td> <td>Success</td> </tr> <tr> <td>2</td> <td>Error</td> </tr> <tr> <td>others</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Meaning	0	Invalid	1	Success	2	Error	others	Reserved
	Value	Meaning													
	0	Invalid													
1	Success														
2	Error														
others	Reserved														
8	Set Data0	0	RW1S	Showing that FW Data0 at AXICNF058 is enabled.											
9	Set Data1	0	RW1S	Showing that FW Data1 at AXICNF05C is enabled.											
AXICNF058	31 to 0	FW Data0	H'00000 0000	R/W	Write data.										
AXICNF05C	31 to 0	FW Data1	H'00000 0000	R/W	Write data.										

When starting FW Download, the System first sets AXICNF050.FW Download Enable to 1, and then starts delivering data to the Host.

After writing a value to AXICNF058 or AXICNF05C, and setting value 1 to the corresponding bit of AXICNF050.SetData0/1, the System shall put the data delivery on hold until the bit changes to 0.

FW Data0/1 can be used in either of the following ways.

- Use FW Data0 and FW Data1 alternately.
- Use only FW Data0

After writing the last data to FW Data, the System sets AXICNF050.FW Download Enable to 0 and notifies the Host that Data transfer completes.

After the System makes a notification and confirms that AXICNF050.Result Code is 1 (Success), the flow completes.

Then if Result Code is 2 (Error), it indicates that Host cannot be used due to some error in FW Download.

(Almost caution is illegally data load.)

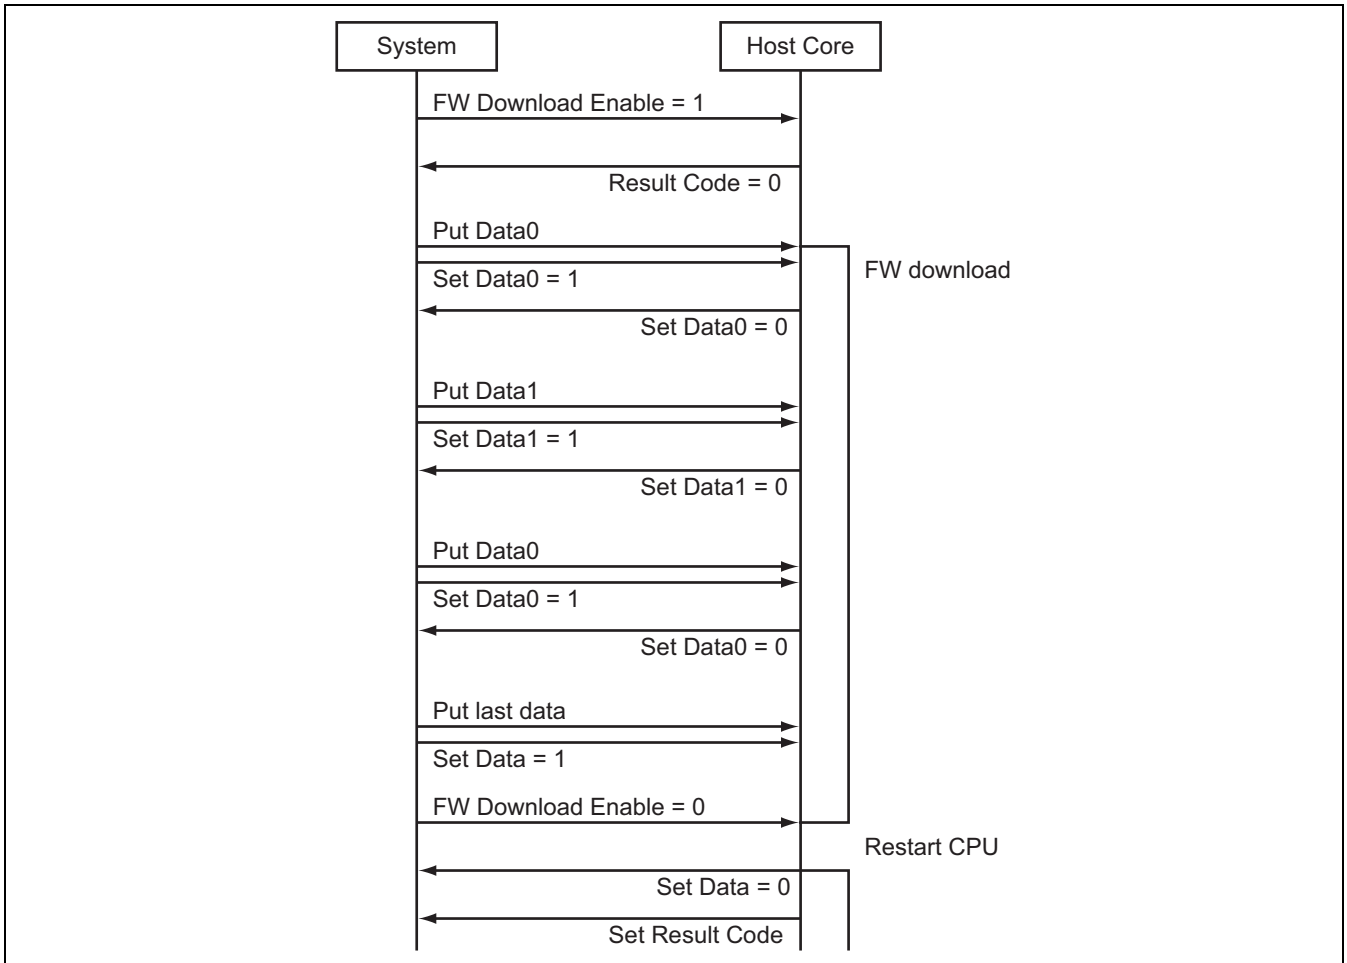

Figure 54.6 The Flow of FW Download

### 54.4.2 Battery Charging

The USB3.0 host controller supports the Battery Charging function of A-Device, which is on the supply side.

In the A-Device, the function is controlled by HW/FW of Host Core.

And it is required that CLk60 is working before starting Battery Charging flow.

Note: For details, refer to Battery Charging Specification Revision1.2.

#### 54.4.2.1 A-Device side (Charging Port Device)

The Battery Charging function is used to pull more current from VBUS than specified in USB specification.

Following Port Modes are supported in A-Device;

- Standard Downstream Port (SDP)
- Charging Downstream Port (CDP)
- Dedicated Charging Port (DCP)

##### (1) Setting BC\_MODE

At first for HW preparing, it shall be set Battery Charging Mode at BC\_MODE[3:0] at Battery Charging Register in AXI Register.

(Refer to section 54.2.3.2, AXI Register Overview, H'230 to H'233)

Battery Charging								
H'233	—	—	—	—	—	—	—	PTPWR_CTRL
H'232	—	—	—	—	—	—	Renesas Private field	
H'231	—	—	—	—	—	LCLK_NOSTOP_FREQ		
H'230	—	—	—	—	BC_MODE			

**Table 54.6 Setting Value for Battery Charging**

Setting Value	BC_MODE	Description
0	Always SDP Mode	Default value after resetting HW. A-Device operates in the “SDP” mode both normal function state and D3 state.
1	Always CDP Mode	A-Device operates in the “CDP” mode both normal function state and D3 state.
2	SDP-DCP Auto-change Mode	A-Device operates in the “SDP” mode in a normal function state and operates in the “DCP” mode in the D3 state.
3	CDP-DCP Auto-change Mode	A-Device operates in the “CDP” mode in a normal function state and operates in the “DCP” mode in the D3 state.

**Table 54.7 BC Mode and Port Type in D0 and D3 State**

<b>BC_MODE</b>	<b>Normal Operation (D0) Port Type</b>	<b>Suspended (D3) Port Type</b>
Always SDP Mode	SDP	SDP
Always CDP Mode	CDP	CDP
SDP-DCP Auto-change Mode	SDP	DCP <b>(Note1)</b>
CDP-DCP Auto-change Mode	CDP	DCP <b>(Note1)</b>

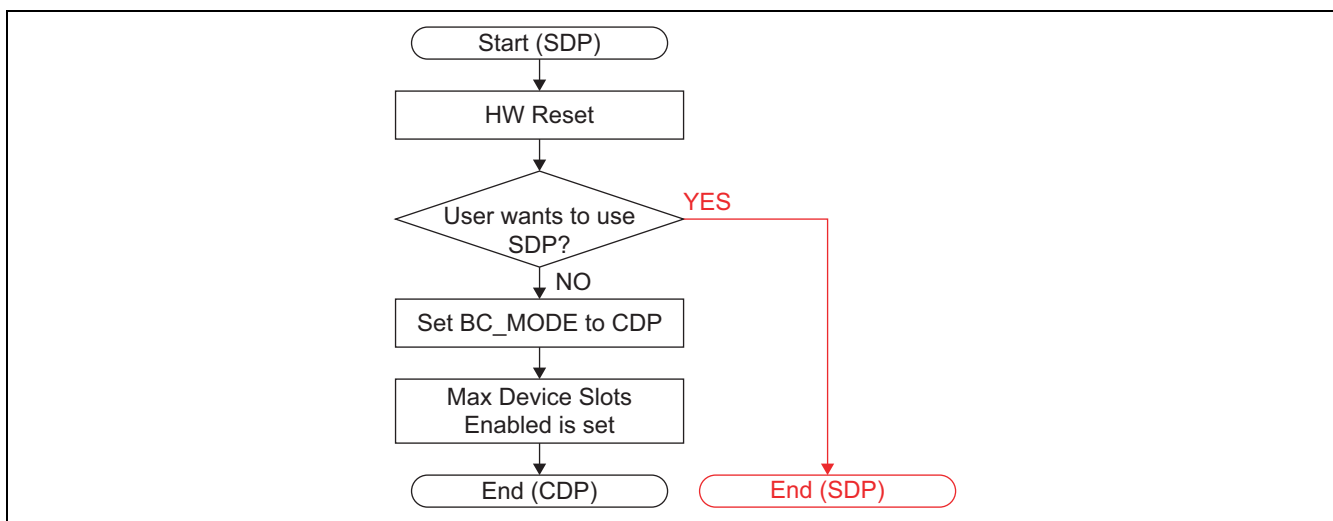

Notes: 1. If WakeOnConnect/WakeOnDisconnect is valid, it shall be kept Port type in Normal Operation A-Device has the following operation modes and can change these modes dynamically in the D0 state (Normal operation) and the D3 state (Suspended).  
 2. For the description of D0 and D3, refer to section 54.4.3.1, Power Management Capability).

**(2) Each case of changing BC\_MODE**

**Case-1)** After Host HW Reset, BC\_MODE is set “Always SDP Mode”.

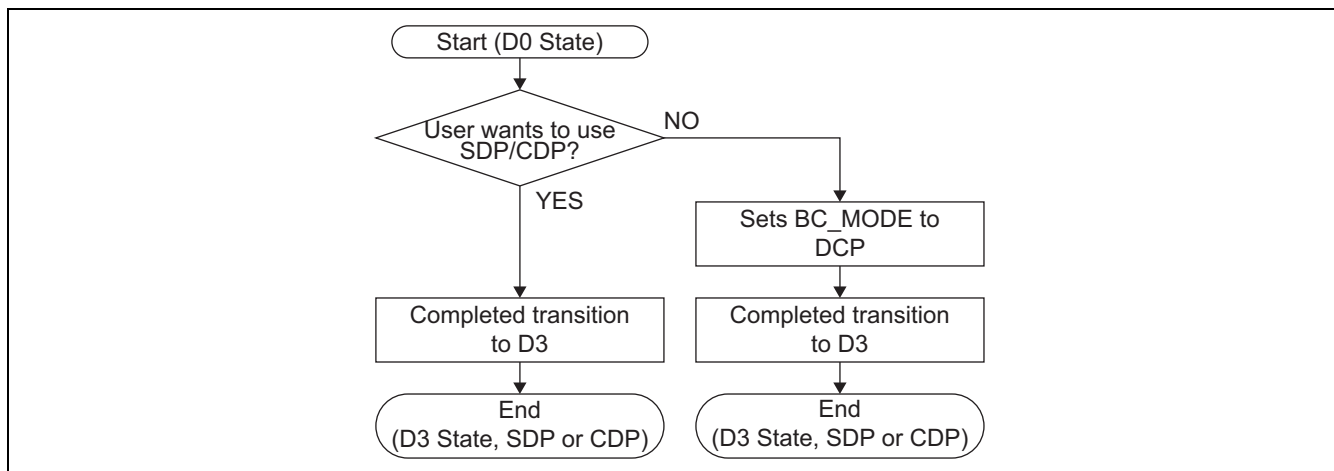

SDP is a default Mode.

Red-colored flow in Figure 54.7 is for default setting.

**Figure 54.7 Default Setting**

**Case-2)** If user wants to change Mode from SDP/CDP to DCP Mode during A-device working, BC\_MODE shall be changed when transition from D0 to D3.

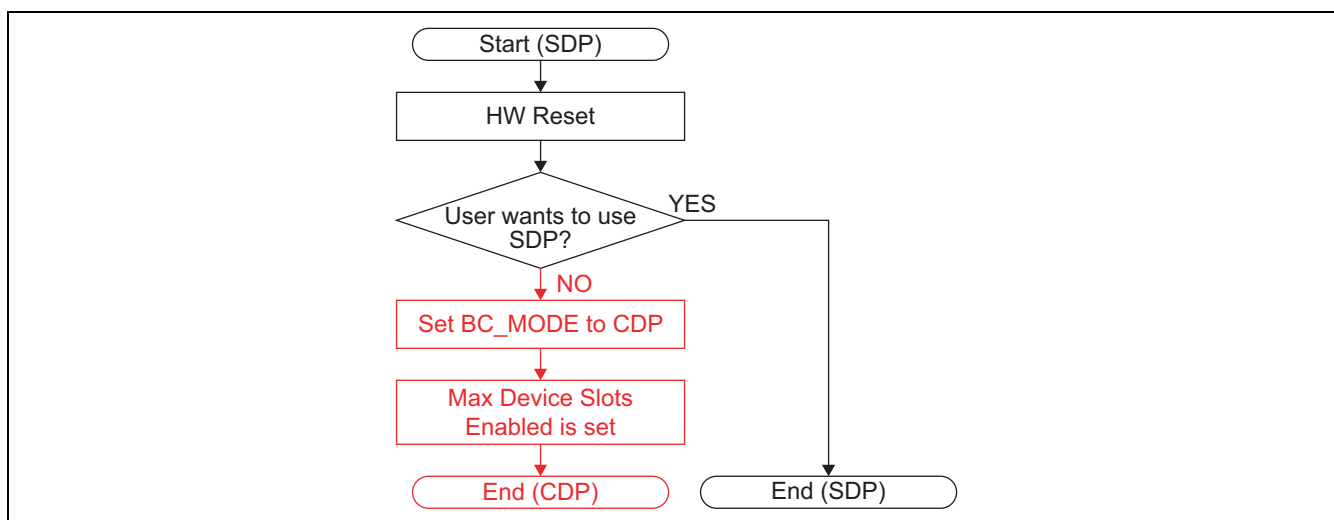

**Figure 54.8 Changing BC\_MODE during Transition between D0 and D3 States**

**Case-3)** When user wants to use A-Device with except default (SDP) Mode after Host HW Reset, BC\_MODE shall be changed before setting value of “Max Device Slots Enabled” in xHCI CONFIG register [H'058].

For the selectable modes, refer to Table 54.7.

Red-colored flow in Figure 54.9 is for BC\_MODE setting.

**Figure 54.9 Changing BC\_MODE**

**[Caution]**

- On the port in which WakeOnConnect/WakeOnDisconnect is enabled, a transition to DCP is not allowed because the port shall detect connect/disconnect of Device.
- When going D3 state with connecting USB device, current Mode shall be kept up setting because that any USB communication doesn't continue with setting DCP.

When changing Battery Charging type, it is required by Battery Charging Specification that VBUS shall be off more than 100-ms and prompting reconnection of device. Host FW operates this process.

### 54.4.3 Power Management

#### 54.4.3.1 Power Management Capability

USB3.0 host controller Host Core sets pseudo D3 state.

It is controlled by Extended Power Management Capability register.

- Extended Power Management Capability

This register controls pseudo PCIe Power State.

Bit 15: PME Status: Showing which there was a Wakeup event during pseudo D3 state

Bit 8: PME Enable: It asserts an interrupt from pseudo D3 state at Wakeup.

When this bit is set to 1, if PME Status is changed 1 then the interrupt occurs.

Bit [1:0]: Power State: Setting pseudo Power state.

The valid value is as follows.

0: D0 (Do not save power)

3: D3 (Do power save)

Note: In the after section, D3 means pseudo D3 state which is described here.

#### 54.4.3.2 Low Power Management of Receiver Detection

It is intended to saving power of Receiver Detection circuit at PHY Hard Macro (PHYHM).

There are two ways, setting initial value in define file and changing value at field of Register.

For changing value, the field shall be set before starting FW download when occurs after reset.

##### (1) D3

USB3.0 Common Block operates periodically Receiver Detection with LCLK during RxDetect state of LTSSM and P3 of PHY state.

However if a system is in Suspend and WakeOnConnect is disabled, there is no need to do Receiver Detection.

To reduce power consumption of PHY by above discarded Receiver Detection, FW can halt the process.

##### (2) D0

Receiver Detection at opened Port in D0 shall be operated.

HW operates reducing power at interval of Receiver Detection.

TimeMax is that decides operational interval of Detection in P3.

Figure 54.10 Low-Power of Receiver Detection

54.4.3.3 Power Control for Each State

The overview of power control state flow is shown as below.

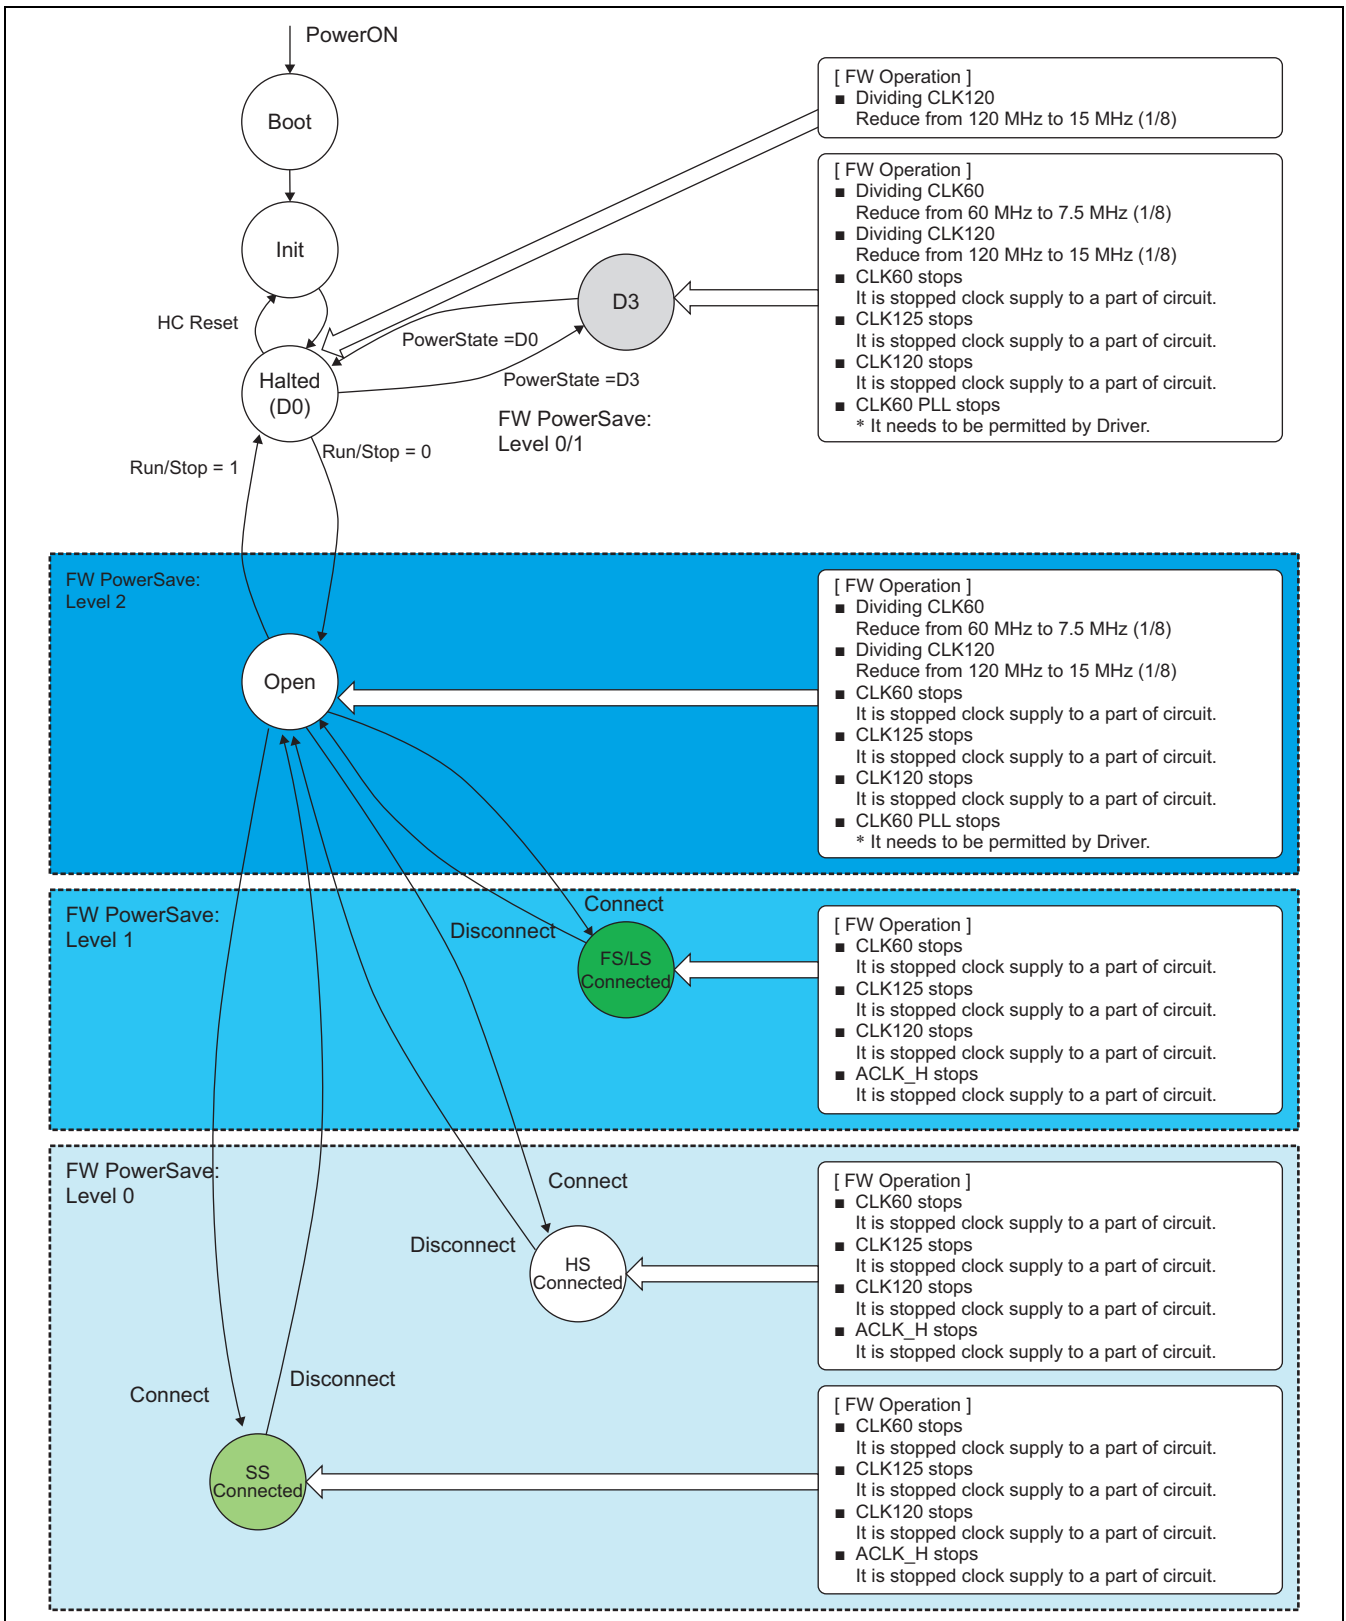

Figure 54.11 Overview of Power Control State Flow

#### 54.4.3.4 Clock Termination by USB3PHY and LTSSM State

USB3PHY may stop PLL which generates CLK125 by USB3PHY's power state.

**Table 54.8 LTSSM State and USB3PHY Condition**

LTSSM State	USB3PHY		Supplement
	POWERDOWN	PLL Operation	
SS.Disabled	P2	Run	
Rx.Detect	P2	Run	Default
	P0	Run	
	P3	Stop	
U0	P0	Run	
U1	P1	Run	
U2	P2	Run	
U3	P0	Run	
	P3	Stop	
U3 → U3_Wakeup, Reset	P0	Run	Transition by receiving LFPS
U3 → RemoteWakeup	P0	Run	Transition is required by PLS (Need Register operation)
Other	P0	Run	

#### 54.4.3.5 Flow of System Suspend and Resume

When following all permission for suspend are met, system goes to suspend.

- Host system sets AXH\_CON.SYS\_SUSPEND to 1 and completes host core's preparations for suspend.

When host core resumes from System Suspend, user shall confirm the bit of B2\_PLL\_ACTIVE at AXH\_STA register [H'104 to H'107] in AXI register is set to 1 before accessing register.

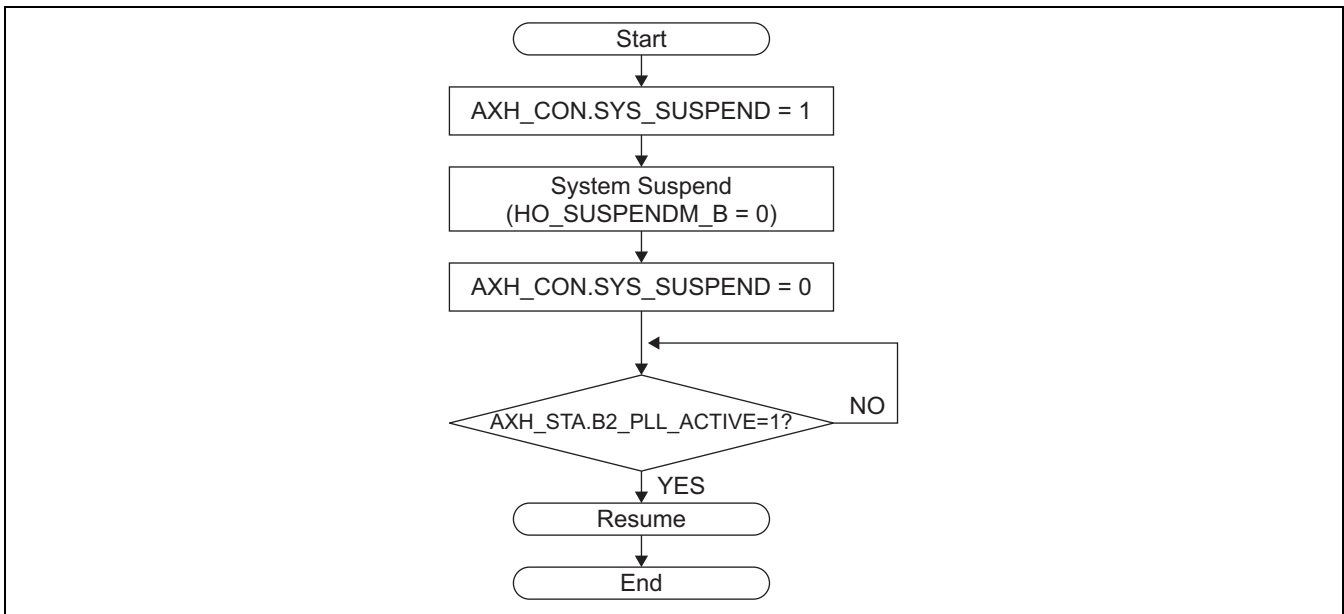

Figure 54.12 System Suspend and Resume Flow

### 54.4.4 Power Control

The process of VBUS ON/OFF and Over Current detection are described below.

#### 54.4.4.1 VBUS On

When VBUS will be on, at first host driver shall execute processes as below.

Figure 54.13 Flow of VBUS On

#### 54.4.4.2 VBUS Off

When port power will be off, at first host driver shall execute processes as below.

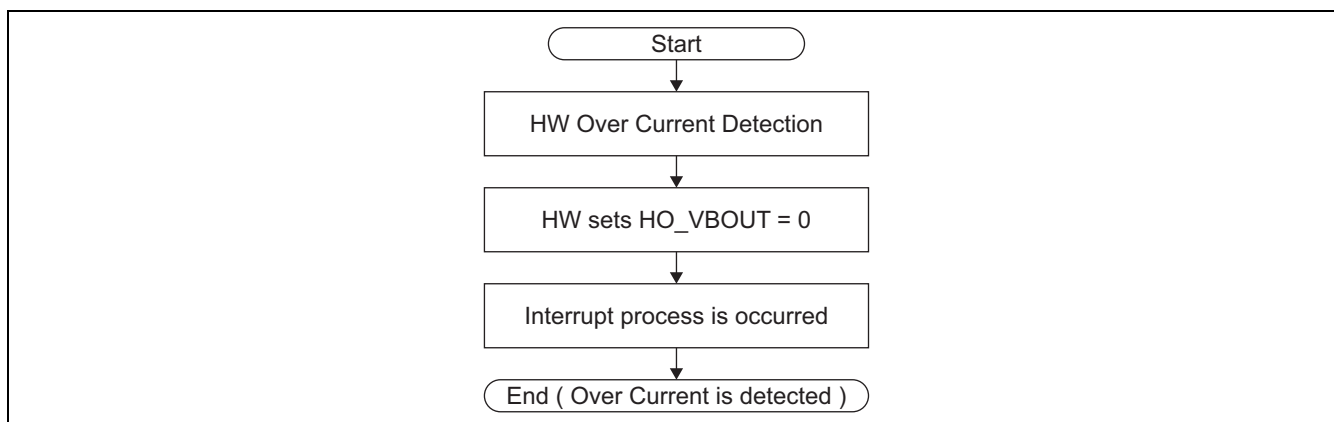

Figure 54.14 Flow of VBUS Off

#### 54.4.4.3 Over Current Detection

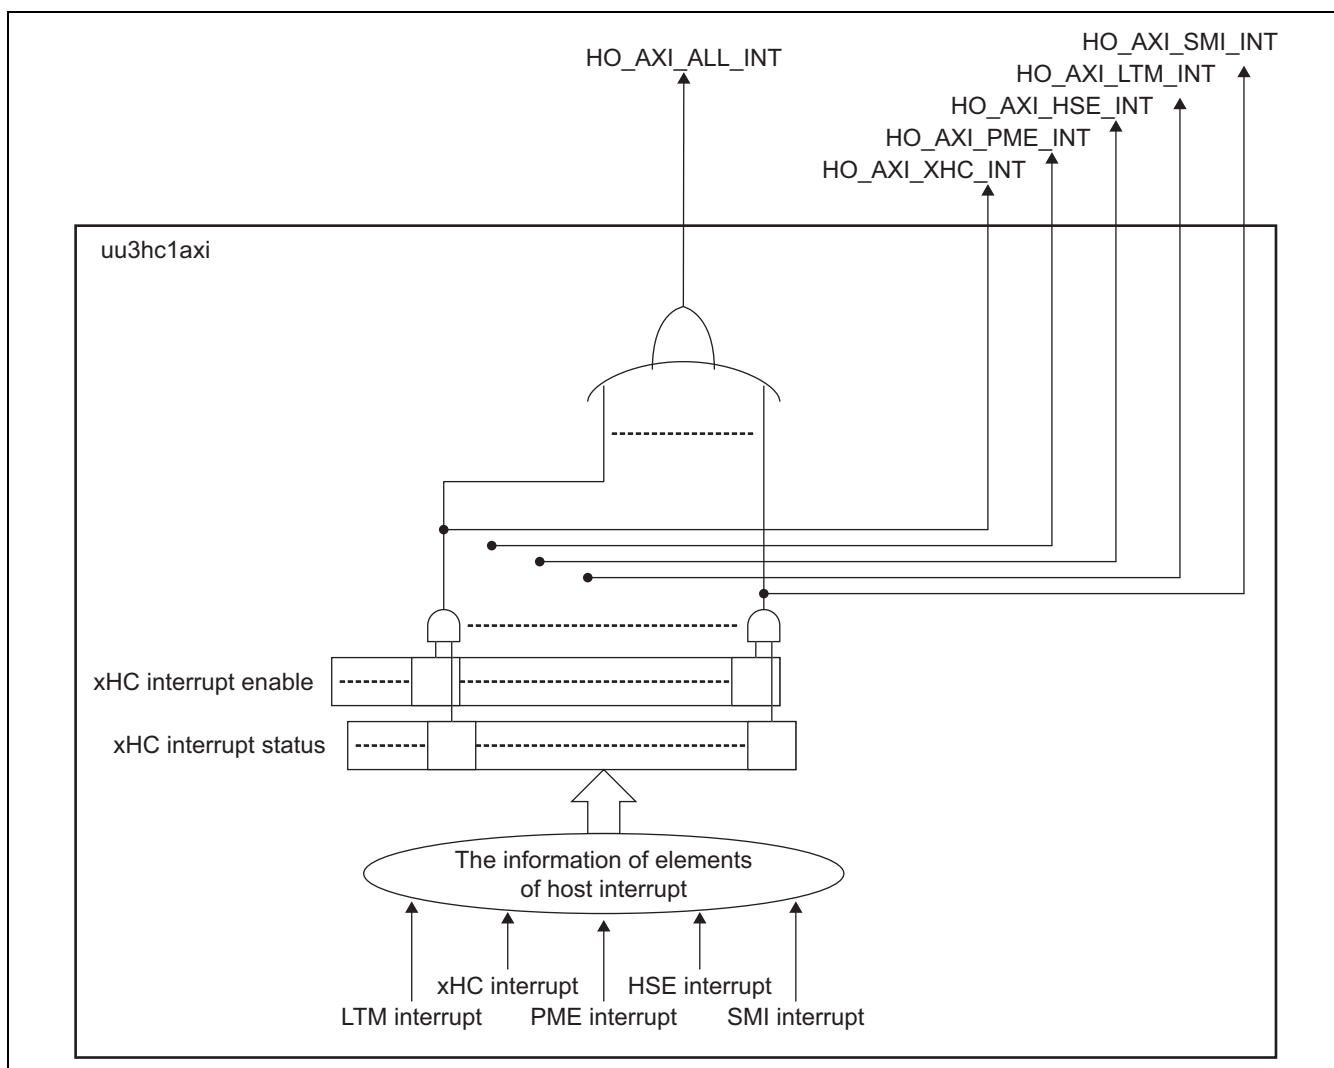

When port will detect over current during the core working, following flow is executed on host.

**Figure 54.15 Flow of Over Current Detection**

### 54.4.5 Structure of Notification for Elements of Interrupt

In USB3.0 host controller, the elements of interrupt are noticed by following layered structure.

**Figure 54.16 Interrupt Layered Structure**

- This Host core doesn't use WAKEB but PME. Interrupt pin by PME is HO\_AXI\_INT\_PME.

Note: About occurrence factor of PME interrupt, refer to xHCI Specification.

- Interrupt occurrence factor of xHCI shall be switched its meaning as PCIINT.
- The abstract of Interrupt signals from Figure 54.16 are below.

**Table 54.9 Function of Interrupt Signals**

Signal Name	Function
HO_AXI_INT_XHC	xHCI Interrupt
HO_AXI_INT_PME	PME Interrupt
HO_AXI_INT_HSE	HSE Interrupt
HO_AXI_INT_LTM	LTM Interrupt
HO_AXI_INT_SMI	SMI Interrupt
HO_AXI_INT_ALL	All Interrupt Signals from Host Core are logical ORed.

#### 54.4.6 Implementation Constraint of Host Core

The USB3.0 host controller core has implementation constraint.

- 1 Packet shall be composed of 8TRB or less.

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

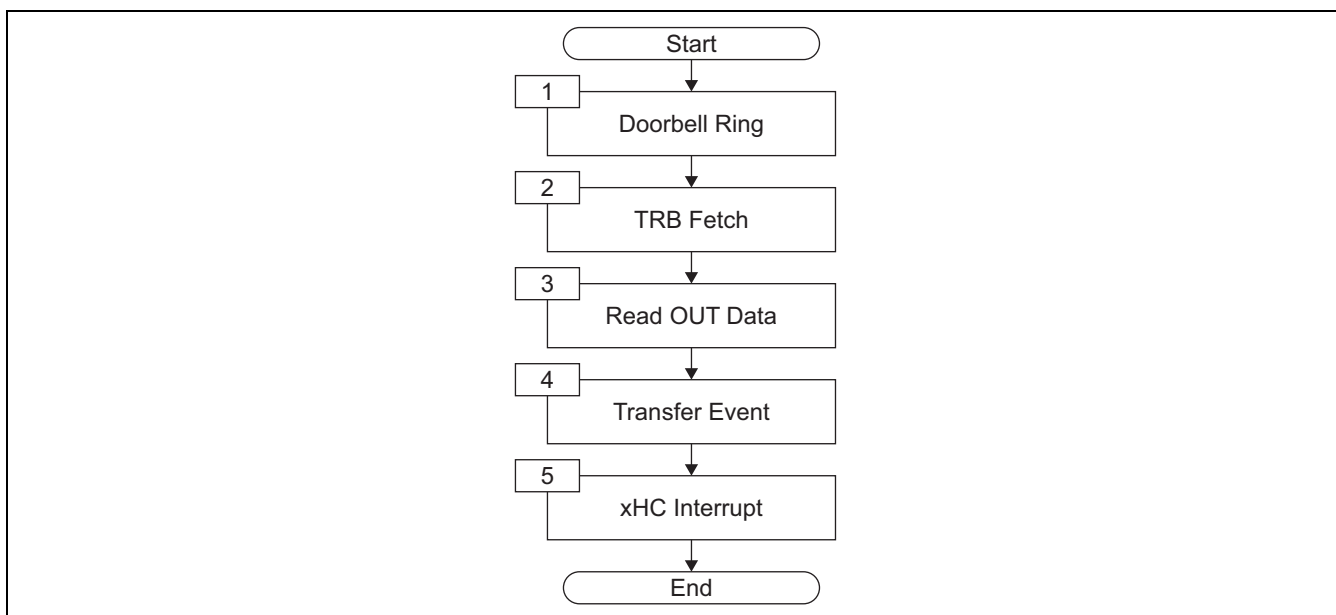

## 54.5 Example of Transaction

This section describes transaction when using Host core. As examples, Bulk OUT and Bulk IN transactions are described. The USB3.0 host controller core complies with xHCI Specification.

Refer to xHCI Specification for details.

### 54.5.1 Bulk OUT Transaction

Bulk OUT transaction flow is shown as below.

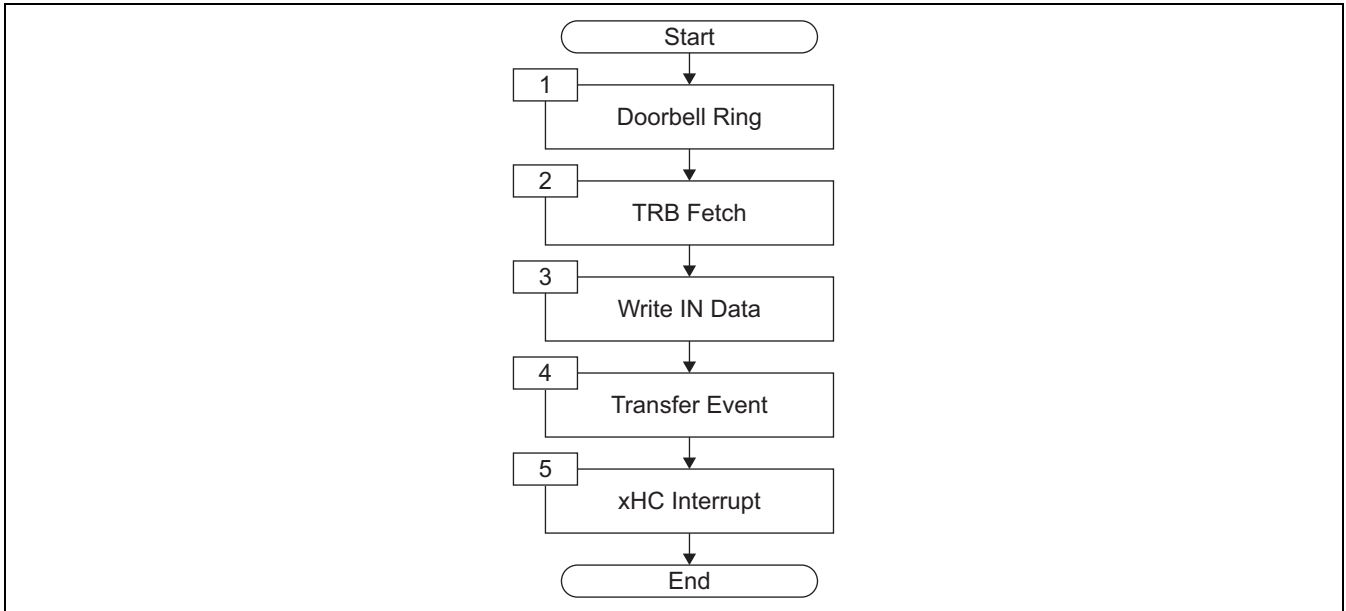

**Figure 54.17 Example of Bulk OUT Transaction Flow**

- 1) Doorbell Ring  
System rings Doorbell to prepare Transfer Data.
- 2) TRB Fetch  
Host core fetches TRB from OUT Transfer Ring,
- 3) Read OUT Data  
Host reads OUT Data from Data Buffer Pointer.
- 4) Transfer Event  
Host writes Transfer Event TRB to Event Ring.
- 5) xHC Interrupt  
Host sends Interrupt to System.

### 54.5.2 Bulk IN Transaction

Bulk IN transaction flow is shown as below.

**Figure 54.18 Example of Bulk IN Transaction Flow**

- 1) Doorbell Ring  
System rings Doorbell to prepare Transfer Data.
- 2) TRB Fetch  
Host core fetches TRB from OUT Transfer Ring,
- 3) Write IN Data  
Host writes IN Data to Data Buffer Pointer.
- 4) Transfer Event  
Host writes Transfer Event TRB to Event Ring.
- 5) xHC Interrupt  
Host sends Interrupt to System.

## 54.6 Power IC Interface Connection

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

The USB3.0 host controller core has power signal detection.

- Power IC has Outputting Over Current Flag signal and the USB3.0 host controller can detect the signal.
- Battery Charging function is able to use at the USB3.0 host controller.

### 54.6.1 Usable Power IC type

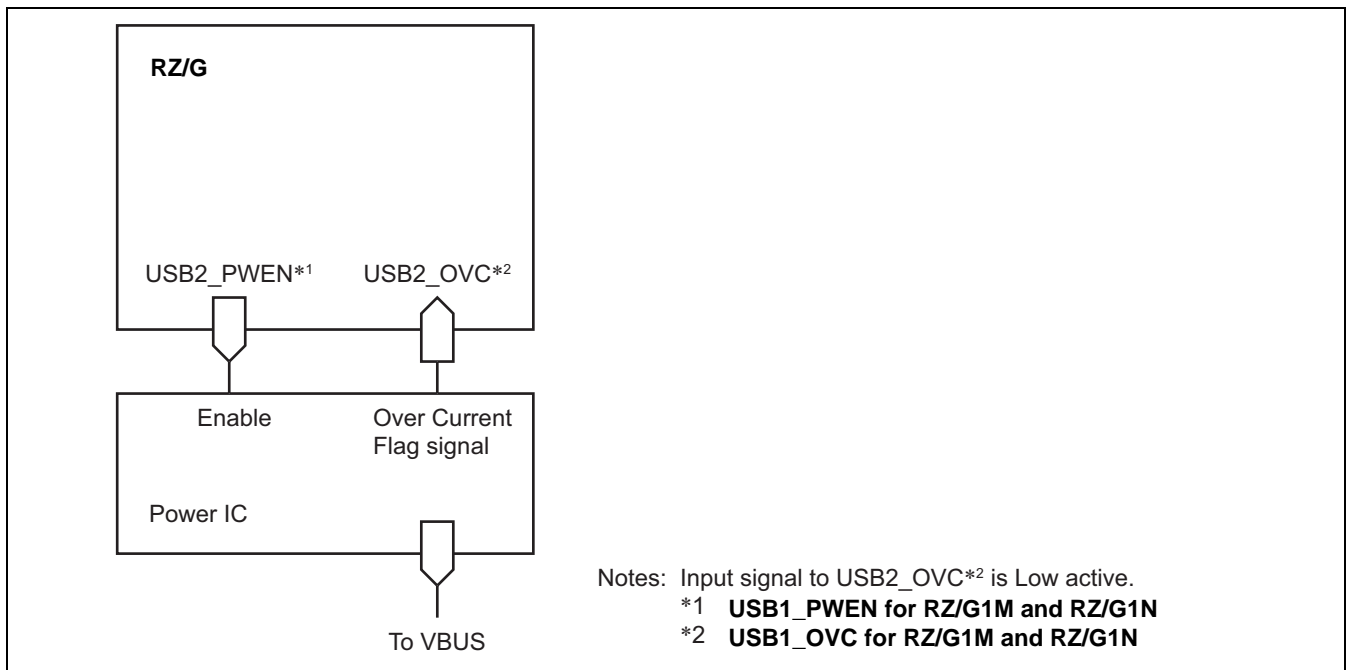

Figure 54.19 Usable Power IC Type

Table 54.10 Setting Registers and Signals for Power IC

Signal	
USB2_OVC*2	USB2_PWEN*1
Connecting to Over Current Flag signal	Connecting to Enable

Notes: 1. USB1\_PWEN for RZ/G1M and RZ/G1N.  
 2. USB1\_OVC for RZ/G1M and RZ/G1N.

• **Restriction**

Do not use another type of Power IC.

# 55. RCLK Watchdog Timer

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

This LSI includes the RCLK watchdog timer (RWDT).

This LSI can be reset by the overflow of the counter when the value of the counter has not been updated because of a system runaway.

The RWDT is a single-channel timer that uses the RCLK as an input and can be used as a watchdog timer.

In RZ/G1H, M, N and E, RCLK is a clock, which is generated by the clock pulse generator (CPG).

## 55.1 Features

- One channel is provided.
- Can be used as a watchdog timer. Reset is generated when the counter overflows.
- A counter input clock can be chosen from:  
Clocks (RCLK/1 to RCLK/(128 × 60 × 30)) that are obtained by dividing the RCLK.

Figure 55.1 shows block diagrams of the RWDT.

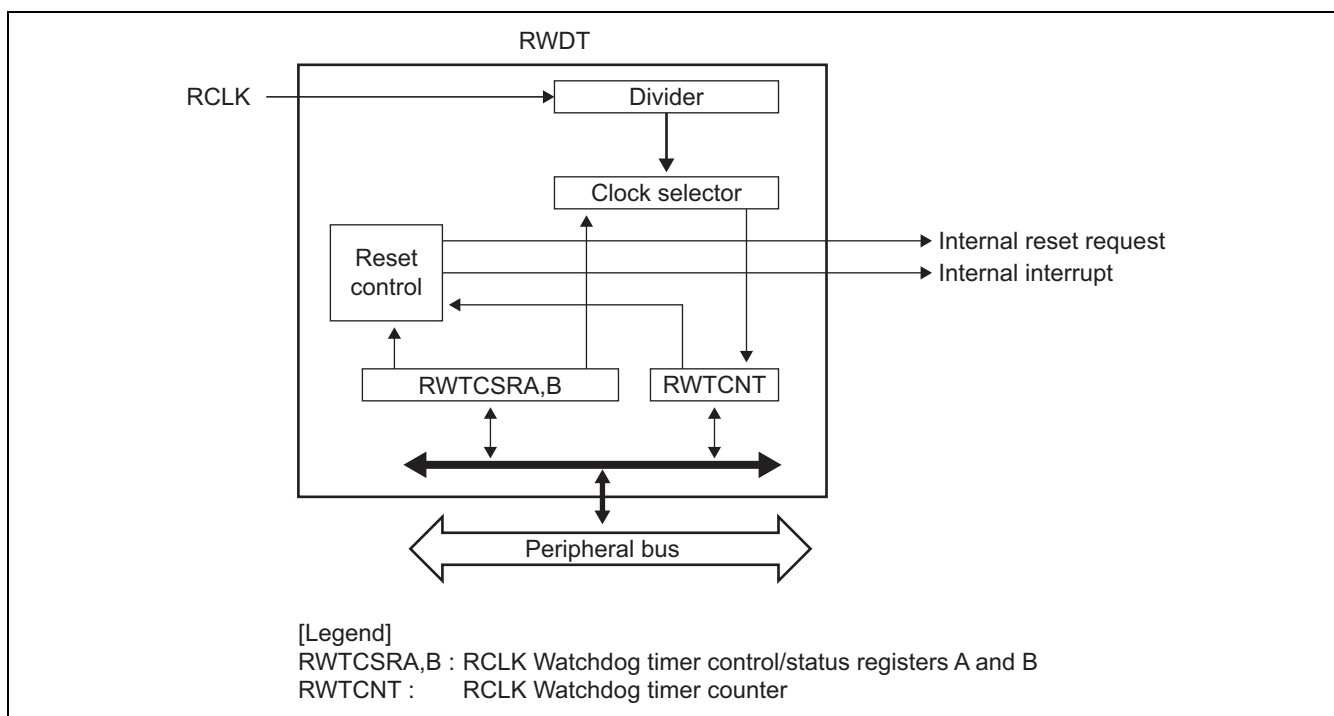

Figure 55.1 Block Diagram of RWDT

## 55.2 Register Descriptions for RWDT

Table 55.2 shows the RWDT register configuration. Table 55.3 shows the register state in each processing mode.

**Table 55.2 Register Configuration of RWDT**

Name	Abbreviation	R/W	Address	Access Size	RZ/G Series Products			
					RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
RCLK watchdog timer counter	RWTCNT	R/W	H'E602 0000	16/32*	√	√	√	√
RCLK watchdog timer control/status register A	RWTCSRA	R/W	H'E602 0004	8/32*	√	√	√	√
RCLK watchdog timer control/status register B	RWTCSR B	R/W	H'E602 0008	8/32*	√	√	√	√

Note: \* Write is performed in 32 bits and read in 16 or 8 bits.

**Table 55.3 Register State of RWDT in Each Processing Mode**

Register Abbreviation	Reset Caused by Other than Overflow	Reset Caused by Overflow*
<b>Register</b>	<b>Bit</b>	
RWTCNT	All	Initialized
RWTCSRA	WOVF	Retained
	Other than WOVF	Initialized
RWTCSR B	All	Initialized

Note: \* RWDT overflow reset.

### 55.2.1 RCLK Watchdog Timer Counter (RWTCNT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

RWTCNT is a 16-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a Reset. The RWTCNT counter is initialized to H'0000 by a power-on reset and RWDT software reset.

Use a long word access to write to the RWTCNT counter, with H'5A5A in the upper byte. Use a word access to read RWTCNT.

### 55.2.2 RCLK Watchdog Timer Control/Status Register A (RWTCRA)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

RWTCRA is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flag, and enable bit.

Use a long word access to write to RWTCRA, with H'A5A5A5 in the upper byte. Use a byte access to read RWTCRA.

Bit:	7	6	5	4	3	2	1	0
	TME	—	WRFLG	WOVF	WOVFE	CKS0[2:0]		
Initial value:	0	0	0	0	1	1	1	1
R/W:	R/W	R	R	R/(W)	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TME	0	R/W	Starts and stops timer operation. 0: Timer disabled: Count-up stops and RWTCNT value is retained 1: Timer enabled
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WRFLG	0	R	Write Status Flag When this bit is 1, write access to RWTCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to RWTCNT is masked for synchronization after the writing to RWTCNT. Confirm that this flag is 0 when RWTCNT is written to continuously.
4	WOVF	0	R/(W)	Indicates that the RWTCNT has overflowed. This bit isn't initialized by a generated reset by an overflow of RWDT. Write 0 to this bit before using the RWDT. 0: No overflow 1: RWTCNT has overflowed Note: Only 0 can be written to clear the flag.
3	WOVFE	1	R/W	Overflow Interrupt Disable/Enable 0: Disables interrupts due to overflow 1: Enables interrupts due to overflow

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS0[2:0]	111	R/W	<p>RTC Clock Select</p> <p>These bits select the clock to be used for the RWTCNT count from the eight types obtainable by dividing the RCLK. The overflow period that is shown inside the parenthesis in the table is the value when the RCLK is 31.7 kHz*.</p> <p>Note. * 1560 MHz/(1024 × 48) = 31.73828125 kHz</p> <p>000: R<math>\phi</math> (2.1 s (RWTCNT: H'FF00 = 8.06 ms))</p> <p>001: R<math>\phi</math>/4 (8.2 s (RWTCNT: H'FF00 = 32.2 ms))</p> <p>010: R<math>\phi</math>/16 (33.0 s (RWTCNT: H'FF00 = 129.0 ms))</p> <p>011: R<math>\phi</math>/32 (66.0 s (RWTCNT: H'FF00 = 258.0 ms))</p> <p>100: R<math>\phi</math>/64 (132.0 s (RWTCNT: H'FF00 = 516.0 ms))</p> <p>101: R<math>\phi</math>/128 (264.0 s (RWTCNT: H'FF00 = 1.03 s))</p> <p>110: R<math>\phi</math>/1024 (2112.0 s (RWTCNT: H'FF00 = 8.25 s))</p> <p>111: RCLK select expanded mode</p> <p>The clock cycle varies depending on the CKS1 bit in RWTCSR B. Its initial value is R<math>\phi</math>/4096 (8438.0 s (RWTCNT: H'FF00 = 33.0 s)).</p>

Note: These overflow periods are calculated from the rounded value of R $\phi$ =31.7 kHz.

### 55.2.3 RCLK Watchdog Timer Control/Status Register B (RWTCSR B)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

RWTCSR B is an 8-bit readable/writable register composed of bits to select the clock used for the count.

Use a word access to write to RWTCSR B, with H'A5A5A5 in the upper byte. Use a byte access to read RWTCSR B.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	0	R	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	CKS1[5:0]	All 0	R/W	RCLK Select for RCLK Select Expanded Mode Selects the clock used for the RWTCNT count when the CKS0 bit in RWTCSCRA is B'111. The following table shows the time values used to cause an overflow from the counter H'0000(Overflow time from counter H'FF00). Assuming that $R\phi/128 = 264 \text{ s}$ (1.01 s), the overflow cycle in the table is calculated for the case when the RCLK is 31.7 kHz.

CKS1[3:0]	CKS1[5:4]			
	B'00	B'01	B'10	B'11
H'0	8438 s (33 s)	—	—	—
H'1	264 s (1.01 s)	1320 s (5.05 s)	264 min (1.01 min)	— (5.05 min)
H'2	528 s (2.02 s)	2640 s (10.1 s)	528 min (2.02 min)	— (10.1 min)
H'3	1055 s (3.03 s)	5280 s (15.2 s)	1056 min (3.03 min)	— (15.2 min)
H'4	4219 s (4.04 s)	— (20.2 s)	— (4.04 min)	— (20.2 min)
H'5	— (5.05 s)	— (25.3 s)	— (5.05 min)	— (25.3 min)
H'6	— (6.06 s)	— (30.3 s)	— (6.06 min)	— (30.3 min)
H'7	— (7.07 s)	— (35.4 s)	— (7.07 min)	— (—)
H'8	— (8.08 s)	— (40.4 s)	— (8.08 min)	— (—)
H'9	— (9.09 s)	— (45.5 s)	— (9.09 min)	— (—)
H'A	— (10.1 s)	— (50.5 s)	— (10.1 min)	— (—)
H'B	— (—)	— (55.6 s)	— (—)	— (—)
H'C	— (—)	— (60.6 s)	— (—)	— (—)
from H'D	— (—)	— (—)	— (—)	— (—)

Note: - (-): Reserved, - (xxx): Not recommendable  
These overflow periods are calculated from the rounded value of  $R\phi = 31.7 \text{ kHz}$ .

**55.2.4 Notes on Register Access**

RWTCSRA: Bits TME, CKS0

RWTCSRБ: Bits CKS1

After writing a value in this register, it is possible to read that value immediately, but it is not reflected in operation. 2 cycles of RCLK need to be inputted until the set-up value is reflected.

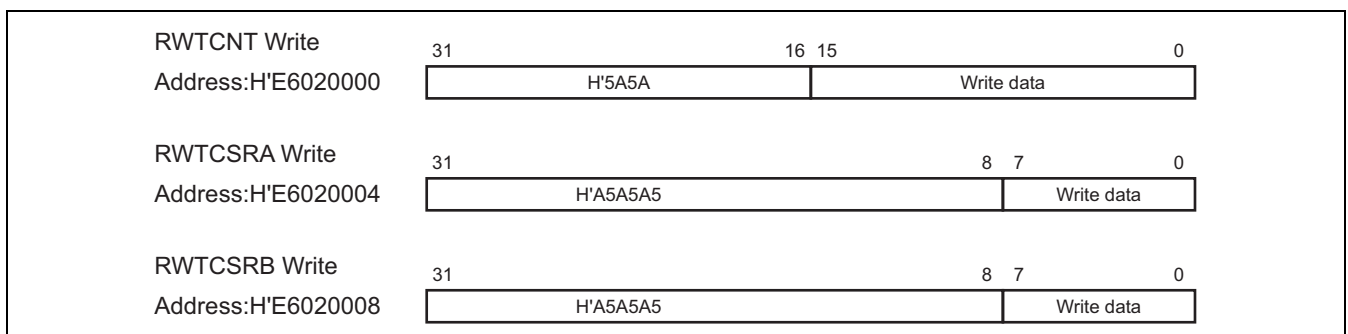

RWTCNT: Bits 15 to 0

After writing a value in this register, it is possible to read that value immediately, but it is not reflected in operation. 2 cycles of RCLK need to be inputted until the set-up value is reflected. Writing to this register, once started, is protected from further write operations until the writing operation has been completed. Read RWTCSRA. If WRFLG is 0, the next value can be written in RWTCNT.

The writing procedure to RWTCNT, RWTCSRA, and RWTCSRБ differs from that of other registers with the purpose of preventing an unintended write. The procedure for writing to these registers is given below.

**Writing to RWTCNT, RWTCSRA, and RWTCSRБ:**

- These registers must be written by a long word transfer instruction. They cannot be written by a byte or word transfer instruction.
- When writing to RWTCNT, set the upper byte to H'5A5A and transfer the lower byte as the write data. When writing to RWTCSRA and RWTCSRБ, set the upper byte to H'A5A5A5 and transfer the lower byte as the write data.

**Figure 55.2 Writing to RWTCNT, RWTCSRA, and RWTCSRБ**

## 55.3 RWDT Usage

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 55.3.1 Control of System Runaway

After a reset, RWDT is disabled. When the counter overflow occurs after the counter starts, an internal reset is again generated. By this function, a reset can be automatically generated even when this LSI has caused a system runaway. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.

Take the following steps to use the RWDT.

1. Clear the TME bit in RWTCSSRA to 0 to temporarily stop counting.  
(Confirm that RCLK was input more than 2 cycles.)
2. Write H'0000 or the set value in RWTCNT.
3. Clear the WOVF bit in RWTCSSRA to 0.
4. Set the kind of count clock to the CKS0[2:0] bits in RWTCSSRA, and CKS1[5:0] bits in RWTCSSRB.
5. Confirm that RWTCSSRA.WRFLG becomes 0.  
If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the TME bit in RWTCSSRA to 1.  
(TME and CKS0 can't be set at the same time. When setting that at the same time, behavior isn't guaranteed.)
7. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.
8. When RWTCNT overflows, Reset is generated because the RWDT sets the WOVF flag in RWTCSSRA to 1. At this time, RWTCNT, RWTCSSRA (excluding the WOVF bit), and RWTCSSRB are initialized.

Execute a power-on reset or a software reset at that time and initialize RWDT.

When not initializing and using RWDT, behavior isn't guaranteed.

### 55.3.2 Module Stop

A setup of a stop of the Clock by a Module Stop signal is possible when RWDT is an Idle state. The Idle state of RWDT is when the condition of following all was satisfied.

- When RWTCSSRA.TME bit is 0
- When RWTCSSRA.WRFLG is 0
- When 3 or more cycles have passed in RCLK since the last Register access

### 55.3.3 Debugging Operation

When debugging the CPU core, stop counting up RWTCNT and retain the value of RWTCNT.

## 56. 16-Bit Timer Pulse Unit (TPU)

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

This LSI has a 16-bit timer pulse unit (TPU), which consists of four 16-bit timers.

### 56.1 Features

The TPU0 has the following features.

- Four timers are incorporated.
- Four pulse outputs are possible.
- Each timer of the TPU0 has four general registers (TGRA, TGRB, TGRC, and TGRD) for each timer. TGRA enables an output compare setting. TGRB, TGRC and TGRD in each timer can be used as timer-counter clearing registers. TGRC and TGRD can also be used as buffer registers.
- The following operations can be set for each timer.
  - Waveform output on compare match: output of a 0 or 1 or toggling of output is selectable.
  - Counter clearing operation: Counters can be cleared in response to a compare match.
  - PWM mode allows the output of a PWM waveform with any duty cycle.
  - The four outputs can be used to produce PWM output in up to four phases.
- A stepping motor control mode is available for timer 0.
- Buffer operation can be set for each timer.
- Automatic rewriting of values in output compare registers is possible.
- One interrupt request from TPU0
  - Enabling or disabling of compare match and counter overflows as interrupt sources can be set independently for each timer.
  - In stepping motor control mode, enabling or disabling of state transitions, requests for data, and overflows of data as interrupt sources is possible for timer 0.

Table 56.1 shows the TPU0 functions.

**Table 56.1 TPU0 Functions**

Item		Timer 0	Timer 1	Timer 2	Timer 3
Counter clock		CP $\phi$ /1	CP $\phi$ /1	CP $\phi$ /1	CP $\phi$ /1

### 56.2.1 Timer Control Register (TPU0\_TCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TCR is provided for each of timers 0 to 3 and is used to control TPU0\_TCNT. TPU0\_TCR is initialized to H'0000 by a reset.

Writing to TPU0\_TCR is only allowed only when TPU0\_TCNT is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
7 to 5	CCLR[2:0]	000	R/W	Counter Clear Specify the TPU0_TCNT clearing source. 000: TPU0_TCNT clearing disabled 001: TPU0_TCNT cleared in response to TPU0_TGRA compare match 010: TPU0_TCNT cleared in response to TPU0_TGRB compare match 011: Setting prohibited 100: TPU0_TCNT clearing disabled 101: TPU0_TCNT cleared in response to TPU0_TGRC compare match 110: TPU0_TCNT cleared in response to TPU0_TGRD compare match 111: Setting prohibited
4, 3	CKEG[1:0]	00	R/W	Clock Edge Select the input clock edge for counting up. Counting of both edges by the internal clock has the same effect as halving the cycle of the input clock (e.g., the rate of counting both edges of $CP\phi/4$ is same as the rate of counting rising edges of $CP\phi/2$ ). When the phase coefficient mode is selected, this setting is ignored. 00: Count rising edges 01: Count falling edges* 1X: Count both edges* [Legend] X: Don't care Note: * If the input clock is $CP\phi/1$ , the timer does not operate with this setting.
2 to 0	TPSC[2:0]	000	R/W	Timer Prescaler Select the clock for counting by TPU0_TCNT. The clock source can be selected independently for each timer. Table 56.5 shows the clock sources that can be set for each timer. For more information on count clock selection, see Table 56.6.

**Table 56.5 TPU Clock Sources**

Timer	Internal Clock: CP $\phi$			
	Clock $\phi/1$	Clock $\phi/4$	Clock $\phi/16$	Clock $\phi/64$
0	√	√	√	√
1	√	√	√	√
2	√	√	√	√
3	√	√	√	√

[Legend]

√: Setting

**Table 56.6 Count Clock Selection by the TPSC[2:0] Bits**

Timer	TPSC[2]	TPSC[1]	TPSC[0]	Description
0 to 3	0	0	0	Internal clock $\phi/1$ (initial value)
			1	Internal clock $\phi/4$
			0	Internal clock $\phi/16$
			1	Internal clock $\phi/64$
1	*	*		Setting prohibited

[Legend]

\*: Don't care.

Note: Internal clock: CP $\phi$

### 56.2.2 Timer Mode Register (TPU0\_TMDR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMDR is provided for each of timers 0 to 3, and is used to specify the operating mode of the corresponding timer. TPU0\_TMDR is initialized to H'0000 by a reset.

Writing to TPU0\_TMDR is only allowed when TPU0\_TCNT is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BFWT	BFB	BFA	—	MD[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
6	BFWT	0	R/W	Buffer Write Timing Specifies when to update TPU0_TGRA and TPU0_TGRB when TPU0_TGRC and TPU0_TGRD are in use as compare match buffers. When TPU0_TGRC and TPU0_TGRD are not in use as compare match buffer registers, this has no effect. 0: TPU0_TGRA and TPU0_TGRB are rewritten on a compare match with the counters. 1: TPU0_TGRA and TPU0_TGRB are rewritten on clearing of the counter.
5	BFB	0	R/W	Buffer Operation B Specifies operation mode of TPU0_TGRB. 0: TPU0_TGRB is in normal operation. 1: TPU0_TGRB and TPU0_TGRD are used for buffered operation.
4	BFA	0	R/W	Buffer Operation A Specifies operation mode of TPU0_TGRA. 0: TPU0_TGRA normal operation. 1: TPU0_TGRA and TPU0_TGRC are used for buffered operation.
3	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
2 to 0	MD[2:0]	000	R/W	Timer Operating Mode Specifies the timer operating mode. 000: Normal operation 001: Setting prohibited 010: PWM mode 011 to 111: Setting prohibited

**56.2.3 Timer I/O Control Register (TPU0\_TIOR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TIOR is provided for each of timers 0 to 3, and is used to control the corresponding TPU0TO0 to TPUTO3 pins. TPU0\_TIOR is initialized to H'0000 by a reset.

Writing to TPU0\_TIOR is only allowed when TPU0\_TCNT is stopped. Note that the setting of TPU0\_TMDR may affect TPU0\_TIOR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IOA[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	IOA[2:0]	000	R/W	I/O Control Bits IOA2 to IOA0 specify the functions of TPU0_TGRA and the TPU0TO0 to TPUTO3 pins. For details, see Table 56.7.

**Table 56.7 Settings for Bits IOA[2:0], Initial States of Pins TPUTO0 to TPUTO3, and Results of Matching with TPU0\_TGRA**

Timer	IOA[2]	IOA[1]	IOA[0]	Description
0 to 3	0	0	0	Always output 0 (initial value)
			1	Initial output from the TPU0TO0 to TPUTO3 pins is 0
			0	Output 0 on compare match with TPU0_TGRA.*
			1	Output 1 on compare match with TPU0_TGRA.
0 to 3	0	1	0	Toggle output on compare match with TPU0_TGRA.*
			1	Always output 1
			0	Initial output from the TPU0TO0 to TPUTO3 pins is 1
			1	Output 0 on compare match with TPU0_TGRA.
0 to 3	1	0	0	Output 1 on compare match with TPU0_TGRA.*
			1	Output 1 on compare match with TPU0_TGRA.*
			0	Toggle output on compare match with TPU0_TGRA.*
			1	Toggle output on compare match with TPU0_TGRA.*

Note: \* This setting is prohibited in PWM mode.

### 56.2.4 Timer Interrupt Enable Register (TPU0\_TIER)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TIER is provided for each of timers 0 to 3 and is used to enable or disable the sources of interrupt requests for the corresponding timer. TPU0\_TIER is initialized to H'0000 by a reset. Bits 8 to 13 are only present in timer 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMD OFE	TMD RFE	TMS 1ER	TMS 1ET	TMS 1EA	TMS 1ES	—	—	—	TC1EV	TG1ED	TG1EC	TG1EB	TG1EA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
13	TMDOFE	0	R/W	Motor Control Data Transfer Overflow Detection Enable This bit enables or disables interrupt request in response to the state of the TMDOFS flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMDOFS flag disabled 1: Interrupt request in response to the TMDOFS flag enabled
12	TMDRFE	0	R/W	Motor Control Data Transfer Request Detection Enable This bit enables or disables interrupt request in response to the state of the TMDRFS flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMDRFS flag disabled 1: Interrupt request in response to the TMDRFS flag enabled
11	TMS1ER	0	R/W	Motor Control Deceleration Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFR flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFR flag disabled 1: Interrupt request in response to the TMCFR flag enabled
10	TMS1ET	0	R/W	Motor Control Normal Transition Detection Enable This bit enables or disables interrupt request in response to the state of the TMCFT flag in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. 0: Interrupt request in response to the TMCFT flag disabled 1: Interrupt request in response to the TMCFT flag enabled

Bit	Bit Name	Initial Value	R/W	Description
9	TMS1EA	0	R/W	<p>Motor Control Acceleration Transition Detection Enable</p> <p>This bit enables or disables interrupt request in response to the state of the TMCFA flag in the stepping motor control mode of timer 0.</p> <p>This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified.</p> <p>0: Interrupt request in response to the TMCFA flag disabled 1: Interrupt request in response to the TMCFA flag enabled</p>

2	TG1EC	0	R/W	<p>TPU0_TGR Interrupt Enable C</p> <p>This bit enables or disables interrupt request in response to the state of the TGFC bit.</p> <p>0: Interrupt request in response to the TGFC bit disabled 1: Interrupt request in response to the TGFC bit enabled</p>
1	TG1EB	0	R/W	<p>TPU0_TGR Interrupt Enable B</p> <p>This bit enables or disables interrupt request in response to the state of the TGFB bit.</p> <p>0: Interrupt request in response to the TGFB bit disabled 1: Interrupt request in response to the TGFB bit enabled</p>
0	TG1EA	0	R/W	<p>TPU0_TGR Interrupt Enable A</p> <p>This bit enables or disables interrupt request in response to the state of the TGFA bit.</p> <p>0: Interrupt request in response to the TGFA bit disabled 1: Interrupt request in response to the TGFA bit enabled</p>

### 56.2.5 Timer Status Registers (TPU0\_TSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TSR is provided for each of timers 0 to 3 and indicates the state of the corresponding timer. TPU0\_TSR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMD OFS	TMD RFS	TMCFR	TMCFT	TMCFA	TMCFS	—	—	—	TCFV	TGFD	TGFC	TGFB	TGFA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
13	TMDOFS	0	R/(W)*	Motor Control Data Transfer Overflow Detection This flag indicates that a data transfer overflow has been detected in the stepping motor control mode of timer 0. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMDOFS bit after reading the TMDOFS bit while TMDOFS is set to 1 [Setting condition] When the DMA transfer overflow occurs
12	TMDRFS	0	R/(W)*	Motor Control Data Transfer Request Detection This flag indicates that a data transfer request interrupt has been detected in the stepping motor control mode of timer 0. If DMA transfer is not in use, data are written to TPU0_TGRD0 in response to this interrupt. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMDRFS bit after reading the TMDRFS bit while TMDRFS is set to 1 [Setting condition] When data transfer request occurs
11	TMCFR	0	R/(W)*	Motor Control Deceleration Transition Detection This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the deceleration state. This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified. [Clearing condition] Writing 0 to the TMCFR bit after reading TMCFR bit = 1 [Setting condition] When the sequence state is shifted to the deceleration state

Bit	Bit Name	Initial Value	R/W	Description
10	TMCFT	0	R/(W)*	<p>Motor Control Normal Transition Detection</p> <p>This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the normal state.</p> <p>This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified.</p> <p>[Clearing condition]</p> <p>Writing 0 to the TMCFT bit after reading TMCFT bit = 1</p> <p>[Setting condition]</p> <p>When the sequence state is shifted to the normal state</p>
9	TMCFA	0	R/(W)*	<p>Motor Control Acceleration Transition Detection</p> <p>This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the acceleration state.</p> <p>This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified.</p> <p>[Clearing condition]</p> <p>Writing 0 to the TMCFA bit after reading TMCFA bit = 1</p> <p>[Setting condition]</p> <p>When the sequence state is shifted to the acceleration state</p>
8	TMCFS	0	R/(W)*	<p>Motor Control Stop Transition Detection</p> <p>This flag indicates that the current sequence state of timer 0 in the stepping motor control mode is the stop state.</p> <p>This bit is reserved in timers 1 to 3, is always read as 0, and cannot be modified.</p> <p>[Clearing condition]</p> <p>Writing 0 to the TMCFS bit after reading TMCFS bit = 1</p> <p>[Setting condition]</p> <p>When the sequence state is shifted to the stop state</p>
7 to 5	—	All 0	R	<p>Reserved</p> <p>These bits are always read as 0 and cannot be modified.</p>
4	TCFV	0	R/(W)*	<p>Overflow</p> <p>This flag indicates that TPU0_TCNT has overflowed.</p> <p>[Clearing condition]</p> <p>Writing 0 to the TCFV bit after reading TCFV bit = 1</p> <p>[Setting condition]</p> <p>When the value of TPU0_TCNT overflows (when its value changes from H'FFFF to H'0000)</p>
3	TGFD	0	R/(W)*	<p>Compare Flag D</p> <p>This flag indicates that the values of TPU0_TCNT and TPU0_TGRD have matched (a compare match).</p> <p>[Clearing condition]</p> <p>Writing 0 to the TGFD bit after reading TGFD bit = 1</p> <p>[Setting condition]</p> <p>When the values of TPU0_TCNT and TPU0_TGRD have matched</p>

Bit	Bit Name	Initial Value	R/W	Description
2	TGFC	0	R/(W)*	<p>Compare Flag C</p> <p>This flag indicates that the values of TPU0_TCNT and TPU0_TGRC have matched (a compare match).</p> <p>[Clearing condition]</p> <p>Writing 0 to the TGFC bit after reading TGFC bit = 1</p> <p>[Setting condition]</p> <p>When the values of TPU0_TCNT and TPU0_TGRC have matched</p>
1	TGFB	0	R/(W)*	<p>Compare Flag B</p> <p>This flag indicates that the values of TPU0_TCNT and TPU0_TGRB have matched (a compare match).</p> <p>[Clearing condition]</p> <p>Writing 0 to the TGFB bit after reading TGFB bit = 1</p> <p>[Setting condition]</p> <p>When the values of TPU0_TCNT and TPU0_TGRB have matched</p>
0	TGFA	0	R/(W)*	<p>Output Compare Flag A</p> <p>This flag indicates that the values of TPU0_TCNT and TPU0_TGRA have matched (a compare match).</p> <p>[Clearing condition]</p> <p>Writing 0 to the TGFA bit after reading TGFA bit = 1</p> <p>[Setting condition]</p> <p>When the values of TPU0_TCNT and TPU0_TGRA are matched</p>

Note: \* Only 0 can be written to clear the flag.

### 56.2.6 Timer Counter (TPU0\_TCNT)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TCNT is a 16-bit counter, and is provided for each of timers 0 to 3.

TPU0\_TCNT is initialized to H'0000 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	—	All 0	R/W	Timer Counter Bits

**56.2.7 Timer General Register A to D (TPU0\_TGRA/TPU0\_TGRB/TPU0\_TGRC/TPU0\_TGRD)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TGRA, TPU0\_TGRB, TPU0\_TGRC and TPU0\_TGRD are 16 bits general registers that are provided for each of timers 0 to 3. TPU0\_TGRC and TPU0\_TGRD can be designated for operation as buffer registers\*. TPU0\_TGR is initialized to H'FFFF by a reset.

Note: \* The combinations of TPU0\_TGR registers and buffer registers are TPU0\_TGRA with TPU0\_TGRC and TPU0\_TGRB with TPU0\_TGRD.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	—	All 1	R/W	Timer General Register Bits

### 56.2.8 Timer Start Register (TPU0\_TSTR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TSTR is used to start or stop the timer counter (TCNT) of timers 0 to 3.

TPU0\_TSTR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TMST	CST3	CST2	CST1	CST0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TMST	0	R/W	Motor Control Sequence Start Selects whether to start or stop the motor control sequence. This bit is cleared to 0 when the timer has shifted to the stop state after motor control operation was started. 0: Stops motor control sequence 1: Starts motor control sequence
3	CST3	0	R/W	Counter Start Selects whether to start or stop the TPU0_TCNT3 operation. 0: Stops the TPU0_TCNT3 counting operation 1: Starts the TPU0_TCNT3 counting operation
2	CST2	0	R/W	Counter Start Selects whether to start or stop the TPU0_TCNT2 operation. 0: Stops the TPU0_TCNT2 counting operation 1: Starts the TPU0_TCNT2 counting operation
1	CST1	0	R/W	Counter Start Selects whether to start or stop the TPU0_TCNT1 operation. 0: Stops the TPU0_TCNT1 counting operation 1: Starts the TPU0_TCNT1 counting operation
0	CST0	0	R/W	Counter Start Selects whether to start or stop the TPU0_TCNT0 operation. 0: Stops the TPU0_TCNT0 counting operation 1: Starts the TPU0_TCNT0 counting operation

### 56.2.9 Motor Control Setting Register (TPU0\_TMIR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMIR is used to configure operation in the motor control mode.

TPU0\_TMIR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TDMAE	MTRPAT DOWN	MTRPATKING [1:0]	MTRON	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TDMAE	0	R/W	Selection of DMA Use Selects whether to use DMA for step interval input (writing to TPU0_TGRD0) in the motor control mode. 0: DMA is not used. 1: DMA is used.
3	MTRPAT DOWN	0	R/W	Operation and Stop Patterns Transition Ascending/Descending Select Selects the direction of transitions within operation and stop patterns as ascending or descending in the motor control mode. 0: Ascending 1: Descending
2, 1	MTRPAT KIND[1:0]	00	R/W	Operation and Stop Pattern Type Select Selects the number of patterns in the cycles of stop and start patterns in the motor control mode. 00: Four 01: Eight 10: Setting prohibited 11: Setting prohibited
0	MTRON	0	R/W	TPU Mode/Stepping Motor Control Mode Select 0: TPU mode 1: Stepping motor control mode  Note: This bit also controls a selecting signal to switch TPU0TO0 to TPU0TO 3 outputs. Set this bit to 1 after making initial settings for the pattern cycle. Do not modify this bit during the counter operation.

### 56.2.10 Motor Deceleration (Stop) Transition Register (TPU0\_TMRR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMRR is used to place timer 0 in to the deceleration state from the normal state, in the motor control mode.

TPU0\_TMRR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REDU ON0	REDU ON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
1	REDUON0	0	R/W	This bit is used to force a transition of timer 0 to the deceleration (or stop) state from the normal state in motor control mode. Note that the state transition only proceeds when pattern 0 is the currently specified pattern. Setting this bit has no effect if timer 0 is not in the normal state. This bit is automatically cleared to 0 when the state of timer 0 shifts to the stop state. 0: No operation 1: Timer 0 is forcibly placed in the deceleration (or stop) state from the normal state.
0	REDUON	0	R/W	This bit is used to force a transition of timer 0 to the deceleration (or stop) state from the normal state in motor control mode. Setting this bit has no effect if timer 0 is not in the normal state. This bit is automatically cleared to 0 when the state of timer 0 shifts to the stop state. 0: No operation 1: Timer 0 is forcibly placed in the deceleration (or stop) state from the normal state.

### 56.2.11 Motor Control Status Register (TPU0\_TMSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMSR is a read-only register that indicates the sequence state in motor control mode.

TPU0\_TMSR is initialized to H'0001 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SITR	SITT	SITA	SITS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
3	SITR	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is deceleration. 0: The sequence state is not deceleration.
2	SITT	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is normal. 0: The sequence state is not normal.
1	SITA	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is acceleration. 0: The sequence state is not acceleration.
0	SITS	1	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is stop. 0: The sequence state is not stop.

### 56.2.12 Motor Operation Pattern Storing Register 0 (TPU0\_TMMPR0)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMMPR0 is used to set motor operation patterns [3] to [0] in motor control mode.

TPU0\_TMMPR0 is initialized to H'0000 by a reset.

### 56.2.16 Motor Output Pattern Storing Register (TPU0\_TMOPR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMOPR is used to specify the motor output pattern in motor control mode. When read, it indicates the pattern currently being output. Writing to this register while the sequence is in the stop state leads to output of the pattern with the corresponding number. TPU0\_TMOPR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	NOWPAT[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	NOWPAT [2:0]	000	R/W	In motor control mode, Reading: The pattern number currently being output is read. Writing: If the sequence is in the stop state, the pattern corresponding to the written pattern number is output.

### 56.2.17 Motor Acceleration Step Count Register (TPU0\_TMASR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMASR is used to set the number of steps in the acceleration state of motor control mode. TPU0\_TMASR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	AS[15:0]	H'0000	R/W	Specify the number of steps in the acceleration state of motor control mode. When the setting is H'0000, the acceleration state is skipped.

### 56.2.18 Motor Normal the Number of Steps Register (TPU0\_TMTSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMTSR is used to set the number of steps in the normal state of motor control mode. TPU0\_TMTSR is initialized to H'0000 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TS[15:0]	H'0000	R/W	Specify the number of steps in the normal state of motor control mode.  When the setting is H'0000, the normal state is maintained until 1 is written to the REDUON0 bit or REDUON bit in TPU0_TMRR.

### 56.2.19 Motor Deceleration the Number of Steps Register (TPU0\_TMRSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMRSR is used to set the number of steps in the deceleration state of motor control mode. TPU0\_TMRSR is initialized to H'0000 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RS[15:0]	H'0000	R/W	Specify the number of steps in the deceleration state of motor control mode.  When the setting is H'0000, the deceleration state is skipped.

### 56.2.20 Motor Control Sequence Counter Register (TPU0\_TMSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMSCR indicates or controls the value of the sequence counter in motor control mode. Writing to this register is only allowed when the motor control mode is in use and the current state is the normal state.

TPU0\_TMSCR is initialized to H'0000 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	SC[15:0]	H'0000	R/W	Value of Sequence Counter in Motor Control Mode Reading: The value of the sequence counter is read. Writing: Writing is only allowed in the normal state. The written value is directly stored in the sequence counter.

### 56.2.21 Motor Control Normal Counter Register (TPU0\_TMTCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TPU0\_TMTCR is a read-only register that indicates the number of steps in the normal state of motor control mode.

TPU0\_TMTCR is initialized to H'0000 by a reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TCR[15:0]	H'0000	R	Indicate the number of steps in the normal state of motor control mode.

## 56.3 Operation

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 56.3.1 Overview

An overview of operation in the various modes is given below.

#### (1) Ordinary Operation

Each timer has TPU0\_TCNT and TPU0\_TGR registers. TPU0\_TCNT counts up, and is capable of free-running operation and counting to define periods corresponding to register settings.

#### (a) Buffered Operation

When a compare match occurs, the buffer register value in the corresponding timer is transferred to TPU0\_TGR. Either a compare match or clearing of the counter can be selected as the trigger that defines the timing of updating from a buffer register.

#### (b) PWM Mode

In PWM mode, a PWM waveform is output. The duty cycle can be set by TPU0\_TGR. PWM waveforms with duty cycles in the range from 0 to 100% can be output in accord with the settings of TPU0\_TGRA and TPU0\_TGRB.

#### (c) Stepping Motor Control Mode

Pre-defined patterns can be output from TPU0TO3 to TPU0TO0 by placing timer 0 to stepping motor control mode.

### 56.3.2 Basic Functions

#### (1) Counter Operation

When a bit from among CST3 to CST0 in TPU0\_TSTR is set to 1, the TPU0\_TCNT for the corresponding timer starts counting. A TPU0\_TCNT can operate as a free-running counter, periodic counter, and so on.

#### (a) Example of Procedure for Setting up Counter Operations

Figure 56.2 shows an example of the procedure for setting up counter operation.

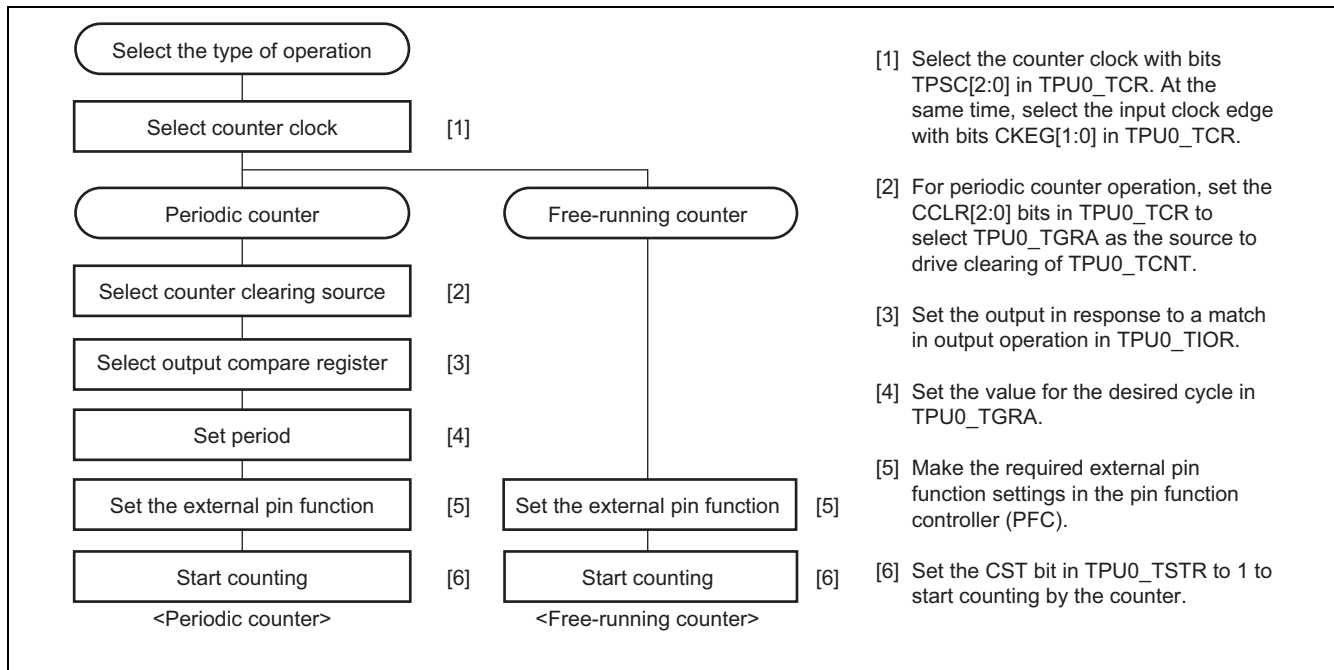

Figure 56.2 Example of Procedure for Setting up Counter Operation

**(b) Free-Running Counter Operation and Periodic Counter Operation**

Immediately after a reset, the TPU0\_TCNT counters are all designated as free-running counters. When the relevant bit in TPU0\_TSTR is set to 1, the corresponding TPU0\_TCNT starts counting up as a free-running counter. When TPU0\_TCNT has overflowed (when its value changes from H'FFFF to H'0000), the TCFV bit in TPU0\_TSR is set to 1. After it overflows, TPU0\_TCNT starts counting up again from H'0000.

Figure 56.3 illustrates free-running counter operation.

**Figure 56.3 Free-Running Counter Operation**

When a compare match is selected as the source to drive clearing of TPU0\_TCNT, the TPU0\_TCNT counter for the relevant timer operates as a periodic counter (counting a period defined by a general register). The TPU0\_TGR register for setting the period is designated as the output compare register, and counter clearing in response to a compare match is selected by means of bits CCLR[2:0] in TPU0\_TCR. After the settings have been made, TPU0\_TCNT starts counting as a periodic counter when the corresponding bit in TPU0\_TSTR is set to 1. When the counted value matches the value in the selected TPU0\_TGR, the TGF bit in TPU0\_TSR is set to 1 and TPU0\_TCNT is cleared to H'0000.

After a compare match, TPU0\_TCNT starts counting up again from H'0000.

Figure 56.4 illustrates periodic counter operation.

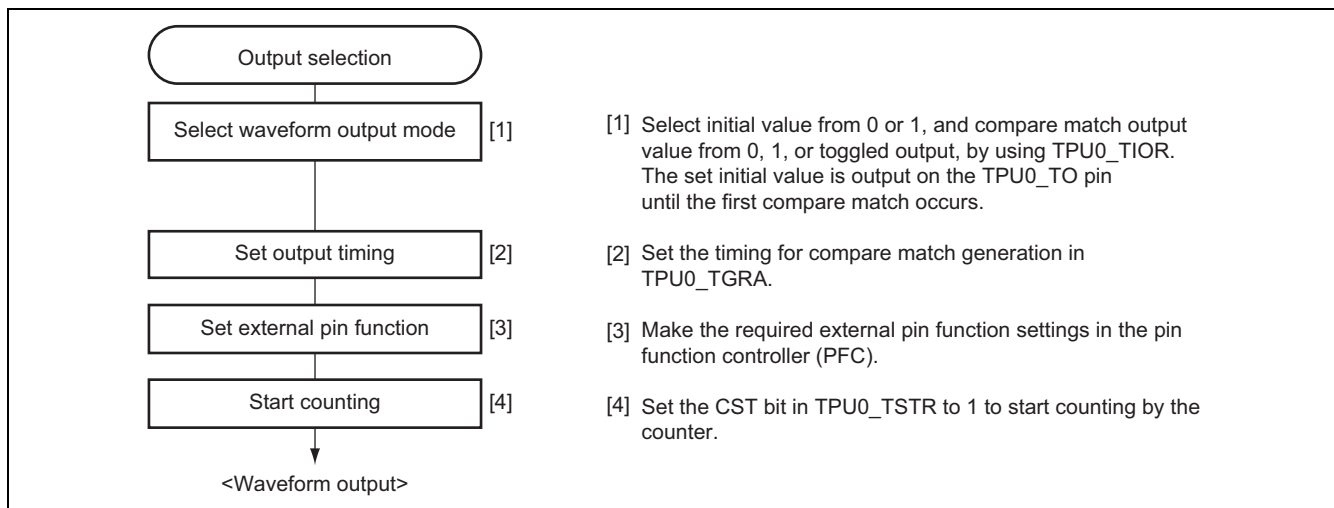

**Figure 56.4 Periodic Counter Operation**

**(2) Waveform Output by Compare Match**

The TPU can be set for the output of logical 0 or 1, or toggling of the output on the output pin in response to a compare match with TPU0\_TGRA.

**(a) Example of Procedure for Setting up Waveform Output under Compare Match Control**

Figure 56.5 shows an example of the procedure for setting up waveform output under compare match control.

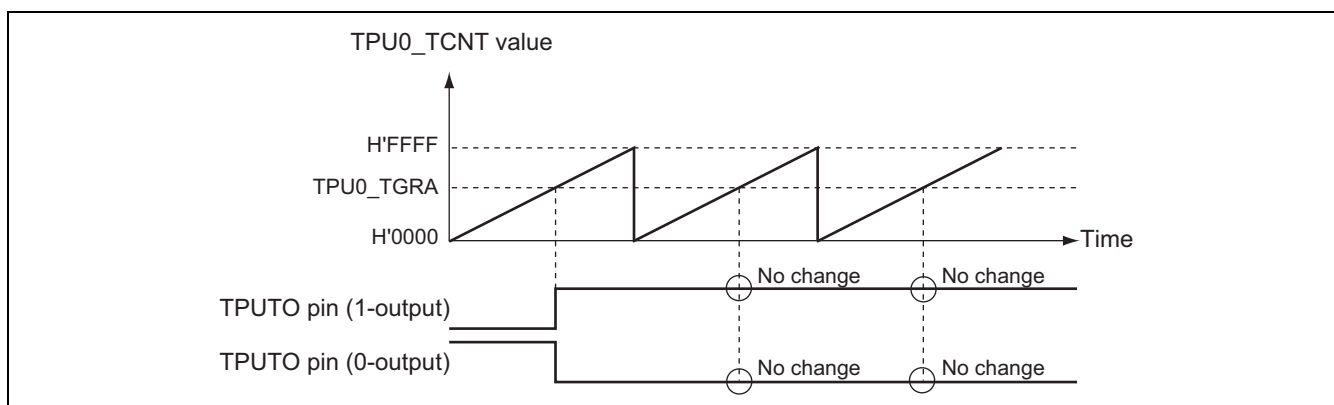

**Figure 56.5 Example of Procedure for Setting up Waveform Output under Compare Match Control**

**(b) Examples of Waveform Output Operation**

Figure 56.6 shows an example of the output of 0 or 1.

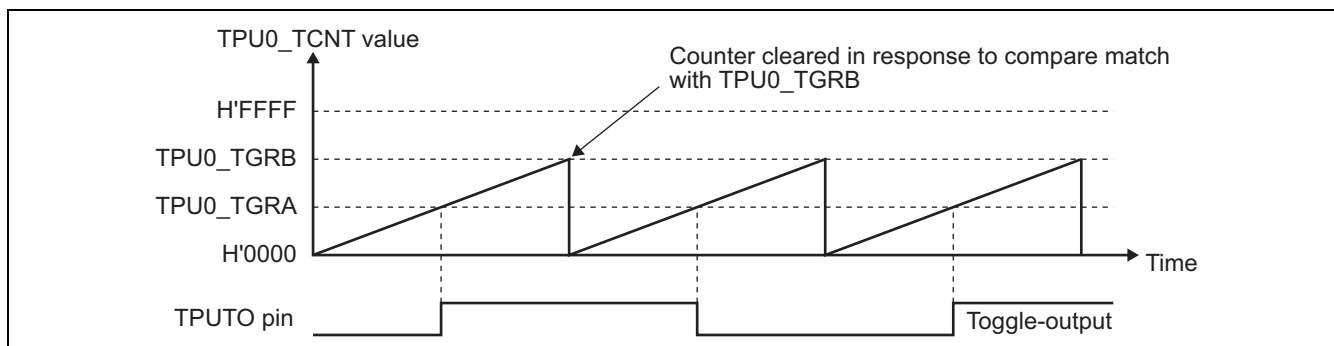

In this example, TPU0\_TCNT has been designated as a free-running counter, and settings have been made so that 1 or 0 is output in response to compare match A. When the set level is the same as the level on the pin, the level on the pin does not change.

**Figure 56.6 Example of Output of 0 or 1**

Figure 56.7 shows an example of toggled output.

In this example, TPU0\_TCNT has been designated as a periodic counter (with counter clearing handled by compare match B), and settings have been made so that the output is toggled in response to compare match A.

**Figure 56.7 Example of Toggled Output Operation**

### 56.3.3 Buffered Operation

TPU0\_TGRC and TPU0\_TGRD can be used as buffer registers.

Table 56.8 shows the register combinations used in buffered operation.

**Table 56.8 Register Combinations in Buffered Operation**

Timer General Register	Buffer Register
TPU0_TGRA	TPU0_TGRC
TPU0_TGRB	TPU0_TGRD

When a compare match occurs, the value in the buffer register for the corresponding timer is transferred to the timer general register. Either a compare match or clearing of the counter can be selected as the trigger that defines the timing of updating from a buffer register.

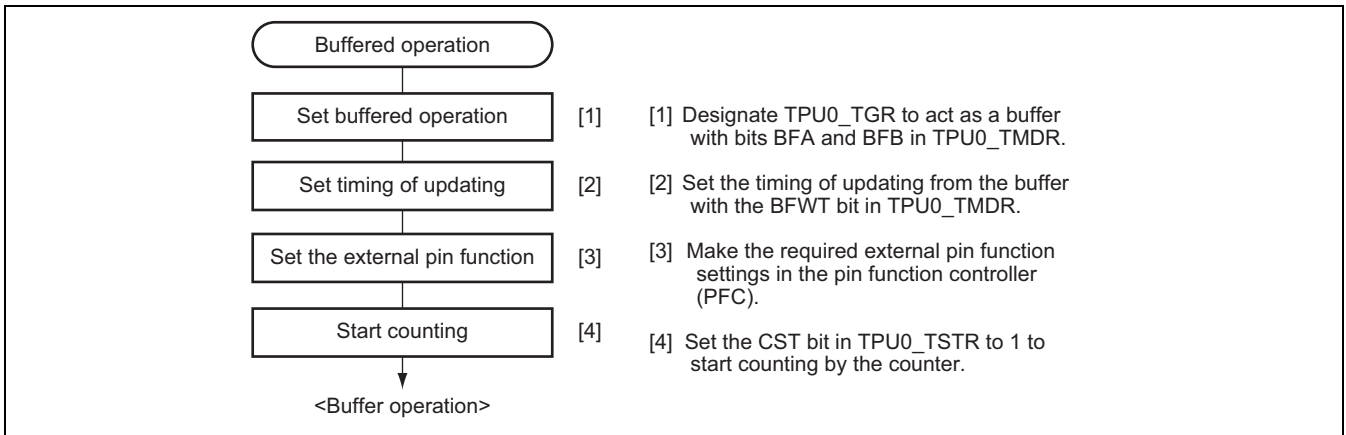

This operation is illustrated in Figure 56.8.

**Figure 56.8 Buffered Compare Match Operation**

**(1) Example of Procedure for Setting up Buffered Operation**

Figure 56.9 shows an example of the procedure for setting up buffered operation.

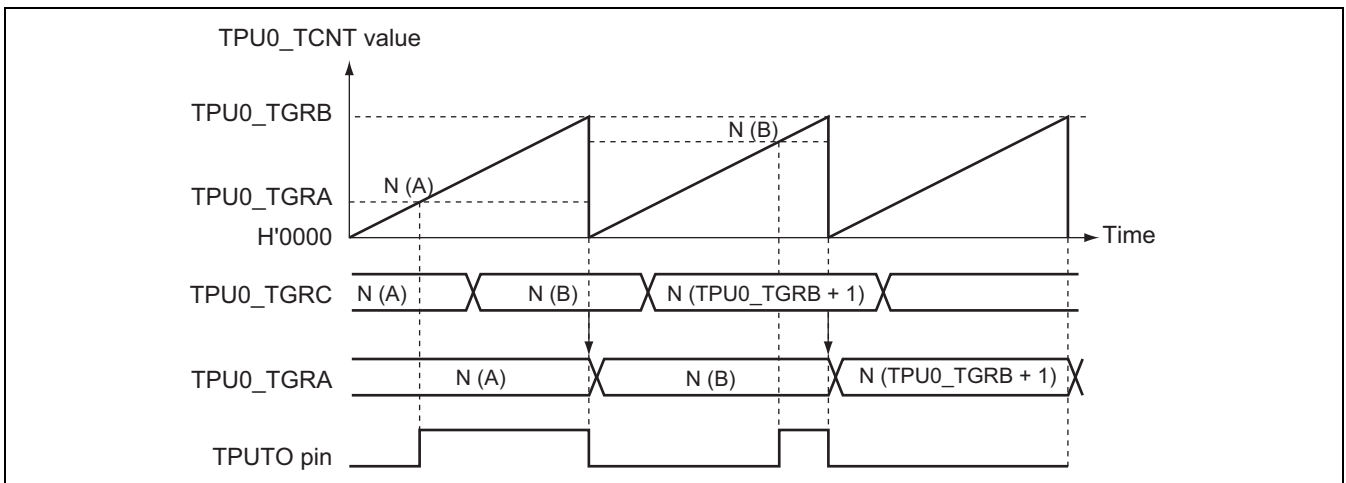

**Figure 56.9 Example of Procedure for Setting up Buffered Operation**

**(2) Examples of Buffered Operation**

Figure 56.10 shows an example of operation in which PWM mode has been designated for timer 0, and buffered operation has been designated for TPU0\_TGRA and TPU0\_TGRC. The settings used in this example are for clearing of TPU0\_TCNT in response to compare match B, output of 1 (on the TPU0TO0 to 3 for the selected timer) on compare match A, output of 0 as the initial value by clearing the counter, and the timing for updating from the buffer register as clearing of the counter.

When compare match A occurs, the output changes. When counter clearing is generated by a match with TPU0\_TGRB, the output changes and the value in buffer register TPU0\_TGRC is simultaneously transferred to the timer general register TPU0\_TGRA. This operation is repeated every time compare match A occurs.

For details on the PWM mode, see section 56.3.4, PWM Mode.

**Figure 56.10 Example of Buffer Operation**

### 56.3.4 PWM Mode

In PWM mode, PWM waveforms are output from the output pins. The output of 0 or 1 can be selected as the response to a compare match with the given TPU0\_TGRA.

Designating TPU0\_TGRB compare match as the counter clearing source enables setting of the overall cycle in that register. All timers can be independently placed in PWM mode.

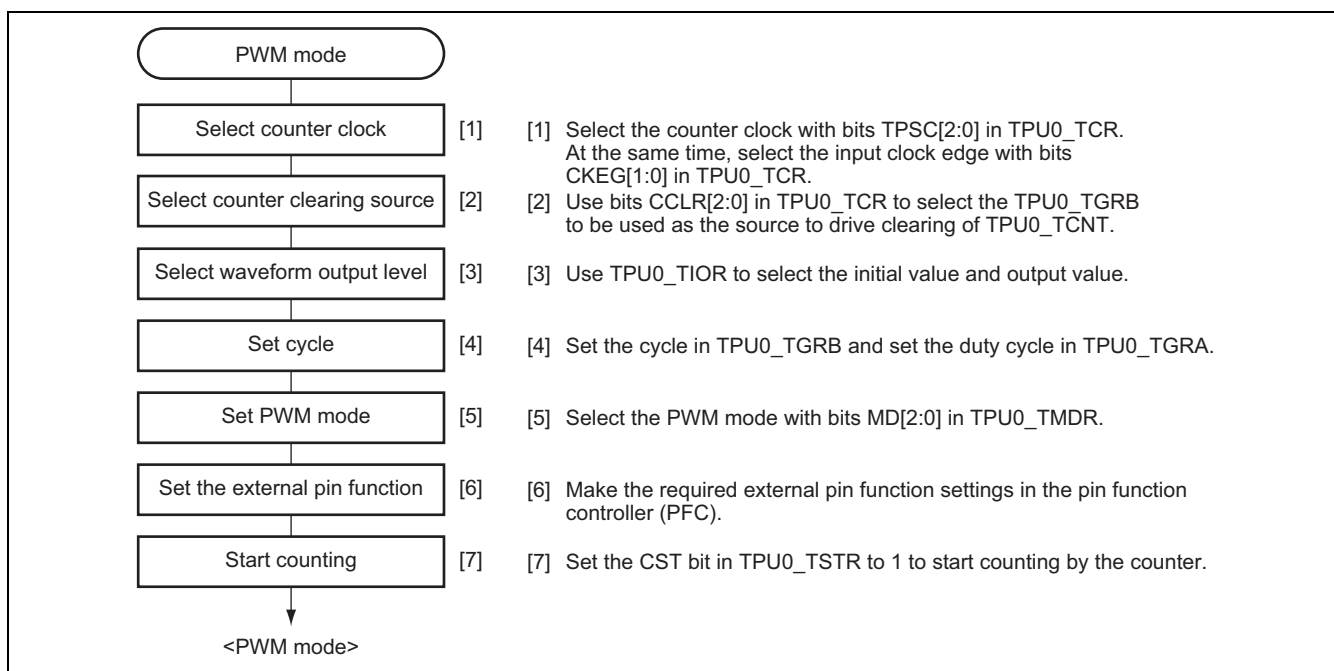

PWM output is generated from the output pins by using TPU0\_TGRA and TPU0\_TGRB to control the duty cycle and period, respectively. The initial output specified by TPU0\_TIOR is output on the output pin by counter clearing in response to a compare match with the period register. Be sure to set TPU0\_TIOR so that the initial output level is different from the compare match output. Selecting the same level or toggled output leads to no operation.

Conditions for 0% and 100% duty cycles are shown below.

- 0% duty cycle: The setting of the duty-cycle register (TPU0\_TGRA) being equal to that of the period register plus one (TPU0\_TGRB + 1)
- 100% duty cycle: The setting of the duty-cycle register (TPU0\_TGRA) being 0

#### (1) Example of Procedure for Setting up PWM Mode Operation

Figure 56.11 shows an example of the procedure for setting up the PWM mode operation.

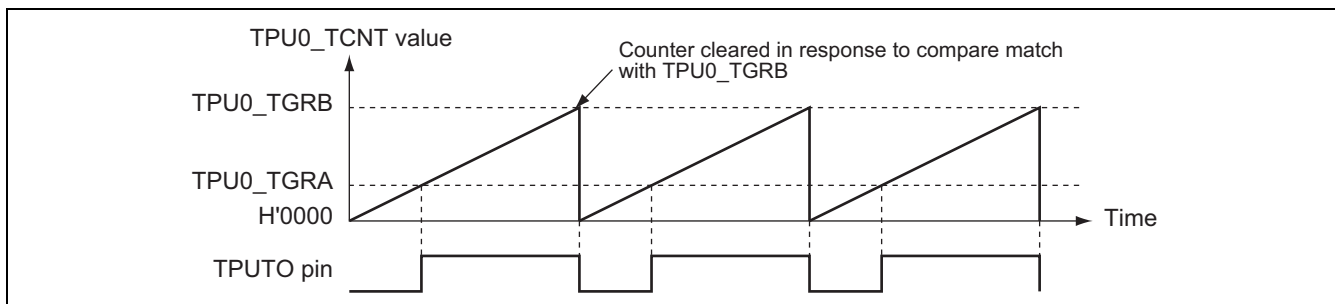

**Figure 56.11 Example of Procedure for Setting up PWM Mode Operation**

**(2) Examples of PWM Mode Operation**

Figure 56.12 shows an example of PWM mode operation.

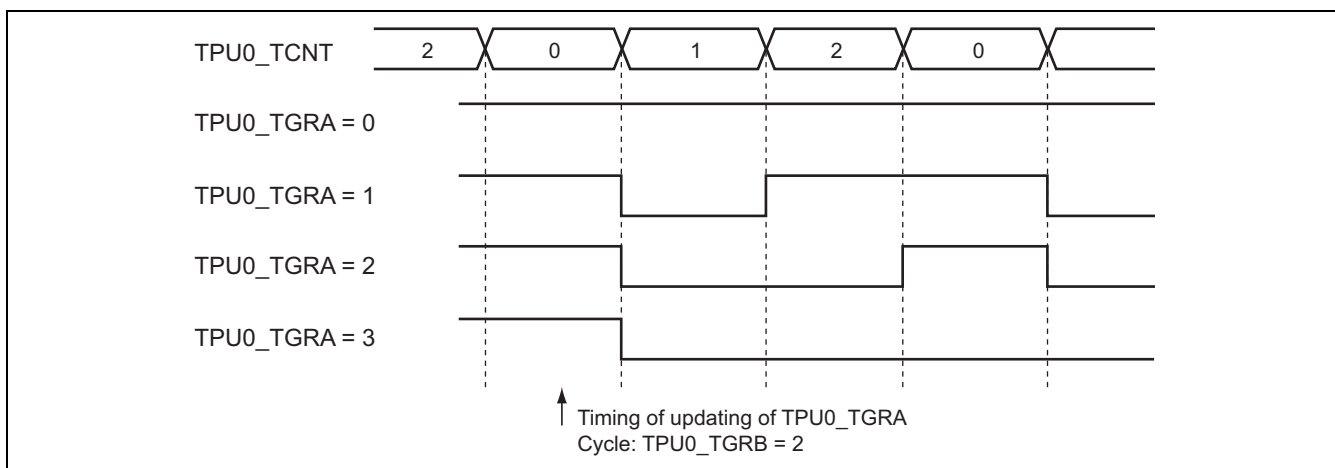

In this example, compare match with TPU0\_TGRB is set as the source to drive clearing of TPU0\_TCNT, 0 is set as the initial output value for TPU0\_TGRA, and 1 is set as the output value on a compare match with TPU0\_TGRA.

In this case, the value set in TPU0\_TGRB defines the cycle time (period), and the value set in TPU0\_TGRA defines the duty cycle.

**Figure 56.12 Example of PWM Mode Operation (1)**

Figure 56.13 shows an example of PWM waveform output with 0% and 100% duty cycles in PWM mode.

**Figure 56.13 Example of PWM Mode Operation (2)**

### 56.3.5 Stepping-Motor Control Mode

#### (1) Features of Stepping-Motor Control Mode

- This mode is for the output of signals for stepping-motor control on four pins and is only available for timer 0.
- States of the output pins change in response to compare matches with the counter of timer 0.
- By using the DMAC or an interrupt to rewrite the values of the compare-match registers, the intervals between transitions of the states of the output pins can be specified as desired.
- Specified patterns are output on the output pins.
- Four or eight patterns can be selected.
- The pattern-number counter is incremented or decremented by 1 on every compare match with the counter on timer 0. When the pattern-number counter overflows in normal mode, its value returns to 0. When the pattern-number counter underflows, its value becomes 3 (for a four-pattern cycle) or 7 (for an eight-pattern cycle).
- Patterns consist of stop patterns and operating patterns. Operating patterns are output while the counter is running, and stop patterns are output while the counter is stopped.
- While the counter is running, operation is in three states (the acceleration, deceleration, and normal states). Only for acceleration and deceleration, the interval between changes of pattern can be controlled.
- The acceleration or deceleration state can be skipped by writing H'0000 to TPU0\_TMASR and TPU0\_TMRSR.
- TPU0\_TMRR can be used to force a transition from the normal to the deceleration state.

#### (2) Glossary

Sequence State:	The four states in the sequence, i.e. the acceleration, normal, deceleration, and stop states
Sequence Counter:	Counter to control transitions to next sequence states The sequence counter is decremented with every compare match with the counter of timer 0 and, when the value reaches 1, the control state will make the transition to the next state in the sequence on a further compare match with the counter of timer 0.
Auto Mode:	Mode of operation when a value other than H'0000 has been written to TPU0_TMTSR The number of pattern transitions in the normal state corresponding to the setting of TPU0_TMTSR, and this is followed by an automatic transition to the deceleration state (or, if TPU0_TMRSR = H'0000, a transition to the stop state).
Manual Mode:	Mode of operation when H'0000 has been written to TPU0_TMTSR. In this case, the transition from the normal to the deceleration state (or the stop state if TPU0_TMRSR = H'0000) is not made unless 1 is written to the REDUON0 and REDUON bits in TPU0_TMRR.
Pulse Mode:	Mode of operation when H'0000 has been written to TPU0_TMASR and TPU0_TMRSR. Operation is only in the normal state, so the output pattern is changed with a constant interval.
Step:	The pattern is changed with every compare match with the counter of timer 0. Step refers to the interval of time between the change to one pattern and the change to the next.
Operation Pattern:	The four-bit patterns for output in the acceleration, normal, and deceleration states.
Stop Pattern:	The four-bit patterns for output in the stop state.

### (3) Setting up Basic Motor Control Operation

An example of operation in stepping motor control is shown in Figure 56.14.

Stepping-motor control mode allows the output of patterns with a variable step interval.

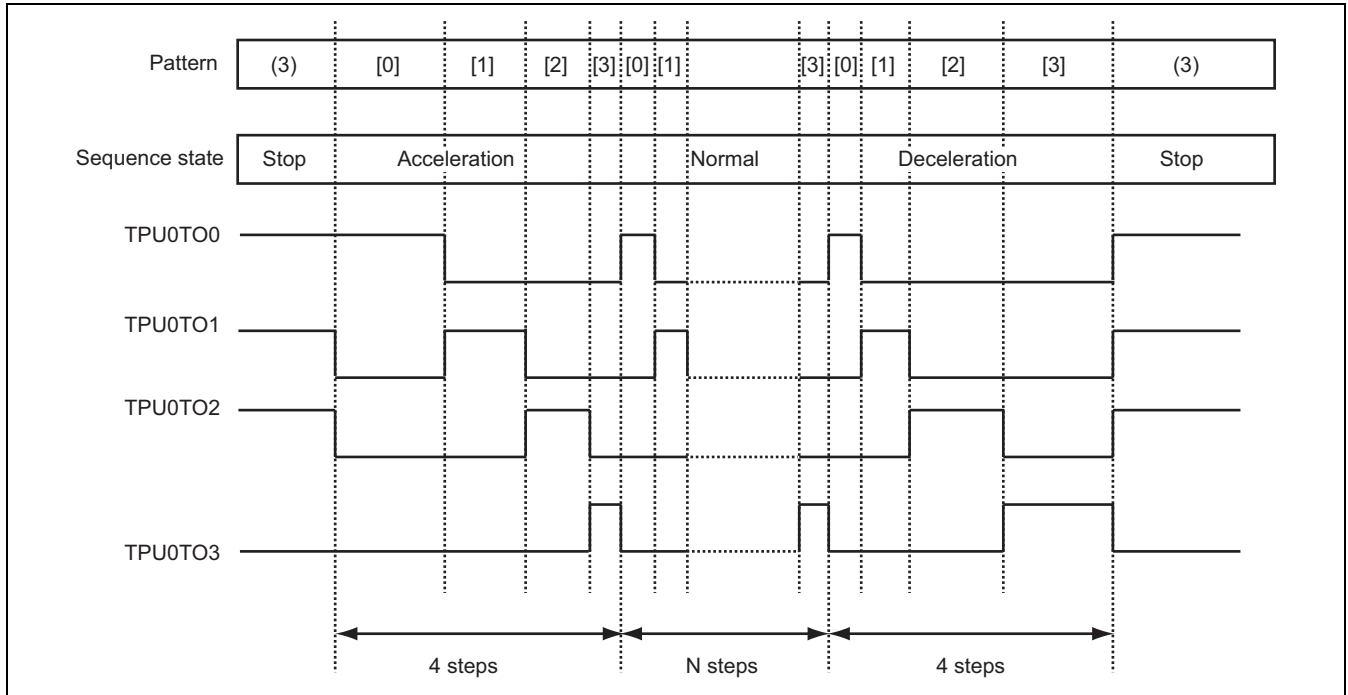

Figure 56.14 Example of Stepping-Motor Control

**(a) Compare Match Settings for Timer 0**

For stepping motor control, set TPU0\_TCR0 and TPU0\_TMDR0 as follows:

**Table 56.9 Compare Match Settings for Timer 0**

Register	Setting	Description
TPU0_TCR0	B'0000 0000 0100 0xxx	CCLR[2:0] bits = B'010 CKEG[1:0] bits = B'00 TPSC[2:0] bits = B'xxx (optional)
TPU0_TMDR0	B'0000 0000 0110 0000	BFWT bit = 1 BFB bit = 1 BFA bit = 0 MD[2:0] bits = B'000

[Legend]

x: Don't care.

With the above settings, TPU0\_TGRD0 is used as a buffer register for TPU0\_TGRB0, and the contents of the general register are rewritten when the timer counter is cleared. The step interval can be changed by using DMA transfer or interrupt control to write a desired value to TPU0\_TGRD0.

The TPSC[2:0] bits in TPU0\_TCR0 are for a timer prescaler setting. The step interval is calculated from the following formula.

**[For RZ/G1H, RZ/G1M, and RZ/G1N]**

With  $CP\phi$  at 15 MHz, B'011 as the value of TPSC[2:0] in TPU0\_TCR0, H'1425 as the value of TPU0\_TGRD0, the result is  $66.7 \text{ ns} \times 64 \times 5157 \text{ (H'1425)} = 25,380,691.2 \text{ ns} \cong 22 \text{ ms}$ . That is, the pattern will change after approximately 22 ms.

**[RZ/G1E]**

With  $CP\phi$  at 32.5 MHz, B'011 as the value of TPSC[2:0] in TPU0\_TCR0, H'1425 as the value of TPU0\_TGRD0, the result is  $30.8 \text{ ns} \times 64 \times 5157 \text{ (H'1425)} = 10,165,478.4 \text{ ns} \cong 10 \text{ ms}$ . That is, the pattern will change after approximately 10 ms.

**(b) Sequence State and the Number of Steps**

In stepping-motor control mode, operation is in three states (acceleration, normal, and deceleration) while the counter is running. In the acceleration and deceleration states, the step interval can be changed. Accordingly, the value of TPU0\_TGRD0 must be changed the same number of times as the patterns are changed.

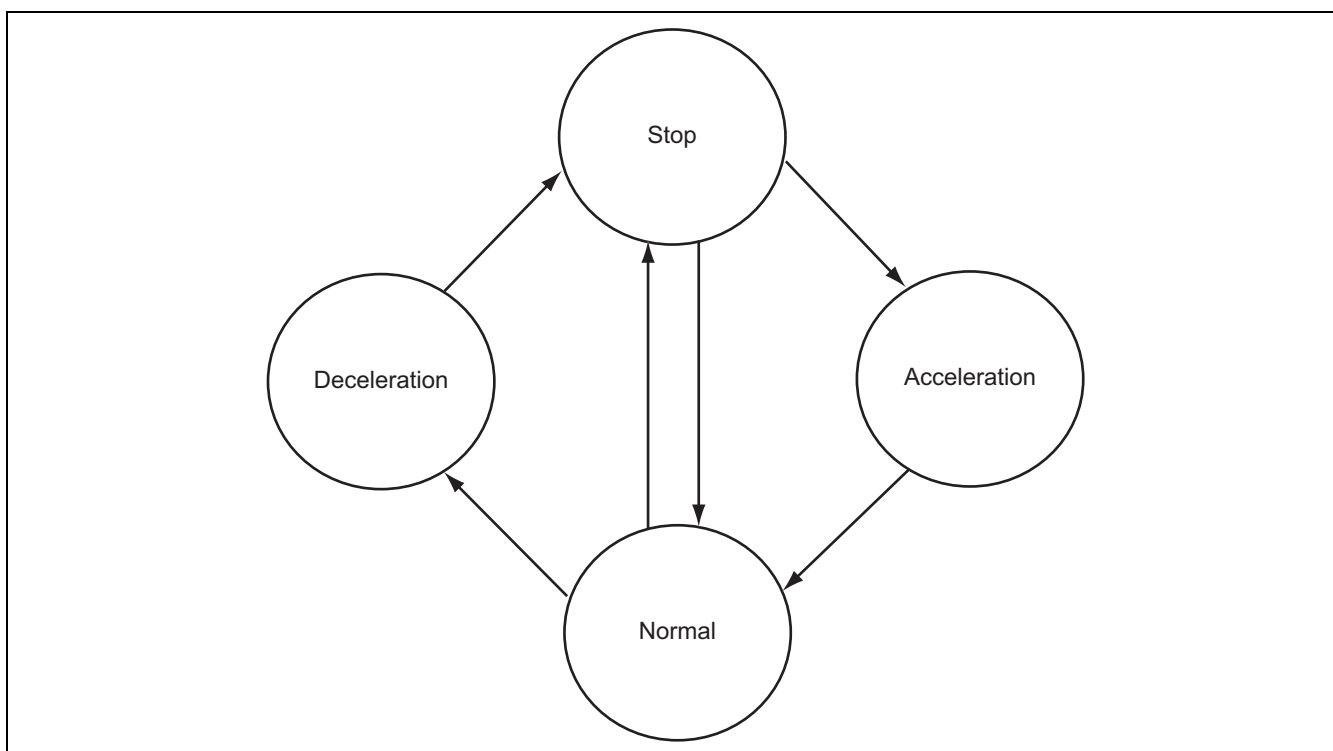

In the normal state, the step interval cannot be changed. So, TPU0\_TGRD0 is only set once for a period in the normal state.

The numbers of steps in the acceleration, normal, and deceleration states are set in TPU0\_TMASR, TPU0\_TMTSR, and TPU0\_TMRSR, respectively. If H'0000 is written to TPU0\_TMASR or TPU0\_TMRSR, the corresponding state is skipped. Furthermore, the manual mode can be selected by writing H'0000 to TPU0\_TMTSR. In this mode, the transition from normal mode can only be initiated by changing the value in TPU0\_TMRR.

Table 56.10 gives descriptions of the sequence states and Figure 56.15 shows the transitions between sequence states.

**Table 56.10 Description of Sequence States**

Start/Stop	State	Description	
		Step Interval	Definition in TPU0_TGRD0
Start	Acceleration	Variable	The number of steps specified for this state
	Normal	Fixed	Only once
	Deceleration	Variable	The number of steps specified for this state
Stop	Stop	—	—

**Figure 56.15 Sequence State Transition**

**(c) Setting of the Step Interval**

Direct memory access or interrupt-driven transfer can be used to set the step interval

- DMA transfer

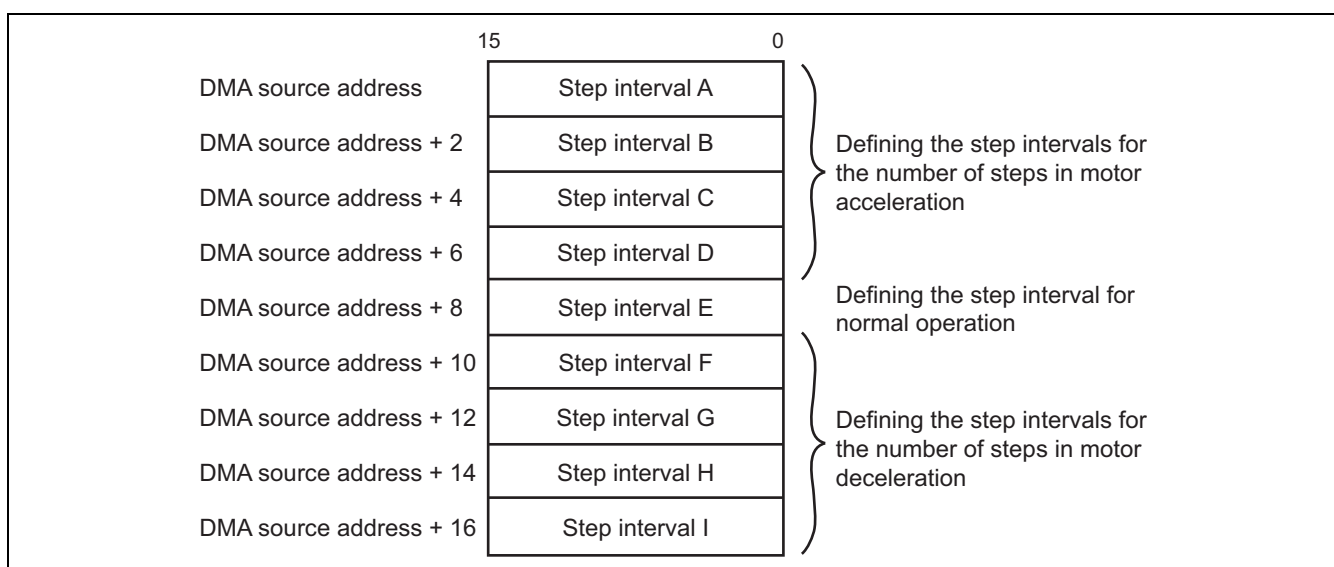

Setting the TDMAE bit in TPU0\_TMIR to 1 selects the use of DMA transfer to modify the step interval.

The number of requests for DMA transfer is given by  $TPU0\_TMASR + 1$  (to transfer the step interval for the normal state) +  $TPU0\_TMRSR$ . The step intervals must be defined in sequence from the address indicated by the DMA source address register. Figure 56.16 shows an example of timing in operation with DMA transfer requests used to set the step intervals. Figure 56.17 shows the corresponding definitions of step intervals in the address map.

Table 56.11 lists an example of the DMA settings.

**Figure 56.16 Operation with DMA Transfer Requests Used to Adjust the Step Interval**

**Figure 56.17 Address Map of Step Interval Definitions for the Example of Operation**

**Table 56.11 DMA Settings**

DMA Register	Setting	Description
DMA source address register	H'XXXX XXXX	Address where the table of step intervals starts
DMA destination address register	H'E70F 0034	Address of TPU0_TGRD0
DMA transfer count register	H'0000 0000	(Setting for the maximum number of transfer operations) *
DMA transfer count register B	H'XXXX XXXX	The number of DMA transfer requests is set in the higher- and lower-order 16 bits. (for Figure 56.16, H'0009 0009)
DMA channel control register	H'E670 80*C	Reload mode: Use source address registers (SARs) as the source for reloading. Fixed destination address. Incrementation of source addresses. The DMA extension resource selector is used. DMA transfer is in word (two-byte) units. The other bits are in the default settings.
DMA extension resource selector	H'F1 in the bit field for the selected DMA channel	Select TPU0
DMA operation register	H'0001	Permits DMA transfer on all channels. The other bits are in the default settings

Note: \* Transfer is stopped when the value of the DMA transfer counter reaches 0, so change the value of the DMA transfer counter back to 1 after TPU-related operations are finished.

- Interrupt-driven transfer

Setting the TMDRFE bit in TPU0\_TIER0 to 1 allows the use of interrupt-driven transfer to change the step interval.

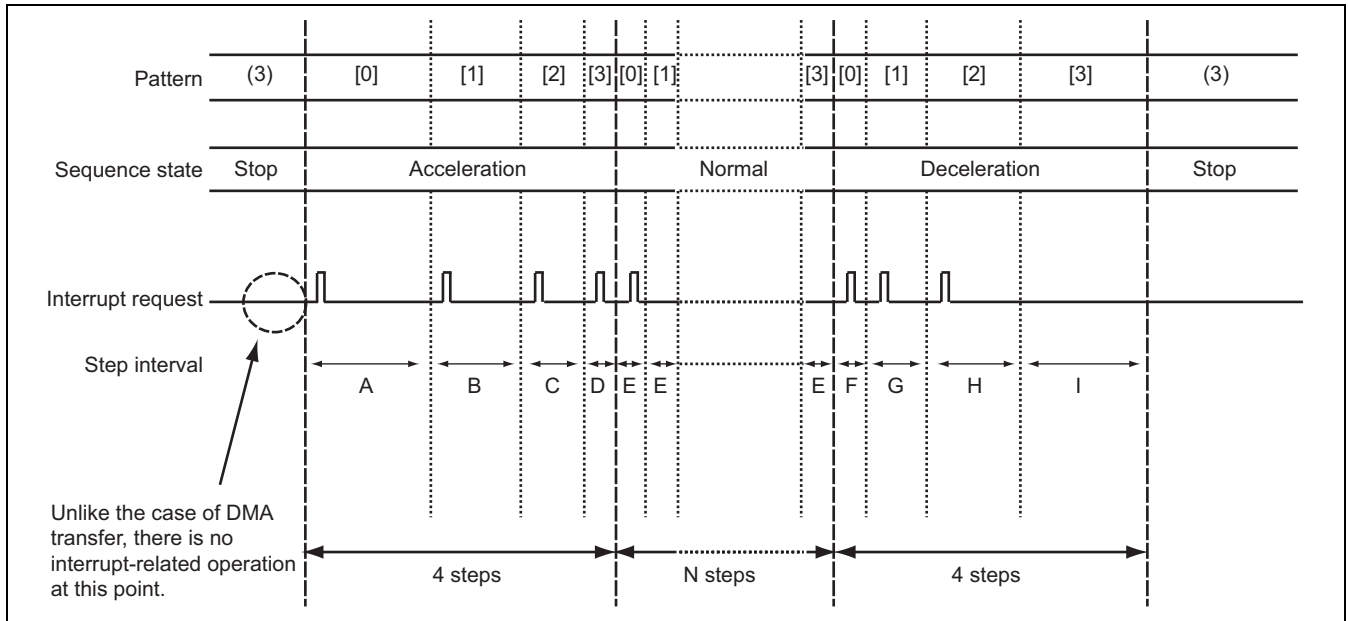

$TPU0\_TMASR-1 + 1$  (to transfer the step interval in the normal state) + TPU0\_TMRSR gives the number of times TPU0\_TGRD0 must be written to by interrupt-driven transfer.

This method is unlike DMA transfer in that an interrupt is not generated when the initial transfer is required. The initial value should thus be written to TPU0\_TGRD0 before counter operation starts.

Once interrupt generation starts, the interrupt handler writes the step intervals to TPU0\_TGRD0 and writes 0 to the TMDRFS bit after reading it as 1.

Figure 56.18 shows an example of timing in operation with interrupt-driven transfer used to set the step intervals.

**Figure 56.18 Interrupt-Driven Adjustment of the Step Interval**

The step-intervals in the example of operation shown in Figure 56.18 are defined in the following stages.

- Write step interval A to TPU0\_TGRD0 before starting the counter.
  - Write step interval B to TPU0\_TGRD0 in response to the first interrupt.
  - Write step interval C to TPU0\_TGRD0 in response to the second interrupt.
  - Write step interval D to TPU0\_TGRD0 in response to the third interrupt.
  - Write step interval E to TPU0\_TGRD0 in response to the fourth interrupt.
  - Write step interval F to TPU0\_TGRD0 in response to the fifth interrupt.
  - Write step interval G to TPU0\_TGRD0 in response to the sixth interrupt.
  - Write step interval H to TPU0\_TGRD0 in response to the seventh interrupt.
  - Write step interval I to TPU0\_TGRD0 in response to the eighth interrupt.
- } Defining the step intervals for the number of steps in motor acceleration
- } Defining the step interval for normal operation
- } Defining the step intervals for the number of steps in motor deceleration

**(d) Pattern Setting**

In stepping-motor control mode, each four-bit value for output on pins TPU0TO0 to TPU0TO3 is regarded as a single pattern. The patterns are in a sequence, and a compare match with the timer counter triggers each transition to the next pattern.

The following rules apply to pattern transfer.

- Either a four- or an eight-pattern cycle may be used. The number is determined by the MTRPATKIND bit in TPU0\_TMIR0.
- Each pattern is indicated by a pattern number. The current pattern number is either incremented or decremented on each compare match with the timer counter. Incrementation or decrementation of the pattern numbers is determined by the MTRPATDOWN bit in TPU0\_TMIR0.
- The pattern-number counter returns to 0 when it overflows. When it underflows, the pattern number becomes three (for a four-pattern cycle) or seven (for an eight-pattern cycle).
- Operating patterns are defined as the output patterns in the acceleration, normal, and deceleration states, and stop patterns are defined as the output patterns in the stop state. In transitions from an operating pattern to a stop pattern, the pattern number remains the same. In transitions from a stop pattern to an operating pattern, the current pattern number changes to that of the next pattern.

The operating patterns are set in TPU0\_TMMPR0 and TPU0\_TMMPR1, and the stop patterns are set in TPU0\_TMSPR0 and TPU0\_TMSPR1.

Table 56.12 lists the order of patterns for different settings of the MTRPATDOWN and MTRPATKIND bits in TPU0\_TMIR.

**Table 56.12 Settings of the MTRPATDOWN and MTRPATKIND Bits in TPU0\_TMIR and Orders of Patterns**

TPU0_TMIR		Example of Pattern Order (Operating Pattern [ ], Stop Pattern ( ))
MTRPATDOWN Bit	MTRPATKIND Bits	
0	B'00	[0] → [1] → [2] → [3] → [0] → [1] → [2] → [3] → (3) → [0]
1		[0] → [3] → [2] → [1] → [0] → [3] → [2] → [1] → (1) → [0]
0	B'01	[0] → [1] → [2] → [3] → [4] → [5] → [6] → [7] → (7) → [0]
1		[0] → [7] → [6] → [5] → [4] → [3] → [2] → [1] → (1) → [0]

**(e) Specifying the Output Pattern in the Stop State**

Specifying a pattern number in the NOWPAT[2:0] bits of TPU0\_TMOPR while output is in the stop state leads to output of the corresponding pattern on pins TPU0TO3 to TPU0TO0. The initial value is 0.

**(f) Selecting the Stepping-Motor Control Mode**

Stepping-motor control by the TPU circuit is selected by setting the MTRON bit in TPU0\_TMIR to 1. The output on pins TPU0TO3 to TPU0TO0 is switched to the output corresponding to stepping-motor control.

Switching should proceed while the motor is stopped.

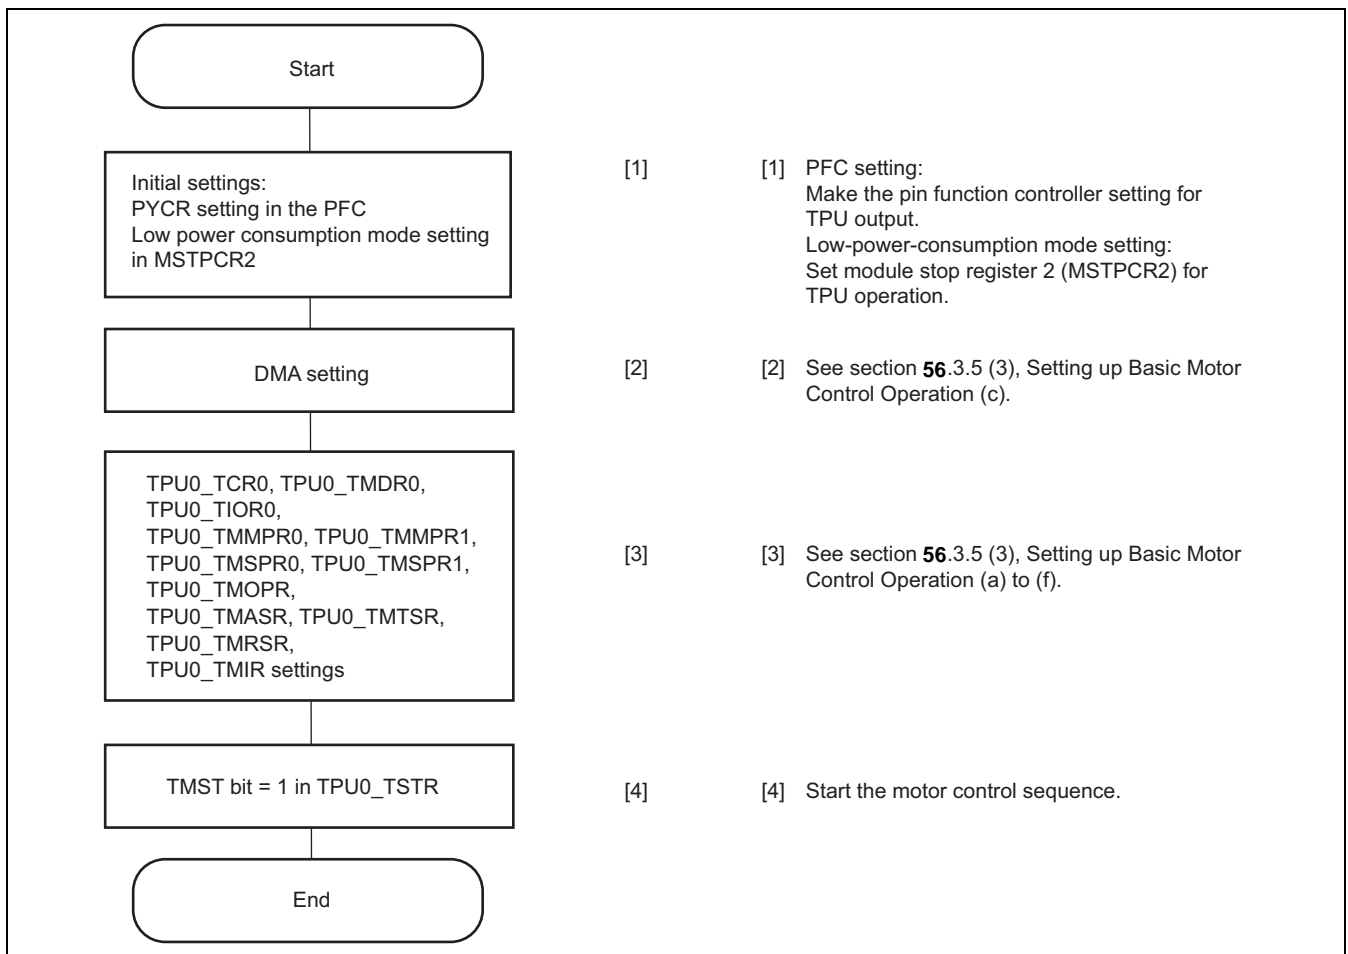

The stop pattern specified as pattern 0 in TPU0\_TMOPR is output after switching. Therefore, verify the value in TPU0\_TMOPR or write the desired pattern to TPU0\_TMOPR.

**(g) Starting Stepping-Motor Control**

Stepping-motor control is started by setting the TMST bit in TPU0\_TSTR to 1. This bit is automatically cleared (to 0) in the stop state after motor-control operations are over.

**(h) Example of the Procedure for Setting up Stepping-Motor Control**

Figure 56.19 is a flowchart of stepping-motor control.

**Figure 56.19 Flowchart**

#### (4) Changing the Number of Steps in the Normal State.

The number of steps in the normal state is set in TPU0\_TMTSR. The operations for changing the number of steps are described under (a) and (b) below.

In manual mode (TPU0\_TMTSR = H'0000), the operation under (a) is the only way of switching from the normal state.

##### (a) Changes by TPU0\_TMRR

Writing 1 to the REDUON0 bit or the REDUON bit in TPU0\_TMRR initiates the transition to the deceleration state (or, if TPU0\_TMRSR = H'0000, to the stop state).

Table 56.13 describes how operation in response to the writing of 1 to the REDUON0 bit varies with the operating state. Table 56.14 describes how operation in response to the writing of 1 to the REDUON bit varies with the operating state.

**Table 56.13 Timing of Writing 1 to the REDUON0 Bit and Operation**

Timing of Writing 1 to the REDUON0 Bit	Operation
Acceleration	Operation continues normally until the end of acceleration. Control then enters the normal state.
Normal	Control remains in the normal state until the pattern number becomes [0]. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) follows the end of this step in the normal state.
Deceleration	Writing 1 to the bit has no effect on deceleration.
Stop	TPU0_TMRR is cleared to H'0000 after control has made the transition from the normal or deceleration state to the stop state. When 1 is written to the REDUON0 bit after control is in the stop state, the sequence in the next round of motor control continues until the pattern number in the normal state becomes [0]. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of this step in the normal state.

**Table 56.14 Timing of Writing 1 to the REDUON Bit and Operation**

Timing to Write 1 in REDUON Bit	Operation
Acceleration	Operation continues normally until the end of acceleration.
Normal	The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made after a single step in the normal state.
Deceleration	Writing 1 to the bit has no effect on deceleration.
Stop	TPU0_TMRR is cleared to H'0000 after control has made the transition from the normal or deceleration state to the stop state. When 1 is written to the REDUON0 bit after control is in the stop state, the sequence in the next round of motor control continues until it enters the normal state. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of a single step in the normal state.

**(b) Changing the Number of Steps by Changing the Value in TPU0\_TMSCR**

In auto mode (i.e. when TPU0\_TMTSR  $\neq$  H'0000), TMSCR indicates the remaining number of steps in the current state.

When the control sequence is in the normal state, the number of steps can be changed by writing the desired number of steps. Writing is ineffective in states other than the normal state.

Do not write to this register when control is in manual mode (TPU0\_TMTSR = H'0000).

**(5) Acquiring the Number of Steps in the Normal State**

In the stop state, TPU0\_TMTCR can be read to acquire the number of steps in the normal state of the immediately preceding sequence.

**(6) Pulse Mode**

Writing H'0000 to TPU0\_TMASR and TPU0\_TMRSR selects operation in the normal state alone, with a constant step interval. That is, operation starts with the step interval defined for the normal mode and the interval does not subsequently change. This is referred to as pulse mode operation.

Examples of pulse-mode operation are described below.

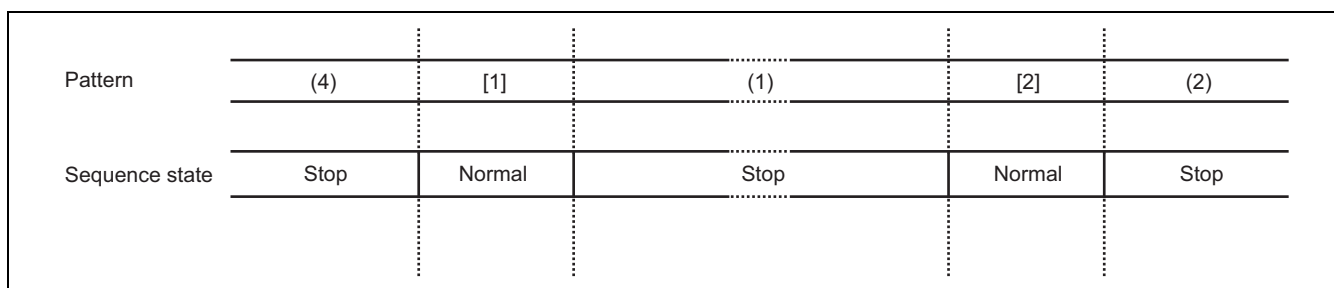

**(a) Single-Pulse Shifts in Pulse Mode and Auto Mode**

Table 56.15 gives an example of register settings for single-pulse steps in auto mode.

Figure 56.20 is a timing chart for single-pulse shifts in auto mode.

**Table 56.15 Register Settings to Select One Pulse as the Number of Steps in Auto Mode**

Register Setting Value	Contents
TPU0_TMASR: H'0000	No acceleration state
TPU0_TMTSR: H'0001	Only one step in the normal state
TPU0_TMRSR: H'0000	No deceleration state

**Figure 56.20 Timing of Single-Pulse Shifts in Auto Mode**

### (b) Single-Pulse Shifts in Pulse Mode and Manual Mode

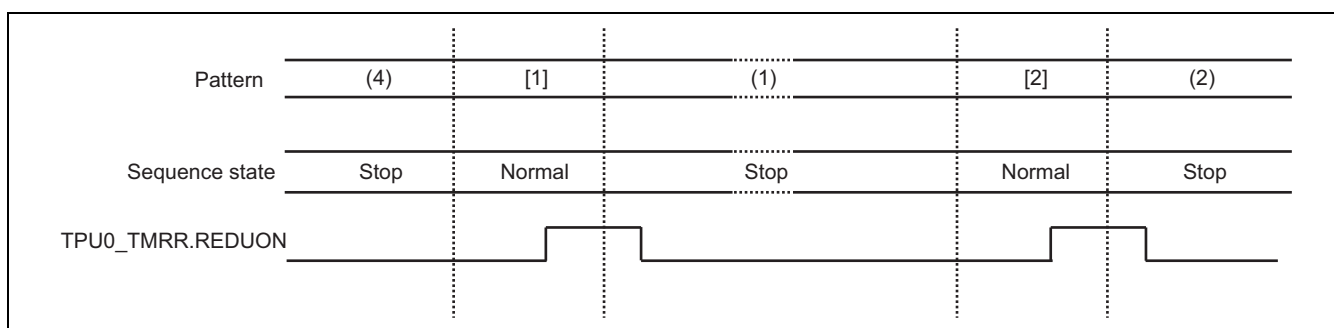

In manual mode, setting the REDUON0 or REDUON bit in TPU0\_TMRR to 1 while the sequence is in the normal state enables a single pulse shift.

Table 56.16 gives an example of register settings for single-pulse steps in manual mode.

Figure 56.21 is a timing chart for single-pulse shifts in manual mode.

**Table 56.16 Register Settings to Select One Pulse as the Number of Steps in Manual Mode**

Register Setting Value	Contents
TPU0_TMASR: H'0000	No acceleration state
TPU0_TMTSR: H'0000	Looping in the normal state
TPU0_TMRSR: H'0000	No deceleration state

**Figure 56.21 Timing of Single-Pulse Shifts in Manual Mode**

### (7) Interrupts

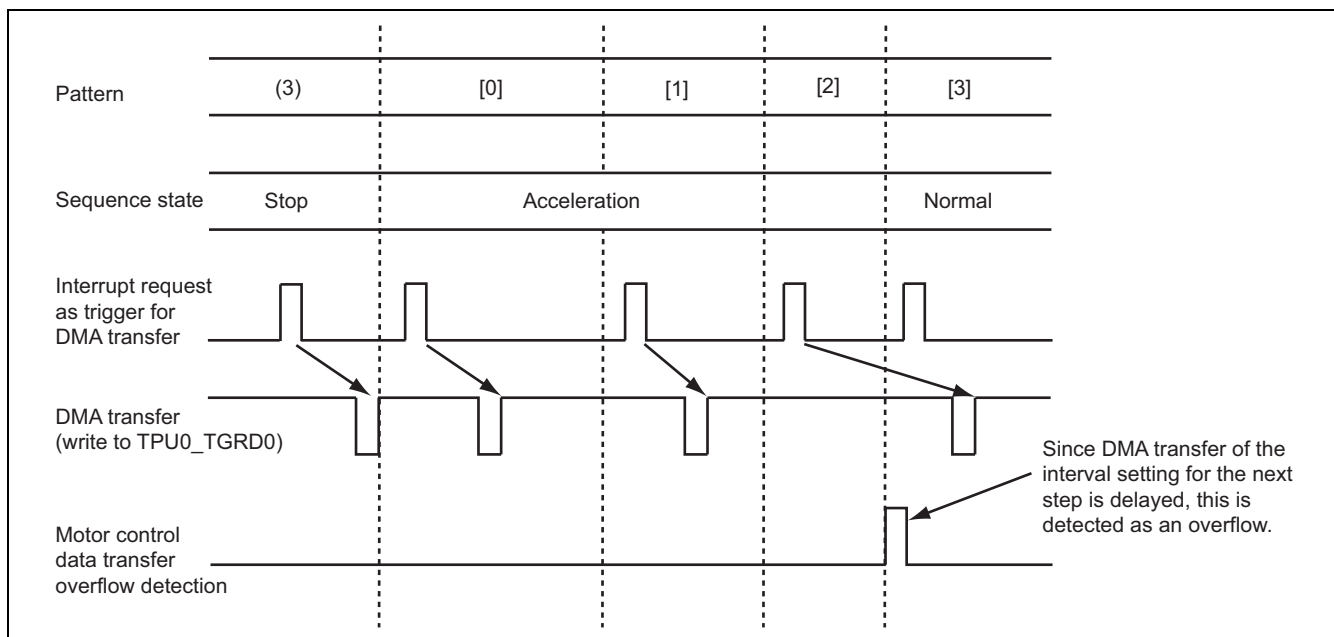

Timer 0 has six added interrupt conditions for use with stepping-motor control mode.

The interrupt conditions are described below.

#### (a) Detection of Overflows of Data Transferred for Motor Control

Setting the TMDOFE bit in TPU0\_TIER0 to 1 selects the detection of overflows of data transferred for motor control (motor control data transfer overflows). Here, overflow refers to the condition where buffer-related operation, i.e. the transfer of the data from TPU0\_TGRD0, is delayed; that is, when the operation TPU0\_TGRD0→TPU0\_TGRB0 is delayed. To cancel this interrupt, write 0 to the TMDOFS bit of TPU0\_TSR0 after having read it as 1.

Figure 56.22 shows an example of DMA transfer where an overflow in data transfer for motor control occurs and detection of overflows has been enabled.

**Figure 56.22 DMA Transfer with Detection of Motor Control Data Transfer Overflows Enabled**

Since this interrupt is for use in the debugging of defective operation, normal operation will not be restored even if it is detected.

#### (b) Detection of Requirement for Transfer of Motor control Data

Detection of requirements for the transfer of motor control data (detect motor control data transfer request) is enabled by setting the TMDRFE bit of TPU0\_TIER0. This interrupt is generated when the next pattern interval is to be changed from the current interval. On detection of this interrupt, the handler should write the setting for the next interval to TPU0\_TGRD0 and then write 0 to the TMDRFS bit of TPU0\_TSR0 after having read it as 1.

This interrupt is not available if DMA transfer has been selected (the TDMAE bit in TPU0\_TMIR = 1).

See Figure 56.18 for an example of usage of this interrupt.

#### (c) Detecting the Transition to Deceleration

Setting the TMS1ER bit in TPU0\_TIER0 to 1 enables detection of the transition to deceleration. The handler should clear the TMCFR flag of TPU0\_TSR0 by writing 0 to the bit after having read it as 1.

#### (d) Detecting the Transition to the Normal State

Setting the TMS1ET bit in TPU0\_TIER0 to 1 enables detection of the transition to the normal state. The handler should clear the TMCFT flag of TPU0\_TSR0 by writing 0 to the bit after having read it as 1.

#### (e) Detecting the Transition to Acceleration

Setting the TMS1EA bit in TPU0\_TIER0 to 1 enables detection of the transition to acceleration. The handler should clear the TMCFA flag of TPU0\_TSR0 by writing 0 to the bit after having read it as 1.

#### (f) Detecting the Transition to the Stop State

Setting the TMS1ES bit in TPU0\_TIER0 to 1 enables detection of the transition to the stop state. The handler should clear the TMCFS flag of TPU0\_TSR0 by writing 0 to the bit after having read it as 1.

**(8) Checking the State of Operation**

Read TPU0\_TMSR and TPU0\_TMSCR to check the current state of operations. TPU0\_TMSCR indicates the value resulting from decrementation (on every compare match with the timer counter) from the values in the number of steps register (TPU0\_TMASR, TPU0\_TMTSR, or TPU0\_TMRSR) during sequence transitions.

Figure 56.23 shows how the values in TPU0\_TMSR and TPU0\_TMSCR vary through the four states. As is shown in the figure, the current step within the overall sequence of state transitions can be estimated by, for example, reading TPU0\_TMSR = H'0008 and TPU0\_TMSCR = H'0003 in the interval indicated in the figure below.

**Figure 56.23 Values of TPU0\_TMSR and TPU0\_TMSCR**

# 57A. Compare Match Timer 0 (CMT0)

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

## 57A.1 Features

- Two channels
- 16 bits/32 bits can be selected as counter size (bit-width).
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- Following four clocks can be selected as counter clocks:
  - RCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operation is selectable.
- Compare match or overflow can be selected as interrupt source.
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

Figure 57A.1 shows a block diagram of the CMT0.

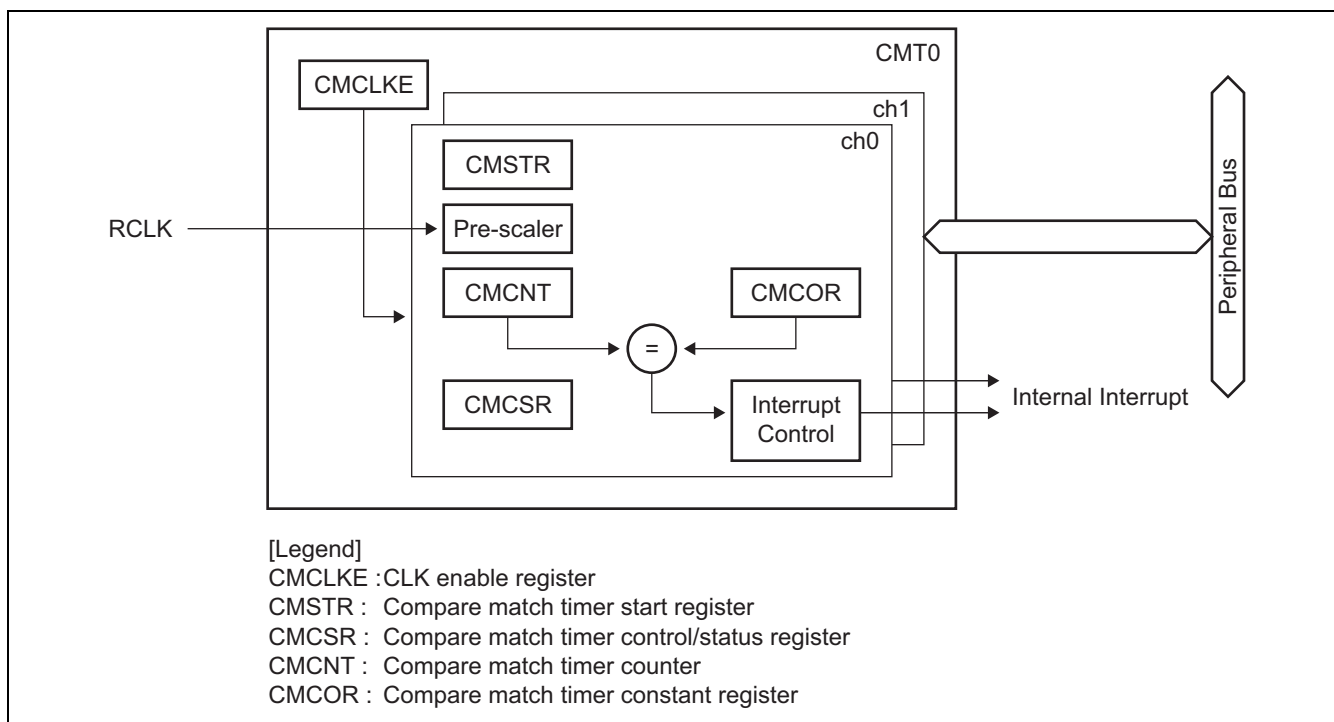

Figure 57A.1 Block Diagram of CMT0

## 57A.2 Register Descriptions

Table 57A.1 shows the CMT0 register configuration. Table 57A.2 shows the register states in each operating mode.

0	STR0	1	R/W	Count Start These bits specify start/halt of compare match timer counter (CMCNTn). 0: CMCNTn halts 1: CMCNTn starts counting

### 57A.2.3 Compare Match Timer Control/Status Registers 0 and 1 (CMCSR0, CMCSR1)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCSRn (n = 0/1) is a 32-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/(W)	R/(W)	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	0	R/(W)	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNTn) and compare match timer constant register (CMCORn) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNTn and CMCORn values have not matched. [Clearing condition] Write 0 to CMF 1: CMCNTn and CMCORn values have matched. Note: Only 0 can be written to clear the flag.
14	OVF	0	R/(W)	Overflow Flag This flag indicates whether the compare match timer counter (CMCNTn) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNTn has not overflowed. [Clearing condition] Write 0 to OVF 1: CMCNTn has overflowed. Note: Only 0 can be written to clear the flag.
13	WRFLG	0	R	Write State Flag Write access to CMCNTn is prohibited, while this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNTn is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNTn.

Bit	Bit Name	Initial Value	R/W	Description
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	0	R/W	Compare Match Timer Counter Size Specify whether the compare match timer counter (CMCNTn) is used as a 16-bit counter or a 32-bit counter. This bit specifies the valid size of compare match timer constant register (CMCORn). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter. Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
8	CMM	1	R/W	Compare Match Mode Specify counter operation mode. 0: One-shot operation 1: Free-running operation Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
7, 6	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode. Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS[2:0]	111	R/W	<p>Clock Select</p> <p>These bits select the input clock to CMCNTn. When the count start bit (STRO) in CMSTRn is set to 1, CMCNTn begins incrementing with the clock selected by these bits.</p> <p>000: Setting prohibited                      001: Setting prohibited                      010: Setting prohibited                      011: Setting prohibited                      100: RCLK/8                      101: RCLK/32                      110: RCLK/128                      111: RCLK/1</p> <p>Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.</p>

**57A.2.4 Compare Match Timer Counters 0 and 1 (CMCNT0, CMCNT1)**

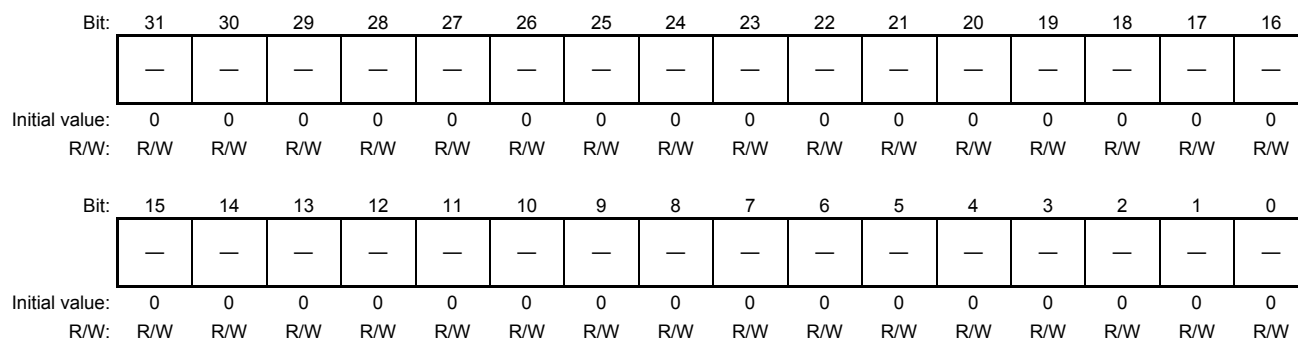

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCNTn (n = 0 to 1) is a 32-bit register that is used as an up-counter.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel.

When the 16-bit counter operation is selected by the CMS bit, bits 31 to 16 of this register become invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bits.

When CMCNTn is read during the counter operation, the read value may be wrong because different clock is used between counter and bus-interface. For exact value, read this register continuously, until same values are read from this register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R/W	<p>Compare match timer counter bit31 to 0</p> <p>Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.</p>

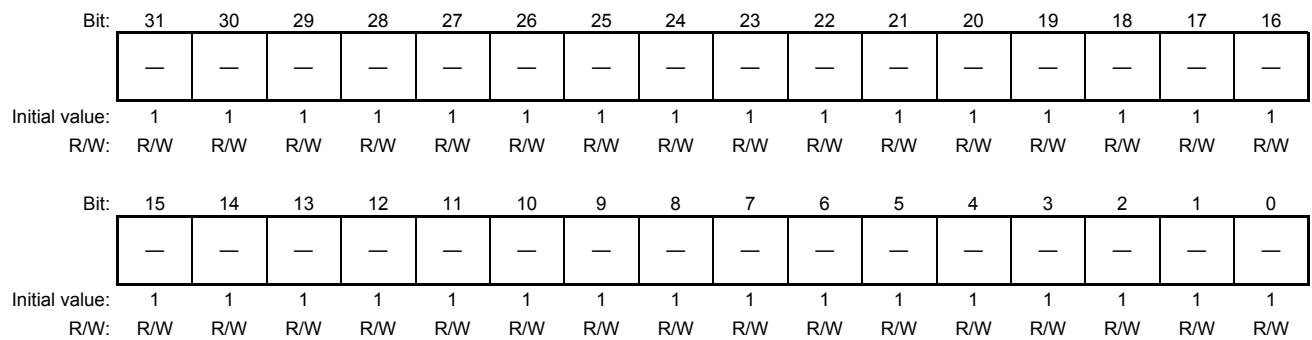

**57A.2.5 Compare Match Timer Constant Registers 0 and 1 (CMCOR0, CMCOR1)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCORn (n = 0/1) is a 32-bit register that sets the compare match period with CMCNTn.

When the 16-bit counter operation is selected by the CMS bit in CMCSRn, bits 15 to 0 of this register become valid. Write H'0000 to upper 16bits in 16-bit counter operation.

An overflow is detected when CMCNTn is cleared to 0 and this register is H'FFFFFFFF.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 1	R/W	Compare match timer constant register bit31 to 0 Note: Refer to section 57A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 57A.3 Operation

#### 57A.3.1 Counter Operation

The CMT0 starts the operation of the counter by writing 1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, during the compare match timer n (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

One-shot operation is selected by setting the CMM bit in CMCSRn to 0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'00000000 and the CMF bit in CMCSRn is set to 1. Counting by CMCNTn stops after it has been cleared.

To detect an overflow interrupt, set the value in CMCORn to H'FFFFFFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'00000000 and the CMF and OVF bits in CMCSRn are set to 1.

Figure 57A.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

Free-running operation is selected by setting the CMM bit in CMCSRn to 1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'00000000 and the CMF bit in CMCSRn is set to 1. CMCNTn resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CMCORn to H'FFFFFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'00000000 and the CMF and OVF bits in CMCSRn are set to 1.

Figure 57A.3 Counter Operation (Free-Running Operation)

### 57A.3.2 Counter Size

In this module, the size of the counter can be selected from 16, or 32 bits. This is selected by the CMS bit in CMCSRn.

When the 16-bit size is selected, H'0000 should be used as upper 16 bits of write data to CMCORn. To detect an overflow interrupt, CMCORn must be set to H'0000FFFF.

### 57A.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

- RCLK: 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMCSRn. CMCNTn is incremented at the rising edge of the selected clock.

### 57A.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear the internal interrupt request to the CPU, the CMF bit should be set to 0. Set the CMF bit to 0 in the handling routine for the CMT0 interrupt.

### 57A.3.5 CMT0 Register Access

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

CMCSRn: Bits CKS, CMM, CMS, CMR, DBGIVD

CMCORn: Bits 31 to 0

CMSTRn: Bit STR0

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

And for following registers, write access is prohibited, while previously written data is under writing. Do not perform next write access, while CMCSRn.WRFLG is 1.

CMCNT\*: Bits 31 to 0

### 57A.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to 0). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 57A.4 shows the set timing of the CMF bit.

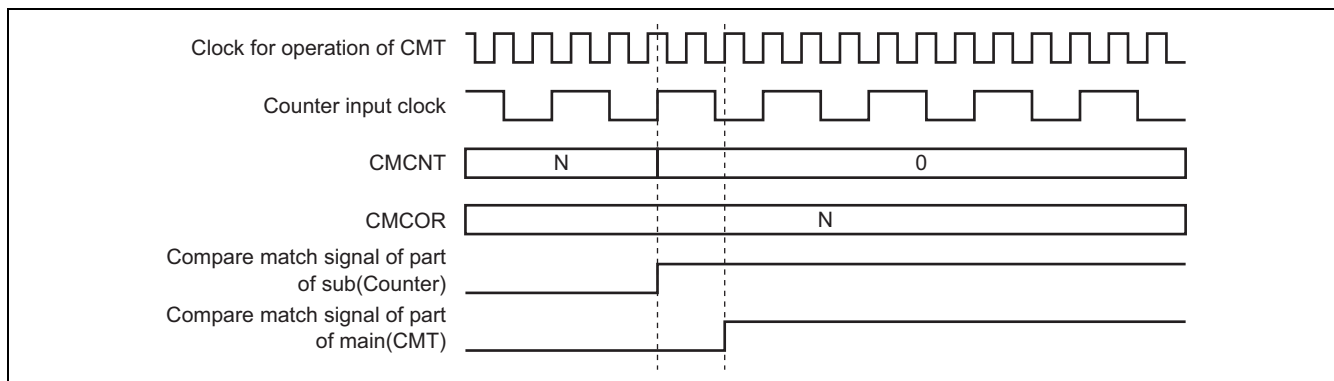

Figure 57A.4 CMF Set Timing

Set the CMF bit as 0. The CMF flag is cleared immediately.

### 57A.3.7 CMT0 Usage

Take the following steps to use the CMT0.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.  
(Confirm that RCLK was input more than 2 cycles.)
2. Write H'00000000 on CMCNTn.
3. Set counter size, compare match mode, type of counter clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.  
If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1.  
(Refer to section 57A.3.5, CMT0 Register Access)

### 57A.3.8 Module Stop/ CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Please confirm that, following conditions are satisfied, before stopping counter's clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in RCLK, since the last Register access

## 57B. Compare Match Timer 1 (CMT1)

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 57B.1 Features

- Eight channels
- 16 bits/32 bits/48 bits can be selected as counter size (bit-width).
- 48-bit constant registers and 48-bit up counters that can be written or read at any time.
- For channel 0 to 4, following twelve clocks can be selected as counter clock.
  - CP $\phi$  (CPEX $\phi$ )\*: 1/8, 1/32, 1/128, and 1/1
    - Note: Clock name CP $\phi$  is for RZ/G1H, M and N, CPEX $\phi$  is for RZ/G1E; Both CP $\phi$  and CPEX $\phi$  are divided-by-2 of the EXTAL clock.
  - RCLK: 1/1, 1/8, 1/32, and 1/128
  - Pseudo 32 kHz: 1/1, 1/8, 1/32, and 1/128
- For channel 5 to 7, following four clocks can be selected as counter clock.
  - RCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operations are selectable.
- Compare match can be used as interrupt source.
- Support Module standby mode.
- RCLK-synchronous counter start/stop mode for channel 0
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

Figure 57B.1 shows a block diagram of the CMT1.

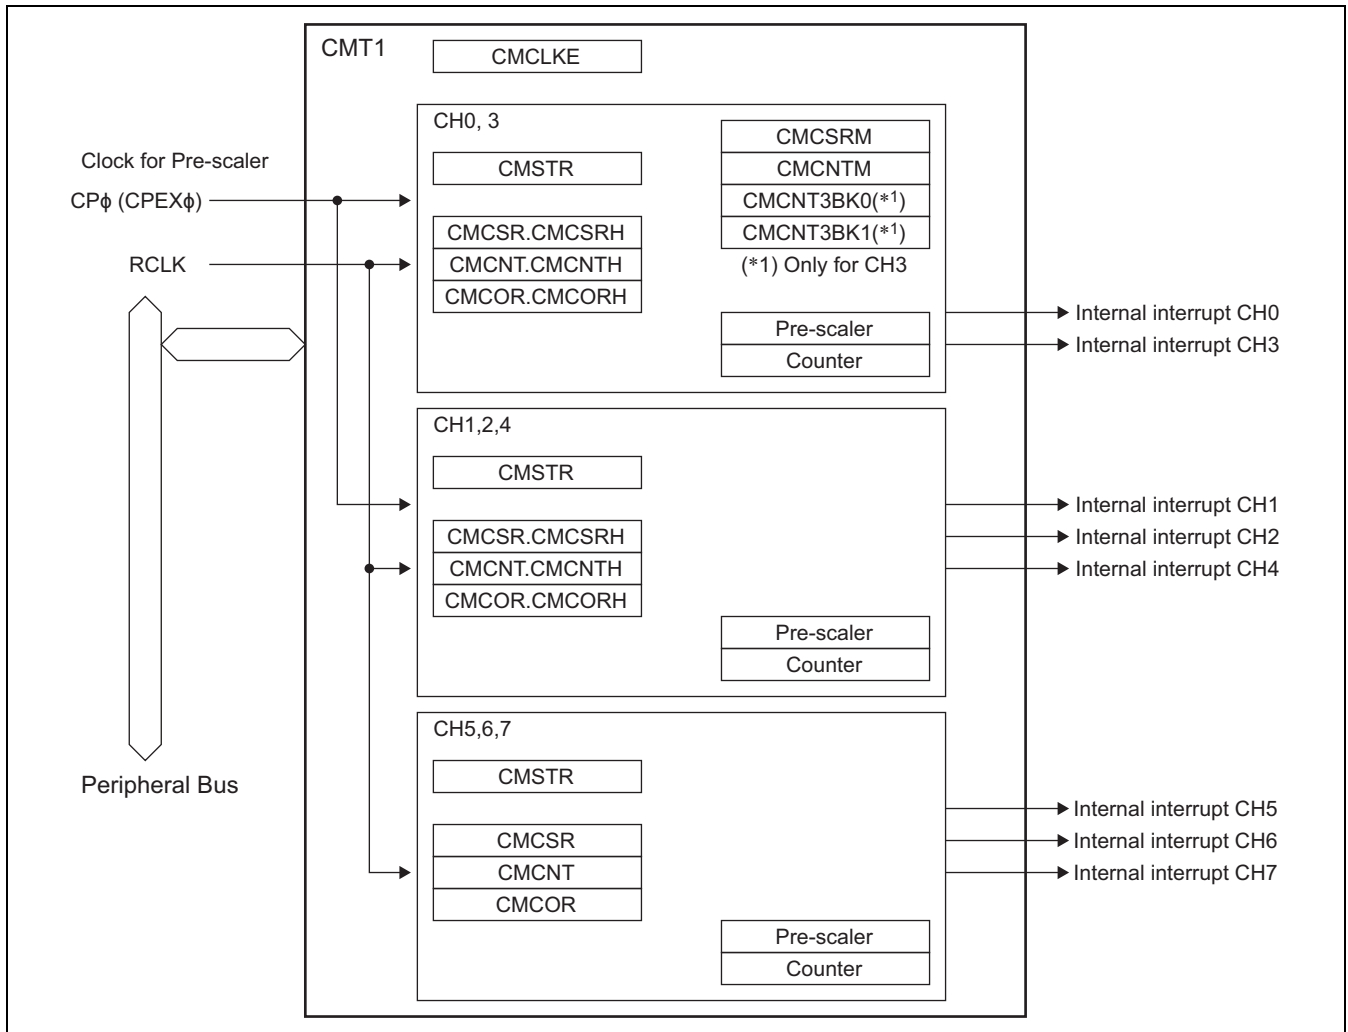

Figure 57B.1 Block Diagram of CMT1

## 57B.2 Register Descriptions

Table 57B.1 shows the CMT1 register configuration. Table 57B.2 shows the register states in each operating mode.

### 57B.2.1 CLK Enable Register (CMCLKE)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCLKE is a 32bits register, which specify clock supply to each channel. When there are unused channels, set '0' as this register, to stop supplying clock to the channel. It is prohibited to stop clock supply, while counter is working.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 57B.2.3 Compare Match Timer Control/Status Registers 0 to 7 (CMCSRn)

CMCSRn (n = 0 to 7) is a 32-bit register that indicates the occurrence of compare match, enable interrupt and set the counter input clock.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

#### (1) CMCSR0

Note: CMSH, CKSH For write or read, refer to section 57B.3.5, Register Access.

**57B.2.5 Compare Match Timer Counters 0 to 7 (CMCNTn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCNTn (n = 0 to 7) is a 32-bit register which is used as an up-counter of each channel.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel. When the 16-bit counter operation is selected by the CMCSRH.CMSH and CMCSR.CMS bits, bits 31 to 16 of this register is invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bit.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R/W	Compare match timer counter bit31 to 0

Note: For access to this register, refer to section 57B.3.5, Register Access.

**57B.2.6 Compare Match Timer Counters H 0 to 4 (CMCNTHn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCNTHn (n = 0 to 4) is a 32-bit register which is used as an up-counter for channel0 to 4.

To specify counter operation, set compare match timer control/status register n (CMCSRn/CMCSRHn), before starting operation of corresponding channel. When the 48-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter. The value written to this register is reflected to counter behavior, when lower data is written to CMCNTn. Write the upper data to this register first. The value is not reflected to counter’s behavior, if data is not written to CMCNTn later.

When reading the value of 48-bit counter, upper 16-bit can be read out by reading bits 15 to 0 of this register. At the same time of the reading, the value of 48-bit counter is stored to the read-buffer. After reading CMCNTHn, lower 32-bit can be read out by reading CMCNTn.

Note: If CMCNTn is read out before reading CMCNTHn, the read out value of 48-bit counter may not be correct.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15 to 0	—	All 0	R/W	Compare match timer counter H bit15 to 0 Note: For access to this register, refer to section 57B.3.5, Register Access.

**57B.2.7 Compare Match Timer Constant Registers 0 to 7 (CMCORN)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCORN is a 32-bit register which specify the compare match period of CMCNTn for each channel.

When the 16-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 31 to 16 of this register is invalid. When data is written to this register in 16-bit operation mode, write H'0000 as upper 16bit.

An overflow is detected when CMCNTn is cleared to 0 and this register is H'FFFFFFFF (when the 16-bit counter operation it is H'0000 FFFF).

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 1	R/W	Compare match timer constant register bit31 to 0 Note: For access to this register, refer to section 57B.3.5, Register Access.

**57B.2.8 Compare Match Timer Constant Registers H0 to 4 (CMCORHn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCORHn is a 32-bit register which specify the compare match period with CMCNTHn for channel0 to 4.

When the 48-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter.

An overflow is detected when CMCNTHn is cleared to 0 and this register is H'FFFF.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15 to 0	—	All 1	R/W	Compare match timer constant register H bit15 to 0 Note: For access to this register, refer to section 57B.3.5, Register Access.

**57B.2.9 Compare Match Timer Counter 3 Backup 0 (CMCNT3BK0)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCNT3BK0 is a 32-bit register which stores a copy of the CMCNT3 value immediately after the counter in channel 0 stops in RCLK-synchronous channel 0 counter start/stop mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R	Compare match timer counter 3 backup 0 bit31 to 0

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15	WRFLG	0	R	Write state flag. When this Bit is 1, CMCNTMn cannot be cleared. After CMCNTMn is cleared, this bit become 1 for a while (*), for indicating synchronization period. Needs to confirm this flag is 0 or wait the period enough when continuously clearing. Note: * In the maximum, "Counter input clock 6 cycle " <ul style="list-style-type: none"> <li>Counter input clock CMCSRn.CKS2 = 0: CPφ (CPEXφ) CMCSRn.CKS2 = 1: RCLK</li> </ul>
14 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	CMPCLR	0	R/W	Counter Clear [When writing] 0: No operation 1: Clears counter When CMPCLR and CMPSTART are written 1 at the same time, the counter starts after clearing the counter. [When reading] This bit is always read as 0.
0	CMPSTART	0	R/W	Count Start This bit specifies start/halt of the compare match timer match counter (CMCNTMn) of each channel. 0: CMCNTMn Halts 1: CMCNTMn Starts counting

**57B.2.12 Compare Match Timer Match Counters 0 and 3 (CMCNTMn)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

CMCNTMn is a 32-bit register which is used as an up-counter. This register is only present in channels 0 and 3.

A counter operation is set by the compare match timer match control/status register (CMCSRm). After the counter CMCNTn starts, this counter increases whenever at a compare match.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R	Compare match timer match counter bit31 to 0

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

### 57B.3 Operation

#### 57B.3.1 Counter Operation

The CMT1 starts the operation of the counter by writing H'1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, while the compare match timer (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

One-shot operation is selected by setting the CMM bit in CMCSRn to H'0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'0000 0000 and the CMF bit in CMCSRn is set to H'1. Counting by CMCNTn stops after it has been cleared.

To detect an overflow interrupt, set the value in CMCORn to H'FFFF FFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000 0000 and the CMF and OVF bits in CMCSRn are set to H'1.

Figure 57B.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

Free-running operation is selected by setting the CMM bit in CMCSRn to H'1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000 0000 and the CMF bit in CMCSRn is set to H'1. CMCNTn resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CMCORn to H'FFFF FFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'0000 0000 and the CMF and OVF bits in CMCSRn are set to H'1.

**Figure 57B.3 Counter Operation (Free-Running Operation)**

### 57B.3.2 Counter Size

In this module, the size of the counter can be selected from 16, 32, or 48 bits. This is selected by the CMS bit in CMCSRn and CMSH bit in CMCSRHn.

When the 16-bit/32-bit size is selected, upper 32 bits/16 bits of CMCORn is ignored. To detect an overflow interrupt, the value 1 must be set to valid bits of CMCORn.

(for example, H'00000000FFFF, H'0000FFFFFFFF)

### 57B.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

Channels 0 to 4:	CP $\phi$ (CPEX $\phi$ ) clock:	1/1, 1/8, 1/32, and 1/128
	RCLK:	1/1, 1/8, 1/32, and 1/128
	Pseudo 32-kHz:	1/1, 1/8, 1/32 and 1/128
Channel 5 to 7:	RCLK:	1/1, 1/8, 1/32, and 1/128

CP $\phi$  (CPEX $\phi$ ) for RZ/G1H/M/N is a clock, which is generated based on EXTAL, and divided by 2; for RZ/G1E is a clock from PLL1 via common divider. For details of these clocks, refer to section 7, Clock Pulse Generator (CPG).

Pseudo 32-kHz is a clock, which is generated inside this module. Refer to section 57B.3.8, Pseudo 32-kHz Counter.

The clock for the counter is selected by the CKS bits in CMCSRn and CKSH bit in CMCSRHn. CMCNTn is incremented at the rising edge of the selected clock.

### 57B.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear the internal interrupt request to the CPU, the CMF bit should be set to H'0. Set the CMF bit to 0 in the handling routine for the CMT1 interrupt.

### 57B.3.5 Register Access

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

- CMCSRn: Bits CH0SSIE(ch0), CMS, CMM, CMR[1:0], DBGIVD, CKS[2:0]
- CMCORn, CMCORHn
- CMSTRn: Bit STR0RS, STR0
- CMCSRMn: Bit CMPCLR, CMPSTART

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK or CP $\phi$  (CPEX $\phi$ )), for reflecting written data to counter behavior. After writing data to this register, next write access is prohibited, until CMCSRn.WRFLG become 0.

- CMCNTn, CMCNTHn

### 57B.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to H'0000). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 57B.4 shows the set timing of the CMF bit.

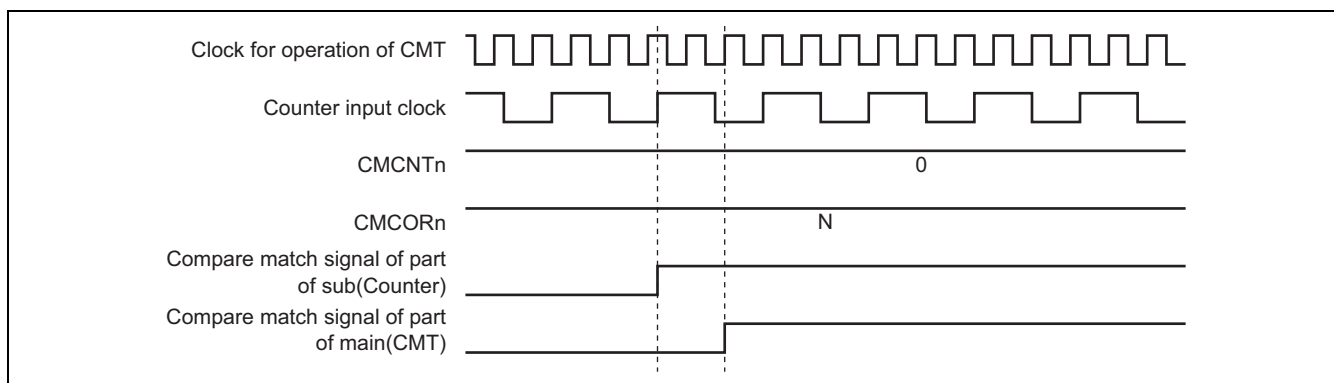

Figure 57B.4 CMF Set Timing

Set the CMF bit to 0. The CMF flag is cleared immediately.

### 57B.3.7 RCLK-Synchronous Counter Start/Stop Mode in Channel 0

The CMT1 provides the RCLK-synchronous counter start/stop mode in channel 0, in which channels 0 and 3 can be used together for time measurement.

Figure 57B.5 shows a flow chart for preparation.

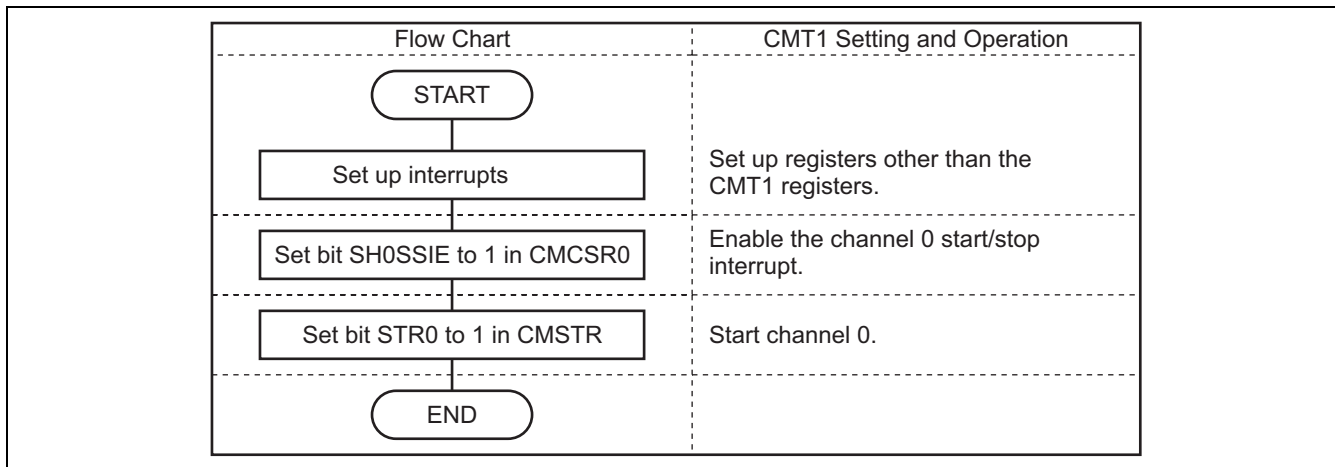

Figure 57B.6 shows a flow chart for starting measurement.

Figure 57B.7 shows a flow chart for stopping measurement.

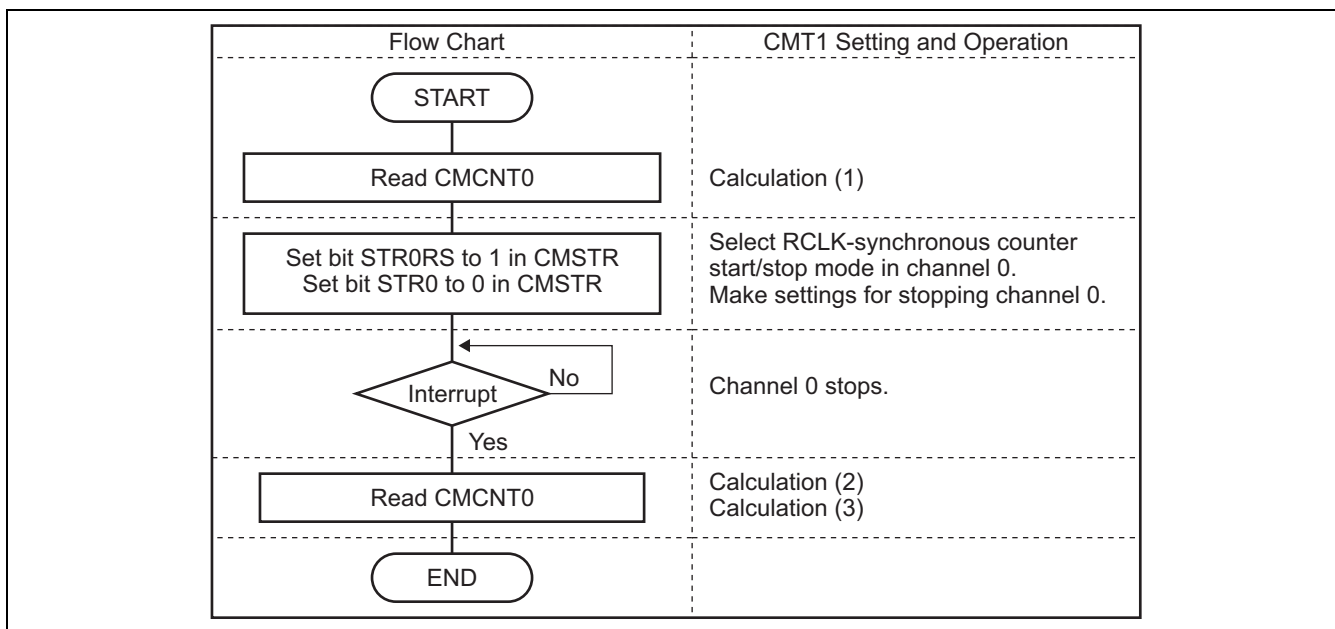

Figure 57B.8 shows a timing chart when measurement starts.

Figure 57B.9 shows a timing chart when measurement stops.

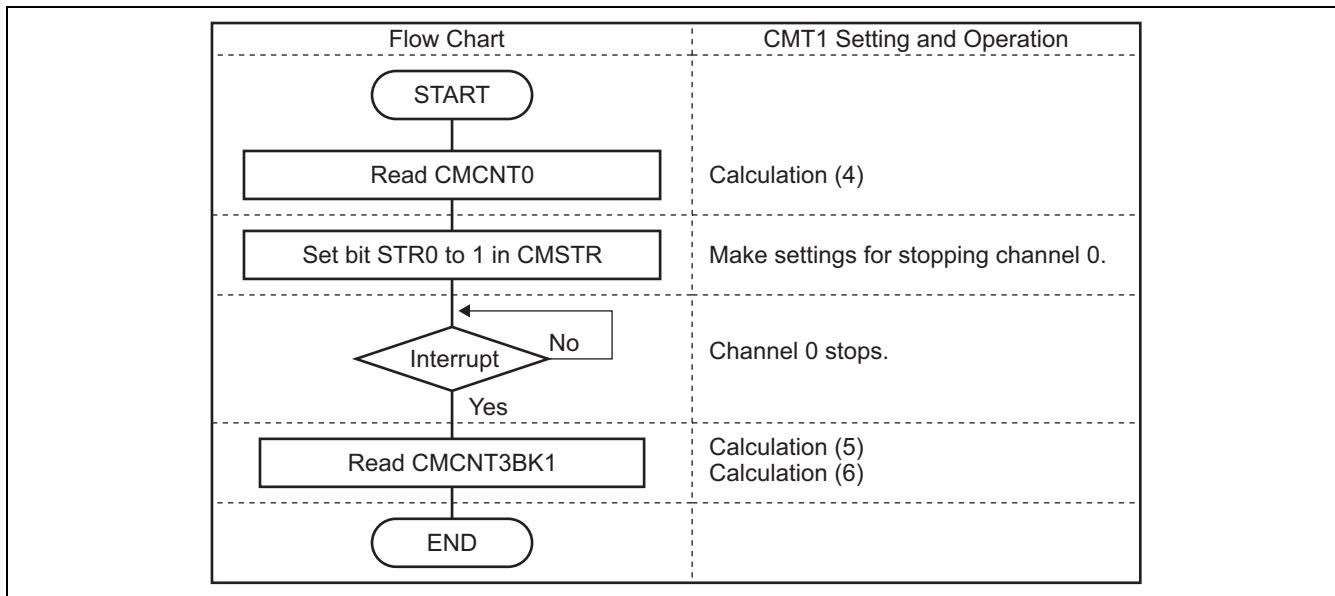

Figure 57B.10 shows how to calculate the time measured by the counters.

**Figure 57B.5 Flow Chart for Preparation**

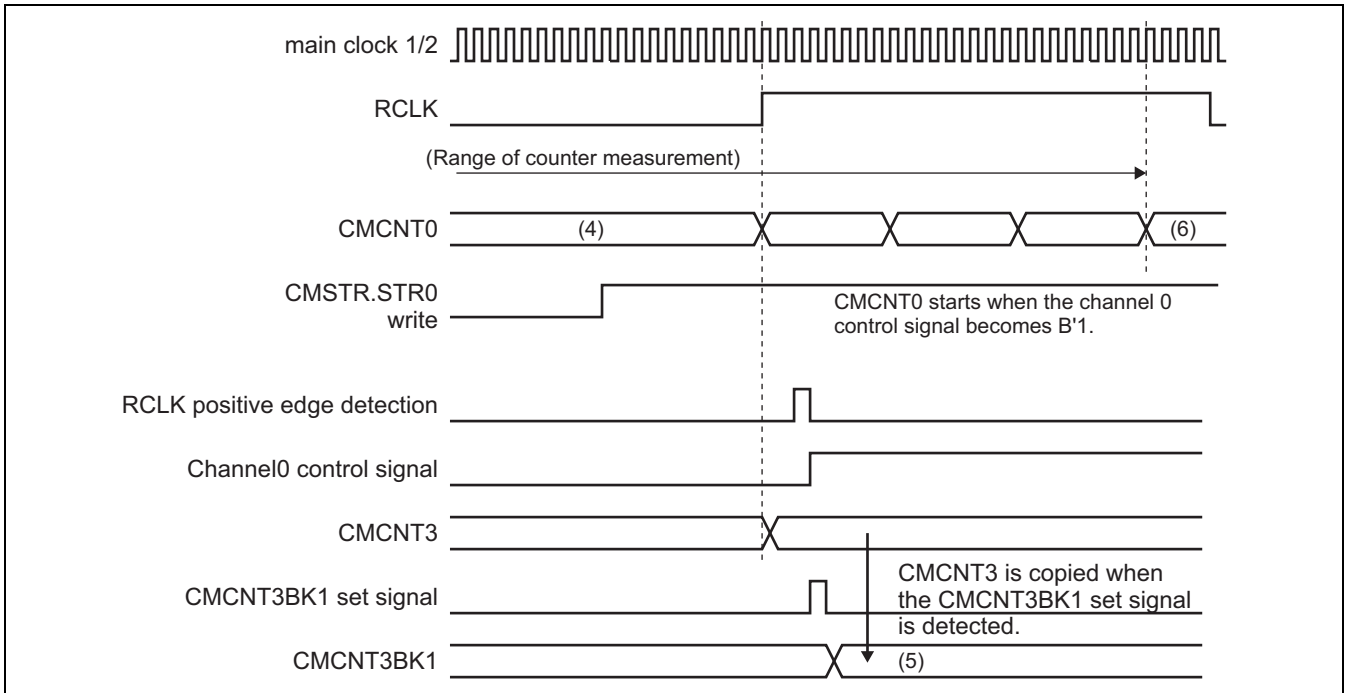

**Figure 57B.6 Flow Chart for Starting Measurement**

**Figure 57B.7 Flow Chart for Stopping Measurement**

**Figure 57B.8 Timing Chart When Measurement Starts**

**Figure 57B.9 Timing Chart When Measurement Stops**

$$(((2) - (1)) + ((6) - (4) - 1)) \times \text{Tapc} + ((5) - (3)) \times \text{Tr}$$

Tapc : Cycle of main clock 1/2  
 Tr : Cycle of RCLK

**Figure 57B.10 Calculation of Time Measured by Counters**

### 57B.3.8 Pseudo 32-kHz Counter

Pseudo 32-kHz clock is created inside this module, based on RCLK by Pseudo 32-kHz Counter. By removing 3 edge of RCLK every 128 cycle, Pseudo 32-kHz clock is generated. By this edge removing, frequency of this clock becomes 128/131 of RCLK.

### 57B.3.9 CMT1 Usage

Take the following steps to use the CMT1.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.  
(Confirm that Counter input clock was input more than 2 cycles.)
2. Write H'00000000 on CMCNTn.
3. Set counter size, compare match mode, kind of count clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.  
If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1 (refer to section 57B.3.5, Register Access).

### 57B.3.10 Module Stop/ CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Please confirm that, following conditions are satisfied, before stopping counter's clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in Counter input clock since the last Register access

## 58. Timer Unit (TMU)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

This LSI includes a 32-bit timer unit (TMU) with 12 channels (channels 0 to 11).

Channels 0 to 2, 3 to 5, 6 to 8, and 9 to 11 are grouped into timers 0, 1, 2 and 3, respectively.

For channels 0 to 2, CP $\phi$  is provided as a base clock. For channels 3 to 11, P $\phi$  is provided.

### 58.1 Features

TMU has the following features:

- Auto-reload type 32-bit down counter is provided for each channel
- Input capture function provided: Channels 5 and 8
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel
- Selection of five counter input clocks: Channels 0 to 2  
Five peripheral clocks (CP $\phi$ /4, CP $\phi$ /16, CP $\phi$ /64, CP $\phi$ /256, and CP $\phi$ /1024)
- Selection of six counter input clocks: Channels 3 to 8  
External clock (TCLK1/2), and five peripheral clocks (P $\phi$ /4, P $\phi$ /16, P $\phi$ /64, P $\phi$ /256, and P $\phi$ /1024)
- Selection of five counter input clocks: Channels 9 to 11  
Five peripheral clocks (P $\phi$ /4, P $\phi$ /16, P $\phi$ /64, P $\phi$ /256, and P $\phi$ /1024)
- Two interrupt sources  
One underflow source (each channel) and one input capture source (channels 5 and 8)

Figure 58.1 show block diagrams of TMU.

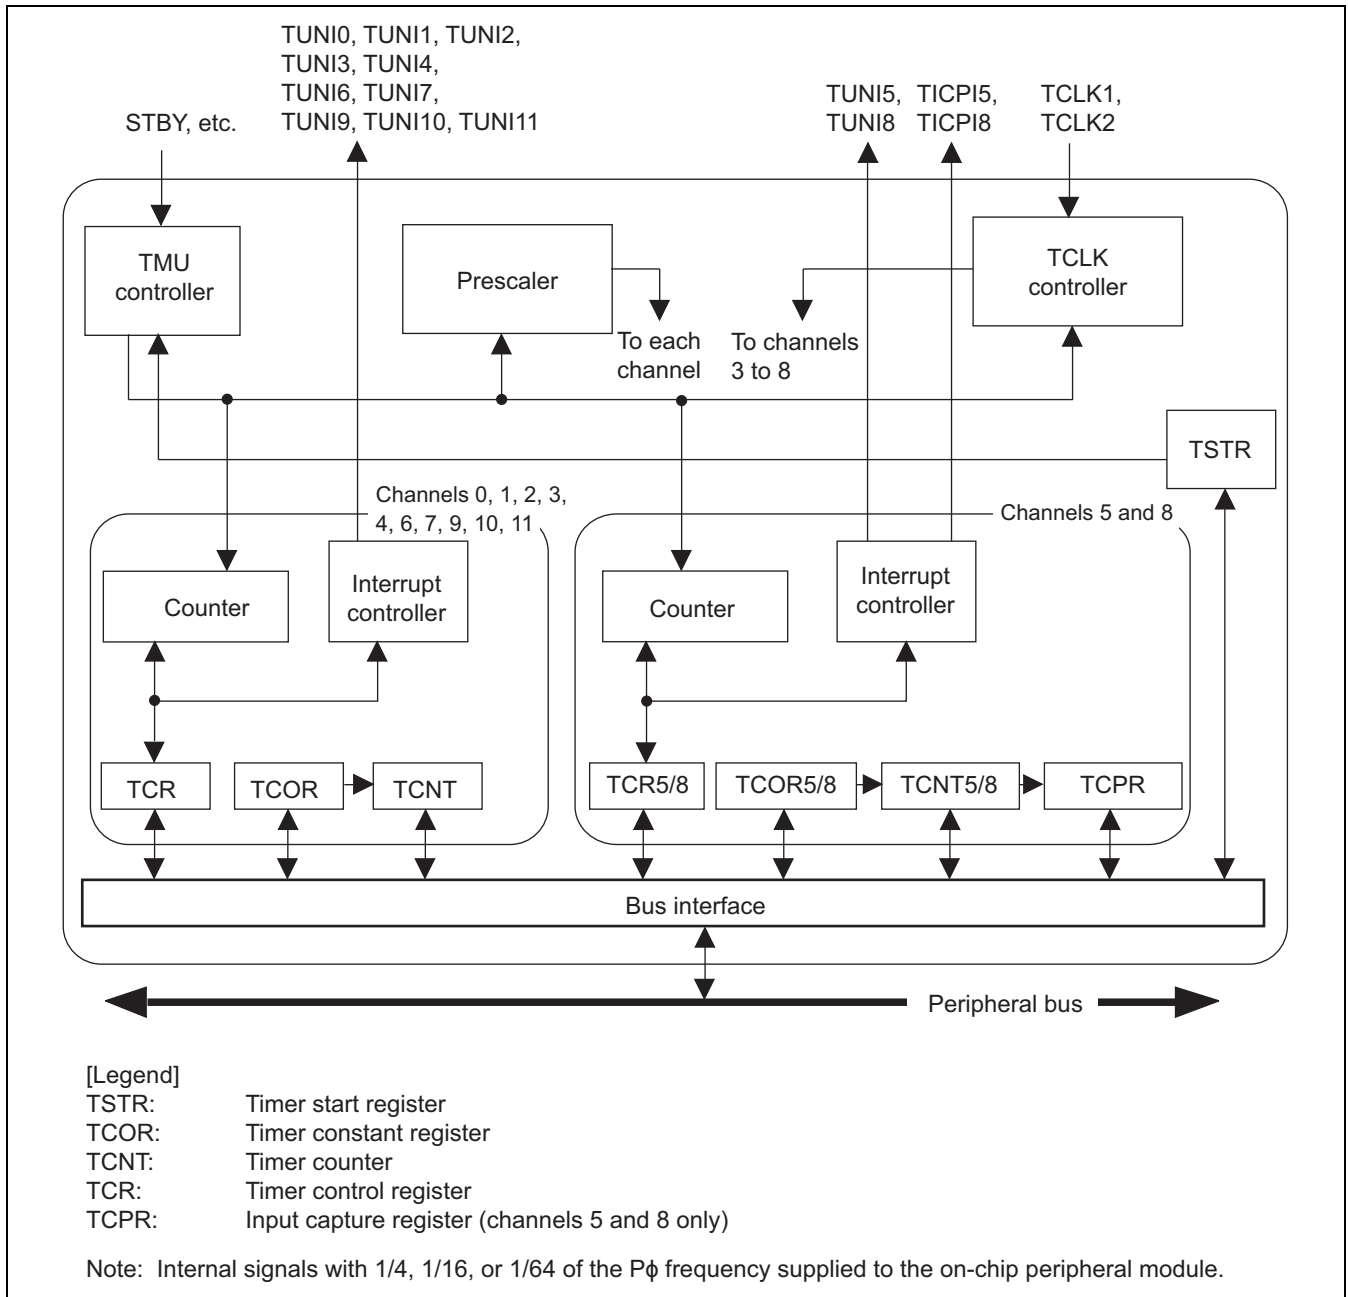

Figure 58.1 Block Diagram of TMU

## 58.2 Input/Output Pins

Table 58.1 shows the pin configuration of the TMU.

**Table 58.1 Pin Configuration**

Name	Abbreviation	I/O	Function	RZ/G Series Products			
				RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Clock input 1	TCLK1	Input	External clock input pin for channels 3 to 5/ input capture control input pin for channel 5	√	√	√	√
Clock input 2	TCLK2	Input	External clock input pin for channels 6 to 8/ input capture control input pin for channel 8	√	√	√	√

### 58.3 Register Descriptions

The TMU has the following registers. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

**Table 58.2 Register Configuration (1)**

### 58.3.2 Timer Constant Registers (TCORn) (n = 0 to 11)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TCOR are 32-bit readable/writable registers. After underflow has been generated according to the result of the TCNT countdown, the value of TCOR is set to TCNT and TCNT continues countdown from the value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 58.3.3 Timer Counters (TCNTn) (n = 0 to 11)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TCNT are 32-bit readable/writable registers that count down upon the input clock selected using the bits TPSC2 to TPSC0 in TCR.

When a TCNT countdown results in an underflow, the UNF in TCR of corresponding channel is set. At the same time, the value of TCOR is set to TCNT and TCNT continues countdown from that value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 58.3.4 Timer Control Registers (TCRn) (n = 0 to 11)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TCR are 16-bit readable/writable registers that select a count clock and edge when an external clock is selected, and control an interrupt generation when the flag that indicates the generation of a TCNT is set to 1. TCR of channels 5 and 8 control the input capture function and generation of an interrupt during the input capture.

## [Legend]

X: Don't care

Notes: 1. Reserved in channels 0, 1, 2, 3, 4, 6, 7, 9, 10, and 11 (initial value is 0 and read-only).

2. Writing 1 does not change the value.

### 58.3.5 Input Capture Registers n (TCPRn)

Note: n = 5 and 8

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

TCPR5 and TCPR8 are read-only 32-bit registers used for the input capture function provided only in channels 5 and 8. The ICPE and CKEG bits in TCR5 and TCR8 control the input capture function. When an input capture occurs, the value of TCNT5 is copied to TCPR5, and the value of TCNT8 is copied to TCPR8. The values of TCNT5 and TCNT8 are set in TCPR5 and TCPR8, respectively, only when the ICPF bits in TCR5 and TCR8 are 0.

## 58.4 Operation

Each channel has a 32-bit timer counter (TCNT) and 32-bit timer constant register (TCOR). TCNT counts down. The auto-reload function enables synchronized counting and external-event counting. Channels 5 and 8 have an input capture function.

### 58.4.1 Counter Operation

When the bits STR8 to STR0 in TSTR0 to TSTR3 are set to 1, TCNT of corresponding channel starts counting. When TCNT underflows, the UNF flag of corresponding TCR is set. In this case, if the UNIE bit in TCR is set to 1, an interrupt request is sent to the CPU. Also, the value is copied from TCOR to TCNT and the down-count operation is continued (Auto reload function).

#### (1) Procedure for setting count operation

Figure 58.2 shows an example of the procedure for setting the count operation.

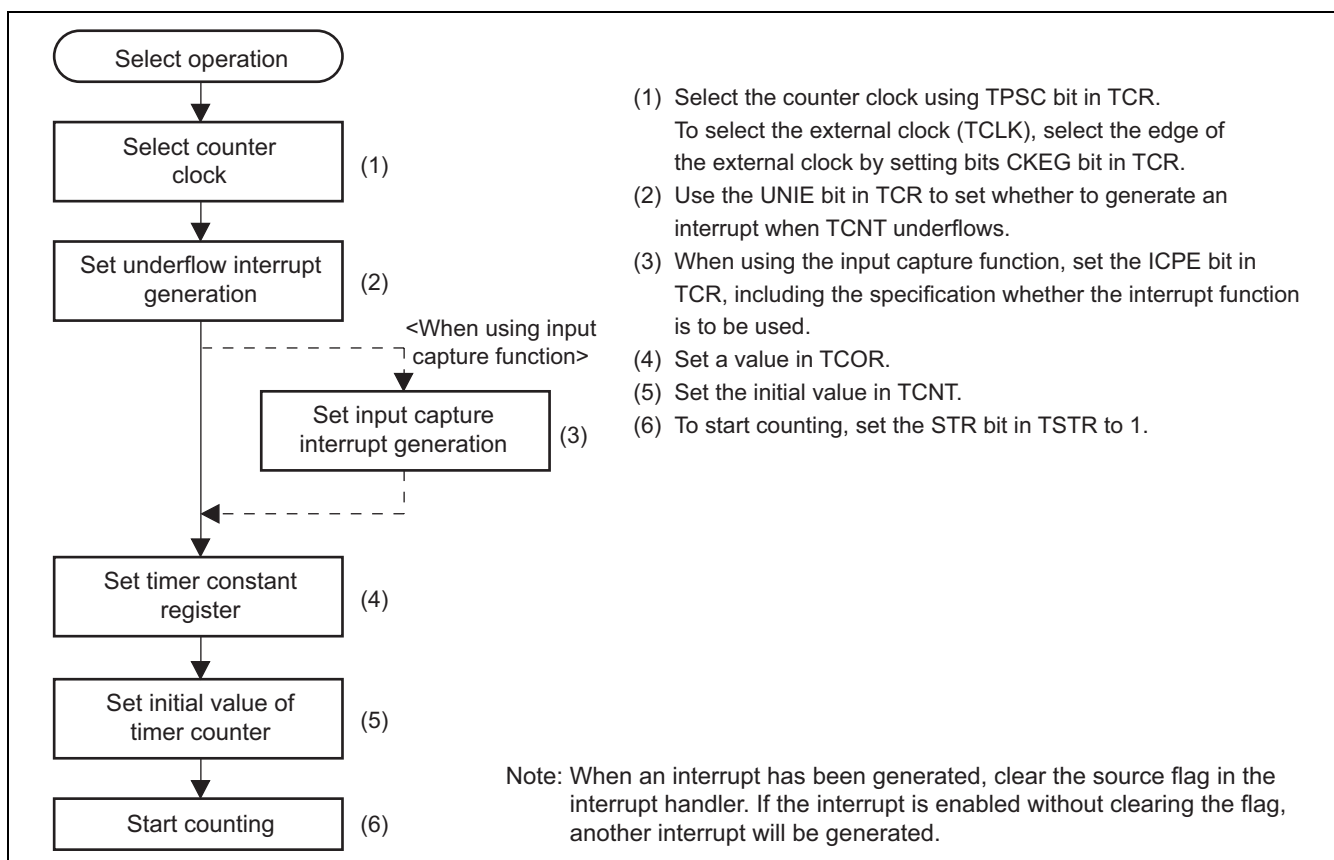

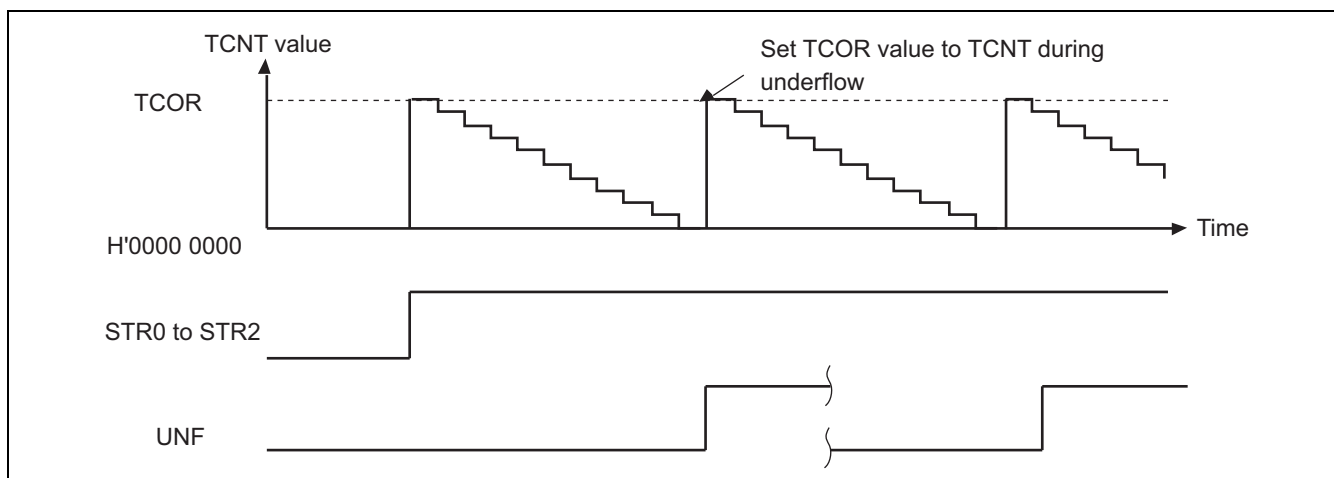

Figure 58.2 Procedure for Setting Count Operation

**(2) Auto-reload count operation**

Figure 58.3 shows the TCNT auto-reload operation.

**Figure 58.3 TCNT Auto-Reload Operation**

**(3) TCNT count timing**

- Internal clock operation

Five clocks ( $P\phi/4$ ,  $P\phi/16$ ,  $P\phi/64$ ,  $P\phi/256$ ,  $P\phi/1024$ ) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR. Figure 58.4 shows the timing.

**Figure 58.4 Count Timing when Internal Clock is Operating**

- External clock operation

Set the bits TPSC3 to TPSC0 in TCR to select the external clock pin (TCLK) as the timer clock. Use the bits CKEG1 and CKEG0 in TCR to select the detection edge. Rise, fall, or both can be selected.

Figure 58.5 shows the timing for both-edge detection.

**Figure 58.5 Count Timing when External Clock is Operating**

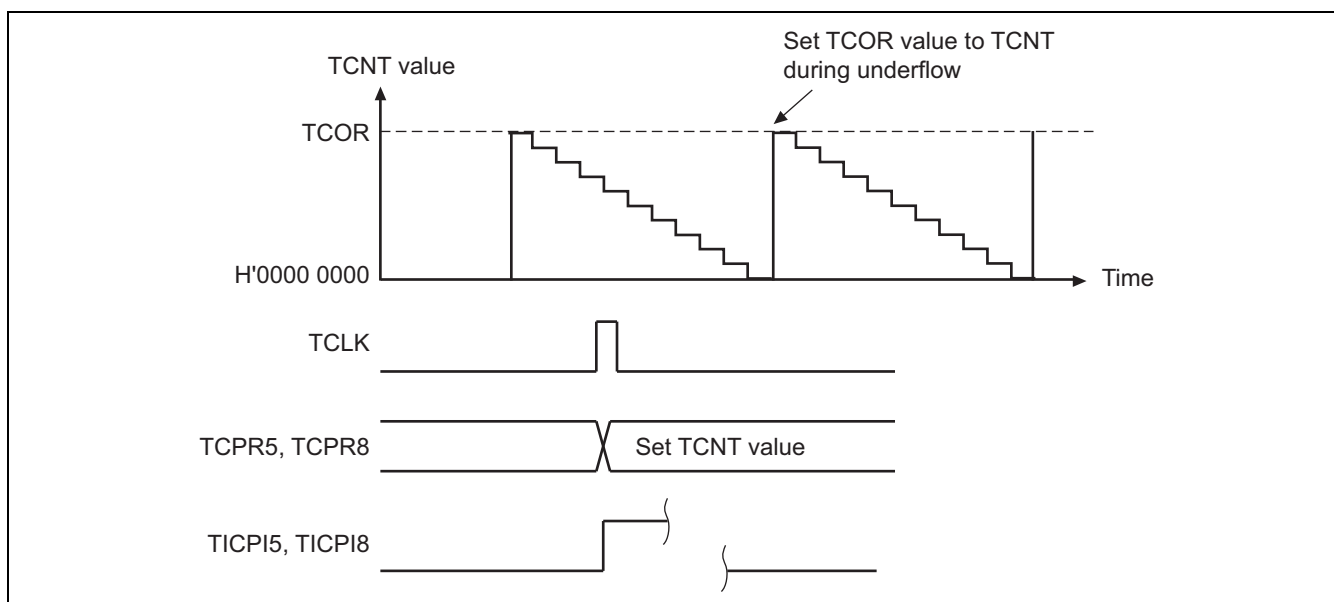

### 58.4.2 Input Capture Function

Channels 5 and 8 have the input capture function. When using the input capture function, follow the procedure shown below.

1. Set the timer operating clock as an internal clock with bits TPSC3 to TPSC0 in TCR.
2. Set use of the input capture function and whether to generate an interrupt on using it with bits ICPE1 and ICPE0 in TCR.
3. Specify either rising edge or falling edge of the TCLK pin to be used to set the value of TCNT to TCPR5 and TCPR8 with bits CKEG1 and CKEG0 in TCR.

Only when an input capture is occurred and the ICPF bits in TCR5 and TCR8 are 0, the values of TCNT5 and TCNT8 are set in TCPR5 and TCPR8, respectively.

Figure 58.6 shows the operating timing when the input capture function is used (the rising edge of TCLK is used).

**Figure 58.6 Operating Timing when Using Input Capture Function**

## 58.5 Interrupt

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

The TMU interrupt sources are underflow interrupt or input capture interrupt when the input capture function is used. The underflow interrupt is generated at each channel. The input capture interrupt is generated at channels 5 and 8 only.

An underflow interrupt request is generated (for each channel) when both the UNF bit and the interrupt enable bit for that channel are set to 1.

When the input capture function is used and the input capture request is generated, an interrupt request is generated if the ICPF bit in TCR5 or TCR8 is 1 and the input capture control bits ICPE1 and ICPE0 in TCR5 and TCR8 are 11.

Table 58.4 shows the TMU interrupt sources.

**Table 58.4 TMU Interrupt Sources**

Channel	Interrupt Sources	Description	RZ/G Series Products			
			RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
0	TUNI0	Underflow interrupt 0	√	√	√	√

## 58.6 Usage Notes

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 58.6.1 Writing to Registers

When writing to the TMU registers, clear the start bits (STR11 to STR0) of the corresponding TSTR channel to stop the timer counting.

Writing to TSTR and clearing bits UNF and ICPF in TCR can be executed during counting. To clear flags UNF and ICPF during counting, do not change the values of bits other than those to be cleared.

### 58.6.2 Reading TCNT Register

Reading from TCNT is performed synchronously with the timer count operation. When timer counting and register read processing are performed simultaneously, the value before TCNT counting down is read.

### 58.6.3 External Clock Frequency

The frequency of external clock (TCLK) for each channel should be  $P\phi/4$  or less.

## 59. PWM Timer

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 59.1 Overview

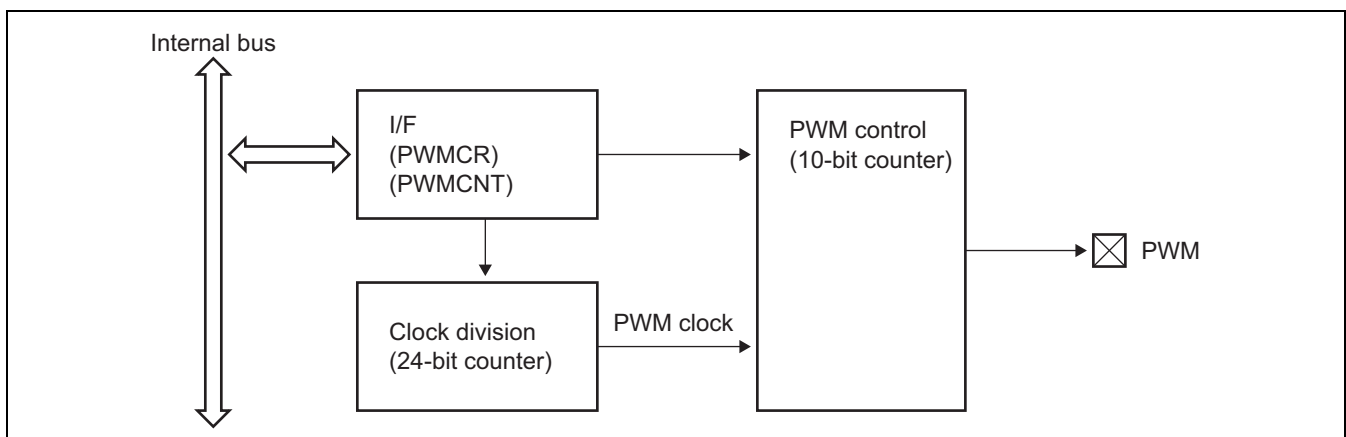

This LSI incorporates a seven-channel pulse width modulation (PWM) timer.

#### 59.1.1 Features

- PWM output cycle settable (10 bits)
- PWM output cycle settable within the range from 2 cycles to  $2^{24} \times 1024$  cycles of internal bus clock  $P\phi$  (i.e. from 30.77 ns to 264 seconds when  $P\phi = 65$  MHz)
- High-level width of the PWM output signal settable (10 bits)
- Continuous pulse output or single pulse output selectable

#### 59.1.2 Block Diagram

Figure 59.1 shows a block diagram of the PWM timer.

**Figure 59.1 Block Diagram of PWM Timer**

### 59.1.3 Input/Output pins

Table 59.1 shows the pin configuration of the PWM timer.

**Table 59.1 Pin Configuration**

Pin Name	I/O	Function	RZ/G Series Products			
			RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E

	PWM count register	PWMCNT	R/W	H' E6E3 6004	32	√	√	√	√

Note: Do not access addresses other than those listed above. If access is attempted, a malfunction may occur.

**Table 59.3 Register States in Each Operating Mode**

<b>Name</b>	<b>Abbreviation</b>	<b>Power-on Reset</b>	<b>Module Standby</b>
PWM control register	PWMCR	H'0000 0000	Retained
PWM count register	PWMCNT	H'0000 0000	Retained

The registers of the PWM timer are mapped into the internal bus address space.

## 59.2 Register Description

Registers in the PWM timer are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0.

—/W: Write-only. The read value is undefined.

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PH0									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
25 to 16	CYC0	H'000	R/W	PWM Cycle Sets the PWM output cycle. The cycle set by these bits is the sum of the high-level and low-level periods. Setting H'000 is prohibited.
15 to 10	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
9 to 0	PH0	H'000	R/W	PWM High-Level Period Sets the period for which the PWM timer outputs a high-level signal. Setting H'000 is prohibited.

Note: For the CYC0 and PH0 bits, set the number of cycles to be counted of the PWM clock signal whose frequency has been set by the CC0 and CCMD bits in the PWM control register.

### 59.3 Description of Operation

RZ/G1H

RZ/G1N

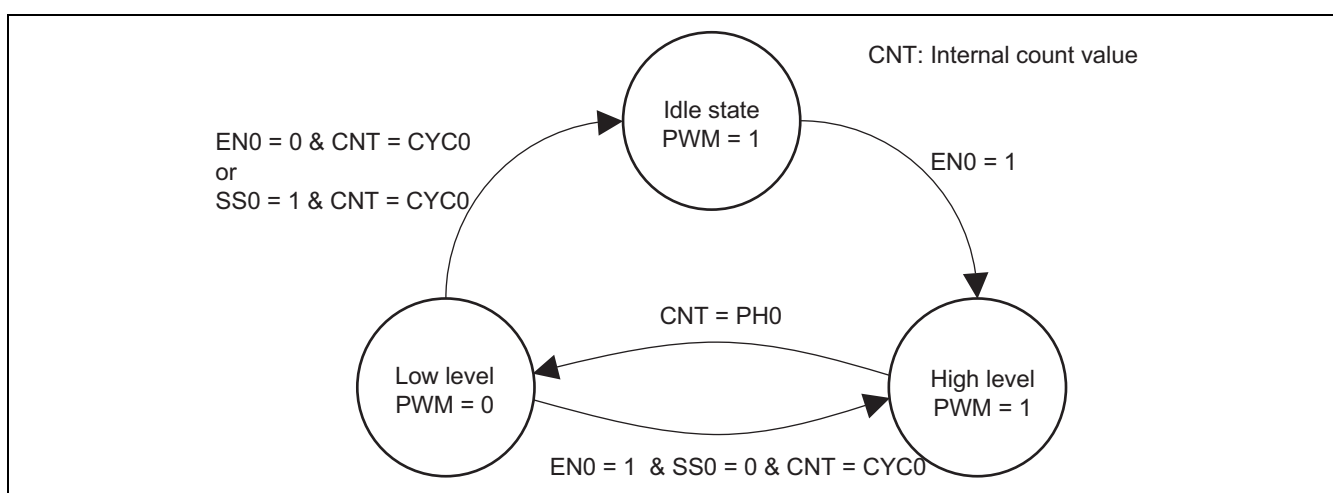

RZ/G1M

RZ/G1E

The duty ratio of a PWM output pulse can be obtained by setting a high-level period and a cycle. The timer channel counts the PWM clock signal pulses using a 10-bit counter to generate the PWM output pulse having the specified period and cycle. When the channel function is enabled ( $EN0 = 1$ ), the timer outputs a high level until the counter value reaches the value set in the PH0 bits of the PWM count register (PWMCNT). The output goes low when the PH0 value is reached, and is held low until the counter value reaches the value set in the CYC0 bits of PWMCNT. When the CYC0 value is reached, the output goes high and the counter is reset.

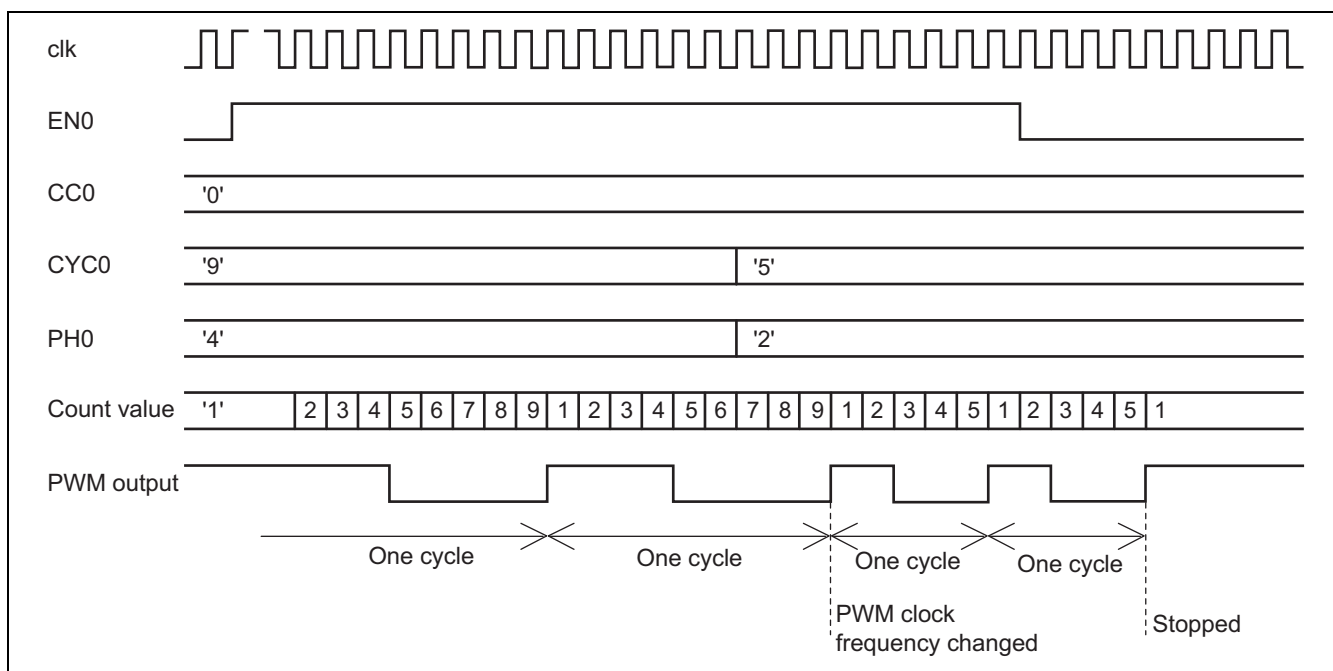

Unless the channel function is enabled, the output is held high, and the counter is held in the reset state.

Figure 59.2 shows the PWM state transition during the operation described above.

**Figure 59.2 PWM Timer State Transition**

Note that after a channel has been enabled by writing 1 to  $EN0$ , the number of clock pulses before output of the first falling edge from a channel is greater than the value set in the PWM control register and PWM count register by up to four cycles of the  $P\phi$  clock. After that, the PWM output rises and falls according to a set timing. Figure 59.3 schematically shows this output timing. This figure shows an internal operation.

**Figure 59.3 PWM Output Timing**

1. The period from enabling the channel to the first falling edge output from the channel is the sum of a set value and up to four cycles of the  $P\phi$  clock.
2. After that, the PWM high and low widths are the same as the set values.
3. When the PWM count register is changed during operation ( $EN0 = 1$ ), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
4. When the CC0 and CCMD bit values in the PWM control register are changed during operation ( $EN0 = 1$ ), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
5. To stop the timer operation, write 0 to the EN0 bit. The timer stops operation after completing the output of the current cycle. Note that, however, if 1 is written to EN0 again before completing the output of the current cycle, the timer does not stop but continues to operate.
6. For the PWM timer output, continuous pulse output mode and single pulse output mode are supported. In continuous pulse output mode, the timer outputs pulses continuously while EN0 is 1. In single pulse output mode, the timer outputs a single pulse. In this mode, EN0 is automatically cleared.
7. To change the values of the clock control bits (CC0) and the CC0 frequency division mode bit (CCMD) in the PWMCR register and of the PWM cycle bits (CYC0) and the PWM high-level period bits (PH0) in the PWMCNT register at the same time during the PWM operation, the following procedure should be followed:
  1. Write 1 to the SYNC bit. (Write the original set values to the other bits in PWMCR.)
  2. Change the PWMCNT value.
  3. Change the CC0 and CCMD values in PWMCR. (Write the original set values to the other bits in PWMCR. The SYNC bit should be held at 1.)

By following the above procedure, the new PWMCNT value is reflected in the timer operation synchronously with PWMCR setting.

When changing only the PWMCNT value while SYNC = 1, writing to PWMCR is required after changing the PWMCNT value. In this case, write the same values as the original set values to the PWMCR bits. On the other hand, when changing only the PWMCR value, writing to PWMCNT is not required.

If PWMCNT and PWMCR values are changed while SYNC = 0, the change to the values might not be completed within a single PWM output cycle but actually take two or more cycles. This may disturb the period or duty cycle of the PWM output.

Note that, when the PWCNT value is changed while SYNC = 1, the new values are read from PWMCNT even before PWMCR is set.

## 59.4 Usage Note

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

When using the PWM timer, note the following points.

When the CYC0 value is equal to or smaller than PH0 value in the PWM count register, the PWM output is held high. In this case, to start pulse output, clear EN0 to 0, set CYC0 to the value greater than the PH0 value, and then set EN0 to 1.

Note that, a maximum period equivalent to  $CYC0 = H'3FF$  at the set PWM clock frequency may be required before pulse output is started.

## 60. Thermal Sensor (THS/TSC)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 60.1 Overview

This LSI provides a thermal sensor module that measures the temperature ( $T_j$ ) inside the LSI.

#### 60.1.1 Features

- (1) Measures temperature  $T_j$  with an accuracy of  $\pm 5^\circ\text{C}$  over the range of temperatures from  $-40^\circ\text{C}$  to  $125^\circ\text{C}$ .
- (2) Provides reference to temperature  $T_j$  as measured from outside the chip with the use of external LSI pins (VTHREF and VTHSENSE).
- (3) Provides reference to the result of measuring the temperature in  $5^\circ\text{C}$  units by access to registers.
- (4) Capable of generating interrupts when the detected temperature  $T_j$  within the LSI rises above or falls below a specified temperature.
- (5) Capable of removing noise due to the detection of rises and falls in the temperature by applying a chattering prevention circuit.

#### 60.1.2 Block Diagram

The block diagram of the thermal sensor module is shown below. The thermal sensor consists of the thermal sensor (THS) which is an analog circuit for measuring temperature and the thermal sensor controller (TSC) which controls the analog circuit.

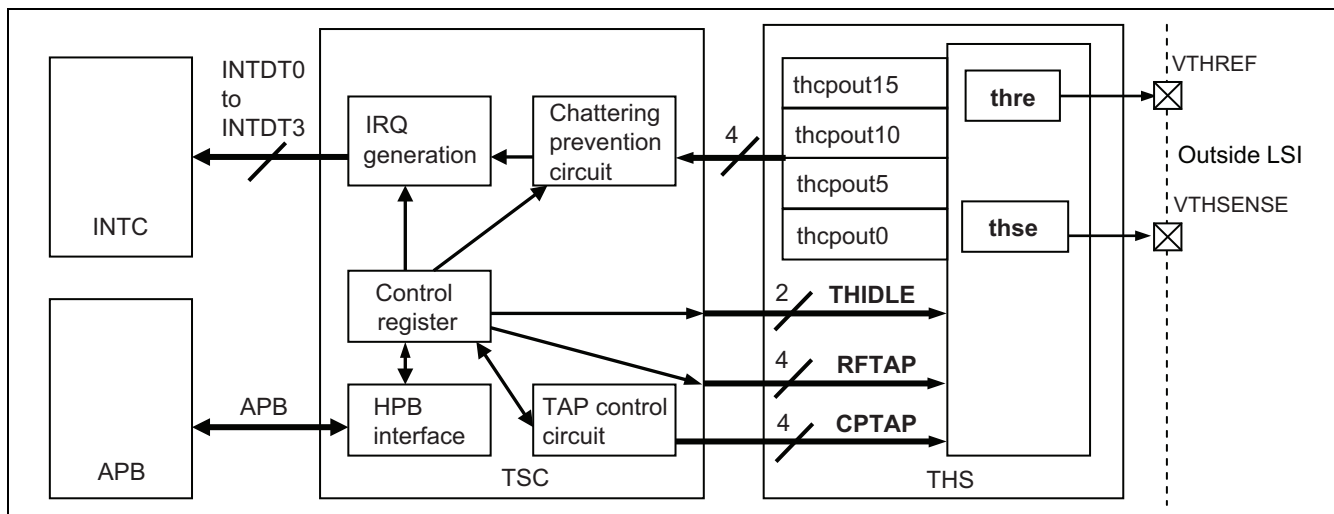

Figure 60.1 THS/TSC Block Diagram

Three signals THIDLE, RFTAP (4 bits) and CPTAP (4 bits) are output from the TSC to the THS. THIDLE stops or starts the THS operation, RFTAP adjusts the analog circuit operation, and CPTAP specifies the temperature range to be measured by the thermal sensor. Setting the CPTAP bits determines the reference temperature for measurement, and the THS determines if the chip temperature is above  $0^\circ\text{C}$ ,  $5^\circ\text{C}$ ,  $10^\circ\text{C}$ , or  $15^\circ\text{C}$  of the reference temperature. For CPTAP, either of the following can be selected: the use of the fixed value specified by the register or the use of the value determined by the TAP control circuit so that the temperatures near the current chip temperature can be measured.

Note: In the RZ/G series products, RFTAP and CPTAP are determined automatically by hardware by setting the CPCTL bit in the THSCR register to 1.

Four signals, thecpout0, thecpout5, thecpout10, and thecpout15, are output from the THS to the TSC. These signals indicate the temperature measured by the thermal sensor; whether or not the chip temperature is above 0°C, 5°C, 10°C, or 15°C of the reference temperature. Through use of the registers in the TSC, the chip temperature calculated from these signals can be read and temperature rise or drop can be notified by generating an interrupt on the rising or falling edge of these signals. In addition, the chattering prevention circuit in the TSC prevents the noise generated in the analog circuit.

The THS is provided with two pins that output voltage to the outside of the LSI. The chip temperature can be measured from outside the chip by measuring the voltages on these pins.

### 60.1.3 External Pins

**Table 60.1 Pin Configuration**

Pin Name	Symbol	I/O	Function
Thermal sensor output voltage	VTHSENSE	Analog I/O	Outputs a voltage correlated with the temperature T <sub>j</sub> in the LSI.
Thermal sensor output reference voltage	VTHREF	Analog I/O	Outputs a reference voltage used to convert the voltage output from the VTHSENSE pin into a digital signal.

For details, refer to section 60.3.4, Temperature Measurement Using External Pins.

### 60.1.4 Register Configuration

Table 60.2 shows the list of registers. The base address is H'E61F 0000.

Any address other than those listed in the table must not be written to. Otherwise, correct operation is not guaranteed. The read value is undefined.

**Table 60.2 Register Configuration**

## 60.2 Register Description

[Legend for register description]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

Data is accessed in longword units.

### 60.2.1 Interrupt Status Register (STR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: When an interrupt signal is input from the THS, 1 is set to this register. To clear the status, 0 should be written to or read from this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PRTFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	Tj03ST	Tj02ST	Tj01ST	Tj00ST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R/W	Reserved
30	PRTFLG	0	R/W	Interrupt Temperature Status Flag 0: Normal operation 1: This bit is set to 1 when the internal temperature in the LSI exceeds the threshold temperature that has been specified in the INTCTLR register. This bit is cleared to 0 by writing 0 after the Tj*ST bit in the STR register has been cleared.
29 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	Tj03ST	0	R/W	Tj03 Detection Status 0: Not detected. 1: The Tj03 threshold temperature specified by CTEMP3[5:0] in the INTCTLR register is detected. This bit is cleared by writing or reading 0.
2	Tj02ST	0	R/W	Tj02 Detection Status 0: Not detected. 1: The Tj02 threshold temperature specified by CTEMP2[5:0] in the INTCTLR register is detected. This bit is cleared by writing or reading 0.
1	Tj01ST	0	R/W	Tj01 Detection Status 0: Not detected. 1: The Tj01 threshold temperature specified by CTEMP1[5:0] in the INTCTLR register is detected. This bit is cleared by writing or reading 0.
0	Tj00ST	0	R/W	Tj00 Detection Status 0: Not detected. 1: The Tj00 threshold temperature specified by CTEMP0[5:0] in the INTCTLR register is detected. This bit is cleared by writing or reading 0.

### 60.2.2 Interrupt Enable Register (ENR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: ENR controls enabling or disabling the interrupt output from the THS.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	Tj03_EN	Tj02_EN	Tj01_EN	Tj00_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	Tj03_EN	0	R/W	Enables comparing the CTEMP3[5:0] bits in the INTCTLR register with the CTEMP[5:0] bits in the THSSR register. 0: Disable 1: Enable
2	Tj02_EN	0	R/W	Enables comparing the CTEMP2[5:0] bits in the INTCTLR register with the CTEMP[5:0] bits in the THSSR register. 0: Disable 1: Enable
1	Tj01_EN	0	R/W	Enables comparing the CTEMP1[5:0] bits in the INTCTLR register with the CTEMP[5:0] bits in the THSSR register. 0: Disable 1: Enable
0	Tj00_EN	0	R/W	Enables comparing the CTEMP0[5:0] bits in the INTCTLR register with the CTEMP[5:0] bits in the THSSR register. 0: Disable 1: Enable

### 60.2.3 Interrupt Mask Register (INT\_MASK)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: INT\_MASK masks output of an interrupt request signal to the INTC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	Tj03INT_MSK	Tj02INT_MSK	Tj01INT_MSK	Tj00INT_MSK
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	—	All 1	R/W	Reserved These bits are always read as 1. The write value should always be 1.
15 to 12	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	—	All 1	R/W	Reserved These bits are always read as 1. The write value should always be 1.
7 to 4	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.
3	Tj03INT_MSK	1	R/W	Selects whether or not the Tj03 interrupt request is masked when Tj03ST in the STR register is 1. 0: Mask is cleared. 1: Masked.
2	Tj02INT_MSK	1	R/W	Selects whether or not the Tj02 interrupt request is masked when Tj02ST in the STR register is 1. 0: Mask is cleared. 1: Masked.
1	Tj01INT_MSK	1	R/W	Selects whether or not the Tj01 interrupt request is masked when Tj01ST in the STR register is 1. 0: Mask is cleared. 1: Masked.
0	Tj00INT_MSK	1	R/W	Selects whether or not the Tj00 interrupt request is masked when Tj00ST in the STR register is 1. 0: Mask is cleared. 1: Masked.

**60.2.4 Positive/Negative Logic Select Register (POSNEG)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: POSNEG selects rising edge detection (positive logic) or falling edge detection (negative logic) of the interrupt input signal. Set this register before setting mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	POSNEG3-0			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	POSNEG3 to POSNEG0	0001	R/W	Selects the edge polarity of the interrupt input signal. 0: Detects a rising edge. (An interrupt is generated when Tj rises above a specified temperature.) 1: Detects a falling edge. (An interrupt is generated when Tj falls below a specified temperature.)

### 60.2.5 Edge/Level Sensing Select Register (EDGLEVEL)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: EDGLEVEL selects edge detection for the interrupt input ports.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	EDGLEVEL3-0			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	EDGLEVEL3 to EDGLEVEL0	1111	R/W	Specifies the method to detect interrupt signal input. Select edge detection. 0: Selects level detection. (Setting prohibited) 1: Selects edge detection. Use the thermal sensor with this field set to the initial value.

**60.2.6 Chattering Prevention ON/OFF Setting Register (FILONOFF)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: FILONOFF turns on or off chattering input prevention.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FILONOFF3-0			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FILONOFF3 to FILONOFF0	1111	R/W	Turns on or off the chattering prevention circuit. 0: Chattering prevention is off. 1: Chattering prevention is on.

When chattering prevention is on, an interrupt input signal is sampled four times in 25 μs cycles\*. An interrupt is generated only when the same input level is detected four times. When the same input level is detected three or less times of sampling, it is judged as chattering and an interrupt is not generated. Accordingly, when the filtering function is used, an input signal needs to be four or more clock cycles long for 100 μs cycle sampling.

Note: \* Since the clock used is generated by dividing cpck by 335, one cycle is 22 μs when cpck is 15 MHz.

Figure 60.2 Sampling Timing Chart

### 60.2.7 THS Control Register (THSCR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: THSCR specifies the THS operating mode.

The THS is in the operating state in the initial state. When not using the thermal sensor, place it in the idle state by setting this register. This register also selects the method to set the comparator offset, and sets an offset value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CPCTL	—	—	THIDLE1-0	RFTAP3-0			CPTAP3-0					
Initial value:	0	0	0	0	0	0	0	0	-	-	-	-	0	0	1	1
R/W:	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CPCTL	0	R/W	Specifies the method to set the offset (CPTAP) of the comparator in the THS. 0: Setting prohibited 1: TAP value is determined automatically by hardware. When 1 is set, an offset value appropriate for measuring the current chip temperature is selected by hardware. For details, refer to section 60.3.3, Temperature Measurement Using Register (When CPCTL = 1). Note: Set this bit to 1 when using the thermal sensor.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	THIDLE1, THIDLE0	00	R/W	Selects either the normal operating state or the idle state of the THS. 00: Normal operating state 01: Setting prohibited 10: Normal operating state (output from VTHSENSE or VTHREF is stopped) 11: Idle state Set this bit to 11 (idle state) when the thermal sensor is not used.
7 to 4	RFTAP3 to RFTAP0	—	R/W	Sets an offset value (RFTAP) of the op amp in the THS. Note: These bits are determined automatically by hardware. The write value should always be same value with read value just before.
3 to 0	CPTAP3 to CPTAP0	H'3	R/W	Sets the offset value (CPTAP) of the comparator in the THS. Note: These bits have no effect.

**60.2.8 THS Status Register (THSSR)**

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	—

Function: THSSR indicates the status of the thermal sensor.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 60.3 Operation

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

#### 60.3.1 Flow of Register Initialization

Shown below is flow of register initialization for the thermal sensor.

If the settings of (1) are changed, an unexpected interrupt may be generated within the module. In that case, cancel the interrupt with steps (2) and (3) before using the thermal sensor.

**Figure 60.3 Flow of Register Initialization**

### 60.3.2 Temperature Measurement Using Register (When CPCTL = 0)

Setting is prohibited.

### 60.3.3 Temperature Measurement Using Register (When CPCTL = 1)

The following describes the method to measure the chip temperature by using a comparator offset value determined by the TAP control circuit. Setting the CPCTL bit (bit 12) in THSCR to 1 allows an offset value to be determined by the TAP control circuit.

The TAP control circuit increases an offset value by 1 when the chip temperature is determined to rise above the upper limit of the measurable temperature range, and decreases it by 1 when determined to fall below the lower limit. Such determination is performed by detecting a low-to-high transition of thcpout15 or a high-to-low transition of thcpout0. Note that, an offset value cannot be less than 0 or 15 or more.

Once an offset value is changed, the value is not changed again for 300  $\mu$ s.

When reading the temperature measurement result from a register, read the value of the CTEMP5 to CTEMP0 bits in THSSR.

Do not use the value of the CTEMP5 to CTEMP0 bits in THSSR immediately after a change to the offset value for the TAP control circuit because the new offset setting will not yet have been reflected in the value. When CPCTL is 1, hardware automatically updates the offset value but since software is not informed of the timing of updates, consecutively read the value of the CTEMP5 to CTEMP0 bits in THSSR at an interval of at least 300  $\mu$ s and only accept the result when the same value is read twice (since the temperature changes more gradually than the 300  $\mu$ s interval, as long as a change to the offset value is not made during the interval between reading of the CTEMP5 to CTEMP0 bits in THSSR, the same value will be read out.)

By setting 0 or 1 in the positive/negative logic select register (POSNEG) and specifying the temperatures that cause interrupts in the INTCTLR register, the INTDT3 to INTDT0 interrupts can be generated when the chip temperature rises above or falls below the temperatures specified in the INTCTLR register.

However, immediately after a change to the offset value for the TAP control circuit, an interrupt may be generated before completion of the temperature measurement at the changed offset value. If an interrupt is generated at such a time, read out the value of the CTEMP5 to CTEMP0 bits in THSSR a second time after 300  $\mu$ s, check whether or not the interrupt was valid, and if it was, proceed with interrupt processing.

### 60.3.4 Temperature Measurement Using External Pins

For temperature measurement with the external pins, connect the external circuit to the VTHSENSE and VTHREF pins and calculate the temperature based on the output voltages on these pins.

#### (1) External Pins Used for Temperature Measurement

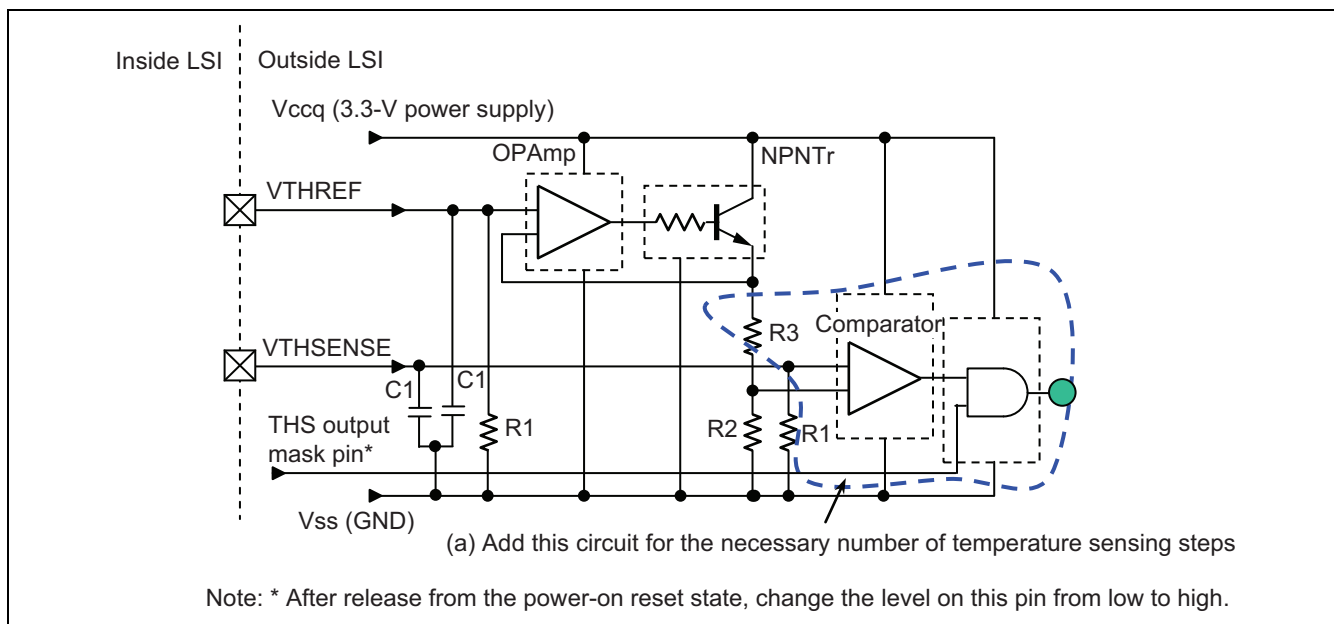

In temperature measurement with the external pins, the pins shown in Table 60.3 are used.

**Table 60.3 External Pins Used for Temperature Measurement**

Pin Name	Output Voltage Range [V]	Maximum Allowed Input/Output Current [ $\mu$ A]	Tj Accuracy
VTHSENSE	360 mV (min.) to 750 mV (max.)	$\pm 8$	The accuracy of Tj is $\pm 5^\circ\text{C}$ max. {(VHTREF - VTHSENSE) specification} (This does not include error such as device accuracy of the recommended external connection circuit).  The temperature range for detection is $-40^\circ\text{C}$ to $125^\circ\text{C}$ .  When Tj is outside the range of $-40^\circ\text{C}$ to $125^\circ\text{C}$ , the operation and accuracy cannot be guaranteed.
VTHREF	1.18 V (min.) to 1.32 V (max.)	$\pm 8$	

#### (2) Recommended External Connection Circuit

Figure 60.4 shows a recommended external connection circuit for the THS used for temperature measurement with the external pins.

**Figure 60.4 Recommended External Connection Circuit for THS**

The recommended external connection circuit outputs a high level at a desired temperature. By using VTHREF, which is affected by the noise equal to the external noise that affects VTHSENSE, the external noise is canceled out, and thus the accuracy of Tj is improved.

In addition, the number of steps for digitizing a measured temperature Tj (the number of temperatures with which an actual temperature is compared) can be increased by adding the circuit part indicated with (a) in the figure.

The followings should be considered for the wiring of VTHSENSE and VTHREF.

1. For jumper wiring use a twisted pair.
2. For substrate wiring, arrange differential lines as close to each other as possible on the board.

To obtain low-to-high output at  $T_j = 125^\circ\text{C}$ , the constants of the circuit components are as follows:

$$R1 = 560 \text{ k}\Omega, C1 = 0.1 \text{ }\mu\text{F}$$

$$\begin{aligned} \text{Reference value: } R2 &= 340 \text{ }\Omega, R3 = 280 \text{ }\Omega \text{ (E96) } T_j \text{ at } 125.0^\circ\text{C} \\ & (R2 = 340 \text{ }\Omega, R3 = 287 \text{ }\Omega \text{ (E96) } T_j \text{ at } 120.3^\circ\text{C}) \end{aligned}$$

For R2 and R3, E96 series resistor with a tolerance of  $\pm 0.1\%$  is recommended. The error of this resistor will be the same value as the error produced when  $T_j$  is digitalized. A material which is little affected by the temperature is recommended for the resistor. Note that, R2 and R3 can be configured from two or more resistors.

The accuracy of R1 is not a problem since R1 is used as a pull-down resistor.

C1 is a bypass capacitor. Be sure to mount this even when the recommended external connection circuit is not to be used.

### (3) Calculation Formula

Temperature  $T_j$  can be calculated from the voltages on VTHSENSE and VTHREF as follows.

$$T_j = (VTHREF - VTHSENSE + \text{temperature coefficient 2}) / \text{temperature coefficient 1} \text{ [}^\circ\text{C]}$$

VTHSENSE, VTHREF: measured voltages [V]

Temperature coefficient 1:  $-1.60 \text{ [mV/}^\circ\text{C]}$

Temperature coefficient 2:  $-761.4 \text{ [mV]}$

Example: When VTHSENSE is  $0.681 \text{ [V]}$  and VTHREF is  $1.243 \text{ [V]}$ ,  $T_j$  is calculated as  $125^\circ\text{C}$  as follows.

$$T_j = ((1.243 - 0.681) \times 1000 - 761.4) / (-1.60) = 124.6 \text{ [}^\circ\text{C]}$$

## 60.4 Usage Notes

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

1. When the THS is not used, connect the VTHSENSE and VTHREF pins to GND or leave them open. The THS operates in the initial state. Accordingly, when the THS is not used, the THIDLE bit in THSCR should be set to 1 to place the THS in the idle state. When connecting the VTHSENSE and VTHREF pins to GND, be sure to place the THS in the idle state in the same manner.
2. The guaranteed accuracy of the outputs on the VTHSENSE and VTHREF pins is {(VHTREF - VTHSENSE) specification guaranteed accuracy  $\pm 5^{\circ}\text{C}$  max.} over the temperature range from  $-40^{\circ}\text{C}$  to  $125^{\circ}\text{C}$ . Take measurement errors into account in designing the user system. Note that, when the internal registers of the TSC are used for measurement of the chip temperature, the operation of the sensor is not guaranteed outside the range of  $-40^{\circ}\text{C}$  to  $125^{\circ}\text{C}$  within which operation of the logic circuit is guaranteed.

**Table 60.4 Accuracy of  $T_j$  in Temperature Detection by the Thermal Sensor**

$T_j$ [ $^{\circ}\text{C}$ ]	$T_j$ Accuracy
$T_j > 125^{\circ}\text{C}$	Operation and accuracy are not guaranteed.
$-40^{\circ}\text{C} \leq T_j \leq 125^{\circ}\text{C}$	$\pm 5^{\circ}\text{C}$ {(VHTREF - VTHSENSE) specification}
$-40^{\circ}\text{C} > T_j$	Operation and accuracy are not guaranteed.

3. When  $T_j$  exceeds  $125^{\circ}\text{C}$ , correct operation and device characteristics are not guaranteed.  
Although this module provides a bit for detecting  $T_j = 135^{\circ}\text{C}$ , this bit should only be used for fail-safe operation where the LSI is stopped on the verge of a thermal runaway condition (but has not yet entered that state) and the power consumption is increasing rapidly.
4. The recommended external connection circuit outputs a digital signal that is used to control the LSI from outside according to the LSI temperature  $T_j$ .  
For instance, this circuit can be used as an external fail-safe circuit to stop the power supply to the LSI when thermal runaway occurs and the LSI becomes uncontrollable because of high temperature. Instead of an external connection circuit, an ADC can be connected to detect  $T_j$  with high resolution.  
The external circuit should be used after the THS output mask pin is determined. An AND gate is included in the recommended circuit to avoid signal transmission to subsequent stages before the THS output mask pin is determined.  
However, when a clock signal is input to the PLL and the LSI is in the state after power-on reset, an output can be obtained on the VTHSENSE and VTHREF pins of the THS even when the THS output mask pin is not determined. In this case, it is recommended that the THS output mask pin of the AND circuit in the recommended circuit should be connected with the power-on reset pin via an inverter (low  $\rightarrow$  high for operation).
5. The result of temperature measurement by using the thermal sensor will not be correct over the  $300\ \mu\text{s}$  period after a change to the TAP offset value. For the reasons explained in the descriptions in sections 60.3.2 and 60.3.3, do not take account of results of measurement immediately after a change to the offset value.

## 61. System Controller (SYSC)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 61.1 Overview

The SYSC module controls the supply of power to CPUs (Cortex-A15\*<sup>1\*2</sup>, and Cortex-A7\*<sup>1\*3</sup>), RGX\*<sup>1</sup>, and SGX\*<sup>2\*3</sup>, with the aim of low leakage power. When a module is not in use, shutting off power to the module further lowers leakage power than just stopping supply of the clock signal.

For the RZ/G1E, only pseudo power off is supported. In pseudo power off mode, clock distribution for target modules are stopped with reset assert, but shutting off power-line for reducing leakage current is not supported. In this section, 'power off' means pseudo power off for the RZ/G1E.

#### 61.1.1 Features

- Support shutoff and resumption of power in the following four\*<sup>2\*3</sup>, or 11\*<sup>1</sup> power domains.

##### [RZ/G1H]

Cortex-A15 CPU0 to CPU3 (including the L1 cache)  
 Cortex-A15 SCU (including the L2 cache)  
 Cortex-A7 CPU0 to CPU3 (including the L1 cache)  
 Cortex-A7 SCU (including the L2 cache)  
 RGX

##### [RZ/G1M/N]

Cortex-A15 CPU0/CPU1 (including the L1 cache)  
 Cortex-A15 SCU (including the L2 cache)  
 SGX

##### [RZ/G1E]

Cortex-A7 CPU0/CPU1 (including the L1 cache)  
 Cortex-A7 SCU (including the L2 cache)  
 SGX

- Only power to the domains listed below is on (i.e. the domains are in the power-resume state) after a power-on reset.

##### [RZ/G1H]

Cortex-A15 CPU0 and Cortex-A15 SCU, if MD6 = 0 and MD7 = 0 (Cortex-A15 boot)  
 Cortex-A7 CPU0 and Cortex-A7 SCU, if MD6 = 1 and MD7 = 0 (Cortex-A7 boot)

##### [RZ/G1M/N]

Cortex-A15 CPU0 and Cortex-A15 SCU, if MD6 = 0 and MD7 = 0 (Cortex-A15 boot)

##### [RZ/G1E]

Cortex-A7 CPU0 and Cortex-A7 SCU, if MD6 = 1 and MD7 = 0 (Cortex-A7 boot)

Other domains are in the shutoff state after a power-on reset.

- Control of supplying and shutting off power is independent for each target domain, with the following exceptions.

##### [RZ/G1H]

SCU for the Cortex-A15s can't be switched off while power to any of Cortex-A15 CPU0/1/2/3 is on.  
 SCU of the Cortex-A7s can't be switched off while power to any of Cortex-A7 CPU0/1/2/3 is on.

##### [RZ/G1M/N]

SCU of the Cortex-A15s can't be switched off while power to either or both of Cortex-A15 CPU0/1 is on.

##### [RZ/G1E]

SCU of the Cortex-A7s can't be switched off while power to either or both of Cortex-A7 CPU0/1 is on.

- Resumption of the supply of power to Cortex-A15s (CPU0 to CPU3\*<sup>1</sup>/CPU1\*<sup>2</sup>, SCU), and Cortex-A7s (CPU0 to CPU3\*<sup>1</sup>/CPU1\*<sup>3</sup> and SCU) is controlled by interrupts in each domain.
- Power for Cortex-A15s (CPU0 to CPU3\*<sup>1</sup>/CPU1\*<sup>2</sup>) or Cortex-A7s (CPU0 to CPU3\*<sup>1</sup>/CPU1\*<sup>3</sup>) can be shut off by WFI instructions

Notes: 1. Applicable to the RZ/G1H  
2. Applicable to the RZ/G1M and N  
3. Applicable to the RZ/G1E

61.1.2 Block Diagram

Figures 61.1 to 61.3 are block diagrams of the SYSC.

Connected to the internal peripheral bus (the APB bus), the SYSC operates in coordination with the CPG, the RESET module, the CPU, and the debugger; it contains a module that controls the objects of power shutoff.

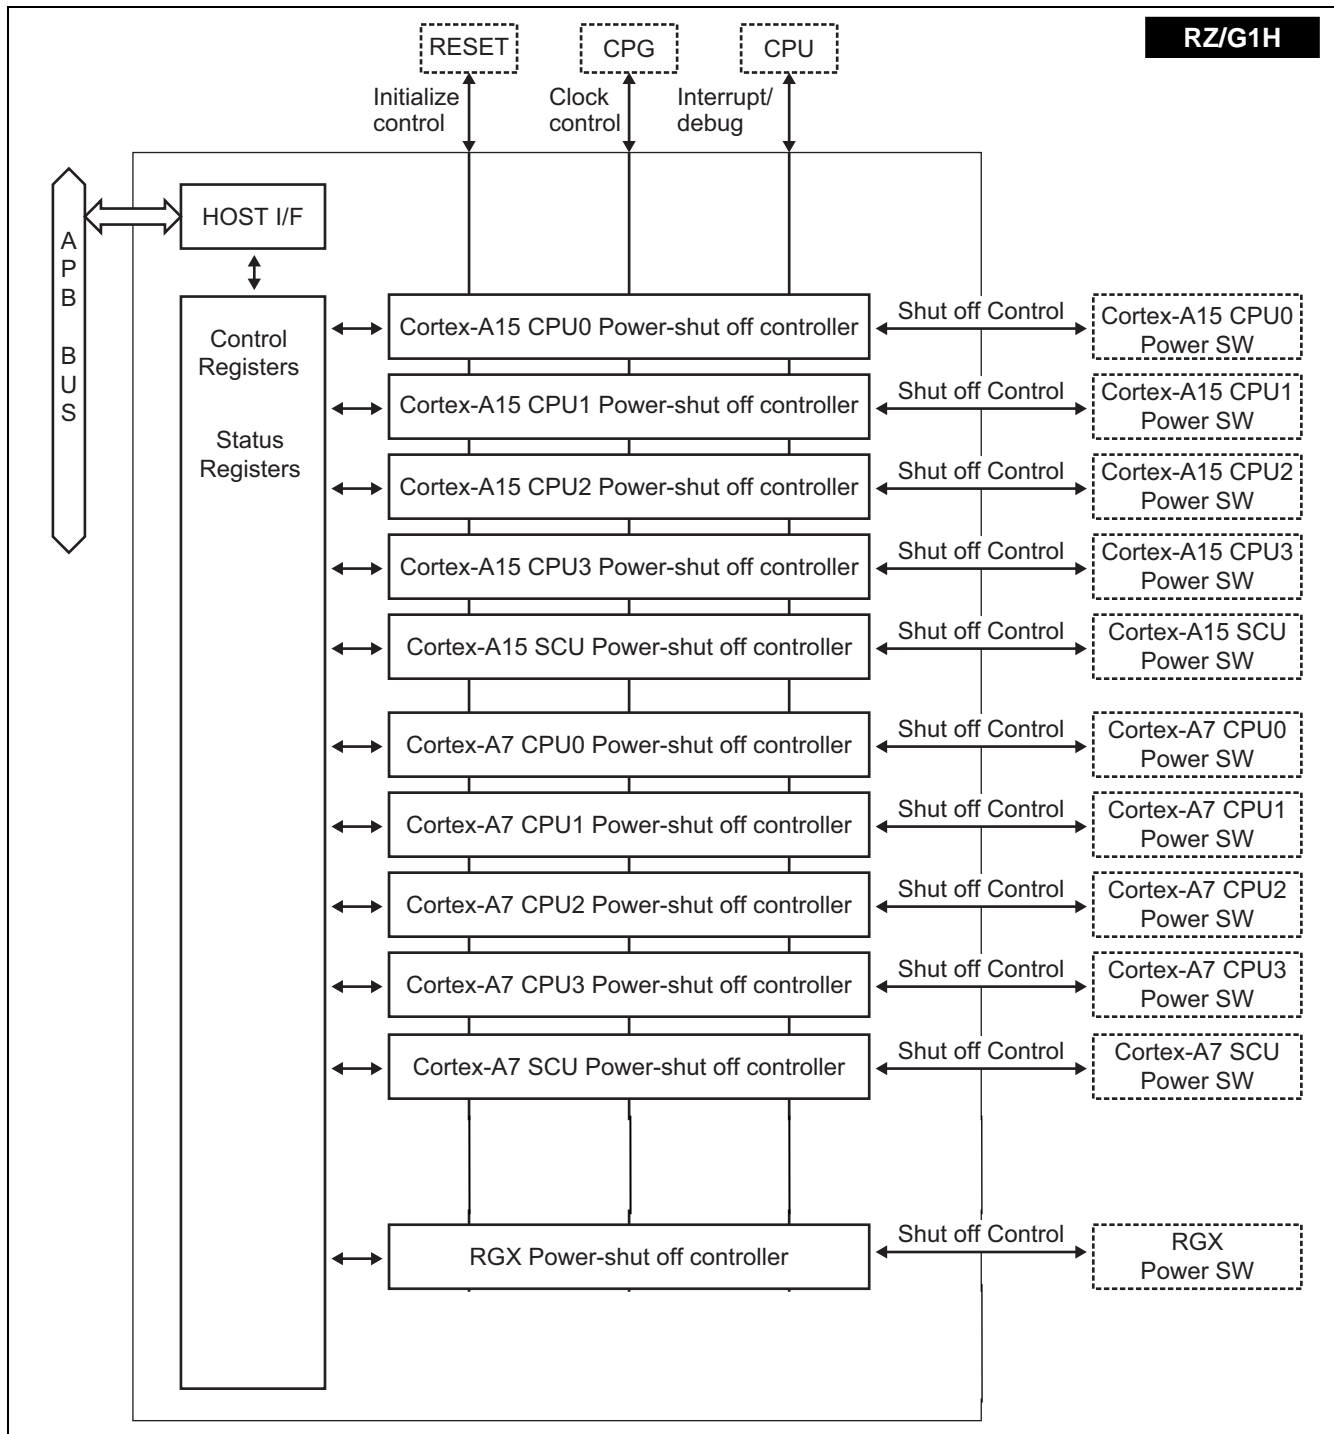

Figure 61.1 Block Diagram [RZ/G1H]

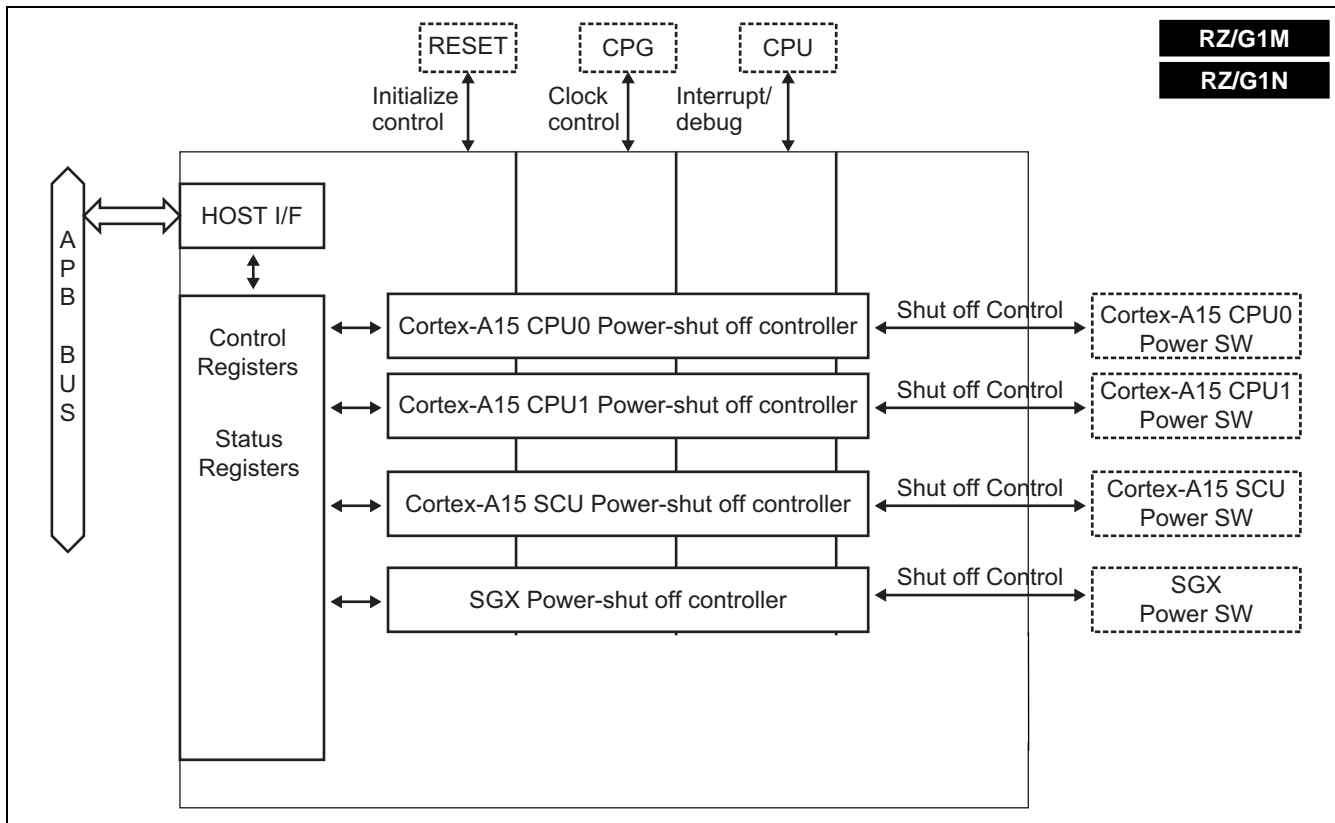

Figure 61.2 Block Diagram [RZ/G1M / N]

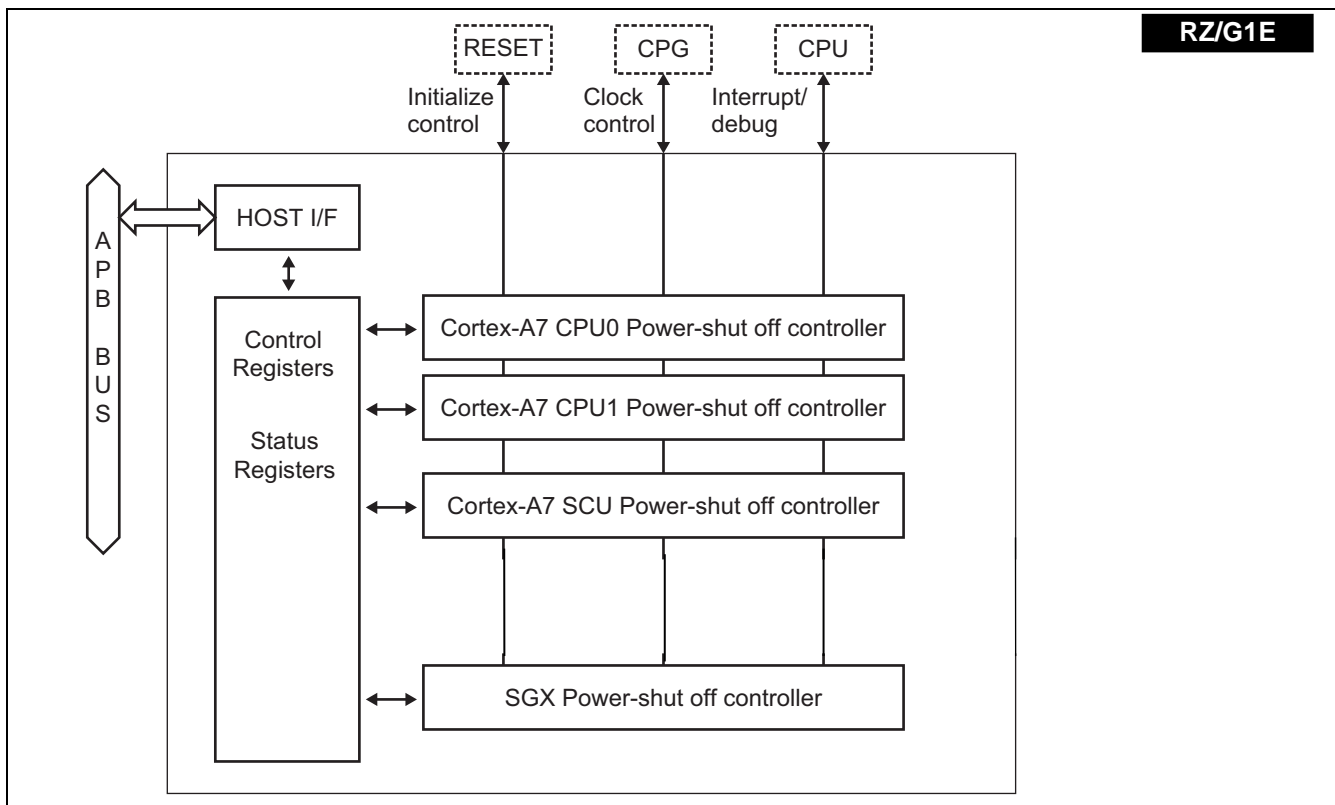

Figure 61.3 Block Diagram [RZ/G1E]

### 61.1.3 Input/Output Pins

The SYSC has no input/output pins.

## 61.2 Register Configuration

Tables 61.1 to 61.2 list the SYSC registers.

Base-address of SYSC is H'E618 0000.

Do not write to addresses other than those listed below, otherwise normal operation cannot be guaranteed. Values read from other addresses are undefined.

[Legend]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be the initial value.

—/W: Write-only. The read value is undefined.

## 61.2.1 Common Registers

These registers are used to control the shutting off of power to the various modules with respect to the common settings, the interrupts, as well as external events.

### 61.2.1.1 SYSC Status Register (SYSCSR)

RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
√	√	√	√

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
21	CA7-SCU	0	R	Indicates Cortex-A7 SCU power-processing status. [RZ/G1H/E]  This bit is set to 1 when the CA7-SCU bit in the interrupt enable register is 1 upon completion of the Cortex-A7 SCU power shutoff or power resume processing. If the CA7-SCU bit in the interrupt enable register is 0, this bit is not set to 1 even when the Cortex-A7 SCU power shutoff or power resume processing is completed. An interrupt request is issued when the CA7-SCU bit in the interrupt mask register is 0 and this bit is 1.  0: Power shutoff or power resume processing of CA7-SCU is not completed. 1: Power shutoff or power resume processing of CA7-SCU is completed.
—	—	0	R	Reserved [RZ/G1M/N]  This bit is always read as 0. The write value should always be 0.
20	RGX/ SGX	0	R	Indicates RGX power-processing status. [RZ/G1H] Indicates SGX power-processing status. [RZ/G1M/N/E]  This bit is set to 1 when the RGX/SGX bit in the interrupt enable register is 1 upon completion of the RGX/SGX power shutoff or power resume processing. If the RGX/SGX bit in the interrupt enable register is 0, this bit is not set to 1 even when the RGX/SGX power shutoff or power resume processing is completed. An interrupt request is issued when the RGX/SGX bit in the interrupt mask register is 0 and this bit is 1.  0: Power shutoff or power resume processing of RGX/SGX is not completed. 1: Power shutoff or power resume processing of RGX/SGX is completed.
19 to 17	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.
16	—	0	R	Reserved  This bit is always read as 0. The write value should always be 0.
15 to 13	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.
12	CA15- SCU	0	R	Indicates Cortex-A15 SCU power-processing status. [RZ/G1H/M/N]  This bit is set to 1 when the CA15-SCU bit in the interrupt enable register is 1 upon completion of the Cortex-A15 SCU power shutoff or power resume processing. If the CA15-SCU bit in the interrupt enable register is 0, this bit is not set to 1 even when the Cortex-A15 SCU power shutoff or power resume processing is completed. An interrupt request is issued when the CA15-SCU bit in the interrupt mask register is 0 and this bit is 1.  0: Power shutoff or power resume processing of Cortex-A15 SCU is not completed. 1: Power shutoff or power resume processing of Cortex-A15 SCU is completed.
—	—	0	R	Reserved [RZ/G1E]  This bit is always read as 0. The write value should always be 0.
11 to 9	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8 to 5	CA7-CPU[3:0]/ CA7-CPU[1:0]	All 0	R	<p>Indicates Cortex-A7 CPU3-0 power-processing status. [RZ/G1H]</p> <p>Reserved (bits 8 and 7) and indicates Cortex-A7 CPU1-0 power-processing status (bits 6 and 5). [RZ/G1E]</p> <p>This bit is set to 1 when the CA7-CPU[3:0] / CPU[1:0] bit in the interrupt enable register is 1 upon completion of the Cortex-A7 core CPU3-0 / CPU1-0 power shutoff or power resume processing. If the Cortex-A7 CPU[3:0] / CPU[1:0] bit in the interrupt enable register is 0, this bit is not set to 1 even when power shutoff or power resume processing for the Cortex-A7 core CPU3-0 / CPU1-0 is completed. An interrupt request is issued when the CA7-CPU[3:0] / CPU[1:0] bit in the interrupt mask register is 0 and this bit is 1.</p> <p>0: Power shutoff or power resume processing of Cortex-A7 CPU3-0 / CPU1-0 is not completed.</p> <p>1: Power shutoff or power resume processing of Cortex-A7 CPU3-0 / CPU1-0 is completed.</p> <p>Regarding RZ/G1E, Bit 8/7 of this field is reserved. Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	—	1	R	Reserved [RZ/G1M/N/E] This bit is always read as 1. The write value should always be 1.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
21	CA7-SCU	1	R/W	Controls the interrupt output when the Cortex-A7 SCU power shutoff or power resume processing is complete. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1. [RZ/G1H/E]  0: Does not mask the interrupt when the Cortex-A7 SCU power shutoff or power resume processing is complete. 1: Masks the interrupt when the Cortex-A7 SCU power shutoff or power resume processing is complete.
—	—	1	R	Reserved [RZ/G1M/N]  This bit is always read as 1. The write value should always be 1.
20	RGX/ SGX	1	R/W	Controls the interrupt output when the RGX[RZ/G1H] / SGX[RZ/G1M/N/E] power shutoff or power resume processing is complete. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1.  0: Does not mask the interrupt when the RGX / SGX power shutoff or power resume processing is complete. 1: Masks the interrupt when the RGX / SGX power shutoff or power resume processing is complete.
19 to 17	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.
16	—	1	R/W	Reserved  This bit is always read as 1. The write value should always be 1.
15 to 13	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.
12	CA15-SCU	1	R/W	Controls the interrupt output when the Cortex-A15 SCU [RZ/G1H/M/N] power shutoff or power resume processing is complete. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1.  0: Does not mask the interrupt when the Cortex-A15 SCU power shutoff or power resume processing is complete. 1: Masks the interrupt when the Cortex-A15 SCU power shutoff or power resume processing is complete.
—	—	1	R/W	Reserved [RZ/G1E]  This bit is always read as 1. The write value should always be 1.
11 to 9	—	All 0	R	Reserved  These bits are always read as 0. The write value should always be 0.
8 to 5	CA7-CPU[3:0]/ CA7-CPU[1:0]	All 1	R/W	Controls the interrupt output when power shutoff or power resume processing for the Cortex-A7 core CPU3-0 [RZ/G1H] / CPU[1:0] [RZ/G1E] is complete. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1.  0: Does not mask the interrupt when power shutoff or power resume processing for the Cortex-A7 core CPU3-0 is complete. 1: Masks the interrupt when power shutoff or power resume processing for the Cortex-A7 core CPU3-0 is complete.  Regarding RZ/G1E , Bit 8/7 of this field is reserved. These bits are always read as 1. The write value should always be 1.
—	—	All 1	R	Reserved [RZ/G1M/N]  The write value should always be 1.
4	—	0	R	Reserved  This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CA15-CPU[3:0]/ CA15-CPU[1:0]	All 1	R/W	<p>Controls the interrupt output when power shutoff or power resume processing for the Cortex-A15 core CPU3-0 [RZ/G1H] / CPU[1:0] [RZ/G1M/N] is complete. ### 61.2.2 Power Control Registers for ARM CPUs

These registers control power status of Cortex-A15 and Cortex-A7 CPUs.

In the detailed description of these registers, the register names corresponding to the modules are denoted as "n (n: 0/6)". The "n" and the module names correspond as follows:

Cortex-A15: n = 0

Cortex-A7: n = 6

#### 61.2.2.1 Power Status Register n (PWRSRn)

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	CPU[3:0]/ CPU[1:0]	All 0	R	Indicates whether a power shutoff or power resume request by a preceding register write to CPU3-0 [RZ/G1H] /CPU1-0 [RZ/G1M/N/E] was accepted or not. 0: Either a preceding power shutoff or power resume request to CPU3-0 / CPU1-0 was accepted. 1: Either a preceding power shutoff or power resume request to CPU3-0 / CPU1-0 was not accepted. Regarding RZ/G1M/N/E, Bit 3/2 of this field is reserved. These bits are always read as 0. The write value should always be 0.

### 61.2.3 Power Control Registers for RGX, and SCU of Cortex-A15

These registers control power shutoff/resume of following modules. In the detailed description of these registers that follows, the register names corresponding to the modules are denoted as "n (n: 2/3/4/5)". The "n" and the module names correspond as follows:

RGX [RZ/G1H] / SGX [RZ/G1M/N/E] : n = 2

Cortex-A7 SCU: n = 3

Cortex-A15 SCU: n = 5

#### 61.2.3.1 Power Status Register n (PWRSRn) (n = 2/3/5)

Note: n = 2/3/5 [RZ/G1H] , n = 2/5 [RZ/G1M/N] , n = 2/3 [RZ/G1E]

31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ERR	0	R	Indicates that either a power shutoff or power resume request by a preceding register write to the module was issued when such requests were not acceptable. 0: Either a preceding power shutoff or power resume request to the module was accepted. 1: Either a preceding power shutoff or power resume request to the module was not accepted.

## 61.3 Operations

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

### 61.3.1 Power Control of ARM CPUs

The ARM CPUs can be powered off by executing the WFI instruction. Similarly, power of ARM CPU core can be resumed either by controlling the CPG (APMU) registers or by an IRQ or FIQ interrupt.

For detail of power control by CPG (APMU) registers, see section 7B, Advanced Power Management Unit for AP-System Core (APMU).

#### (1) Power Control by WFI Instruction and Interrupts

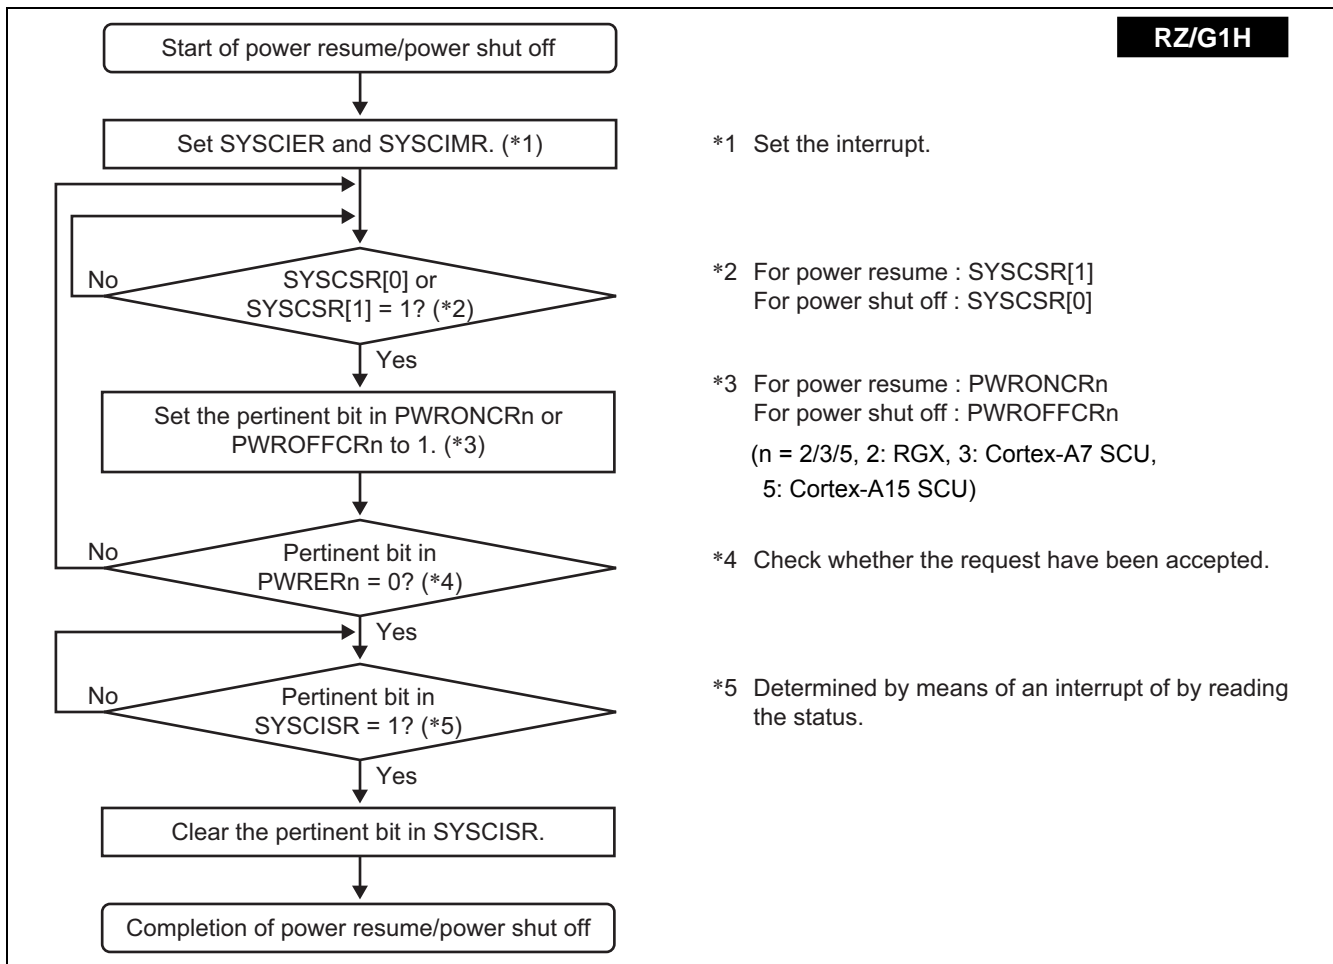

The power shutdown by the WFI instruction is performed only when Cortex-A7\*<sup>2</sup>/ Cortex-A15\*<sup>1</sup> CPU<sup>n</sup>\*<sup>3</sup> power status control register (CA7CPU<sup>n</sup>\*<sup>3</sup>CR\*<sup>1</sup>, CA15CPU<sup>n</sup>\*<sup>3</sup>CR\*<sup>2</sup>) is in the core standby mode. In case of other setting, power shutdown sequence is not activated by the WFI instruction. See section 7B, Advanced Power Management Unit for AP-System Core (APMU).

Power can be resumed by an IRQ or FIQ interrupt on the ARM core. After resuming power of Cortex-A7\*<sup>2</sup>/ Cortex-A15\*<sup>1</sup> CPUs by IRQ/FIQ, read the value of SYSCOFSR/SYSCOFSR2\*<sup>2</sup> registers. Without reading those registers after power-resuming, the shutdown sequence of related CPUs will not start.

- Notes:
1. Applicable to the RZ/G1H, RZ/G1M, and RZ/G1N
  2. Applicable to the RZ/G1H and RZ/G1E
  3. n = 0 to 3 [RZ/G1H]  
n = 0, 1 [RZ/G1M, RZ/G1N, and RZ/G1E]

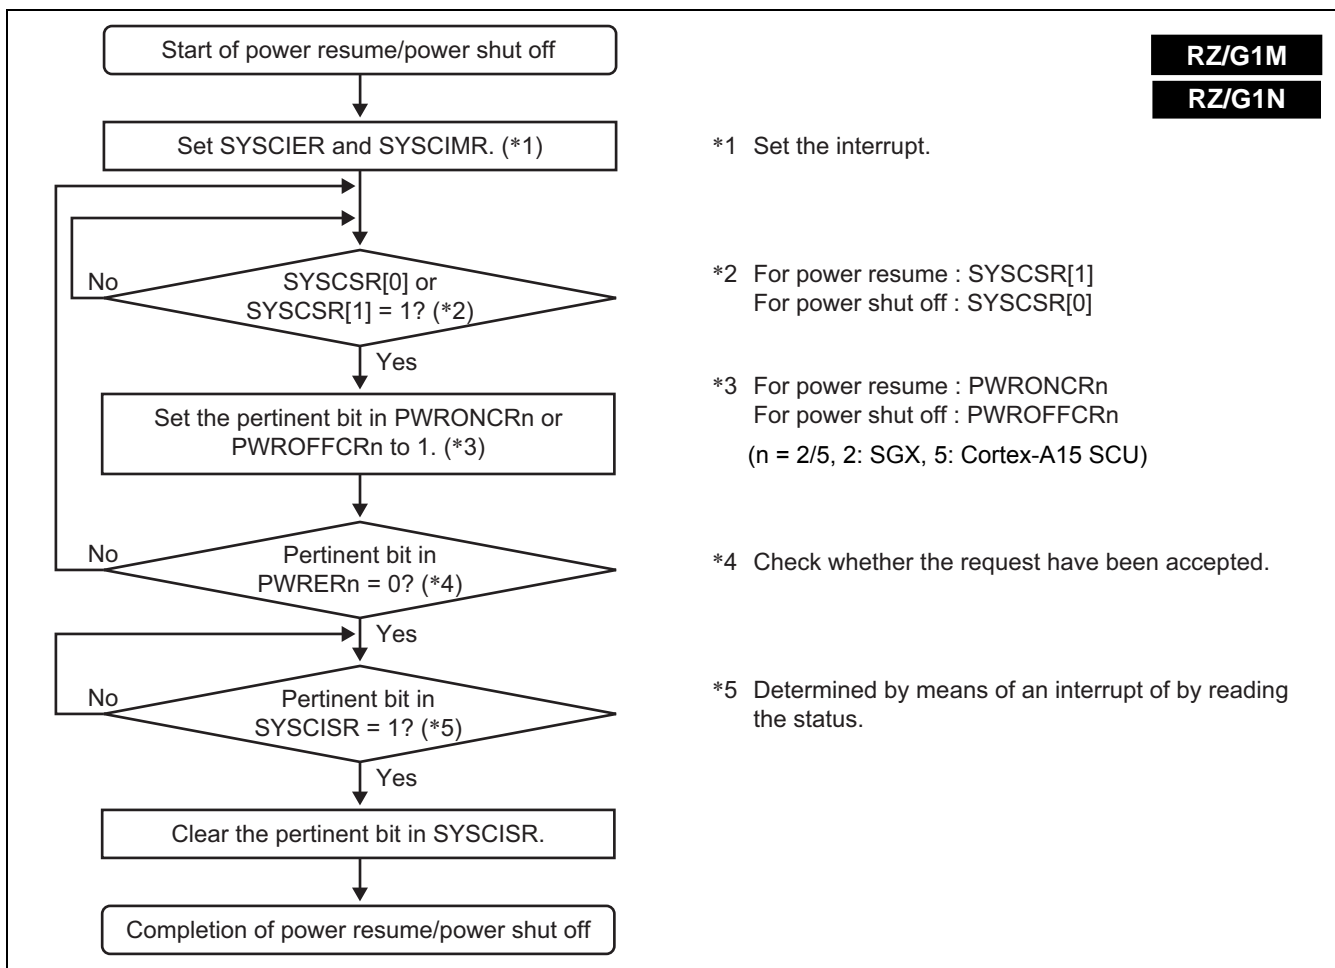

**61.3.2 Power Control of non-ARM-CPU modules**

Power control on modules other than the ARM CPUs can be performed exclusively by means of SYSC registers. Such power control should be performed with reference to the flowchart given below:

**Figure 61.4 Power Resume/Shutoff Flowchart on non-ARM-CPU by Means of SYSC Registers [RZ/G1H]**

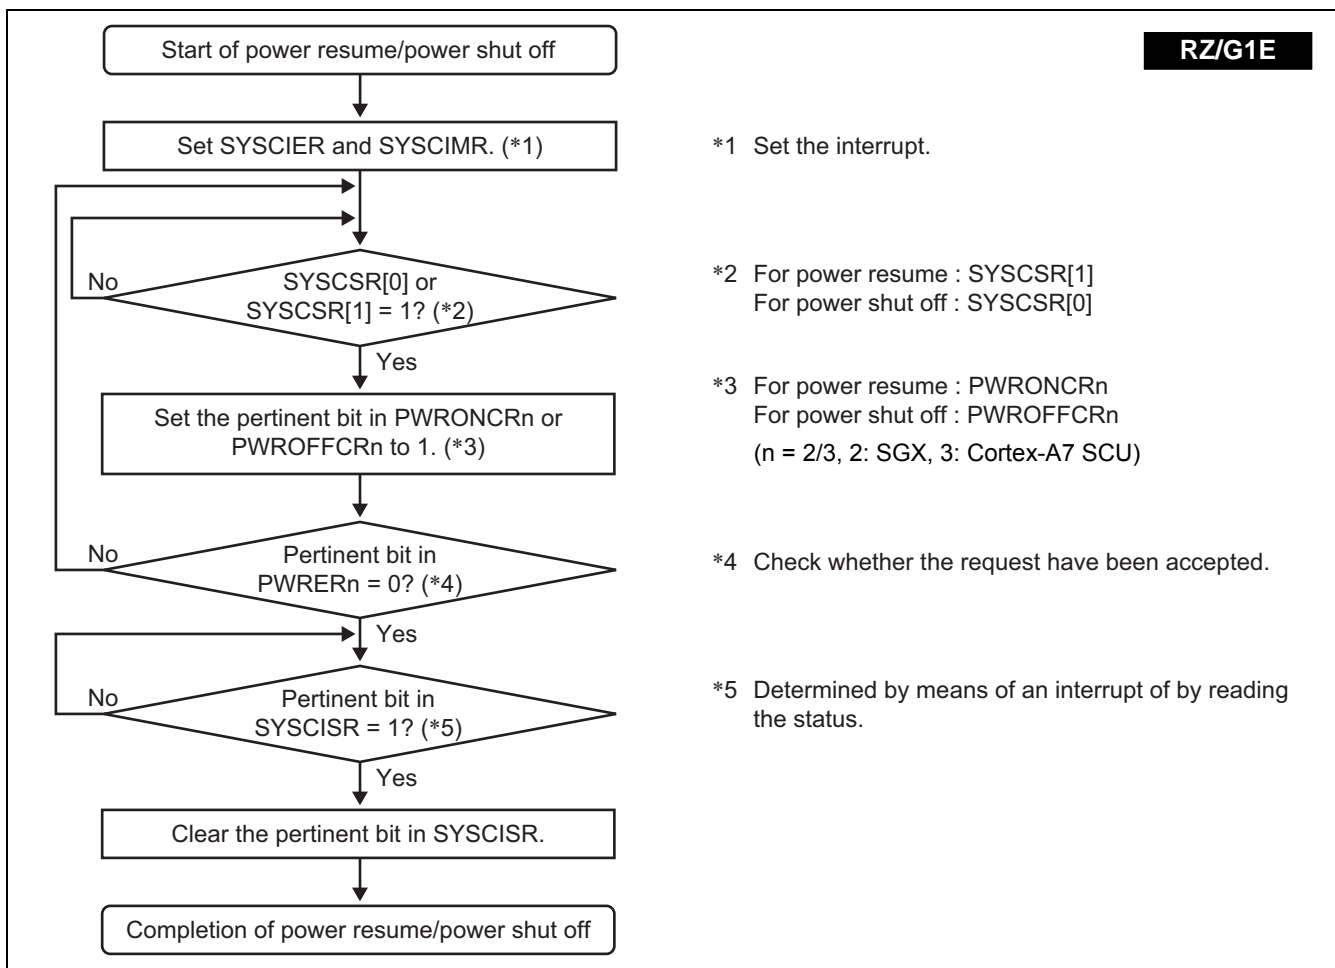

**RZ/G1M**  
**RZ/G1N**

- \*1 Set the interrupt.
- \*2 For power resume : SYSCSR[1]  
For power shut off : SYSCSR[0]
- \*3 For power resume : PWRONCRn  
For power shut off : PWROFFCRn  
(n = 2/5, 2: SGX, 5: Cortex-A15 SCU)
- \*4 Check whether the request have been accepted.
- \*5 Determined by means of an interrupt of by reading the status.

**Figure 61.5 Power Resume/Shutoff Flowchart on non-ARM-CPU by Means of SYSC Registers [RZ/G1M/N]**

**RZ/G1E**

- \*1 Set the interrupt.
- \*2 For power resume : SYSCSR[1]  
For power shut off : SYSCSR[0]
- \*3 For power resume : PWRONCRn  
For power shut off : PWROFFCRn  
(n = 2/3, 2: SGX, 3: Cortex-A7 SCU)
- \*4 Check whether the request have been accepted.
- \*5 Determined by means of an interrupt of by reading the status.

**Figure 61.6 Power Resume/Shutoff Flowchart on non-ARM-CPU by Means of SYSC Registers [RZ/G1E]**

## 61.4 Usage Notes

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

1. For modules other than the ARM CPUs, resume or shutoff sequences on more than one module cannot be executed simultaneously. Whether or not a resume or shutoff sequence can be accepted is indicated in the SYSC status register.
2. The ARM CPUs can simultaneously execute resume or shutoff sequences for the CPU0 to CPU<sup>n</sup>\*1 of the ARM core only if those sequences are simultaneously activated. Resume and shutoff sequences cannot be executed simultaneously even for the CPU0 to CPU<sup>n</sup>\*1 of the ARM core.
3. If power for the ARM core is controlled by the WFI instruction or interrupts, such actions can potentially be in contention with power control by means of the SYSC register at an unexpected timing. Such control should be performed with references to the flowchart shown in Figures 61.4 to 61.6.
4. For a module for which power is shut down, register settings and memory contents are not retained; any necessary information should be saved before power is shut off.
5. Shutting off and resuming power requires several hundreds of microseconds.

Note: CPU0 to CPU3 [RZ/G1H]  
 CPU0, CPU1 [RZ/G1M/N/E]

# 62. CoreSight

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

## 62.1 Features

- JTAG interface
  - Supports dedicated 5-pin JTAG and SWD
- Supports the cross trigger between following IPs.
  - Cortex-A15 CPU. [Only RZ/G1H, RZ/G1M, RZ/G1N]
  - Cortex-A7 CPU. [Only RZ/G1H, RZ/G1E]
  - CoreSight
- Tracing function
  - ETM is installed for each Cortex-A7 CPU
  - PTM is installed for each Cortex-A15 CPU
  - A maximum of 16 bits × 390 Mbps (145-MHz DDR) trace\* data pin output
  - 16-Kbyte embedded trace FIFO (ETF)

Note: \* Design frequency of internal logic. This is limited by IO buffer performance.

## 62.2 Block Diagram

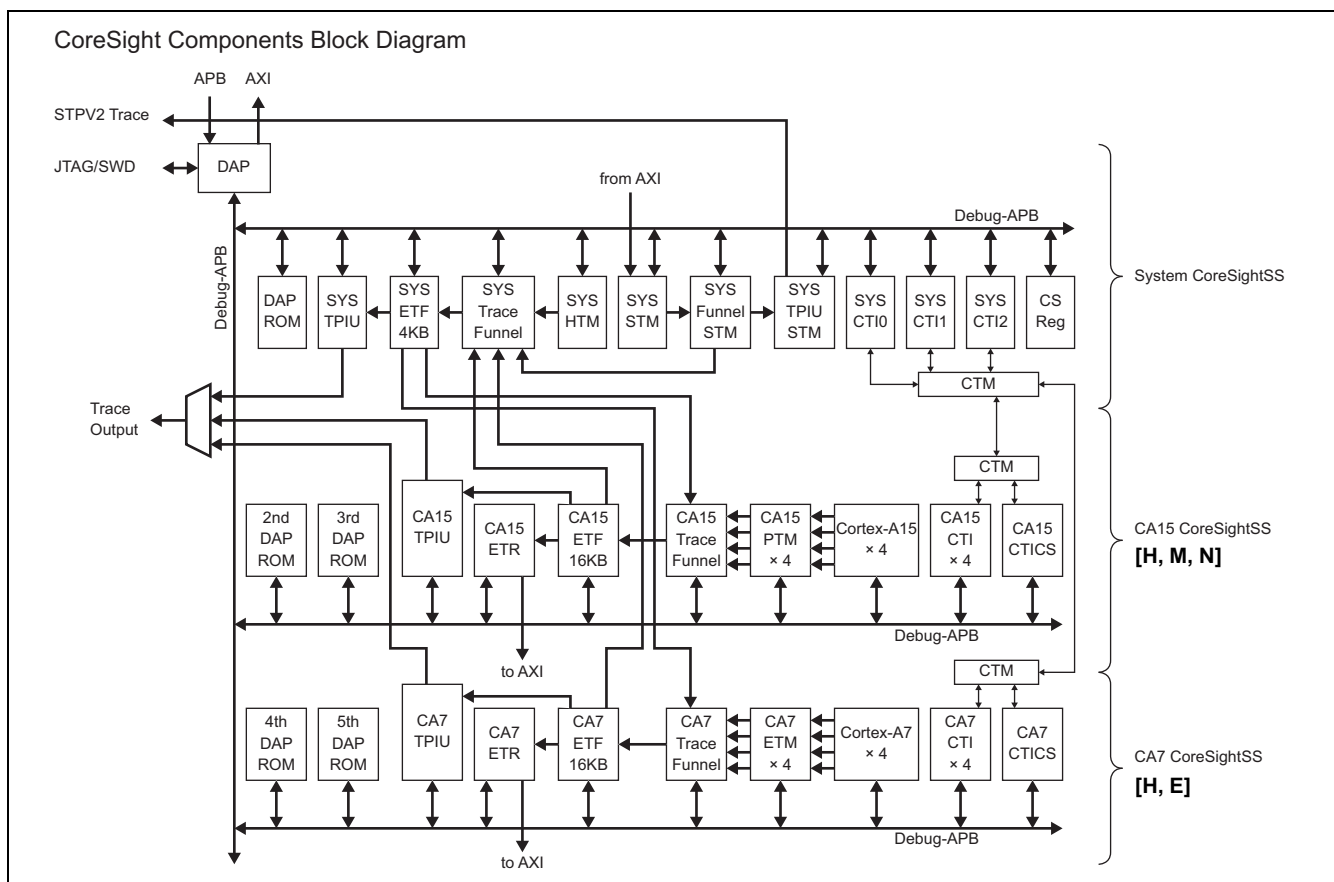

Figure 62.1 CoreSight Block Diagram

## 62.3 Input/Output Pins

### 62.3.1 JTAG Pins

5-pin JTAG and SWD are supported as dedicated pins.

**Table 62.1 RZ/G1H JTAG Pins**

Function Name	JTAG1 1.8V	JTAG2 1.8V	JTAG3 1.8V	I/O
TRST	TRST#	SD0_CMD	SD1_CMD	Input

EDBGREQ	—	SD1_DATA3	MMC_D3	IN

- Notes:
1. Please refer section 5, Pin Function Controller (PFC) to know the initial states of pull-up/down control each pins. Basically, the pull-up control initial states of JTAG2/3 multiplexed with SD/MMC pins are disabled.
  2. If the JTAG Ports are not selected by debug related MD pins (MD[11:10], MD[21:20], MDT[1:0] pins are all low level), TRST# pin of JTAG1 should be set Low level or drove with the same level of PRESET# pin.
  3. JTAG1, JTAG2 and JTAG3 and Trace ports support 1.8 V only.

### 62.3.2 Trace Pins

A maximum of 16-bit trace ports are supported as multiplexed pins.

## 63. Electrical Characteristics

### 63.1 Absolute Maximum Ratings

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

**Table 63.1.1 Absolute Maximum Ratings**

Item	Value	Unit	Remarks
Power supply voltage (3.3 V) (VCCQ, VCCQ33_MLBP, VCCQ_SD (SDHI), VD331)	-0.3 to +4.6	V	H, M and N
Power supply voltage (3.3 V) (VCCQ, VCCQ_SD/VCCQ_MMC_SD (SDHI), VD331)			E
Power supply voltage (1.8 V) (AVDD, VCCQ18, VCCQ_ISO, VCCQ_SD (SDR50/SDR104), VDD_CPGPLL, VDDA_SATA0/1, VDDQ_LVDS, VCCQ18_MLBP, VDDQ_M0APLL, VDDQ_M1APLL, VDDQ_M0DPLL, VDDQ_M1DPLL, VDDQ_M1MPLL, DU/DU0_LVDS0/LVDS_PLL1_VCC (H/M), DU_LVDS1_PLL1_VCC (H only), VDD_MLBPPLL, VDD_MLBPPLL0, VDD_MLBPPLL1)	-0.3 to +2.5	V	H, M and N (DU_LVDS1_PLL1_VCC: H only)
Power supply voltage (1.8 V) (AVDD, VCCQ18, VCCQ_SD/VCCQ_MMC_SD (SDR50/SDR104), VDD_CPGPLL, VDD_MLBPPLL, VDDQ_M0APLL, VDDQ_M0DPLL)			E
Power supply voltage (1.5V) (VDDQ_M0)	-0.3 to +1.875	V	—
Power supply voltage (1.5V) (VDDQ_M1, VDDQ_M1A)			H and M
Power supply voltage (1.35 V) (VDDQ_M0)	-0.3 to +1.75	V	—
Power supply voltage (1.35 V) (VDDQ_M1, VDDQ_M1A)			H and M
Power supply voltage (1.0 V) (VDD)	-0.3 to +1.26	V	—
Power supply voltage (1.0 V) (VDD_DVFS, VDDD_SATA0/1)			H, M and N
Input voltage (3.3-V I/O, 3.3-V tolerant I/O)	-0.3 to VCCQ + 0.3	V	*1
Input voltage (3.3-V I/O)	-0.3 to VCCQ33_MLBP + 0.3	V	*1, H, M and N
Input voltage (3.3-V I/O [SDHI])	-0.3 to VCCQ_SD/VCCQ_MMC_ SD + 0.3	V	*1, H, M, N and E
Input voltage (1.8-V I/O)	-0.3 to VCCQ18 + 0.3	V	*2, except for 3.3-V tolerant I/O
Input voltage (1.8-V I/O [SDHI (SDR50/SDR104)])	-0.3 to VCCQ_SD/VCCQ_MMC_ SD + 0.3	V	*2, H, M, N and E
Input voltage (1.8-V I/O)	-0.3 to VCCQ18_MLBP + 0.3	V	*2, H, M and N
Input voltage (1.5-V I/O [DDR3])	-0.3 to VDDQ_M0/M1/M1A + 0.3	V	*3, H and E, M1/M1A: H

Item	Value	Unit	Remarks
Input voltage (1.35-V I/O [DDR3L])	-0.3 to VDDQ_M0/M1/M1A + 0.3	V	*4, M and N, M1/M1A: M
Input voltage (1.0-V I/O [SATA])	-0.3 to VDDD_SATA0/1 + 0.3	V	*5, H, M and N
Input voltage (USB0_OVC/VBUS pin, USB1_OVC pin [USB2.0])	-0.3 to VCCQ + 0.3	V	*1, H, M, N and E
Output voltage (3.3-V I/O, 3.3-V tolerant I/O)	-0.3 to VCCQ + 0.3	V	*1
Output voltage (3.3-V I/O)	-0.3 to VCCQ33_MLBP + 0.3	V	*1, H, M and N
Output voltage (3.3-V I/O [SDHI])	-0.3 to VCCQ_SD/VCCQ_MMC_ SD + 0.3	V	*1, H, M, N and E
Output voltage (1.8-V)	-0.3 to VCCQ18 + 0.3	V	*2, except for 3.3-V tolerant I/O
Output voltage (1.8-V I/O [SDHI (SDR50/SDR104)])	-0.3 to VCCQ_SD/VCCQ_MMC_ SD + 0.3	V	*2, H, M, N and E
Output voltage (1.8-V I/O [DU/LVDS])	-0.3 to VDDQ_LVDS + 0.3	V	*2, H, M and N
Output voltage (1.8-V I/O)	-0.3 to VCCQ18_MLBP + 0.3	V	*2, H, M and N
Output voltage (1.5-V I/O [DDR3])	-0.3 to VDDQ_M0/M1/M1A + 0.3	V	*3, H and E, M1/M1A: H
Output voltage (1.35-V I/O [DDR3L])	-0.3 to VDDQ_M0/M1/M1A + 0.3	V	*4, M and N, M1/M1A: M
Output voltage (1.0-V I/O [SATA])	-0.3 to VDDD_SATA0/1 + 0.3	V	*5, H, M and N
Operating temperature	-40 to +105	°C	Tc (case)
	-40 to +85	°C	Ta (ambient)
Storage temperature	-55 to +125	°C	Ta (ambient)

Notes: Permanent damage to the LSI may result if absolute maximum ratings are exceeded. In normal operation, this LSI should be used within the specifications described in the following descriptions. If this LSI is not used within the specifications, the reliability of this LSI may lower.

Voltages are referenced at GND = VSS = AVSS = 0 V.

Abbreviations in the tables have the following meanings.

SDHI: SDHI does not operate through SDR50/SDR104.

SDHI (SDR50/SDR104): SDHI operates through SDR50/SDR104.

For details of the number of channels or available modules, refer to each manual; SHDI, DU/LVDS, SATA/PCIEC/USB3.0, DBSC3 (DDR) and USB2.0 (AVDD).

1. Do not exceed 4.6 V.
2. Do not exceed 2.5 V.
3. Do not exceed 1.875V.
4. Do not exceed 1.75V.
5. Do not exceed 1.26V.

## 63.2 Power Supply

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

**Table 63.2.1 Power Supply (H, M, N and E)**

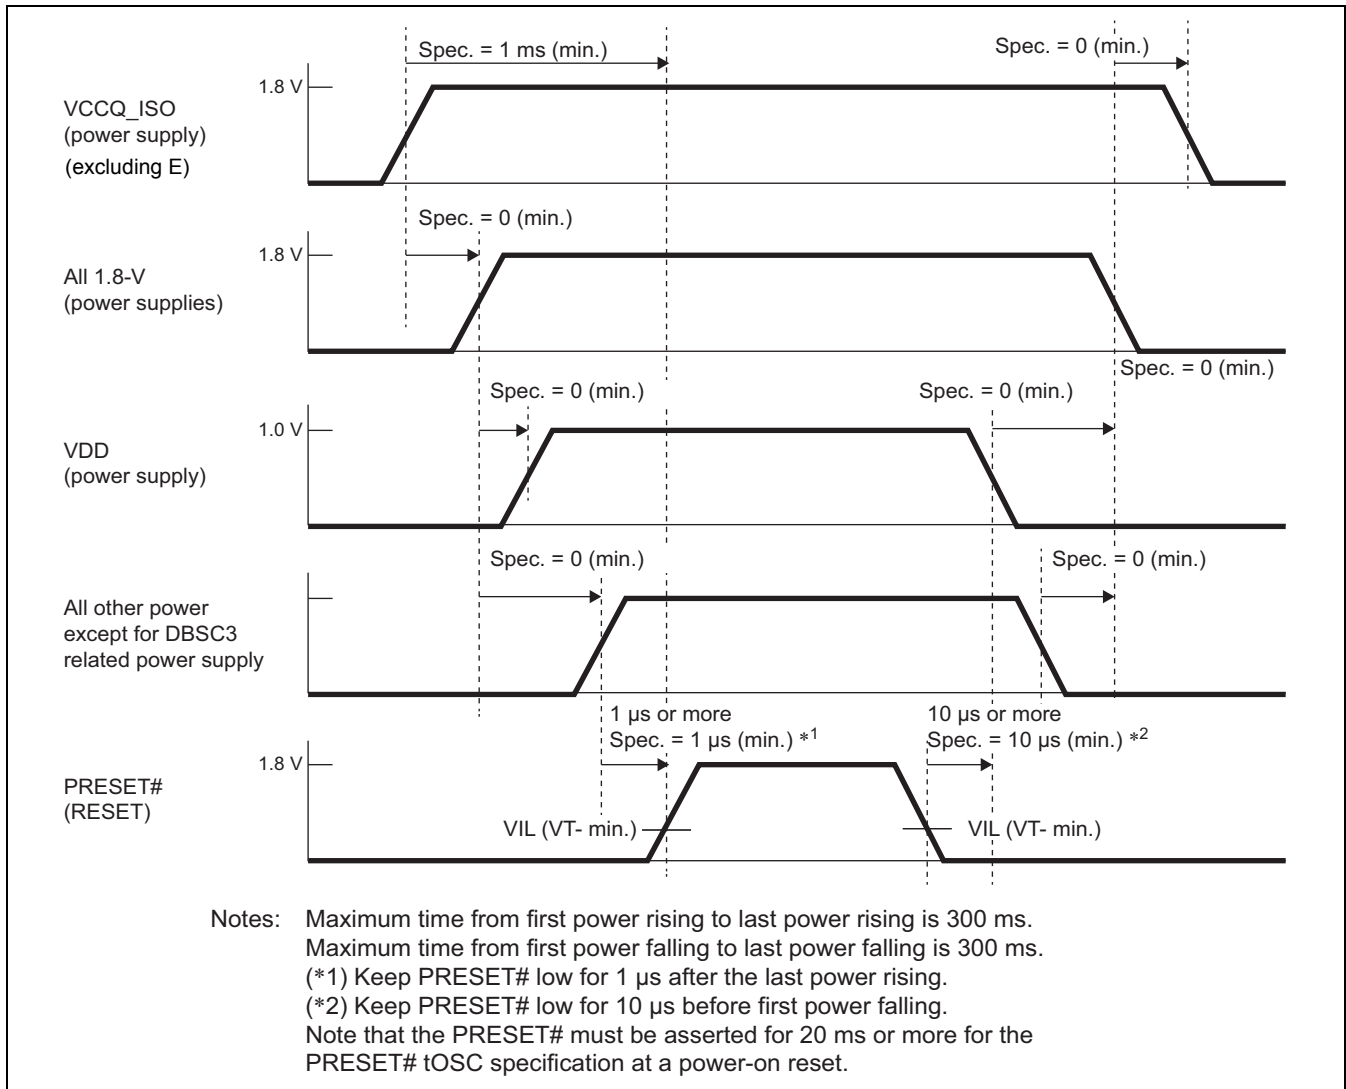

Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (Internal)	VDD	0.98	1.03	1.08	V	VDD for power supply and VSS for ground
Power supply (3.3-V I/O)	VCCQ	3.0	3.3	3.6	V	VCCQ for power supply and VSS for ground
Power supply (3.3-V I/O) (excluding E)	VCCQ33_MLBP	3.0	3.3	3.6	V	VCCQ33_MLBP for power supply and VSS for ground
Power supply (3.3-V I/O [SDHI])	VCCQ_SD0 to VCCQ_SD3, VCCQ_MMC_SD2	3.0	3.3	3.6	V	VCCQ_SD0 to VCCQ_SD3, VCCQ_MMC_SD2 for power supply and VSS for ground
Power supply ([VCCQ_ISO]) (excluding E)	VCCQ_ISO	1.7	1.8	1.9	V	VCCQ_ISO for power supply and VSS for ground
Power supply (1.8-V I/O [VCCQ18])	VCCQ18	1.7	1.8	1.9	V	VCCQ18 for power supply and VSS for ground
Power supply (1.8-V I/O) (excluding E)	VCCQ18_MLBP	1.7	1.8	1.9	V	VCCQ18_MLBP for power supply and VSS for ground
Power supply (1.8-V I/O [SDHI(SDR50/SDR104)])	VCCQ_SD0 to VCCQ_SD3, VCCQ_MMC_SD2	1.7	1.8	1.9	V	VCCQ_SD0 to VCCQ_SD3, VCCQ_MMC_SD2 for power supply and VSS for ground
Power supply (1.8-V I/O [DU/LVDS]) (excluding E)	VDDQ_LVDS	1.7	1.8	1.9	V	VDDQ_LVDS for power supply and VSS for ground
Power supply (1.5-V I/O [DDR3])	VDDQ_M0 (H, M, N, E), VDDQ_M1 (H, M), VDDQ_M1A (H, M)	1.425	1.5	1.575	V	VDDQ_M0, VDDQ_M1 and VDDQ_M1A for power supply and VSS for ground
Power supply (1.35-V I/O [DDR3L])	VDDQ_M1 (H, M), VDDQ_M1A (H, M)	1.283	1.35	1.450	V	
Power supply (USB3.0) (excluding E)	VDDA_SATA0	1.7	1.8	1.9	V	VDDA_SATA0 for power supply and VSS_SATA0 for ground
	VDDD_SATA0	0.98	1.03	1.08	V	VDDD_SATA0 for power supply and VSS_SATA0 for ground
Power supply (PCI-E) (excluding E)	VDDA_SATA1 (H, M)	1.7	1.8	1.9	V	VDDA_SATA1 for power supply and VSS_SATA1 for ground
	VDDA_SATA0 (N)					VDDA_SATA0 for power supply and VSS_SATA0 for ground
	VDDD_SATA1 (H, M)	0.98	1.03	1.08	V	VDDD_SATA1 for power supply and VSS_SATA1 for ground
	VDDD_SATA0 (N)					VDDD_SATA0 for power supply and VSS_SATA0 for ground

Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (SATA) (excluding E)	VDDA_SATA0 (H, M, N)	1.7	1.8	1.9	V	VDDA_SATA0, VDDA_SATA1 for power supply and VSS_SATA0, VSS_SATA1 for ground respectively
	VDDA_SATA1 (H, M)					
	VDDD_SATA0 (H, M, N)	0.98	1.03	1.08	V	VDDD_SATA0, VDDD_SATA1 for power supply and VSS_SATA0, VSS_SATA1 for ground respectively
	VDDD_SATA1 (H, M)					
Power supply (PLL [CPG])	VDD_CPGPLL	1.7	1.8	1.9	V	VDD_CPGPLL for power supply and VSS_CPGPLL for ground
Power supply (PLL [DDR3/DDR3L])	VDDQ_M0DPLL VDDQ_M1DPLL VDDQ_M1MPLL VDDQ_M0APLL VDDQ_M1APLL	1.7	1.8	1.9	V	VDDQ_M0DPLL, VDDQ_M1DPLL, VDDQ_M1MPLL, VDDQ_M0APLL, VDDQ_M1APLL for power supply and VSSQ_M0DPLL, VSSQ_M1DPLL, VSSQ_M1MPLL, VSSQ_M0APLL, VSSQ_M1APLL for ground respectively
Power supply (PLL [DU/LVDS]) (excluding E)	DU/DU0_LVDS0/L VDS_PLL1_VCC (H/M/N), DU_LVDS1_PLL1 _VCC (H)	1.7	1.8	1.9	V	DU/DU0_LVDS0/LVDS_PLL1_V CC, DU_LVDS1_PLL1_VCC for power supply and DU/DU0_LVDS0/LVDS_PLL1_V SS, DU_LVDS1_PLL1_VSS for ground respectively
Power supply (PLL)	VDD_MLBPLL	1.7	1.8	1.9	V	VDD_MLBPLL for power supply and VSS_MLBPLL for ground
	VDD_MLBPPLL0 (H,M,N)	1.7	1.8	1.9	V	VDD_MLBPPLL0 for power supply and VSS_MLBPPLL0 for ground
	VDD_MLBPPLL1 (H,M,N)	1.7	1.8	1.9	V	VDD_MLBPPLL1 for power supply and VSS_MLBPPLL1 for ground
Power supply (USB2.0)	AVDD	1.7	1.8	1.9	V	AVDD for power supply and AVSS for ground
	VD331	3.0	3.3	3.6	V	VD331 for power supply and VSS for ground
	VD181	1.7	1.8	1.9	V	VD181 for power supply and VSS for ground
Power supply (DVFS) (excluding E)	VDD_DVFS	0.98	1.03	1.08	V	VDD_DVFS for power supply and VSS for ground

### 63.3 Sequence of Turning On/Off Power Supplies

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

#### (1) Power Sequence (Abstract)

(2) Power Sequence (Details)

63.3.1 Wave form definition for power sequence

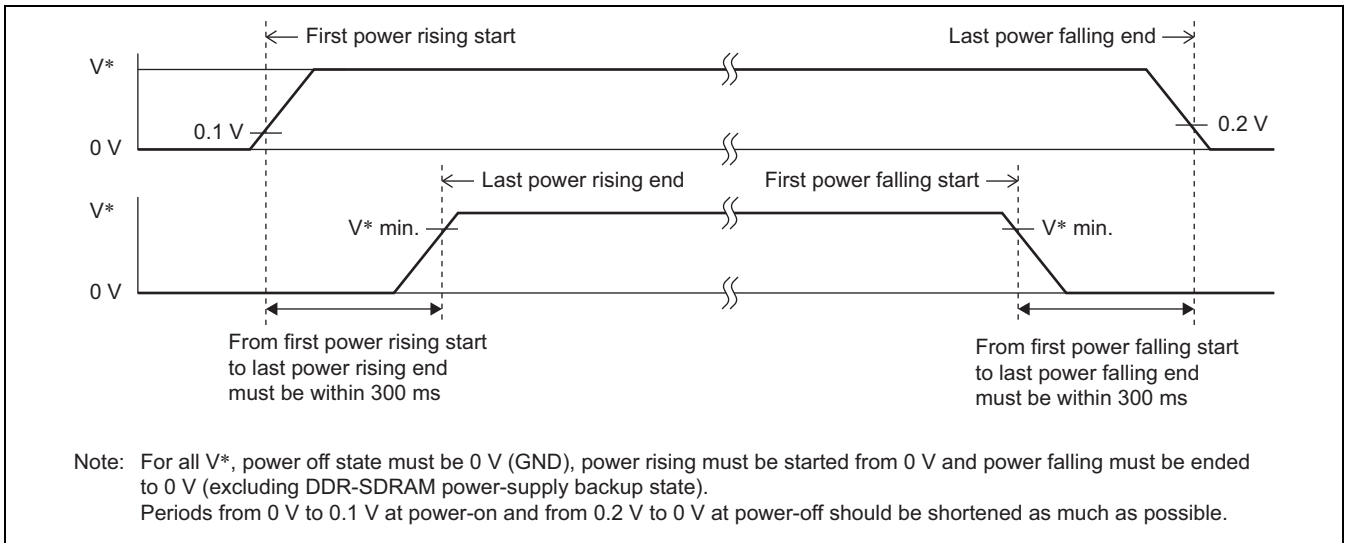

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

This definition is for the different voltage power supply for example between 1.8-V and 3.3-V, it is possible to turn on or off at the same time for the same voltage power supply.

63.3.2 Power On and Power Off Wave Form

<b>RZ/G1H</b>	<b>RZ/G1N</b>
<b>RZ/G1M</b>	<b>RZ/G1E</b>

## 63.4 DC Characteristics

**Table 63.4.1 Supply Current (RZ/G1H and M)**
**RZ/G1H**
**RZ/G1M**

Conditions: Each power supply and ground are separated, ground is 0 V respectively,  
 T<sub>c</sub> = -40 to +105 °C (-20 to +105 °C for SDR104 only).

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
Supply current (internal)	Normal	IDD	—	—	5300	mA	VDD = 1.08 V [H]
					3600	mA	VDD = 1.08 V [M]
Supply current (internal)	Normal	IDD_DVFS	—	—	11200	mA	VDD_DVFS = 1.08 V [H]
					5500	mA	VDD_DVFS = 1.08 V [M]
Supply current (3.3-V I/O)	Normal	ICCQ	—	—	100	mA	VCCQ = 3.6 V Local bus Access only case Current from/to external load is not included.
Supply current (3.3-V I/O)	Normal	ICCQ33_MLBP	—	—	80.0	mA	VCCQ33_MLBP = 3.6 V
Supply current (3.3-V I/O [SDHI])	Normal	ICCQ_SD0	—	—	18.0	mA	VCCQ_SD = 3.6 V
		ICCQ_SD1 (H only)	—	—	18.0		
		ICCQ_SD2	—	—	18.0		
		ICCQ_SD3	—	—	18.0		
Supply current (1.8-V I/O [VCCQ_ISO])	Normal	ICCQ_ISO	—	—	78	mA	VCCQ_ISO = 1.90 V
Supply current (1.8-V I/O)	Normal	ICCQ18	—	—	30	mA	VCCQ18 = 1.90 V
Supply current (1.8-V I/O)	Normal	ICCQ18_MLBP	—	—	10.0	mA	VCCQ18_MLBP = 1.90 V
Supply current (1.8-V I/O [SDHI] (SDR50, SDR104))	Normal	ICCQ_SD0	—	—	30	mA	VCCQ_SD = 1.90 V T <sub>c</sub> = -20 to +105 °C for SDR104 (SDR104: SD0 only)
		ICCQ_SD1 (H only)	—	—	30		
		ICCQ_SD2	—	—	30

**Table 63.4.9 DC Characteristics (I2C/IIC open-drain 1.8-V I/O)**

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
External pull-up voltage	VPU18	1.7	1.8	1.9	V	—	I2Cn_SCL/SDA and IICm_SCL/SDA pins (I2C/IIC open-drain assigned channels)* <sup>1</sup>
	VPU33	3.0	3.3	3.6	V	3.3 V tolerant* <sup>2</sup>	
Input high voltage	VIH	VCCQ18 × 0.7	—	VPU18 + 0.3	V	—	
		VCCQ18 × 0.7	—	VPU33 + 0.3	V	3.3 V tolerant* <sup>2</sup>	
Input low voltage	VIL	-0.3	—	0.3 × VCCQ18	V	—	
Output low voltage	VOL	—	—	0.2 × VCCQ18	V	IOL = 2 mA	
		—	—	0.4	V	IOL = 3 mA, 3.3 V tolerant* <sup>2</sup>	
Output low current	IOL	3	—	—	mA	VOL = 0.4 V 3.3 V tolerant* <sup>2</sup>	

Notes: 1. Available OD channel number of each product is as follows:

[H] n=0 and 3, m=0 and 3

[M, N] n=5, m=3

[E] m=1 (n: not available).

For details of I2C and IIC channel and the output buffer type relation, refer to section 44, I2C and section 45, IIC in the manual.

2. When using 1.8V I2C/IIC pins as 3.3 V tolerant, all the VPU33 power supply for the I2C/IIC of this LSI must keep the same power on/off sequence as the VCCQ of this LSI.

RZ/G1H

RZ/G1E

**Table 63.4.10 DC Characteristics (1.5-V I/O [DDR3])**

DDR3 channel 1 is available for H (VDDQ\_M1, M1xxx signals)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage (MDQ pin)	VIH	VREF + 0.1	—	—	V	VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	M0DQ, M0DQS, M1DQ, and M1DQS pins
Input low voltage (MDQ pin)	VIL	—	—	VREF - 0.1	V		
Input high voltage	VIH	0.7 × VDDQ_M0, VDDQ_M1	—	—	V	VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	M0BKPRST# and M1BKPRST# pins
Input low voltage	VIL	—	—	0.3 × VDDQ_M0, VDDQ_M1	V		
Differential input reference voltage	VREF	0.49 × VDDQ_M0, VDDQ_M1	0.50 × VDDQ_M0, VDDQ_M1	0.51 × VDDQ_M0, VDDQ_M1	V	VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	*1
DC differential input voltage	VIHD	0.2	—	—	V	M0DQS = M1DQS = H, VIN = VDDQ_M0, VDDQ_M1/2 VDD = 1.0 V <sub>typ</sub> , VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	M0DQS and M1DQS pins
DC differential input voltage	VILD	—	—	-0.2	V	M0DQS = M1DQS = L, VIN = VDDQ_M0, VDDQ_M1/2, VDD = 1.0 V <sub>typ</sub> , VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	
DC differential input voltage	VIN	0.35	—	-0.35	V	VIHD = 200 mV or VILD = -200 mV, VDD = 1.0 V <sub>typ</sub> , VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	
Input high voltage (AC)	VIH (AC)	VREF - 0.175	—	—	V	—	—
Input low voltage (AC)	VIL (AC)	—	—	VREF + 0.175	V	—	—

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
AC differential input cross point voltage	VIX (AC)	0.5 × VDDQ_M0, VDDQ_M1 - 0.15	—	0.5 × VDDQ_M0, VDDQ_M1 + 0.15	V	VDDQ_M0 = VDDQ_M1 = 1.425 to 1.575 V	M0DQS and M1DQS pins *2
AC differential output cross point voltage	VOX (AC)	VREF - 0.125	—	VREF + 0.125	V	—	M0CK, M0DQS, M1CK, and M1DQS pins (PU,PD not used, 5.5kohm used, 500ohm used)
High Hi-Z leak current	IOZH	—	—	4	μA	—	Other than M0ZQ and M1ZQ pins
Low Hi-Z leak current	IOZL	-4	—	—	μA	—	
High Hi-Z leak current	IOZH	—	—	5	μA	—	M0ZQ and M1ZQ pins
Low Hi-Z leak current	IOZL	-5	—	—	μA	—	
Pin capacitance	CL	—	—	15	pF	—	All pins*3
PLL power supply	*4	1.62	1.8	1.98	V	—	—

- Notes: 1. Peak to peak ac noise on VREF may not exceed ±2 % of VREF.  
 2. The VIX (AC) indicates the voltage at which differential input signals cross each other. The typical value of VIX (AC) is expected to be 0.5 × VDDQ\_M0, VDDQ\_M1.  
 3. Except power supply pins.  
 4. VDDQ\_M0APLL, VDDQ\_M1APLL, VDDQ\_M1MPLL, VDDQ\_M0DPLL0 to VDDQ\_M0DPLL3 pins.

EXHSYNC# input high level width	tEXHHW	4tDCYC	—	—	ns	
EXVSYNC# input low level width	tEXVLW	3HC	—	—	tDCYC	
ODDF# setup time 1*4	tOD1	(ys+yw) × HC	—	—	tDCYC	
ODDF# setup time 2*4	tOD2	1HC	—	—	tDCYC	

Notes: 1. For correspondence between these signals and pin names, refer to Table 63.8.3.

2. Clock signal is input from DOTCLKIN and then output from DOTCLKOUT without being frequency-divided.

3. This electrical characteristic is applicable when the DR0D bit (bit 21) in the display output control register (DORCR) is set to 1. When the DR1D bit is cleared to 0, this characteristic is the same as the display digital data output delay time (tDD). Min value of tDCYC will be twice. This electrical characteristic applies to only DU0 output.

4. ys, yw and HC in Min value of ODDF# setup time 1 and ODDF# setup time 2 (tOD1 and tOD2);

ys: From rise of VSYNC to display start position in the vertical direction of the display screen (unit: raster line)

yw: Vertical display period of display screen (unit: raster line)

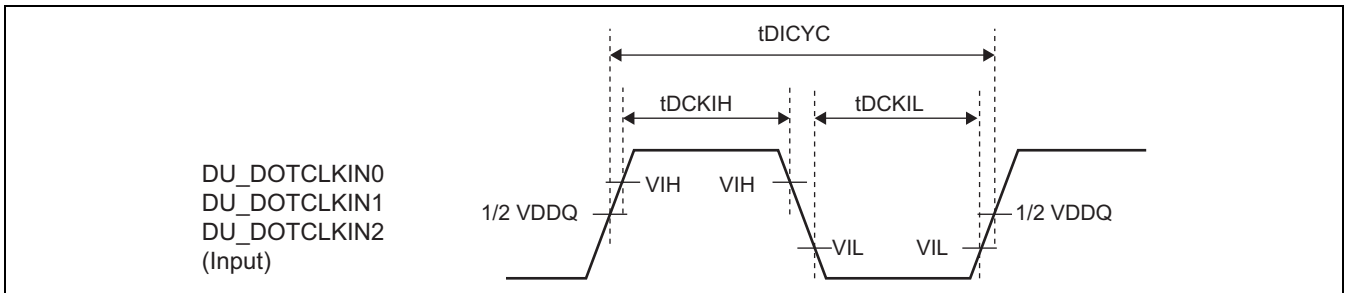

HC: Horizontal scan period (unit: dot clock)

ETH_RX_ER setup time	$t_{RRERS}$	4	—	—	ns	Figure 63.12.3
ETH_RX_ER hold time	$t_{RRERH}$	2.5	—	—	ns	

**Figure 63.12.1 RMII Transmission Timing**

**Figure 63.12.2 RMII Reception Timing (Normal Operation)**

**Figure 63.12.3 RMII Reception Timing (Case When Error Occurs)**

**(1) ETH\_MDC (Management Data Clock) timing specification (setup time and hold time)**

Although ETH\_MDC is a reference clock for the serial management interface (SMI), ETH\_MDC input setup time and ETH\_MDC input hold time are not specified.

**(2) ETH\_MDIO (Management Data Input/Output) timing provision (setup time and hold time)**

The AC specifications for the SMI (PHY side) from the IEEE are as follows:

ETH\_MDC input cycle  $\geq 400$  ns.

ETH\_MDC input pulse width at each level  $\geq 160$  ns

ETH\_MDIO input setup and hold times  $\geq 10$  ns (PHY latches the MAC output on rising edges of ETH\_MDC).

ETH\_MDIO output delay time = 0 to 300 ns (delay time from a rising edge of ETH\_MDC)

The ETH\_MDC output, ETH\_MDIO output, and ETH\_MDIO input latching depend on software adjusting settings in the PHY interface register (PIR). Adjust the ETH\_MDC output (period) and ETH\_MDIO output (timing of changes) to satisfy the AC input specs on the PHY side. To adjust the timing of ETH\_MDIO input latching, consider the AC output specifications on the PHY side.

Spike pulse width suppressed by the input filter	t <sub>SP</sub>	—	—	0	50	ns	

- Notes. 1. All values are referenced at VCCQ × 0.3 and VCCQ × 0.7 levels.  
 2. To satisfy the I2C-bus specification, pull-up resistors (R<sub>p</sub>) with the appropriate resistance must be included depending on the total of bus capacitive load of each line.  
 Pull-up resistor range should be following, refer Table 63.19.2.  
 $R_{p(max)} = t_r / (0.8473 \times C_b)$   
 $R_{p(min)} = (VCCQ - V_{OL(max)}) / I_{OL}$   
 3. The total capacity (C<sub>b</sub>) should be less than or equal to 100 pF

Notes: t<sub>MMCφ</sub> is for one cycle of MMCxφ.

\* Set 1 to the ODTS bit of CE\_ODATSEL (data output phase select register) for this specification.

### Limitation of Transfer Performance for MMC

When the MMC module of the RZ/G series products operates with all of the following condition 1 to 3, the transfer performance of the MMC interface is limited up to 35 MB/s at MMC\_CLK = 48.75 MHz by the internal latency.

#### Condition

- 1) MMC transfer data size is over 1024 bytes.
- 2) MMC dedicated RAM (1024 bytes) all data has been transferred.
- 3) MMC continues data transfer after 1024 bytes of dedicated RAM data transferred.

The MMC\_CLK stops by each 512 bytes transfer. If this becomes a problem for the external device, set the MMC\_CLK frequency less than 35.45 MHz (i.e., 35.45 MB/s) by CE\_CLK\_CTRL.CLKDIV [3:0].

For details, refer to section 49.4.2, Limitation of Transfer Performance.

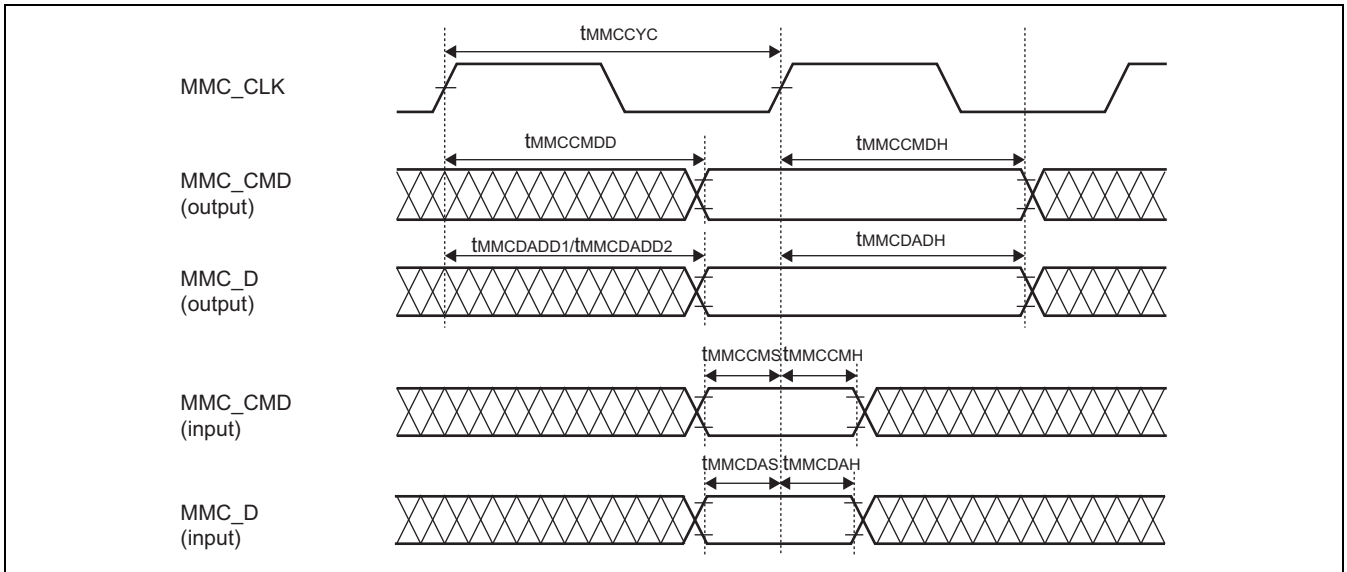

Figure 63.22.1 MMC Signal Timing

## 63.23 Serial ATA (Gen2)

RZ/G1H

RZ/G1N

RZ/G1M

RZ/G1E

The description in this section is compliant with the following Serial ATA standard:  
'Serial ATA International Organization: Serial ATA Revision 3.1, July 18, 2011'.

**Table 63.23.1 Serial ATA (Gen2) Interface Characteristics (RZ/G1H, M and N)**

Conditions: VDDA\_SATA0/1 = 1.8 V, VDDD\_SATA0/1 = 1.03 V, VSS\_SATA0/1 = GND = 0 V, Tc = -40 to +105°C

Test Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
RX Differential Input Voltage (Gen1i)	Vdiff RX	325	—	600	mVppd	*1
RX Differential Input Voltage (Gen2i)	Vdiff RX	275	—	750	mVppd	*1

# Appendix A. Product Register (PRR)

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

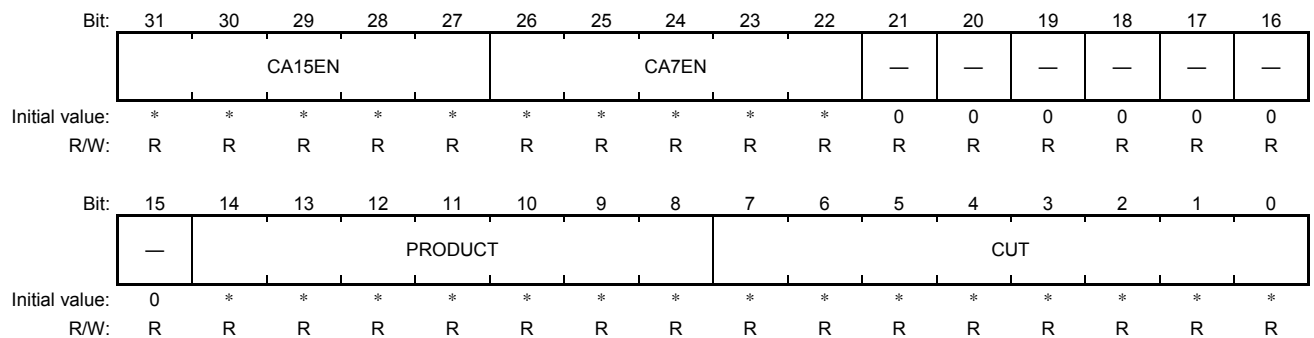

## A.1 Overview

PRR indicates the product version and which of the ARM Cortex cores is present.

## A.2 Register Descriptions

The following describes the details of the product register (PRR).

Register Name	Abbreviation	R/W	Address	Initial Value (Power-On Reset by PRESET# Pin)	Initial Value (Software Reset)	Access Size	RZ/G Series Products			
							RZ/G1H	RZ/G1M	RZ/G1N	RZ/G1E
Product register	PRR	R	H'FF00 0044	*	*	32 bits	√	√	√	√

Note: \* The settings of these bits are explained overleaf. Except in the RZ/G1E, where bits 31 to 27 are fixed, and the RZ/G1M, and N, where bits 26 to 22 are fixed, they depend on the product and the configuration you have ordered. Bits for processors that are never present in a given product are read as 1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	CA15EN	It depends on the product. See the description.	R	<p>Cortex-A15 CPU State</p> <p>[RZ/G1H]</p> <p>Bit 31 Cortex-A15 State</p> <p>0: The product has four Cortex-A15 CPUs. 1: The product does not have four Cortex-A15 CPUs.</p> <p>Bit 30 Cortex-A15 CPU3 State</p> <p>0: The product has Cortex-A15 CPU3. 1: The product does not have Cortex-A15 CPU3.</p> <p>Bit 29 Cortex-A15 CPU2 State</p> <p>0: The product has Cortex-A15 CPU2. 1: The product does not have Cortex-A15 CPU2.</p> <p>Bit 28 Cortex-A15 CPU1 State</p> <p>0: The product has Cortex-A15 CPU1. 1: The product does not have Cortex-A15 CPU1.</p> <p>Bit 27 Cortex-A15 CPU0 State</p> <p>0: The product has Cortex-A15 CPU0. 1: The product does not have Cortex-A15 CPU0.</p> <p>[RZ/G1M/N]</p> <p>Bit 31 Cortex-A15 State</p> <p>0: The product has two Cortex-A15 CPUs. 1: The product does not have two Cortex-A15 CPUs.</p> <p>Bit 30 Reserved. The read value is always 1.</p> <p>Bit 29 Reserved. The read value is always 1.</p> <p>Bit 28 Cortex-A15 CPU1 State</p> <p>0: The product has Cortex-A15 CPU1. 1: The product does not have Cortex-A15 CPU1.</p> <p>Bit 27 Cortex-A15 CPU0 State</p> <p>0: The product has Cortex-A15 CPU0. 1: The product does not have Cortex-A15 CPU0.</p> <p>[RZ/G1E]</p> <p>Bit 31 Reserved. The read value is always 1.</p> <p>Bit 30 Reserved. The read value is always 1.</p> <p>Bit 29 Reserved. The read value is always 1.</p> <p>Bit 28 Reserved. The read value is always 1.</p> <p>Bit 27 Reserved. The read value is always 1.</p>

Bit	Bit Name	Initial Value	R/W	Description
26 to 22	CA7EN	It depends on the product. See the description.	R	<p>Cortex-A7 CPU State</p> <p>[RZ/G1H]</p> <p>Bit 26 Cortex-A7 State</p> <p>0: The product has four Cortex-A7 CPUs. 1: The product does not have four Cortex-A7 CPUs.</p> <p>Bit 25 Cortex-A7 CPU3 State</p> <p>0: The product has Cortex-A7 CPU3. 1: The product does not have Cortex-A7 CPU3.</p> <p>Bit 24 Cortex-A7 CPU2 State</p> <p>0: The product has Cortex-A7 CPU2. 1: The product does not have Cortex-A7 CPU2.</p> <p>Bit 23 Cortex-A7 CPU1 State</p> <p>0: The product has Cortex-A7 CPU1. 1: The product does not have Cortex-A7 CPU1.</p> <p>Bit 22 Cortex-A7 CPU0 State</p> <p>0: The product has Cortex-A7 CPU0. 1: The product does not have Cortex-A7 CPU0.</p> <p>[RZ/G1M/N]</p> <p>Bit 26 Reserved. ## Appendix B. Sequence of Activation for RZ/G Series Products

RZ/G1H	RZ/G1N
RZ/G1M	RZ/G1E

The following describes the initialization sequence of a RZ/G series product.

### (1) Selection of Master Boot Processor and External Boot Device

Select the master boot processor by placing the required levels on the MD6 and MD7 pins and external boot device by placing the required levels on the MD1, MD2, and MD3 pins before booting up the LSI. For details, see section 18, Booting.

Note: The following steps from (2) to (6) are not included in the sequence described in section 18, Booting because these steps are not relevant to booting. Note, however, that steps (2) to (6) must be executed before restoring the power supply to modules, including CPUs other than the master boot processor, to which the power has been cut off.

### (2) Stopping the RWDT

To prevent the watchdog timer issuing an unexpected reset or interrupt while the activation sequence is in progress, be sure to disable the RCLK watchdog timer (RDWT). Enable their operation at an appropriate time after the activation sequence is completed. For details, see section 8, Reset (RST), section 11, Interrupt Controller for AP-System Core (INTC-SYS), and section 55, RCLK Watchdog Timer.

Notes: 1. Use the RWTCSSRA register to disable the RWDT.  
2. Currently, the reset and interrupt signals caused by the watchdog timer overflowing are initially masked in RZ/G series products. Accordingly, this step of disabling the watchdog timers within the activation sequence is not mandatory. However, this step is implemented in the sample driver to ensure that they are masked.

### (3) Selecting the Functions of Multiplexed Pins

When a pin function other than that selected by the initial setting is to be used, set the relevant registers in the pin function controller (PFC). Note that, before setting these registers, the LSI multiplexed pin setting register (PMMR) must be appropriately set to prevent incorrect writing to registers. For details, see section 5, Pin Function Controller (PFC).

Note: When a GPIO function different from that selected by the initial setting is to be used, start by setting the GPIO attributes before setting the pin function controller.

### (4) Initial Settings for Operating Frequency Required by the Main Processor, Cache, MMU, and Interrupt Controller

Make initial settings for operating frequency required by the master processor, cache, MMU, and interrupt control. The operating frequencies are set by using the registers FRQCRC (for Cortex-A15), and PLL0CR in the clock pulse generator (CPG). The details of the functional specifications for the CPU required for setting the cache, MMU, and interrupt control are not included in this manual; use the sample driver included in the board support package (BSP).

Note: The FRQCRC register is not present in the RZ/G1E.

### (5) Initial Settings for Local Bus Control

When an external device is to be connected to the local bus (bits MD[3:1] are set to 000), make initial settings for the registers including CSWCR as required before starting access to the external device. For details, see section 14, LBSC within Bus Bridge.

## (6) Initial Settings for Memory Controllers

When a program is to be stored in and run from SDRAM, make initial settings for the required registers in the DBSC3 and S3CTRL modules. For details, see section 15, External Bus Controller for DDR3-SDRAM and section 15A, S3 Cache Controller (S3CTRL).

Note: QoS and split settings in the DBSC3 and S3CTRL modules are also required. For details, use the sample driver included in the board support package (BSP) for reference, as well as referring to the sections of the manual indicated above.

## (7) Settings for Restoring Power Supply to Functional Modules to be Used Immediately after Activation (Other than Cortex-A7 and Cortex-A15)

In the initial state, power may not be supplied to some modules to be used. Accordingly, for modules to be used immediately after activation, set the control registers in the system controller (SYSC) as required and read the status registers to check that the power supply has been restored. For details on the sequence for restoring the power supply, see section 61, System Controller (SYSC).

Note that the power control bits for the snoop control units (SCUs) of Cortex-A15 and Cortex-A7 are available in the SYSC, however, the supply of power to an SCU is automatically restored when the power supply for the respective CPU is separately restored by controlling the registers in the advanced power management unit for AP-system core (APMU). Accordingly, this step in controlling the power supply to the SCUs of Cortex-A15 and Cortex-A7 does not require explicit action.

Notes: 1. Cortex-A15 is not present in the RZ/G1E. Cortex-A7 is not present in the RZ/G1M, and RZ/G1N.  
2. The settings for modules other than those to be used immediately after activation can be made separately before the modules are used.

## (8) Settings for Release from the Module Reset State and the Supply of Clock Signals to Functional Modules to be Used Immediately after Activation (Other than CPUs)

In the initial state, clock signals may not be being supplied to all modules to be used. Accordingly, for modules to be used immediately after activation, set the xxxCKCR registers (xxx represents a module name) for the respective modules in the clock pulse generator (CPG) or set the SMSTPCRn registers (n = 0 to 11) in the module standby and software reset control block of the CPG. For details, see section 7, Clock Pulse Generator (CPG) and section 7A, Module Standby and Software Reset.

Note: The settings for modules other than those to be used immediately after activation can be made separately before the modules are used.

## (9) Setting of Boot Address of the CPU (as Required)

To switch the boot address to an area in the DDR memory to which high-speed access is possible, start by downloading the required program to the specified area and set the starting address for execution in the boot address register (SBAR, or SBAR2) for the relevant CPU. This setting is not required if the boot address is not to be changed. For details, see section 8, Reset (RST).

## (10) Restoring the Power Supply to a CPU Other than the Master Boot Device

Before using a CPU (Cortex-A15 or Cortex-A7) other than the master boot processor, start by checking the PRR register described in Appendix A to confirm which CPU is available for use. If activation of a CPU disabled by the PRR register is attempted, the clock pulse generator may not operate properly.\*<sup>1</sup>

To use a CPU (Cortex-A15 or Cortex-A7) other than the master boot processor, set the Cortex-A7/Cortex-A15 debug resource reset control register (CA7DBGRCR/CA15DBGRCR) in the APMU module and set the relevant control register in the same module to restore the power supply. Then, read the status registers in the APMU and SYSC modules to check whether the power supply has actually been restored. This procedure must be followed for each CPU until restoration of the power supply is confirmed. For details, see section 7B, Advanced Power Management Unit for AP-System Core (APMU), and section 61, System Controller (SYSC).

Notes: Cortex-A15 is not present in the RZ/G1E. Cortex-A7 is not present in the RZ/G1M, and RZ/G1N.

1. This step can be skipped if you already know which CPU is available for use.

#### **(11) Releasing CPUs Other than the Master Boot Processor from the Reset State**

When a CPU (Cortex-A15 or Cortex-A7) other than the master boot processor is to be used, clear the relevant bit in the Cortex-A15/Cortex-A7 reset control register (CA15RESCNT/CA7RESCNT) to 0 to release it from the reset state. To reduce fluctuations in current, release the CPUs from the reset state one at a time.

Note: Cortex-A15 is not present in the RZ/G1E. Cortex-A7 is not present in the RZ/G1M, and RZ/G1N.

This is the end of the required initial settings and all the CPUs to be used will have been activated.

- Notes:
1. There is no particular order for steps (3) to (10) in this sequence, except that the settings in step (5) must be made before step (9).
  2. In consideration of system performance, we recommend making the settings in steps (3) and (4) during the earlier stages of the sequence.
  3. The settings in some steps of this sequence might be re-made by the OS.
