APPLICATION INFORMATION

These modules are designed to be used as the power stage of a three-phase AC induction motor drive. They may be used for up to 460 VAC applications. Switching frequencies up to 15 kHz were considered in the design.

Gate resistance recommendations have been listed. These choices were based on the common gate drive circuit shown in Figure 16. However, significant improvements in E_{off} may be gained by either of two methods: use of a negative gate bias, or use of the gate drive shown in Figure 17. Separate turn-on and turn-off gate resistors give the best results; in this case, $R_{G(off)}$ should be chosen as small as possible while limiting current to prevent damage to the gate drive IC. Designers should also note that turn-on and turn-off delay times are measured from the rising and falling edges of the gate drive output, not the gate voltage waveform.

Since all three modules use similar technology, most of the graphs showing typical performance have been normalized. Actual values are listed for each size in the table, "Electrical Characteristics." Data on the graphs reflect performance using the common gate drive circuit shown in Figure 16.

The first three curves, showing DC characteristics, are normalized for I_{Cmax} . The devices all perform similarly at rated current. The curves extend to $I_{C(pk)}$, the maximum allowable instantaneous current.

The next two graphs, turn-off and turn-on times versus I_C , are also normalized for I_{Cmax} . In addition, the time scales are normalized. Turn-off times are normalized to $t_{d(off)}$ at 25°C at rated current with recommended R_G , while turn-on times are normalized to t_r at 25°C at rated current with recommended R_G .

The graphs showing switching times as a function of R_G are similarly normalized. R_G has been normalized to the rec-

ommended value listed under "Electrical Characteristics." The time axes are normalized exactly as for the corresponding graphs showing variation with I_C .

Similar transformations have been made for the next two figures, showing E_{on} and E_{off} . Energies have been normalized to E_{off} at 25°C at I_{Cmax} with the recommended R_G . I_C has been normalized to I_{Cmax} , and R_G has been normalized to the recommended value.

Reverse recovery characteristics are also normalized. I_C has again been normalized to I_{Cmax} . Reverse recovery time t_{rr} has been normalized to t_{rr} at 25°C at I_{Cmax} . Peak reverse recovery current I_{rrm} has been normalized to I_{rrm} at 25°C at I_{Cmax} , then multiplied by 10.

Capacitance has been normalized to device rated I_{Cmax} . Since all modules are rated for the same voltage, the voltage scale on Figure 11 does not need to be normalized.

Typical transient thermal impedance is shown for a diode and for an IGBT. All diodes behave quite similarly, as do all IGBTs.

The last two graphs, V_{GE} versus Q_G and $RBSOA$, are not normalized.

Many issues beyond the ratings must be considered in a system design. Dynamic characteristics can all be affected by external circuit parameters. For example, excessive bus inductance can dramatically increase voltage overshoot during switching, increasing the switching energy. The choice of gate drive IC can have quite a large effect on rise and fall times, corresponding to differences in switching energies. In many cases, this can be compensated by simply changing the gate resistor accordingly — a gate driver with a lower drive capability requires a smaller gate resistor. Ultimately, the module must be tested in the final system to characterize its performance.
