

# T66H0002A

# 160 output LCD Segment/Common Driver IC

---

## FEATURES

- Number of LCD drive outputs : 160
- Supply voltage for LCD drive :  
+15.0 to +45.0 V
- Supply voltage for the logic system :  
+2.5 to +5.5 V
- Low power consumption
- Low output impedance

## DESCRIPTION

The T66H0002A is a 160-output segment/common driver IC suitable for driving large/medium scale dot matrix LCD panels, and is used in personal computers/work stations. Through the use of SST (Super Slim TCP) technology, it is ideal for substantially decreasing the size of the frame section of the LCD module. The T66H002A is good both as a segment driver and a common driver, and it can create a low power consuming, high resolution LCD.

## Segment mode:

1. Shift clock frequency : 14 MHz (MAX.) (VDD=+5.0V±10%)  
: 8 MHz(MAX.) (VDD=+2.5V~+4.5V)
2. Adopts a data bus system
3. 4-bit/8-bit parallel input modes are selectable with a mode (MD) pin
4. Automatic transfer function of an enable signal
5. Automatic counting function which, in the chip selection mode, causes the internal clock to be stopped by automatically counting 160 bits of input data
6. Line latch circuits are reset when / DISPOFF low active

## Common mode:

- Shift clock frequency : 4 MHz (MAX.)
- Built-in 160-bit bi-directional shift register (divisible into 80 bits x 2)
- Available in a single mode (160-bit shift register) or in a dual mode (80-bit shift register x 2)
  - a. Y1 → Y160 Single mode
  - b. Y160 → Y1 Single mode
  - c. Y1 → Y80, Y81 → Y160 Dual mode
  - d. Y160 → Y81, Y80 → Y1 Dual mode

The above 4 shift directions are pin selectable

**FUNCTIONAL OPERATIONS OF EACH BLOCK**

BLOCK	FUNCTION
Active Control	In case of segment mode, controls the selection or non-selection of the chip. Following and LP signal input, and after the chip selection signal is input, a selection signal is generated internally until 160 bits of data have been read in. Once data input has been completed, a selection signal for cascade connection is output, and the chip is non-selected. In case of common mode, controls the input/output data of bi-directional pins.
SP Conversion & Data Control	In case of segment mode, keeps input data which are 2 clocks of XCK at 4-bit parallel input mode in latch circuit, or keeps input data which are 1 clock of XCK at 8-bit parallel input mode in latch circuit; after that they are put on the internal data 8 bits at a time.
Data Latch Control	In case of segment mode, selects the state of the data latch which reads in the data bus signals. The shift direction is controlled by the control logic. For every 16 bits of data read in, the selection signal shifts one bit based on the state of the control circuit.
Data Latch	In case of segment mode, latches the data on the data bus. The latch state of each LCD drive output pin is controlled by the control logic and the data latch control; 160 bits of data are read in 20 sets of 8 bits.
Line Latch/Shift Register	In case of segment mode, all 160 bits which have been read into the data latch are simultaneously latched at the falling edge of the LP signal, and are output to the level shifter block. In case of common mode, shifts data from the data input pin at the falling edge of the LP signal.
Level Shifter	The logic voltage signal is level-shifted to the LCD drive voltage level, and in output to the driver block.
4-Level driver	Drives the LCD drive output pins from the line latch/shift register data, and selects one of 4 levels( $V_0, V_{12}, V_{43},$ or $V_{ss}$ ) based on the S/C, FR and /DISPOFF signals.
Control Logic	Controls the operation of each block. In case of segment mode, when an LP signal has been input, all blocks are rest and the control logic waits for the selection signal output from the active control block. Once the selection signal has been output, operation of the data latch and data transmission is controlled, 160 bits of data are read in , and the chip in non-selected. In case of common mode, controls the direction of data shift.

## PRECAUTIONS

### Precautions when connecting or disconnecting the power supply

This IC has a high-voltage LCD driver, so it may be permanently damaged by high current which may flow if voltage is supplied to the LCD drive power supply while the logic system power supply is floating. The details are as follows.

- When connecting the power supply, connect the LCD drive power after connecting the logic system power. Furthermore, when disconnecting the power, disconnect the logic system power after disconnecting the LCD drive power.
- It is advisable to connect the serial resistor (50 to 100  $\Omega$ ) or fuse to the LCD drive power  $V_0$  of the system as a current limiter. Set up a suitable value of the resistor in consideration of the display grade.

And when connecting the logic power supply, the logic condition of this IC inside is insecure. Therefore connect the LCD drive power supply after resetting logic condition of this IC inside on /DISPOFF function. After that, cancel the /DISPOFF function after the LCD drive power supply has become stable. Furthermore, when disconnecting the power, set the LCD drive output pins to level  $V_s$  on /DISPOFF function. Then disconnect the logic system power after disconnecting the LCD drive power. When connecting the power supply, follow the recommended sequence shown here.
