Notes

1. All voltages referenced to V_{SS} .
2. This parameter is sampled. V_{CC} , $V_{CCQ} = +3.3V$; $T_A = 25^\circ C$; pin under test biased at 1.4V; $f = 1$ MHz.
3. I_{DD} is dependent on output loading and cycle rates. Specified values are obtained with mini-mum cycle time and the outputs open.
4. Enables on-chip refresh and address counters.
5. The minimum specifications are used only to indicate cycle time at which proper operation over the full temperature range is ensured.
6. An initial pause of $100\mu s$ is required after power-up, followed by two AUTO REFRESH commands, before proper device operation is ensured. (V_{CC} and V_{CCQ} must be powered up simultaneously. V_{SS} and V_{SSQ} must be at same potential.) The two AUTO REFRESH command wake-ups should be repeated any time the tREF refresh requirement is exceeded.
7. AC characteristics assume $t_r = 1$ ns.
8. In addition to meeting the transition rate specification, the clock and CKE must transit between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}) in a mono-tonic manner.
9. Outputs measured at 1.5V with equivalent load:

10. t_{HZ} defines the time at which the output achieves the open circuit condition; it is not a reference to V_{OH} or V_{OL} . The last valid data element will meet t_{OH} before going High-Z.
11. AC timing and I_{DD} tests have $V_{IL} = 0V$ and $V_{IH} = 3V$ with timing referenced to 1.5V crossover point. If the input transition time is longer than 1ns, then the timing is referenced at $V_{IL} (MAX)$ and $V_{IH} (MIN)$ and no longer at the 1.5V crossover point.
12. Other input signals are allowed to transition no more than once every two clocks and are other-wise at valid V_{IH} or V_{IL} levels.
13. I_{DD} specifications are tested after the device is properly initialized.

14. Timing actually specified by t_{CKS} ; clock(s) specified as a reference only at minimum cycle rate.
15. Timing actually specified by t_{WR} plus t_{RP} ; clock(s) specified as a reference only at minimum cycle rate.
16. Timing actually specified by t_{WR} .
17. Required clocks are specified by JEDEC functionality and are not dependent on any timing parameter.
18. The I_{DD} current will increase or decrease proportionally according to the amount of frequency alteration for the test condition.
19. Address transitions average one transition every two clocks.
20. CLK must be toggled a minimum of two times during this period.
21. Based on $t_{CK} = 10$ ns for 10, and $t_{CK} = 7.5$ ns for 7 and 7.5.
22. V_{IH} overshoot: $V_{IH} (MAX) = V_{CCQ} + 2V$ for a pulse width ≤ 3 ns, and the pulse width cannot be greater than one third of the cycle rate. V_{IL} under-shoot: $V_{IL} (MIN) = -2V$ for a pulse width ≤ 3 ns.
23. The clock frequency must remain constant (stable clock is defined as a signal cycling within timing constraints specified for the clock pin) during access or precharge states (READ, WRITE, including t_{WR} , and PRECHARGE commands). CKE may be used to reduce the data rate.
24. Auto precharge mode only. The precharge timing budget (t_{RP}) begins 7ns for 7; 7.5ns for 7.5 and 7.5ns for 10 after the first clock delay, after the last WRITE is executed. May not exceed limit set for precharge mode.
25. Precharge mode only.
26. JEDEC and PC133, PC100 specify three clocks.
27. t_{AC} for 7/7.5 at CL = 3 with no load is 4.6ns and is guaranteed by design.
28. Parameter guaranteed by design.
