

## ■ General Description

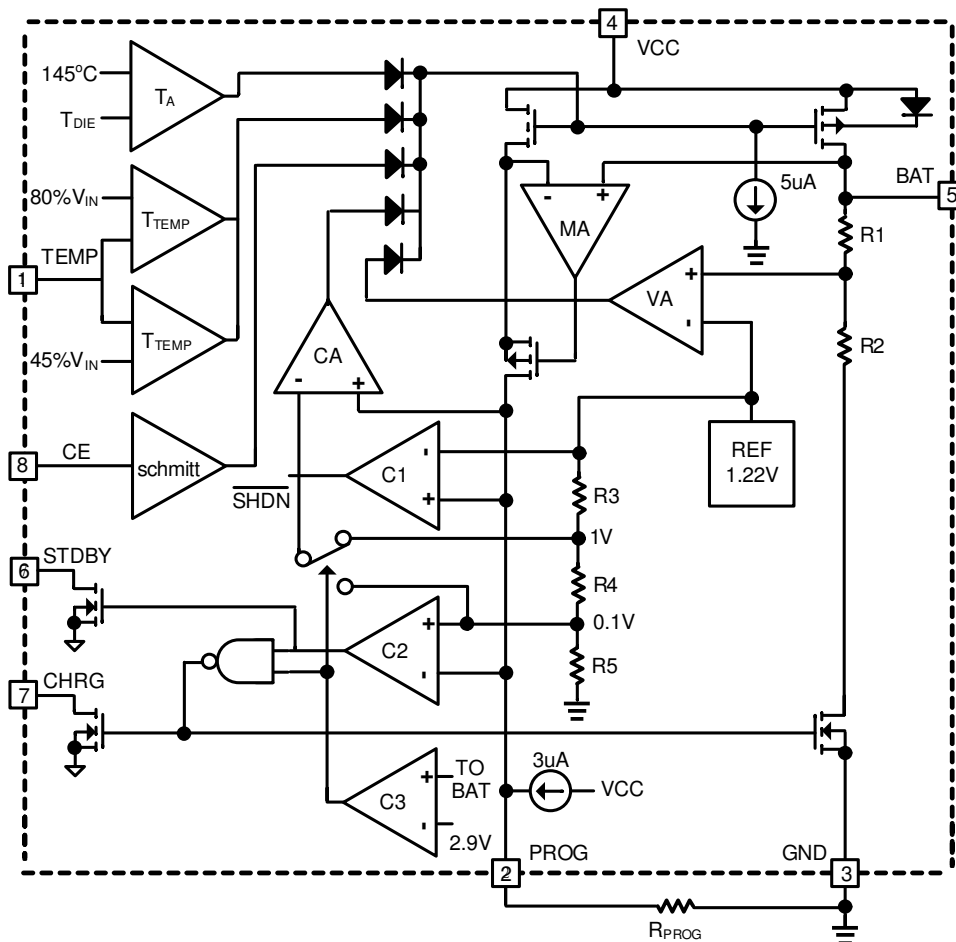

The AME2056 is constant-current/constant-voltage linear charger IC for single cell lithium-ion batteries. The battery charge termination voltage is fixed at 4.2V, the charge current can be programmed an external resistor up to 1000mA(Max.). In the trickle charge mode, the trickle charge voltage is 2.9V that automatically terminates the charge cycle when the charge current drops to 1/10 the programmed value after the final float voltage is reached. Other features includes Thermal Shutdown, Soft-start Function, Battery temperature detector, under-voltage lockout, automatic recharge and two Status indication for Charge Status, no battery and battery failure indicators.

## ■ Applications

- Charging docks, charging cradles
- Low Cost and Small Size Chargers
- Cellular phones

## ■ Features

- Standalone Li-Ion Battery Charging
- Programmable Charge Current
- Charge Termination Voltage: 4.2V(Typ.)
- Trickle Charge Voltage: 2.9V(Typ.)
- Standby Current: 55 $\mu$ A(Typ.)
- No Sense Resistor or Blocking Diode Required
- Constant-current/constant-voltage Operation
- Automatic Recharge
- Battery temperature Detector
- C/10 Charge Termination
- Two Status indication for Charge Status, no battery and battery failure indicators
- Soft-start Function
- Thermal Shutdown
- Available in SOP-8/PP, MSOP-8, SOT-25, TSOT-25A and DFN-8D(2x2x0.75mm) Package
- Green Products Meet RoHS Standards

## ■ Detailed Description

The AME2056 is a linear battery charger designed for single cell lithium-ion batteries. The charger has CC/CV modes with programmable charging current. Charging current is programmed by an external resistor. No blocking diode or external sense resistor are required.

### State Diagram of A Typical Charge Cycle

A charge cycle starts when the  $V_{CC}$  pin voltage rises above the UVLO threshold. If the voltage at BAT pin is smaller than 2.9V, the charger is operating in trickle mode. AME2056 supplies 1/10 programmed current to the battery. When the BAT pin voltage is greater than 2.9V, the charger enters constant-current mode. The charger supplies the programmed current to the battery. When the voltage at BAT pin approaches the float voltage (4.2V), the charger operates in constant-voltage mode and the charging current is decreased. A charge cycle is terminated when the charging current drops below 1/10 programmed current after the float voltage is reached. When the charging current falls below 1/10 programmed charging current for longer than  $T_{TERM}$  (1.8ms), charging is terminated. The AME2056 enters in standby mode.

### Setting Charge Current

The charging current can be programmed by a resistor connected from the PROG pin to ground. The battery charging current is 1200 times the PROG pin flowing out current. The value of required resistor can be calculated by the following equation:

$$R_{PROG} = \frac{1200}{I_{CHG(MAX)}}$$

The instantaneous charging current provided to the battery can be determined by monitoring the PROG pin voltage with the following equation:

$$I_{CHG} = \frac{1200}{R_{PROG}}$$

**Charge status indicator**

AME2056 has two status indicators  $\overline{\text{CHRG}}$  and  $\overline{\text{STDBY}}$ . When the charger is operating in charging status, the  $\overline{\text{CHRG}}$  and  $\overline{\text{STDBY}}$  outputs enter strong pull-down and high impedance status, respectively. If the battery is in full status, the  $\overline{\text{CHRG}}$  and  $\overline{\text{STDBY}}$  outputs enter high impedance and strong pull-down, respectively. When the TEMP pin voltage is greater than  $V_{\text{TEMP-H}}$  or lower than  $V_{\text{TEMP-L}}$ , the  $\overline{\text{CHRG}}$  and  $\overline{\text{STDBY}}$  outputs enter high impedance.

When the TEMP pin is short to ground for disable the temperature protection and the battery is not to connect BAT pin, the light of  $\overline{\text{CHRG}}$  and  $\overline{\text{STDBY}}$  are flicker and bright, respectively.

Charger's Status	Red led $\overline{\text{CHRG}}$	Green led $\overline{\text{STDBY}}$
Charging	light	dark
Battery in full state	dark	light
Under-voltage, battery's temperature is to high or too low, or not connect to battery(use TEMP)	dark	dark
BAT pin is connected to 10uF capacitor, No battery mode (TEMP=GND)	Green LED bright, Red LED flicker	

**Thermal Protection**

The internal thermal feedback loop of AME2056 reduces the charging current when the die temperature rises above approximately 145°C. The function protects the AME2056 from excessive temperature and allow user to push the limits of the power handing capability without risk of damaging AME2056.

### Battery Temperature Fault Monitoring

In the battery over-temperature condition, the charger will turn off the internal pass device. Two internal compared voltage references  $V_{TEMP-H}$  and  $V_{TEMP-L}$  are  $80\% \times V_{CC}$  and  $45\% \times V_{CC}$ , respectively. When the voltage at TEMP pin rises above  $V_{TEMP-H}$  or falls below  $V_{TEMP-L}$ , AME2056 stops charging. After the system recover from a temperature fault, the charger will resume operation. If applications do not need the function, short the TEMP pin to ground.

The resistance of R1 and R2 are set according to the battery temperature range and the value of thermal sensitive resistor. Assume the battery is equipped with NTC thermistor and the temperature range is  $T_L$  to  $T_H$  ( $T_L < T_H$ ). The thermistor resistance  $R_T$  decreases as temperature increases from  $T_L$  to  $T_H$ .

The TEMP pin voltage can be calculated as:

$$V_{TEMP} = \frac{R2 // R_T}{R1 + R2 // R_T} \times V_{CC}$$

The  $V_{TEMP}$  decreases as the temperature increase from  $T_L$  to  $T_H$ .

R1 and R2 resistance are set for temperature:

$$0.8 \times V_{CC} = V_{TEMP-H} = \frac{R2 // R_{TL}}{R1 + R2 // R_{TL}} \times V_{CC} \quad \text{at } T_L$$

$$0.45 \times V_{CC} = V_{TEMP-L} = \frac{R2 // R_{TH}}{R1 + R2 // R_{TH}} \times V_{CC} \quad \text{at } T_H$$

Where  $R_{TL}$  and  $R_{TH}$  are the thermistor resistances at  $T_L$  and  $T_H$ , respectively.

The R1 and R2 can be derived as following:

$$R_1 = \frac{R_{TL} \times R_{TH} \times (0.8 - 0.45)}{(R_{TL} - R_{TH}) \times 0.8 \times 0.45}$$

$$R_2 = \frac{R_{TL} \times R_{TH} \times (0.8 - 0.45)}{R_{TL} \times (0.45 - 0.8 \times 0.45) - R_{TH} \times (0.8 - 0.8 \times 0.45)}$$

### Under Voltage Lockout (UVLO)

The AME2056 incorporates an under voltage lockout circuit to keep the device disabled when  $V_{CC}$  is below the UVLO rising threshold voltage. Once the UVLO rising threshold voltage is reached, the device start-up begins. The device operates until  $V_{CC}$  falls below the UVLO falling threshold voltage. The typical hysteresis in the UVLO comparator is 200mV.

### Manual Shutdown

The AME2056 can be shutdown by removing RPROG or pull the CE pin to the low-level voltage. A new charge cycle is restarted by reconnecting the program resistor or pulling the CE pin to high-level voltage.

### Automatic Recharge

After the charge cycle is terminated, the AME2056 monitors the BAT pin voltage by a comparator with a 1.8ms filter time ( $T_{RECHARGE}$ ). When the BAT pin voltage drops below 4.1V, a charge cycle restarts. The function can keep the battery near a fully charged condition.

### Stability Considerations

In constant-current mode, the feedback loop includes the PROG pin. Because of the additional pole created by the PROG pin capacitor and resistor. The equivalent capacitance on this pin must be kept to minimum for the maximum allowed program resistor. The pole frequency created by the PROG pin should be kept above 100kHz. When the PROG pin is loaded with a capacitor, CPROG, the following equation can be used to calculate the maximum resistance.

$$R_{PROG} \leq \frac{1}{2 \times \pi \times 10^5 \times C_{PROG}}$$

Generally, the average battery current may be of interest to the user rather than instantaneous current. A simple RC filter can be used on the PROG pin to measure the average battery current as shown in Figure 1. A 10K resistor has been added between the PROG pin and the filter capacitor to ensure stability.

Figure 1

**Power Dissipation**

AME2056 has thermal feedback protection to reduce the charging current in overload condition, so the power dissipation is required to consider. The power dissipation definition is:

$$P_D = (V_{CC} - V_{BAT}) \times I_{BAT}$$

Where  $P_D$  is power dissipated,  $V_{CC}$  is the input supply current,  $V_{BAT}$  is the battery voltage and  $I_{BAT}$  is the charge current.

AME2056 will automatically reduce the charging current to maintain the die temperature under 145°C approximately, so it is not necessary to check maximum power dissipation. The ambient temperature of thermal feedback protection is:

$$T_A = 145^\circ C - P_D \times \theta_{JA} = 145^\circ C - (V_{CC} - V_{BA}) \times \theta_{JA}$$

For example: AME2056 operating from a 5V power providing 0.8A to a 3.75V Li-Ion battery. The maximum ambient temperature which the AME2056 operates in 0.8A condition can be calculated:

$$T_A = 145^\circ C - (5V - 3.75V) \times 0.8A \times 84^\circ C/W = 57^\circ C$$

The AME2056 can be used above 57°C, but the charging current will be reduced below 0.8A. The charging current can be calculated:

$$I_{BAT} = \frac{145^\circ C - T_A}{(V_{CC} - V_{BAT}) \times \theta_{JA}}$$

According to the previous example with ambient temperature of 90°C, the charging current is reduced to:

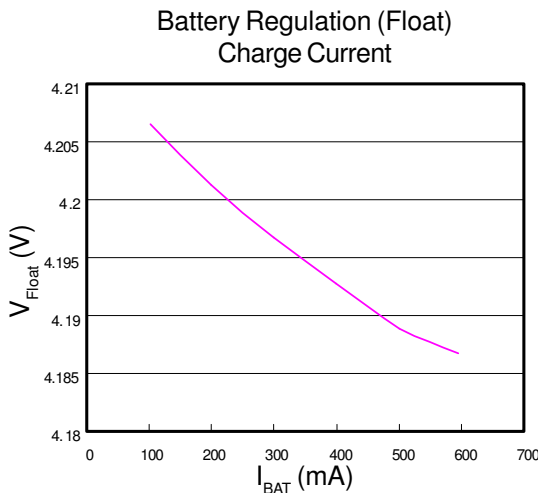

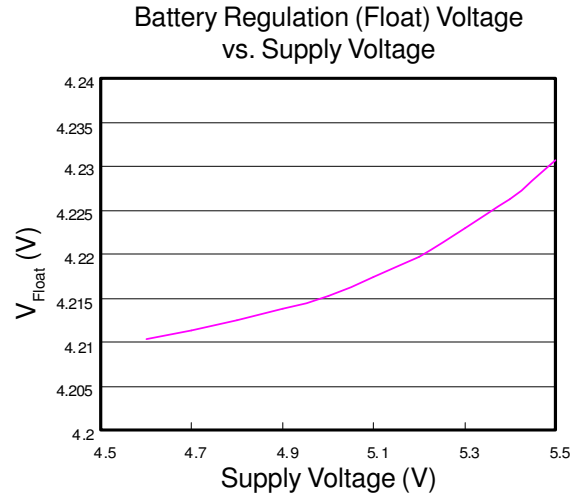

$$I_{BAT} = \frac{145^\circ C - 90^\circ C}{(5 - 3.75) \times 84} = 524mA$$

**Layout Consideratons**

The good thermal conduction PCB layout is very important to apply to maximize the available charging current. The thermal path is from the die to the PCB. The PCB is the heat sink. The copper pads footprint should be as large as possible and expand out to large copper areas to spread and dissipate the heat to the ambient. Other heat source must be considered when designing a PCB layout because they will affect overall temperature rise and maximum charging current.

**V<sub>cc</sub> Bypass Capacitor**

Many types of capacitors can be used as input bypass capacitor. However, the high voltage transients can be generated under some start-up conditions when using the self-resonant and high Q characteristics of ceramic capacitors. Adding a 0.4Ω resistor in series with an X5R ceramic capacitors will minimize start-up voltage transients.
