

2.5V or 3.3V, 200-MHz, 12-Output Zero Delay Buffer

Features

- Output frequency range: 8.33MHz to 200MHz
- Input frequency range: 6.25MHz to 125MHz
- 2.5V or 3.3V operation
- Split 2.5V / 3.3V outputs
- $\pm 2\%$ (max) Output duty cycle variation
- 12 Clock outputs: drive up to 24 clock lines
- One feedback output
- Three reference clock inputs: LVPECL or LVCMOS
- 300pS (max) output-output skew
- Phase-locked loop (PLL) bypass mode
- 'SpreadTrak'
- Output enable/disable
- Pin-compatible with CY29773, MPC9773 and MPC973
- Industrial temperature range: -40°C to $+85^{\circ}\text{C}$
- 52pin 1.0mm TQFP package
- RoHS Compliance

The ASM5I9773 features one LVPECL and two LVCMOS reference clock inputs and provides 12 outputs partitioned in three banks of four outputs each. Each bank divides the VCO output per SEL(A:C) settings (see Table 2. Function Table (Configuration Controls)). These dividers allow output-to-input ratios of 8:1, 6:1, 5:1, 4:1, 3:1, 8:3, 5:2, 2:1, 5:3, 3:2, 4:3, 5:4, 1:1, and 5:6. Each LVCMOS-compatible output can drive 50 Ω series- or parallel-terminated transmission lines. For series-terminated transmission lines, each output can drive one or two traces, giving the device an effective fanout of 1:24.

The PLL is ensured stable, given that the VCO is configured to run between 200MHz to 500MHz. This allows a wide range of output frequencies, from 8MHz to 200MHz. For normal operation, the external feedback input FB_IN is connected to the feedback output FB_OUT. The internal VCO is running at multiples of the input reference clock set by the feedback divider (see Table 1. Frequency Table).

When PLL_EN is LOW, PLL is bypassed and the reference clock directly feeds the output dividers. This mode is fully static and the minimum input clock frequency specification does not apply.

Functional Description

The ASM5I9773 is a low-voltage high-performance 200MHz PLL-based zero delay buffer designed for high speed clock distribution applications.

Notes:

1. PU = Internal pull up, PD = Internal pull down.
2. A 0.1µF bypass capacitor should be placed as close as possible to each positive power pin (<0.2"). If these bypass capacitors are not close to the pins their high frequency filtering characteristics will be cancelled by the lead inductance of the traces.
3. AVDD and VDD pins must be connected to a power supply level that is at least equal or higher than that of VDDQA, VDDQB, and VDDQC power supply pins.

‘SpreadTrak’

Many systems being designed now utilize a technology called Spread Spectrum Frequency Timing Generation. PCS5I9773 is designed so as not to filter off the Spread Spectrum feature of the Reference Input, assuming it exists.

When a zero delay buffer is not designed to pass the Spread Spectrum feature through, the result is a significant amount of tracking skew which may cause problems in the systems requiring synchronization.

Notes:

- V_{CMR} (DC) is the crossing point of the differential input signal. Normal operation is obtained when the crossing point is within the V_{CMR} range and the input swing is within the V_{PP} (DC) specification.
- Driving one 50 Ω parallel terminated transmission line to a termination voltage of V_{TT} . Alternatively, each output drives up to two 50 Ω series terminated transmission lines.
- Inputs have pull-up or pull-down resistors that affect the input current.

SYNC Output

In situations where output frequency relationships are not integer multiples of each other the SYNC output provides a signal for system synchronization. The PCS5I9773 monitors the relationship between the QA and the QC output clocks. It provides a low going pulse, one period in duration, one period prior to the coincident rising edges of the QA and QC outputs. The duration and the placement

of the pulse depend on the higher of the QA and QC output frequencies. The following timing diagram illustrates various waveforms for the SYNC output. Note that the SYNC output is defined for all possible combinations of the QA and QC outputs even though under some relationships the lower frequency clock could be used as a synchronizing signal.

Power Management

The individual output enable/freeze control of the PCS5I9773 allows the user to implement unique power management schemes into the design. The outputs are stopped in the logic '0' state when the freeze control bits are activated. The serial input register contains one programmable freeze enable bit for 12 of the 14 output

clocks. The QC0 and FB_OUT outputs can not be frozen with the serial port, this avoids any potential lock up situation, should an error occur in the loading of the serial data. An output is frozen when a logic '0' is programmed and enabled when a logic '1' is written. The enabling and

rev 0. 4

freezing of individual outputs is done in such a manner as to eliminate the possibility of partial "runt" clocks.

The serial input register is programmed through the SDATA input by writing a logic '0' start bit followed by 12

NRZ freeze enable bits. The period of each SDATA bit equals the period of the free running SCLK signal. The SDATA is sampled on the rising edge of SCLK.

D0-D3 are the control bits for QA0-QA3, respectively
D4-D7 are the control bits for QB0-QB3, respectively
D8-D10 are the control bits for QC1-QC3, respectively
D11 is the control bit for SYNC
