

# THS4150, THS4151 HIGH-SPEED DIFFERENTIAL I/O AMPLIFIERS

SLOS321D – MAY 2000 – REVISED JANUARY 2004

## features

- **High Performance**
  - 150 MHz –3 dB Bandwidth ( $V_{CC} = \pm 5$  V)
  - 650 V/ $\mu$ s Slew Rate ( $V_{CC} = \pm 15$  V)
  - –89 dB Third Harmonic Distortion at 1 MHz
  - –83 dB Total Harmonic Distortion at 1 MHz
  - 7.6 nV/ $\sqrt{\text{Hz}}$  Input-Referred Noise
- **Differential Input/Differential Output**
  - Balanced Outputs Reject Common-Mode Noise
  - Differential Reduced Second Harmonic Distortion
- **Wide Power Supply Range**
  - $V_{CC} = 5$  V Single Supply to  $\pm 15$  V Dual Supply
- $I_{CC(SD)} = 1$  mA ( $V_{CC} = \pm 5$ ) in Shutdown Mode (THS4150)

## description

The THS415x is one in a family of fully differential input/differential output devices fabricated using Texas Instruments' state-of-the-art BiCom1 complementary bipolar process.

The THS415x is made of a true fully-differential signal path from input to output. This design leads to an excellent common-mode noise rejection and improved total harmonic distortion.

### RELATED DEVICES

| DEVICE  | DESCRIPTION                                         |
|---------|-----------------------------------------------------|
| THS412x | 100 MHz, 43 V/ $\mu$ s, 3.7 nV/ $\sqrt{\text{Hz}}$  |
| THS413x | 150 MHz, 51 V/ $\mu$ s, 1.3 nV/ $\sqrt{\text{Hz}}$  |
| THS414x | 160 MHz, 450 V/ $\mu$ s, 6.5 nV/ $\sqrt{\text{Hz}}$ |

## typical A/D application circuit

## key applications

- Single-Ended To Differential Conversion
- Differential ADC Driver
- Differential Antialiasing
- Differential Transmitter and Receiver
- Output Level Shifter

### HIGH-SPEED DIFFERENTIAL I/O FAMILY

| DEVICE  | NUMBER OF CHANNELS | SHUTDOWN |
|---------|--------------------|----------|
| THS4150 | 1                  | X        |
| THS4151 | 1                  | –        |

### THS4151 TOTAL HARMONIC DISTORTION VS FREQUENCY

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

| CDM                                                                                                    | 1500 V                       |
| MM                                                                                                     | 200 V                        |

<sup>†</sup> Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: The THS415x may incorporate a PowerPad™ on the underside of the chip. This acts as a heatsink and must be connected to a thermally dissipative plane for proper power dissipation. Failure to do so may result in exceeding the maximum junction temperature which could permanently damage the device. See TI technical brief SLMA002 and SLMA004 for more information about utilizing the PowerPad™ thermally enhanced package.

NOTE 2: The absolute maximum temperature under any condition is limited by the constraints of the silicon process.

NOTE 3: The maximum junction temperature for continuous operation is limited by package constraints. Operation above this temperature may result in reduced reliability and/or lifetime of the device.

DISSIPATION RATING TABLE

| PACKAGE | θ <sub>JA</sub> ‡<br>(°C/W) | θ <sub>JC</sub><br>(°C/W) | POWER RATINGS§        |                       |

| D       | 97.5                        | 38.3                      | 1.02 W                | 410 mW                |
| DGN     | 58.4                        | 4.7                       | 1.71 W                | 685 mW                |
| DGK     | 260                         | 54.2                      | 385 mW                | 154 mW                |

‡ This data was taken using the JEDEC standard High-K test PCB.

§ Power rating is determined with a junction temperature of 125°C. This is the point where distortion starts to substantially increase. Thermal management of the final PCB should strive to keep the junction temperature at or below 125°C for best performance and long term reliability.

## APPLICATION INFORMATION

### resistor matching

Resistor matching is important in fully differential amplifiers. The balance of the output on the reference voltage depends on matched ratios of the resistors. CMRR, PSRR, and cancellation of the second harmonic distortion will diminish if resistor mismatch occurs. Therefore, it is recommended to use 1% tolerance resistors or better to keep the performance optimized.

$V_{OCM}$  sets the dc level of the output signals. If no voltage is applied to the  $V_{OCM}$  pin, it will be set to the midrail voltage internally defined as:

$$\frac{(V_{CC+}) + (V_{CC-})}{2}$$

In the differential mode, the  $V_{OCM}$  on the two outputs cancel each other. Therefore, the output in the differential mode is the same as the input when gain is 1.  $V_{OCM}$  has a high bandwidth capability up to the typical operation range of the amplifier. For the prevention of noise going through the device, use a 0.1  $\mu$ F capacitor on the  $V_{OCM}$  pin as a bypass capacitor. Figure 30 shows the simplified diagram of the THS415x.

Figure 30. THS415x Simplified Diagram

## APPLICATION INFORMATION

### data converters

Data converters are one of the most popular applications for the fully differential amplifiers. The following schematic shows a typical configuration of a fully differential amplifier attached to a differential ADC.

Figure 31. Fully Differential Amplifier Attached to a Differential ADC

Fully differential amplifiers can operate with a single supply.  $V_{OCM}$  defaults to the midrail voltage,  $V_{CC}/2$ . The differential output may be fed into a data converter. This method eliminates the use of a transformer in the circuit. If the ADC has a reference voltage output ( $V_{ref}$ ), then it is recommended to connect it directly to the  $V_{OCM}$  of the amplifier using a bypass capacitor for stability. For proper operation, the input common-mode voltage to the input terminal of the amplifier should not exceed the common-mode input voltage range.

Figure 32. Fully Differential Amplifier Using a Single Supply

# THS4150, THS4151 HIGH-SPEED DIFFERENTIAL I/O AMPLIFIERS

SLOS321D – MAY 2000 – REVISED JANUARY 2004

## APPLICATION INFORMATION

### data converters (continued)

Some single supply applications may require the input voltage to exceed the common-mode input voltage range. In such cases, the following circuit configuration is suggested to bring the common-mode input voltage within the specifications of the amplifier.

Figure 33. Circuit With Improved Common-Mode Input Voltage

The following equation is used to calculate  $R_{PU}$ :

$$R_{PU} = \frac{V_P - V_{CC}}{(V_{IN} - V_P) \frac{1}{R_G} + (V_{OUT} - V_P) \frac{1}{R_F}}$$

### driving a capacitive load

Driving capacitive loads with high-performance amplifiers is not a problem as long as certain precautions are taken. The first is to realize that the THS415x has been internally compensated to maximize its bandwidth and slew rate performance. When the amplifier is compensated in this manner, capacitive loading directly on the output will decrease the device's phase margin leading to high-frequency ringing or oscillations. Therefore, for capacitive loads of greater than 10 pF, it is recommended that a resistor be placed in series with the output of the amplifier, as shown in Figure 34. A minimum value of 20 Ω should work well for most applications. For example, in 50-Ω transmission systems, setting the series resistor value to 20 Ω both isolates any capacitance loading and provides the proper line impedance matching at the source end.

Figure 34. Driving a Capacitive Load

## APPLICATION INFORMATION

### Active antialias filtering

For signal conditioning in ADC applications, it is important to limit the input frequency to the ADC. Low-pass filters can prevent the aliasing of the high frequency noise with the frequency of operation. The following figure presents a method by which the noise may be filtered in the THS415x.

Figure 35. Antialias Filtering

The transfer function for this filter circuit is:

$$H_d(f) = \left[ \frac{K}{-\left(\frac{f}{\text{FSF} \times f_c}\right)^2 + \frac{1}{Q} \frac{jf}{\text{FSF} \times f_c} + 1} \right] \times \left[ \frac{\frac{R_t}{2R_4 + R_t}}{1 + \frac{j2\pi f R_4 R_t C_3}{2R_4 + R_t}} \right] \quad \text{Where } K = \frac{R_2}{R_1}$$

$$\text{FSF} \times f_c = \frac{1}{2\pi \sqrt{2 \times R_2 R_3 C_1 C_2}} \quad \text{and} \quad Q = \frac{\sqrt{2 \times R_2 R_3 C_1 C_2}}{R_3 C_1 + R_2 C_1 + K R_3 C_1}$$

K sets the pass band gain,  $f_c$  is the cutoff frequency for the filter, FSF is a frequency-scaling factor, and Q is the quality factor.

$$\text{FSF} = \sqrt{\text{Re}^2 + |\text{Im}|^2} \quad \text{and} \quad Q = \frac{\sqrt{\text{Re}^2 + |\text{Im}|^2}}{2\text{Re}}$$

where Re is the real part, and Im is the imaginary part of the complex pole pair. Setting  $R_2 = R$ ,  $R_3 = mR$ ,  $C_1 = C$ , and  $C_2 = nC$  results in:

$$\text{FSF} \times f_c = \frac{1}{2\pi RC \sqrt{2 \times mn}} \quad \text{and} \quad Q = \frac{\sqrt{2 \times mn}}{1 + m(1 + K)}$$

Start by determining the ratios, m and n, required for the gain and Q of the filter type being designed, then select C and calculate R for the desired  $f_c$ .

SLOS321D – MAY 2000 – REVISED JANUARY 2004

## PRINCIPLES OF OPERATION

### theory of operation

The THS415x is a fully differential amplifier. Differential amplifiers are typically *differential in/single out*, whereas fully differential amplifiers are *differential in/differential out*.

Figure 36. Differential Amplifier Versus a Fully Differential Amplifier

To understand the THS415x fully differential amplifiers, the definition for the pinouts of the amplifier are provided.

$$\text{Input voltage definition} \quad V_{ID} = (V_{I+}) - (V_{I-}) \quad V_{IC} = \frac{(V_{I+}) + (V_{I-})}{2}$$

$$\text{Output voltage definition} \quad V_{OD} = (V_{O+}) - (V_{O-}) \quad V_{OC} = \frac{(V_{O+}) + (V_{O-})}{2}$$

$$\text{Transfer function} \quad V_{OD} = V_{ID} \times A_{(f)}$$

$$\text{Output common mode voltage} \quad V_{OC} = V_{OCM}$$

Figure 37. Definition of the Fully Differential Amplifier

## PRINCIPLES OF OPERATION

### theory of operation (continued)

The following schematics depict the differences between the operation of the THS415x, fully differential amplifier, in two different modes. Fully differential amplifiers can work with differential input or can be implemented as single in/differential out.

Note: For proper operation, maintain symmetry by setting  $R_{f1} = R_{f2} = R_f$  and  $R_{(g)1} = R_{(g)2} = R_{(g)} \Rightarrow A = R_f/R_{(g)}$

Figure 38. Amplifying Differential Signals

RECOMMENDED RESISTOR VALUES

| GAIN | $R_{(g)} \Omega$ | $R_f \Omega$ |
|------|------------------|--------------|
| 1    | 390              | 390          |
| 2    | 374              | 750          |
| 5    | 402              | 2010         |
| 10   | 402              | 4020         |

Figure 39. Single In With Differential Out

If each output is measured independently, each output is one-half of the input signal when gain is 1. The following equations express the transfer function for each output:

$$V_{O+} = \frac{V_{I+}}{2} + V_{OCM}$$

The second output is equal and opposite in sign:

$$V_{O-} = -\frac{V_{I+}}{2} + V_{OCM}$$

$V_{OCM}$  will be set to midrails if it is not derived by any external power source.

Fully differential amplifiers may be viewed as two inverting amplifiers. In this case, the equation of an inverting amplifier holds true for gain calculations. One advantage of fully differential amplifiers is that they offer twice as much dynamic range compared to single-ended amplifiers. For example, a 1- $V_{PP}$  ADC can only support an input signal of 1  $V_{PP}$ . If the output of the amplifier is 2  $V_{PP}$ , then it will not be practical to feed a 2- $V_{PP}$  signal into the targeted ADC. Using a fully differential amplifier enables the user to break down the output into two 1- $V_{PP}$  signals with opposite signs and feed them into the differential input nodes of the ADC. In practice, the designer has been able to feed a 2-V peak-to-peak signal into a 1-V differential ADC with the help of a fully differential amplifier. The final result indicates twice as much dynamic range.

# THS4150, THS4151 HIGH-SPEED DIFFERENTIAL I/O AMPLIFIERS

SLOS321D – MAY 2000 – REVISED JANUARY 2004

## PRINCIPLES OF OPERATION

### theory of operation (continued)

Figure 40 illustrates the increase in dynamic range. The gain factor should be considered in this scenario. The THS415x fully differential amplifier offers an improved CMRR and PSRR due to its symmetrical input and output. Furthermore, second harmonic distortion is improved. Second harmonics tend to cancel because of the symmetrical output.

Figure 40. Fully Differential Amplifier With Two 1-V<sub>PP</sub> Signals

Similar to the standard inverting amplifier configuration, input impedance of a fully differential amplifier is selected by the input resistor,  $R_{(g)}$ . If input impedance is a constraint in design, the designer may choose to implement the differential amplifier as an instrumentation amplifier. This configuration improves the input impedance of the fully differential amplifier. The following schematic depicts the general format of instrumentation amplifiers.

The general transfer function for this circuit is:

$$\frac{V_{OD}}{V_{IN1} - V_{IN2}} = \frac{R_f}{R_{(g)}} \left( 1 + \frac{2R_2}{R_1} \right)$$

Figure 41. Fully Differential Instrumentation Amplifier

---

## PRINCIPLES OF OPERATION

### circuit layout considerations

To achieve the levels of high frequency performance of the THS415x, follow proper printed-circuit board high frequency design techniques. A general set of guidelines is given below. In addition, a THS415x evaluation board is available to use as a guide for layout or for evaluating the device performance.

- **Ground planes**—It is highly recommended that a ground plane be used on the board to provide all components with a low inductive ground connection. However, in the areas of the amplifier inputs and output, the ground plane can be removed to minimize the stray capacitance.
- **Proper power supply decoupling**—Use a 6.8- $\mu$ F tantalum capacitor in parallel with a 0.1- $\mu$ F ceramic capacitor on each supply terminal. It may be possible to share the tantalum among several amplifiers depending on the application, but a 0.1- $\mu$ F ceramic capacitor should always be used on the supply terminal of every amplifier. In addition, the 0.1- $\mu$ F capacitor should be placed as close as possible to the supply terminal. As this distance increases, the inductance in the connecting trace makes the capacitor less effective. The designer should strive for distances of less than 0.1 inches between the device power terminals and the ceramic capacitors.
- **Sockets**—Sockets are not recommended for high-speed operational amplifiers. The additional lead inductance in the socket pins will often lead to stability problems. Surface-mount packages soldered directly to the printed-circuit board is the best implementation.
- **Short trace runs/compact part placements**—Optimum high frequency performance is achieved when stray series inductance has been minimized. To realize this, the circuit layout should be made as compact as possible, thereby minimizing the length of all trace runs. Particular attention should be paid to the inverting input of the amplifier. Its length should be kept as short as possible. This will help to minimize stray capacitance at the input of the amplifier.
- **Surface-mount passive components**—Using surface-mount passive components is recommended for high frequency amplifier circuits for several reasons. First, because of the extremely low lead inductance of surface-mount components, the problem with stray series inductance is greatly reduced. Second, the small size of surface-mount components naturally leads to a more compact layout thereby minimizing both stray inductance and capacitance. If leaded components are used, it is recommended that the lead lengths be kept as short as possible.

SLOS321D – MAY 2000 – REVISED JANUARY 2004

## PRINCIPLES OF OPERATION

### power-down mode

The power-down mode is used when power saving is required. The power-down terminal ( $\overline{\text{PD}}$ ) found on the THS415x is an active low terminal. If it is left as a no-connect terminal, the device will always stay on due to an internal 50 k $\Omega$  resistor to  $V_{CC}$ . The threshold voltage for this terminal is approximately 1.4 V above  $V_{CC-}$ . This means that if the  $\overline{\text{PD}}$  terminal is 1.4 V above  $V_{CC-}$ , the device is active. If the  $\overline{\text{PD}}$  terminal is less than 1.4 V above  $V_{CC-}$ , the device is off. For example, if  $V_{CC-} = -5$  V, then the device is on when  $\overline{\text{PD}}$  reaches 3.6 V, ( $-5$  V + 1.4 V =  $-3.6$  V). By the same calculation, the device is off below  $-3.6$  V. It is recommended to pull the terminal to  $V_{CC-}$  in order to turn the device off. The following graph shows the simplified version of the power-down circuit. While in the power-down state, the amplifier goes into a high-impedance state. The amplifier output impedance is typically greater than 1 M $\Omega$  in the power-down state.

Figure 42. Simplified Power-Down Circuit

Due to the similarity of the standard inverting amplifier configuration, the output impedance appears to be very low while in the power-down state. This is because the feedback resistor ( $R_f$ ) and the gain resistor ( $R_{(g)}$ ) are still connected to the circuit. Therefore, a current path is allowed between the input of the amplifier and the output of the amplifier. An example of the closed-loop output impedance is shown in Figure 43.

Figure 43

## PRINCIPLES OF OPERATION

### general PowerPAD design considerations

The THS415x is available packaged in a thermally-enhanced DGN package, which is a member of the PowerPAD family of packages. This package is constructed using a downset leadframe upon which the die is mounted [see Figure 44(a) and Figure 44(b)]. This arrangement results in the lead frame being exposed as a thermal pad on the underside of the package [see Figure 44(c)]. Because this thermal pad has direct thermal contact with the die, excellent thermal performance can be achieved by providing a good thermal path away from the thermal pad.

The PowerPAD package allows for both assembly and thermal management in one manufacturing operation. During the surface-mount solder operation (when the leads are being soldered), the thermal pad can also be soldered to a copper area underneath the package. Through the use of thermal paths within this copper area, heat can be conducted away from the package into either a ground plane or other heat dissipating device.

The PowerPAD package represents a breakthrough in combining the small area and ease of assembly of the surface mount with the, heretofore, awkward mechanical methods of heatsinking.

More complete details of the PowerPAD™ installation process and thermal management techniques can be found in the Texas Instruments Technical Brief, *PowerPAD Thermally Enhanced Package (SLMA002)*. This document can be found at the TI web site ([www.ti.com](http://www.ti.com)) by searching on the key word PowerPAD. The document can also be ordered through your local TI sales office. Refer to literature number SLMA002 when ordering.

NOTE A: The thermal pad is electrically isolated from all terminals in the package.
