

CAT871, CAT872

Dual Input Reset Generator

Description

CAT871, CAT872 are dual input reset generators designed to restart microprocessor and microcontroller based systems when the watchdog timer or other resetting mechanisms have become disabled or failed.

CAT871, CAT872 monitor two inputs and output an active low reset pulse after both inputs have been active (logic low) for a factory preset minimum time. The reset pulse width is 2.2 ms for CAT871 and 70 ms for CAT872. Releasing either input from its active state before the minimum timeout period resets the internal timer and both inputs must return to being active before the timer will restart with a fresh count down.

CAT871, CAT872's open drain output is capable of sinking up to 3 mA of current and may be wire-OR'd with other open drain devices to drive a common reset input.

Features

- Operate on 1.65 V to 5.5 V Power Supplies
- Ultra Low Quiescent Current: 10 nA (typical)
- Schmitt Trigger Inputs
- 8 Factory Preset Delay Times from 0.5 s to 5 s to Choose From
- Small μ LLGA-6 Package: 1.45 x 1.0 x 0.4 mm
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

Typical Applications

- Mobile Phones
- PDAs
- MP3 Players
- Personal Navigation Devices

FUNCTIONAL BLOCK DIAGRAM

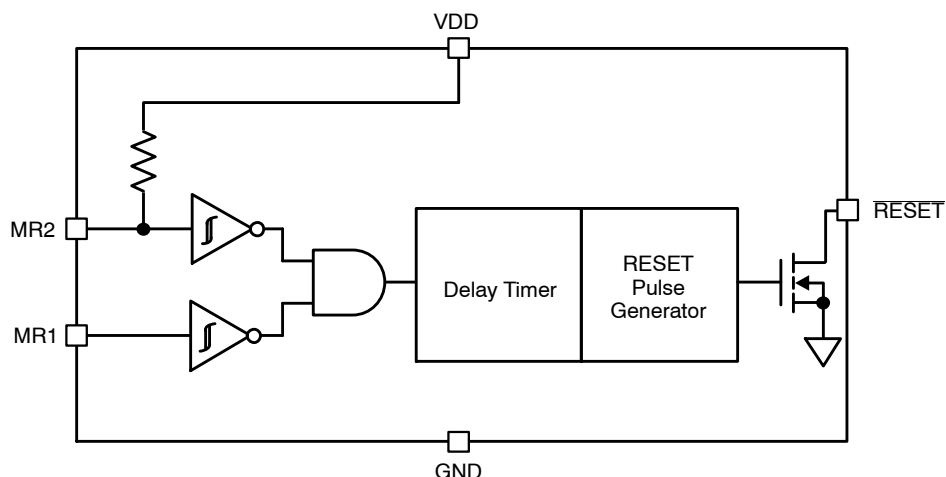

Figure 2. Functional Block Diagram

Table 1. PIN FUNCTION DESCRIPTION

Pin No.	Pin Name	Description
1	MR1	Manual reset input #1. CMOS input.
2	MR2	Manual reset input #2. CMOS input.
3	NIC	No Internal Connection. A voltage or signal applied to this pin will have no effect on device operation.
4	GND	System Ground.
5	RESET	Reset Output. Active-low open drain output.
6	VDD	Positive Power Supply.

Table 2. ABSOLUTE MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Input Voltage Range	V_{DD}	-0.3 to 6	V
Output Voltage Range	V_{OUT}	-0.3 to 6 or $(V_{DD} + 0.3)$, whichever is lower	V
Input Voltage; MR2, MR1	V_{IN}	-0.3 to 6 or $(V_{DD} + 0.3)$, whichever is lower	V
Maximum Junction Temperature	$T_{J(max)}$	150	°C
Output Current; RESET	I_{OUT}	10	mA
Storage Temperature Range	T_{STG}	-65 to 150	°C
ESD Capability, Human Body Model (Note 1)	ESD_{HBM}	2	kV
ESD Capability, Machine Model (Note 1)	ESD_{MM}	200	V
Lead Temperature Soldering Reflow (SMD Styles Only), Pb-Free Versions (Note 2)	T_{SLD}	260	°C

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

1. This device series incorporates ESD protection and is tested by the following methods:

ESD Human Body Model tested per AEC-Q100-002 (EIA/JESD22-A114)

ESD Machine Model tested per AEC-Q100-003 (EIA/JESD22-A115)

Latch-up Current Maximum Rating: ≤ 150 mA per JEDEC standard: JESD78

2. For information, please refer to our Soldering and Mounting Techniques Reference Manual, SOLDERRM/D

SYSTEM DESCRIPTION AND APPLICATIONS INFORMATION

General

CAT871, CAT872 are designed for the manual resetting of microprocessors and microcontrollers when normal resetting mechanisms have failed. To prevent accidental resets, CAT871, CAT872 require both manual reset inputs be held low for a prescribed period before a reset pulse is issued to the system processor.

Manual Reset Inputs

MR1 and MR2 are Schmitt trigger CMOS inputs. Both inputs must go low and stay low for a predetermined period (t_{LOW_DELAY}) to generate a single reset pulse on the output. MR1 and MR2 operate independently and may be brought low at any time and in any order. The last input to reach 0 V starts the delay timer.

MR1 is a standard CMOS input and MR2 is also a CMOS input with an internal 200 k Ω pull-up resistor, thus MR2 can be left floating whereas MR1 must be biased by a pull-up resistor, powered switch or some other means external to the IC. (Consult factory for other input biasing options)

Delay Timer

When both MR1 and MR2 go low, an internal timing cycle is initiated. If any input goes high before the countdown timer has concluded its cycle, the timer will reset and will restart from the beginning when MR1 and MR2 return to being low.

If both manual reset inputs (MR1 and MR2) remain low after a reset pulse is issued, no second reset pulse will be issued after that.

Reset Output

CAT871, CAT872 provide an active-low open drain output to be wire-OR'd with other open drain reset devices. This output will sink up to 3 mA and as such will not be loaded down by low value (strong) pull-up resistors. The reset pulse is typically 2 ms long for CAT871 and 70 ms long for CAT872 and is issued at the conclusion of the delay timer's countdown sequence.

CAT871, CAT872 will not generate a reset pulse at power-up.

Delay Timer Testing

To aid in-circuit testing of the delay timer, a special test function has been included in CAT871, CAT872. This test mode, TOC, allows the delay timer to clock at an accelerated rate. Upon the conclusion of the countdown a standard width reset pulse will be issued and the chip will exit test mode.

To initiate TOC, MR1 \rightarrow 0 V and a fast external CLK (typically 1 MHz) is applied on MR2, with the falling edge of the first clock pulse on MR2 delayed with t_P from MR1 \rightarrow 0 V. CAT871, CAT872 look for 8 sequential pulses to appear on MR2 within 35 μ s to confirm TOC is desired. After the rising edge of the 8'th pulse, there will be a delay of 250 μ s typical followed by a standard reset pulse at the reset output. This delay is independent of the normal timeout delay setting.

After issuing the reset pulse, CAT871, CAT872 exit TOC mode and returns to normal operation. If at any time during TOC both MR1 and MR2 are HIGH, CAT871, CAT872 will immediately exit TOC mode.

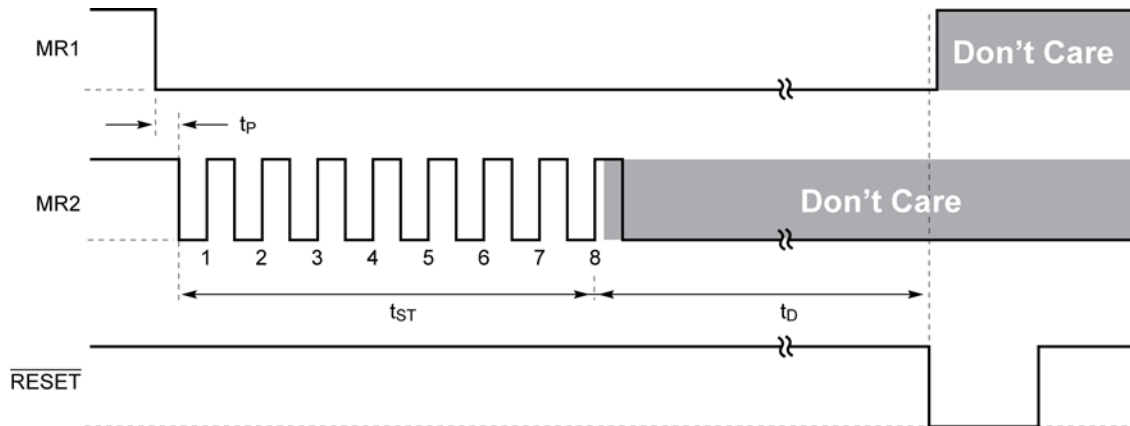

Figure 12. TOC Mode

APPLICATION INFORMATION

Reset Pulse Operation

When both MR1 and MR2 inputs are kept low, a single reset pulse is generated after the delay $t_{\text{LOW_DELAY}}$. Even with both MR1 and MR2 maintained low continuously after that time, no second reset pulse will be generated. The delay timer restarts if either MR1 or MR2 (or both) input transitions from high to low, as shown in the timing diagram in Figure 13.

System with Two Different Power Supply Voltages

The reset generator can be used in a system where the supply VDD is different than the MR1, MR2 input logic. Figure 14 shows an application schematic where the microcontroller uses a supply VBAT (3.6 V) that is higher

than the VDD rail (1.8 V). MR1 and MR2 inputs are activated here by two separate switches connected to GND and pulling the inputs low when pressed. The Schottky diode provides the supply isolation needed between the CAT871/CAT872 (VDD) and the microcontroller (VBAT).

Operation with Low VDD Voltage and Brownout Condition

The CAT871, CAT872 reset generators require a minimum supply voltage VDD of 1.65 V to guarantee the normal operation within the specification. To prevent small VDD supply glitch, a small ceramic capacitor can be added between the VDD pin and GND.
