

MIC2250

High Efficiency Low EMI Boost Regulator

General Description

The MIC2250 is a general purpose DC/DC boost switching regulator that features low noise, EMI reduction circuitry, and high efficiency across a wide output current range.

The MIC2250 is optimized for noise-sensitive hand held battery powered applications. A proprietary control method allows low ripple across the output voltage and current ranges. The MIC2250 incorporates a pseudo-random dithering function to reduce EMI levels up to 10dB enabled by the DITH pin.

The MIC2250 is designed for use with inductor values from 4.7 μ H to 22 μ H, and is stable with ceramic capacitors from 1 μ F to 22 μ F.

The MIC2250 attains a high peak efficiency up to 90% at 100mA and excellent light load efficiency of 80% at 1mA.

High power density is achieved with the MIC2250's internal 34V/2A rated switch, allowing it to power large loads in a tiny footprint.

The MIC2250 is available in a 8-pin 2mm x 2mm MLF[®] leadless package option with an operating junction temperature range of -40°C to +125°C.

Data sheets and support documentation can be found on Micrel's web site at: www.micrel.com.

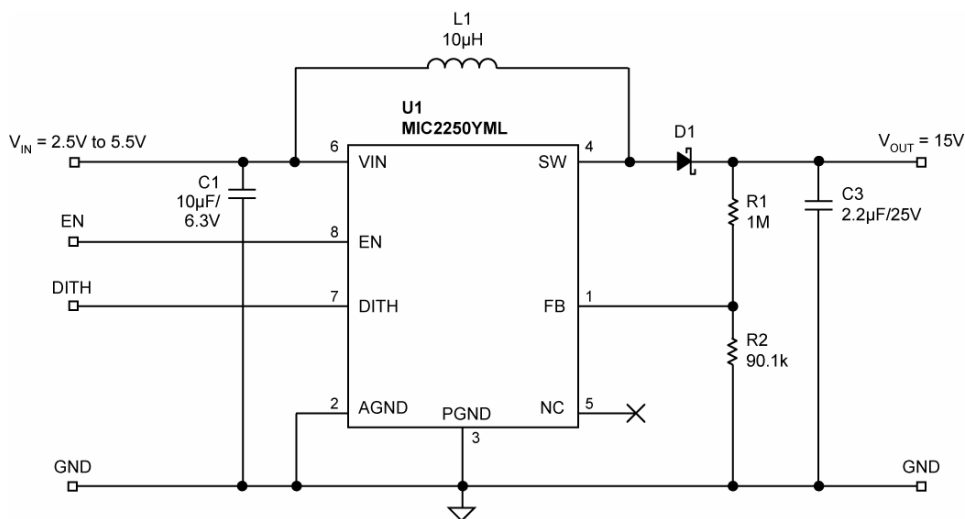

Features

- Over 80% efficient for a 300:1 load range
- 2.5V to 5.5V input voltage range
- Output voltage adjustable to 32V
- 2A switch current
- Constant peak current control reduces output ripple
- EMI reduction circuitry
- Stable with small ceramic capacitors
- <1 μ A shutdown current
- UVLO and thermal shutdown
- 8-pin 2mm x 2mm leadless MLF[®] package
- -40°C to +125°C junction temperature range

Applications

- LCD/OLED display bias supply
- CCD bias supply
- Mobile Phones, PDA, Media Players, GPS PND
- Haptic displays
- Local 5V, 15V, 24V rail

Typical Application

MLF and MicroLeadFrame are registered trademarks of Amkor Technology, Inc.

Ordering Information

Part Number	Marking ⁽¹⁾	Junction Temp. Range	Package ⁽³⁾	Lead Finish
MIC2250YML	ZAA ⁽²⁾	-40° to +125°C	8-Pin 2mm x 2mm MLF [®]	Pb-Free

Note:

1. Pin 1 identifier = "•".
2. Overbar (—) may not be to scale.
3. MLF is GREEN RoHs compliant package. Lead finish is NiPdAu. Mold compound is Halogen Free.

Pin Configuration

Pin Description

Pin Number	Pin Name	Pin Function
1	FB	Feedback (Input): 1.24V output voltage sense node. $V_{OUT} = 1.24V (1 + R1/R2)$
2	AGND	Analog Ground. Connect to power ground.
3	PGND	Power Ground.
4	SW	Switch Node (Input): Internal power NMOS drain.
5	NC	Not Internally Connected.
6	VIN	Supply (Input): 2.5V to 5.5V input voltage.
7	DITH	Frequency Dithering (Input): Connect this pin high to enable pseudo-random on-time dithering to reduce EMI. Connect this pin-to-ground to disable this function.
8	EN	Enable (Input): Logic high enables the regulator. Logic low shuts down the regulator. Do not leave floating.
EPAD	GND	Ground (Return): Exposed backside pad. Connect to power ground.

Absolute Maximum Ratings⁽¹⁾

Supply Voltage (V_{IN})	6V
Switch Voltage (V_{SW})	-0.3V to 34V
Enable Voltage (V_{EN})	-0.3V to V_{IN}
FB Voltage (V_{FB})	6V
Switch Current (I_{SW})	3.5A
Ambient Storage Temperature (T_s)	-65°C to +150°C
ESD Rating ⁽⁴⁾	ESD Sensitive

Operating Ratings⁽²⁾

Supply Voltage (V_{IN})	2.5V to 5.5V
Enable Voltage (V_{EN})	0V to V_{IN}
Junction Temperature (T_J) ⁽³⁾	-40°C to +125°C
Junction Thermal Resistance	
2mm x 2mm MLF-8 (θ_{JA})	90°C/W

Electrical Characteristics⁽⁵⁾

$V_{IN} = V_{EN} = 3.6V$; $V_{DITH} = 0V$; $V_{OUT} = 15V$; $I_{OUT} = 40mA$; $T_A = 25^\circ C$, unless otherwise noted. **Bold** values indicate $-40^\circ C \leq T_J \leq +125^\circ C$.

Symbol	Parameter	Condition	Min	Typ	Max	Units
V_{IN}	Input Voltage Range		2.5		5.5	V
V_{ULVO}	Under-voltage Lockout	V_{IN} rising	1.8	2	2.4	V
I_Q	Quiescent Current	$V_{FB} = 1.5V$ (not switching)		52	80	μA
I_{SD}	Shutdown Current	$V_{EN} = 0V$, Note 6		0.1	1	μA
V_{FB}	Feedback Voltage		1.20	1.24	1.277	V
		$-40^\circ C \leq T_J \leq +125^\circ C$	1.19		1.29	V

		Turn OFF			0.4	V
I_{EN}	Enable Pin Current	$V_{EN} = V_{IN} = 5.0V$		0.1	2	μA
T	Thermal Shutdown Threshold			170		$^\circ C$
		Hysteresis		10		$^\circ C$

Notes:

- Absolute maximum ratings indicate limits beyond which damage to the component may occur.
- The device is not guaranteed to function outside its operating rating.
- The maximum allowable power dissipation is a function of the maximum junction temperature, $T_{J(Max)}$, the junction-to-ambient thermal resistance, θ_{JA} , and the ambient temperature, T_A . The maximum allowable power dissipation will result in excessive die temperature, and the regulator will go into thermal shutdown.
- Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5k Ω in series with 100pF.
- Specification for packaged product only.
- $I_{SD} = I_{VIN}$.
- Guaranteed by design.

Functional Diagram

Functional Description

VIN

The input supply (VIN) provides power to the internal MOSFETs and control circuitry for the switch mode regulator. The operating input voltage range is from 2.5V to 5.5V. An input capacitor with a minimum voltage rating of 6.3V is recommended. Refer to the layout recommendations for details.

EN

A logic level input of 1.5V or higher enables the regulator. A logic input of 0.4V or less places the regulator in shutdown mode which reduces the supply current to less than 1μA. The MIC2250 features built-in soft start circuitry that reduces in-rush current and prevents the output voltage from overshooting during startup. Do not leave the Enable pin floating.

SW

The MIC2250 has an internal MOSFET switch that connects directly to one end of the inductor (SW pin) and provides a current path to ground during switching cycles. The source of the internal MOSFET connects through a current sense resistor to ground.

PGND

The power ground pin is the high current path to ground. The current loop for the power ground should be as small as possible and separate from the analog ground (AGND). Refer to the layout recommendations for more details.

AGND

Analog ground (AGND) is the ground path for the biasing and control circuitry. The current loop for the signal ground should be separate from the power ground (PGND) loop. Refer to the layout recommendations for more details.

DITH

The DITH function is a frequency dithering technique that reduces EMI noise by spreading the boost regulators' noise spectrum. This technique reduces the EMI peaks by distributing the switching frequency across a wider spectrum. Connect this pin high to enable the pseudo-random on-time dithering. Connect this pin to ground to disable this function.

FB

The feedback pin (FB) allows the regulated output voltage to be set by applying an external resistor divider network. The internal reference voltage is 1.24V. The output voltage is calculated from the following equation:

$$V_{\text{OUT}} = 1.24V \left(1 + \frac{R1}{R2} \right)$$

Application Information

Overview

The MIC2250 Boost Regulator utilizes a combination of PFM & Current Mode Control to achieve very high efficiency over a wide range of output load. This innovative design is the basis for the regulator's high efficiency, excellent stability, and self compensation technique. The boost regulator performs a power conversion that results in an output voltage that is greater than the input. Operation starts with activating an internal MOSFET switch which draws current through the inductor (L1). While one end of the inductor is fixed at V_{IN} , the other end is switched up and down. While the switch is on, the current through the inductor increases. When the switch is off the inductor current continues to flow through the output diode.

The current flow imposes a voltage across the inductor, which is added to V_{IN} to produce a higher voltage V_{OUT} . At low power levels (typically less than 1W), the period varies between switching cycles, indicative of Pulse Frequency Modulation (PFM). As the output power increases beyond approximately 1W, the period between switching cycles continues to decrease and the power (switch current) delivered with each cycle increases indicative of Current Mode control.

PFM Regulation

The error amplifier compares the regulator's reference voltage with the feedback voltage obtained from the output resistor voltage divider network. The resulting error voltage acts as a correction input signal to the control block. The control block generates two signals that turn on and off the output MOSFET switch. An increase in load current causes V_{OUT} and V_{FB} to decrease in value. The control loop then changes the switching frequency to increase the energy transferred to the output capacitor to regulate the output voltage. A reduction in load causes V_{OUT} and V_{FB} to increase. Now the control loop compensates by reducing the effective switching frequency, thus reducing the amount of energy delivered to the output capacitor in order to keep the output voltage within regulation.

Current Mode Regulation

The control block's oscillator starts the cycle by setting the MOSFET switch control flip flop. The switch then turns on. This flip flop is reset when the switch current ramp reaches the threshold set by the error amplifier. If the error amplifier indicates that V_{FB} is either too high or too low, then the threshold for the comparator measuring the switch current is appropriately adjusted to bring V_{OUT} back to within regulation limits. The level of the error signal also sets the off time of the switch. A higher error signal (output voltage is low) will reduce off time to increase energy transfer to the output. A lower error

signal (output voltage is high) will conversely, increase off time to reduce energy transfer to the output.

Component Selection

Resistors

An external resistive divider network (R1 and R2) with its center tap connected to the feedback pin sets the output voltage. The appropriate R1 and R2 values for the desired output voltage are calculated by:

$$R2 = \frac{R1}{\left(\frac{V_{OUT}}{1.24V} - 1\right)}$$

Large resistor values are recommended to reduce light load operating current, and improve efficiency. The table below gives a good compromise between quiescent current and accuracy. Additionally, a feedforward capacitor (C_{FF}) (placed in parallel with R1) may be added to improve transient performance. Recommended values are suggested below:

V_{OUT}	Suggested R1	C_{FF}
5V to 10V	100k	4.7nF
10V to 15V	240k	2.2nF
15V to 32V	1M	470pF

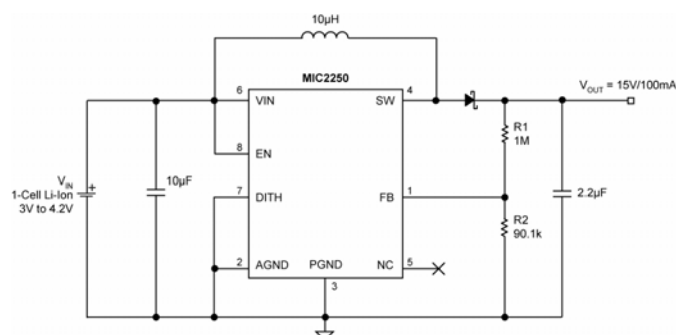

Figure 1. Typical Application Circuit

Inductor

Inductor selection is a balance between efficiency, stability, cost, size, and rated current. For most applications, inductors in the range 4.7µH to 22µH are recommended. Larger inductance values reduce the peak-to-peak ripple current, thereby reducing both the DC losses and the transition losses for better efficiency. The inductor's DC resistance (DCR) also plays an important role. Since the majority of the input current (minus the MIC2250 operating current) is passed through the inductor, higher DCR inductors will reduce efficiency at higher load currents. Figure 2 shows the comparison of efficiency between a 140mΩ DCR, 4.7µH inductor and a 190mΩ DCR, 10µH inductor. The switch current limit for the MIC2250 is typically 2A. The

saturation current rating of the selected inductor should be 20-30% higher than the 2A specification for proper operation.

Figure 2. Efficiency Comparison Between Lower and Higher Inductor Values

Input Capacitor

The boost converter exhibits a triangular current waveform at its input, so an input capacitor is required to decouple this waveform and thereby reduce the input voltage ripple. A 10uF to 22uF ceramic capacitor should be sufficient for most applications. A minimum input capacitance of 1uF is recommended. The input capacitor should be as close as possible to the inductor and the MIC2250, with short PCB traces for good noise

performance.

Output Capacitor

Output capacitor selection is also a trade-off between performance, size, and cost. Increasing C_{OUT} will lead to an improved transient response however the size and cost also increase. X5R and X7R ceramic capacitors are recommended. For most applications, 2.2uF to 22uF should be sufficient.

Diode

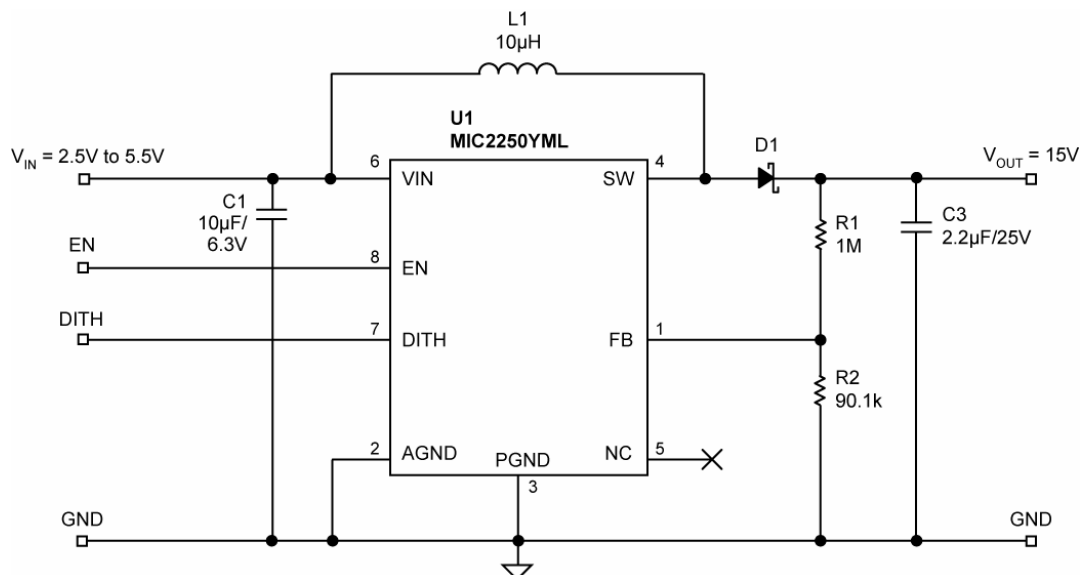

The MIC2250 requires an external diode for operation. The diode must be rated for the peak inductor current, and its reverse voltage rating must be greater than the output voltage. A Schottky diode is recommended for lower output voltages due to its lower forward voltage drop and reverse recovery time. However, at higher output voltages (>10V), a high speed diode such as LS4148 can be more efficient as it has the advantage of considerably lower leakage currents, especially at higher temperatures. This will greatly improve light load efficiency when compared to a Schottky diode.

For example: At 70°C ambient temperature, V_{IN} = 2.5V, V_{OUT} = 24V at no load.

Input current (Vishay SL04 Schottky) = 2.1mA

Input current (Generic LS4148) = 0.37mA
