

Micropower Single Supply Rail-to-Rail Input-Output Precision Op Amp

The EL8188 is a micropower precision op amp optimized for single supply operation at 5V and can operate down to 2.4V.

The EL8188 draws minimal supply current while meeting excellent DC-accuracy, noise, and output drive specifications. Competing devices seriously degrade these parameters to achieve rail-to-rail operation and microamp supply current. Offset current, voltage and current noise, slew rate, and gain-bandwidth product are all 2X to 10X better than on previous micropower rail-to-rail op amps.

The EL8188 can be operated from one lithium cell or two Ni-Cd batteries. The input range includes both the positive and negative rails. The output swings to both rails.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Features

- 50μA supply current
- 1mV typ offset voltage
- 2pA input bias current
- 266kHz gain-bandwidth product
- 0.13V/μs slew rate
- Single supply operation down to 2.4V
- Rail-to-rail input and output
- Output sources and sinks 26mA load current
- Pb-free plus anneal available (RoHS compliant)

Applications

- Battery- or solar-powered systems
- 4mA to 20mA current loops
- Handheld consumer products
- Medical devices
- Thermocouple amplifiers
- Photodiode pre-amps
- pH probe amplifiers

Application Information

Introduction

The EL8188 is a rail-to-rail input and output (RRIO), micro-power, precision, single supply op amp with an enable feature. This amplifier is designed to operate from single supply (2.4V to 5.0V) or dual supply ($\pm 1.2V$ to $\pm 2.5V$) while drawing only 50 μA of supply current. The device achieves rail-to-rail input and output operation while eliminating the drawbacks of many conventional RRIO op amps.

Rail-to-Rail Input

The PFET input stage of the EL8188 has an input common-mode voltage range that includes the negative and positive supplies without introducing offset errors or degrading performance like some existing rail-to-rail input op amps. Many rail-to-rail input stages use two differential input pairs: a long-tail PNP (or PFET) and an NPN (or NFET). Severe penalties result from using this topology. As the input signal moves from one supply rail to the other, the op amp switches from one input pair to the other causing drastic changes in input offset voltage and an undesired change in the input offset current's magnitude and polarity.

The EL8188 achieves rail-to-rail input performance without sacrificing important precision specifications and without degrading distortion performance. The EL8188's input offset voltage exhibits a smooth behavior throughout the entire common-mode input range.

Rail-to-Rail Output

A pair of complementary MOSFET devices achieves rail-to-rail output swing. The NMOS sinks current to swing the output in the negative direction, while the PMOS sources current to swing the output in the positive direction. The EL8188 with a 100k Ω load swings to within 3mV of the supply rails.

Enable/Disable Feature

The EL8188 features an active low $\overline{\text{ENABLE}}$ pin that when pulled up to at least 2V disables the output, and drops the already low I_{CC} to a 3 μA trickle. The $\overline{\text{ENABLE}}$ pin has an internal pull down, so an undriven pin pulls to the negative rail, thereby enabling the op amp by default.

The high impedance output during disable allows for connecting multiple EL8188s together to implement a Mux Amp. The outputs are connected together and activating the appropriate $\overline{\text{ENABLE}}$ pin selects the desired channel. If utilizing non-unity gain op amp configurations, then the loading effects of the disabled amplifiers' feedback networks must be considered when evaluating the active amplifier's performance in Mux Amp configurations.

Note that feedthrough from the IN+ to IN- pins occurs on any Mux Amp disabled channel where the input differential voltage exceeds 0.5V (e.g., active channel $V_{OUT} = 1V$, while disabled channel $V_{IN} = GND$), so the mux implementation is best suited for small signal applications. If large signals are required, use series IN+ resistors, or large value R_{FS} , to keep the feedthrough current low enough to minimize the impact on the active channel. See the "Usage Implications" on page 8 for more details.

IN+ and IN- Input Protection

In addition to ESD protection diodes to each supply rail, the EL8188 has additional back-to-back protection diodes across the differential input terminals (see "Circuit 1" on page 7). Obviously, one of these diodes conducts if the magnitude of the differential input voltage ever exceeds the diode's V_F .

Usage Implications

If the input differential voltage is expected to exceed 0.5V, an external current limiting resistor must be used to ensure the input current never exceeds 5mA. For noninverting unity gain applications the current limiting can be via a series IN+ resistor, or via a feedback resistor of appropriate value. For other gain configurations, the series IN+ resistor is the best choice, unless the feedback (R_F) and gain setting (R_G) resistors are both sufficiently large to limit the input current to 5mA.

Large differential input voltages can arise from several sources:

- 1) During open loop (comparator) operation. Used this way, the IN+ and IN- voltages don't track, so differentials arise.
- 2) When the amplifier is disabled but an input signal is still present. An R_L or R_G to GND keeps the IN- at GND, while the varying IN+ signal creates a differential voltage. Mux Amp applications are similar, except that the active channel V_{OUT} determines the voltage on the IN- terminal.
- 3) When the slew rate of the input pulse is considerably faster than the op amp's slew rate. If the V_{OUT} can't keep up with the IN+ signal, a differential voltage results, and visible distortion occurs on the input and output signals. To avoid this issue, keep the input slew rate below 0.2V/ μ s, or use appropriate current limiting resistors.

Large (>2V) differential input voltages can also cause an increase in disabled I_{CC} .

ENABLE Input Protection

The ENABLE input has internal ESD protection diodes to both the positive and negative supply rails, limiting the input voltage range to within one diode beyond the supply rails (see "Circuit 2" on page 7). If the input voltage is expected to exceed V_{S+} or V_{S-} , then an external series resistor should be added to limit the current to 5mA.

Output Current Limiting

The EL8188 has no internal current-limiting circuitry. If the output is shorted, it is possible to exceed the "Absolute Maximum Rating" for "operating junction temperature", potentially resulting in the destruction of the device.

Power Dissipation

It is possible to exceed the +150°C maximum junction temperature (T_{JMAX}) under certain load and power-supply conditions. It is therefore important to calculate T_{JMAX} for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in

the safe operating area. These parameters are related as follows:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times PD_{MAX}) \quad (EQ. 1)$$

where PD_{MAX} is calculated using:

$$PD_{MAX} = V_S \times I_{SMAX} + (V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L} \quad (EQ. 2)$$

where:

- T_{MAX} = Maximum ambient temperature
- θ_{JA} = Thermal resistance of the package
- PD_{MAX} = Maximum power dissipation of the amplifier
- V_S = Supply voltage
- I_{MAX} = Maximum supply current of the amplifier
- V_{OUTMAX} = Maximum output voltage swing of the application
- R_L = Load resistance

Proper Layout Maximizes Precision

To achieve the optimum levels of high input impedance (i.e., low input currents) and low offset voltage, care should be taken in the circuit board layout. The PC board surface must remain clean and free of moisture to avoid leakage currents between adjacent traces. Surface coating of the circuit board will reduce surface moisture and provide a humidity barrier, reducing parasitic resistance on the board. When input leakage current is a paramount concern, the use of guard rings around the amplifier inputs will further reduce leakage currents. Figure 18 shows a guard ring example for a unity gain amplifier that uses the low impedance amplifier output at the same voltage as the high impedance input to eliminate surface leakage. The guard ring does not need to be a specific width, but it should form a continuous loop around both inputs. For further reduction of leakage currents, mount components to the PC board using Teflon standoffs.

FIGURE 18. GUARD RING EXAMPLE FOR UNITY GAIN AMPLIFIER

Typical Applications

FIGURE 19. pH PROBE AMPLIFIER

A general-purpose combination pH probe has extremely high output impedance typically in the range of $10\text{G}\Omega$ to $12\text{G}\Omega$. Low loss and expensive Teflon cables are often used to connect the pH probe to the meter electronics. Figure 19 details a low-cost alternative solution using the EL8188 and a low-cost coax cable. The EL8188 PMOS high impedance input senses the pH probe output signal and buffers it to drive the coax cable. Its rail-to-rail input nature also eliminates the need for a bias resistor network required by other amplifiers in the same application.

FIGURE 20. THERMOCOUPLE AMPLIFIER

Thermocouples are the most popular temperature sensing devices because of their low cost, interchangeability, and ability to measure a wide range of temperatures. In Figure 20, the EL8188 converts the differential thermocouple voltage into single-ended signal with 10X gain. The EL8188's rail-to-rail input characteristic allows the thermocouple to be biased at ground and permits the op amp to operate from a single 5V supply.
