

Features

- 8-bit Microcontroller Compatible with MCS[®]51 Products
- Enhanced 8051 Architecture
 - Single-clock Cycle per Byte Fetch
 - Up to 20 MIPS Throughput at 20 MHz Clock Frequency
 - Fully Static Operation: 0 Hz to 20 MHz
 - On-chip 2-cycle Hardware Multiplier
 - 128 x 8 Internal RAM
 - 4-level Interrupt Priority
- Nonvolatile Program Memory
 - 2K Bytes of In-System Programmable (ISP) Flash Memory
 - Endurance: Minimum 10,000 Write/Erase Cycles
 - Data Retention: Minimum 10 Years
 - Serial Interface for Program Downloading
 - 32-byte Fast Page Programming Mode
 - 64-byte User Signature Array
 - 2-level Program Memory Lock for Software Security
- Peripheral Features
 - Two 16-bit Enhanced Timer/Counters
 - Two 8-bit PWM Outputs
 - Enhanced UART with Automatic Address Recognition and Framing Error Detection
 - Enhanced Master/Slave SPI with Double-buffered Send/Receive
 - Programmable Watchdog Timer with Software Reset
 - Analog Comparator with Selectable Interrupt and Debouncing
 - 8 General-purpose Interrupt Pins
- Special Microcontroller Features
 - Two-wire On-chip Debug Interface
 - Brown-out Detection and Power-on Reset with Power-off Flag
 - Internal RC Oscillator
 - Low Power Idle and Power-down Modes
 - Interrupt Recovery from Power-down Mode
- I/O and Packages
 - Up to 14 Programmable I/O Lines
 - Configurable I/O with Quasi-bidirectional, Input, Push-pull Output, and Open-drain Modes
 - 5V Tolerant I/O
 - 16-lead TSSOP/SOIC/PDIP
- Operating Conditions
 - 2.4V to 5.5V V_{CC} Voltage Range
 - -40°C to 85°C Temperature Range

1. Description

The AT89LP216 is a low-power, high-performance CMOS 8-bit microcontroller with 2K bytes of In-System Programmable Flash memory. The device is manufactured using Atmel's high-density nonvolatile memory technology and is compatible with the industry-standard MCS-51 instruction set. The AT89LP216 is built around an enhanced CPU core that can fetch a single byte from memory every clock cycle. In the classic 8051 architecture, each fetch requires 6 clock cycles, forcing instructions to execute in 12, 24 or 48 clock cycles. In the AT89LP216 CPU, instructions need only 1 to 4 clock cycles providing 6 to 12 times more throughput than the standard 8051. Seventy percent of instructions need only as many clock cycles as they

8-bit Microcontroller with 2K Bytes Flash

AT89LP216

Preliminary

have bytes to execute, and most of the remaining instructions require only one additional clock. The enhanced CPU core is capable of 20 MIPS throughput whereas the classic 8051 CPU can deliver only 4 MIPS at the same current consumption. Conversely, at the same throughput as the classic 8051, the new CPU core runs at a much lower speed and thereby greatly reduces power consumption.

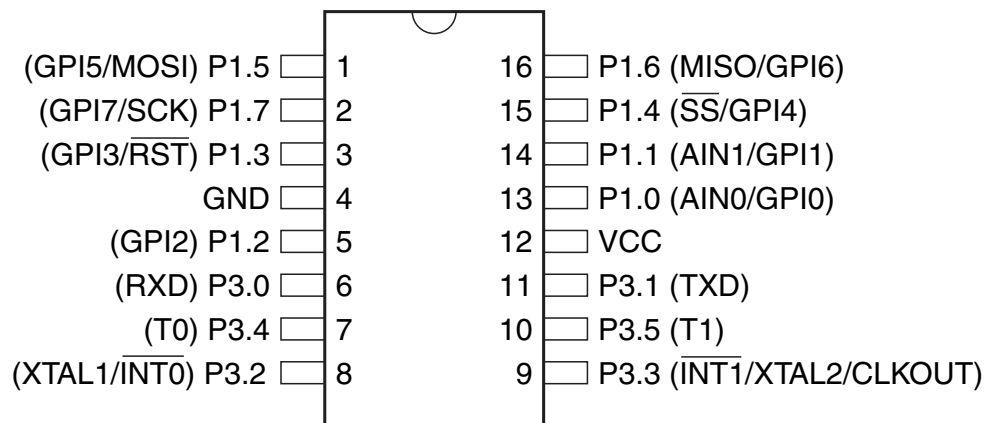

The AT89LP216 provides the following standard features: 2K bytes of In-System Programmable Flash memory, 128 bytes of RAM, up to 12 I/O lines, two 16-bit timer/counters, two PWM outputs, a programmable watchdog timer, a full-duplex serial port, a serial peripheral interface, an internal RC oscillator, on-chip crystal oscillator, and a four-level, six-vector interrupt system.

The two timer/counters in the AT89LP216 are enhanced with two new modes. Mode 0 can be configured as a variable 9- to 16-bit timer/counter and Mode 1 can be configured as a 16-bit auto-reload timer/counter. In addition, the timer/counters may independently drive a pulse width modulation output.

The I/O ports of the AT89LP216 can be independently configured in one of four operating modes. In quasi-bidirectional mode, the ports operate as in the classic 8051. In input mode, the ports are tristated. Push-pull output mode provides full CMOS drivers and open-drain mode provides just a pull-down. In addition, all 8 pins of Port 1 can be configured to generate an interrupt using the general-purpose interrupt interface. The I/O pins of the AT89LP216 tolerate voltages higher than the device's own power supply, up to 5.5V. When the device is supplied at 2.4V and all I/O ports receive 5.5V, the total back flowing current on all I/Os is less than 100 μ A.

2. Pin Configuration

2.1 AT89LP216: 16-lead PDIP/SOIC/TSSOP

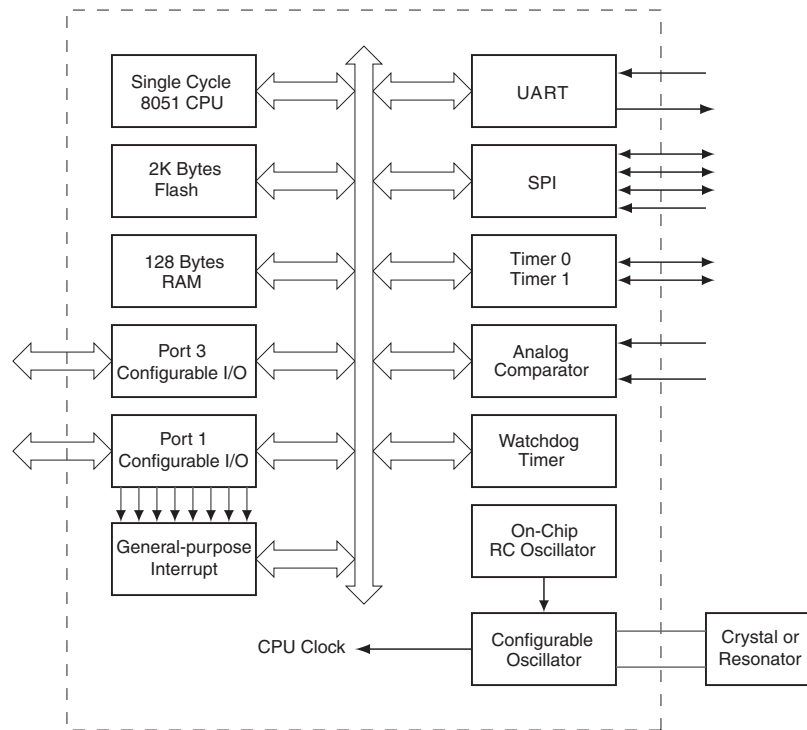

3. Pin Description

Table 3-1. AT89LP216 Pin Description

Pin	Symbol	Type	Description
1	P1.5	I/O I/O I	P1.5: User-configurable I/O Port 1 bit 5. MOSI: SPI master-out/slave-in. When configured as master, this pin is an output. When configured as slave, this pin is an input. GPI5: General-purpose Interrupt input 5.
2	P1.7	I/O I/O I	P1.7: User-configurable I/O Port 1 bit 7. SCK: SPI Clock. When configured as master, this pin is an output. When configured as slave, this pin is an input. GPI7: General-purpose Interrupt input 7.
3	P1.3	I/O I I I	P1.3: User-configurable I/O Port 1 bit 3 (if Reset Fuse is disabled). RST: External Active-Low Reset input (if Reset Fuse is enabled. See “External Reset” on page 14.). GPI3: General-purpose Interrupt input 3. DCL: Serial Clock input for On-Chip Debug Interface when OCD is enabled.
4	GND	I	Ground
5	P1.2	I/O I	P1.2: User-configurable I/O Port 1 bit 2. GPI2: General-purpose Interrupt input 2.
6	P3.0	I/O I	P3.0: User-configurable I/O Port 3 bit 0. RXD: Serial Port Receiver Input.
7	P3.4	I/O I/O	P3.4: User-configurable I/O Port 3 bit 4. TO: Timer/Counter 0 External Input or PWM Output.
8	P3.2	I/O I I/O	P3.2: User-configurable I/O Port 3 bit 2. XTAL1: Input to the inverting oscillator amplifier and internal clock generation circuits. It may be used as a port pin if the internal RC oscillator is selected as the clock source. DDA: Serial Data input/output for On-Chip Debug Interface when OCD is enabled and the internal RC oscillator is selected as the clock source.
9	P3.3	I/O O O I/O	P3.3: User-configurable I/O Port 3 bit 3. XTAL2: Output from inverting oscillator amplifier. It may be used as a port pin if the internal RC oscillator is selected as the clock source. CLKOUT: When the internal RC oscillator is selected as the clock source, may be used to output the internal clock divided by 2. DDA: Serial Data input/output for On-Chip Debug Interface when OCD is enabled and the external clock is selected as the clock source.
10	P3.5	I/O I/O	P3.5: User-configurable I/O Port 3 bit 5. T1: Timer/Counter 1 External input or PWM output.
11	P3.1	I/O O	P3.1: User-configurable I/O Port 3 bit 1. TXD: Serial Port Transmitter Output.
12	VDD	I	Supply Voltage
13	P1.0	I/O I I	P1.0: User-configurable I/O Port 1 bit 0. AIN0: Analog Comparator Positive input. GPI0: General-purpose Interrupt input 0.
14	P1.1	I/O I I	P1.1: User-configurable I/O Port 1 bit 1. AIN1: Analog Comparator Negative input. GPI1: General-purpose Interrupt input 1
15	P1.4	I/O I I	P1.4: User-configurable I/O Port 1 bit 4. SS: SPI slave select input. GPI4: General-purpose Interrupt input 4.
16	P1.6	I/O I/O I	P1.6: User-configurable I/O Port 1 bit 6. MISO: SPI master-in/slave-out. When configured as master, this pin is an input. When configured as slave, this pin is an output. GPI6: General-purpose Interrupt input 6.

4. Block Diagram

Figure 4-1. AT89LP216 Block Diagram

5. Comparison to Standard 8051

The AT89LP216 is part of a family of devices with enhanced features that are fully binary compatible with the MCS-51 instruction set. In addition, most SFR addresses, bit assignments, and pin alternate functions are identical to Atmel's existing standard 8051 products. However, due to the high performance nature of the device, some system behaviors are different from those of Atmel's standard 8051 products such as AT89S52 or AT89S2051. The differences from the standard 8051 are outlined in the following paragraphs.

5.1 System Clock

The CPU clock frequency equals the external XTAL1 frequency. The oscillator is no longer divided by 2 to provide the internal clock, and x2 mode is not supported.

5.2 Instruction Execution with Single-cycle Fetch

The CPU fetches one code byte from memory every clock cycle instead of every six clock cycles. This greatly increases the throughput of the CPU. As a consequence, the CPU no longer executes instructions in 12 to 48 clock cycles. Each instruction executes in only 1 to 4 clock cycles. See ["Instruction Set Summary" on page 59](#) for more details.

5.3 Interrupt Handling

The interrupt controller polls the interrupt flags during the last clock cycle of any instruction. In order for an interrupt to be serviced at the end of an instruction, its flag needs to have been latched as active during the next to last clock cycle of the instruction, or in the last clock cycle of the previous instruction if the current instruction executes in only a single clock cycle.

The external interrupt pins, $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$, are sampled at every clock cycle instead of once every 12 clock cycles. Coupled with the shorter instruction timing and faster interrupt response, this leads to a higher maximum rate of incidence for the external interrupts.

5.4 Timer/Counters

By default the Timer/Counters is incremented at a rate of once per clock cycle. This compares to once every 12 clocks in the standard 8051. A common prescaler is available to divide the time base for all timers and reduce the increment rate. The TPS bits in the CLKREG SFR control the prescaler ([Table 9-2 on page 12](#)). Setting TPS = 1011B will cause the timers to count once every 12 clocks.

The external Timer/Counter pins, T0 and T1, are sampled at every clock cycle instead of once every 12 clock cycles. This increases the maximum rate at which the Counter modules may function.

5.5 Serial Port

The baud rate of the UART in Mode 0 is 1/2 the clock frequency, compared to 1/12 the clock frequency in the standard 8051; and output data is only stable around the rising edge of the serial clock. It should also be noted that when using Timer 1 to generate the baud rate in Mode 1 or Mode 3, the timer counts at the clock frequency and not at 1/12 the clock frequency. To maintain the same baud rate in the AT89LP216 while running at the same frequency as a standard 8051, the time-out period must be 12 times longer. Mode 1 of Timer 1 supports 16-bit auto-reload to facilitate longer time-out periods for generating low baud rates.

5.6 Watchdog Timer

The Watchdog Timer in AT89LP216 counts at a rate of once per clock cycle. This compares to once every 12 clocks in the standard 8051. A common prescaler is available to divide the time base for all timers and reduce the counting rate.

5.7 I/O Ports

The I/O ports of the AT89LP216 may be configured in four different modes. By default all the I/O ports revert to input-only (tristated) mode at power-up or reset. In the standard 8051, all ports are weakly pulled high during power-up or reset. To enable 8051-like ports, the ports must be put into quasi-bidirectional mode by clearing the P1M0 and P3M0 SFRs. The user can also configure the ports to start in quasi-bidirectional mode by disabling the Tristate-Port User Fuse. When this fuse is disabled, P1M0 and P3M0 will reset to 00h instead of FFh and the ports will be weakly pulled high.

5.8 Reset

The $\overline{\text{RST}}$ pin of the AT89LP216 is active-low as compared with the active high reset in the standard 8051. In addition, the $\overline{\text{RST}}$ pin is sampled every clock cycle and must be held low for a minimum of two clock cycles, instead of 24 clock cycles, to be recognized as a valid reset.

6. Memory Organization

The AT89LP216 uses a Harvard Architecture with separate address spaces for program and data memory. The program memory has a regular linear address space with support for up to 64K bytes of directly addressable application code. The data memory has 128 bytes of internal RAM and 128 bytes of Special Function Register I/O space. The AT89LP216 does not support external data memory or external program memory.

6.1 Program Memory

The AT89LP216 contains 2K bytes of on-chip In-System Programmable Flash memory for program storage. The Flash memory has an endurance of at least 10,000 write/erase cycles and a minimum data retention time of 10 years. The reset and interrupt vectors are located within the first 59 bytes of program memory (refer to [Table 12-1 on page 19](#)). Constant tables can be allocated within the entire 2K program memory address space for access by the MOVC instruction. The AT89LP216 does not support external program memory.

Figure 6-1. Program Memory Map

A map of the AT89LP216 program memory is shown in [Figure 6-1](#). In addition to the 2K code space from 0000h to 07FFh, the AT89LP216 also supports a 64-byte User Signature Array and a 32-byte Atmel Signature Array that are accessible by the CPU in a read-only fashion. In order to read from the signature arrays, the SIGEN bit in AUXR1 must be set. While SIGEN is one, MOVC A,@A+DPTR will access the signature arrays. The User Signature Array is mapped to addresses 0040h to 007Fh and the Atmel Signature Array is mapped to addresses 0000h to 001Fh. SIGEN must be cleared before using MOVC to access the code memory.

The Atmel Signature Array is initialized with the Device ID in the factory. The User Signature Array is available for user identification codes or constant parameter data. Data stored in the signature array is not secure. Security bits will disable writes to the array; however, reads are always allowed.

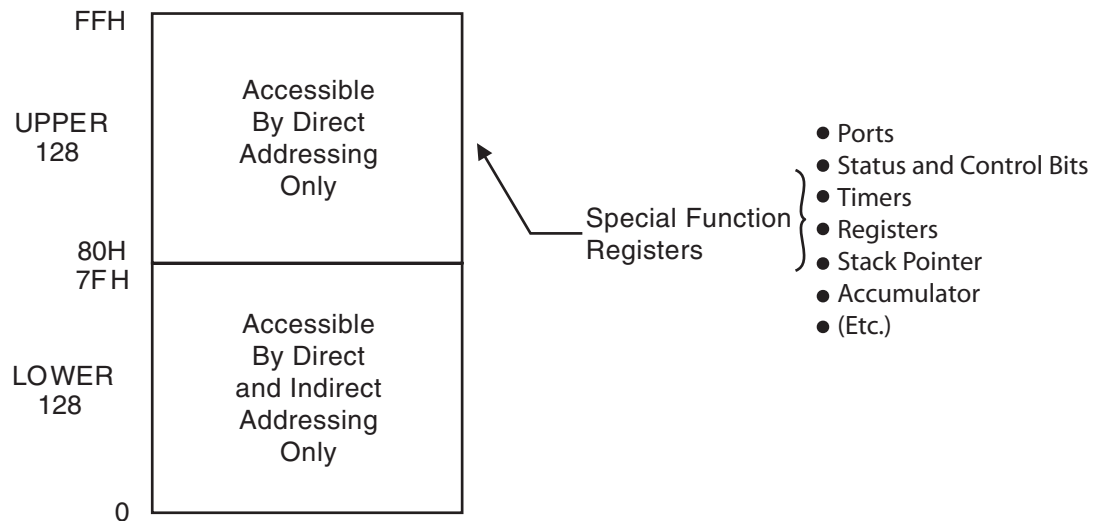

Table 6-1. AUXR1 – Auxiliary Register 1

AUXR1 = A2H					Reset Value = XXXX 0XXXB			
Not Bit Addressable								
	–	–	–	–	SIGEN	–	–	–
Bit	7	6	5	4	3	2	1	0

6.2 Data Memory

The AT89LP216 contains 128 bytes of general SRAM data memory plus 128 bytes of I/O memory mapped into a single 8-bit address space. The 128 bytes of data memory may be accessed through both direct and indirect addressing of the lower 128 byte addresses. The 128 bytes of I/O memory reside in the upper 128-byte address space (Figure 6-2). The I/O memory can only be accessed through direct addressing and contains the Special Function Registers (SFRs). Indirect accesses to the upper 128-byte addresses will return invalid data. The lowest 32 bytes of data memory are grouped into 4 banks of 8 registers each. The RS0 and RS1 bits (PSW.3 and PSW.4) select which register bank is in use. Instructions using register addressing will only access the currently specified bank. The AT89LP216 does not support external data memory.

Figure 6-2. Data Memory Map

7. Special Function Registers

A map of the on-chip memory area called the Special Function Register (SFR) space is shown in [Table 7-1](#).

Note that not all of the addresses are occupied, and unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect. User software should not write to these unlisted locations, since they may be used in future products to invoke new features.

- Notes:
1. All SFRs in the left-most column are bit-addressable.
 2. Reset value is xx11 1111B when Tristate-Port Fuse is enabled and xx00 0000B when disabled.

8. Enhanced CPU

The AT89LP216 uses an enhanced 8051 CPU that runs at 6 to 12 times the speed of standard 8051 devices (or 3 to 6 times the speed of X2 8051 devices). The increase in performance is due to two factors. First, the CPU fetches one instruction byte from the code memory every clock cycle. Second, the CPU uses a simple two-stage pipeline to fetch and execute instructions in parallel. This basic pipelining concept allows the CPU to obtain up to 1 MIPS per MHz. A simple example is shown in [Figure 8-1](#).

The MCS-51 instruction set allows for instructions of variable length from 1 to 3 bytes. In a single-clock-per-byte-fetch system this means each instruction takes at least as many clocks as it has bytes to execute. The majority of instructions in the AT89LP216 follow this rule: the instruction execution time in clock cycles equals the number of bytes per instruction with a few exceptions. Branches and Calls require an additional cycle to compute the target address and some other complex instructions require multiple cycles. See [“Instruction Set Summary” on page 59](#) for more detailed information on individual instructions. [Figures 8-2 and 8-3](#) show examples of 1- and 2-byte instructions.

Figure 8-1. Parallel Instruction Fetches and Executions

Figure 8-2. Single-cycle ALU Operation (Example: INC R0)

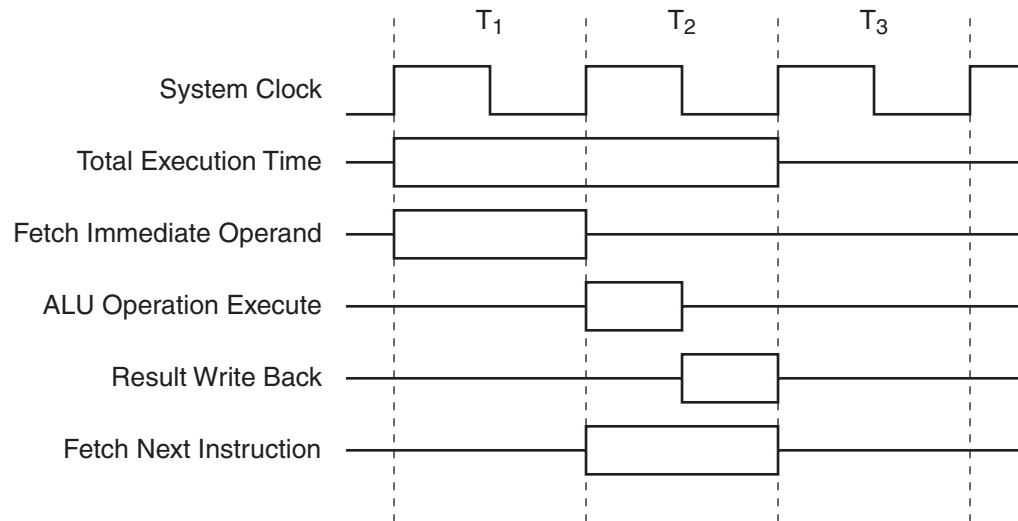

Figure 8-3. Two-cycle ALU Operation (Example: ADD A, #data)

8.1 Restrictions on Certain Instructions

The AT89LP216 is an economical and cost-effective member of Atmel's growing family of micro-controllers. It contains 2K bytes of Flash program memory. It is fully compatible with the MCS-51 architecture, and can be programmed using the MCS-51 instruction set. However, there are a few considerations one must keep in mind when utilizing certain instructions to program this device. All the instructions related to jumping or branching should be restricted such that the destination address falls within the physical program memory space of the device, which is 2K bytes for the AT89LP216. This should be the responsibility of the software programmer. For example, LJMP 7E0H would be a valid instruction, whereas LJMP 900H would not.

8.1.1 Branching Instructions

The LCALL, LJMP, ACALL, AJMP, SJMP, and JMP @A+DPTR unconditional branching instructions will execute correctly as long as the programmer keeps in mind that the destination branching address must fall within the physical boundaries of the program memory size (locations 000H to 7FFH for the AT89LP216). Violating the physical space limits may cause unknown program behavior. With the CJNE [...], DJNZ [...], JB, JNB, JC, JNC, JBC, JZ, and JNZ conditional branching instructions, the same previous rule applies. Again, violating the memory boundaries may cause erratic execution. For applications involving interrupts the normal interrupt service routine address locations of the 8051 family architecture have been preserved.

8.1.2 MOVX-related Instructions, Data Memory

The AT89LP216 contains 128 bytes of internal data memory. RAM accesses to addresses above 7FH will return invalid data. Furthermore, the stack depth is limited to 128 bytes, the amount of available RAM. The Stack Pointer should not be allowed to point to locations above 7FH. External DATA memory access is not supported in this device, nor is external PROGRAM memory execution. Therefore, no MOVX [...] instructions should be included in the program.

A typical 8051 assembler will still assemble instructions, even if they are written in violation of the restrictions mentioned above. It is the responsibility of the user to know the physical features and limitations of the device being used and to adjust the instructions used accordingly.

9. System Clock

The system clock is generated directly from one of three selectable clock sources. The three sources are the on-chip crystal oscillator, external clock source, and internal RC oscillator. The clock source is selected by the Clock Source User Fuses as shown in [Table 9-1](#). No internal clock division is used to generate the CPU clock from the system clock. See [“User Configuration Fuses” on page 71](#).

Table 9-1. Clock Source Settings

Clock Source Fuse 1	Clock Source Fuse 0	Selected Clock Source
0	0	Crystal Oscillator
0	1	Reserved
1	0	External Clock on XTAL1
1	1	Internal 8 MHz RC Oscillator

9.1 Crystal Oscillator

When enabled, the internal inverting oscillator amplifier is connected between XTAL1 and XTAL2 for connection to an external quartz crystal or ceramic resonator. When using the crystal oscillator, P3.2 and P3.3 will have their inputs and outputs disabled. When using the crystal oscillator, XTAL2 should not be used to drive a board-level clock without a buffer.

9.2 External Clock Source

The external clock option disables the oscillator amplifier and allows XTAL1 to be driven directly by the clock source. XTAL2 may be left unconnected, used as P3.3 I/O, or configured to output a divided version of the system clock.

9.3 Internal RC Oscillator

The AT89LP216 has an internal RC oscillator tuned to 8.0 MHz $\pm 2.5\%$. When enabled as the clock source, XTAL1 and XTAL2 may be used as P3.2 and P3.3 respectively. XTAL2 may also be configured to output a divided version of the system clock. The frequency of the oscillator may be adjusted by changing the RC Adjust Fuses. (See [“User Configuration Fuses” on page 71](#)).

9.4 System Clock Out

When the AT89LP216 is configured to use either an external clock or the internal RC oscillator, a divided version of the system clock may be output on XTAL2 (P3.3). The clock out feature is enabled by setting the COE bit in CLKREG. The two CDV bits determine the clock divide ratio. For example, setting COE = “1” and CDIV = “00” when using the internal oscillator will result in a 3.950 MHz ($\pm 5\%$) clock output on P3.3. P3.3 must be configured as an output in order to use the clock out feature.

Table 9-2. CLKREG – Clock Control Register

CLKREG = 8FH					Reset Value = 0000 0000B			
Not Bit Addressable								
	TPS3	TPS2	TPS1	TPS0	–	CDV1	CDV0	COE
Bit	7	6	5	4	3	2	1	0

Symbol	Function															
TPS3 TPS2 TPS1 TPS0	Timer Prescaler. The Timer Prescaler selects the time base for Timer 0, Timer 1 and the Watchdog Timer. The prescaler is implemented as a 4-bit binary down counter. When the counter reaches zero it is reloaded with the value stored in the TPS bits to give a division ratio between 1 and 16. By default the timers will count every clock cycles (TPS = 0000B). To configure the timers to count at a standard 8051 rate of once every 12 clock cycles, TPS should be set to 1011B.															
CDV1 CDV0	Clock Out Division. Determines the frequency of the clock output relative to the system clock. <table border="1"> <thead> <tr> <th>CDIV1</th> <th>CDIV0</th> <th>Clock Out Frequency</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>f/2</td> </tr> <tr> <td>0</td> <td>1</td> <td>f/4</td> </tr> <tr> <td>1</td> <td>0</td> <td>f/8</td> </tr> <tr> <td>1</td> <td>1</td> <td>f/16</td> </tr> </tbody> </table>	CDIV1	CDIV0	Clock Out Frequency	0	0	f/2	0	1	f/4	1	0	f/8	1	1	f/16
CDIV1	CDIV0	Clock Out Frequency														
0	0	f/2														
0	1	f/4														
1	0	f/8														
1	1	f/16														
COE	Clock Out Enable. Set COE to output a divided version of the system clock on XTAL2 (P3.3). The internal RC oscillator or external clock source must be selected in order to use this feature.															

10. Reset

During reset, all I/O Registers are set to their initial values, the port pins are tristated, and the program starts execution from the Reset Vector, 0000H. The AT89LP216 has five sources of reset: power-on reset, brown-out reset, external reset, watchdog reset, and software reset.

10.1 Power-on Reset

A Power-on Reset (POR) is generated by an on-chip detection circuit. The detection level is nominally 1.4V. The POR is activated whenever V_{CC} is below the detection level. The POR circuit can be used to trigger the start-up reset or to detect a supply voltage failure in devices without a brown-out detector. The POR circuit ensures that the device is reset from power-on. A power-on sequence is shown in [Figure 10-1 on page 13](#). When V_{CC} reaches the Power-on Reset threshold voltage V_{POR} , an initialization sequence lasting t_{POR} is started. When the initialization sequence completes, the start-up timer determines how long the device is kept in POR after V_{CC} rise. The POR signal is activated again, without any delay, when V_{CC} falls below the POR threshold level. A Power-on Reset (i.e. a cold reset) will set the POF flag in PCON. The internally generated reset can be extended beyond the power-on period by holding the \overline{RST} pin low longer than the time-out.

Figure 10-1. Power-on Reset Sequence (BOD Disabled)

If the Brown-out Detector (BOD) is also enabled, the start-up timer does not begin counting until after V_{CC} reaches the BOD threshold voltage V_{BOD} as shown in Figure 10-2. However, if this event occurs prior to the end of the initialization sequence, the timer must first wait for that sequence to complete before counting.

Figure 10-2. Power-on Reset Sequence (BOD Enabled)

Note: t_{POR} is approximately $92 \mu s \pm 5\%$.

The start-up timer delay is user-configurable with the Start-up Time User Fuses and depends on the clock source (Table 10-1). The start-up delay should be selected to provide enough settling time for V_{CC} and the selected clock source. The Start-Up Time fuses also control the length of the start-up time after a Brown-out Reset or when waking up from Power-down during internally timed mode.

Table 10-1. Start-up Timer Settings

SUT Fuse 1	SUT Fuse 0	Clock Source	$t_{SUT} (\pm 5\%) \mu s$
0	0	Internal RC/External Clock	16
		Crystal Oscillator	1024
0	1	Internal RC/External Clock	512
		Crystal Oscillator	2048
1	0	Internal RC/External Clock	1024
		Crystal Oscillator	4096
1	1	Internal RC/External Clock	4096
		Crystal Oscillator	16384

10.2 Brown-out Reset

The AT89LP216 has an on-chip Brown-out Detection (BOD) circuit for monitoring the V_{CC} level during operation by comparing it to a fixed trigger level. The trigger level for the BOD is nominally 2.2V. The purpose of the BOD is to ensure that if V_{CC} fails or dips while executing at speed, the system will gracefully enter reset without the possibility of errors induced by incorrect execution. A BOD sequence is shown in Figure 10-3. When V_{CC} decreases to a value below the trigger level V_{BOD} , the internal reset is immediately activated. When V_{CC} increases above the trigger level, the start-up timer releases the internal reset after the specified time-out period has expired (Table 10-1). The Brown-out Detector must be enabled by setting the BOD Enable Fuse. (See “User Configuration Fuses” on page 71.).

Figure 10-3. Brown-out Detector Reset

10.3 External Reset

The P1.3/ \overline{RST} pin can function as either an active-LOW reset input or as a digital general-purpose I/O, P1.3. The Reset Pin Enable Fuse, when set to “1”, enables the external reset input function on P1.3. (See “User Configuration Fuses” on page 71.). When cleared, P1.3 may be used as an input or output pin. When configured as a reset input, the pin must be held low for at least two clock cycles to trigger the internal reset.

Note: During a power-up sequence, the fuse selection is always overridden and therefore the pin will always function as a reset input. **An external circuit connected to this pin should not hold this pin LOW during a power-on sequence as this will keep the device in reset until the pin transitions high.** After the power-up delay, this input will function either as an external reset input or as a digital input as defined by the fuse bit. Only a power-up reset will temporarily override the selection defined by the reset fuse bit. Other sources of reset will not override the reset fuse bit. P1.3/ \overline{RST} also serves as the In-System Programming (ISP) enable. ISP is enabled when the external reset pin is held low. When the reset pin is disabled by the fuse, ISP may only be entered by pulling P1.3 low during power-up.

10.4 Watchdog Reset

When the Watchdog times out, it will generate an internal reset pulse lasting 16 clock cycles. Watchdog reset will also set the WDTOVF flag in WDTCON. To prevent a Watchdog reset, the watchdog reset sequence 1EH/E1H must be written to WDTRST before the Watchdog times out. See “Programmable Watchdog Timer” on page 57. for details on the operation of the Watchdog.

10.5 Software Reset

The CPU may generate an internal 16-clock cycle reset pulse by writing the software reset sequence 5AH/A5H to the WDRST register. A software reset will set the SWRST bit in WDTCON. See “Software Reset” on page 58. for more information on software reset.

11. Power Saving Modes

The AT89LP216 supports two different power-reducing modes: Idle and Power-down. These modes are accessed through the PCON register.

11.1 Idle Mode

Setting the IDL bit in PCON enters idle mode. Idle mode halts the internal CPU clock. The CPU state is preserved in its entirety, including the RAM, stack pointer, program counter, program status word, and accumulator. The Port pins hold the logic states they had at the time that Idle was activated. Idle mode leaves the peripherals running in order to allow them to wake up the CPU when an interrupt is generated. The timers, UART, SPI, and GPI blocks continue to function during Idle. The comparator and watchdog may be selectively enabled or disabled during Idle. Any enabled interrupt source or reset may terminate Idle mode. When exiting Idle mode with an interrupt, the interrupt will immediately be serviced, and following RETI the next instruction to be executed will be the one following the instruction that put the device into Idle.

11.2 Power-down Mode

Setting the Power-down (PD) bit in PCON enters Power-down mode. Power-down mode stops the oscillator and powers down the Flash memory in order to minimize power consumption. Only the power-on circuitry will continue to draw power during Power-down. During Power-down, the power supply voltage may be reduced to the RAM keep-alive voltage. The RAM contents will be retained, but the SFR contents are not guaranteed once V_{CC} has been reduced. Power-down may be exited by external reset, power-on reset, or certain interrupts.

11.2.1 Interrupt Recovery from Power-down

Three external interrupts may be configured to terminate Power-down mode. XTAL1 or XTAL2, when not used for the crystal oscillator or external clock, may be used to exit Power-down through external interrupts $\overline{INT0}$ (P3.2) and $\overline{INT1}$ (P3.3). To wake up by external interrupt $\overline{INT0}$ or $\overline{INT1}$, that interrupt must be enabled and configured for level-sensitive operation. General purpose interrupt 3 (GPI3) can also wake up the device when the \overline{RST} pin is disabled. GPI3 must be enabled and configured for low level detection in order to terminate Power-down.

When terminating Power-down by an interrupt, two different wake-up modes are available. When PWDEX in PCON is zero, the wake-up period is internally timed as shown in Figure 11-1. At the falling edge on the interrupt pin, Power-down is exited, the oscillator is restarted, and an internal timer begins counting. The internal clock will not be allowed to propagate to the CPU until after the timer has timed out. After the time-out period the interrupt service routine will begin. The time-out period is controlled by the Start-up Timer Fuses (see Table 10-1 on page 14). The interrupt pin need not remain low for the entire time-out period.

Figure 11-1. Interrupt Recovery from Power-down (PWDEX = 0)

When PWDEX = “1”, the wake-up period is controlled externally by the interrupt. Again, at the falling edge on the interrupt pin, power-down is exited and the oscillator is restarted. However, the internal clock will not propagate until the rising edge of the interrupt pin as shown in Figure 11-2. The interrupt pin should be held low long enough for the selected clock source to stabilize. After the rising edge on the pin the interrupt service routine will be executed.

Figure 11-2. Interrupt Recovery from Power-down (PWDEX = 1)

11.2.2 Reset Recovery from Power-down

The wake-up from Power-down through an external reset is similar to the interrupt with PWDEX = “0”. At the falling edge of \overline{RST} , Power-down is exited, the oscillator is restarted, and an internal timer begins counting as shown in Figure 11-3. The internal clock will not be allowed to propagate to the CPU until after the timer has timed out. The time-out period is controlled by the Start-up Timer Fuses. (See Table 10-1 on page 14). If \overline{RST} returns high before the time-out, a two clock cycle internal reset is generated when the internal clock restarts. Otherwise, the device will remain in reset until \overline{RST} is brought high.

Figure 11-3. Reset Recovery from Power-down.

Table 11-1. PCON – Power Control Register

PCON = 87H		Reset Value = 000X 0000B						
Not Bit Addressable								
Bit	SMOD1	SMOD0	PWDEX	POF	GF1	GF0	PD	IDL
	7	6	5	4	3	2	1	0
Symbol	Function							
SMOD1	Double Baud Rate bit. Doubles the baud rate of the UART in Modes 1, 2, or 3.							
SMOD0	Frame Error Select. When SMOD0 = 1, SCON.7 is SM0. When SMOD0 = 0, SCON.7 is FE. Note that FE will be set after a frame error regardless of the state of SMOD0.							
PWDEX	Power-down Exit Mode. When PWDEX = 1, wake up from Power-down is externally controlled. When PWDEX = 0, wake up from Power-down is internally timed.							
POF	Power Off Flag. POF is set to “1” during power up (i.e. cold reset). It can be set or reset under software control and is not affected by RST or BOD (i.e. warm resets).							
GF1, GF0	General-purpose Flags							
PD	Power-down bit. Setting this bit activates power-down operation.							
IDL	Idle Mode bit. Setting this bit activates Idle mode operation							

12. Interrupts

The AT89LP216 provides 7 interrupt sources: two external interrupts, two timer interrupts, a serial port interrupt, a general-purpose interrupt, and an analog comparator interrupt. These interrupts and the system reset each have a separate program vector at the start of the program memory space. Each interrupt source can be individually enabled or disabled by setting or clearing a bit in the interrupt enable register IE. The IE register also contains a global disable bit, EA, which disables all interrupts.

Each interrupt source (with the **exception** of the Analog Comparator) can be individually programmed to one of four priority levels by setting or clearing bits in the interrupt priority registers IP and IPH. The Analog Comparator is fixed at the lowest priority level. An interrupt service routine in progress can be interrupted by a higher priority interrupt, but not by another interrupt of the same or lower priority. The highest priority interrupt cannot be interrupted by any other interrupt source. If two requests of different priority levels are pending at the end of an instruction, the request of higher priority level is serviced. If requests of the same priority level are pending at the end of an instruction, an internal polling sequence determines which request is serviced. The polling sequence is based on the vector address; an interrupt with a lower vector address has higher priority than an interrupt with a higher vector address. Note that the polling sequence is only used to resolve pending requests of the same priority level.

The External Interrupts $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ can each be either level-activated or edge-activated, depending on bits IT0 and IT1 in Register TCON. The flags that actually generate these interrupts are the IE0 and IE1 bits in TCON. When the service routine is vectored to, hardware clears the flag that generated an external interrupt only if the interrupt was edge-activated. If the interrupt was level activated, then the external requesting source (rather than the on-chip hardware) controls the request flag.

The Timer 0 and Timer 1 Interrupts are generated by TF0 and TF1, which are set by a rollover in their respective Timer/Counter registers (except for Timer 0 in Mode 3). When a timer interrupt is generated, the on-chip hardware clears the flag that generated it when the service routine is vectored to.

The Serial Port Interrupt is generated by the logic OR of RI and TI in SCON plus SPIF in SPSR. None of these flags is cleared by hardware when the service routine is vectored to. In fact, the service routine normally must determine whether RI, TI, or SPIF generated the interrupt, and the bit must be cleared by software.

A logic OR of all eight flags in the GPIF register causes the general-purpose interrupt. None of these flags is cleared by hardware when the service routine is vectored to. The service routine must determine which bit generated the interrupt, and the bit must be cleared in software. If the interrupt was level activated, then the external requesting source must de-assert the interrupt before the flag may be cleared by software.

The CF bit in ACSR generates the Comparator Interrupt. The flag is not cleared by hardware when the service routine is vectored to and must be cleared by software.

Most of the bits that generate interrupts can be set or cleared by software, with the same result as though they had been set or cleared by hardware. That is, interrupts can be generated and pending interrupts can be canceled in software. The two exceptions are the SPI interrupt flag SPIF and the general-purpose interrupt flags in GPIF. These flags are only set by hardware and may only be cleared by software.

Table 12-1. Interrupt Vector Addresses

Interrupt	Source	Vector Address
System Reset	RST or POR or BOD	0000H
External Interrupt 0	IE0	0003H
Timer 0 Overflow	TF0	000BH
External Interrupt 1	IE1	0013H
Timer 1 Overflow	TF1	001BH
Serial Port	RI or TI or SPIF	0023H
General-purpose Interrupt	GPIF	002BH
Analog Comparator	CF	0033H

12.1 Interrupt Response Time

The interrupt flags may be set by their hardware in any clock cycle. The interrupt controller polls the flags in the last clock cycle of the instruction in progress. If one of the flags was set in the preceding cycle, the polling cycle will find it and the interrupt system will generate an LCALL to the appropriate service routine as the next instruction, provided that the interrupt is not blocked by any of the following conditions: an interrupt of equal or higher priority level is already in progress; the instruction in progress is RETI or any write to the IE, IP, or IPH registers. Either of these conditions will block the generation of the LCALL to the interrupt service routine. The second condition ensures that if the instruction in progress is RETI or any access to IE, IP or IPH, then at least one more instruction will be executed before any interrupt is vectored to. The polling cycle is repeated at the last cycle of each instruction, and the values polled are the values that were present at the previous clock cycle. If an active interrupt flag is not being serviced because of one of the above conditions and is no longer active when the blocking condition is removed, the denied interrupt will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle is new.

If a request is active and conditions are met for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction executed. The call itself takes four cycles. Thus, a minimum of five complete clock cycles elapsed between activation of an interrupt request and the beginning of execution of the first instruction of the service routine. A longer response time results if the request is blocked by one of the previously listed conditions. If an interrupt of equal or higher priority level is already in progress, the additional wait time depends on the nature of the other interrupt's service routine. If the instruction in progress is not in its final clock cycle, the additional wait time cannot be more than 3 cycles, since the longest are only 4 cycles long. If the instruction in progress is RETI or an access to IE or IP, the additional wait time cannot be more than 7 cycles (a maximum of three more cycles to complete the instruction in progress, plus a maximum of 4 cycles to complete the next instruction). Thus, in a single-interrupt system, the response time is always more than 5 clock cycles and less than 13 clock cycles. See [Figure 12-1](#) and [Figure 12-2](#).

Figure 12-1. Minimum Interrupt Response Time

13. I/O Ports

The AT89LP216 can be configured for between 9 and 12 I/O pins. The exact number of I/O pins available depends on the clock and reset options as shown in [Table 13-1](#). All port pins are 5V tolerant, that is they can be pulled up or driven to 5.5V even when operating at a lower V_{CC} such as 3V.

Table 13-1. I/O Pin Configurations

Clock Source	Reset Option	Number of I/O Pins
External Crystal or Resonator	External \overline{RST} Pin	11
	No external reset	12
External Clock	External \overline{RST} Pin	12
	No external reset	13
Internal RC Oscillator	External \overline{RST} Pin	13
	No external reset	14

13.1 Port Configuration

All port pins on the AT89LP216 may be configured to one of four modes: quasi-bidirectional (standard 8051 port outputs), push-pull output, open-drain output, or input-only. Port modes may be assigned in software on a pin-by-pin basis as shown in [Table 13-2](#). The Tristate-Port User Fuse determines the default state of the port pins. When the fuse is enabled, all port pins default to input-only mode after reset. When the fuse is disabled, all port pins, with the exception of P1.0 and P1.1, default to quasi-bidirectional mode after reset and are weakly pulled high. Each port pin also has a Schmitt-triggered input for improved input noise rejection. During Power-down all the Schmitt-triggered inputs are disabled with the exception of P1.3, P3.2 and P3.3, which may be used to wake up the device. Therefore, P1.3, P3.2 and P3.3 should not be left floating during Power-down

Table 13-2. Configuration Modes for Port x, Bit y

PxM0.y	PxM1.y	Port Mode
0	0	Quasi-bidirectional
0	1	Push-pull Output
1	0	Input Only (High Impedance)
1	1	Open-Drain Output

13.1.1 Quasi-bidirectional Output

Port pins in quasi-bidirectional output mode function similar to standard 8051 port pins. A Quasi-bidirectional port can be used both as an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low. When the pin is driven low, it is driven strongly and able to sink a large current. There are three pull-up transistors in the quasi-bidirectional output that serve different purposes.

One of these pull-ups, called the “very weak” pull-up, is turned on whenever the port latch for the pin contains a logic “1”. This very weak pull-up sources a very small current that will pull the pin high if it is left floating.

A second pull-up, called the “weak” pull-up, is turned on when the port latch for the pin contains a logic “1” and the pin itself is also at a logic “1” level. This pull-up provides the primary source current for a quasi-bidirectional pin that is outputting a “1”. If this pin is pulled low by an external device, this weak pull-up turns off, and only the very weak pull-up remains on. In order to pull the pin low under these conditions, the external device has to sink enough current to overpower the weak pull-up and pull the port pin below its input threshold voltage.

The third pull-up is referred to as the “strong” pull-up. This pull-up is used to speed up low-to-high transitions on a quasi-bidirectional port pin when the port latch changes from a logic “0” to a logic “1”. When this occurs, the strong pull-up turns on for two CPU clocks quickly pulling the port pin high. The quasi-bidirectional port configuration is shown in [Figure 13-1](#). The input circuitry of P1.3, P3.2 and P3.3 is not disabled during Power-down (see [Figure 13-3](#)).

Figure 13-1. Quasi-bidirectional Output

13.1.2 Input-only Mode

The input only port configuration is shown in [Figure 13-2](#). The output drivers are tristated. The input includes a Schmitt-triggered input for improved input noise rejection. The input circuitry of P1.3, P3.2 and P3.3 is not disabled during Power-down (see [Figure 13-3](#)). Input pins can be safely driven to 5.5V even when operating at lower V_{CC} levels; however, the input threshold of the Schmitt trigger will be set by the V_{CC} level and must be taken into consideration.

Figure 13-2. Input Only

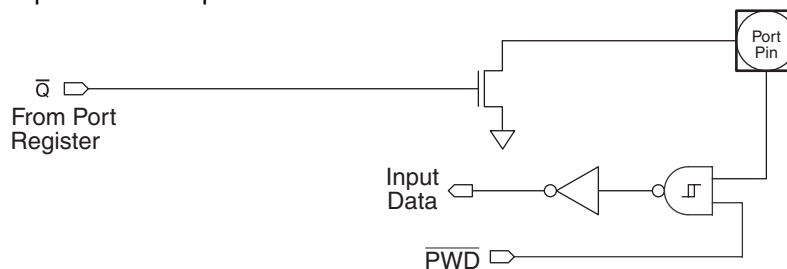

Figure 13-3. Input Only for P1.3, P3.2 and P3.3

13.1.3 Open-drain Output

The open-drain output configuration turns off all pull-ups and only drives the pull-down transistor of the port pin when the port latch contains a logic “0”. To be used as a logic output, a port configured in this manner must have an external pull-up, typically a resistor tied to V_{CC} . The pull-down for this mode is the same as for the quasi-bidirectional mode. The open-drain port configuration is shown in [Figure 13-4](#). The input circuitry of P1.3, P3.2 and P3.3 is not disabled during Power-down (see [Figure 13-3](#)). Open-drain pins can be safely pulled high to 5.5V even when operating at lower V_{CC} levels; however, the input threshold of the Schmitt trigger will be set by the V_{CC} level and must be taken into consideration.

Figure 13-4. Open-Drain Output

13.1.4 Push-pull Output

The push-pull output configuration has the same pull-down structure as both the open-drain and the quasi-bidirectional output modes, but provides a continuous strong pull-up when the port latch contains a logic “1”. The push-pull mode may be used when more source current is needed from a port output. The push-pull port configuration is shown in [Figure 13-5](#). The input circuitry of P1.3, P3.2 and P3.3 is not disabled during Power-down (see [Figure 13-3](#)).

Figure 13-5. Push-pull Output

13.2 Port 1 Analog Functions

The AT89LP216 incorporates an analog comparator. In order to give the best analog performance and minimize power consumption, pins that are being used for analog functions must have both their digital outputs and digital inputs disabled. Digital outputs are disabled by putting the port pins into the input-only mode as described in [“Port Configuration” on page 22](#). Digital inputs on P1.0 and P1.1 are disabled whenever the Analog Comparator is enabled by setting the CEN bit in ACSR. CEN forces the \overline{PWD} input on P1.0 and P1.1 low, thereby disabling the Schmitt trigger circuitry. P1.0 and P1.1 will always default to input-only mode after reset regardless of the state of the Tristate-Port Fuse.

13.3 Port Read-Modify-Write

A read from a port will read either the state of the pins or the state of the port register depending on which instruction is used. Simple read instructions will always access the port pins directly. Read-modify-write instructions, which read a value, possibly modify it, and then write it back, will always access the port register. This includes bit write instructions such as CLR or SETB as they actually read the entire port, modify a single bit, then write the data back to the entire port. See [Table 13-3](#) for a complete list of Read-Modify-Write instruction which may access the ports.

Table 13-3. Port Read-Modify-Write Instructions

Mnemonic	Instruction	Example
ANL	Logical AND	ANL P1, A
ORL	Logical OR	ORL P1, A
XRL	Logical EX-OR	XRL P1, A
JBC	Jump if bit set and clear bit	JBC P3.0, LABEL
CPL	Complement bit	CPL P3.1
INC	Increment	INC P1
DEC	Decrement	DEC P3
DJNZ	Decrement and jump if not zero	DJNZ P3, LABEL
MOV PX.Y, C	Move carry to bit Y of Port X	MOV P1.0, C
CLR PX.Y	Clear bit Y of Port X	CLR P1.1
SETB PX.Y	Set bit Y of Port X	SETB P3.2

13.4 Port Alternate Functions

Most general-purpose digital I/O pins of the AT89LP216 share functionality with the various I/Os needed for the peripheral units. Table 13-5 lists the alternate functions of the port pins. Alternate functions are connected to the pins in a logic AND fashion. In order to enable the alternate function on a port pin, that pin must have a “1” in its corresponding port register bit, otherwise the input/output will always be “0”. Furthermore, each pin must be configured for the correct input/output mode as required by its peripheral before it may be used as such. Table 13-4 shows how to configure a generic pin for use with an alternate function.

Table 13-4. Alternate Function Configurations for Pin y of Port x

PxM0.y	PxM1.y	Px.y	I/O Mode
0	0	1	bidirectional (internal pull-up)
0	1	1	output
1	0	X	input
1	1	1	bidirectional (external pull-up)

Table 13-5. Port Pin Alternate Functions

Port Pin	Configuration Bits		Alternate Function	Notes
	PxM0.y	PxM1.y		
P1.0	P1M0.0	P1M1.0	AIN0	input-only
			GPI0	
P1.1	P1M0.1	P1M1.1	AIN1	input-only

P3.5	P3M0.5	P3M1.5	T1	
P3.6	not configurable		CMPOUT	Pin is tied to comparator output

14. Enhanced Timer/Counters

The AT89LP216 has two 16-bit Timer/Counter registers: Timer 0 and Timer 1. As a Timer, the register increase every clock cycle by default. Thus, the register counts clock cycles. Since a clock cycle consists of one oscillator period, the count rate is equal to the oscillator frequency. The timer rate can be prescaled by a value between 1 and 16 using the Timer Prescaler (see [Table 9-2 on page 12](#)). Both Timers share the same prescaler.

As a Counter, the register is incremented in response to a 1-to-0 transition at its corresponding input pin, T0 or T1. The external input is sampled every clock cycle. When the samples show a high in one cycle and a low in the next cycle, the count is incremented. The new count value appears in the register during the cycle following the one in which the transition was detected. Since 2 clock cycles are required to recognize a 1-to-0 transition, the maximum count rate is 1/2 of the oscillator frequency. There are no restrictions on the duty cycle of the input signal, but it should be held for at least one full clock cycle to ensure that a given level is sampled at least once before it changes.

Furthermore, the Timer or Counter functions for Timer 0 and Timer 1 have four operating modes: variable width timer, 16-bit auto-reload timer, 8-bit auto-reload timer, and split timer. The control bits C/T in the Special Function Register TMOD select the Timer or Counter function. The bit pairs (M1, M0) in TMOD select the operating modes.

14.1 Mode 0 – Variable Width Timer/Counter

Both Timers in Mode 0 are 8-bit Counters with a variable prescaler. The prescaler may vary from 1 to 8 bits depending on the PSC bits in TCONB, giving the timer a range of 9 to 16 bits. By default the timer is configured as a 13-bit timer compatible to Mode 0 in the standard 8051. [Figure 14-1](#) shows the Mode 0 operation as it applies to Timer 1 in 13-bit mode. As the count rolls over from all “1”s to all “0”s, it sets the Timer interrupt flag TF1. The counter input is enabled to the Timer when TR1 = 1 and either GATE = 0 or $\overline{INT1} = 1$. Setting GATE = 1 allows the Timer to be controlled by external input $\overline{INT1}$, to facilitate pulse width measurements. TR1 is a control bit in the Special Function Register TCON. GATE is in TMOD. The 13-bit register consists of all 8 bits of TH1 and the lower 5 bits of TL1. The upper 3 bits of TL1 are indeterminate and should be ignored. Setting the run flag (TR1) does not clear the registers.

$$\text{Mode 0: Time-out Period} = \frac{256 \times 2^{PSC0 + 1}}{\text{Oscillator Frequency}} \times (TPS + 1)$$

Note: RH1/RL1 are not required by Timer 1 during Mode 0 and may be used as temporary storage registers.

Figure 14-1. Timer/Counter 1 Mode 0: Variable Width Counter

Mode 0 operation is the same for Timer 0 as for Timer 1, except that TR0, TF0 and $\overline{\text{INT0}}$ replace the corresponding Timer 1 signals in Figure 14-1. There are two different GATE bits, one for Timer 1 (TMOD.7) and one for Timer 0 (TMOD.3). The $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ pins are shared with the XTAL oscillator. They may only be used for the GATE function when using the internal RC oscillator as the system clock.

14.2 Mode 1 – 16-bit Auto-Reload Timer/Counter

In Mode 1 the Timers are configured for 16-bit auto-reload. The Timer register is run with all 16 bits. The 16-bit reload value is stored in the high and low reload registers (RH1/RL1). The clock is applied to the combined high and low timer registers (TH1/TL1). As clock pulses are received, the timer counts up: 0000H, 0001H, 0002H, etc. An overflow occurs on the FFFFH-to-0000H transition, upon which the timer register is reloaded with the value from RH1/RL1 and the overflow flag bit in TCON is set. See Figure 14-2. The reload registers default to 0000H, which gives the full 16-bit timer period compatible with the standard 8051. Mode 1 operation is the same for Timer/Counter 0.

$$\text{Mode 1: Time-out Period} = \frac{(65536 - \{RH0, RL0\})}{\text{Oscillator Frequency}} \times (TPS + 1)$$

Figure 14-2. Timer/Counter 1 Mode 1: 16-bit Auto-Reload

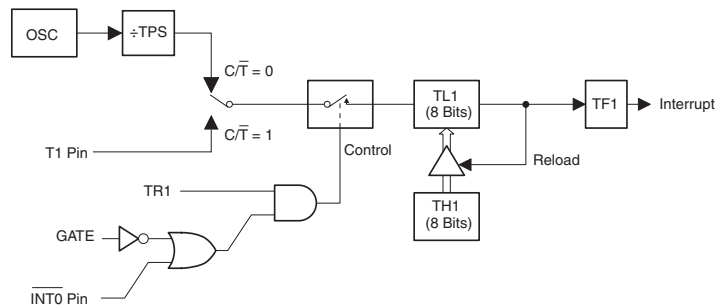

14.3 Mode 2 – 8-bit Auto-Reload Timer/Counter

Mode 2 configures the Timer register as an 8-bit Counter (TL1) with automatic reload, as shown in Figure 14-3. Overflow from TL1 not only sets TF1, but also reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged. Mode 2 operation is the same for Timer/Counter 0.

$$\text{Mode 2: Time-out Period} = \frac{(256 - TH0)}{\text{Oscillator Frequency}} \times (TPS + 1)$$

Figure 14-3. Timer/Counter 1 Mode 2: 8-bit Auto-Reload

Note: RH1/RL1 are not required by Timer 1 during Mode 2 and may be used as temporary storage registers.

14.4 Mode 3 – 8-bit Split Timer

Timer 1 in Mode 3 simply holds its count. The effect is the same as setting TR1 = 0. Timer 0 in Mode 3 establishes TL0 and TH0 as two separate counters. The logic for Mode 3 on Timer 0 is shown in Figure 14-4. TL0 uses the Timer 0 control bits: C/T, GATE, TR0, INT0, and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now controls the Timer 1 interrupt. While Timer 0 is in Mode 3, Timer 1 will still obey its settings in TMOD but cannot generate an interrupt.

Mode 3 is for applications requiring an extra 8-bit timer or counter. With Timer 0 in Mode 3, the AT89LP216 can appear to have three Timer/Counters. When Timer 0 is in Mode 3, Timer 1 can be turned on and off by switching it out of and into its own Mode 3. In this case, Timer 1 can still be used by the serial port as a baud rate generator or in any application not requiring an interrupt.

Figure 14-4. Timer/Counter 0 Mode 3: Two 8-bit Counters

Note: RH0/RL0 are not required by Timer 0 during Mode 3 and may be used as temporary storage registers.

Table 14-1. TCON – Timer/Counter Control Register

TCON = 88H		Reset Value = 0000 0000B						
Bit Addressable								
	TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
Bit	7	6	5	4	3	2	1	0

Symbol	Function
TF1	Timer 1 overflow flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when the processor vectors to interrupt routine.
TR1	Timer 1 run control bit. Set/cleared by software to turn Timer/Counter on/off.
TF0	Timer 0 overflow flag. Set by hardware on Timer/Counter overflow. Cleared by hardware when the processor vectors to interrupt routine.
TR0	Timer 0 run control bit. Set/cleared by software to turn Timer/Counter on/off.
IE1	Interrupt 1 edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.
IT1	Interrupt 1 type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.
IE0	Interrupt 0 edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.
IT0	Interrupt 0 type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.

Table 14-2. TMOD: Timer/Counter Mode Control Register

TMOD = 88H				Reset Value = 0000 0000B				
Not Bit Addressable								
	GATE	C/\bar{T}	M1	M0	GATE	C/\bar{T}	M1	M0
	7	$\bar{6}$	5	4	3	$\bar{2}$	1	0
	Timer1				Timer0			
Gate	Gating control when set. Timer/Counter x is enabled only while \overline{INTx} pin is high and TRx control pin is set. When cleared, Timer x is enabled whenever TRx control bit is set.				Timer 0 gate bit			
C/\bar{T}	Timer or Counter Selector cleared for Timer operation (input from internal system clock). Set for Counter operation (input from Tx input pin).				Timer 0 counter/timer select bit			
M1	Timer 1 Mode bit 1				Timer 0 M1 bit			
M0	Timer 1 Mode bit 0				Timer 0 M0 bit			
	M1	M0	Mode	Operating Mode				
	0	0	0	Variable 9 - 16-bit Timer Mode. 8-bit Timer/Counter THx with TLx as 1 - 8-bit prescaler.				
	0	1	1	16-bit Auto-Reload Mode. 16-bit Timer/Counters THx and TLx are cascaded; there is no prescaler.				
	1	0	2	8-bit Auto Reload. 8-bit auto-reload Timer/Counter THx holds a value which is to be reloaded into TLx each time it overflows.				
	1	1	3	Split Timer Mode. (Timer 0) TL0 is an 8-bit Timer/Counter controlled by the standard Timer 0 control bits. TH0 is an 8-bit timer only controlled by Timer 1 control bits.				
	1	1	3	(Timer 1) Timer/Counter 1 stopped.				

Timer SFR	Purpose	Address	Bit-Addressable
TCON	Control	88H	Yes
TMOD	Mode	89H	No
TL0	Timer 0 low-byte	8AH	No
TL1	Timer 1 low-byte	8BH	No

	PWM1EN	PWM0EN	PSC12	PSC11	PSC10	PSC02	PSC01	PSC00
Bit	7	6	5	4	3	2	1	0

Symbol	Function
PWM1EN	Configures Timer 1 for Pulse Width Modulation output on T1 (P3.5).
PWM0EN	Configures Timer 0 for Pulse Width Modulation output on T0 (P3.4).
PSC12 PSC11 PSC10	Prescaler for Timer 1 Mode 0. The number of active bits in TL1 equals PSC1 + 1. After reset PSC1 = 100B which enables 5 bits of TL1 for compatibility with the 13-bit Mode 0 in AT89S2051.
PSC02 PSC01 PSC00	Prescaler for Timer 0 Mode 0. The number of active bits in TL0 equals PSC0 + 1. After reset PSC0 = 100B which enables 5 bits of TL0 for compatibility with the 13-bit Mode 0 in AT89C52.

14.5 Pulse Width Modulation

On the AT89LP216, Timer 0 and Timer 1 may be independently configured as 8-bit asymmetrical (edge-aligned) pulse width modulators (PWM) by setting the PWM0EN or PWM1EN bits in TCONB, respectively. In PWM Mode the generated waveform is output on the timer's input pin, T0 or T1. Therefore, C/\bar{T} must be set to "0" when in PWM mode and the T0 (P3.4) and T1 (P3.5) must be configured in an output mode. The Timer Overflow Flags and Interrupts will continue to function while in PWM Mode and Timer 1 may still generate the baud rate for the UART. Each PWM channel has four modes selected by the mode bits in TMOD.

An example waveform for Timer 0 in PWM Mode 0 is shown in [Figure 14-5](#). TH0 acts as an 8-bit counter while RH0 stores the 8-bit compare value. When TH0 is 00H the PWM output is set high. When the TH0 count reaches the value stored in RH0 the PWM output is set low. Therefore, the pulse width is proportional to the value in RH0. To prevent glitches, writes to RH0 only take effect on the FFH to 00H overflow of TH0. Setting RH0 to 00H will keep the PWM output low.

Figure 14-5. Asymmetrical Pulse Width Modulation

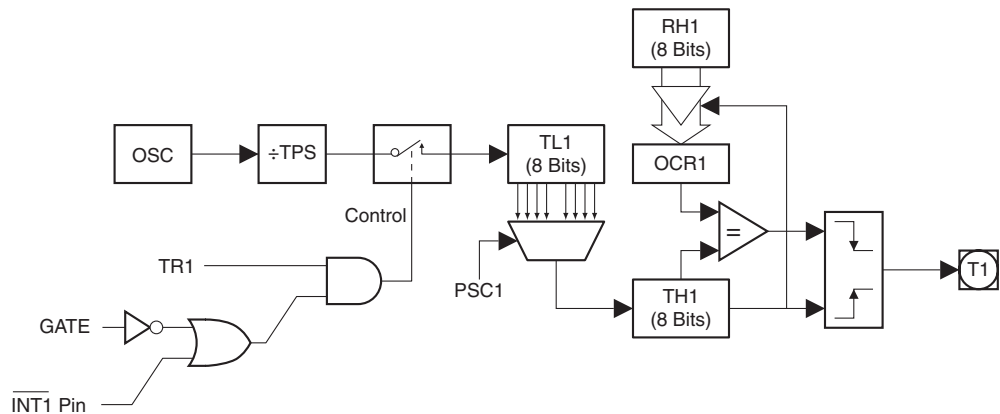

14.5.1 Mode 0 – 8-bit PWM with 8-bit Logarithmic Prescaler

In Mode 0, TLx acts as a logarithmic prescaler driving 8-bit counter THx (see Figure 14-6). The PSCx bits in TCONB control the prescaler value. On THx overflow, the duty cycle value in RHx is transferred to OCRx and the output pin is set high. When the count in THx matches OCRx, the output pin is cleared low. The following formulas give the output frequency and duty cycle for Timer 0 in PWM Mode 0. Timer 1 in PWM Mode 0 is identical to Timer 0.

$$\text{Mode 0: } f_{out} = \frac{\text{Oscillator Frequency}}{256 \times 2^{PSC0+1}} \times \frac{1}{TPS+1}$$

$$\text{Mode 0: } \text{Duty Cycle \%} = 100 \times \frac{RH0}{256}$$

Figure 14-6. Timer/Counter 1 PWM Mode 0

14.5.2 Mode 1 – 8-bit PWM with 8-bit Linear Prescaler

In Mode 1, TLx provides linear prescaling with an 8-bit auto-reload from RLx (see Figure 14-7). On TLx overflow, TLx is loaded with the value of RLx. THx acts as an 8-bit counter. On THx overflow, the duty cycle value in RHx is transferred to OCRx and the output pin is set high. When the count in THx matches OCRx, the output pin is cleared low. The following formulas give the output frequency and duty cycle for Timer 0 in PWM Mode 1. Timer 1 in PWM Mode 1 is identical to Timer 0.

$$\text{Mode 1: } f_{out} = \frac{\text{Oscillator Frequency}}{256 \times (256 - RLO)} \times \frac{1}{TPS+1}$$

$$\text{Mode 1: } \text{Duty Cycle \%} = 100 \times \frac{RH0}{256}$$

Figure 14-7. Timer/Counter 1 PWM Mode 1

14.5.3 Mode 2 – 8-bit Frequency Generator

Timer 0 in PWM Mode 2 functions as an 8-bit Auto-Reload timer, the same as normal Mode 2, with the exception that the output pin T0 is toggled at every TLO overflow (see [Figure 14-8](#)). Timer 1 in PWM Mode 2 is identical to Timer 0. PWM Mode 2 can be used to output a square wave of varying frequency. THx acts as an 8-bit counter. The following formula gives the output frequency for Timer 0 in PWM Mode 2.

$$\text{Mode 2: } f_{out} = \frac{\text{Oscillator Frequency}}{2 \times (256 - TH0)} \times \frac{1}{TPS + 1}$$

Figure 14-8. Timer/Counter 1 PWM Mode 2

Note: {RH0 & RL0}/{RH1 & RL1} are not required by Timer 0/Timer 1 during PWM Mode 2 and may be used as temporary storage registers.

14.5.4 Mode 3 – Split 8-bit PWM

Timer 1 in PWM Mode 3 simply holds its count. The effect is the same as setting TR1 = 0. Timer 0 in PWM Mode 3 establishes TL0 and TH0 as two separate PWM counters in a manner similar to normal Mode 3. PWM Mode 3 on Timer 0 is shown in Figure 14-9. Only the Timer Prescaler is available to change the output frequency during PWM Mode 3. TL0 can use the Timer 0 control bits: GATE, TR0, $\overline{\text{INT0}}$, PWM0EN and TF0. TH0 is locked into a timer function and uses TR1, PWM1EN and TF1. RL0 provides the duty cycle for TL0 and RH0 provides the duty cycle for TH0.

PWM Mode 3 is for applications requiring a single PWM channel and two timers, or two PWM channels and an extra timer or counter. With Timer 0 in PWM Mode 3, the AT89LP216 can appear to have three Timer/Counters. When Timer 0 is in PWM Mode 3, Timer 1 can be turned on and off by switching it out of and into its own Mode 3. In this case, Timer 1 can still be used by the serial port as a baud rate generator or in any application not requiring an interrupt. The following formulas give the output frequency and duty cycle for Timer 0 in PWM Mode 3.

$$\text{Mode 3: } f_{out} = \frac{\text{Oscillator Frequency}}{256} \times \frac{1}{TPS + 1}$$

$$\text{Mode 3, T0: } \text{Duty Cycle \%} = 100 \times \frac{RL0}{256}$$

$$\text{Mode 3, T1: } \text{Duty Cycle \%} = 100 \times \frac{RH0}{256}$$

Figure 14-9. Timer/Counter 0 PWM Mode 3

15. External Interrupts

When the AT89LP216 is configured to use the internal RC Oscillator, XTAL1 and XTAL2 may be used as the $\overline{INT0}$ and $\overline{INT1}$ external interrupt sources. The external interrupts can be programmed to be level-activated or transition-activated by setting or clearing bit IT1 or IT0 in Register TCON. If $ITx = 0$, external interrupt x is triggered by a detected low at the \overline{INTx} pin. If $ITx = 1$, external interrupt x is edge-triggered. In this mode if successive samples of the \overline{INTx} pin show a high in one cycle and a low in the next cycle, interrupt request flag IEx in TCON is set. Flag bit IEx then requests the interrupt. Since the external interrupt pins are sampled once each clock cycle, an input high or low should hold for at least 2 oscillator periods to ensure sampling. If the external interrupt is transition-activated, the external source has to hold the request pin high for at least two clock cycles, and then hold it low for at least two clock cycles to ensure that the transition is seen so that interrupt request flag IEx will be set. IEx will be automatically cleared by the CPU when the service routine is called if generated in edge-triggered mode. If the external interrupt is level-activated, the external source has to hold the request active until the requested interrupt is actually generated. Then the external source must deactivate the request before the interrupt service routine is completed, or else another interrupt will be generated.

16. General-purpose Interrupts

The General-purpose Interrupt (GPI) function provides 8 configurable external interrupts on Port 1. Each port pin can detect high/low levels or positive/negative edges. The GPIEN register select which bits of Port 1 are enabled to generate an interrupt. The GPMOD and GPLS registers determine the mode for each individual pin. GPMOD selects between level-sensitive and edge-triggered mode. GPLS selects between high/low in level mode and positive/negative in edge mode. The pins of Port 1 are sampled every clock cycle. In level-sensitive mode, a valid level must appear in two successive samples before generating the interrupt. In edge-triggered mode, a transition will be detected if the value changes from one sample to the next. When an interrupt condition on a pin is detected, and that pin is enabled, the appropriate flag in the GPIF register is set. The flags in GPIF must be cleared by software.

17. Serial Interface

The serial interface on the AT89LP216 implements a Universal Asynchronous Receiver/Transmitter (UART). The UART has the following features:

- Full-duplex Operation
- 8 or 9 Data Bits
- Framing Error Detection
- Multiprocessor Communication Mode with Automatic Address Recognition
- Baud Rate Generator Using Timer 1
- Interrupt on Receive Buffer Full or Transmission Complete

The serial interface is full-duplex, which means it can transmit and receive simultaneously. It is also receive-buffered, which means it can begin receiving a second byte before a previously received byte has been read from the receive register. (However, if the first byte still has not been read when reception of the second byte is complete, one of the bytes will be lost.) The serial port receive and transmit registers are both accessed at the Special Function Register SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register. The serial port can operate in the following four modes.

- **Mode 0:** Serial data enters and exits through RXD. TXD outputs the shift clock. Eight data bits are transmitted/received, with the LSB first. The baud rate is fixed at 1/2 the oscillator frequency.
- **Mode 1:** 10 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in the Special Function Register SCON. The baud rate is variable based on Timer 1.
- **Mode 2:** 11 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmit, the 9th data bit (TB8 in SCON) can be assigned the value of “0” or “1”. For example, the parity bit (P, in the PSW) can be moved into TB8. On receive, the 9th data bit goes into RB8 in the Special Function Register SCON, while the stop bit is ignored. The baud rate is programmable to either 1/16 or 1/32 the oscillator frequency.
- **Mode 3:** 11 bits are transmitted (through TXD) or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except the baud rate, which is variable based on Timer 1 in Mode 3.

In all four modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

17.1 Multiprocessor Communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received, followed by a stop bit. The 9th bit goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt is activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON.

The following example shows how to use the serial interrupt for multiprocessor communications. When the master processor must transmit a block of data to one of several slaves, it first sends out an address byte that identifies the target slave. An address byte differs from a data byte in that the 9th bit is “1” in an address byte and “0” in a data byte. With SM2 = 1, no slave is interrupted by a data byte. An address byte, however, interrupts all slaves. Each slave can examine the received byte and see if it is being addressed. The addressed slave clears its SM2

bit and prepares to receive the data bytes that follows. The slaves that are not addressed set their SM2 bits and ignore the data bytes.

The SM2 bit has no effect in Mode 0 but can be used to check the validity of the stop bit in Mode 1. In a Mode 1 reception, if SM2 = 1, the receive interrupt is not activated unless a valid stop bit is received.

Table 17-1. SCON – Serial Port Control Register

SCON Address = 98H						Reset Value = 0000 0000B		
Bit Addressable								
	SM0/FE	SM1	SM2	REN	TB8	RB8	T1	RI
Bit	7	6	5	4	3	2	1	0
(SMOD0 = 0/1) ⁽¹⁾								

Symbol	Function																									
FE	Framing error bit. This bit is set by the receiver when an invalid stop bit is detected. The FE bit is not cleared by valid frames and must be cleared by software. The SMOD0 bit must be set to enable access to the FE bit. FE will be set regardless of the state of SMOD0.																									
SM0	Serial Port Mode Bit 0, (SMOD0 must = 0 to access bit SM0)																									
SM1	Serial Port Mode Bit 1																									
	<table border="1"> <thead> <tr> <th>SM0</th> <th>SM1</th> <th>Mode</th> <th>Description</th> <th>Baud Rate⁽²⁾</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>shift register</td> <td>$f_{osc}/2$</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>8-bit UART</td> <td>variable (Timer 1)</td> </tr> <tr> <td>1</td> <td>0</td> <td>2</td> <td>9-bit UART</td> <td>$f_{osc}/32$ or $f_{osc}/16$</td> </tr> <tr> <td>1</td> <td>1</td> <td>3</td> <td>9-bit UART</td> <td>variable (Timer 1)</td> </tr> </tbody> </table>	SM0	SM1	Mode	Description	Baud Rate ⁽²⁾	0	0	0	shift register	$f_{osc}/2$	0	1	1	8-bit UART	variable (Timer 1)	1	0	2	9-bit UART	$f_{osc}/32$ or $f_{osc}/16$	1	1	3	9-bit UART	variable (Timer 1)
	SM0	SM1	Mode	Description	Baud Rate ⁽²⁾																					
	0	0	0	shift register	$f_{osc}/2$																					
0	1	1	8-bit UART	variable (Timer 1)																						
1	0	2	9-bit UART	$f_{osc}/32$ or $f_{osc}/16$																						
1	1	3	9-bit UART	variable (Timer 1)																						
SM2	Enables the Automatic Address Recognition feature in Modes 2 or 3. If SM2 = 1 then RI will not be set unless the received 9th data bit (RB8) is 1, indicating an address, and the received byte is a Given or Broadcast Address. In Mode 1, if SM2 = 1 then RI will not be activated unless a valid stop bit was received, and the received byte is a Given or Broadcast Address. In Mode 0, SM2 should be 0.																									
REN	Enables serial reception. Set by software to enable reception. Clear by software to disable reception.																									
TB8	The 9th data bit that will be transmitted in Modes 2 and 3. Set or clear by software as desired.																									
RB8	In Modes 2 and 3, the 9th data bit that was received. In Mode 1, if SM2 = 0, RB8 is the stop bit that was received. In Mode 0, RB8 is not used.																									
T1	Transmit interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or at the beginning of the stop bit in the other modes, in any serial transmission. Must be cleared by software.																									
RI	Receive interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or halfway through the stop bit time in the other modes, in any serial reception (except see SM2). Must be cleared by software.																									

- Notes: 1. SMOD0 is located at PCON.6.
 2. f_{osc} = oscillator frequency.

17.2 Baud Rates

The baud rate in Mode 0 is fixed as shown in the following equation:

$$\text{Mode 0 Baud Rate} = \frac{\text{Oscillator Frequency}}{2}$$

The baud rate in Mode 2 depends on the value of the SMOD1 bit in Special Function Register PCON.7. If SMOD1 = 0 (the value on reset), the baud rate is 1/32 of the oscillator frequency. If SMOD1 = 1, the baud rate is 1/16 of the oscillator frequency, as shown in the following equation:

$$\text{Mode 2 Baud Rate} = \frac{2^{\text{SMOD1}}}{32} \times (\text{Oscillator Frequency})$$

17.2.1 Using Timer 1 to Generate Baud Rates

The Timer 1 overflow rate determines the baud rates in Modes 1 and 3. When Timer 1 is the baud rate generator, the baud rates are determined by the Timer 1 overflow rate and the value of SMOD1 according to the following equation:

$$\text{Modes 1, 3 Baud Rate} = \frac{2^{\text{SMOD1}}}{32} \times (\text{Timer 1 Overflow Rate})$$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either timer or counter operation in any of its 3 running modes. In the most typical applications, it is configured for timer operation in auto-reload mode (high nibble of TMOD = 0010B). In this case, the baud rate is given by the following formula:

$$\text{Modes 1, 3 Baud Rate} = \frac{2^{\text{SMOD1}}}{32} \times \frac{\text{Oscillator Frequency}}{[256 - (\text{TH1})]} \times \frac{1}{\text{TPS} + 1}$$

Programmers can achieve very low baud rates with Timer 1 by configuring the Timer to run as a 16-bit auto-reload timer (high nibble of TMOD = 0001B). In this case, the baud rate is given by the following formula.

$$\text{Modes 1, 3 Baud Rate} = \frac{2^{\text{SMOD1}}}{32} \times \frac{\text{Oscillator Frequency}}{[256 - (\text{RH1}, \text{RL1})]} \times \frac{1}{\text{TPS} + 1}$$

Table 17-2 lists commonly used baud rates and how they can be obtained from Timer 1.

Table 17-2. Commonly Used Baud Rates Generated by Timer 1 (TPS = 0000B)

Baud Rate	f _{OSC} (MHz)	SMOD1	Timer 1		
			C/T	Mode	Reload Value
Mode 0: 1 MHz	2	X	X	X	X
Mode 2: 375K	12	0	X	X	X
62.5K	12	1	0	2	F4H
19.2K	11.059	1	0	2	DCH
9.6K	11.059	0	0	2	DCH
4.8K	11.059	0	0	2	B8H
2.4K	11.059	0	0	2	70H
1.2K	11.059	0	0	1	FEE0H
137.5	11.986	0	0	1	F55CH
110	6	0	0	1	F958H
110	12	0	0	1	F304H

17.3 More About Mode 0

Serial data enters and exits through RXD. TXD outputs the shift clock. Eight data bits are transmitted/received, with the LSB first. The baud rate is fixed at 1/2 the oscillator frequency. [Figure 17-1 on page 42](#) shows a simplified functional diagram of the serial port in Mode 0 and associated timing.

Transmission is initiated by any instruction that uses SBUF as a destination register. The “write to SBUF” signal also loads a “1” into the 9th position of the transmit shift register and tells the TX Control Block to begin a transmission. The internal timing is such that one full machine cycle will elapse between “write to SBUF” and activation of SEND.

SEND transfers the output of the shift register to the alternate output function line of P3.0, and also transfers Shift Clock to the alternate output function line of P3.1. At the falling edge of Shift Clock the contents of the transmit shift register are shifted one position to the right.

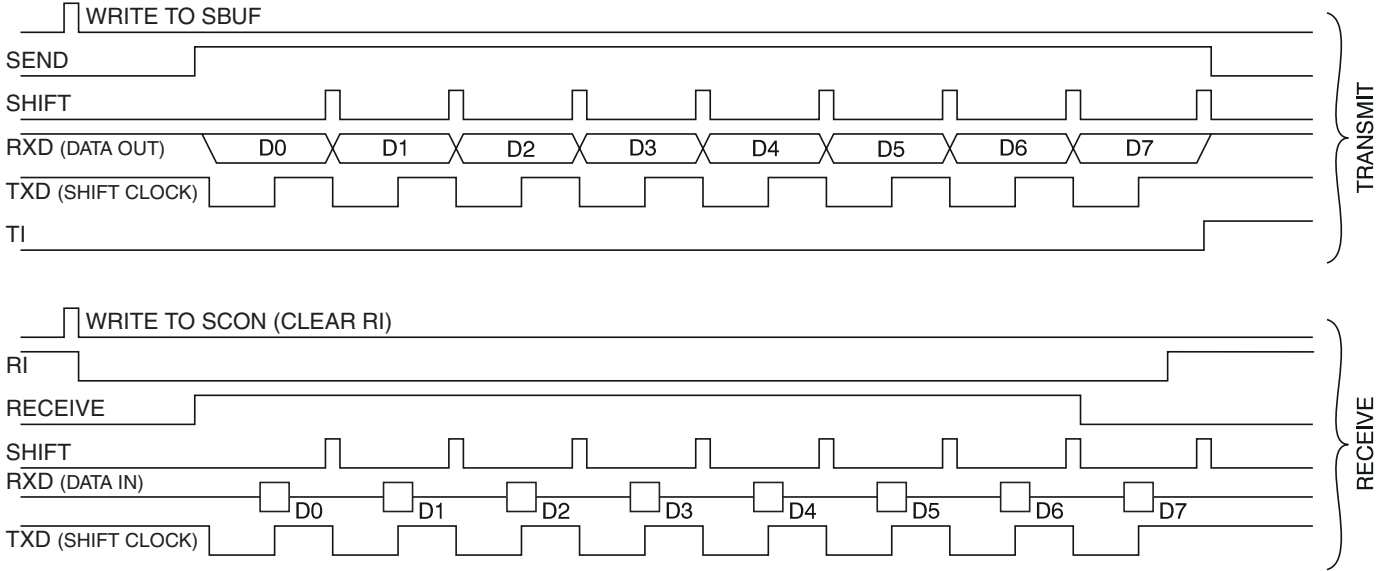

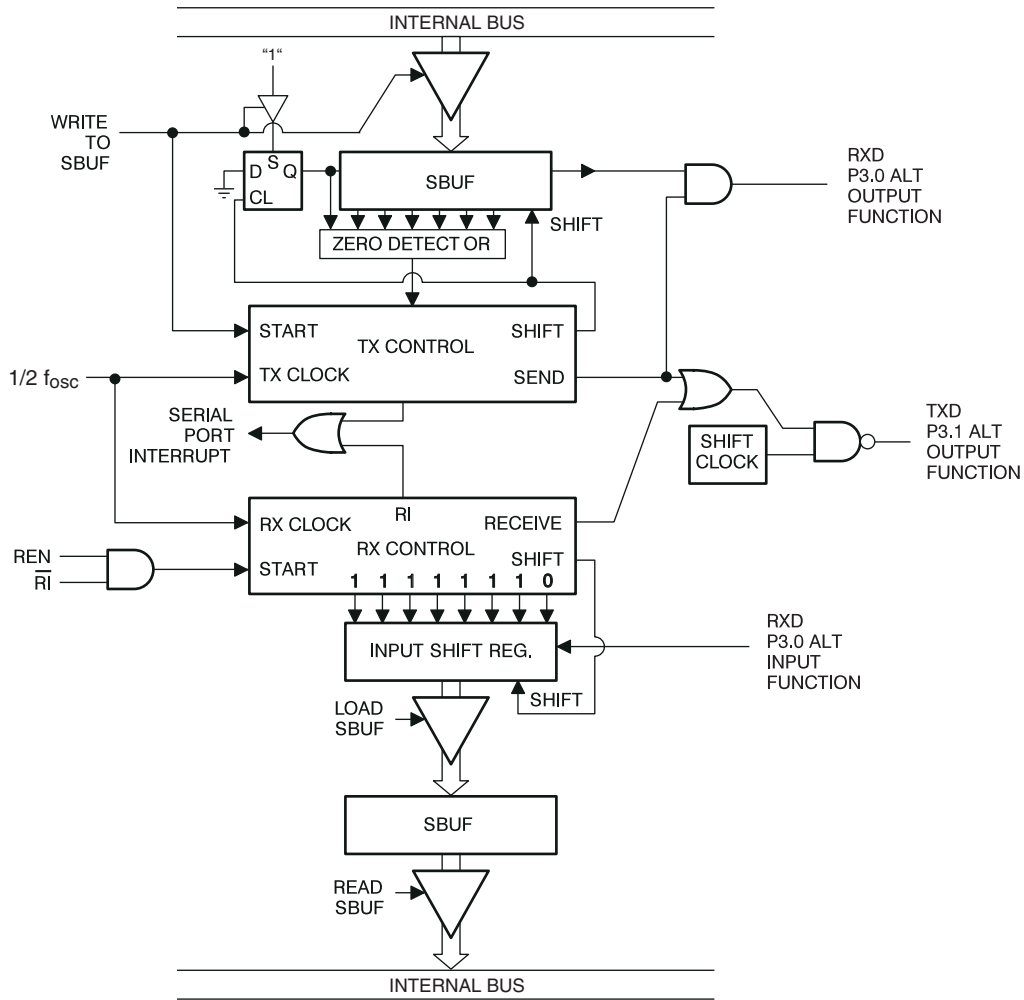

As data bits shift out to the right, “0”s come in from the left. When the MSB of the data byte is at the output position of the shift register, the “1” that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain “0”s. This condition flags the TX Control block to do one last shift, then deactivate SEND and set TI.

Reception is initiated by the condition REN = 1 and R1 = 0. At the next clock cycle, the RX Control unit writes the bits 11111110 to the receive shift register and activates RECEIVE in the next clock phase.

RECEIVE enables Shift Clock to the alternate output function line of P3.1. At the falling edge of Shift Clock the contents of the receive shift register are shifted one position to the left. The value that comes in from the right is the value that was sampled at the P3.0 pin at rising edge of Shift Clock.

As data bits come in from the right, “1”s shift out to the left. When the “0” that was initially loaded into the right-most position arrives at the left-most position in the shift register, it flags the RX Control block to do one last shift and load SBUF. Then RECEIVE is cleared and RI is set.

Figure 17-1. Serial Port Mode 0

17.4 More About Mode 1

Ten bits are transmitted (through TXD), or received (through RXD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in SCON. In the AT89LP216, the baud rate is determined by the Timer 1 overflow rate. Figure 17-2 shows a simplified functional diagram of the serial port in Mode 1 and associated timings for transmit and receive.

Transmission is initiated by any instruction that uses SBUF as a destination register. The “write to SBUF” signal also loads a “1” into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission actually commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. Thus, the bit times are synchronized to the divide-by-16 counter, not to the “write to SBUF” signal.

The transmission begins when $\overline{\text{SEND}}$ is activated, which puts the start bit at TXD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TXD. The first shift pulse occurs one bit time after that.

As data bits shift out to the right, “0”s are clocked in from the left. When the MSB of the data byte is at the output position of the shift register, the “1” that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain “0”s. This condition flags the TX Control unit to do one last shift, then deactivate $\overline{\text{SEND}}$ and set TI. This occurs at the tenth divide-by-16 rollover after “write to SBUF.”

Reception is initiated by a 1-to-0 transition detected at RXD. For this purpose, RXD is sampled at a rate of 16 times the established baud rate. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written into the input shift register. Resetting the divide-by-16 counter aligns its roll-overs with the boundaries of the incoming bit times.

The 16 states of the counter divide each bit time into 16ths. At the 7th, 8th, and 9th counter states of each bit time, the bit detector samples the value of RXD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done to reject noise. In order to reject false bits, if the value accepted during the first bit time is not 0, the receive circuits are reset and the unit continues looking for another 1-to-0 transition. If the start bit is valid, it is shifted into the input shift register, and reception of the rest of the frame proceeds.

As data bits come in from the right, “1”s shift out to the left. When the start bit arrives at the left-most position in the shift register, (which is a 9-bit register in Mode 1), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8 and to set RI is generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

RI = 0 and

Either SM2 = 0, or the received stop bit = 1

If either of these two conditions is not met, the received frame is irretrievably lost. If both conditions are met, the stop bit goes into RB8, the 8 data bits go into SBUF, and RI is activated. At this time, whether or not the above conditions are met, the unit continues looking for a 1-to-0 transition in RXD.

Figure 17-2. Serial Port Mode 1

17.5 More About Modes 2 and 3

Eleven bits are transmitted (through TXD), or received (through RXD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmit, the 9th data bit (TB8) can be assigned the value of “0” or “1”. On receive, the 9th data bit goes into RB8 in SCON. The baud rate is programmable to either 1/16 or 1/32 of the oscillator frequency in Mode 2. Mode 3 may have a variable baud rate generated from Timer 1.

Figures 17-3 and 17-4 show a functional diagram of the serial port in Modes 2 and 3. The receive portion is exactly the same as in Mode 1. The transmit portion differs from Mode 1 only in the 9th bit of the transmit shift register.

Transmission is initiated by any instruction that uses SBUF as a destination register. The “write to SBUF” signal also loads TB8 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. Thus, the bit times are synchronized to the divide-by-16 counter, not to the “write to SBUF” signal.

The transmission begins when $\overline{\text{SEND}}$ is activated, which puts the start bit at TXD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TXD. The first shift pulse occurs one bit time after that. The first shift clocks a “1” (the stop bit) into the 9th bit position of the shift register. Thereafter, only “0”s are clocked in. Thus, as data bits shift out to the right, “0”s are clocked in from the left. When TB8 is at the output position of the shift register, then the stop bit is just to the left of TB8, and all positions to the left of that contain “0”s. This condition flags the TX Control unit to do one last shift, then deactivate SEND and set TI. This occurs at the 11th divide-by-16 rollover after “write to SBUF.”

Reception is initiated by a 1-to-0 transition detected at RXD. For this purpose, RXD is sampled at a rate of 16 times the established baud rate. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written to the input shift register.

At the 7th, 8th and 9th counter states of each bit time, the bit detector samples the value of RXD. The value accepted is the value that was seen in at least 2 of the 3 samples. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit continues looking for another 1-to-0 transition. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame proceeds.

As data bits come in from the right, “1”s shift out to the left. When the start bit arrives at the left-most position in the shift register (which in Modes 2 and 3 is a 9-bit register), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8 and to set RI is generated if, and only if, the following conditions are met at the time the final shift pulse is generated:

RI = 0, and

Either SM2 = 0 or the received 9th data bit = 1

If either of these conditions is not met, the received frame is irretrievably lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bits go into SBUF. One bit time later, whether the above conditions were met or not, the unit continues looking for a 1-to-0 transition at the RXD input.

Note that the value of the received stop bit is irrelevant to SBUF, RB8, or RI.

Figure 17-3. Serial Port Mode 2

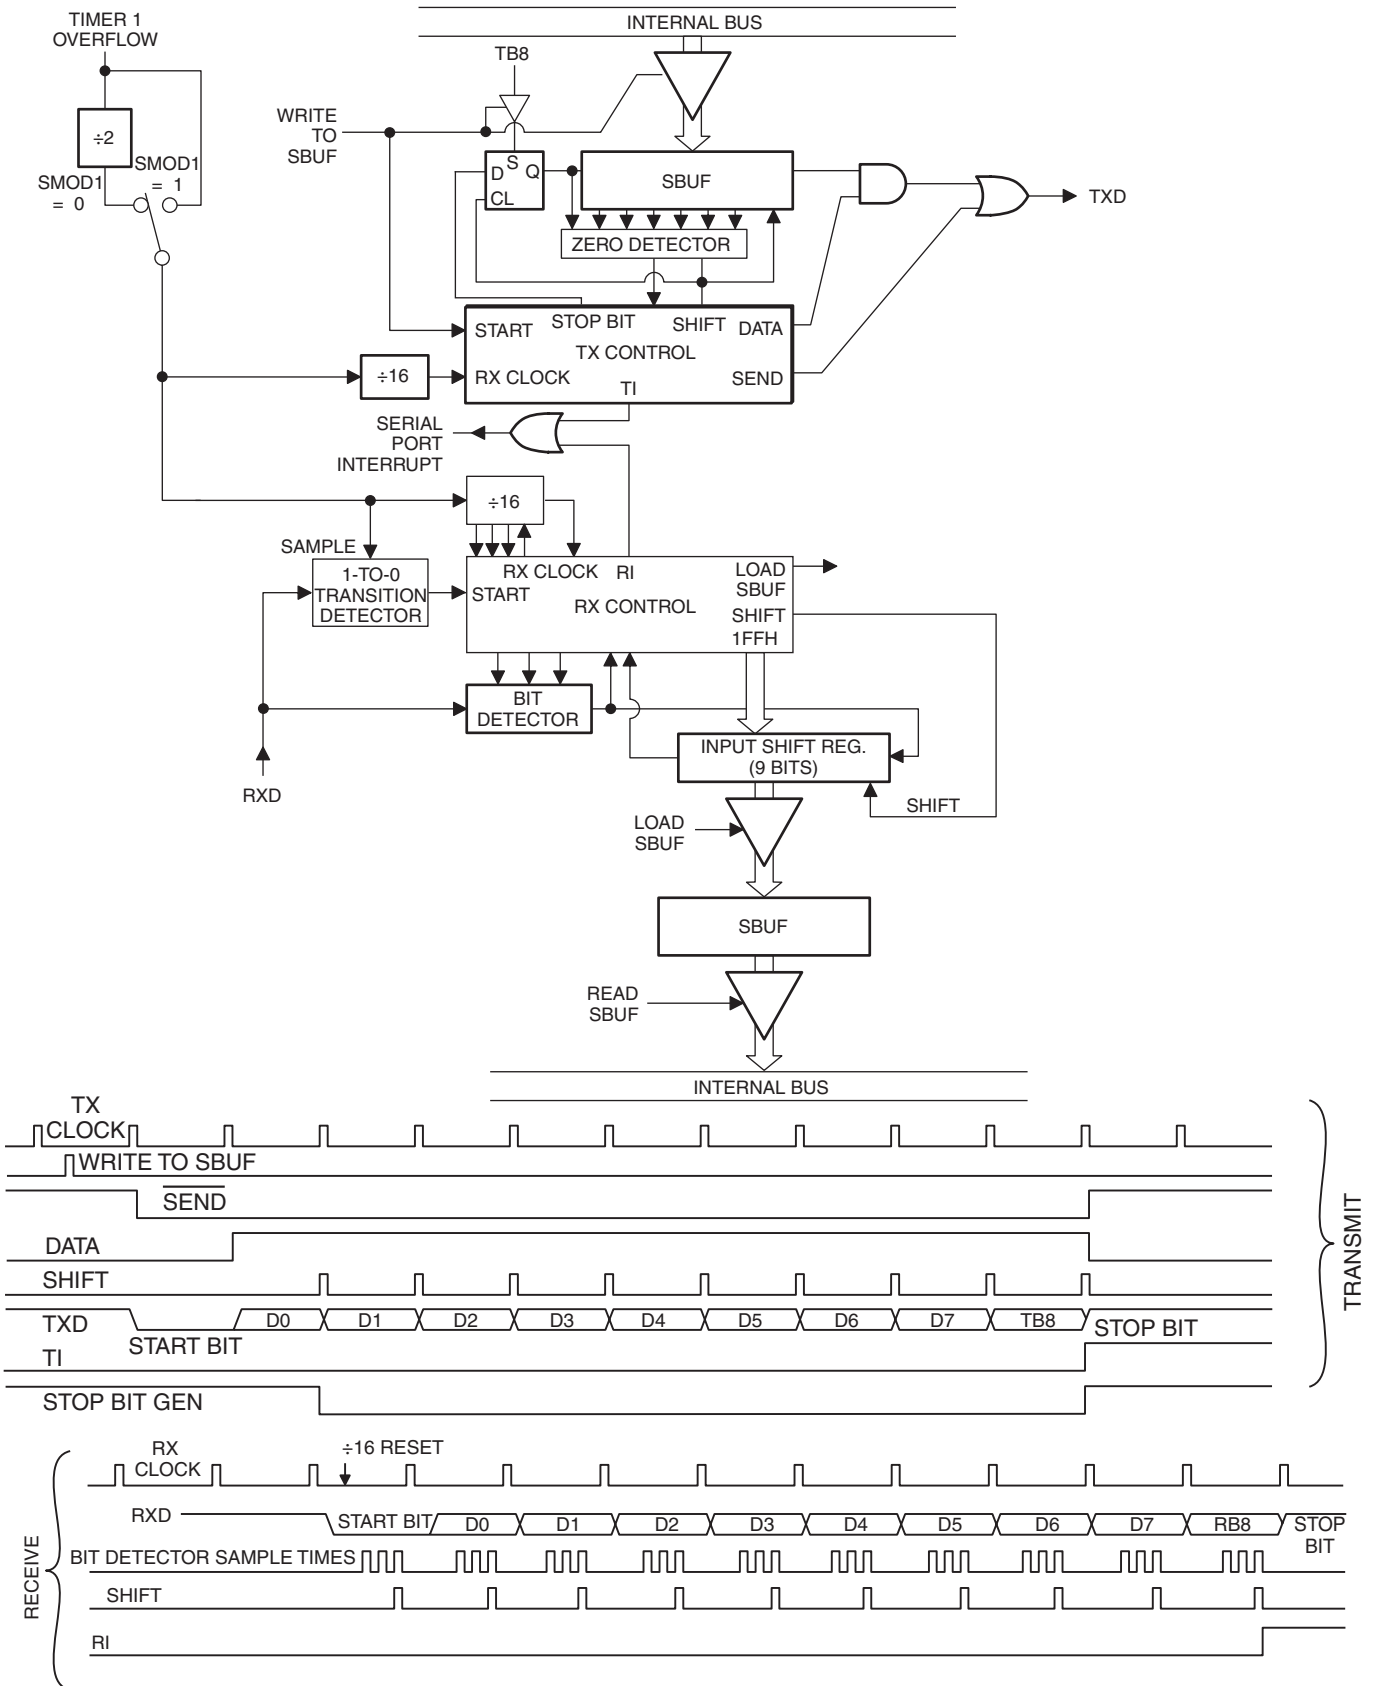

Figure 17-4. Serial Port Mode 3

17.6 Framing Error Detection

In addition to all of its usual modes, the UART can perform framing error detection by looking for missing stop bits, and automatic address recognition. When used for framing error detect, the UART looks for missing stop bits in the communication. A missing bit will set the FE bit in the SCON register. The FE bit shares the SCON.7 bit with SM0 and the function of SCON.7 is determined by PCON.6 (SMOD0). If SMOD0 is set then SCON.7 functions as FE. SCON.7 functions as SM0 when SMOD0 is cleared. When used as FE, SCON.7 can only be cleared by software.

17.7 Automatic Address Recognition

Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9th bit UART modes, Mode 2 and Mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the “Given” address or the “Broadcast” address. The 9th bit mode requires that the 9th information bit to be a “1” to indicate that the received information is an address and not data.

The 8th bit mode is called Mode 1. In this mode the RI flag will be set if SM2 is enabled and the information received has a valid stop bit following the 8th address bits and the information is either a Given or Broadcast address.

Mode 0 is the Shift Register mode and SM2 is ignored.

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave’s address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are “don’t care”. The SADEN mask can be logically ANDed with the SADDR to create the “Given” address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples show the versatility of this scheme:

Slave 0	SADDR = 1100 0000
	SADEN = <u>1111 1101</u>
	Given = 1100 00X0

Slave 1	SADDR = 1100 0000
	SADEN = <u>1111 1110</u>
	Given = 1100 000X

In the previous example, SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a “0” in bit 0 and it ignores bit 1. Slave 1 requires a “0” in bit 1 and bit 0 is ignored. A unique address for slave 0 would be 1100 0010 since slave 1 requires a “0” in bit 1. A unique address for slave 1 would be 1100 0001 since a “1” in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system, the following could be used to select slaves 1 and 2 while excluding slave 0:

Slave 0 SADDR = 1100 0000
 SADEN = 1111 1001
 Given = 1100 0XX0

Slave 1 SADDR = 1110 0000
 SADEN = 1111 1010
 Given = 1110 0X0X

Slave 2 SADDR = 1110 0000
 SADEN = 1111 1100
 Given = 1110 00XX

In the above example, the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2, use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logic OR of SADDR and SADEN. Zeros in this result are treated as don't cares. In most cases, interpreting the don't cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR (SFR address 0A9H) and SADEN (SFR address 0B9H) are loaded with "0"s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares". This effectively disables the Automatic Addressing mode and allows the microcontroller to use standard 80C51-type UART drivers which do not make use of this feature.

18. Serial Peripheral Interface

The serial peripheral interface (SPI) allows high-speed synchronous data transfer between the AT89LP216 and peripheral devices or between multiple AT89LP216 devices. The SPI features include the following:

- Full-duplex, 3-wire Synchronous Data Transfer
- Master or Slave Operation
- Maximum Bit Frequency = $f_{OSC}/4$
- LSB First or MSB First Data Transfer
- Four Programmable Bit Rates in Master Mode
- End of Transmission Interrupt Flag
- Write Collision Flag Protection
- Double-buffered Receive
- Double-buffered Transmit (Enhanced Mode Only)
- Wake up from Idle Mode (Slave Mode Only)

The interconnection between master and slave CPUs with SPI is shown in Figure 18-1. The four pins in the interface are Master-In/Slave-Out (MISO), Master-Out/Slave-In (MOSI), Shift Clock (SCK), and Slave Select (\overline{SS}). The SCK pin is the clock output in master mode, but is the clock input in slave mode. The MSTR bit in SPCR determines the directions of MISO and MOSI. Also notice that MOSI connects to MOSI and MISO to MISO. In master mode, $\overline{SS}/P1.4$ is ignored and may be used as a general-purpose input or output. In slave mode, \overline{SS} must be driven low to select an individual device as a slave. When \overline{SS} is driven high, the slave's SPI port is deactivated and the MOSI/P1.5 pin can be used as a general-purpose input.

Figure 18-1. SPI Master-slave Interconnection

The SPI has two modes of operation: normal (non-buffered write) and enhanced (buffered write). In normal mode, writing to the SPI data register (SPDR) of the master CPU starts the SPI clock generator and the data written shifts out of the MOSI pin and into the MOSI pin of the slave CPU. Transmission may start after an initial delay while the clock generator waits for the next full bit slot of the specified baud rate. After shifting one byte, the SPI clock generator stops, setting the end of transmission flag (SPIF) and transferring the received byte to the read buffer (SPDR). If both the SPI interrupt enable bit (SPIE) and the serial port interrupt enable bit (ES) are set, an interrupt is requested. Note that SPDR refers to either the write data buffer or the read data buffer, depending on whether the access is a write or read. In normal mode, because the write buffer is transparent (and a write access to SPDR will be directed to the shift buffer), any attempt to write to SPDR while a transmission is in progress will result in a write collision with WCOL set. However, the transmission will still complete normally, but the new byte will be ignored and a new write access to SPDR will be necessary.

Enhanced mode is similar to normal mode except that the write buffer holds the next byte to be transmitted. Writing to SPDR loads the write buffer and sets WCOL to signify that the buffer is full and any further writes will overwrite the buffer. WCOL is cleared by hardware when the buffered byte is loaded into the shift register and transmission begins. If the master SPI is currently idle, i.e. if this is the first byte, then after loading SPDR, transmission of the byte starts and WCOL is cleared immediately. While this byte is transmitting, the next byte may be written to SPDR. The Load Enable flag (LDEN) in SPSR can be used to determine when transmission has started. LDEN is asserted during the first four bit slots of a SPI transfer. The master CPU should first check that LDEN is set and that WCOL is cleared before loading the next byte. In enhanced mode, if WCOL is set when a transfer completes, i.e. the next byte is available, then the SPI immediately loads the buffered byte into the shift register, resets WCOL, and continues transmission without stopping and restarting the clock generator. As long as the CPU can keep the write buffer full in this manner, multiple bytes may be transferred with minimal latency between bytes.

Table 18-1. SPCR – SPI Control Register

SPCR Address = E9H				Reset Value = 0000 0000B				
Not Bit Addressable								
	SPIE	SPE	DORD	MSTR	CPOL	CPHA	SPR1	SPR0
Bit	7	6	5	4	3	2	1	0

Symbol	Function															
SPIE	SPI interrupt enable. This bit, in conjunction with the ES bit in the IE register, enables SPI interrupts: SPIE = 1 and ES = 1 enable SPI interrupts. SPIE = 0 disables SPI interrupts.															
SPE	SPI enable. SPI = 1 enables the SPI channel and connects \overline{SS} , MOSI, MISO and SCK to pins P1.4, P1.5, P1.6, and P1.7. SPI = 0 disables the SPI channel.															
DORD	Data order. DORD = 1 selects LSB first data transmission. DORD = 0 selects MSB first data transmission.															
MSTR	Master/slave select. MSTR = 1 selects Master SPI mode. MSTR = 0 selects slave SPI mode.															
CPOL	Clock polarity. When CPOL = 1, SCK is high when idle. When CPOL = 0, SCK of the master device is low when not transmitting. Please refer to figure on SPI clock phase and polarity control.															
CPHA	Clock phase. The CPHA bit together with the CPOL bit controls the clock and data relationship between master and slave. Please refer to figure on SPI clock phase and polarity control.															
SPR0 SPR1	<p>SPI clock rate select. These two bits control the SCK rate of the device configured as master. SPR1 and SPR0 have no effect on the slave. The relationship between SCK and the oscillator frequency, F_{OSC}, is as follows:</p> <table style="margin-left: 20px; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;"><u>SPR1</u></th> <th style="text-align: left;"><u>SPR0</u></th> <th style="text-align: left;"><u>SCK</u></th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">$f_{OSC}/4$</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">$f_{OSC}/8$</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">$f_{OSC}/32$</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">$f_{OSC}/64$</td> </tr> </tbody> </table>	<u>SPR1</u>	<u>SPR0</u>	<u>SCK</u>	0	0	$f_{OSC}/4$	0	1	$f_{OSC}/8$	1	0	$f_{OSC}/32$	1	1	$f_{OSC}/64$
<u>SPR1</u>	<u>SPR0</u>	<u>SCK</u>														
0	0	$f_{OSC}/4$														
0	1	$f_{OSC}/8$														
1	0	$f_{OSC}/32$														
1	1	$f_{OSC}/64$														

- Notes:
1. Set up the clock mode before enabling the SPI: set all bits needed in SPCR except the SPE bit, then set SPE.
 2. Enable the master SPI prior to the slave device.
 3. Slave echoes master on the next Tx if not loaded with new data.

Table 18-2. SPDR – SPI Data Register

SPDR Address = EAH				Reset Value = 00H (after cold reset) unchanged (after warm reset)				
Not Bit Addressable								
	SPD7	SPD6	SPD5	SPD4	SPD3	SPD2	SPD1	SPD0
Bit	7	6	5	4	3	2	1	0

Table 18-3. SPSR – SPI Status Register

SPSR Address = E8H					Reset Value = 000X X000B			
Not Bit Addressable								
	SPIF	WCOL	LDEN	–	–	SSIG	DISSO	ENH
Bit	7	6	5	4	3	2	1	0

Symbol	Function
SPIF	SP interrupt flag. When a serial transfer is complete, the SPIF bit is set and an interrupt is generated if SPIE = 1 and ES = 1. The SPIF bit is cleared by reading the SPI status register followed by reading/writing the SPI data register.
WCOL	When ENH = 0: Write collision flag. The WCOL bit is set if the SPI data register is written during a data transfer. During data transfer, the result of reading the SPDR register may be incorrect, and writing to it has no effect. The WCOL bit (and the SPIF bit) are cleared by reading the SPI status register followed by reading/writing the SPI data register. When ENH = 1: WCOL works in Enhanced mode as Tx Buffer Full. Writing during WCOL = 1 in enhanced mode will overwrite the waiting data already present in the Tx Buffer. In this mode, WCOL is no longer reset by the SPIF reset but is reset when the write buffer has been unloaded into the serial shift register.
LDEN	Load enable for the Tx buffer in enhanced SPI mode. When ENH is set, it is safe to load the Tx Buffer while LDEN = 1 and WCOL = 0. LDEN is high during bits 0 - 3 and is low during bits 4 - 7 of the SPI serial byte transmission time frame.
SSIG	Slave Select Ignore. If SSIG = 0, the SPI will only operate in slave mode if \overline{SS} (P1.4) is pulled low. When SSIG = 1, the SPI ignores \overline{SS} in slave mode and is active whenever SPE (SPCR.6) is set. P1.4 may be used as a regular I/O pin when SSIG = 1.
DISSO	Disable slave output bit. When set, this bit causes the MISO pin to be tri-stated so more than one slave device can share the same interface with a single master. Normally, the first byte in a transmission could be the slave address and only the selected slave should clear its DISSO bit.
ENH	Enhanced SPI mode select bit. When ENH = 0, SPI is in normal mode, i.e. without write double buffering. When ENH = 1, SPI is in enhanced mode with write double buffering. The Tx buffer shares the same address with the SPDR register.

Figure 18-2. SPI Shift Register Diagram

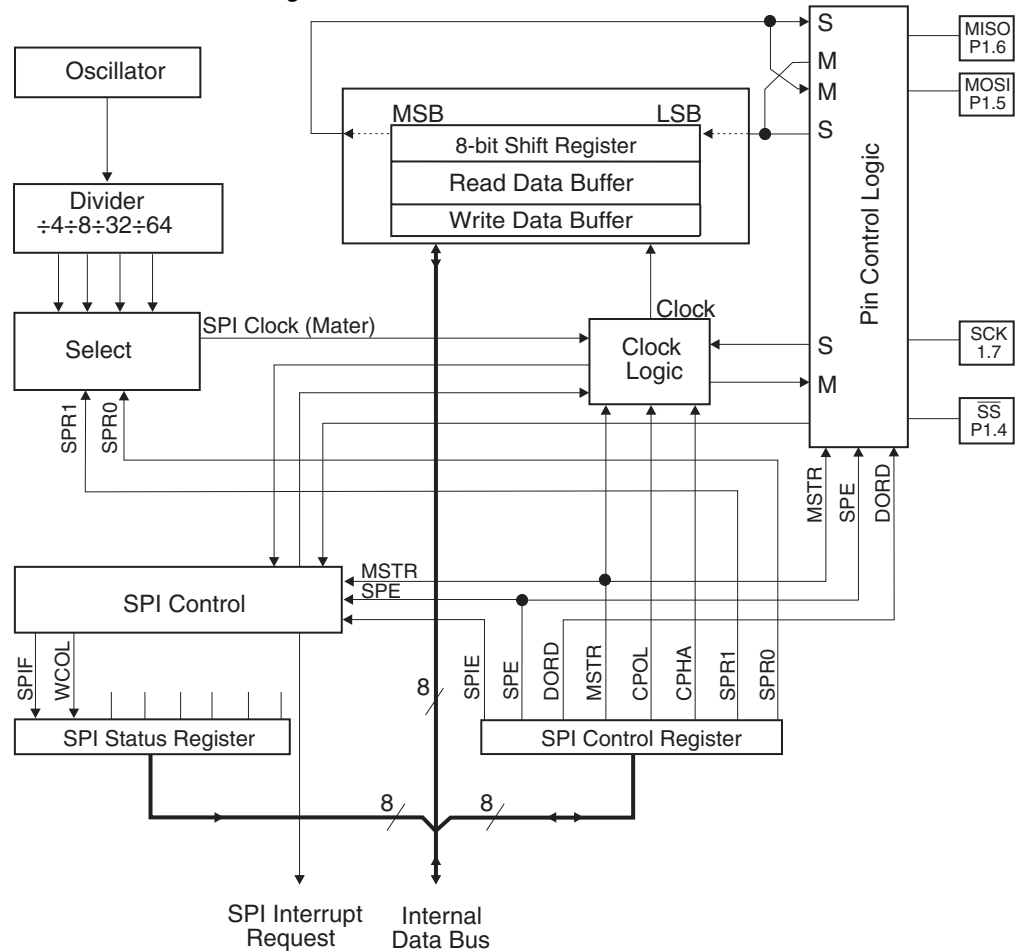

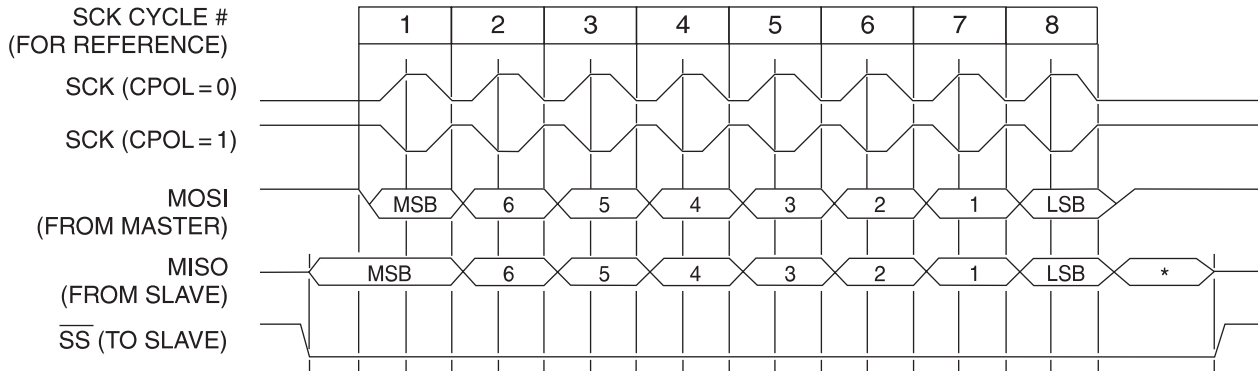

Figure 18-3. SPI Block Diagram

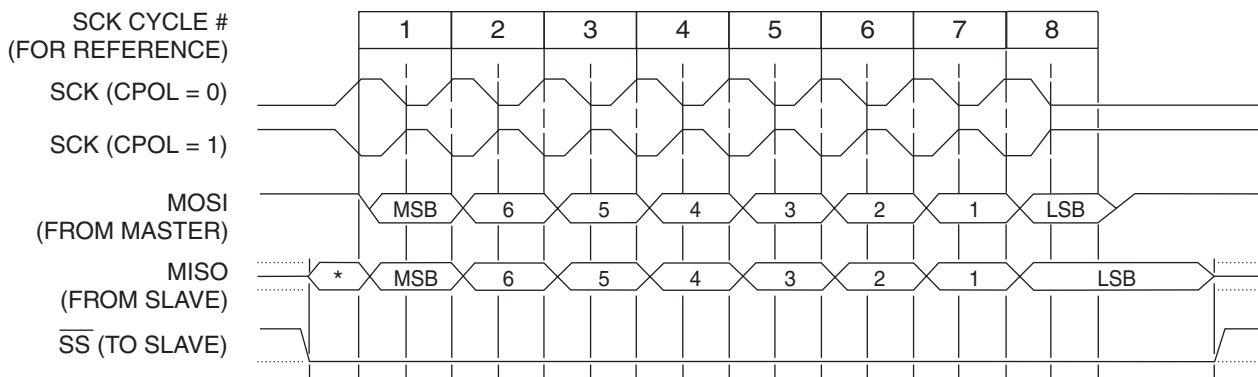

The CPHA (Clock PHase), CPOL (Clock POLarity), and SPR (Serial Peripheral clock Rate = baud rate) bits in SPCR control the shape and rate of SCK. The two SPR bits provide four possible clock rates when the SPI is in master mode. In slave mode, the SPI will operate at the rate of the incoming SCK as long as it does not exceed the maximum bit rate. There are also four possible combinations of SCK phase and polarity with respect to the serial data. CPHA and CPOL determine which format is used for transmission. The SPI data transfer formats are shown in Figures 18-4 and 18-5. To prevent glitches on SCK from disrupting the interface, CPHA, CPOL, and SPR should not be modified while the interface is enabled, and the master device should be enabled before the slave device(s).

Figure 18-4. SPI Transfer Format with CPHA = 0

Note: *Not defined but normally MSB of character just received.

Figure 18-5. SPI Transfer Format with CPHA = 1

Note: *Not defined but normally LSB of previously transmitted character.

19. Analog Comparator

A single analog comparator is provided on the AT89LP216. The analog comparator has the following features:

- Comparator Output Flag and Interrupt
- Selectable Interrupt Condition
 - High- or Low-level
 - Rising- or Falling-edge
 - Output Toggle
- Hardware Debouncing Modes

Comparator operation is such that the output is a logic “1” when the positive input AIN0 (P1.0) is greater than the negative input AIN1 (P1.1). Otherwise the output is a zero. Setting the CEN bit in ACSR enables the comparator. When the comparator is first enabled, the comparator output and interrupt flag are not guaranteed to be stable for 10 μ s. The corresponding comparator interrupt should not be enabled during that time, and the comparator interrupt flag must be cleared before the interrupt is enabled in order to prevent an immediate interrupt service. Before enabling the comparator the analog inputs should be tristated by putting P1.0 and P1.1 into input-only mode. See “Port 1 Analog Functions” on page 25.

The comparator may be configured to cause an interrupt under a variety of output value conditions by setting the CM bits in ACSR. The comparator interrupt flag CF in ACSR is set whenever the comparator output matches the condition specified by CM. The flag may be polled by software or may be used to generate an interrupt and must be cleared by software.

19.1 Comparator Interrupt with Debouncing

The comparator output is sampled every clock cycle. The conditions on the analog inputs may be such that the comparator output will toggle excessively. This is especially true if applying slow moving analog inputs. Three debouncing modes are provided to filter out this noise. In debouncing mode, the comparator uses Timer 1 to modulate its sampling time. When a relevant transition occurs, the comparator waits until two Timer 1 overflows have occurred before resampling the output. If the new sample agrees with the expected value, CF is set. Otherwise, the event is ignored. The filter may be tuned by adjusting the time-out period of Timer 1. Because Timer 1 is free running, the debouncer must wait for two overflows to guarantee that the sampling delay is at least 1 time-out period. Therefore, after the initial edge event, the interrupt may occur between 1 and 2 time-out periods later. See Figure 19-1.

By default the comparator is disabled during Idle mode. To allow the comparator to function during Idle, the CIDL bit in ACSR must be set. When CIDL is set, the comparator can be used to wake-up the CPU from Idle if the comparator interrupt is enabled. The comparator is always disabled during Power-down mode.

Figure 19-1. Negative Edge with Debouncing Example

Table 19-1. ACSR – Analog Comparator Control & Status Register

ACSR = 97H		Reset Value = XXX0 0000B						
Not Bit Addressable								
	–	–	CIDL	CF	CEN	CM3	CM1	CM0
Bit	7	6	5	4	3	2	1	0

Symbol	Function																																				
CIDL	Comparator Idle Enable. If CIDL = 1 the comparator will continue to operate during Idle mode. If CIDL = 0 the comparator is powered down during Idle mode. The comparator is always shut down during Power-down mode.																																				
CF	Comparator Interrupt Flag. Set when the comparator output meets the conditions specified by the CM [2:0] bits and CEN is set. The flag must be cleared by software. The interrupt may be enabled/disabled by setting/clearing bit 6 of IE.																																				
CEN	Comparator Enable. Set this bit to enable the comparator. Clearing this bit will force the comparator output low and prevent further events from setting CF. When CEN = 1 the analog input pins, P1.0 and P1.1, have their digital inputs disabled.																																				
CM [2:0]	Comparator Interrupt Mode <table border="1"> <thead> <tr> <th>CM2</th> <th>CM1</th> <th>CM0</th> <th>Interrupt Mode</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>Negative (Low) level</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>Positive edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>Toggle with debouncing⁽¹⁾</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>Positive edge with debouncing⁽¹⁾</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>Negative edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>Toggle</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>Negative edge with debouncing⁽¹⁾</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>Positive (High) level</td> </tr> </tbody> </table>	CM2	CM1	CM0	Interrupt Mode	0	0	0	Negative (Low) level	0	0	1	Positive edge	0	1	0	Toggle with debouncing ⁽¹⁾	0	1	1	Positive edge with debouncing ⁽¹⁾	1	0	0	Negative edge	1	0	1	Toggle	1	1	0	Negative edge with debouncing ⁽¹⁾	1	1	1	Positive (High) level
CM2	CM1	CM0	Interrupt Mode																																		
0	0	0	Negative (Low) level																																		
0	0	1	Positive edge																																		
0	1	0	Toggle with debouncing ⁽¹⁾																																		
0	1	1	Positive edge with debouncing ⁽¹⁾																																		
1	0	0	Negative edge																																		
1	0	1	Toggle																																		
1	1	0	Negative edge with debouncing ⁽¹⁾																																		
1	1	1	Positive (High) level																																		

Note: 1. Debouncing modes require the use of Timer 1 to generate the sampling delay.

20. Programmable Watchdog Timer

The programmable Watchdog Timer (WDT) protects the system from incorrect execution by triggering a system reset when it times out after the software has failed to feed the timer prior to the timer overflow. By Default the WDT counts CPU clock cycles. The prescaler bits, PS0, PS1 and PS2 in SFR WDTCON are used to set the period of the Watchdog Timer from 16K to 2048K clock cycles. The Timer Prescaler can also be used to lengthen the time-out period (see [Table 9-2 on page 12](#)) The WDT is disabled by Reset and during Power-down mode. When the WDT times out without being serviced, an internal RST pulse is generated to reset the CPU. See [Table 20-1](#) for the available WDT period selections.

Table 20-1. Watchdog Timer Time-out Period Selection

WDT Prescaler Bits			Period ⁽¹⁾ (Clock Cycles)
PS2	PS1	PS0	
0	0	0	16K
0	0	1	32K
0	1	0	64K
0	1	1	128K
1	0	0	256K
1	0	1	512K
1	1	0	1024K
1	1	1	2048K

Note: 1. The WDT time-out period is dependent on the system clock frequency.

$$\text{Time-out Period} = \frac{2^{(PS+14)}}{\text{Oscillator Frequency}} \times (TPS + 1)$$

The Watchdog Timer consists of a 14-bit timer with 7-bit programmable prescaler. Writing the sequence 1EH/E1H to the WDTRST register enables the timer. When the WDT is enabled, the WDTEN bit in WDTCON will be set to “1”. To prevent the WDT from generating a reset when it overflows, the watchdog feed sequence must be written to WDTRST before the end of the time-out period. To feed the watchdog, two write instructions must be sequentially executed successfully. Between the two write instructions, SFR reads are allowed, but writes are not allowed. The instructions should move 1EH to the WDTRST register and then 1EH to the WDTRST register. An incorrect feed or enable sequence will cause an immediate watchdog reset. The program sequence to feed or enable the watchdog timer is as follows:

```
MOV WDTRST, #01Eh
MOV WDTRST, #0E1h
```

20.1 Software Reset

A Software Reset of the AT89LP216 is accomplished by writing the software reset sequence 5AH/A5H to the WDTRST SFR. The WDT does not need to be enabled to generate the software reset. A normal software reset will set the SWRST flag in WDTCON. However, if at any time an incorrect sequence is written to WDTRST (i.e. anything other than 1EH/E1H or 5AH/A5H), a software reset will immediately be generated and both the SWRST and WDTOVF flags will be set. In this manner an intentional software reset may be distinguished from a software error-generated reset. The program sequence to generate a software reset is as follows:

```
MOV WDTRST, #05Ah
```

```
MOV WDTRST, #0A5h
```

Table 20-2. WDTCON – Watchdog Control Register

WDTCON Address = A7H					Reset Value = 0000 X000B			
Not Bit Addressable								
	PS2	PS1	PS0	WDIDLE	–	SWRST	WDTOVF	WDTEN
Bit	7	6	5	4	3	2	1	0
Symbol	Function							
PS2 PS1 PS0	Prescaler bits for the watchdog timer (WDT). When all three bits are cleared to 0, the watchdog timer has a nominal period of 16K clock cycles. When all three bits are set to 1, the nominal period is 2048K clock cycles.							
WDIDLE	Disable/enable the Watchdog Timer in IDLE mode. When WDIDLE = 0, WDT continues to count in IDLE mode. When WDIDLE = 1, WDT freezes while the device is in IDLE mode.							
SWRST	Software Reset Flag. Set when a software reset is generated by writing the sequence 5AH/A5H to WDTRST. Also set when an incorrect sequence is written to WDTRST. Must be cleared by software.							
WDTOVF	Watchdog Overflow Flag. Set when a WDT reset is generated by the WDT timer overflow. Also set when an incorrect sequence is written to WDTRST. Must be cleared by software.							
WDTEN	Watchdog Enable Flag. This bit is READ-ONLY and reflects the status of the WDT (whether it is running or not). The WDT is disabled after any reset and must be re-enabled by writing 1EH/E1H to WDTRST							

Table 20-3. WDTRST – Watchdog Reset Register

WDTCON Address = A6H					(Write-Only)			
Not Bit Addressable								
	–	–	–	–	–	–	–	
Bit	7	6	5	4	3	2	1	0
<p>The WDT is enabled by writing the sequence 1EH/E1H to the WDTRST SFR. The current status may be checked by reading the WDTCON bit in WDTCON. To prevent the WDT from resetting the device, the same sequence 1EH/E1H must be written to WDTRST before the time-out interval expires. A software reset is generated by writing the sequence 5AH/A5H to WDTRST.</p>								

21. Instruction Set Summary

The AT89LP216 is fully binary compatible with the MCS-51 instruction set. The difference between the AT89LP216 and the standard 8051 is the number of cycles required to execute an instruction. Instructions in the AT89LP216 may take 1, 2, 3 or 4 clock cycles to complete. The execution times of most instructions may be computed using [Table 21-1](#).

Table 21-1. Instruction Execution Times and Exceptions

22. On-Chip Debug System

The AT89LP216 On-Chip Debug (OCD) System uses a two-wire serial interface to control program flow; read, modify, and write the system state; and program the nonvolatile memory. The OCD System has the following features:

- Complete program flow control
- Read-Modify-Write access to all internal SFRs and data memories
- Four hardware program address breakpoints
- Unlimited program software breakpoints using BREAK instruction
- Break on stack overflow/underflow
- Break on Watchdog overflow
- Non-intrusive operation
- Programming of nonvolatile memory

22.1 Physical Interface

The On-Chip Debug System uses a two-wire synchronous serial interface to establish communication between the target device and the controlling emulator system. The OCD interface is controlled by two User Fuses. OCD is enabled by clearing the OCD $\overline{\text{Enable}}$ Fuse. When OCD is enabled, the $\overline{\text{RST}}$ port pin is configured as an input for the Debug Clock (DCL). Either the XTAL1 or XTAL2 pin is configured as a bi-directional data line for the Debug Data (DDA) depending on the clock source selected. If the External Clock is selected, XTAL2 is configured as DDA. If the Internal RC Oscillator is selected, XTAL1 is configured as DDA. The OCD device connections are shown in [Figure 22-1](#). When OCD is enabled, the type of interface used depends on the OCD Interface Select User Fuse. This fuse selects between a normal two-wire interface (TWI) and a fast two-wire interface (FTWI). It is the duty of the user to program this fuse to the correct setting for their debug system at the same time they enable OCD (see [“User Configuration Fuses”](#) on page 71).

Figure 22-1. AT89LP216 On-Chip Debug Connections

When designing a system where On-Chip Debug will be used, the following observations must be considered for correct operation:

- P1.3/ $\overline{\text{RST}}$ cannot be connected directly to V_{CC} and any external capacitors connect to $\overline{\text{RST}}$ must be removed.
- All external reset sources must be removed.
- The quartz crystal and any capacitors on XTAL1 or XTAL2 must be removed and an external clock signal must be driven on XTAL1 if the user does not wish to use the internal RC oscillator. Some emulator systems may provide a user-configurable clock for this purpose.

22.2 Software Breakpoints

The AT89LP216 microcontroller includes a BREAK instruction for implementing program memory breakpoints in software. A software breakpoint can be inserted manually by placing the BREAK instruction in the program code. Some emulator systems may allow for automatic insertion/deletion of software breakpoints. The Flash memory must be re-programmed each time a software breakpoint is changed. Frequent insertions/deletions of software breakpoints will reduce the data retention of the nonvolatile memory. Devices used for debugging purposes should not be shipped to end customers. The BREAK instruction is treated as a two-cycle NOP when OCD is disabled.

22.3 Limitations of On-Chip Debug

The AT89LP216 is a low-cost, low-pincount yet fully-featured microcontroller that multiplexes several functions on its limited I/O pins. Some device functionality must be sacrificed to provide resources for On-Chip Debugging. The On-Chip Debug System has the following limitations:

- The Debug Clock pin (DCL) is physically located on that same pin as Port Pin P1.3 and the External Reset (\overline{RST}). Therefore, neither P1.3 nor an external reset source may be emulated when OCD is enabled.
- The Debug Data pin (DDA) is physically located on either the XTAL1/P3.2 or XTAL2/P3.3 pin. The crystal oscillator is therefore not supported during debug. The user must select either the Internal RC Oscillator or the External Clock source to provide the system clock. Devices fused for the crystal oscillator will default to external clock mode when OCD is enabled.
- When using the Internal RC Oscillator during debug, DDA is located on the XTAL1/P3.2 pin. The $\overline{INT0}$ function cannot be emulated in this mode.
- When using the External Clock during debug, DDA is located on the XTAL2/P3.3 pin and the system clock drives XTAL1/P3.2. The $\overline{INT0}$, $\overline{INT1}$ and CLKOUT functions cannot be emulated in this mode.
- The AT89LP216 does not support In-Application Programming and therefore the device must be reset before changing the program code during debugging. This includes the insertion/deletion of software breakpoints.
- When using the Watchdog Overflow to generate a break in place of a reset, the state of the Watchdog will not be reset. An OCD Reset command should be sent to the device prior to resuming normal execution to ensure correct Watchdog behavior.

23. Programming the Flash Memory

The Atmel AT89LP216 microcontroller features 2K bytes of on-chip In-System Programmable Flash program memory. In-System Programming allows programming and reprogramming of the microcontroller positioned inside the end system. Using a simple 4-wire SPI interface, the In-System programmer communicates serially with the AT89LP216 microcontroller, reprogramming all nonvolatile memories on the chip. In-System Programming eliminates the need for physical removal of the chips from the system. This will save time and money, both during development in the lab, and when updating the software or parameters in the field. The ISP interface of the AT89LP216 includes the following features:

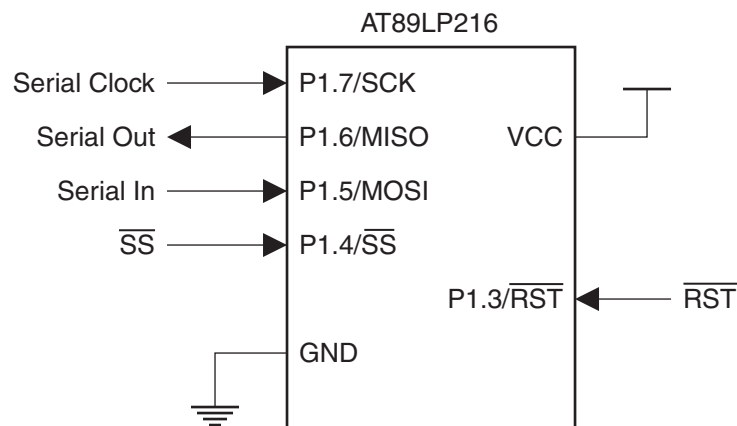

- Four-wire SPI Programming Interface
- Active-low Reset Entry into Programming
- Slave Select allows multiple devices on same interface
- User Signature Array
- Flexible Page Programming
- Row Erase Capability
- Page Write with Auto-Erase Commands
- Programming Status Register

For more detailed information on In-System Programming, refer to the Application Note entitled “AT89LP In-System Programming Specification”.

23.1 Physical Interface

In-System Programming utilizes the Serial Peripheral Interface (SPI) pins of an AT89LP216 microcontroller. The SPI is a full-duplex synchronous serial interface consisting of four wires: Serial Clock (SCK), Master-In/Slave-out (MISO), Master-out/Slave-in (MOSI), and an active-low Slave Select (\overline{SS}). When programming an AT89LP216 device, the programmer always operates as the SPI master, and the target system always operates as the SPI slave. To enter or remain in In-System Programming mode the device’s reset line (\overline{RST}) must be held active (low). With the addition of VCC and GND, an AT89LP216 microcontroller can be programmed with a minimum of seven connections as shown in [Figure 23-1](#).

Figure 23-1. In-System Programming Device Connections

The In-System Programming Interface is the only means of externally programming the AT89LP216 microcontroller. The ISP Interface can be used to program the device both in-system and in a standalone serial programmer. The ISP Interface does not require any clock other than SCK and is not limited by the system clock frequency. During In-System Programming the system clock source of the target device can operate normally.

When designing a system where In-System Programming will be used, the following observations must be considered for correct operation:

- The ISP interface uses the SPI clock mode 0 (CPOL = 0, CPHA = 0) exclusively with a maximum frequency of 5 MHz.
- The AT89LP216 will enter programming mode only when its reset line ($\overline{\text{RST}}$) is active (low). To simplify this operation, it is recommended that the target reset can be controlled by the In-System programmer. To avoid problems, the In-System programmer should be able to keep the entire target system reset for the duration of the programming cycle. The target system should never attempt to drive the four SPI lines while reset is active.
- The $\overline{\text{RST}}$ input may be disabled to gain an extra I/O pin. In these cases the $\overline{\text{RST}}$ pin will always function as a reset during power up. To enter programming the $\overline{\text{RST}}$ pin must be driven low prior to the end of Power-On Reset (POR). After POR has completed the device will remain in ISP mode until $\overline{\text{RST}}$ is brought high. Once the initial ISP session has ended, the power to the target device must be cycled OFF and ON to enter another session.
- The $\overline{\text{SS}}$ pin should not be left floating during reset if ISP is enabled.
- The ISP Enable Fuse must be set to allow programming during any reset period. If the ISP Fuse is disabled, ISP may only be entered at POR.

23.2 Memory Organization

The AT89LP216 offers 2K bytes of In-System Programmable (ISP) nonvolatile Flash code memory. In addition, the device contains a 64-byte User Signature Array and a 32-byte read-only Atmel Signature Array. The memory organization is shown in [Table 23-1](#) and [Figure 23-2](#). The memory is divided into pages of 32 bytes each. A single read or write command may only access a single page in the memory. Each memory type resides in its own address space and is accessed by commands specific to that memory. However, all memory types share the same page size.

User configuration fuses are mapped as a row in the memory, with each byte representing one fuse. From a programming standpoint, fuses are treated the same as normal code bytes except they are not affected by Chip Erase. Fuses can be enabled at any time by writing 00h to the appropriate locations in the fuse row. However, to disable a fuse, i.e. set it to FFh, the **entire** fuse row must be erased and then reprogrammed. The programmer should read the state of all the fuses into a temporary location, modify those fuses which need to be disabled, then issue a Fuse Write with Auto-Erase command using the temporary data. Lock bits are treated in a similar manner to fuses except they may only be erased (unlocked) by Chip Erase.

Table 23-1. Code Memory Size

Device #	Code Size	Page Size	# Pages	Address Range
AT89LP216	2K bytes	32 bytes	64	0000H - 07FFH

Figure 23-2. AT89LP216 Memory Organization

23.3 Command Format

Programming commands consist of an opcode byte, two address bytes, and zero or more data bytes. In addition, all command packets must start with a two-byte preamble of AAH and 55H. The preamble increases the noise immunity of the programming interface by making it more difficult to issue unintentional commands. [Figure 23-3 on page 68](#) shows a simplified flow chart of a command sequence.

A sample command packet is shown in [Figure 23-4 on page 68](#). The \overline{SS} pin defines the packet frame. \overline{SS} must be brought low before the first byte in a command is sent and brought back high after the final byte in the command has been sent. The command is not complete until \overline{SS} returns high. Command bytes are issued serially on MOSI. Data output bytes are received serially on MISO. Packets of variable length are supported by returning \overline{SS} high when the final required byte has been transmitted. In some cases command bytes have a don't care value. Don't care bytes in the middle of a packet must be transmitted. Don't care bytes at the end of a packet may be ignored.

Page oriented instructions always include a full 16-bit address. The higher order bits select the page and the lower order bits select the byte within that page. The AT89LP216 allocates 5 bits for byte address and 6 bits for page address. The page to be accessed is always fixed by the page address as transmitted. The byte address specifies the starting address for the first data byte. After each data byte has been transmitted, the byte address is incremented to point to the next data byte. This allows a page command to linearly sweep the bytes within a page. If the byte address is incremented past the last byte in the page, the byte address will roll over to the first byte in the same page. While loading bytes into the page buffer, overwriting previously loaded bytes will result in data corruption.

For a summary of available commands, see [Table 23-2 on page 69](#).

Figure 23-3. Command Sequence Flow Chart

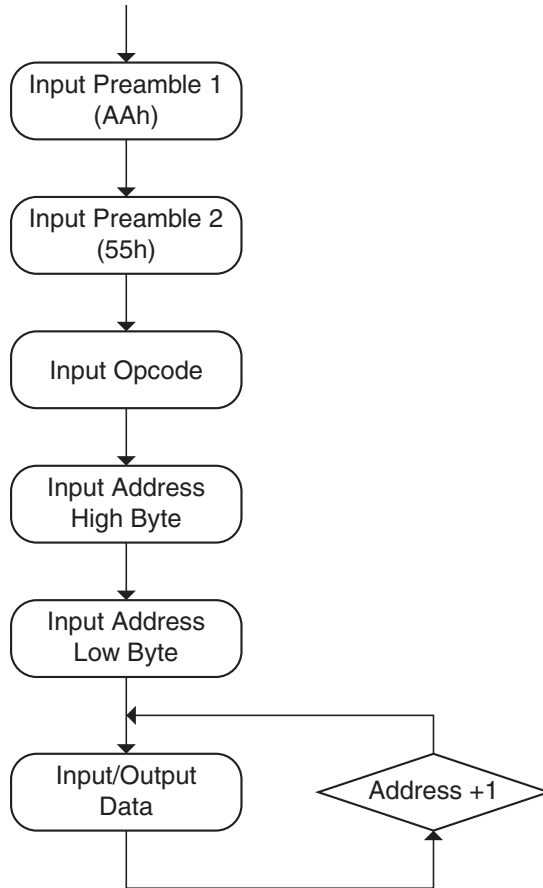

Figure 23-4. ISP Command Packet

Table 23-2. Programming Command Summary

Command	Opcode	Addr High	Addr Low	Data 0	Data n
Program Enable ⁽¹⁾	1010 1100	0101 0011	–	–	–
Chip Erase	1000 1010	–	–	–	–

Write User Signature Page ⁽²⁾	0101 0010	xxxx xxxx	xaab bbbb	DataIn 0 ... DataIn n	
Write User Signature Page with Auto-Erase ⁽²⁾	0111 0010	xxxx xxxx	xaab bbbb	DataIn 0 ... DataIn n	
Read User Signature Page ⁽²⁾	0011 0010	xxxx xxxx	xaab bbbb	DataOut 0 ... DataOut n	
Read Atmel Signature Page ⁽²⁾⁽⁶⁾	0011 1000	xxxx xxxx	xxxb bbbb	DataOut 0 ... DataOut n	

- Notes:
1. Program Enable must be the **first** command issued after entering into programming mode.
 2. Any number of Data bytes from 1 to 32 may be written/read. The internal address is incremented between each byte.
 3. Each byte address selects one fuse or lock bit. Data bytes must be 00h or FFh.
 4. See [Table 23-5 on page 71](#) for Fuse definitions.
 5. See [Table 23-4 on page 70](#) for Lock Bit definitions.

6. Atmel Signature Bytes:

AT89LP216: Address 00H = 1EH
 01H = 29H
 02H = FFH

7. Symbol Key:

- a: Page Address Bit
- b: Byte Address Bit
- x: Don't Care Bit

23.4 Status Register

The current state of the memory may be accessed by reading the status register. The status register is shown in [Table 23-3](#).

Table 23-3. Status Register

Bit	–	–	–	–	$\overline{\text{LOAD}}$	SUCCESS	$\overline{\text{WRTINH}}$	$\overline{\text{BUSY}}$
	7	6	5	4	3	2	1	0

Symbol	Function
$\overline{\text{LOAD}}$	Load flag. Cleared low by the load page buffer command and set high by the next memory write. This flag signals that the page buffer was previously loaded with data by the load page buffer command.
SUCCESS	Success flag. Cleared low at the start of a programming cycle and will only be set high if the programming cycle completes without interruption from the brownout detector.
$\overline{\text{WRTINH}}$	Write Inhibit flag. Cleared low by the brownout detector (BOD) whenever programming is inhibited due to V_{CC} falling below the minimum required programming voltage. If a BOD episode occurs during programming, the SUCCESS flag will remain low after the cycle is complete. $\overline{\text{WRTINH}}$ low also forces $\overline{\text{BUSY}}$ low.
$\overline{\text{BUSY}}$	Busy flag. Cleared low whenever the memory is busy programming or if write is currently inhibited.

23.5 $\overline{\text{DATA}}$ Polling

The AT89LP216 implements $\overline{\text{DATA}}$ polling to indicate the end of a programming cycle. While the device is busy, any attempted read of the last byte written will return the data byte with the MSB complemented. Once the programming cycle has completed, the true value will be accessible. During Erase the data is assumed to be FFh and $\overline{\text{DATA}}$ polling will return 7FH. When writing multiple bytes in a page, the $\overline{\text{DATA}}$ value will be the last data byte loaded before programming begins, not the written byte with the highest physical address within the page.

23.6 Flash Security

The AT89LP216 provides two Lock Bits for Flash Code Memory security. Lock bits can be left unprogrammed (FFh) or programmed (00h) to obtain the protection levels listed in [Table 23-4](#). Lock bits can only be erased (set to FFh) by Chip Erase. Lock bit mode 2 disables programming of all memory spaces, including the User Signature Array and User Configuration Fuses. User fuses must be programmed before enabling Lock bit mode 2 or 3. Lock bit mode 3 implemented mode 2 and also blocks reads from the code memory; however, reads of the User Signature Array, Atmel Signature Array, and User Configuration Fuses are still allowed.

Table 23-4. Lock Bit Protection Modes

Program Lock Bits (by address)			Protection Mode
Mode	00h	01h	
1	FFh	FFh	No program lock features
2	00h	FFh	Further programming of the Flash is disabled
3	00h	00h	Further programming of the Flash is disabled and verify (read) is also disabled; OCD is disabled

23.7 User Configuration Fuses

The AT89LP216 includes 19 user fuses for configuration of the device. Each fuse is accessed at a separate address in the User Fuse Row as listed in Table 23-5. Fuses are cleared by programming 00h to their locations. Programming FFh to fuse location will cause that fuse to maintain its previous state. To set a fuse (set to FFh) the fuse row must be erased and then reprogrammed using the Fuse Write with Auto-erase command. The default state for all fuses is FFh.

Table 23-5. User Configuration Fuse Definitions

Address	Fuse Name	Description
00 – 01h	Clock Source – CS[0:1] ⁽²⁾	Selects source for the system clock: CS1 CS0 Selected Source 00h 00h Crystal Oscillator (XTAL) 00h FFh Reserved FFh 00h External Clock on XTAL1 (XCLK) FFh FFh Internal RC Oscillator (IRC)
02 – 03h	Start-up Time – SUT[0:1]	Selects time-out delay for the POR/BOD/PWD wake-up period: SUT1 SUT0 Selected Time-out 00h 00h 1 ms (XTAL); 16 μs (XCLK/IRC) 00h FFh 2 ms (XTAL); 512 μs (XCLK/IRC) FFh 00h 4 ms (XTAL); 1 ms (XCLK/IRC) FFh FFh 16 ms (XTAL); 4 ms (XCLK/IRC)
04h	Reset Pin Enable ⁽³⁾	FFh: $\overline{\text{RST}}$ pin functions as reset 00h: $\overline{\text{RST}}$ pin functions as general purpose I/O
05h	Brown-Out Detector Enable	FFh: Brown-out Detector Enabled 00h: Brown-out Detector Disabled
06h	On-Chip Debug $\overline{\text{Enable}}$	FFh: On-Chip Debug Disabled 00h: On-Chip Debug Enabled
07h	ISP Enable ⁽³⁾	FFh: In-System Programming Enabled 00h: In-System Programming Disabled (Enabled at POR only)
08 – 0FH	RC Oscillator Frequency Adjustment [0:7]	Adjusts the frequency of the internal RC oscillator.
10H	User Signature Programming	FFh: Programming of User Signature Disabled 00h: Programming of User Signature Enabled
11H	Tristate Ports	FFh: I/O Ports start in input-only mode (tristated) after reset 00h: I/O Ports start in quasi-bidirectional mode after reset
12H	OCD Interface Select	FFh: Normal two-wire interface 00h: Fast two-wire interface

- Notes:
1. The default state for all fuses is FFh.
 2. Changes to these fuses will only take effect after a device POR.
 3. Changes to these fuses will only take effect after the ISP session terminates by bringing $\overline{\text{RST}}$ high.

23.8 Programming Interface Timing

This section details general system timing sequences and constraints for entering or exiting In-System Programming as well as parameters related to the Serial Peripheral Interface during ISP. The general timing parameters for the following waveform figures are listed in section “[Timing Parameters](#)” on page 75.

23.8.1 Power-up Sequence

Execute this sequence to enter programming mode immediately after power-up. In the $\overline{\text{RST}}$ pin is disabled or if the ISP Fuse is disabled, this is the only method to enter programming (see “[External Reset](#)” on page 14).

1. Apply power between VCC and GND pins. $\overline{\text{RST}}$ should remain low.
2. Wait at least t_{PWRUP} and drive $\overline{\text{SS}}$ high.
3. Wait at least t_{SUT} for the internal Power-on Reset to complete. The value of t_{SUT} will depend on the current settings of the device.
4. Start programming session.

Figure 23-5. Serial Programming Power-up Sequence

23.8.2 Power-down Sequence

Execute this sequence to power-down the device **after** programming.

1. Drive SCK low.
2. Wait at least t_{SSD} and bring $\overline{\text{SS}}$ high.
3. Tristate MOSI.
4. Wait at least t_{SSZ} and then tristate $\overline{\text{SS}}$ and SCK.
5. Wait no more than t_{PWRDN} and power off VCC.

Figure 23-6. Serial Programming Power-down Sequence

23.8.3 ISP Start Sequence

Execute this sequence to exit CPU execution mode and enter ISP mode when the device has passed Power-On Reset and is already operational.

1. Drive $\overline{\text{RST}}$ low.
2. Drive $\overline{\text{SS}}$ high.
3. Wait $t_{\text{RLZ}} + t_{\text{STL}}$.
4. Start programming session.

Figure 23-7. In-System Programming (ISP) Start Sequence

23.8.4 ISP Exit Sequence

Execute this sequence to exit ISP mode and resume CPU execution mode.

1. Drive SCK low.
1. Wait at least t_{SSD} and drive $\overline{\text{SS}}$ high.
2. Tristate MOSI.
3. Wait at least t_{SSZ} and bring $\overline{\text{RST}}$ high.
4. Tristate SCK.
5. Wait t_{RHZ} and tristate $\overline{\text{SS}}$.

Figure 23-8. In-System Programming (ISP) Exit Sequence

Note: The waveforms on this page are not to scale.

23.8.5 Serial Peripheral Interface

The Serial Peripheral Interface (SPI) is a byte-oriented full-duplex synchronous serial communication channel. During In-System Programming, the programmer always acts as the SPI master and the target device always acts as the SPI slave. The target device receives serial data on MOSI and outputs serial data on MISO. The Programming Interface implements a standard SPI Port with a fixed data order and For In-System Programming, bytes are transferred MSB first as shown in [Figure 23-9](#). The SCK phase and polarity follow SPI clock mode 0 (CPOL = 0, CPHA = 0) where bits are sampled on the rising edge of SCK and output on the falling edge of SCK. For more detailed timing information see [Figure 23-10](#).

Figure 23-9. ISP Byte Sequence

Figure 23-10. Serial Programming Interface Timing

23.8.6 Timing Parameters

The timing parameters for [Figure 23-5](#), [Figure 23-6](#), [Figure 23-7](#), [Figure 23-8](#), and [Figure 23-10](#) are shown in [Table](#) .

Table 23-6. Programming Interface Timing Parameters

Symbol	Parameter	Min	Max	Units
t_{CLCL}	System Clock Cycle Time	0	60	ns
t_{PWRUP}	Power On to \overline{SS} High Time	10		μ s
t_{POR}	Power-on Reset Time		100	μ s
t_{PWRDN}	\overline{SS} Tristate to Power Off		1	μ s
t_{RLZ}	\overline{RST} Low to I/O Tristate	t_{CLCL}	$2 t_{CLCL}$	ns
t_{STL}	\overline{RST} Low Settling Time	100		ns
t_{RHZ}	\overline{RST} High to \overline{SS} Tristate	0	$2 t_{CLCL}$	ns
t_{SCK}	Serial Clock Cycle Time	200 ⁽¹⁾		ns
t_{SHSL}	Clock High Time	75		ns
t_{SLSH}	Clock Low Time	50		ns
t_{SR}	Rise Time		25	ns
t_{SF}	Fall Time		25	ns
t_{SIS}	Serial Input Setup Time	10		ns
t_{SIH}	Serial Input Hold Time	10		ns
t_{SOH}	Serial Output Hold Time		10	ns
t_{SOV}	Serial Output Valid Time		35	ns
t_{SOE}	Output Enable Time		10	ns
t_{SOX}	Output Disable Time		25	ns
t_{SSE}	\overline{SS} Enable Lead Time	t_{SLSH}		ns
t_{SSD}	\overline{SS} Disable Lag Time	t_{SLSH}		ns
t_{ZSS}	SCK Setup to \overline{SS} Low	25		ns
t_{SSZ}	SCK Hold after \overline{SS} High	25		ns
t_{WR}	Write Cycle Time	2.5		ms
t_{AWR}	Write Cycle with Auto-Erase Time	5		ms
t_{ERS}	Chip Erase Cycle Time	7.5		ms

Note: 1. t_{SCK} is independent of t_{CLCL} .

24. Electrical Characteristics

24.1 Absolute Maximum Ratings*

Operating Temperature	-40°C to +85°C
Storage Temperature	-65°C to +150°C
Voltage on Any Pin with Respect to Ground.....	-0.7V to +5.5V
Maximum Operating Voltage	5.5V
DC Output Current.....	15.0 mA

*NOTICE: Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

24.2 DC Characteristics

$T_A = -40^\circ\text{C}$ to 85°C , $V_{CC} = 2.4\text{V}$ to 5.5V (unless otherwise noted)

Symbol	Parameter	Condition	Min	Max	Units	
V_{IL}	Input Low-voltage		-0.5	$0.2 V_{CC} - 0.1$	V	
V_{IH}	Input High-voltage		$0.2 V_{CC} + 0.9$	$V_{CC} + 0.5$	V	
V_{OL}	Output Low-voltage (Ports 1, 3) ⁽¹⁾ 809	$I_{OL} = 10\text{ mA}$, $V_{CC} = 2.7\text{V}$, $T_A = 85^\circ\text{C}$		0.5	V	
V_{OH}	Output High-voltage (Ports 1, 3) With Weak Pull-ups Enabled	$I_{OH} = -80\ \mu\text{A}$, $V_{CC} = 5\text{V} \pm 10\%$	2.4		V	
		$I_{OH} = -30\ \mu\text{A}$	$0.75 V_{CC}$		V	
		$I_{OH} = -12\ \mu\text{A}$	$0.9 V_{CC}$		V	
V_{OH1}	Output High-voltage (Ports 1, 3) With Strong Pull-ups Enabled	$I_{OH} = -10\text{ mA}$, $T_A = 85^\circ\text{C}$	$0.9 V_{CC}$			
I_{IL}	Logic 0 Input Current (Ports 1, 3)	$V_{IN} = 0.45\text{V}$		-50	μA	
I_{TL}	Logic 1 to 0 Transition Current (Ports 1, 3)	$V_{IN} = 2\text{V}$, $V_{CC} = 5\text{V} \pm 10\%$		-750	μA	
I_{LI}	Input Leakage Current (Port P1.0, P1.1)	$0 < V_{IN} < V_{CC}$		± 10	μA	
V_{OS}	Comparator Input Offset Voltage	$V_{CC} = 5\text{V}$		20	mV	
V_{CM}	Comparator Input Common Mode Voltage		0	V_{CC}	V	
RRST	Reset Pull-down Resistor		50	150	$\text{k}\Omega$	
C_{IO}	Pin Capacitance	Test Freq. = 1 MHz, $T_A = 25^\circ\text{C}$		10	pF	
I_{CC}	Power Supply Current	Active Mode, 12 MHz, $V_{CC} = 5.5\text{V}/3\text{V}$		5.5/3.5	mA	
		Idle Mode, 12 MHz, $V_{CC} = 5.5\text{V}/3\text{V}$ P1.0 & P1.1 = 0V or V_{CC}		1.2/1	mA	
	Power-down Mode ⁽²⁾	$V_{CC} = 5.5\text{V}$, P1.0 & P1.1 = 0V or V_{CC}			100	μA
		$V_{CC} = 3\text{V}$, P1.0 & P1.1 = 0V or V_{CC}			20	μA

- Notes: 1. Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
 Maximum I_{OL} per port pin: 10 mA
 Maximum total I_{OL} for all output pins: 15 mA
 If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
2. Minimum V_{CC} for Power-down is 2V.

24.3 Serial Peripheral Interface Timing

Table 24-1. SPI Master Characteristics

Symbol	Parameter	Min	Max	Units
t_{CLCL}	Oscillator Period	41.6		ns
t_{SCK}	Serial Clock Cycle Time	$4t_{CLCL}$		ns
t_{SHSL}	Clock High Time	$t_{SCK}/2 - 25$		ns
t_{SLSH}	Clock Low Time	$t_{SCK}/2 - 25$		ns
t_{SR}	Rise Time		25	ns
t_{SF}	Fall Time		25	ns
t_{SIS}	Serial Input Setup Time	10		ns
t_{SIH}	Serial Input Hold Time	10		ns
t_{SOH}	Serial Output Hold Time		10	ns
t_{SOV}	Serial Output Valid Time		35	ns

Table 24-2. SPI Slave Characteristics

Symbol	Parameter	Min	Max	Units
t_{CLCL}	Oscillator Period	41.6		ns
t_{SCK}	Serial Clock Cycle Time	$4t_{CLCL}$		ns
t_{SHSL}	Clock High Time	$1.5 t_{CLCL} - 25$		ns
t_{SLSH}	Clock Low Time	$1.5 t_{CLCL} - 25$		ns
t_{SR}	Rise Time		25	ns
t_{SF}	Fall Time		25	ns
t_{SIS}	Serial Input Setup Time	10		ns
t_{SIH}	Serial Input Hold Time	10		ns
t_{SOH}	Serial Output Hold Time		10	ns
t_{SOV}	Serial Output Valid Time		35	ns
t_{SOE}	Output Enable Time		10	ns
t_{SOX}	Output Disable Time		25	ns
t_{SSE}	Slave Enable Lead Time	10		ns
t_{SSD}	Slave Disable Lag Time	0		ns

Figure 24-1. SPI Master Timing (CPHA = 0)

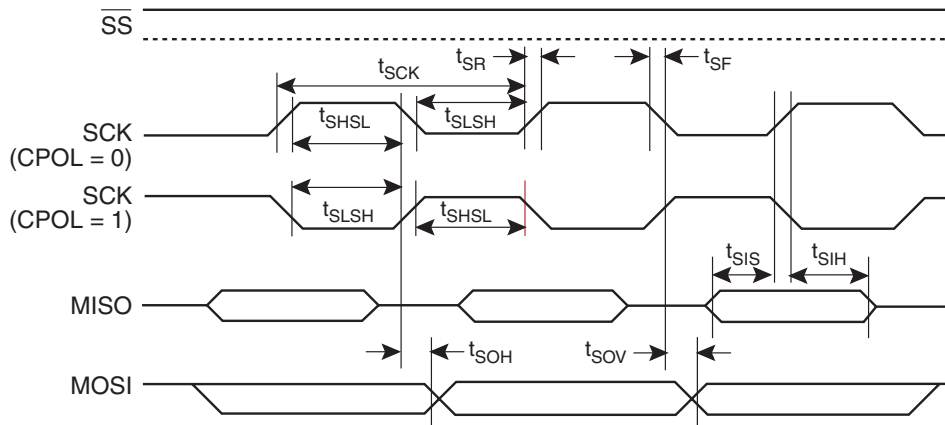

Figure 24-2. SPI Slave Timing (CPHA = 0)

Figure 24-3. SPI Master Timing (CPHA = 1)

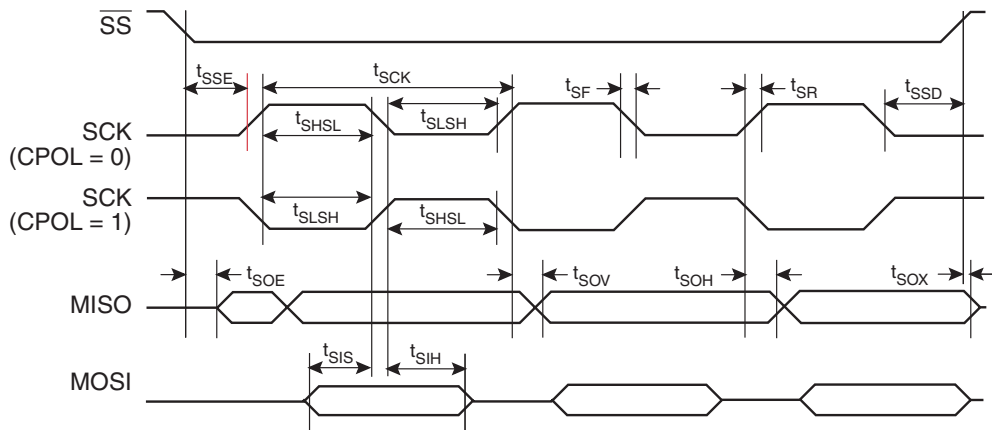

Figure 24-4. SPI Slave Timing (CPHA = 1)

24.4 External Clock Drive

Figure 24-5. External Clock Drive Waveform

Symbol	Parameter	$V_{CC} = 2.4V \text{ to } 5.5V$		Units
		Min	Max	
$1/t_{CLCL}$	Oscillator Frequency	0	20	MHz
t_{CLCL}	Clock Period	50		ns
t_{CHCX}	High Time	12		ns
t_{CLCX}	Low Time	12		ns
t_{CLCH}	Rise Time		5	ns
t_{CHCL}	Fall Time		5	ns

24.5 Serial Port Timing: Shift Register Mode

The values in this table are valid for $V_{CC} = 2.4V$ to $5.5V$ and Load Capacitance = 80 pF .

Symbol	Parameter	Variable Oscillator		Units
		Min	Max	
t_{XLXL}	Serial Port Clock Cycle Time	$2t_{CLCL} - 15$		μs
t_{QVXH}	Output Data Setup to Clock Rising Edge	$t_{CLCL} - 15$		ns
t_{XHQX}	Output Data Hold after Clock Rising Edge	$t_{CLCL} - 15$		ns
t_{XHDX}	Input Data Hold after Clock Rising Edge	0		ns
t_{XHDL}	Input Data Valid to Clock Rising Edge	15		ns

Figure 24-6. Shift Register Mode Timing Waveform

24.6 Test Conditions

24.6.1 AC Testing Input/Output Waveform⁽¹⁾

Note: 1. AC Inputs during testing are driven at $V_{CC} - 0.5V$ for a logic "1" and $0.45V$ for a logic "0". Timing measurements are made at V_{IH} min. for a logic "1" and V_{IL} max. for a logic "0".

24.6.2 Float Waveform⁽¹⁾

Note: 1. For timing purposes, a port pin is no longer floating when a 100 mV change from load voltage occurs. A port pin begins to float when 100 mV change from the loaded V_{OH}/V_{OL} level occurs.

24.6.3 I_{CC} Test Condition, Active Mode, All Other Pins are Disconnected

24.6.4 I_{CC} Test Condition, Idle Mode, All Other Pins are Disconnected

24.6.5 Clock Signal Waveform for I_{CC} Tests in Active and Idle Modes, $t_{CLCH} = t_{CHCL} = 5$ ns

24.6.6 I_{CC} Test Condition, Power-down Mode, All Other Pins are Disconnected, $V_{CC} = 2V$ to $5.5V$

25. Ordering Information

25.1 Standard Package

Speed (MHz)	Power Supply	Ordering Code	Package	Operation Range
20	2.4V to 5.5V	AT89LP216-20PI AT89LP216-20SI AT89LP216-20XI	16P3 16S2 16X	Industrial (-40° C to 85° C)

25.2 Green Package Option (Pb/Halide-free)

Speed (MHz)	Power Supply	Ordering Code	Package	Operation Range
20	2.4V to 5.5V	AT89LP216-20PU AT89LP216-20SU AT89LP216-20XU	16P3 16S2 16X	Industrial (-40° C to 85° C)

Package Types
