

DBL 3842

CURRENT MODE PWM CONTROLLER

The DBL3842, high performance current mode controller, provides the necessary features to off-line and DC-DC fixed frequency current control applications offering the designer a cost effective solution with minimal external components.

Internally protection circuitry includes built-in input and reference under-voltage lockout and current limiting with hysteresis. Also other characteristics of internal circuit provide improved line regulation, enhanced load response, trimmed oscillation for precise duty cycle control, a temperature compensated reference, high gain error amplifier, current sensing comparator and totempole output designed to source and sink high peak current from a capacitive load such as the gate of a power MOSFET.

8DIP

Unit : mm

FEATURES

- Optimized for off-line control
- Low start up and operating current
- Pulse by pulse current limiting
- Enhanced load response characteristic
- Current mode operation to 500KHz
- Undervoltage lockout with 6V hysteresis
- Internally trimmed bandgap reference about 5V
- Automatic feed forward compensation
- High current totem-pole output

☐ MAXIMUM RATINGS($T_a=25^{\circ}\text{C}$)

Characteristics	Symbol	Rating	Unit
Supply Voltage	V_{cc}	30	V
Current Sense and Vfb Input	V_{in}	-0.3 to V_{cc}	V
Total Power Supply and Zener Current	$I_{cc} + I_z$	30	mA
Output Sink or Source Current	I_o	1	A
Error Amp Output Sink Current	I_{eo}	10	mA
Operating Ambient Temperature	T_a	0 to 70	$^{\circ}\text{C}$
Storage Temperature Range	T_{stg}	-65 to 150	$^{\circ}\text{C}$
Power Dissipation at $T_a \leq 50^{\circ}\text{C}$	P_d	1	W

* note) All voltages are with respect to PIN5, and current are positive into the specified pin.

☐ PIN DESCRIPTION

PIN NO	FUNCTION	DESCRIPTION
1	Compensation	Error amplifier output and is made available for loop compensation.
2	Voltage feedback	Inverting input of error amplifier, normally connected to the switching power supply output through a resistor divider.
3	Current sense	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate the output.
4	R_t/C_t	The oscillator frequency and maximum output duty cycle are programmed by connecting resistor R_t to V_{ref} and capacitor C_t to ground.
5	Ground	This pin is the combined control circuitry and power ground.
6	Output	This output directly drives the gate of a power MOSFET. Peak currents up to 1.0A are sourced and sunk by this pin.
7	V_{cc}	This pin is the positive supply of the control IC.
8	V_{ref}	This is the reference output, it provides charging current for capacitor C_t through resistor R_t .

- Adjust V_{cc} above the start threshold before setting at 15V

☐ INFORMATION IN USING IC

1. UNDERVOLTAGE LOCKOUT

To prevent erratic output behavior which activating the power switch with extraneous leakage currents, during under voltage lock-out. Output(pin6) should be shunted to ground with a bleeder resistor.

The V_{cc} comparator upper and lower threshold are 16V/10V. The large hysteresis and low start up currents makes it ideally suited in off – line converter application where efficient bootstrap start – up techniques are required.

2. OSCILLATOR WAVEFORMS AND MAXIMUM DUTY CYCL

The oscillator frequency is programmed by the values selected for the timing components R_t and C_t . C_t is charged from 5V, V_{ref} , through resistor R_t to approximately 2.8V and discharged to 1.2V by an internal current sink.

During the discharge of C_t , the oscillator generates an internal blanking pulse and the center input NOR gate high.

This makes output to be in a low state and control the amount of output dead time.

3. ERROR AMP CONFIGURATION

Error amp output(Pin1) is provided for external loop compensation and error amp can source or sink up to 0.5mA. The non-inverting input is internally biased at 2.5V and is not pinned out.

The converter output voltage is typically divided down and monitored by the inverting input(pin2).

□ INFORMATION IN USING IC(continued)

4. CURRENT SENSE CIRCUIT

$$I_{peak} = \frac{R(V_{pin1} - 2V_{be})}{3R \times R_s}$$

A normal operating conditions occurs when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the current sense comparator threshold will be internally clamped to 1.0V. Therefore the maximum peak switch current is $I_{pk(max)} = 1.0V/R_s$, and under the normal operating conditions the peak inductor current controlled by the voltage at pin1.

5. SHUTDOWN TECHNIQUES

Shutdown of the DBL3842 can be accomplished by two methods; either raise pin3 above 1V or pull pin1 below a voltage two diodes drops above ground. Either method causes the output of the PWM comparator to be high(refer to

block diagram). The PWM latch is reset dominant so that the output will remain low until the next clock cycle after the shutdown condition at pins 1 and/or 3 is removed.

In one example, an externally latched shutdown may be accomplished by adding an SCR which turn off, allowing the SCR to reset.

6. OPEN LOOP TEST

High peak currents associated with capacitive loads necessitate careful grounding techniques. Timing and bypass capacitors should be connected close to Pin 5 in a single point ground. The transistor and 5KΩ potentiometer are used to sample the oscillator waveform and apply an adjustable ramp to Pin 3.

7. SLOPE COMPENSATION

A fraction of the oscillator ramp can be resistively summed with the current sense signal to provide slope compensation for converters requiring duty cycle over 50%. Note that capacitor C, forms a filter with R2 to suppress the leading edge switch spikes.
