

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

## General Description

The MAX1195 is a 3V, dual, 8-bit analog-to-digital converter (ADC) featuring fully differential wideband track-and-hold (T/H) inputs, driving two ADCs. The MAX1195 is optimized for low-power, small size, and high-dynamic performance for applications in imaging, instrumentation and digital communications. This ADC operates from a single 2.7V to 3.6V supply, consuming only 87mW while delivering a typical signal-to-noise and distortion (SINAD) of 48.5dB at an input frequency of 20MHz and a sampling rate of 40Msps. The T/H-driven input stages incorporate 400MHz (-3dB) input amplifiers. The converters may also be operated with single-ended inputs. In addition to low operating power, the MAX1195 features a 3mA sleep mode as well as a 0.1μA power-down mode to conserve power during idle periods.

An internal 2.048V precision bandgap reference sets the full-scale range of the ADC. A flexible reference structure allows the use of this internal or an externally applied reference, if desired, for applications requiring increased accuracy or a different input voltage range.

The MAX1195 features parallel, CMOS-compatible three-state outputs. The digital output format can be set to two's complement or straight offset binary through a single control pin. The device provides for a separate output power supply of 1.7V to 3.6V for flexible interfacing with various logic families. The MAX1195 is available in a 7mm x 7mm, 48-pin TQFP package, and is specified for the extended industrial (-40°C to +85°C) temperature range.

Pin-compatible higher speed versions of the MAX1195 are also available. Refer to the MAX1197 data sheet for 60Msps and the MAX1198 data sheet for 100Msps. In addition to these speed grades, this family will include a multiplexed output version (MAX1196, 40Msps), for which digital data is presented time interleaved and on a single, parallel 8-bit output port.

For a 10-bit, pin-compatible upgrade, refer to the MAX1183 data sheet. With the N.C. pins of the MAX1195 internally pulled down to ground, this ADC becomes a drop-in replacement for the MAX1183.

## Applications

|                                 |                  |
|---------------------------------|------------------|
| Baseband I/Q Sampling           | WLAN, WWAN, WLL, |
| Multichannel IF Sampling        | MMDS Modems      |
| Ultrasound and Medical Imaging  | Set-Top Boxes    |
| Battery-Powered Instrumentation | VSAT Terminals   |

## Features

- ◆ Single 2.7V to 3.6V Operation
- ◆ Excellent Dynamic Performance
  - 48.5dB/46.7dB SINAD at  $f_{IN} = 20\text{MHz}/200\text{MHz}$
  - 68.7dBc/55.7dBc SFDR at  $f_{IN} = 20\text{MHz}/200\text{MHz}$
- ◆ -72dB Interchannel Crosstalk at  $f_{IN} = 20\text{MHz}$
- ◆ Low Power
  - 87mW (Normal Operation)
  - 9mW (Sleep Mode)
  - 0.3μW (Shutdown Mode)
- ◆ 0.05dB Gain and  $\pm 0.05^\circ$  Phase Matching
- ◆ Wide  $\pm 1\text{Vp-p}$  Differential Analog Input Voltage Range
- ◆ 400MHz -3dB Input Bandwidth
- ◆ On-Chip 2.048V Precision Bandgap Reference
- ◆ User-Selectable Output Format—Two's Complement or Offset Binary
- ◆ Pin-Compatible 8-Bit and 10-Bit Upgrades Available

## Ordering Information

| PART       | TEMP RANGE     | PIN-PACKAGE |
|------------|----------------|-------------|
| MAX1195ECM | -40°C to +85°C | 48 TQFP-EP* |

\*EP = Exposed paddle

Functional Diagram and Pin Compatible Upgrades table appear at end of data sheet.

## Pin Configuration

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

## ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

(V<sub>DD</sub> = OV<sub>DD</sub> = 3V, 0.1μF and 2.2μF capacitors from REFP, REFN, and COM to GND; REFOUT connected to REFIN through a 10kΩ resistor, V<sub>IN</sub> = 2V<sub>P-P</sub> (differential with respect to COM), C<sub>L</sub> = 10pF at digital outputs, f<sub>CLK</sub> = 40MHz, T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless otherwise noted. ≥+25°C guaranteed by production test, <+25°C guaranteed by design and characterization. Typical values are at T<sub>A</sub> = +25°C.)

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

## ELECTRICAL CHARACTERISTICS (continued)

( $V_{DD} = OV_{DD} = 3V$ ,  $0.1\mu F$  and  $2.2\mu F$  capacitors from REFP, REFN, and COM to GND; REFOUT connected to REFIN through a  $10k\Omega$  resistor,  $V_{IN} = 2V_{P-P}$  (differential with respect to COM),  $C_L = 10pF$  at digital outputs,  $f_{CLK} = 40MHz$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.  $\geq +25^\circ C$  guaranteed by production test,  $< +25^\circ C$  guaranteed by design and characterization. Typical values are at  $T_A = +25^\circ C$ .)

## ELECTRICAL CHARACTERISTICS (continued)

( $V_{DD} = OV_{DD} = 3V$ ,  $0.1\mu F$  and  $2.2\mu F$  capacitors from REFP, REFN, and COM to GND; REFOUT connected to REFIN through a  $10k\Omega$  resistor,  $V_{IN} = 2V_{P-P}$  (differential with respect to COM),  $C_L = 10pF$  at digital outputs,  $f_{CLK} = 40MHz$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.  $\geq +25^\circ C$  guaranteed by production test,  $< +25^\circ C$  guaranteed by design and characterization. Typical values are at  $T_A = +25^\circ C$ .)

| Phase Matching                     |          | fINA or B = 20MHz at -1dB FS (Note 10) |     | ±0.05        |     | Degrees |

**Note 1:** Guaranteed by design. Not subject to production testing.

**Note 2:** Intermodulation distortion is the total power of the intermodulation products relative to the total input power.

**Note 3:** Analog attenuation is defined as the amount of attenuation of the fundamental bin from a converted FFT between two applied input signals with the same magnitude (peak-to-peak) at  $f_{IN1}$  and  $f_{IN2}$ .

**Note 4:** REFIN and REFOUT should be bypassed to GND with a 0.1 $\mu F$  (min) and 2.2 $\mu F$  (typ) capacitor.

**Note 5:** REFP, REFN, and COM should be bypassed to GND with a 0.1 $\mu F$  (min) and 2.2 $\mu F$  (typ) capacitor.

**Note 6:** Typical analog output current at  $f_{INA\&B} = 20MHz$ . For digital output currents vs. analog input frequency, see *Typical Operating Characteristics*.

**Note 7:** See Figure 3 for detailed system timing diagrams. Clock to data valid timing is measured from 50% of the clock level to 50% of the data output level.

**Note 8:** Crosstalk rejection is tested by applying a test tone to one channel and holding the other channel at DC level. Crosstalk is measured by calculating the power ratio of the fundamental of each channel's FFT.

**Note 9:** Amplitude matching is measured by applying the same signal to each channel and comparing the magnitude of the fundamental of the calculated FFT.

**Note 10:** Phase matching is measured by applying the same signal to each channel and comparing the phase of the fundamental of the calculated FFT. The data from both ADC channels must be captured simultaneously during this test.

**Note 11:** SINAD settles to within 0.5dB of its typical value in unbuffered external reference mode.

Figure 1. Pipelined Architecture—Stage Blocks

## Detailed Description

The MAX1195 uses a seven-stage, fully differential, pipelined architecture (Figure 1) that allows for high-speed conversion while minimizing power consumption. Samples taken at the inputs move progressively through the pipeline stages every half-clock cycle. Including the delay through the output latch, the total clock-cycle latency is five clock cycles.

Flash ADCs convert the held input voltages into a digital code. Internal MDACs convert the digitized results back into analog voltages, which are then subtracted from the original held input signals. The resulting error

signals are then multiplied by two, and the residues are passed along to the next pipeline stages where the process is repeated until the signals have been processed by all seven stages.

### Input Track-and-Hold Circuits

Figure 2 displays a simplified functional diagram of the input T/H circuits in both track and hold mode. In track mode, switches S1, S2a, S2b, S4a, S4b, S5a, and S5b are closed. The fully differential circuits sample the input signals onto the two capacitors (C2a and C2b) through switches S4a and S4b. S2a and S2b set the common mode for the amplifier input, and open simul-

## Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

Figure 2. MAX1195 T/H Amplifiers

taneously with S1 sampling the input waveform. Switches S4a, S4b, S5a, and S5b are then opened before switches S3a and S3b connects capacitors C1a and C1b to the output of the amplifier and switch S4c is closed. The resulting differential voltages are held on capacitors C2a and C2b. The amplifiers are used to charge capacitors C1a and C1b to the same values originally held on C2a and C2b. These values are then presented to the first-stage quantizers and isolate the

pipelines from the fast-changing inputs. The wide input bandwidth T/H amplifiers allow the MAX1195 to track and sample/hold analog inputs of high frequencies ( $> \text{Nyquist}$ ). Both ADC inputs (INA+, INB+ and INA-, INB-) can be driven either differentially or single-ended. Match the impedance of INA+ and INA-, as well as INB+ and INB-, and set the common-mode voltage to mid-supply ( $V_{DD}/2$ ) for optimum performance.

## Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

Figure 3. System Timing Diagram

### Analog Inputs and Reference Configurations

The full-scale range of the MAX1195 is determined by the internally generated voltage difference between REFP ( $V_{DD}/2 + V_{REFIN}/4$ ) and REFN ( $V_{DD}/2 - V_{REFIN}/4$ ). The full-scale range for both on-chip ADCs is adjustable through the REFIN pin, which provides high input impedance is provided for this purpose.

The MAX1195 provides three modes of reference operation:

- Internal reference mode
- Buffered external reference mode
- Unbuffered external reference mode

In internal reference mode, connect the internal reference output REFOUT to REFIN through a resistor (e.g.,  $10k\Omega$ ) or resistor divider, if an application requires a reduced full-scale range. For stability and noise-filtering purposes, bypass REFIN with a  $>10nF$  capacitor to GND. In internal reference mode, REFOUT, COM, REFP, and REFN become low-impedance outputs.

In buffered external reference mode, adjust the reference voltage levels externally by applying a stable and accurate voltage at REFIN. In this mode, COM, REFP,

and REFN are outputs. REFOUT can be left open or connected to REFIN through a  $>10k\Omega$  resistor.

In unbuffered external reference mode, connect REFIN to GND. This deactivates the on-chip reference buffers for REFP, COM, and REFN. With their buffers shut down, these nodes become high-impedance inputs and can be driven through separate, external reference sources.

For detailed circuit suggestions and how to drive this dual ADC in buffered/unbuffered external reference mode, see the *Applications Information* section.

### Clock Input (CLK)

The MAX1195's CLK input accepts a CMOS-compatible clock signal. Since the interstage conversion of the device depends on the repeatability of the rising and falling edges of the external clock, use a clock with low jitter and fast rise and fall times ( $<2ns$ ). In particular, sampling occurs on the rising edge of the clock signal, requiring this edge to provide lowest possible jitter. Any significant aperture jitter would limit the SNR performance of the on-chip ADCs as follows:

$$SNR = 20 \times \log \frac{1}{2 \times \pi \times f_{IN} \times t_{AJ}}$$

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

Figure 4. Output Timing Diagram

where  $f_{IN}$  represents the analog input frequency and  $t_{AJ}$  is the time of the aperture jitter.

Clock jitter is especially critical for undersampling applications. The clock input should always be considered as an analog input and routed away from any analog input or other digital signal lines.

The MAX1195 clock input operates with a voltage threshold set to  $V_{DD}/2$ . Clock inputs with a duty cycle other than 50% must meet the specifications for high and low periods as stated in the *Electrical Characteristics* table.

## System Timing Requirements

Figure 3 depicts the relationship between the clock input, analog input, and data output. The MAX1195 samples at the rising edge of the input clock. Output data for channels A and B is valid on the next rising edge of the input clock. The output data has an internal latency of five clock cycles. Figure 3 also determines the relationship between the input clock parameters and the valid output data on channels A and B.

## Digital Output Data (D0A/B–D7A/B), Output Data Format Selection (T/B), Output Enable (OE)

All digital outputs, D0A–D7A (channel A) and D0B–D7B (channel B), are TTL/CMOS-logic compatible. There is a five-clock-cycle latency between any particular sample and its corresponding output data. The output coding can either be straight offset binary or two's complement (Table 1) controlled by a single pin (T/B). Pull T/B low to select offset binary and high to activate two's complement output coding. The capacitive load on the digital outputs D0A–D7A and D0B–D7B should be kept as low as possible ( $<15\text{pF}$ ), to avoid large digital currents that could feed back into the analog portion of the MAX1195, thereby degrading its dynamic performance. Using buffers on the digital outputs of the ADCs can further isolate the digital outputs from heavy capacitive loads. To further improve the dynamic performance of

\* $V_{REF} = V_{REFP} - V_{REFN}$

the MAX1195, small series resistors (e.g.,  $100\Omega$ ) can be added to the digital output paths close to the MAX1195.

Figure 4 displays the timing relationship between output enable and data output valid, as well as power-down/wake-up and data output valid.

## Power-Down and Sleep Modes

The MAX1195 offers two power-save modes—sleep mode (SLEEP) and full power-down (PD) mode. In sleep mode (SLEEP = 1), only the reference bias circuit is active (both ADCs are disabled), and current consumption is reduced to 3mA.

To enter full power-down mode, pull PD high. With  $\overline{OE}$  simultaneously low, all outputs are latched at the last value prior to the power down. Pulling  $\overline{OE}$  high forces the digital outputs into a high-impedance state.

## Applications Information

Figure 5 depicts a typical application circuit containing two single-ended-to-differential converters. The internal reference provides a  $V_{DD}/2$  output voltage for level-shifting purposes. The input is buffered and then split to a voltage follower and inverter. One lowpass filter per amplifier suppresses some of the wideband noise associated with high-speed operational amplifiers. The user can select the  $R_{ISO}$  and  $C_{IN}$  values to optimize the filter performance, to suit a particular application. For the application in Figure 5, a  $R_{ISO}$  of  $50\Omega$  is placed before the capacitive load to prevent ringing and oscillation. The  $22\text{pF}$   $C_{IN}$  capacitor acts as a small filter capacitor.

Figure 5. Typical Application for Single-Ended-to-Differential Conversion

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

Figure 6. Transformer-Coupled Input Drive

## Using Transformer Coupling

An RF transformer (Figure 6) provides an excellent solution to convert a single-ended source signal to a fully differential signal, required by the MAX1195 for optimum performance. Connecting the center tap of the transformer to COM provides a  $V_{DD}/2$  DC level shift to the input. Although a 1:1 transformer is shown, a step-up transformer can be selected to reduce the drive requirements. A reduced signal swing from the input driver, such as an op amp, can also improve the overall distortion.

In general, the MAX1195 provides better SFDR and THD with fully differential input signals than single-ended drive, especially for very high input frequencies. In differential input mode, even-order harmonics are lower as both inputs (INA+, INA- and/or INB+, INB-) are balanced, and each of the ADC inputs only requires half the signal swing compared to single-ended mode.

Figure 7. Using an Op Amp for Single-Ended, AC-Coupled Input Drive

## Single-Ended AC-Coupled Input Signal

Figure 7 shows an AC-coupled, single-ended application. Amplifiers like the MAX4108 provide high speed, high bandwidth, low noise, and low distortion to maintain the integrity of the input signal.

## Buffered External Reference Drives Multiple ADCs

Multiple-converter systems based on the MAX1195 are well suited for use with a common reference voltage. The REFIN pin of those converters can be connected directly to an external reference source.

A precision bandgap reference like the MAX6062 generates an external DC level of 2.048V (Figure 8), and exhibits a noise voltage density of 150nV/√Hz. Its output passes through a 1-pole lowpass filter (with 10Hz cutoff frequency) to the MAX4250, which buffers the reference before its output is applied to a second 10Hz lowpass filter. The MAX4250 provides a low offset voltage (for high gain accuracy) and a low noise level. The

## MAX 1195

passive 10Hz filter following the buffer attenuates noise produced in the voltage reference and buffer stages. This filtered noise density, which decreases for higher frequencies, meets the noise levels specified for precision ADC operation.

Connecting each REFIN to analog ground disables the internal reference of each device, allowing the internal reference ladders to be driven directly by a set of external reference sources. Followed by a 10Hz low-pass filter and precision voltage divider, the MAX6066 generates a DC level of 2.500V. The buffered outputs of this divider are set to 2.0V, 1.5V, and 1.0V, with an accuracy that depends on the tolerance of the divider resistors. The three voltages are buffered by the MAX4252, which provides low noise and low DC offset. The individual voltage followers are connected to 10Hz lowpass filters, which filter both the reference voltage and amplifier noise to a level of  $3\text{nV}/\sqrt{\text{Hz}}$ . The 2.0V and

Note that the common power supply for all active components removes any concern regarding power-supply sequencing when powering up or down. With the outputs of the MAX4252 matching better than 0.1%, the buffers and subsequent lowpass filters can be replicated to support as many as 32 ADCs. For applications that require more than 32 matched ADCs, a voltage reference and divider string common to all converters is highly recommended.

A frequently used modulation technique in digital communications applications is quadrature amplitude modulation (QAM). Typically found in spread-spectrum-based systems, a QAM signal represents a carrier frequency modulated in both amplitude and phase. At the transmitter, modulating the baseband signal with

MAX1195

Figure 10. Typical QAM Application Using the MAX1195

Figure 11. T/H Aperture Timing

## Grounding, Bypassing, and Board Layout

The MAX1195 requires high-speed board layout design techniques. Locate all bypass capacitors as close to the device as possible, preferably on the same side as the ADC, using surface-mount devices for minimum inductance. Bypass  $V_{DD}$ ,  $REFP$ ,  $REFN$ , and  $COM$  with two parallel 0.1 $\mu$ F ceramic capacitors and a 2.2 $\mu$ F bipolar capacitor to GND. Follow the same rules to bypass the digital supply ( $OV_{DD}$ ) to OGND. Multilayer boards with separated ground and power planes produce the highest level of signal integrity. Consider the use of a split ground plane arranged to match the physical location of the analog ground (GND) and the digital output driver ground (OGND) on the ADC's package. The two ground planes should be joined at a

single point so the noisy digital ground currents do not interfere with the analog ground plane. The ideal location for this connection can be determined experimentally at a point along the gap between the two ground planes, which produces optimum results. Make this connection with a low-value, surface-mount resistor (1 $\Omega$  to 5 $\Omega$ ), a ferrite bead, or a direct short.

Alternatively, all ground pins could share the same ground plane, if the ground plane is sufficiently isolated from any noisy, digital systems ground plane (e.g., downstream output buffer or DSP ground plane). Route high-speed digital signal traces away from the sensitive analog traces of either channel. Make sure to isolate the analog input lines to each respective converter to minimize channel-to-channel crosstalk. Keep all signal lines short and free of 90° turns.

## Static Parameter Definitions

### Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best-straight-line fit or a line drawn between the endpoints of the transfer function, once offset and gain errors have been nullified. The static linearity parameters for the MAX1195 are measured using the best-straight-line-fit method.

### Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1LSB. A DNL error specification of less than 1LSB guarantees no missing codes and a monotonic transfer function.

# Dual, 8-Bit, 40Msps, 3V, Low-Power ADC with Internal Reference and Parallel Outputs

## Dynamic Parameter Definitions

### Aperture Jitter

Figure 11 depicts the aperture jitter ( $t_{AJ}$ ), which is the sample-to-sample variation in the aperture delay.

### Aperture Delay

Aperture delay ( $t_{AD}$ ) is the time defined between the rising edge of the sampling clock and the instant when an actual sample is taken (Figure 11).

### Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N-bits):

$$\text{SNR}_{\text{dB}}[\text{max}] = 6.02\text{dB} \times N + 1.76\text{dB}$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

### Signal-to-Noise Plus Distortion

SINAD is computed by taking the ratio of the RMS signal to all spectral components minus the fundamental and the DC offset.

### Effective Number of Bits

Effective number of bits (ENOB) specifies the dynamic performance of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of

quantization noise only. ENOB for a full-scale sinusoidal input waveform is computed from:

$$\text{ENOB} = \frac{\text{SINAD} - 1.76}{6.02}$$

### Total Harmonic Distortion

THD is typically the ratio of the RMS sum of the first four harmonics of the input signal to the fundamental itself. This is expressed as:

$$\text{THD} = 20 \times \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2}}{V_1}$$

where  $V_1$  is the fundamental amplitude, and  $V_2$  through  $V_5$  are the amplitudes of the 2nd- through 5th-order harmonics.

### Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio expressed in decibels of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest spurious component, excluding DC offset.

### Intermodulation Distortion

The two-tone intermodulation distortion (IMD) is the ratio expressed in decibels of either input tone to the worst third-order (or higher) intermodulation products. The individual input tone levels are at -7dB full scale and their envelope is at -1dB full scale.

## Package Information

(The package drawing(s) in this data sheet may not reflect the most current specifications. For the latest package outline information, go to [www.maxim-ic.com/packages](http://www.maxim-ic.com/packages).)

### NOTES:

1. ALL DIMENSIONS AND TOLERANCING CONFORM TO ANSI Y14.5-1982.
2. DATUM PLANE (H) IS LOCATED AT MOLD PARTING LINE AND COINCIDENT WITH LEAD, WHERE LEAD EXITS PLASTIC BODY AT BOTTOM OF PARTING LINE.
3. DIMENSIONS D1 AND E1 DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE MOLD PROTRUSION IS 0.254 MM ON D1 AND E1 DIMENSIONS.
4. THE TOP OF PACKAGE IS SMALLER THAN THE BOTTOM OF PACKAGE BY 0.15 MILLIMETERS.
5. DIMENSION b DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.08 MM TOTAL IN EXCESS OF THE b DIMENSION AT MAXIMUM MATERIAL CONDITION.
6. CONTROLLING DIMENSION: MILLIMETER.
7. THIS OUTLINE CONFORMS TO JEDEC PUBLICATION 95 REGISTRATION MO-136, VARIATIONS AC AND AE.
8. LEADS SHALL BE COPLANAR WITHIN .004 INCH.
9. EXPOSED DIE PAD SHALL BE COPLANAR WITH BOTTOM OF PACKAGE WITHIN 2 MILS (.05 MM).
10. DIMENSIONS X & Y APPLY TO EXPOSED PAD (EP) VERSIONS ONLY. SEE INDIVIDUAL PRODUCT DATASHEET TO DETERMINE IF A PRODUCT USES EXPOSED PAD PACKAGE.
