# Hi-Speed Universal Serial Bus peripheral controller Rev. 03 — 25 August 2004 Prei

**Preliminary data** 

#### **General description**

The ISP1582 is a cost-optimized and feature-optimized Hi-Speed Universal Serial Bus (USB) peripheral controller. It fully complies with *Universal Serial Bus* Specification Rev. 2.0, supporting data transfer at high-speed (480 Mbit/s) and full-speed (12 Mbit/s).

The ISP1582 provides high-speed USB communication capacity to systems based on microcontrollers or microprocessors. It communicates with a microcontroller or microprocessor of a system through a high-speed general-purpose parallel interface.

The ISP1582 supports automatic detection of Hi-Speed USB system operation. Original USB fall-back mode allows the device to remain operational under full-speed conditions. It is designed as a generic USB peripheral controller so that it can fit into all existing device classes, such as imaging class, mass storage devices, communication devices, printing devices and human interface devices.

The internal generic Direct Memory Access (DMA) block allows easy integration into data streaming applications.

The modular approach to implementing a USB peripheral controller allows the designer to select the optimum system microcontroller from the wide variety available. The ability to reuse existing architecture and firmware investments shortens the development time, eliminates risk and reduces cost. The result is fast and efficient development of the most cost-effective USB peripheral solution.

The ISP1582 is ideally suited for many types of peripherals, such as: printers, scanners, digital still cameras, USB-to-Ethernet links, cable and DSL modems. The low power consumption during suspend mode allows easy design of equipment that is compliant to the ACPI™, OnNow™ and USB power management requirements.

The ISP1582 also incorporates features such as SoftConnect™, a reduced frequency crystal oscillator, and integrated termination resistors. These features allow significant cost savings in system design and easy implementation of advanced USB functionality into PC peripherals.

#### Hi-Speed USB peripheral controller

#### 2. Features

- Complies fully with:
  - Universal Serial Bus Specification Rev. 2.0
  - Most Device Class specifications
  - ◆ ACPI<sup>™</sup>, OnNow<sup>™</sup> and USB power management requirements.
- Supports data transfer at high-speed (480 Mbit/s) and full-speed (12 Mbit/s)
- High performance USB peripheral controller with integrated Serial Interface Engine (SIE), Parallel Interface Engine (PIE), FIFO memory and data transceiver
- Automatic Hi-Speed USB mode detection and Original USB fall-back mode
- Supports sharing mode
- Supports V<sub>BUS</sub> sensing
- High-speed DMA interface
- Fully autonomous and multiconfiguration DMA operation
- 7 IN endpoints, 7 OUT endpoints and a fixed control IN/OUT endpoint
- Integrated physical 8 kbytes of multiconfiguration FIFO memory
- Endpoints with double buffering to increase throughput and ease real-time data transfer
- Bus-independent interface with most microcontrollers and microprocessors
- 12 MHz crystal oscillator with integrated PLL for low EMI
- Software-controlled connection to the USB bus (SoftConnect<sup>TM</sup>)
- Low-power consumption in operation and power-down modes; suitable for use in bus-powered USB devices
- Supports Session Request Protocol (SRP) that complies with On-The-Go Supplement to the USB Specification Rev. 1.0a
- Internal power-on and low-voltage reset circuits; also supports software reset
- Operation over the extended USB bus voltage range (DP, DM and V<sub>BUS</sub>)
- 5 V tolerant I/O pads at 3.3 V
- Operating temperature range from –40 °C to +85 °C
- Available in HVQFN56 halogen-free and lead-free package.

# 3. Applications

- Personal digital assistant
- Digital video camera
- Digital still camera
- 3G mobile phone
- MP3 player
- Communication device, for example: router and modem
- Printer
- Scanner.

#### **Hi-Speed USB peripheral controller**

#### 4. Abbreviations

**DMA** — Direct Memory Access

**EMI** — ElectroMagnetic Interference

FS — Full-speed

**GDMA** — Generic DMA

**HS** — High-speed

**MMU** — Memory Management Unit

NRZI — Non-Return-to-Zero Inverted

OTG - On-The-Go

PDA — Personal Digital Assistant

PID — Packet IDentifier

PIE — Parallel Interface Engine

PIO — Parallel Input/Output

PLL — Phase-Locked Loop

SE0 — Single-Ended zero

SIE — Serial Interface Engine

SRP — Session Request Protocol

**USB** — Universal Serial Bus.

# 7.2 Pin description

Table 2: Pin description

Table 2.	- uescri	-					
Symbol <sup>[1]</sup>	Pin	Type <sup>[2]</sup>	Description				
AGND	1	-	analog ground				
RPU	2	Α	connect to the external pull-up resistor for pin DP; must be connected to 3.3 V via a 1.5 $k\Omega$ resistor				
DP	3	Α	USB D+ line connection (analog)				
DM	4	Α	USB D- line connection (analog)				
AGND	5	-	analog ground				
RREF	6	Α	connect to the external bias resistor; must be connected to ground via a 12.0 k $\Omega$ ± 1 % resistor				
RESET_N	7	I	reset input (500 $\mu s);$ a LOW level produces an asynchronous reset; connect to $V_{CC}$ for the power-on reset (internal POR circuit)				
			TTL; 5 V tolerant				
EOT	8	I	End-of-transfer input (programmable polarity); used in DMA slave mode only; when not in use, connect this pin to $V_{CC(I/O)}$ through a 10 k $\Omega$ resistor				
			input pad; TTL; 5 V tolerant				
DREQ	9	0	DMA request (programmable polarity) output; when not in use, connect this pin to ground through a 10 k $\Omega$ resistor; see Table 54 and Table 55				
			TTL; 4 ns slew-rate control				
DACK	10	I	DMA acknowledge input (programmable polarity); when not in use, connect this pin to $V_{CC(I/O)}$ through a 10 k $\Omega$ resistor; see Table 54 and Table 55				
			TTL; 5 V tolerant				
DIOR	11	I	DMA read strobe input (programmable polarity); when not in use, connect this pin to $V_{CC(I/O)}$ through a 10 k $\Omega$ resistor; see Table 54 and Table 55				
			TTL; 5 V tolerant				
DIOW	12	I	DMA write strobe input (programmable polarity); when not in use, connect this pin to $V_{CC(I/O)}$ through a 10 k $\Omega$ resistor; see Table 54 and Table 55				
			TTL; 5 V tolerant				
DGND	13	-	digital ground				
INT	14	0	interrupt output; programmable polarity (active HIGH or LOW) and signaling (edge or level triggered)				
			CMOS output; 8 mA drive				
CS_N	15	I	chip select input input pad; TTL; 5 V tolerant				
RD_N	16		read strobe input				
	. •	•	input pad; TTL; 5 V tolerant				
WR_N	17	ı	write strobe input

DATA14	46	I/O	bit 14 of bidirectional data bus				
			bidirectional pad; 4 ns slew-rate control; TTL; 5 V tolerant				
DATA15	47	I/O	bit 15 of bidirectional data bus				
			bidirectional pad; 4 ns slew-rate control; TTL; 5 V tolerant				
V <sub>CC(I/O)</sub> [3]	48	-	supply voltage; used to supply voltage to the I/O pads; see Section 8.14				
$V_{\text{BUS}}$	49	Α	USB bus power pin sensing input; used to detect whether the host is connected or not; it is an output for $V_{BUS}$ pulsing in OTG mode; when $V_{BUS}$ is not detected, pin RPU is internally disconnected from pin DP in approximately 4 ns; connect a 1 $\mu F$ electrolytic capacitor and a 1 $M\Omega$ pull-down resistor to ground; see Section 8.12				
V [3]	50		5 V tolerant				
V <sub>CC(1V8)</sub> <sup>[3]</sup>	50	-	regulator output voltage (1.8 V $\pm$ 0.15 V); tapped out voltage from the internal regulator; this regulated voltage can drive external devices up to 1 mA; decouple this pin using 4.7 $\mu$ F and 0.1 $\mu$ F capacitors; see Section 8.14				
XTAL2	51	0	crystal oscillator output (12 MHz); connect a fundamental parallel-resonant crystal; leave this pin open-circuit when using an external clock source on pin XTAL1; see Table 83				
XTAL1	52	I	crystal oscillator input (12 MHz); connect a fundamental parallel-resonant crystal or an external clock source (leaving pin XTAL2 unconnected); see Table 83				
V <sub>CC<sup>[3]</sup></sub>	53	-	supply voltage (3.3 V $\pm$ 0.3 V); this pin supplies the internal voltage regulator and the analog circuit; see Section 8.14				
V <sub>CC</sub> [3]	54	-	supply voltage (3.3 V $\pm$ 0.3 V); this pin supplies the internal voltage regulator and the analog circuit; see Section 8.14				

 Table 2:
 Pin description...continued

Symbol <sup>[1]</sup>	Pin	Type <sup>[2]</sup>	Description
WAKEUP	55	I	wake-up input; when this pin is at the HIGH level, the chip is prevented from getting into the suspend state and the chip wakes up from the suspend state; when not in use, connect this pin to ground through a 10 k $\Omega$ resistor input pad; TTL; 5 V tolerant
SUSPEND	56	0	suspend state indicator output; used as a power switch control output for powered-off application or as a resume signal to the CPU for powered-on application CMOS output; 8 mA drive
GND	exposed die pad	-	ground supply; down bonded to the exposed die pad (heatsink); to be connected to DGND during PCB layout

<sup>[1]</sup> Symbol names ending with underscore N (for example, NAME\_N) represent active LOW signals.

<sup>[2]</sup> All outputs and I/O pins can source 4 mA.

<sup>[3]</sup> Add a decoupling capacitor (0.1  $\mu$ F) to all the supply pins. For better EMI results, add a 0.01  $\mu$ F capacitor in parallel to the 0.1  $\mu$ F.

Hi-Speed USB peripheral controller

#### 8. Functional description

The ISP1582 is a high-speed USB peripheral controller. It implements the Hi-Speed USB or the Original USB physical layer and the packet protocol layer. It maintains up to 16 USB endpoints concurrently (control IN and control OUT, 7 IN and 7 OUT configurable) along with endpoint EP0 setup, which accesses the setup buffer. The USB Chapter 9 protocol handling is executed by means of external firmware.

For high-bandwidth data transfer, the integrated DMA handler can be invoked to transfer data to or from external memory or devices. The DMA interface can be configured by writing to the proper DMA registers (see Section 9.4).

The ISP1582 supports Hi-Speed USB and Original USB signaling. The USB signaling speed is automatically detected.

The ISP1582 has 8 kbytes of internal FIFO memory, which is shared among the enabled USB endpoints.

There are 7 IN endpoints, 7 OUT endpoints and 2 control endpoints that are a fixed 64 bytes long. Any of the 7 IN and 7 OUT endpoints can be separately enabled or disabled. The endpoint type (interrupt, isochronous or bulk) and packet size of these endpoints can be individually configured depending on the requirements of the application. Optional double buffering increases the data throughput of these data endpoints.

The ISP1582 requires 3.3 V power supply. It has 5 V tolerant I/O pads when operating at  $V_{CC(I/O)} = 3.3$  V and an internal 1.8 V regulator for powering the analog transceiver.

The ISP1582 operates on a 12 MHz crystal oscillator. An integrated  $40 \times PLL$  clock multiplier generates the internal sampling clock of 480 MHz.

#### 8.1 DMA interface, DMA handler and DMA registers

The DMA block can be subdivided into two blocks: the DMA handler and the DMA interface.

The firmware writes to the DMA command register to start a DMA transfer (see Table 47). The command opcode determines whether a generic DMA or PIO transfer will start. The handler interfaces to the same FIFO (internal RAM) as used by the USB core. On receiving the DMA command, the DMA handler directs the data from the endpoint FIFO to the external DMA device or from the external DMA device to the endpoint FIFO.

The DMA interface configures the timing and the DMA handshake. Data can be transferred using either the DIOR and DIOW strobes or by the DACK and DREQ handshakes. The DMA configurations are set up by writing to the DMA Configuration register (see Table 52 and Table 53).

For a generic DMA interface, Generic DMA (GDMA) slave mode can be used.

**Remark:** The DMA endpoint buffer length must be a multiple of 4 bytes.

For details on DMA registers, see Section 9.4.

#### Hi-Speed USB peripheral controller

#### 8.2 Hi-Speed USB transceiver

The analog transceiver directly interfaces to the USB cable through integrated termination resistors. The high-speed transceiver requires an external resistor (12.0 k $\Omega$  ± 1 %) between pin RREF and ground to ensure an accurate current mirror that generates the Hi-Speed USB current drive. A full-speed transceiver is integrated as well. This makes the ISP1582 compliant to Hi-Speed USB and Original USB, supporting both the high-speed and full-speed physical layers. After automatic speed detection, the Philips Serial Interface Engine (SIE) sets the transceiver to use either high-speed or full-speed signaling.

#### 8.3 MMU and integrated RAM

The Memory Management Unit (MMU) and the integrated RAM provide the conversion between the USB speed (full-speed: 12 Mbit/s, high-speed: 480 Mbit/s) and the microcontroller handler or the DMA handler. The data from the USB bus is stored in the integrated RAM, which is cleared only when the microcontroller has read or written all data from or to the corresponding endpoint buffer or when the DMA handler has read or written all data from or to the endpoint buffer. The OUT endpoint buffer can also be cleared forcibly by setting bit CLBUF in the Control Function register. A total of 8 kbytes RAM is available for buffering.

#### 8.4 Microcontroller interface and microcontroller handler

The microcontroller handler allows the external microcontroller or microprocessor to access the register set in the Philips SIE as well as the DMA handler. The initialization of the DMA configuration is done through the microcontroller handler.

#### 8.5 OTG SRP module

The OTG supplement defines a Session Request Protocol (SRP), which allows a B-device to request the A-device to turn on  $V_{BUS}$  and start a session. This protocol allows the A-device, which may be battery-powered, to conserve power by turning off  $V_{BUS}$  when there is no bus activity while still providing a means for the B-device to initiate bus activity.

Any A-device, including a PC or laptop, can respond to SRP. Any B-device, including a standard USB peripheral, can initiate SRP.

The ISP1582 is a device that can initiate SRP.

#### 8.6 Philips high-speed transceiver

#### 8.6.1 Philips Parallel Interface Engine (PIE)

In the high-speed (HS) transceiver, the Philips PIE interface uses a 16-bit parallel bidirectional data interface. The functions of the HS module also include bit-stuffing or destuffing and Non-Return-to-Zero Inverted (NRZI) encoding or decoding logic.

#### 8.6.2 Peripheral circuit

To maintain a constant current driver for HS transmit circuits and to bias other analog circuits, an internal band gap reference circuit and an RREF resistor form the reference current. This circuit requires an external precision resistor (12.0 k $\Omega$  ± 1 %) connected to the analog ground.

Hi-Speed USB peripheral controller

#### 8.6.3 HS detection

The ISP1582 handles more than one electrical state—full-speed (FS) or high-speed (HS)—under the USB specification. When the USB cable is connected from the peripheral to the host controller, the ISP1582 defaults to the FS state until it sees a bus reset from the host controller.

During the bus reset, the peripheral initiates an HS chirp to detect whether the host controller supports Hi-Speed USB or Original USB. Chirping must be done with the pull-up resistor connected and the internal termination resistors disabled. If the HS handshake shows that there is an HS host connected, then the ISP1582 switches to the HS state.

In the HS state, the ISP1582 should observe the bus for periodic activity. If the bus remains inactive for 3 ms, the peripheral switches to the FS state to check for a Single-Ended Zero (SE0) condition on the USB bus. If an SE0 condition is detected for the designated time (100  $\mu s$  to 875  $\mu s$ ; refer to section 7.1.7.6 of the USB specification Rev. 2.0), the ISP1582 switches to the HS chirp state to perform an HS detection handshake. Otherwise, the ISP1582 remains in the FS state adhering to the bus-suspend specification.

#### 8.7 Philips Serial Interface Engine (SIE)

The Philips SIE implements the full USB protocol layer. It is completely hardwired for speed and needs no firmware intervention. The functions of this block include: synchronization pattern recognition, parallel or serial conversion, bit (de)stuffing, CRC checking or generation, Packet IDentifier (PID) verification or generation, address recognition, handshake evaluation or generation.

#### 8.8 SoftConnect

The connection to the USB is established by pulling pin DP (for full-speed devices) HIGH through a 1.5 k $\Omega$  pull-up resistor. In the ISP1582, an external 1.5 k $\Omega$  pull-up resistor must be connected between pin RPU and 3.3 V. Pin RPU connects the pull-up resistor to pin DP, when bit SOFTCT in the Mode register is set (see Table 20 and Table 21). After a hardware reset, the pull-up resistor is disconnected by default (bit SOFTCT = 0). The USB bus reset does not change the value of bit SOFTCT.

When the  $V_{BUS}$  is not present, the SOFTCT bit must be set to logic 0 to comply with the back-drive voltage.

#### 8.9 System controller

The system controller implements the USB power-down capabilities of the ISP1582. Registers are protected against data corruption during wake-up following a resume (from the suspend state) by locking the write access until an unlock code has been written in the Unlock Device register (see Table 73 and Table 74).

#### 8.10 Output pins status

Table 3 illustrates the behavior of output pins when  $V_{CC(I/O)}$  is supplied with  $V_{CC}$  in various operating conditions.

#### Hi-Speed USB peripheral controller

Table 3: ISP1582 pin status<sup>[1]</sup>

V <sub>CC</sub>	V <sub>CC(I/O)</sub>	State	Pin				
			RESET_N	INT_N	SUSPEND	DREQ	DATA[15:0]
0 V	V <sub>CC</sub>	dead <sup>[2]</sup>	X	X	X	X	X
0 V	$V_{CC}$	plug-out <sup>[3]</sup>	Χ	LOW	HIGH	high-Z	input
0 V -> 3.3 V	$V_{CC}$	plug-in <sup>[4]</sup>	Χ	LOW	HIGH	high-Z	high-Z
3.3 V	$V_{CC}$	reset	LOW	HIGH	LOW	high-Z	high-Z
3.3 V	$V_{CC}$	normal	HIGH	HIGH	LOW	high-Z	high-Z

- [1] X: Don't care.
- [2] Dead: The USB cable is plugged-out and  $V_{CC(I/O)}$  is not available.
- [3] Plug-out: The USB cable is not present but  $V_{CC(I/O)}$  is available.
- [4] Plug-in: The USB cable is being plugged-in and V<sub>CC(I/O)</sub> is available.

#### 8.11 Interrupt

#### 8.11.1 Interrupt output pin

The Interrupt Configuration register of the ISP1582 controls the behavior of the INT output pin. The polarity and signaling mode of pin INT can be programmed by setting bits INTPOL and INTLVL of the Interrupt Configuration register (R/W: 10h); see Table 24. Bit GLINTENA of the Mode register (R/W: OCh) is used to enable pin INT. Default settings after reset are active LOW and level mode. When pulse mode is selected, a pulse of 60 ns is generated when the OR-ed combination of all interrupt bits changes from logic 0 to logic 1.

Figure 4 shows the relationship between the interrupt events and pin INT.

Each of the indicated USB and DMA events is logged in a status bit of the Interrupt register and the DMA Interrupt Reason register, respectively. Corresponding bits in the Interrupt Enable register and the DMA Interrupt Enable register determine whether or not an event will generate an interrupt.

Interrupts can be masked globally by means of bit GLINTENA of the Mode register; see Table 21.

Field CDBGMOD[1:0] of the Interrupt Configuration register controls the generation of the INT signals for the control pipe. Field DDBGMODIN[1:0] of the Interrupt Configuration register controls the generation of the INT signals for the IN pipe. Field DDBGMODOUT[1:0] of the Interrupt Configuration register controls the generation of the INT signals for the OUT pipe; see Table 25.

**ISP1582** 

#### **Hi-Speed USB peripheral controller**

#### 8.11.2 Interrupt control

Bit GLINTENA in the Mode register is a global enable/disable bit. The behavior of this bit is given in Figure 5.

Event A: When an interrupt event occurs (for example, SOF interrupt) with bit GLINTENA set to logic 0, an interrupt will not be generated at pin INT. It will, however, be registered in the corresponding Interrupt register bit.

Event B: When bit GLINTENA is set to logic 1, pin INT is asserted because bit SOF in the Interrupt register is already set.

Event C: If the firmware sets bit GLINTENA to logic 0, pin INT will still be asserted. The bold dashed line shows the desired behavior of pin INT.

Deassertion of pin INT can be achieved either by clearing all the Interrupt register or the DMA Interrupt Reason register, depending on the event.

**Remark:** When clearing an interrupt event, perform write to all the bytes of the register.

For more information on interrupt control, see Section 9.2.2, Section 9.2.5 and Section 9.5.1.

#### 8.12 V<sub>BUS</sub> sensing

Pin  $V_{BUS}$  is one of the ways to wake up the clock when the ISP1582 is suspended with bit CLKAON set to logic 0 (clock off option).

To detect whether the host is connected or not, that is  $V_{BUS}$  sensing, a 1  $M\Omega$  resistor and a 1  $\mu F$  electrolytic capacitor must be added to damp the overshoot upon plug-in.

9397 750 13699

#### Hi-Speed USB peripheral controller

#### 8.13 Power-on reset

The ISP1582 requires a minimum pulse width of 500 μs.

Pin RESET\_N can be either connected to  $V_{CC}$  (using the internal POR circuit) or externally controlled (by the microcontroller, ASIC, and so on). When  $V_{CC}$  is directly connected to pin RESET\_N, the internal pulse width  $t_{PORP}$  will be typically 200 ns.

The power-on reset function can be explained by viewing the dips at t2-t3 and t4-t5 on the  $V_{CC(POR)}$  curve (Figure 9).

- t0 The internal POR starts with a HIGH level.
- **t1** The detector will see the passing of the trip level and a delay element will add another t<sub>PORP</sub> before it drops to LOW.
- **t2-t3** The internal POR pulse will be generated whenever  $V_{CC(POR)}$  drops below  $V_{trip}$  for more than 11  $\mu s$ .
- t4-t5 The dip is too short (< 11  $\mu$ s) and the internal POR pulse will not react and will remain LOW.

Figure 10 shows the availability of the clock with respect to the external POR.

#### Hi-Speed USB peripheral controller

#### 8.14 Power supply

The ISP1582 can be powered by 3.3 V  $\pm$  0.3 V, and 3.3 V at the interface. For connection details, see Figure 11.

If the ISP1582 is powered by  $V_{CC}$  = 3.3 V, an integrated 3.3 V-to-1.8 V voltage regulator provides a 1.8 V supply voltage for the internal logic.

In sharing mode (that is, when  $V_{CC}$  is not present and  $V_{CC(I/O)}$  is present), all the I/O pins are in three-state, the interrupt pin is connected to ground, and the suspend pin is connected to  $V_{CC(I/O)}$ . See Table 3.

#### Hi-Speed USB peripheral controller

Table 4 shows power modes in which the ISP1582 can be operated.

Table 4: Power modes

V <sub>CC</sub>	V <sub>CC(I/O)</sub>	Power mode
V <sub>BUS</sub> <sup>[1]</sup>	V <sub>BUS</sub> <sup>[2]</sup>	bus-powered
self-powered	self-powered	self-powered
V <sub>BUS</sub> <sup>[1]</sup>	self-powered	power-sharing (hybrid)

- [1] Power supply to the IC (V<sub>CC</sub>) is 3.3 V. Therefore, if the application is bus-powered, a 3.3 V regulator needs to be used.
- [2]  $V_{CC(I/O)} = V_{CC}$ . If the application is bus-powered, a voltage regulator needs to be used.

#### 8.14.1 Power-sharing mode

As can be seen in Figure 12, in power-sharing mode,  $V_{CC}$  is supplied by the output of the 5 V-to-3.3 V voltage regulator. The input to the regulator is from  $V_{BUS}$ .  $V_{CC(I/O)}$  is supplied through the power source of the system. When the USB cable is plugged in, the ISP1582 goes through the power-on reset cycle. In this mode, OTG is disabled.

The processor will experience continuous interrupt because the default status of the interrupt pin when operating in sharing mode with the  $V_{BUS}$  not present is LOW. To overcome this, implement external  $V_{BUS}$  sensing circuitry. The output from the voltage regulator can be connected to pin GPIO of the processor to qualify the interrupt from the ISP1582.

**Remark:** When the core power is removed, the ISP1582 must be reset using the RESET\_N pin. The reset pulse width must be 2 ms.

 Table 5:
 Operation truth table for SoftConnect

ISP1582 operation		Power s	Bit SOFTCT in

#### 9.1 Register access

Register access depends on the bus width used. The ISP1582 uses a 16-bit bus access. For single-byte registers, the upper byte (MSByte) must be ignored.

Endpoint specific registers are indexed via the Endpoint Index register. The target endpoint must be selected before accessing the following registers:

- Buffer Length
- Buffer Status
- Control Function
- Data Port
- Endpoint MaxPacketSize
- Endpoint Type.

**Remark:** All reserved bits are not implemented. The bus and bus reset values are not defined. Therefore, writing to these reserved bits will have no effect.

#### 9.2 Initialization registers

#### 9.2.1 Address register (address: 00h)

This register sets the USB assigned address and enables the USB device. Table 18 shows the Address register bit allocation.

Bits DEVADDR will be cleared whenever a bus reset, a power-on reset or a soft reset occurs. Bit DEVEN will be cleared whenever a power-on reset or a soft reset occurs, and will be set after a bus reset.

#### Hi-Speed USB peripheral controller

In response to the standard USB request SET\_ADDRESS, the firmware must write the (enabled) device address to the Address register, followed by sending an empty packet to the host. The **new** device address is activated when the device receives acknowledgment from the host.

Table 18: Address register: bit allocation

Bit	7	6	5	4	3	2	1	0

6 to 0	DEVADDR[6:0]	This field specifies the USB device address.

#### 9.2.2 Mode register (address: 0Ch)

This register consists of 2 bytes (bit allocation: see Table 20).

The Mode register controls resume, suspend and wake-up behavior, interrupt activity, soft reset, clock signals and SoftConnect operation.

Table 20: Mode register: bit allocation

#### Hi-Speed USB peripheral controller

Table 21: Mode register: bit description...continued

Bit Symbol Description  7 CLKAON Clock Always On: Logic 1 indicates that the internal contained always running when in the suspend state. Logic 0 swift internal oscillator and PLL when the device goes into somode. The device will consume less power if this bit is somother. The clock is stopped after a delay of approximately 2 mm.	tches off the
which bit GOSUSP is set.	set to logic 0.
6 SNDRSU <b>Send Resume:</b> Writing logic 1, followed by logic 0 will upstream resume signal of 10 ms duration, after a 5 ms	
5 GOSUSP <b>Go Suspend:</b> Writing logic 1, followed by logic 0 will ac suspend mode.	ctivate
SFRESET Soft Reset: Writing logic 1, followed by logic 0 will ena software-initiated reset to the ISP1582. A soft reset is shardware-initiated reset (via pin RESET_N).	
GLINTENA Global Interrupt Enable: Logic 1 enables all interrupts interrupts can be masked by clearing the corresponding Interrupt Enable register.	
When this bit is not set, an unmasked interrupt will not interrupt trigger on the interrupt pin. If global interrupt, lenabled while there is any pending unmasked interrupt signal will be immediately generated on the interrupt pi interrupt is set to pulse mode, the interrupt events that generated before the global interrupt is enabled may be	however, is t, an interrupt in. (If the were
WKUPCS Wake up on Chip Select: Logic 1 enables wake-up from mode through a valid register read on the ISP1582. (A invoke the chip clock to restart. If you write to the regist clock gets stable, it may cause malfunctioning).	read will
1 PWRON Pin SUSPEND output control.	
0 — Pin SUSPEND is HIGH when the ISP1582 is in the state. Otherwise, pin SUSPEND is LOW.	e suspend
1 — When the device is woken up from the suspend state to be a 1 ms active HIGH pulse on pin SUSPEND. Pin SUSPEND.	
remain LOW in all other states.	

When SoftConnect and  $V_{BUS}$  are not present (except in OTG), the USB bus activities are not qualified. Therefore, the chip will follow the suspend command to enter suspend mode (the clock is controlled by bit CLKAON).

When  $V_{BUS}$  is off, the 1.5 k $\Omega$  pull-up resister is disconnected from pin DP in approximately 4 ns via bit SOFTCT in the Mode register and a suspend interrupt is set with some latency (debounce and disqualify USB traffic).

When bit SOFTCT is set to logic 0, no interrupt is generated. The firmware can issue a suspend command, followed by the resetting of bit SOFTCT to suspend the chip.

If OTG is logic 1, the pull-up resistor on pin DP depends on D+ line ( $V_{BUS}$  sensing status). Bit DP operates as normal, so the firmware must mask suspend and wake-up interrupt events. When SRP is completed, the device should clear OTG.

#### **Hi-Speed USB peripheral controller**

If OTG is logic 0, the status of the pull-up resistor on DP is referred to in Table 22.

Table 22: Status of the chip

V <sub>BUS</sub>	SoftConnect = on	SoftConnect = off
On	pull-up resistor on DP	pull-up resistor on DP is removed; suspend interrupt is immediately set, regardless of the D+ and D- signals
Off	pull-up resistor on DP is removed; suspend interrupt is immediately set, regardless of the D+ and D- signals	pull-up resistor on DP is removed; suspend interrupt is immediately set, regardless of the D+ and D- signals

#### 9.2.3 Interrupt Configuration register (address: 10h)

This 1-byte register determines the behavior and polarity of the INT output. The bit allocation is shown in Table 23. When the USB SIE receives or generates an ACK, NAK or STALL, it will generate interrupts depending on three Debug mode fields.

CDBGMOD[1:0] — Interrupts for the control endpoint 0

DDBGMODIN[1:0] — Interrupts for the DATA IN endpoints 1 to 7

**DDBGMODOUT[1:0]** — Interrupts for the DATA OUT endpoints 1 to 7.

The Debug mode settings for CDBGMOD, DDBGMODIN and DDBGMODOUT allow you to individually configure when the ISP1582 sends an interrupt to the external microprocessor. Table 25 lists the available combinations.

Bit INTPOL controls the signal polarity of the INT output: active HIGH or LOW, rising or falling edge. For level-triggering, bit INTLVL must be made logic 0. By setting INTLVL to logic 1, an interrupt will generate a pulse of 60 ns (edge-triggering).

Table 23: Interrupt Configuration register: bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	CDBGM	IOD[1:0]	DDBGM	ODIN[1:0]	DDBGMO	DOUT[1:0]	INTLVL	INTPOL
Reset	1	1	1	1	1	1	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24: Interrupt Configuration register: bit description

Bit	Symbol	Description
7 to 6	CDBGMOD[1:0]	Control 0 Debug Mode: For values, see Table 25
5 to 4	DDBGMODIN[1:0]	Data Debug Mode IN: For values, see Table 25
3 to 2	DDBGMODOUT[1:0]	Data Debug Mode OUT: For values, see Table 25
1	INTLVL	Interrupt Level: Selects signaling mode on output INT (0 = level; 1 = pulsed). In pulsed mode, an interrupt produces a 60 ns pulse. Bus reset value: unchanged.
0	INTPOL	Interrupt Polarity: Selects signal polarity on output INT (0 = active LOW; 1 = active HIGH). Bus reset value: unchanged.

#### Hi-Speed USB peripheral controller

Table 25: Debug mode settings

Value	CDBGMOD	DDBGMODIN	DDBGMODOUT
00h	interrupt on all ACK and NAK	interrupt on all ACK and NAK	interrupt on all ACK, NYET and NAK
01h	interrupt on all ACK.	interrupt on ACK	interrupt on ACK and NYET
1Xh	interrupt on all ACK and first NAK <sup>[1]</sup>	interrupt on all ACK and first NAK <sup>[1]</sup>	interrupt on all ACK, NYET and first NAK <sup>[1]</sup>

<sup>[1]</sup> First NAK: the first NAK on an IN or OUT token after a previous ACK response.

#### 9.2.4 OTG register (address: 12h)

The bit allocation of the OTG register is given in Table 26.

Table 26: OTG register: bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	rese	erved	DP	BSESSVALID	INITCOND	DISCV	VP	OTG
Reset	-	-	0	-	-	0	0	0
Bus reset	-	-	0	-	-	0	0	0
Access	-	-	R/W	R/W	R/W	R/W	R/W	R/W

Table 27: OTG register: bit description<sup>[1][2][3]</sup>

Bit	Symbol	Description
7 to 6	-	reserved
5	DP	When set, data-line pulsing is started. The default value of this bit is logic 0. This bit must be cleared when data-line pulsing is completed.
4	BSESS VALID	The device can initiate another $V_{BUS}$ discharge sequence after data-line pulsing and $V_{BUS}$ pulsing, and before it clears this bit and detects a session valid.
	This bit is latched to logic 1 once $V_{BUS}$ exceeds the B-device session valid threshold. Once set, it remains at logic 1. To clear this bit, write logic 1. (The ISP1582 continuously updates this bit to logic 1 when the B-session is valid. If the B-session is valid after it is cleared, it is set back to logic 1 by the ISP1582).	
		<b>0</b> — It implies that SRP has failed. To proceed to a normal operation, the device can restart SRP, clear bit OTG or proceed to an error

- the device can restart SRP has failed. To proceed to a normal operation, the device can restart SRP, clear bit OTG or proceed to an error handling process.
- 1 It implies that the B-session is valid. The device clears bit OTG, goes into normal operation mode, and sets bit SOFTCT (DP pull-up) in the Mode register. The OTG host has a maximum of 5 s before it responds to a session request. During this period, the ISP1582 may request to suspend. Therefore, the device firmware must wait for sometime if it wishes to know the SRP result (success—if there is minimum response from the host within 5 s; failure—if there is no response from the host within 5 s).

#### Hi-Speed USB peripheral controller

Table 27: OTG register: bit description<sup>[1][2][3]</sup>...continued

Bit	Symbol	Description
3	INIT COND	Write logic 1 to clear this bit. The device clears this bit, and waits for more than 2 ms to check the bit status. If it reads logic 0, it means that V <sub>BUS</sub> remains lower than 0.8 V, and DP or DM at SE0 during the elapsed time is cleared. The device can then start a B-device SRP. If it reads logic 1, it means that the initial condition of an SRP is violated. So, the device should abort SRP.
		The bit is set to logic 1 by the ISP1582 when initial conditions are not met, and only writing logic 1 clears the bit. (If initial conditions are not met after this bit has been cleared, it will be set again).
		<b>Remark:</b> This implementation does not cover the case if an initial SRP condition is violated when this bit is read and data-line pulsing is started.
2	DISCV	Set to logic 1 to discharge $V_{BUS}$ . The device discharges $V_{BUS}$ before starting a new SRP. The discharge can take as long as 30 ms for $V_{BUS}$ to be charged less than 0.8 V. This bit must be cleared (write logic 0) before starting a session end detection.
1	VP	Set to logic 1 to start $V_{\text{BUS}}$ pulsing. This bit must be set for more than 16 ms and must be cleared before 26 ms.
0	OTG	$1$ — Enables the OTG function. The $V_{BUS}$ sensing functionality will be bypassed.
		<ul> <li>0 — Normal operation. All OTG control bits will be masked. Status bits are undefined.</li> </ul>

No interrupt is designed for OTG. The V<sub>BUS</sub> interrupt, however, may assert as a side effect during the V<sub>BUS</sub> pulsing (see note 2).

#### **Session Request Protocol (SRP):**

The ISP1582 can initiate an SRP. The B-device initiates SRP by data-line pulsing followed by  $V_{BUS}$  pulsing. The A-device can detect either data-line pulsing or  $V_{BUS}$  pulsing.

The ISP1582 can initiate the B-device SRP by performing the following steps:

- 1. Detect initial conditions: read bit INITCOND of the OTG register.
- 2. Start data-line pulsing: set bit DP of the OTG register to logic 1.
- 3. Wait for 5 ms to 10 ms.
- 4. Stop data-line pulsing: set bit DP of the OTG register to logic 0.
- 5. Start V<sub>BUS</sub> pulsing: set bit VP of the OTG register to logic 1.
- 6. Wait for 10 ms to 20 ms.
- 7. Stop V<sub>BUS</sub> pulsing: set bit VP of the OTG register to logic 0.
- 8. Discharge V<sub>BUS</sub> for about 30 ms: optional by using bit DISCV of the OTG register.

<sup>[2]</sup> When OTG is in progress, the V<sub>BUS</sub> interrupt may be set because V<sub>BUS</sub> is charged over V<sub>BUS</sub> sensing threshold or the OTG host has turned on the V<sub>BUS</sub> supply to the device. Even if the V<sub>BUS</sub> interrupt is found during SRP, the device should complete data-line pulsing and V<sub>BUS</sub> pulsing before starting the B\_SESSION\_VALID detection.

<sup>[3]</sup> OTG implementation applies to the device with self-power capability. If the device works in sharing mode, it should provide a switch circuit to supply power to the ISP1582 core during SRP.

#### Hi-Speed USB peripheral controller

Detect bit BSESSVALID of the OTG register for a successful SRP with bit OTG disabled.

The B-device must complete both data-line pulsing and V<sub>BUS</sub> pulsing within 100 ms.

**Remark:** When disabling, OTG data-line pulsing bit DP and  $V_{BUS}$  pulsing bit VP must be cleared by writing logic 1.

#### 9.2.5 Interrupt Enable register (address: 14h)

This register enables or disables individual interrupt sources. The interrupt for each endpoint can be individually controlled via the associated bits IEPnRX or IEPnTX, here n represents the endpoint number. All interrupts can be globally disabled through bit GLINTENA in the Mode register (see Table 20).

An interrupt is generated when the USB SIE receives or generates an ACK or NAK on the USB bus. The interrupt generation depends on Debug mode settings of bit fields CDBGMOD[1:0], DDBGMODIN[1:0] and DDBGMODOUT[1:0].

All data IN transactions use the Transmit buffers (TX), which are handled by bits DDBGMODIN. All data OUT transactions go via the Receive buffers (RX), which are handled by bits DDBGMODOUT. Transactions on control endpoint 0 (IN, OUT and SETUP) are handled by bits CDBGMOD.

Interrupts caused by events on the USB bus (SOF, Pseudo SOF, suspend, resume, bus reset, setup and high-speed status) can also be individually controlled. A bus reset disables all enabled interrupts except bit IEBRST (bus reset), which remains unchanged.

The Interrupt Enable register consists of 4 bytes. The bit allocation is given in Table 28.

Table 28: Interrupt Enable register: bit allocation

5	IEHS_STA	Logic 1 enables interrupt on detection of a high-speed status change.
4	IERESM	Logic 1 enables interrupt on detection of a resume state.
3	IESUSP	Logic 1 enables interrupt on detection of a suspend state.
2	IEPSOF	Logic 1 enables interrupt on detection of a Pseudo SOF.
1	IESOF	Logic 1 enables interrupt on detection of an SOF.
0	IEBRST	Logic 1 enables interrupt on detection of a bus reset.

#### 9.3 Data flow registers

#### 9.3.1 Endpoint Index register (address: 2Ch)

The Endpoint Index register selects a target endpoint for register access by the microcontroller. The register consists of 1 byte, and the bit allocation is shown in Table 30.

#### **Hi-Speed USB peripheral controller**

The following registers are indexed:

- Buffer Length
- Buffer Status
- Control Function
- Data Port
- Endpoint MaxPacketSize
- Endpoint Type.

For example, to access the OUT data buffer of endpoint 1 using the Data Port register, the Endpoint Index register has to be written first with 02h.

**Remark:** The Endpoint Index register and the DMA Endpoint Index register must not point to the same endpoint.

Table 30: Endpoint Index register: bit allocation

Buffer name	EP0SETUP	ENDPIDX	DIR
SETUP	1	00h	0
Data OUT	0	00h	0
Data IN	0	00h	1

#### Hi-Speed USB peripheral controller

#### 9.3.2 Control Function register (address: 28h)

The Control Function register performs the buffer management on endpoints. It consists of 1 byte, and the bit configuration is given in Table 33. The register bits can stall, clear or validate any enabled data endpoint. Before accessing this register, the Endpoint Index register must be written first to specify the target endpoint.

Table 33: Control Function register: bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol		reserved		CLBUF	VENDP	DSEN	STATUS	STALL
Reset	-	-	-	0	0	0	0	0
Bus reset	-	-	-	0	0	0	0	0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 34: Control Function register: bit description

		OI Function register: bit description
Bit	Symbol	Description
7 to 5	-	reserved
4	CLBUF	<b>Clear Buffer:</b> Logic 1 clears the RX buffer of the indexed endpoint; the TX buffer is not affected. The RX buffer is automatically cleared once the endpoint is completely read. This bit is set only when it is necessary to forcefully clear the buffer.
3	VENDP	Validate Endpoint: Logic 1 validates the data in the TX FIFO of an IN endpoint for sending on the next IN token. In general, the endpoint is automatically validated when its FIFO byte count has reached the endpoint MaxPacketSize. This bit is set only when it is necessary to validate the endpoint with the FIFO byte count which is below the Endpoint MaxPacketSize.
2	DSEN	<b>Data Stage Enable</b> : This bit controls the response of the ISP1582 to a control transfer. When this bit is set, the ISP1582 goes to the data stage; otherwise, the ISP1582 will NAK the data stage transfer until the firmware explicitly responds to the setup command.
1	STATUS	Status Acknowledge: Only applicable for control IN/OUT.
		This bit controls the generation of ACK or NAK during the status stage of a SETUP transfer. It is automatically cleared when the status stage is completed, or when a SETUP token is received. No interrupt signal will be generated.
		0 — Sends NAK
		1 — Sends an empty packet following the IN token (host-to-peripheral) or ACK following the OUT token (peripheral-to-host).
0	STALL	<b>Stall Endpoint</b> : Logic 1 stalls the indexed endpoint. This bit is not applicable for isochronous transfers.
		<b>Remark:</b> 'Stall'ing a data endpoint will confuse the Data Toggle bit about the stalled endpoint because the internal logic picks up from where it is stalled. Therefore, the Data Toggle bit must be reset by disabling and reenabling the corresponding endpoint (by setting bit ENABLE to logic 0 or logic 1 in the Endpoint Type register) to reset the PID.

#### 9.3.3 Data Port register (address: 20h)

This 2-byte register provides direct access for a microcontroller to the FIFO of the indexed endpoint. The bit allocation is shown in Table 35.

#### **Hi-Speed USB peripheral controller**

**Peripheral-to-host (IN endpoint):** After each write action, an internal counter is auto incremented by two to the next location in the TX FIFO. When all bytes have been written (FIFO byte count = endpoint MaxPacketSize), the buffer is automatically validated. The data packet will then be sent on the next IN token. When it is necessary to validate the endpoint whose byte count is less than MaxPacketSize, it can be done using the Control Function register (bit VENDP).

**Host-to-peripheral (OUT endpoint)**: After each read action, an internal counter is auto decremented by two to the next location in the RX FIFO. When all bytes have been read, the buffer contents are automatically cleared. A new data packet can then be received on the next OUT token. The buffer contents can also be cleared through the Control Function register (bit CLBUF), when it is necessary to forcefully clear the contents.

**Remark:** The buffer can be automatically validated or cleared by using the Buffer Length register (see Table 37).

Table 35: Data Port register: bit allocation

Bit	Symbol	Description
15 to 8	DATAPORT[15:8]	data (upper byte)
7 to 0	DATAPORT[7:0]	data (lower byte)

#### 9.3.4 Buffer Length register (address: 1Ch)

This register determines the current packet size (DATACOUNT) of the indexed endpoint FIFO. The bit allocation is given in Table 37.

The Buffer Length register is automatically loaded with the FIFO size, when the Endpoint MaxPacketSize register is written (see Table 41). A smaller value can be written when required. After a bus reset, the Buffer Length register is made zero.

**IN endpoint:** When data transfer is performed in multiples of MaxPacketSize, the Buffer Length register is not significant. This register is useful only when transferring data that is not a multiple of MaxPacketSize. The following two examples demonstrate the significance of the Buffer Length register.

#### Hi-Speed USB peripheral controller

Example 1: Consider that the transfer size is 512 bytes and the MaxPacketSize is programmed as 64 bytes, the Buffer Length register need not be filled. This is because the transfer size is a multiple of MaxPacketSize, and the MaxPacketSize packets will be automatically validated because the last packet is also of MaxPacketSize.

Example 2: Consider that the transfer size is 510 bytes and the MaxPacketSize is programmed as 64 bytes, the Buffer Length register should be filled with 62 bytes just before the MCU writes the last packet of 62 bytes. This ensures that the last packet, which is a short packet of 62 bytes, is automatically validated.

Use bit VENDP in the Control register if you are not using the Buffer Length register.

This is applicable only to PIO mode access.

**OUT endpoint:** The DATACOUNT value is automatically initialized to the number of data bytes sent by the host on each ACK.

**Remark:** When using a 16-bit microprocessor bus, the last byte of an odd-sized packet is output as the lower byte (LSByte).

**Remark:** Buffer Length is valid only after an interrupt is generated for the bulk endpoint.

Table 37: Buffer Length register: bit allocation

Table 38: Buffer Length register: bit description

Bit	Symbol	Description
15 to 0	DATACOUNT[15:0]	Determines the current packet size of the indexed endpoint FIFO.

#### 9.3.5 Buffer Status register (address: 1Eh)

This register is accessed using index. The endpoint index must first be set before accessing this register for the corresponding endpoint. It reflects the status of the double buffered endpoint FIFO. This register is valid only when the endpoint is configured to be a double buffer.

Remark: This register is not applicable to the control endpoint.

Table 39 shows the bit allocation of the Buffer Status register.

#### **Hi-Speed USB peripheral controller**

		11 — Both the buffers are filled.

#### 9.3.6 Endpoint MaxPacketSize register (address: 04h)

This register determines the maximum packet size for all endpoints except control 0. The register contains 2 bytes, and the bit allocation is given in Table 41.

Each time the register is written, the Buffer Length registers of all endpoints are reinitialized to the FFOSZ field value. Bits NTRANS control the number of transactions allowed in a single microframe (for high-speed isochronous and interrupt endpoints only).

Table 41: Endpoint MaxPacketSize register: bit allocation

Bit	15	14	13	12	11	10	9	8

#### Hi-Speed USB peripheral controller

Table 42: Endpoint MaxPacketSize register: bit description

	•	The state of the s					
Bit	Symbol	Description					
15 to 13	-	eserved					
12 to 11	NTRANS[1:0]	Number of Transactions. HS mode only.					
		00 — 1 packet per microframe					
		<b>01</b> — 2 packets per microframe					
		10 — 3 packets per microframe					
		11 — reserved.					
		These bits are applicable only for isochronous or interrupt transactions.					
10 to 0	FFOSZ[10:0]	<b>FIFO Size</b> : Sets the FIFO size, in bytes, for the indexed endpoint. Applies to both high-speed and full-speed operations (see Table 43).					

**Table 43: Programmable FIFO size** 

NTRANS[1:0]	FFOSZ[10:0]	Non-isochronous	Isochronous
0h	08h	8 bytes	-
0h	10h	16 bytes	-
0h	20h	32 bytes	-
0h	40h	64 bytes	-
0h	80h	128 bytes	-
0h	100h	256 bytes	-
0h	200h	512 bytes	-
2h	400h	-	3072 bytes

Each programmable FIFO can be independently configured via its Endpoint MaxPacketSize register (R/W: 04h), but the total physical size of all enabled endpoints (IN plus OUT) must not exceed 8192 bytes.

# 9.3.7 Endpoint Type register (address: 08h)

This register sets the endpoint type of the indexed endpoint: isochronous, bulk or interrupt. It also serves to enable the endpoint and configure it for double buffering. Automatic generation of an empty packet for a zero-length TX buffer can be disabled using bit NOEMPKT. The register contains 2 bytes, and the bit allocation is shown in Table 44.

Table 44: Endpoint Type register: bit allocation

Table 45: Endpoint Type register: bit description

Bit	Symbol	Description						
15 to 5	-	reserved						
4	NOEMPKT	No Empty Packet: Logic 0 causes the ISP1582 to return a null length packet for the IN token after the DMA IN transfer is complete. For ATA mode or the IN DMA transfer, which does not require a null length packet after DMA completion, set to logic 1 to disable the generation of the null length packet.						
3	ENABLE	<b>Endpoint Enable</b> : Logic 1 enables the FIFO of the indexed endpoint. The memory size is allocated as specified in the Endpoint MaxPacketSize register. Logic 0 disables the FIFO.						
		<b>Remark:</b> 'Stall'ing a data endpoint will confuse the Data Toggle bit on the stalled endpoint because the internal logic picks up from where it has stalled. Therefore, the Data Toggle bit must be reset by disabling and reenabling the corresponding endpoint (by setting bit ENABLE to logic 0 or logic 1 in the Endpoint Type register) to reset the PID.						
2	DBLBUF	<b>Double Buffering:</b> Logic 1 enables double buffering for the indexed endpoint. Logic 0 disables double buffering.						
1 to 0	ENDPTYP[1:0]	<b>Endpoint Type:</b> These bits select the endpoint type as follows.						
		<b>00</b> — not used						
		<b>01</b> — Isochronous						
		<b>10</b> — Bulk						
		11 — Interrupt.						

## 9.4 DMA registers

The Generic DMA (GDMA) transfer can be done by writing the proper opcode in the DMA Command register. The control bits are given in Table 46.

# GDMA read/write (opcode = 00h/01h) for Generic DMA slave mode

Depending on the MODE[1:0] bit set in the DMA configuration register, either the DACK signal or the DIOR/DIOW signals strobe the data. These signals are driven by the external DMA controller.

GDMA (slave) mode can operate in either counter mode or EOT-only mode.

In counter mode, bit DIS\_XFER\_CNT in the DMA Configuration register must be set to logic 0. The DMA Transfer Counter register must be programmed before any DMA command is issued. The DMA transfer counter is set by writing from the LSByte to the MSByte (address: 34h to 37h). The DMA transfer count is internally updated only after the MSByte has been written. Once the DMA transfer is started, the transfer counter starts decrementing and on reaching 0, bit DMA\_XFER\_OK is set and an

#### Hi-Speed USB peripheral controller

interrupt is generated by the ISP1582. If the DMA master wishes to terminate the DMA transfer, it can issue an EOT signal to the ISP1582. This EOT signal overrides the transfer counter and can terminate the DMA transfer at any time.

In EOT-only mode, DIS\_XFER\_CNT has to be set to logic 1. Although the DMA transfer counter can still be programmed, it will not have any effect on the DMA transfer. The DMA transfer will start once the DMA command is issued. Any of the following three ways will terminate this DMA transfer:

- Detecting an external EOT
- Detecting an internal EOT (short packet on an OUT token)
- Resetting the DMA.

There are three interrupts programmable to differentiate the method of DMA termination: bits INT\_EOT, EXT\_EOT and DMA\_XFER\_OK in the DMA Interrupt Reason register. For details, see Table 58.

Table 46: Control bits for GDMA read/write (opcode = 00h/01h)

	Table 40. Control bits for Committee (opcode = convert)						
Control bits	Description Refere						
<b>DMA Configuratio</b>	n register						
MODE[1:0]	Determines the active read/write data strobe signals.	Table 52					
WIDTH	Selects the DMA bus width: 8 or 16 bits.						
DIS_XFER_CNT	Disables the use of the DMA Transfer Counter.						
DMA Hardware reg	gister						
EOT_POL	Selects the polarity of the EOT signal.	Table 54					
ENDIAN[1:0]	Determines whether the data is to be byte swapped or normal. Applicable only in 16-bit mode.						
ACK_POL, DREQ_POL, WRITE_POL, READ_POL	Select the polarity of the DMA handshake signals.						

**Remark:** The DMA bus defaults to three-state, until a DMA command is executed. All the other control signals are not three-state.

#### 9.4.1 DMA Command register (address: 30h)

The DMA Command register is a 1-byte register (for bit allocation, see Table 47) that initiates all DMA transfer activity on the DMA controller. The register is write-only: reading it will return FFh.

Remark: The DMA bus will be in three-state until a DMA command is executed.

Table 47: DMA Command register: bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol				DMA_C	MD[7:0]

#### Hi-Speed USB peripheral controller

Table 48: DMA Command register: bit description

Bit	Symbol	Description
7 to 0	DMA_CMD[7:0]	DMA command code; see Table 49.

Table 49: DMA commands

Table 43.	DIVIA COMMINANTA	
Code	Name	Description
00h	GDMA Read	<b>Generic DMA IN token transfer (slave mode only):</b> Data is transferred from the external DMA bus to the internal buffer. Strobe: DIOW by external DMA controller.
01h	GDMA Write	<b>Generic DMA OUT token transfer (slave mode only):</b> Data is transferred from the internal buffer to the external DMA bus. Strobe: DIOR by external DMA controller.
02h to 0Dh	-	reserved
0Eh	Validate Buffer	Validate Buffer (for debugging only): Request from the microcontroller to validate the endpoint buffer following a DMA to USB data transfer.
0Fh	Clear Buffer	<b>Clear Buffer:</b> Request from the microcontroller to clear the endpoint buffer after a USB to DMA data transfer.
10h	-	reserved
11h	Reset DMA	Reset DMA: Initializes the DMA core to its power-on reset state.
		<b>Remark:</b> When the DMA core is reset during the Reset DMA command, the DREQ, DACK, DIOW and DIOR handshake pins will be temporarily asserted. This can confuse the external DMA controller. To prevent this, start the external DMA controller <b>only after</b> the DMA reset.
12h	-	reserved
13h	GDMA Stop	<b>GDMA stop</b> : This command stops the GDMA data transfer. Any data in the OUT endpoint that is not transferred by the DMA will remain in the buffer. The FIFO data for the IN endpoint will be written to the endpoint buffer. An interrupt bit will be set to indicate the completion of the DMA Stop command.
14h to FFh	-	reserved

#### 9.4.2 DMA Transfer Counter register (address: 34h)

This 4-byte register sets up the total byte count for a DMA transfer (DMACR). It indicates the remaining number of bytes left for transfer. The bit allocation is given in Table 50.

**For IN endpoint** — As there is a FIFO in the ISP1582 DMA controller, some data may remain in the FIFO during the DMA transfer. The maximum FIFO size is 8 bytes, and the maximum delay time for the data to be shifted to endpoint buffer is 60 ns.

**For OUT endpoint** — Data will not be cleared for the endpoint buffer until all the data has been read from the DMA FIFO.

If the DMA counter is disabled in the DMA transfer, it will still decrement and rollover when it reaches zero.

		1 — 16-bit data bus.

<sup>[1]</sup> The DREQ pin will only be driven only after you perform a write access to the DMA Configuration register (that is, after you have configured the DMA Configuration register).

## 9.4.4 DMA Hardware register (address: 3Ch)

The DMA Hardware register consists of 1 byte. The bit allocation is shown in Table 54.

This register determines the polarity of the bus control signals (EOT, DACK, DREQ, DIOR and DIOW) and DMA mode (master or slave). It also controls whether the upper and lower parts of the data bus are swapped (bits ENDIAN[1:0]) for GDMA (slave) mode.

## 9.4.5 DMA Interrupt Reason register (address: 50h)

This 2-byte register shows the source(s) of DMA interrupt. Each bit is refreshed after a DMA command has been executed. An interrupt source is cleared by writing logic 1 to the corresponding bit. When reading, AND the value of the bits in this register with the value of the corresponding bits in the DMA Interrupt Enable register.

The bit allocation is given in Table 56.

## **Hi-Speed USB peripheral controller**

Table 56: DMA Interrupt Reason register: bit allocation

Bit	15	14	13	12	11	10	9	8

Symbol				rese	erved			
Reset	-	-	-	-	-	-	-	-
Bus reset	-	-	-	-	-	-	-	-
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 57: DMA Interrupt Reason register: bit description

Bit	Symbol	Description
15	TEST3	This bit is set when the DMA transfer for a packet (OUT transfer) terminates before the whole packet has been transferred. This bit is a status bit, and the corresponding mask bit of this register is always logic 0. Writing any value other than logic 0 has no effect.
14 to 13	-	reserved
12	GDMA_STOP	When the GDMA_STOP command is issued to the DMA Command registers, it means the DMA transfer has successfully terminated.
11	EXT_EOT	Logic 1 indicates that an external EOT is detected. This is applicable only in GDMA (slave) mode.
10	INT_EOT	Logic 1 indicates that an internal EOT is detected; see Table 58.
9	-	reserved
8	DMA_XFER_OK	Logic 1 indicates that the DMA transfer has been completed (DMA Transfer Counter has become zero). This bit is only used in GDMA (slave) mode.
7 to 0	-	reserved

Table 58: Internal EOT-functional relation with bit DMA\_XFER\_OK

INT_EOT	DMA_XFER_OK	Description
1	0	During the DMA transfer, there is a premature termination with short packet.
1	1	DMA transfer is completed with short packet and the DMA transfer counter has reached 0.
0	1	DMA transfer is completed without any short packet and the DMA transfer counter has reached 0.

Table 59 shows the status of the bits in the DMA Interrupt Reason register when the corresponding bits in the Interrupt register is set.

#### Hi-Speed USB peripheral controller

Table 59:	Status of the	bits in the	<b>DMA Interrupt</b>	t Reason register <sup>[1][2]</sup>

Status	EXT_EOT	INT_EOT	DMA_XI	FER_OK
			Counter enabled	Counter disabled
IN full	1	0	1	0
IN short	1	0	1	0
OUT full	1	0	1	0
OUT short	1	1 <sup>[3]</sup>	1	0

- [1] 1 indicates that the bit is set and 0 indicates that the bit is not set. A bit is set when the corresponding EOT condition is met. For example; EXT\_EOT is set if external EOT conditions are met (pin EOT active), regardless of other EOT conditions. If multiple EOT conditions are met, the corresponding interrupt bits are set.
- [2] If both EXT\_EOT and DMA\_XFER\_OK conditions are met in DMA for an IN endpoint, the EXT\_EOT interrupt is not set.
- [3] The value of INT\_EOT may not be accurate if an external or internal transfer counter is programmed with a value that is lower than the transfer that the host requests. To terminate an OUT transfer with INT\_EOT, the external or internal DMA counter should be programmed as a multiple of the full-packet length of the DMA endpoint. When a short packet is successfully transferred by DMA, INT\_EOT is set.

#### 9.4.6 DMA Interrupt Enable register (address: 54h)

This 2-byte register controls the interrupt generation of the source bits in the DMA Interrupt Reason register. The bit allocation is given in Table 60. The bit description is given in Table 57.

Logic 1 enables the interrupt generation. After a bus reset, interrupt generation is disabled, with the values turning to logic 0.

Table 60: DMA Interrupt Enable register: bit allocation

Bit	15	14	13	12	11	10	9	8
Symbol	TEST4	rese	ved	IE_GDMA_ STOP	IE_EXT_ EOT	IE_INT_ EOT	reserved	IE_DMA_ XFER_OK

#### Hi-Speed USB peripheral controller

Table 62: DMA Endpoint register: bit description

Bit	Symbol	Description
7 to 4	-	reserved
3 to 1	EPIDX[2:0]	selects the indicated endpoint for DMA access
0	DMADIR	0 — Selects the RX/OUT FIFO for DMA read transfers
		1 — Selects the TX/IN FIFO for DMA write transfers.

The DMA Endpoint register must not reference the endpoint that is indexed by the Endpoint Index register (2Ch) at any time. Doing so would result in data corruption. Therefore, if the DMA Endpoint register is unused, point it to an unused endpoint. If the DMA Endpoint register, however, is pointed to an active endpoint, the firmware must not reference the same endpoint on the Endpoint Index register.

#### 9.4.8 DMA Burst Counter register (address: 64h)

Table 63 shows the bit allocation of the register.

Table 63: DMA Burst Counter register: bit allocation

Bit	15	14	13	12	11	10	9	8	
Symbol	reserved				BURSTCOUNTER[12:8]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	

Table 64: DMA Burst Counter register: bit description

Bit	Symbol	Description
15 to 13	-	reserved
12 to 0	BURSTCOUNTER[12:0]	This register defines the burst length. The counter must be programmed to be a multiple of two in 16-bit mode.
		The value of the burst counter should be programmed such that the buffer counter is a factor of the burst counter.
		For IN endpoint — When the burst counter equals 2, in GDMA mode, DREQ will drop at every DMA read or write cycle.

# 9.5 General registers

#### 9.5.1 Interrupt register (address: 18h)

The Interrupt register consists of 4 bytes. The bit allocation is given in Table 65.

#### Hi-Speed USB peripheral controller

When a bit is set in the Interrupt register, it indicates that the hardware condition for an interrupt has occurred. When the Interrupt register content is nonzero, the INT output will be asserted corresponding to the Interrupt Enable register. On detecting the interrupt, the external microprocessor must read the Interrupt register and mask it with the corresponding bits in the Interrupt Enable register to determine the source of the interrupt.

Each endpoint buffer has a dedicated interrupt bit (EPnTX, EPnRX). In addition, various bus states can generate an interrupt: resume, suspend, pseudo SOF, SOF and bus reset. The DMA controller only has one interrupt bit: the source for a DMA interrupt is shown in the DMA Interrupt Reason register.

Each interrupt bit can be individually cleared by writing logic 1. The DMA Interrupt bit can be cleared by writing logic 1 to the related interrupt source bit in the DMA Interrupt Reason register and writing logic 1 to the DMA bit of the Interrupt register.

Table 66: Interrupt register: bit description

		20
Bit	Symbol	Description
31 to 26	-	reserved
25	EP7TX	Logic 1 indicates the endpoint 7 TX buffer as interrupt source.
24	EP7RX	Logic 1 indicates the endpoint 7 RX buffer as interrupt source.
23	EP6TX	Logic 1 indicates the endpoint 6 TX buffer as interrupt source.
22	EP6RX	Logic 1 indicates the endpoint 6 RX buffer as interrupt source.
21	EP5TX	Logic 1 indicates the endpoint 5 TX buffer as interrupt source.

# Hi-Speed USB peripheral controller

Table 66: Interrupt register: bit description...continued

Bit	Symbol	Description
20	EP5RX	Logic 1 indicates the endpoint 5 RX buffer as interrupt source.
19	EP4TX	Logic 1 indicates the endpoint 4 TX buffer as interrupt source.
18	EP4RX	Logic 1 indicates the endpoint 4 RX buffer as interrupt source.
17	EP3TX	Logic 1 indicates the endpoint 3 TX buffer as interrupt source.
16	EP3RX	Logic 1 indicates the endpoint 3 RX buffer as interrupt source.
15	EP2TX	Logic 1 indicates the endpoint 2 TX buffer as interrupt source.
14	EP2RX	Logic 1 indicates the endpoint 2 RX buffer as interrupt source.
13	EP1TX	Logic 1 indicates the endpoint 1 TX buffer as interrupt source.
12	EP1RX	Logic 1 indicates the endpoint 1 RX buffer as interrupt source.
11	EP0TX	Logic 1 indicates the endpoint 0 data TX buffer as interrupt source.
10	EP0RX	Logic 1 indicates the endpoint 0 data RX buffer as interrupt source.
9	-	reserved
8	EP0SETUP	Logic 1 indicates that a SETUP token was received on endpoint 0.
7	VBUS	Logic 1 indicates V <sub>BUS</sub> is turned on.
6	DMA	<b>DMA status:</b> Logic 1 indicates a change in the DMA Status register.
5	HS_STAT	<b>High speed status:</b> Logic 1 indicates a change from full-speed to high-speed mode (HS connection). This bit is not set, when the system goes into full-speed suspend.
4	RESUME	Resume status: Logic 1 indicates that a status change from suspend to resume (active) was detected.
3	SUSP	<b>Suspend status:</b> Logic 1 indicates that a status change from active to suspend was detected on the bus.
2	PSOF	<b>Pseudo SOF interrupt</b> : Logic 1 indicates that a pseudo SOF or $\mu$ SOF was received. Pseudo SOF is an internally generated clock signal (full-speed: 1 ms period, high-speed: 125 $\mu$ s period) synchronized to the USB bus SOF or $\mu$ SOF.
1	SOF	<b>SOF interrupt:</b> Logic 1 indicates that a SOF or $\mu$ SOF was received.
0	BRESET	<b>Bus reset</b> : Logic 1 indicates that a USB bus reset was detected. When bit OTG in the OTG register is set, BRESET will not be set, instead, this interrupt bit will report SE0 on DP and DM for 2 ms.

#### 9.5.2 Chip ID register (address: 70h)

This read-only register contains the chip identification and the hardware version numbers. The firmware should check this information to determine the functions and features supported. The register contains 3 bytes, and the bit allocation is shown in Table 67.

48 of 66

#### 9.5.5 Unlock Device register (address: 7Ch)

To protect the registers from getting corrupted when the ISP1582 goes into suspend, the write operation is disabled if bit PWRON in the Mode register is set to logic 0. In this case, when the chip resumes, the Unlock Device command must be first issued to this register before attempting to write to the rest of the registers. This is done by writing unlock code (AA37h) to this register.

The bit allocation of the Unlock Device register is given in Table 73.

Table 73: Unlock Device register: bit allocation

	10011 201100	rogiotori bit	anodanon

Symbol				ULCODE	7:0] = 37h				
Reset				not ap	olicable				
Bus reset		not applicable							
Access	W	W	W	W	W	W	W	W	

Table 74: Unlock Device register: bit description

Bit	Symbol	Description
15 to 0	ULCODE[15:0]	Writing data AA37h unlocks the internal registers and FIFOs for writing, following a resume.

When bit PWRON in the Mode register is logic 1, the chip is powered. In such a case, you do not need to issue the Unlock command because the microprocessor is powered and therefore, the RD\_N, WR\_N and CS\_N signals maintain their states.

#### **Hi-Speed USB peripheral controller**

When bit PWRON is logic 0, the RD\_N, WR\_N and CS\_N signals are floating because the microprocessor is not powered. To protect the ISP1582 registers from being corrupted during suspend, register write is locked when the chip goes into suspend. Therefore, you need to issue the Unlock command to unlock the ISP1582 registers.

#### 9.5.6 Test Mode register (address: 84h)

This 1-byte register allows the firmware to set pins DP and DM to predetermined states for testing purposes. The bit allocation is given in Table 75.

**Remark:** Only one bit can be set to logic 1 at a time. This must be implemented for the Hi-Speed USB logo compliance testing.

Table 75: Test Mode register: bit allocation

Bit	7	6	5	4	3	2	1	0
Symbol	FORCEHS	rese	rved	FORCEFS	PRBS	KSTATE	JSTATE	SE0_NAK
Reset	0	-	-	0	0	0	0	0

Table 76: Test Mode register: bit description

Bit	Symbol	Description
7	FORCEHS	logic 1 <sup>[1]</sup> forces the hardware to high-speed mode only and disables the chirp detection logic.
6 to 5	-	reserved.
4	FORCEFS	logic 1 <sup>[1]</sup> forces the physical layer to full-speed mode only and disables the chirp detection logic.
3	PRBS	logic 1 <sup>[2]</sup> sets pins DP and DM to toggle in a predetermined random pattern.
2	KSTATE	writing logic 1 <sup>[2]</sup> sets pins DP and DM to the K state.
1	JSTATE	writing logic 1 <sup>[2]</sup> sets pins DP and DM to the J state.
0	SE0_NAK	writing logic 1 <sup>[2]</sup> sets pins DP and DM to a high-speed quiescent state. The device only responds to a valid high-speed IN token with a NAK.

<sup>[1]</sup> Either FORCEHS or FORCEFS should be set at a time.

<sup>[2]</sup> Of the four bits (PRBS, KSTATE, JSTATE and SE0\_NAK), only one bit should be set at a time.

# 17. Soldering

# 17.1 Introduction to soldering surface mount packages

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *Data Handbook IC26*; *Integrated Circuit Packages* (document order number 9398 652 90011).

There is no soldering method that is ideal for all surface mount IC packages. Wave soldering can still be used for certain surface mount ICs, but it is not suitable for fine pitch SMDs. In these situations reflow soldering is recommended. In these situations reflow soldering is recommended.

#### 17.2 Reflow soldering

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement. Driven by legislation and environmental forces the worldwide use of lead-free solder pastes is increasing.

Several methods exist for reflowing; for example, convection or convection/infrared heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 100 and 200 seconds depending on heating method.

Typical reflow peak temperatures range from 215 to 270 °C depending on solder paste material. The top-surface temperature of the packages should preferably be kept:

- below 225 °C (SnPb process) or below 245 °C (Pb-free process)
  - for all BGA, HTSSON..T and SSOP..T packages
  - for packages with a thickness ≥ 2.5 mm
  - for packages with a thickness < 2.5 mm and a volume ≥ 350 mm<sup>3</sup> so called thick/large packages.
- below 240 °C (SnPb process) or below 260 °C (Pb-free process) for packages with a thickness < 2.5 mm and a volume < 350 mm<sup>3</sup> so called small/thin packages.

Moisture sensitivity precautions, as indicated on packing, must be respected at all times.

#### 17.3 Wave soldering

Conventional single wave soldering is not recommended for surface mount devices (SMDs) or printed-circuit boards with a high component density, as solder bridging and non-wetting can present major problems.

To overcome these problems the double-wave soldering method was specifically developed.

If wave soldering is used the following conditions must be observed for optimal results:

• Use a double-wave soldering method comprising a turbulent wave with high upward pressure followed by a smooth laminar wave.

9397 750 13699

#### Hi-Speed USB peripheral controller

- For packages with leads on two sides and a pitch (e):
  - larger than or equal to 1.27 mm, the footprint longitudinal axis is preferred to be parallel to the transport direction of the printed-circuit board;
  - smaller than 1.27 mm, the footprint longitudinal axis must be parallel to the transport direction of the printed-circuit board.

The footprint must incorporate solder thieves at the downstream end.

 For packages with leads on four sides, the footprint must be placed at a 45° angle to the transport direction of the printed-circuit board. The footprint must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Typical dwell time of the leads in the wave ranges from 3 to 4 seconds at 250 °C or 265 °C, depending on solder material applied, SnPb or Pb-free respectively.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

#### 17.4 Manual soldering

Fix the component by first soldering two diagonally-opposite end leads. Use a low voltage (24 V or less) soldering iron applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C.

When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320  $^{\circ}$ C.

#### 17.5 Package related soldering information

Table 87: Suitability of surface mount IC packages for wave and reflow soldering methods

Package <sup>[1]</sup>	Soldering method		
	Wave	Reflow <sup>[2]</sup>	
BGA, HTSSONT <sup>[3]</sup> , LBGA, LFBGA, SQFP, SSOPT <sup>[3]</sup> , TFBGA, USON, VFBGA	not suitable	suitable	
DHVQFN, HBCC, HBGA, HLQFP, HSO, HSOP, HSQFP, HSSON, HTQFP, HTSSOP, HVQFN, HVSON, SMS	not suitable <sup>[4]</sup>	suitable	
PLCC <sup>[5]</sup> , SO, SOJ	suitable	suitable	
LQFP, QFP, TQFP	not recommended <sup>[5][6]</sup>	suitable	
SSOP, TSSOP, VSO, VSSOP	not recommended <sup>[7]</sup>	suitable	
CWQCCNL <sup>[8]</sup> , PMFP <sup>[9]</sup> , WQCCNL <sup>[8]</sup>	not suitable	not suitable	

<sup>[1]</sup> For more detailed information on the BGA packages refer to the (*LF*)BGA Application Note (AN01026); order a copy from your Philips Semiconductors sales office.

9397 750 13699

<sup>[2]</sup> All surface mount (SMD) packages are moisture sensitive. Depending upon the moisture content, the maximum temperature (with respect to time) and body size of the package, there is a risk that internal or external package cracks may occur due to vaporization of the moisture in them (the so called popcorn effect). For details, refer to the Drypack information in the Data Handbook IC26; Integrated Circuit Packages; Section: Packing Methods.

#### **Hi-Speed USB peripheral controller**

- [3] These transparent plastic packages are extremely sensitive to reflow soldering conditions and must on no account be processed through more than one soldering cycle or subjected to infrared reflow soldering with peak temperature exceeding 217 °C  $\pm$  10 °C measured in the atmosphere of the reflow oven. The package body peak temperature must be kept as low as possible.
- [4] These packages are not suitable for wave soldering. On versions with the heatsink on the bottom side, the solder cannot penetrate between the printed-circuit board and the heatsink. On versions with the heatsink on the top side, the solder might be deposited on the heatsink surface.
- [5] If wave soldering is considered, then the package must be placed at a 45° angle to the solder wave direction. The package footprint must incorporate solder thieves downstream and at the side corners.
- [6] Wave soldering is suitable for LQFP, QFP and TQFP packages with a pitch (e) larger than 0.8 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.65 mm.
- [7] Wave soldering is suitable for SSOP, TSSOP, VSO and VSOP packages with a pitch (e) equal to or larger than 0.65 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.5 mm
- 8] Image sensor packages in principle should not be soldered. They are mounted in sockets or delivered pre-mounted on flex foil. However, the image sensor package can be mounted by the client on a flex foil by using a hot bar soldering process. The appropriate soldering profile can be provided on request.
- [9] Hot bar soldering or manual soldering is suitable for PMFP packages.

#### 19. Data sheet status

Level	Data sheet status <sup>[1]</sup>	Product status <sup>[2][3]</sup>	Definition
I	Objective data	Development	This data sheet contains data from the objective specification for product development. Philips Semiconductors reserves the right to change the specification in any manner without notice.
II	Preliminary data	Qualification	This data sheet contains data from the preliminary specification. Supplementary data will be published at a later date. Philips Semiconductors reserves the right to change the specification without notice, in order to improve the design and supply the best possible product.
III	Product data	Production	This data sheet contains data from the product specification. Philips Semiconductors reserves the right to make changes at any time in order to improve the design, manufacturing and supply. Relevant changes will be communicated via a Customer Product/Process Change Notification (CPCN).

- [1] Please consult the most recently issued data sheet before initiating or completing a design.
- [2] The product status of the device(s) described in this data sheet may have changed since this data sheet was published. The latest information is available on the Internet at URL http://www.semiconductors.philips.com.
- [3] For data sheets describing multiple type numbers, the highest-level product status determines the data sheet status.

#### 20. Definitions

**Short-form specification** — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

Limiting values definition — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 60134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

**Application information** — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

#### 21. Disclaimers

**Life support** — These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors

customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

Right to make changes — Philips Semiconductors reserves the right to make changes in the products - including circuits, standard cells, and/or software - described or contained herein in order to improve design and/or performance. When the product is in full production (status 'Production'), relevant changes will be communicated via a Customer Product/Process Change Notification (CPCN). Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no licence or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.

#### 22. Trademarks

ACPI — is an open industry specification for PC power management, co-developed by Intel Corp., Microsoft Corp. and Toshiba
 OnNow — is a trademark of Microsoft Corp.
 SoftConnect — is a trademark of Koninklijke Philips Electronics N.V.
