General Description

The HV2601/HV2701 devices are low-charge injection, 16-channel, high-voltage analog switch integrated circuits (ICs). These devices are designed for use in applications requiring high-voltage switching controlled by low-voltage control signals, such as medical ultrasound imaging and other piezoelectric transducer drivers. The HV2701 has integrated bleed resistors which eliminate voltage build-up on capacitive loads, such as piezoelectric transducers.

These ICs shift input data into a 16-bit shift register that can then be retained in a 16-bit latch. To reduce any possible clock feed-through noise, the latch enable bar should be left high until all bits are clocked in. Data are clocked in during the rising edge of the clock. Using High-Voltage CMOS technology, these devices combine high-voltage, bilateral DMOS switches and low-power CMOS logic to provide efficient control of high-voltage analog signals.

The device is suitable for various combinations of high-voltage supplies, e.g., V_{PP}/V_{NN} : $+40\text{V}/-160\text{V}$, $+100\text{V}/-100\text{V}$, and $+160\text{V}/-40\text{V}$.

3: All 16 switches go to a state retaining their latched condition at the rising edge of $\overline{LE}$. When $\overline{LE}$ is low, the shift registers data flow through the latch.

4: D_{OUT} is high when data in the shift register 15 are high.

5: Shift registers clocking has no effect on the switch states if $\overline{LE}$ is high.

6: The CLR clear input overrides all other inputs.
