

# M16C/6S Group

### SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

REJ03B0014-0501 Rev.5.01 Dec 10, 2009

# **Overview**

The M16C/6S group are highly integrated single-chip microcomputers with PLC (Power Line Communication) modem core and AFE (Analog Front End) in a 64-pin plastic molded LQFP package, which incorporates IT800 PLC modem technology developed by Yitran Communications Ltd. M16C/60 Series CPU core enables a high level of code efficiency and high-speed operation. In addition, the implementation of Yitran's patented DCSK (Differential Code Shift Keying) spread spectrum modulation technique in the IT800 modem core enables extremely robust communication over the existing electrical wiring, with data rates up to 7.5Kbps. The M16C/6S complies with worldwide regulations (FCC part 15, ARIB and CENELEC bands) and is suitable for a variety of narrowband applications like smart metering and home networking.

# **Applications**

Power Line Communication

# -----Table of Contents-----

Overview	1
Memory	10
Central Processing Unit (CPU)	11
SFR	13
Reset	19
Processor Mode	23
Clock Generation Circuit	27

UART Mode	. 109
Special Mode	. 117
SI/O3 and SI/O4	. 132
Programmable I/O Ports	. 137
Electrical Characteristics	. 149
Flash Memory Version	. 160
IT800AFE (Analog Front End)	. 184
Usage Notes	. 189
Appendix	. 199

Specifications written in this manual are believed to be accurate, but are not guaranteed to be entirely free of error. Specifications in this manual may be changed for functional or performance improvements. Please make sure your manual is the latest edition.

# **Performance Outline**

Table 1.1.1 lists performance outline of M16C/6S group.

Table 1.1.1. Performance outline of M16C/6S group

ltem			Performance	
CPU	Number of basic ins		91 instructions	
	Minimum Instruction E	Execution	65.1 ns (f(BCLK)= 15.36MHz, VCC= 3.0V to 3.6V)	
	time			
	Operation Mode		Single-chip mode	
	Memory Space		1M Byte	
	Memory Capacity	ROM	See Tables 1.1.3 and 1.1.4 Product List	
		RAM	24K Byte	
Peripheral	Port		Input/Output : 21 pins, Input : 1 pin	
Function	Multifunction Timer		Timer A: 16 bits x 5 channels,	
	Serial I/O		2 channels	
			Clock synchronous, UART, I <sup>2</sup> C bus <sup>(1)</sup> ,	
			1 channel	
			UART, I <sup>2</sup> C bus <sup>(1)</sup> ,	
			2 channels	
			Clock synchronous(*)	
			(*) 1 channel is internally connected to IT800	
DMAC			2 channels	
	Watchdog Timer		15 bits x 1 channel (with prescaler)	
	Interrupt		21 internal and 3 external sources, 4 software sources, 7 levels	
	Clock Generation C	Circuit	2 circuits	
			Main clock generation circuit with PLL synthesizer (*),	
			On-chip oscillator,	
			(*) This circuit contains a built-in feedback resister.	
Electrical	Power supply voltage		3.0V to 3.6V	
Characteristics	Power Consumption		70mA (VCC= VCCA= 3.3V, f(XIN)= 5.12MHz)	
Flash memory			3.0V to 3.6V (Topr= 0 to 60°C)	
Version Program and Erase Endurance		ndurance	· ·	
Power consumption Operating Ambient Temperature (2)		D)	70mA (VCC= VCCA= 3.3V, f(XIN)= 5.12MHz)	
		-)	-20 to 85°C	
			-40 to 85°C	
Deales			-40 to 105°C	
Package			64-pin plastic mold LQFP	

#### Notes

- 1. I<sup>2</sup>C Bus is a registered trademark of Koninklijke Philips Electronics N. V.
- 2. See Tables 1.1.5 and 1.1.6 Product code for increased program/erase cycle version, and version of expanded operating ambient temperature.

## IT800 PHY performance outline of M16C/6S group.

The IT800 PHY is a PLC optimized Physical Layer (PHY) which consists of IT800 modem core and internal AFE (Analog Front End). The implementation of Yitran's patented DCSK spread spectrum modulation technique in the IT800 modem core enables extremely robust communication over the existing electrical wiring, with data rates up to 7.5Kbps. In addition to the inherent interference immunity provided by the DCSK modulation, the IT800 PHY utilizes several mechanisms for enhanced communication robustness, such as forward short block soft decoding error correction algorithm and special synchronization algorithms.

The IT800PHY communicates M16C core with clock synchronous serial I/O, interrupt and input/output ports in M16C/6S (Note). M16C/6S requires external AFE. Table 1.1.2 lists IT800 PHY performance outline of M16C/6S group.

Table 1.1.2. IT800 PHY performance outline of M16C/6S group

I	tem	Performance		
Features		High immunity to signal fading, various noise characteristics,		
		impedance modulation and phase/frequency distortion		
		High in-phase and cross-phase reliability		
Modulation Technic	lue	DCSK (Differential Code Shift Keying)*		
		*Yitran patented modulation technique		
Error Correction/De	tection	Forward short-block soft decoding error correction mechanism,		
		CRC-16		
Complies with W/W	Regulations	FCC, ARIB, EN50065-1-CENELEC		
Data Rate &	FCC & ARIB	120-400 KHz		
Frequency Band		7.5Kbps Standard Mode (SM)		
		5.0Kbps Robust Mode (RM)		
		1.25Kbps Extremely Robust Mode (ERM)		
	CENELEC	A-Band (Outdoor): 20-80 KHz		
		B-Band (Indoor): 95-125 KHz		
		2.5 Kbps Robust Mode (RM)		
		0.625Kbps Extremely Robust Mode (ERM)		
Internal AFE		10bit-D/A converter, preamp,		
		1bit-A/D converter x 3 channels		

#### Note:

Direct operation of IT800 PHY is not recommended. Since the Layer 2 (DLL) handles the channel access procedure, using the IT800DLL as such assures coexistence with other IT800 technology based products, regardless of the vendor, protocol and the application. There is NO such coexistence if the device is used in direct operation of IT800 PHY. Note that the coexistence here is not with other technologies but with other IT800 technology based products. As for details, please refer to the next section and Appendix.

#### **About Firmware**

Renesas recommends IT800DLL (Product name: D2DL) as a Data Link Layer (DLL) of M16C/6S group. The IT800 DLL is a PLC optimized DLL especially for the products based on Yitran's IT800 technology. For availability of IT800DLL, please contact Renesas technical support representative. For more details about the IT800DLL advantages, please refer to Appendix.

# **Block Diagram and PLC application Outline**

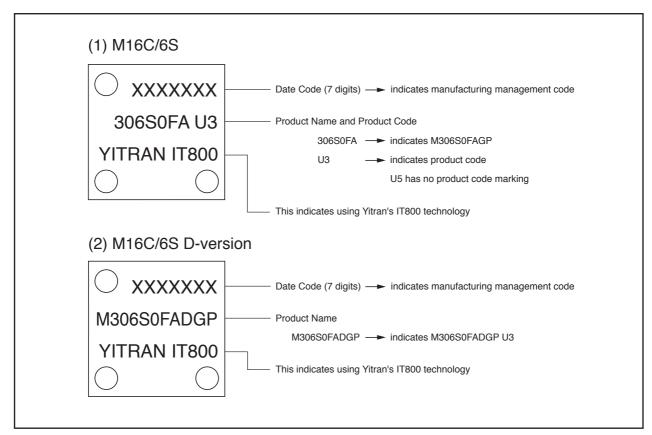

Figure 1.1.3. Marking (Top View)

# **Pin Configuration**

Figures 1.1.4 show the pin configurations (top view).

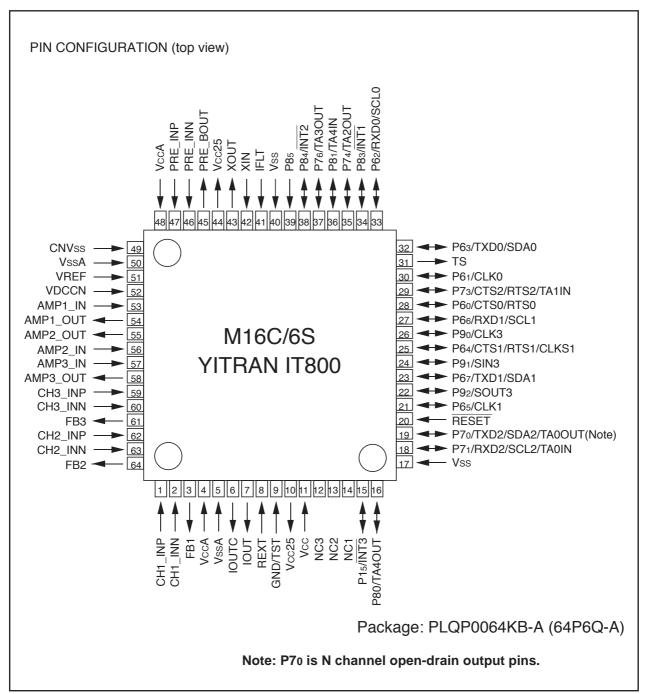

Figure 1.1.4. Pin Configuration (Top View)

# Table 1.1.7 Pin Description (1)

Pin name	Signal name	I/O type	Function	
Vcc, Vss	Power supply input		Apply 3.0V to 3.6V to the Vcc pin. Apply 0V to the Vss pin.	
CNVss	CNVss	Input	This is a pin for changing flash memory mode. Usually, connect to Vss.	
RESET	Reset input	Input	"L" on this input resets the microcomputer.	
XIN	Clock input Clock output	Input Output	I/O pins for the main clock generation circuit. Connect a ceramic resonator or crystal oscillator between XIN and XOUT (3). To use the external clock, input the clock from XIN and leave XOUT open.	
VccA	Analog power supply input	•	This pin is a power supply input of analog circuit. Connect to Vcc.	
VssA	Analog power supply input		This pin is a power supply input of analog circuit. Connect to Vss.	
GND/TST	Input for test	Input	This is input pin for test. Connect to Vss.	
P15	I/O port P1	Input/output	This is an 1-bit I/O port equivalent to P6. By choosing by the program, it functions as an input pin of INT interrupt.	
Vcc25	Power supply		It is the 2.5V power supply pin which is carrying out internal generating.  Connect Vcc25 two pins each other and add stabilization capacity.	
P60 to P67	I/O port P6	Input/output	This is the 8-bit I/O port of CMOS. It has a direction register for choosing I/O, and is made for every pin in an input port or an output port. An input port can choose the existence of pull-up resistance in a 4-bit unit by the program. It functions as an I/O pin of what is chosen by the program which are therefore UARTO and UART1.	
P70, P71, P73, P74, P76	I/O port P7	Input/output	It is an I/O port with a function equivalent to P6 (however, P7o N channel open-drain output). By choosing by the program, it functions as an I/O pin of timers A0 to A3. Moreover, P7o to P73 function also as an I/O pin of UART2.	
P80, P81, P83, P84, P85	I/O port P8	Input/output	P80, P81, P83, and P84 are I/O ports with a function equivalent to P6. By choosing by the program, P80 to P81 function as an I/O pin of timer A4, and P83 to P84 functions as an input pin of TNT interruption.	
	Input port P85	Input	P85 cannot be used as general input pin. Pull-up resistance cannot set up this pin. This pin must be pulled-up externally to Vcc, and be fixed to "H".	
P90 to P92	I/O port P9	Input/output	It is an I/O port with a function equivalent to P6. It functions as an I/O pin of SILO3 by choosing by the program.	
TS	Output port TS	Output	This is the pin with which IT800 controls ON/OFF of an output to the external transmission AMP at the time of power line communication.	
P10	Inner port P10	keep Input	Port for IT800 Testing. Please set Direction Register PD1_0 "0" for keeping Input.	
P11	Inner port P11	keep Input	Port for AFE Testing. Please set Direction Register PD1_1 "0" for keeping Input.	
P40	Inner port P40	Output to IT800	I/O Port for communication between M16C Core and IT800 Modem. Please set Direction Register PD4_0 "1" to Output a signal to IT800. The output signal is connected to TXnRX of IT800 inside of chip.	
P41	Inner port P41	Input from IT800	I/O Port for communication between M16C Core and IT800 Modem (Note.1). Please set Direction Register PD4_1 "0" to Input a signal from IT800. The TS signal is input from IT800 inside of chip.	
P42	Inner port P42	Output to IT800	I/O Port for communication between M16C Core and IT800 Modem. Please set Direction Register PD4_2 "1" to Output a signal to IT800. The output signal is connected to CLR of IT800 inside of chip.	
P53	Inner port P53	Input from IT800	I/O Port for communication between M16C Core and IT800 Modem (Note.1). Please set Direction Register PD5_3 "0" to Input a signal from IT800. The nCD0 signal is input from IT800 inside of chip.	
P54	Inner port P54	Input from IT800	I/O Port for communication between M16C Core and IT800 Modem (Note.1). Please set Direction Register PD5_4 "0" to Input a signal from IT800. The nCD1 signal is input from IT800 inside of chip.	
P56	Inner port P56	Output to IT800	I/O Port for communication between M16C Core and IT800 Modem. Please set Direction Register PD5_6 "1" to Output a signal to IT800. The output signal is connected to nPHY_RES of IT800 inside of chip.	
P82	Inner port P82	Input from IT800	I/O Port for communication between M16C Core and IT800 Modem (Note.1). nINT signal of IT800 is connected to this port inside of chip for carrying out Interrupt function by software.	
P95	Inner port P95	Output to IT800	I/O Port for communication between M16C Core and IT800 Modem. This port is connected to DCLK signal of IT800 inside of chip as SILO4 CLK4 functional Output port by choosing by the program.	
P96	Inner port P96	Output to IT800	I/O Port for communication between M16C Core and IT800 Modem. This port is connected to DI signal of IT800 inside of chip as SILO4 SOUT4 functional Output port by choosing by the program.	
P97	Inner port P97	Input from IT800	I/O Port for communication between M16C Core and IT800 Modem. This port is connected to DI signal of IT800 inside of chip as SILO4 SOUT4 functional Input port by choosing by the program.	

### NOTES:

- 1. In case of Direction Register "1", any signal is not output from M16C to assigned signal of IT800 . Refer to Programmable I/O Ports pages.
- 2. Ask the oscillator maker the oscillation characteristic.

Table 1.1.8 Pin Description (2) (Analog pin)

Pin name	I/O type	Function
PRE-BOUT	Output	This is a pre-amp buffer output.
PRE-INN	Input	This is a pre-amp differential signal input.
PRE-INP	Input	This is a pre-amp differential signal input.
VREF	Input	This is the reference voltage input of amplifier common to channels 1, 2, and 3.
VDCCN	Input	This is a pin for a test. Usually, please carry out a pull-up.
AMP1-IN	Input	This is a channel 1 amplifier input.
AMP1-OUT	Output	This is a channel 1 amplifier output.
AMP2-IN	Input	This is a channel 2 amplifier input.
AMP2-OUT	Output	This is a channel 2 amplifier output.
AMP3-IN	Input	This is a channel 3 amplifier input.
AMP3-OUT	Output	This is a channel 3 amplifier output.
CHI-INP	Input	This is a channel 1 comparator differential input.
CHI-INN	Input	This is a channel 1 comparator differential input.
FB1	Output	This is a channel 1 comparator feedback output.
CH2-INP	Input	This is a channel 2 comparator differential input.
CH2-INN	Input	This is a channel 2 comparator differential input.
FB2	Output	This is a channel 2 comparator feedback output.
CH3-INP	Input	This is a channel 3 comparator differential input.
CH3-INN	Input	This is a channel 3 comparator differential input.
FB3	Output	This is a channel 3 comparator feedback output.
IOUTC	Output	This is the differential current output of DAC.
IOUT	Output	This is the differential current output of DAC.
REXT	Input	This is for external reference resistor of DAC.
IFLT	Input	This is the pin for low path filters of PLL.

M16C/6S Group Memory

# **Memory**

Figure 1.2.1 is a memory map of the M16C/6S group. The address space extends the 1M bytes from address 0000016 to FFFFF16.

The internal ROM is allocated in a lower address direction beginning with address FFFF16. For example, a 96-Kbyte internal ROM is allocated to the addresses from E800016 to FFFF16.

The fixed interrupt vector table is allocated to the addresses from FFFDC16 to FFFFF16. Therefore, store the start address of each interrupt routine here.

The internal RAM is allocated in an upper address direction beginning with address 0040016. For example, a 24-Kbytes internal RAM is allocated to the addresses from 0040016 to 063FF16. In addition to storing data, the internal RAM also stores the stack used when calling subroutines and when interrupts are generated.

The SRF is allocated to the addresses from 0000016 to 003FF16. Peripheral function control registers are located here. Of the SFR, any area which has no functions allocated is reserved for future use and cannot be used by users.

The special page vector table is allocated to the addresses from FFE0016 to FFFDB16. This vector is used by the JMPS or JSRS instruction. For details, refer to the "M16C/60 and M16C/20 Series Software Manual."

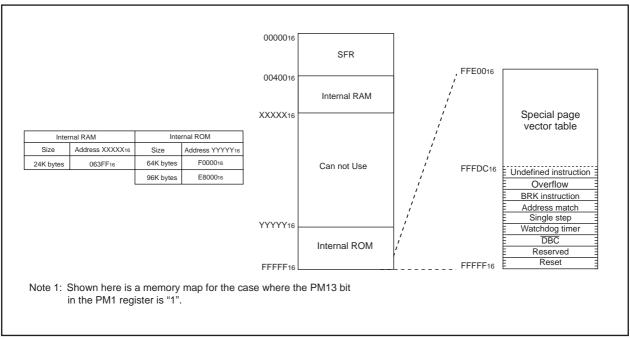

Figure 1.2.1. Memory Map

# **Central Processing Unit (CPU)**

Figure 1.3.1 shows the CPU registers. The CPU has 13 registers. Of these, R0, R1, R2, R3, A0, A1 and FB comprise a register bank. There are two register banks.

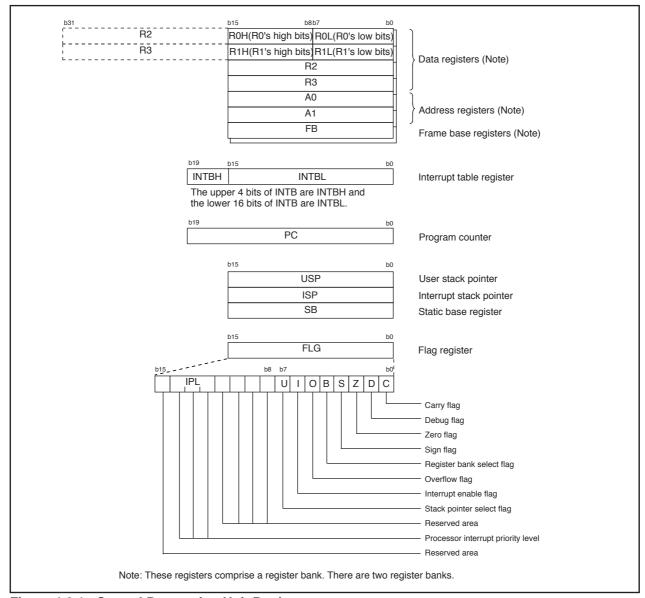

Figure 1.3.1. Central Processing Unit Register

# (1) Data Registers (R0, R1, R2 and R3)

The R0 register consists of 16 bits, and is used mainly for transfers and arithmetic/logic operations. R1 to R3 are the same as R0.

The R0 register can be separated between high (R0H) and low (R0L) for use as two 8-bit data registers. R1H and R1L are the same as R0H and R0L. Conversely, R2 and R0 can be combined for use as a 32-bit data register (R2R0). R3R1 is the same as R2R0.

#### (2) Address Registers (A0 and A1)

The register A0 consists of 16 bits, and is used for address register indirect addressing and address register relative addressing. They also are used for transfers and logic/logic operations. A1 is the same as A0.

In some instructions, registers A1 and A0 can be combined for use as a 32-bit address register (A1A0).

# (3) Frame Base Register (FB)

FB is configured with 16 bits, and is used for FB relative addressing.

## (4) Interrupt Table Register (INTB)

INTB is configured with 20 bits, indicating the start address of an interrupt vector table.

# (5) Program Counter (PC)

PC is configured with 20 bits, indicating the address of an instruction to be executed.

# (6) User Stack Pointer (USP) and Interrupt Stack Pointer (ISP)

Stack pointer (SP) comes in two types: USP and ISP, each configured with 16 bits. Your desired type of stack pointer (USP or ISP) can be selected by the U flag of FLG.

## (7) Static Base Register (SB)

SB is configured with 16 bits, and is used for SB relative addressing.

## (8) Flag Register (FLG)

FLG consists of 11 bits, indicating the CPU status.

### Carry Flag (C Flag)

This flag retains a carry, borrow, or shift-out bit that has occurred in the arithmetic/logic unit.

#### Debug Flag (D Flag)

The D flag is used exclusively for debugging purpose. During normal use, it must be set to "0".

#### Zero Flag (Z Flag)

This flag is set to "1" when an arithmetic operation resulted in 0; otherwise, it is "0".

#### Sign Flag (S Flag)

This flag is set to "1" when an arithmetic operation resulted in a negative value; otherwise, it is "0".

# • Register Bank Select Flag (B Flag)

Register bank 0 is selected when this flag is "0"; register bank 1 is selected when this flag is "1".

#### Overflow Flag (O Flag)

This flag is set to "1" when the operation resulted in an overflow; otherwise, it is "0".

#### • Interrupt Enable Flag (I Flag)

This flag enables a maskable interrupt.

Maskable interrupts are disabled when the I flag is "0", and are enabled when the I flag is "1". The I flag is cleared to "0" when the interrupt request is accepted.

### Stack Pointer Select Flag (U Flag)

ISP is selected when the U flag is "0"; USP is selected when the U flag is "1".

The U flag is cleared to "0" when a hardware interrupt request is accepted or an INT instruction for software interrupt Nos. 0 to 31 is executed.

#### Processor Interrupt Priority Level (IPL)

IPL is configured with three bits, for specification of up to eight processor interrupt priority levels from level 0 to level 7.

If a requested interrupt has priority greater than IPL, the interrupt is enabled.

#### Reserved Area

When write to this bit, write "0". When read, its content is indeterminate.

# Reset

There are four types of resets: a hardware reset, a software reset, an watchdog timer reset, and an oscillation stop detection reset.

#### **Hardware Reset**

A reset is applied using the RESET pin. When an "L" signal is applied to the RESET pin while the power supply voltage is within the recommended operating condition, the pins are initialized (see Table 1.5.1). The oscillation circuit is initialized and the main clock starts oscillating. When the input level at the RESET pin is released from "L" to "H", the CPU and SFR are initialized, and the program is executed starting from the address indicated by the reset vector. The internal RAM is not initialized. If the RESET pin is pulled "L" while writing to the internal RAM, the internal RAM becomes indeterminate.

Figure 1.5.1 shows the example reset circuit. Figure 1.5.2 shows the reset sequence. Table 1.5.1 shows the statuses of the other pins while the RESET pin is "L". Figure 1.5.3 shows the CPU register status after reset. Refer to "SFR" for SFR status after reset.

- 1. When the power supply is stable
- (1) Apply an "L" signal to the RESET pin.
- (2) Supply a clock for 20 cycles or more to the XIN pin.
- (3) Apply an "H" signal to the  $\overline{\text{RESET}}$  pin.
- 2. Power on
- (1) Apply an "L" signal to the RESET pin.
- (2) Let the power supply voltage increase until it meets the recommended operating condition.
- (3) Wait td(P-R) or more until the internal power supply stabilizes.
- (4) Supply a clock for 20 cycles or more to the XIN pin.
- (5) Apply an "H" signal to the RESET pin.

#### **Software Reset**

When the PM03 bit in the PM0 register is set to "1" (microcomputer reset), the microcomputer has its pins, CPU, and SFR initialized. Then the program is executed starting from the address indicated by the reset vector.

Select the main clock for the CPU clock source, and set the PM03 bit to "1" with main clock oscillation satisfactorily stable.

At software reset, some SFR's are not initialized. Refer to "SFR". Also, since the PM01 to PM00 bits in the PM0 register are not initialized, the processor mode remains unchanged.

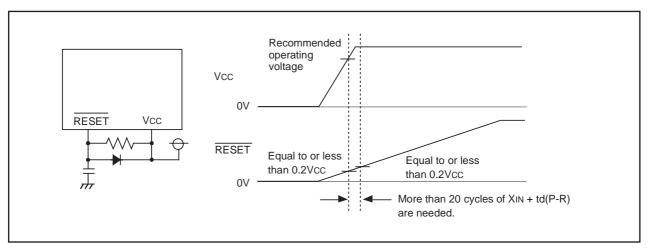

Figure 1.5.1. Example Reset Circuit

# **Watchdog Timer Reset**

Where the PM12 bit in the PM1 register is "1" (reset when watchdog timer underflows), the microcomputer initializes its pins, CPU and SFR if the watchdog timer underflows. Then the program is executed starting from the address indicated by the reset vector.

At watchdog timer reset, some SFR's are not initialized. Refer to "SFR". Also, since the PM01 to PM00 bits in the PM0 register are not initialized, the processor mode remains unchanged.

#### **Oscillation Stop Detection Reset**

Where the CM27 bit in the CM2 register is "0" (reset at oscillation stop detection), the microcomputer initializes its pins, CPU and SFR, coming to a halt if it detects main clock oscillation circuit stop. Refer to the section "oscillation stop, re-oscillation detection function".

At oscillation stop detection reset, some SFR's are not initialized. Refer to the section "SFR". Also, since the PM01 to PM00 bits in the PM0 register are not initialized, the processor mode remains unchanged.

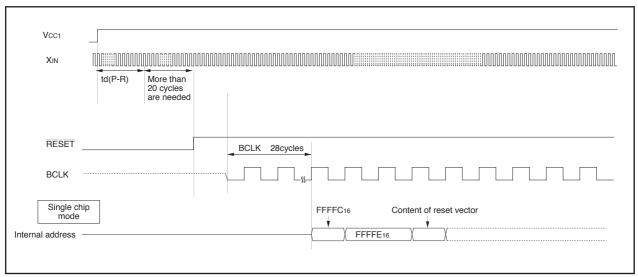

Figure 1.5.2. Reset Sequence

Table 1.5.1. Pin Status When RESET Pin Level is "L"

	Status	
Pin name	CNVss = Vss	
P15, P60 to P67, P70, P71, P73, P74, P76, P80, P81, P83, P84, P85, P90 to P92, TS	Input port	

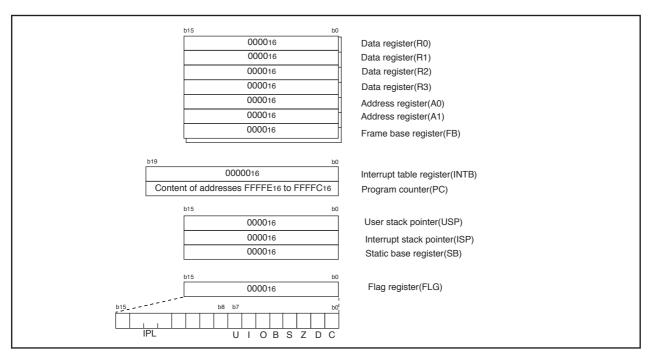

Figure 1.5.3. CPU Register Status After Reset

# **Processor Mode**

# (1) Setting Processor Modes

Processor mode is available only: single-chip mode.

Processor mode is set by using the CNVss pin and the PM01 to PM00 bits in the PM0 register.

Table 1.6.1 shows the processor mode after hardware reset. Table 1.6.2 shows the PM01 to PM00 bits set values and processor modes. For setting Single-chip mode. CNVss should be kept Vss level. And PM01 to PM00 of PM0 register should be set "00."

Table 1.6.1. Processor Mode After Hardware Reset

CNVss pin input level	Processor mode
Vss	Single-chip mode
Vcc	Flash Memory Mode

Table 1.6.2. PM01 to PM00 Bits Set Values and Processor Modes

PM01 to PM00 bits	Processor modes	
002	Single-chip mode	
012		
102	Must not be set	
112		

Figure 1.6.4 show the memory map in single chip mode.

# (2) Setting PLC Mode

PLC mode is simply set by putting P15 High level during RESET.

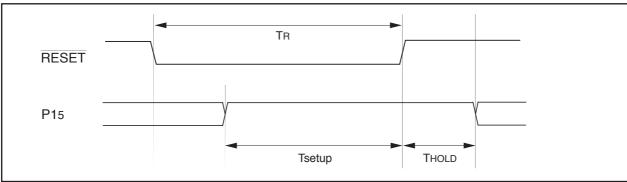

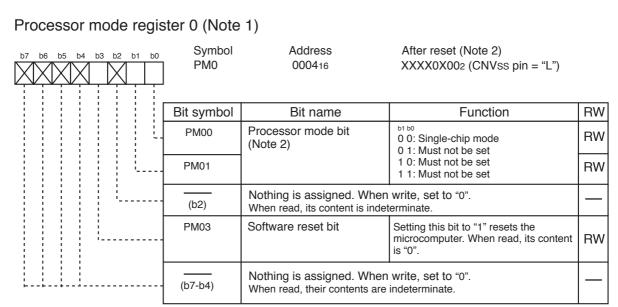

Figure 1.6.1. PLC mode by P15 simply setting

Table 1.6.3. RESET and P15 Input

	min	typ	max
TR	40us		_
Tset up	5us	_	_

Note 1: Write to this register after setting the PRC1 bit in the PRCR register to "1" (write enable).

Note 2: The PM01 to PM00 bits do not change at software reset, watchdog timer reset and oscillation stop detection reset.

Figure 1.6.2. PM0 Register

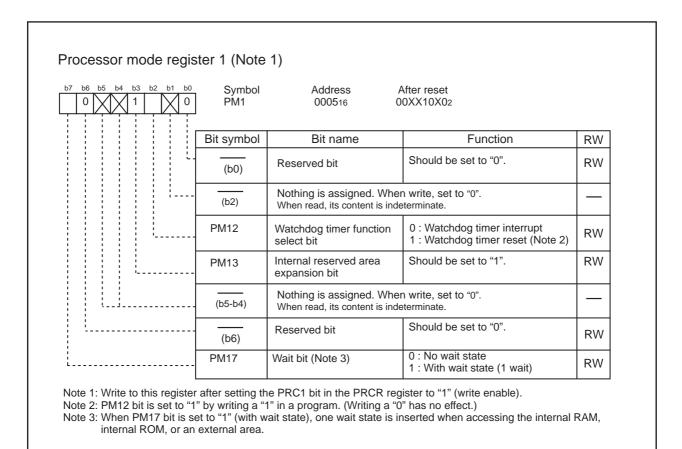

Figure 1.6.3. PM1 Register

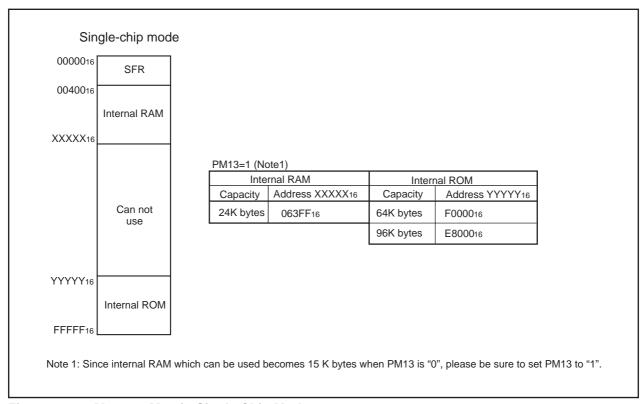

Figure 1.6.4. Memory Map in Single Chip Mode

# **Clock Generation Circuit**

The clock generation circuit contains two oscillator circuits as follows:

- (1) Main clock oscillation circuit
- (2) On-chip Oscillator (oscillation stop detect function)

Table 1.7.1 lists the clock generation circuit specifications. Figure 1.7.1 shows the clock generation circuit. Figures 1.7.2 to 1.7.5 show the clock-related registers.

**Table 1.7.1. Clock Generation Circuit Specifications** 

Item	Main clock oscillation circuit	On-chip Oscillator
Use of clock	CPU clock source     Peripheral function     clock source	CPU clock source     Peripheral function clock source
Clock frequency	5.12 MHz	About 1 MHz
Usable oscillator	Crystal oscillator (Note 1)	
Pins to connect oscillator	XIN, XOUT	
Oscillation stop, restart function	No	Presence
Oscillator status after reset	Oscillating	Stopped
Other	Externally derived clock can be input	

Note. Operating frequency must be  $5.12\ \text{MHz}$ , overall accuracy must be less than  $150\ \text{ppm}$ .

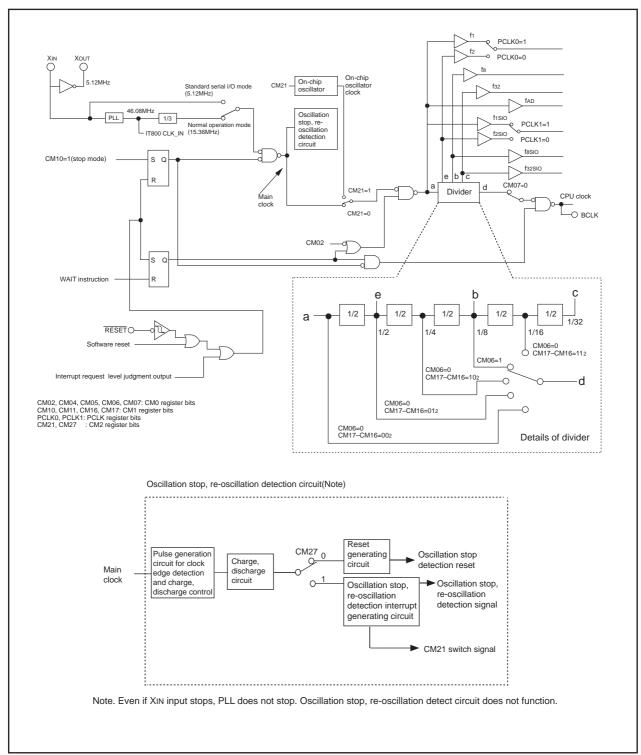

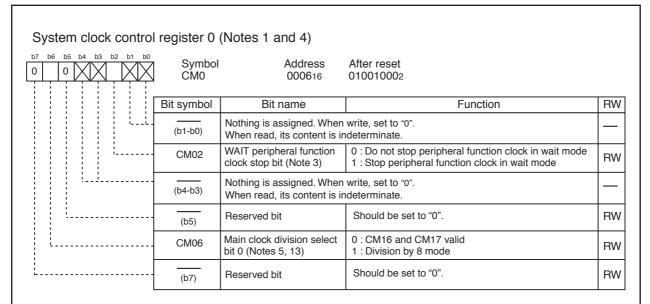

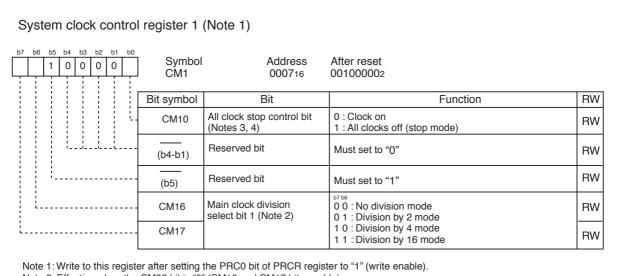

Figure 1.7.1. Clock Generation Circuit

- Note 1: Write to this register after setting the PRC0 bit of PRCR register to "1" (write enable).
- Note 2: When entering stop mode from high or middle speed mode, On-chip Oscillator mode or On-chip Oscillator low power mode, the CM06 bit is set to "1" (divide-by-8 mode).
- Note 3: When the PM21 bit of PM2 register is set to "1" (clock modification disable), writing to the CM02 bits has no effect.
- Note 4: To use the main clock as the clock source for the CPU clock, follow the procedure below.
  - (1) Wait until td(M-L) elapses or the main clock oscillation stabilizes, whichever is longer.
  - (2) Set the CM21 to "0".
- Note 5: During On-chip Oscillator low power dissipation mode, the divide-by-n value can be selected using the CM06 and CM17 to CM16 bits. To return to high or middle speed mode. however, set the CM06 bit to "1". before selecting the desired mode.

Figure 1.7.2. CM0 Register

Note 2: Effective when the CM06 bit is "0" (CM16 and CM17 bits enable).

Note 3: When the CM20 bit of CM2 register is set to "1" (oscillation stop, re-oscillation detection function enabled), do not set the CM10 bit to "1".

Note 4: When the PM21 bit of PM2 register is set to "1" (clock modification disable), writing to the CM10 bits has no effect.

When the PM22 bit of PM2 register is set to "1" (watchdog timer count source is On-chip Oscillator clock), writing to the CM10 bit has no effect.

Figure 1.7.3. CM1 Register

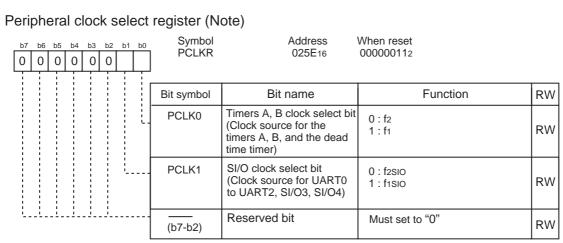

#### Symbol Address After reset 0 0 000C16 CM2 0X0000002(Note 10) Bit symbol Bit name **Function** RW 0: Oscillation stop, re-oscillation Oscillation stop, re-CM20 oscillation detection bit detection function disabled RW (Notes 7, 8, 9, 10) 1: Oscillation stop, re-oscillation detection function enabled 0: Main clock (On-chip Oscillator System clock select bit 2 CM21 turned off) (Notes 2, 3, 6, 10) RW 1: On-chip Óscillator clock (On-chip Oscillator oscillating) Oscillation stop, re-0: Main clock stop, re-oscillation CM22 oscillation detection flag not detected RW (Note 4) 1: Main clock stop, re-oscillation detected XIN monitor flag 0: Main clock oscillating CM23 RO 1: Main clock turned off (Note 5) Reserved bit Must set to "0" RW (b5-b4) Nothing is assigned. When write, set to "0". When read, its (b6) content is indeterminate. 0: Oscillation stop detection reset Operation select bit CM27 1: Oscillation stop, re-oscillation (when an oscillation stop RW re-oscillation is detected) detection interrupt (Note 10)

- Note 1: Write to this register after setting the PRC0 bit of PRCR register to "1" (write enable).
- Note 2: When the CM20 bit is "1" (oscillation stop, re-oscillation detection function enabled), the CM27 bit is "1" (oscillation stop, re-oscillation detection interrupt), and the CPU clock source is the main clock, the CM21 bit is set to "1" (On-chip Oscillator clock) if the main clock stop is detected.
- Note 3: If the CM20 bit is "1" and the CM23 bit is "1" (main clock turned off), do not set the CM21 bit to "0".
- Note 4: This bit becomes "1" at main clock stop detection and main clock re-oscillation detection. When this bit changes from "0" to "1", there arise oscillation stop, re-oscillation detection interrupt. Use this register to discriminate the causes for oscillation stop, re-oscillation detection interrupt and watchdog timer interrupt in the interrupt processing program. By writing "0" in the program, this bit becomes "0". (Even when "1" is written in the program, no change is identified for the bit. Also, this bit is not set to "0" where there occur oscillation stop, re-oscillation detection interrupt.) When the CM22 bit is "1", no oscillation stop, re-oscillation detection interrupt occur even if oscillation stop or re-oscillation is detected.
- Note 5: Read the CM23 bit in an oscillation stop, re-oscillation detection interrupt handling routine to determine the main clock status.
- Note 6: Effective when the CM07 bit of CM0 register is "0".

Oscillation stop detection register (Note 1)

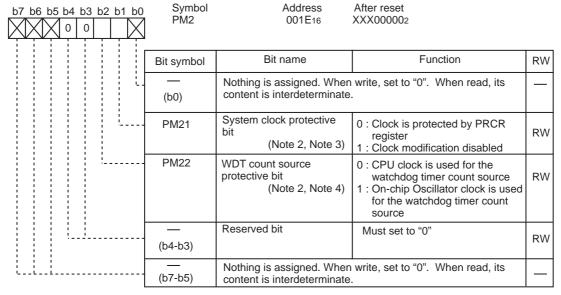

- Note 7: When the PM21 bit of PM2 register is "1" (clock modification disabled), writing to the CM20 bit has no effect
- Note 8: Set the CM20 bit to "0" (disable) before entering stop mode. After exiting stop mode, set the CM20 bit back to "1" (enable).
- Note 9: Set the CM20 bit to "0" (disable) before setting the CM05 bit of CM0 register.
- Note 10: The CM20, CM21 and CM27 bits do not change at oscillation stop detection reset.

Figure 1.7.4. CM2 Register

Note: Write to this register after setting the PRC0 bit of PRCR register to "1" (write enable).

# Processor mode register 2 (Note 1)

Note 1: Write to this register after setting the PRC1 bit of PRCR register to "1" (write enable).

Note 2: Once this bit is set to "1", it cannot be cleared to "0" in a program.

Note 3: Setting the PM21 bit to "1" results in the following conditions:

• The BCLK is not halted by executing the WAIT instruction.

• Writing to the following bits has no effect.

CM02 bit of CM0 register

CM05 bit of CM0 register (main clock is not halted)

CM07 bit of CM0 register

CM10 bit of CM1 register (stop mode is not entered)

CM11 bit of CM1 register

CM20 bit of CM2 register (oscillation stop, re-oscillation detection function settings do not change)

Note 4: Setting the PM22 bit to "1" results in the following conditions:

- The On-chip Oscillator starts oscillating, and the On-chip Oscillator clock becomes the watchdog timer count source.
- The CM10 bit of CM1 register is disabled against write. (Writing a "1" has no effect, nor is stop mode entered.)
- The watchdog timer does not stop when in wait mode or hold state.

Figure 1.7.5. PCLKR Register and PM2 Register

The following describes the clocks generated by the clock generation circuit.

## (1) Main Clock

Main clock is supplied by IT800 with a tripled clock of XIN (main clock oscillator).

This clock is used as the clock source for the CPU and peripheral function clocks. The main clock oscillator circuit is configured by connecting a resonator between the XIN and XOUT pins. The main clock oscillator circuit contains a feedback resistor. The main clock oscillator circuit may also be configured by feeding an externally generated clock to the XIN pin. Figure 1.7.6 shows the examples of main clock connection circuit.

After reset, the main clock divided by 8 is selected for the CPU clock.

Even if XIN input stops, main clock oscillator does not stop.

During stop mode, all clocks of internal M16C core including the main clock are turned off. Refer to "power control".

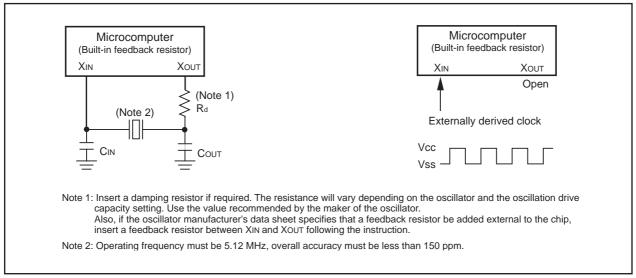

Figure 1.7.6. Examples of Main Clock Connection Circuit

# (3) On-chip Oscillator Clock

This clock, approximately 1 MHz, is supplied by a On-chip Oscillator. This clock is used as the clock source for the CPU and peripheral function clocks. In addition, if the PM22 bit of PM2 register is "1" (Onchip Oscillator clock for the watchdog timer count source), this clock is used as the count source for the watchdog timer.

After reset, the On-chip Oscillator clock is turned off. It is turned on by setting the CM21 bit of CM2 register to "1" (On-chip Oscillator clock), and is used as the clock source for the CPU and peripheral function clocks, in place of the main clock.

## **CPU Clock and Peripheral Function Clock**

Two type clocks: CPU clock to operate the CPU and peripheral function clocks to operate the peripheral functions.

## (1) CPU Clock and BCLK

These are operating clocks for the CPU and watchdog timer.

The clock source for the CPU clock can be chosen to be the main clock, or On-chip Oscillator clock.

If the main clock or On-chip Oscillator clock is selected as the clock source for the CPU clock, the selected clock source can be divided by 1 (undivided), 2, 4, 8 or 16 to produce the CPU clock. Use the CM06 bit in CM0 register and the CM17 to CM16 bits in CM1 register to select the divide-by-n value.

After reset, the main clock divided by 8 provides the CPU clock.

Note that when entering stop mode from high or middle speed mode or On-chip Oscillator mode, the CM06 bit of CM0 register is set to "1" (divide-by-8 mode).

# (2) Peripheral Function Clock(f1, f2, f8, f32, f1SIO, f2SIO, f8SIO, f32SIO)

These are operating clocks for the peripheral functions.

Of these, fi (i = 1, 2, 8, 32) and fisio are derived from the main clock, or On-chip Oscillator clock by dividing them by i. The clock fi is used for timers A, and fisio is used for serial I/O.

When the WAIT instruction is executed after setting the CM02 bit of CM0 register to "1" (peripheral function clock turned off during wait mode), or when the microcomputer is in low power dissipation mode, the fi, and fisio clocks are turned off.

#### **Power Control**

There are three power control modes. For convenience' sake, all modes other than wait and stop modes are referred to as normal operation mode here.

# (1) Normal Operation Mode

Normal operation mode is further classified into three modes.

In normal operation mode, because the CPU clock and the peripheral function clocks both are on, the CPU and the peripheral functions are operating. Power control is exercised by controlling the CPU clock frequency. The higher the CPU clock frequency, the greater the processing capability. The lower the CPU clock frequency, the smaller the power consumption in the chip. If the unnecessary oscillator circuits are turned off, the power consumption is further reduced.

Before the clock sources for the CPU clock can be switched over, the new clock source to which switched must be oscillating stably. If the new clock source is the main clock, allow a sufficient wait time in a program until it becomes oscillating stably.

Where the CPU clock source is changed from the On-chip Oscillator to the main clock, change the operation mode to the medium speed mode (divided by 8 mode) after the clock was divided by 8 (the CM06 bit of CM0 register was set to "1") in the On-chip Oscillator mode.

#### High-speed Mode

The main clock divided by 1 provides the CPU clock.

#### • Medium-speed Mode

The main clock divided by 2, 4, 8 or 16 provides the CPU clock.

#### On-chip Oscillator Mode

The On-chip Oscillator clock divided by 1 (undivided), 2, 4, 8 or 16 provides the CPU clock. The On-chip Oscillator clock is also the clock source for the peripheral function clocks.

Table 1.7.2. Setting Clock Related Bit and Modes

Madaa		CM2 register	CM1 register	CM0 register
Modes	Modes		CM17, CM16	CM06
High-speed	mode	0	002	0
Medium-	divided by 2	0	012	0
speed mode	divided by 4	0	102	0
mode	divided by 8	0	_	1
	divided by 16	0	112	0
On-chip	divided by 1	1	002	0
oscillator mode	divided by 2	1	012	0
	divided by 4	1	102	0
	divided by 8	1	_	1
	divided by 16	1	112	0

Note: The divide-by-n value can be selected the same way as in On-chip Oscillator mode.

## (2) Wait Mode

In wait mode, the CPU clock is turned off, so are the CPU (because operated by the CPU clock) and the watchdog timer. However, if the PM22 bit of PM2 register is "1" (On-chip Oscillator clock for the watchdog timer count source), the watchdog timer remains active. Because the main clock, and On-chip Oscillator clock are on, the peripheral functions using these clocks keep operating.

#### • Peripheral Function Clock Stop Function

If the CM02 bit is "1" (peripheral function clocks turned off during wait mode), the f1, f2, f8, f32, f1SIO, f8SIO, and f32SIO clocks are turned off when in wait mode, with the power consumption reduced that much.

#### • Entering Wait Mode

The microcomputer is placed into wait mode by executing the WAIT instruction.

#### Pin Status During Wait Mode

Table 1.7.3 lists pin status during wait mode

#### Exiting Wait Mode

The microcomputer is moved out of wait mode by a hardware reset or peripheral function interrupt. If the microcomputer is to be moved out of exit wait mode by a hardware reset, set the peripheral function interrupt priority ILVL2 to ILVL0 bits to "0002" (interrupts disabled) before executing the WAIT instruction.

The peripheral function interrupts are affected by the CM02 bit. If CM02 bit is "0" (peripheral function clocks not turned off during wait mode), all peripheral function interrupts can be used to exit wait mode. If CM02 bit is "1" (peripheral function clocks turned off during wait mode), the peripheral functions using the peripheral function clocks stop operating, so that only the peripheral functions clocked by external signals can be used to exit wait mode.

Table 1.7.4 lists the interrupts to exit wait mode.

#### Table 1.7.3. Pin Status During Wait Mode

Pin	Status	
I/O ports	Retains status before wait mode	

Table 1.7.4. Interrupts to Exit Wait Mode

Interrupt	CM02=0	CM02=1
Serial I/O interrupt	Can be used when operating with internal or external clock	Can be used when operating with external clock
Timer A interrupt	Can be used in all modes	Can be used in event counter mode
INT interrupt	Can be used	Can be used

If the microcomputer is to be moved out of wait mode by a peripheral function interrupt, set up the following before executing the WAIT instruction.

- 1. In the ILVL2 to ILVL0 bits of interrupt control register, set the interrupt priority level of the periph eral function interrupt to be used to exit wait mode.
  - Also, for all of the peripheral function interrupts not used to exit wait mode, set the ILVL2 to ILVL0 bits to "0002" (interrupt disable).
- 2. Set the I flag to "1".
- Enable the peripheral function whose interrupt is to be used to exit wait mode.
   In this case, when an interrupt request is generated and the CPU clock is thereby turned on, an interrupt routine is executed.

The CPU clock turned on when exiting wait mode by a peripheral function interrupt is the same CPU clock that was on when the WAIT instruction was executed.

## (3) Stop Mode

In stop mode, all the M16C core's internal oscillator circuits are turned off, so are the CPU clock and the peripheral function clocks. Therefore, the CPU and the peripheral functions clocked by these clocks stop operating.

However, the peripheral functions clocked by external signals keep operating. The following interrupts can be used to exit stop mode.

- INT interrupt
- Timer A, interrupt (when counting external pulses in event counter mode)
- · Serial I/O interrupt (when external clock is selected)

#### • Entering Stop Mode

The microcomputer is placed into stop mode by setting the CM10 bit of CM1 register to "1" (all clocks turned off). At the same time, the CM06 bit of CM0 register is set to "1" (divide-by-8 mode). Before entering stop mode, set the CM20 bit to "0" (oscillation stop, re-oscillation detection function disable).

#### Pin Status in Stop Mode

Table 1.7.5 lists pin status during stop mode

#### Exiting Stop Mode

The microcomputer is moved out of stop mode by a hardware reset or peripheral function interrupt. If the microcomputer is to be moved out of stop mode by a hardware reset, set the peripheral function interrupt priority ILVL2 to ILVL0 bits to "0002" (interrupts disable) before setting the CM10 bit to "1". If the microcomputer is to be moved out of stop mode by a peripheral function interrupt, set up the following before setting the CM10 bit to "1".

- 1. In the ILVL2 to ILVL0 bits of interrupt control register, set the interrupt priority level of the peripheral function interrupt to be used to exit stop mode.
  - Also, for all of the peripheral function interrupts not used to exit stop mode, set the ILVL2 to ILVL0 bits to "0002".
- 2. Set the I flag to "1".
- Enable the peripheral function whose interrupt is to be used to exit stop mode.
   In this case, when an interrupt request is generated and the CPU clock is thereby turned on, an interrupt service routine is executed.

Which CPU clock will be used after exiting stop mode by a peripheral function is determined by the CPU clock that was on when the microcomputer was placed into stop mode as follows:

If the CPU clock before entering stop mode was derived from the main clock: main clock divide-by-8 If the CPU clock before entering stop mode was derived from the On-chip Oscillator clock: On-chip Oscillator clock divide-by-8

Table 1.7.5. Pin Status in Stop Mode

Pin	Status	
I/O ports	Retains status before stop mode	

Reset WAIT CPU operation stopped All oscillators stopped instruction (Note 1) CM10=1 Medium-speed mode (divided-by-8 mode) Wait mode Stop mode Interrupt Interrupt WAIT instruction (Note 1) High-speed, medium-Stop mode Wait mode speed mode Interrupt CM10=1 WAIT instruction CM10=1 (Note 1) On-chip Oscillator mode Wait mode Stop mode Interrupt Interrupt (Note 2) Normal mode Note 1: When the PM21 bit = 0 (system clock protective function unused). Note 2: The On-chip Oscillator clock divided by 8 provides the CPU clock.

Note 3: Write to the CM0 register and CM1 register simultaneously by accessing in word units while CM21=0 (On-chip Oscillator turned off).

Figure 1.7.7 shows the state transition from normal operation mode to stop mode and wait mode.

Figure 1.7.7. State Transition to Stop Mode and Wait Mode

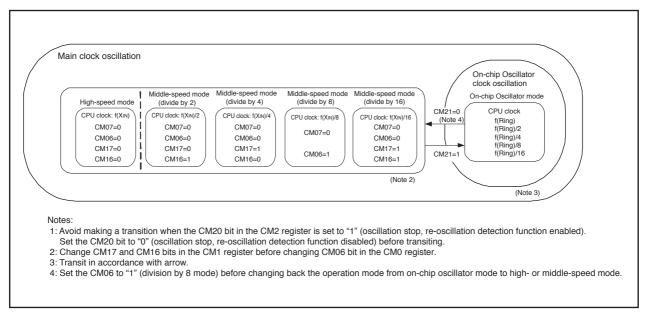

Figure 1.7.8. State Transition in Normal Mode

Table 1.7.6. Allowed Transition and Setting

		State after transition				
		High-speed mode, middle-speed mode	On-chip Oscillator mode	Stop mode	Wait mode	
0	High-speed mode, middle-speed mode	See Table A	(7)	(8)1	(9)	
state	On-chip Oscillator mode	(6)2	See Table A	(8)1	(9)	
Current state	Stop mode	(10) <sup>3</sup>	(10) <sup>3</sup>			
O	Wait mode	(10)	(10)			

--: Cannot transit

Table 1. State Transition with Main Clock Division Ration in High- or Middle-speed Mode

	and On-Chip Oscillator Wode.					
			State	after trans	ition	
		No	Divided	Divided	Divided	Divided
		division	by 2	by 4	by 8	by 16
	No division		(2)	(3)	(5)	(4)
<u>+</u> .	Divided by 2	(1)		(3)	(5)	(4)
Current	Divided by 4	(1)	(2)		(5)	(4)
ر آ	Divided by 8	(1)	(2)	(3)		(4)
	Divided by 16	(1)	(2)	(3)	(5)	/

Table B. Setting and Operation

	Setting	Operation
(1)	CM06 = 0, CM17 = 0 , CM16 = 0	CPU clock no division mode
(2)	CM06 = 0, CM17 = 0 , CM16 = 1	CPU clock division by 2 mode
(3)	CM06 = 0, CM17 = 1 , CM16 = 0	CPU clock division by 4 mode
(4)	CM06 = 0, CM17 = 1 , CM16 = 1	CPU clock division by 16 mode
(5)	CM06 = 1	CPU clock division by 8 mode
(6)	CM21 = 0	Main clock
(7)	CM21 = 1	On-chip Oscillator clock selected
(8)	CM10 = 1	Transition to stop mode
(9)	wait	Transition to wait mode
(10)	Hardware interrupt	Exit stop mode or wait mode

Notes:

1. Avoid making a transition when the CM21 bit is set to "1" (oscillation stop, re-oscillation detection function enabled). Set the CM21 bit to "0" (oscillation stop, re-oscillation detection function disabled) before transiting.

2. Set the CM06 bit to "1" (division by 8 mode) before transiting from On-chip Oscillator mode to high- or middle-speed mode.

3. When exiting stop mode, the CM06 bit is set to "1" (division by 8 mode).

## **System Clock Protective Function**

When the main clock is selected for the CPU clock source, this function disables the clock against modifications in order to prevent the CPU clock from becoming halted by run-away.

If the PM21 bit of PM2 register is set to "1" (clock modification disabled), the following bits are protected against writes:

- · CM02 bit in CM0 register
- · CM10, CM11 bits in CM1 register
- CM20 bit in CM2 register

Before the system clock protective function can be used, the following register settings must be made:

- (1) Set the PRC1 bit of PRCR register to "1" (enable writes to PM2 register).
- (2) Set the PM21 bit of PM2 register to "1" (disable clock modification).
- (3) Set the PRC1 bit of PRCR register to "0" (disable writes to PM2 register).

Do not execute the WAIT instruction when the PM21 bit is "1".

## Oscillation Stop and Re-oscillation Detect Function

The oscillation stop and re-oscillation detect function is such that main clock oscillation circuit stop and re-oscillation are detected. At oscillation stop, re-oscillation detection, reset or oscillation stop, re-oscillation detection interrupt are generated. Which is to be generated can be selected using the CM27 bit of CM2 register. Main clock oscillator of M16C/6S does not stop even if Xin input stops. Oscillation stop re-oscillation detect circuit does not function.

M16C/6S Group Protection

## **Protection**

In the event that a program runs out of control, this function protects the important registers so that they will not be rewritten easily. Figure 1.8.1 shows the PRCR register. The following lists the registers protected by the PRCR register.

- Registers protected by PRC0 bit: CM0, CM1, CM2, and PCLKR registers
- Registers protected by PRC1 bit: PM0, PM1, PM2 registers
- Registers protected by PRC2 bit: PD9, S3C and S4C registers

Set the PRC2 bit to "1" (write enabled) and then write to any address, and the PRC2 bit will be cleared to "0" (write protected). The registers protected by the PRC2 bit should be changed in the next instruction after setting the PRC2 bit to "1". Make sure no interrupts or DMA transfers will occur between the instruction in which the PRC2 bit is set to "1" and the next instruction. The PRC0 and PRC1 bits are not automatically cleared to "0" by writing to any address. They can only be cleared in a program.

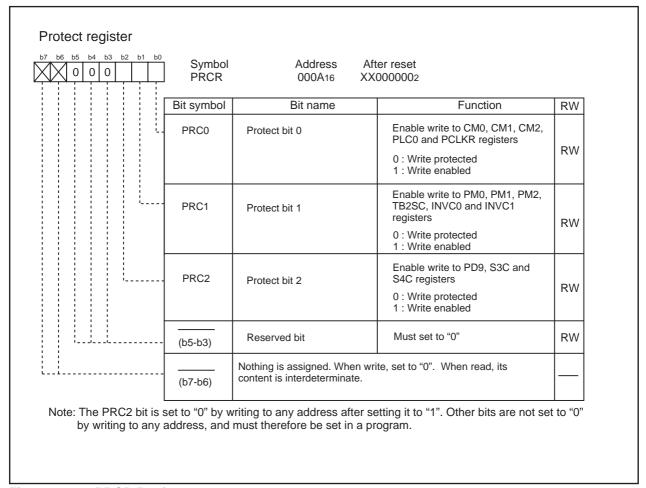

Figure 1.8.1. PRCR Register

# Interrupts

## Type of Interrupts

Figure 1.9.1 shows types of interrupts.

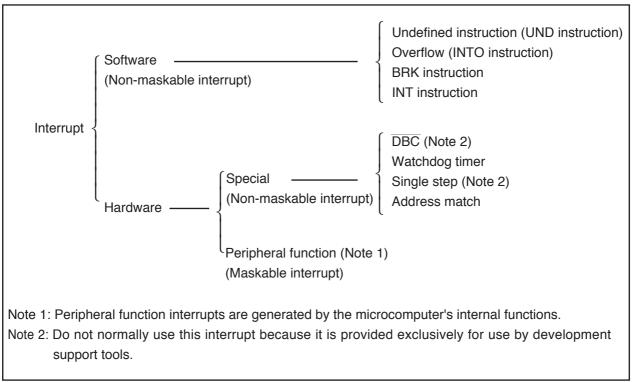

Figure 1.9.1. Interrupts

- Maskable Interrupt: An interrupt which can be enabled (disabled) by the interrupt enable flag (I flag) or whose interrupt priority can be changed by priority level.
- Non-maskable Interrupt: An interrupt which cannot be enabled (disabled) by the interrupt enable flag (I flag) or whose interrupt priority **cannot be changed** by priority level.

## Software Interrupts

A software interrupt occurs when executing certain instructions. Software interrupts are non-maskable interrupts.

#### Undefined Instruction Interrupt

An undefined instruction interrupt occurs when executing the UND instruction.

#### Overflow Interrupt

An overflow interrupt occurs when executing the INTO instruction with the O flag set to "1" (the operation resulted in an overflow). The following are instructions whose O flag changes by arithmetic: ABS, ADC, ADCF, ADD, CMP, DIV, DIVU, DIVX, NEG, RMPA, SBB, SHA, SUB

#### BRK Interrupt

A BRK interrupt occurs when executing the BRK instruction.

#### INT Instruction Interrupt

An INT instruction interrupt occurs when executing the INT instruction. Software interrupt Nos. 0 to 63 can be specified for the INT instruction. Because software interrupt Nos. 4 to 31 are assigned to peripheral function interrupts, the same interrupt routine as for peripheral function interrupts can be executed by executing the INT instruction.

In software interrupt Nos. 0 to 31, the U flag is saved to the stack during instruction execution and is cleared to "0" (ISP selected) before executing an interrupt sequence. The U flag is restored from the stack when returning from the interrupt routine. In software interrupt Nos. 32 to 63, the U flag does not change state during instruction execution, and the SP then selected is used.

#### **Hardware Interrupts**

Hardware interrupts are classified into two types — special interrupts and peripheral function interrupts.

#### (1) Special Interrupts

Special interrupts are non-maskable interrupts.

#### • DBC Interrupt

Do not normally use this interrupt because it is provided exclusively for use by development support tools.

#### Watchdog Timer Interrupt

Generated by the watchdog timer. Once a watchdog timer interrupt is generated, be sure to initialize the watchdog timer. For details about the watchdog timer, refer to the section "watchdog timer".

## • Oscillation Stop and Re-oscillation Detection Interrupt

Generated by the oscillation stop and re-oscillation detection function. For details about the oscillation stop detection function, refer to the section "clock generating circuit".

#### Single-step Interrupt

Do not normally use this interrupt because it is provided exclusively for use by development support tools.

#### Address Match Interrupt

An address match interrupt is generated immediately before executing the instruction at the address indicated by the RMAD0 to RMAD3 register that corresponds to one of the AIER register's AIER0 or AIER1 bit or the AIER2 register's AIER20 or AIER21 bit which is "1" (address match interrupt enabled). For details about the address match interrupt, refer to the section "address match interrupt".

#### (2) Peripheral Function Interrupts

Peripheral function interrupts are maskable interrupts and generated by the microcomputer's internal functions. The interrupt sources for peripheral function interrupts are listed in Table 1.9.1. For details about the peripheral functions, refer to the description of each peripheral function in this manual.

#### Interrupts and Interrupt Vector

One interrupt vector consists of 4 bytes. Set the start address of each interrupt routine in the respective interrupt vectors. When an interrupt request is accepted, the CPU branches to the address set in the corresponding interrupt vector. Figure 1.9.2 shows the interrupt vector.

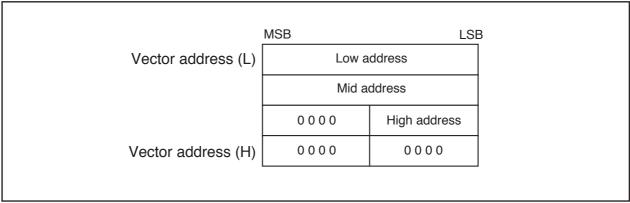

Figure 1.9.2. Interrupt Vector

#### Fixed Vector Tables

The fixed vector tables are allocated to the addresses from FFFDC16 to FFFFF16. Table 1.9.1 lists the fixed vector tables. In the flash memory version of microcomputer, the vector addresses (H) of fixed vectors are used by the ID code check function. For details, refer to the section "flash memory rewrite disabling function".

Table 1.9.1. Fixed Vector Tables

Interrupt source	Vector table addresses	Remarks	Reference
	Address (L) to address (H)		
Undefined instruction	FFFDC16 to FFFDF16	Interrupt on UND instruction	M16C/60, M16C/20
Overflow	FFFE016 to FFFE316	Interrupt on INTO instruction	series software
BRK instruction	FFFE416 to FFFE716	If the contents of address FFFE716 is FF16, program execution starts from the address shown by the vector in the relocatable vector table.	manual
Address match	FFFE816 to FFFEB16		Address match interrupt
Single step (Note)	FFFEC16 to FFFEF16		
Watchdog timer Oscillation stop and re-oscillation detection	FFFF016 to FFFF316		Watchdog timer  Clock generating circuit
DBC (Note)	FFFF416 to FFFF716		generaling eneals
— (Reserved)	FFFF816 to FFFFB16		
Reset	FFFFC16 to FFFFF16		Reset

Note: Do not normally use this interrupt because it is provided exclusively for use by development support tools.

#### • Relocatable Vector Tables

The 256 bytes beginning with the start address set in the INTB register comprise a reloacatable vector table area. Table 1.9.2 lists the relocatable vector tables. Setting an even address in the INTB register results in the interrupt sequence being executed faster than in the case of odd addresses.

Table 1.9.2. Relocatable Vector Tables

Interrupt source	Vector address (Note 1) Address (L) to address (H)	Software interrupt number	Reference
BRK instruction (Note 5)	+0 to +3 (000016 to 000316)	0	M16C/60, M16C/20
(Reserved)		1 to 3	series software manual
ĪNT3	+16 to +19 (001016 to 001316)	4	INT interrupt
(Reserved)	+20 to +23 (001416 to 001716)	5	
(Note 4) Timer B4, UART1 bus collision detect	+24 to +27 (001816 to 001B16)	6	Timer
(Note 4) Timer B3, UART0 bus collision detect	+28 to +31 (001C <sub>16</sub> to 001F <sub>16</sub> )	7	Serial I/O
SI/O4, INT5 (Note 2)	+32 to +35 (002016 to 002316)	8	INT interrupt
SI/O3, INT4 (Note 2)	+36 to +39 (002416 to 002716)	9	Serial I/O
UART 2 bus collision detection	+40 to +43 (002816 to 002B16)	10	Serial I/O
DMA0	+44 to +47 (002C16 to 002F16)	11	D144.0
DMA1	+48 to +51 (003016 to 003316)	12	DMAC
(Reserved)	+52 to +55 (003416 to 003716)	13	
(Reserved)	+56 to +59 (003816 to 003B16)	14	
UART2 transmit, NACK2 (Note 3)	+60 to +63 (003C16 to 003F16)	15	
UART2 receive, ACK2 (Note 3)	+64 to +67 (004016 to 004316)	16	
UART0 transmit, NACK0(Note 3)	+68 to +71 (004416 to 004716)	17	Coriol I/O
UART0 receive, ACK0 (Note 3)	+72 to +75 (004816 to 004B16)	18	Serial I/O
UART1 transmit, NACK1(Note 3)	+76 to +79 (004C16 to 004F16)	19	
UART1 receive, ACK1 (Note 3)	+80 to +83 (005016 to 005316)	20	
Timer A0	+84 to +87 (005416 to 005716)	21	
Timer A1	+88 to +91 (005816 to 005B16)	22	
Timer A2	+92 to +95 (005C16 to 005F16)	23	Timer
Timer A3	+96 to +99 (006016 to 006316)	24	
Timer A4	+100 to +103 (006416 to 006716)	25	
(Reserved)	+104 to +107 (006816 to 006B16)	26	
(Reserved)	+108 to +111 (006C 16 to 006F16)	27	
(Reserved)	+112 to +115 (0070 16 to 007316)	28

Note 1: Address relative to address in INTB.

Note 2: Set the IFSR register's IFSR6 and IFSR7 bits "0".

Note 3: During I<sup>2</sup>C mode, NACK and ACK interrupts comprise the interrupt source.

Note 4: Set the IFSR2A register's IFSR26 and IFSR27 bits "1".

Note 5: These interrupts cannot be disabled using the I flag.

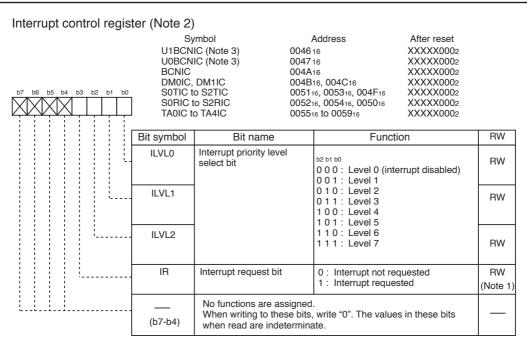

## **Interrupt Control**

The following describes how to enable/disable the maskable interrupts, and how to set the priority in which order they are accepted. What is explained here does not apply to nonmaskable interrupts.

Use the FLG register's I flag, IPL, and each interrupt control register's ILVL2 to ILVL0 bits to enable/disable the maskable interrupts. Whether an interrupt is requested is indicated by the IR bit in each interrupt control register.

Figure 1.9.3 shows the interrupt control registers.

Symbol

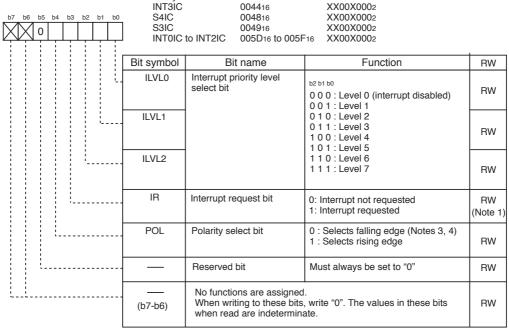

Note 1: This bit can only be reset by writing "0" (Do not write "1").

Note 2: To rewrite the interrupt control registers, do so at a point that does not generate the interrupt request for that register. For details, see the precautions for interrupts.

Address

After reset

Note 3: Use the IFSR2A register to select.

Note 1: This bit can only be reset by writing "0" (Do not write "1")

Note 2: To rewrite the interrupt control register, do so at a point that does not generate the interrupt request for that register. For details, see the precautions for interrupts.

Note 3: If the IFSR register's IFSRi bit (i = 0 to 5) is "1" (both edges), set the INTilC register's POL bit to "0 "(falling edge).

Note 4: Set the S3IC or S4IC register's POL bit to "0" (falling edge) when the IFSR register's IFSR6 bit = 0 (SI/O3 selected) or IFSR7 bit = 0 (SI/O4 selected), respectively.

Figure 1.9.3. Interrupt Control Registers

## I Flag

The I flag enables or disables the maskable interrupt. Setting the I flag to "1" (= enabled) enables the maskable interrupt. Setting the I flag to "0" (= disabled) disables all maskable interrupts.

#### **IR Bit**

The IR bit is set to "1" (= interrupt requested) when an interrupt request is generated. Then, when the interrupt request is accepted and the CPU branches to the corresponding interrupt vector, the IR bit is cleared to "0" (= interrupt not requested).

The IR bit can be cleared to "0" in a program. Note that do not write "1" to this bit.

#### ILVL2 to ILVL0 Bits and IPL

Interrupt priority levels can be set using the ILVL2 to ILVL0 bits.

Table 1.9.3 shows the settings of interrupt priority levels and Table 1.9.4 shows the interrupt priority levels enabled by the IPL.

The following are conditions under which an interrupt is accepted:

- · I flag = "1"
- · IR bit = "1"
- · interrupt priority level > IPL

The I flag, IR bit, ILVL2 to ILVL0 bits and IPL are independent of each other. In no case do they affect one another.

Table 1.9.3. Settings of Interrupt Priority Levels

ILVL2 to ILVL0 bits	Interrupt priority level	Priority order		
0002	Level 0 (interrupt disabled)			
0012	Level 1	Low		
0102	Level 2			
0112	Level 3			
1002	Level 4			
1012	Level 5			
1102	Level 6			
1112	Level 7	High		

Table 1.9.4. Interrupt Priority Levels
Enabled by IPL

IPL	Enabled interrupt priority levels	
0002	Interrupt levels 1 and above are enabled	
0012	Interrupt levels 2 and above are enabled	
0102	Interrupt levels 3 and above are enabled	
0112	Interrupt levels 4 and above are enabled	
1002	Interrupt levels 5 and above are enabled	
1012	Interrupt levels 6 and above are enabled	
1102	Interrupt levels 7 and above are enabled	
1112	All maskable interrupts are disabled	

## **Interrupt Sequence**

An interrupt sequence — what are performed over a period from the instant an interrupt is accepted to the instant the interrupt routine is executed — is described here.

If an interrupt occurs during execution of an instruction, the processor determines its priority when the execution of the instruction is completed, and transfers control to the interrupt sequence from the next cycle. If an interrupt occurs during execution of either the SMOVB, SMOVF, SSTR or RMPA instruction, the processor temporarily suspends the instruction being executed, and transfers control to the interrupt sequence.

The CPU behavior during the interrupt sequence is described below. Figure 1.9.4 shows time required for executing the interrupt sequence.

- (1) The CPU gets interrupt information (interrupt number and interrupt request priority level) by reading the address 0000016. Then it clears the IR bit for the corresponding interrupt to "0" (interrupt not requested).
- (2) The FLG register immediately before entering the interrupt sequence is saved to the CPU's internal temporary register<sup>(Note 1)</sup>.
- (3) The I, D and U flags in the FLG register become as follows:
  - The I flag is cleared to "0" (interrupts disabled).
  - The D flag is cleared to "0" (single-step interrupt disabled).
  - The U flag is cleared to "0" (ISP selected).
  - However, the U flag does not change state if an INT instruction for software interrupt Nos. 32 to 63 is executed.
- (4) The CPU's internal temporary register (Note 1) is saved to the stack.
- (5) The PC is saved to the stack.
- (6) The interrupt priority level of the accepted interrupt is set in the IPL.
- (7) The start address of the relevant interrupt routine set in the interrupt vector is stored in the PC.

After the interrupt sequence is completed, the processor resumes executing instructions from the start address of the interrupt routine.

Note: This register cannot be used by user.

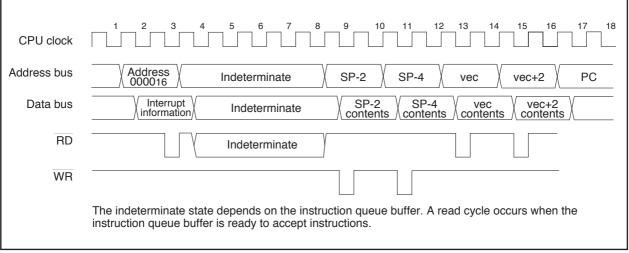

Figure 1.9.4. Time Required for Executing Interrupt Sequence

## **Interrupt Response Time**

Figure 1.9.5 shows the interrupt response time. The interrupt response or interrupt acknowledge time denotes a time from when an interrupt request is generated till when the first instruction in the interrupt routine is executed. Specifically, it consists of a time from when an interrupt request is generated till when the instruction then executing is completed ((a) in Figure 1.9.5) and a time during which the interrupt sequence is executed ((b) in Figure 1.9.5).

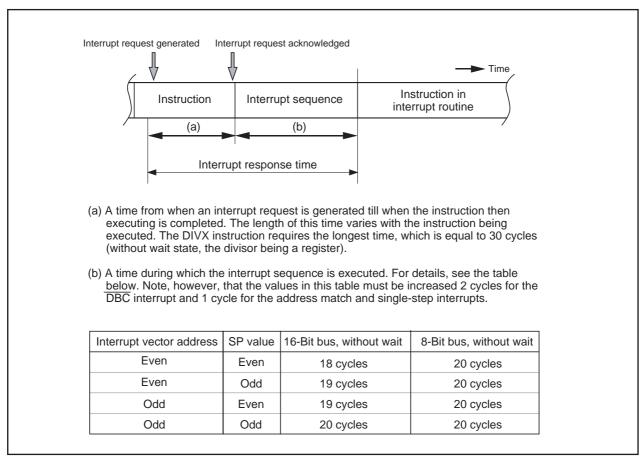

Figure 1.9.5. Interrupt response time

#### Variation of IPL when Interrupt Request is Accepted

When a maskable interrupt request is accepted, the interrupt priority level of the accepted interrupt is set in the IPL.

When a software interrupt or special interrupt request is accepted, one of the interrupt priority levels listed in Table 1.9.5 is set in the IPL. Shown in Table 1.9.5 are the IPL values of software and special interrupts when they are accepted.

Table 1.9.5. IPL Level That is Set to IPL When A Software or Special Interrupt Is Accepted

Interrupt sources	Level that is set to IPL	
Watchdog timer	7	
Software, address match, DBC, single-step	Not changed	

## **Saving Registers**

In the interrupt sequence, the FLG register and PC are saved to the stack.

At this time, the 4 high-order bits of the PC and the 4 high-order (IPL) and 8 low-order bits of the FLG register, 16 bits in total, are saved to the stack first. Next, the 16 low-order bits of the PC are saved. Figure 1.9.6 shows the stack status before and after an interrupt request is accepted.

The other necessary registers must be saved in a program at the beginning of the interrupt routine. Use the PUSHM instruction, and all registers except SP can be saved with a single instruction.

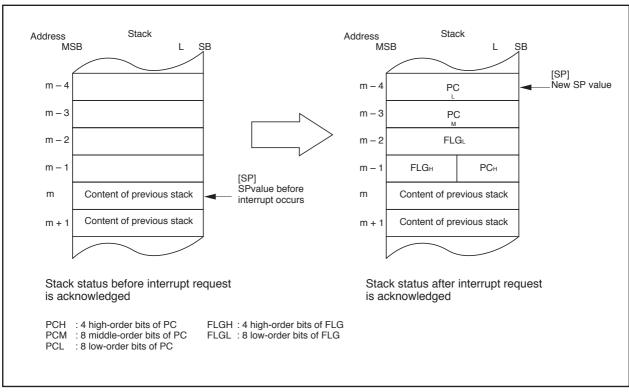

Figure 1.9.6. Stack Status Before and After Acceptance of Interrupt Request

The operation of saving registers carried out in the interrupt sequence is dependent on whether the SP<sup>(Note)</sup>, at the time of acceptance of an interrupt request, is even or odd. If the stack pointer <sup>(Note)</sup> is even, the FLG register and the PC are saved, 16 bits at a time. If odd, they are saved in two steps, 8 bits at a time. Figure 1.9.7 shows the operation of the saving registers.

Note: When any INT instruction in software numbers 32 to 63 has been executed, this is the SP indicated by the U flag. Otherwise, it is the ISP.

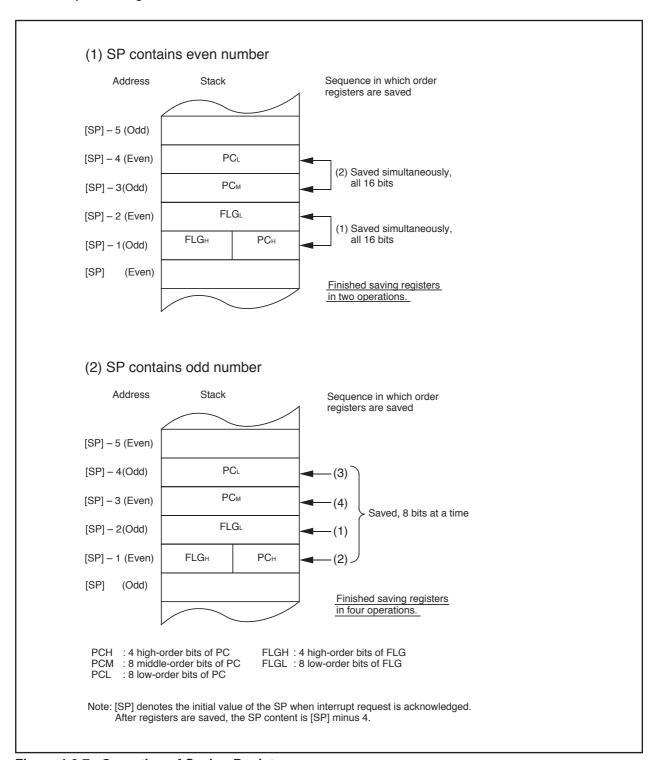

Figure 1.9.7. Operation of Saving Register

## **Returning from an Interrupt Routine**

The FLG register and PC in the state in which they were immediately before entering the interrupt sequence are restored from the stack by executing the REIT instruction at the end of the interrupt routine. Thereafter the CPU returns to the program which was being executed before accepting the interrupt request.

Return the other registers saved by a program within the interrupt routine using the POPM or similar instruction before executing the REIT instruction.

## **Interrupt Priority**

If two or more interrupt requests are generated while executing one instruction, the interrupt request that has the highest priority is accepted.

For maskable interrupts (peripheral functions), any desired priority level can be selected using the ILVL2 to ILVL0 bits. However, if two or more maskable interrupts have the same priority level, their interrupt priority is resolved by hardware, with the highest priority interrupt accepted.

The watchdog timer and other special interrupts have their priority levels set in hardware. Figure 1.9.8 shows the priorities of hardware interrupts.

Software interrupts are not affected by the interrupt priority. If an instruction is executed, control branches invariably to the interrupt routine.

Reset  $> \overline{\text{DBC}} > \text{WDT} > \text{Peripheral function} > \text{Single step} > \text{Address match}$ 

Figure 1.9.8. Hardware Interrupt Priority

## **Interrupt Priority Resolution Circuit**

The interrupt priority resolution circuit is used to select the interrupt with the highest priority among those requested.

Figure 1.9.9 shows the circuit that judges the interrupt priority level.

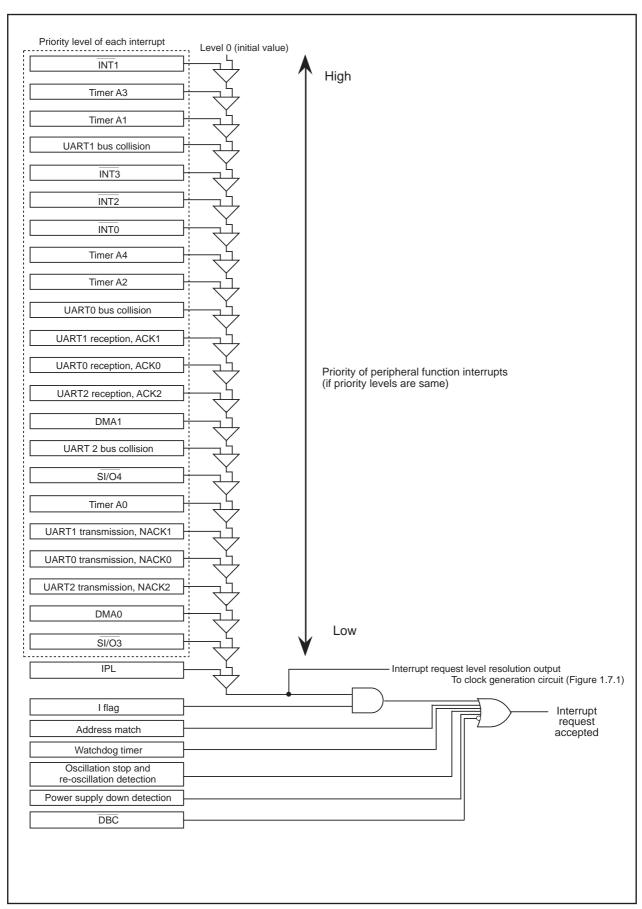

Figure 1.9.9. Interrupts Priority Select Circuit

## **INT** Interrupt

INTi interrupt (i=0 to 3) is triggered by the edges of external inputs. The edge polarity is selected using the IFSR register's IFSRi bit.

Figure 1.9.10 shows the IFSR and IFSR2A registers.

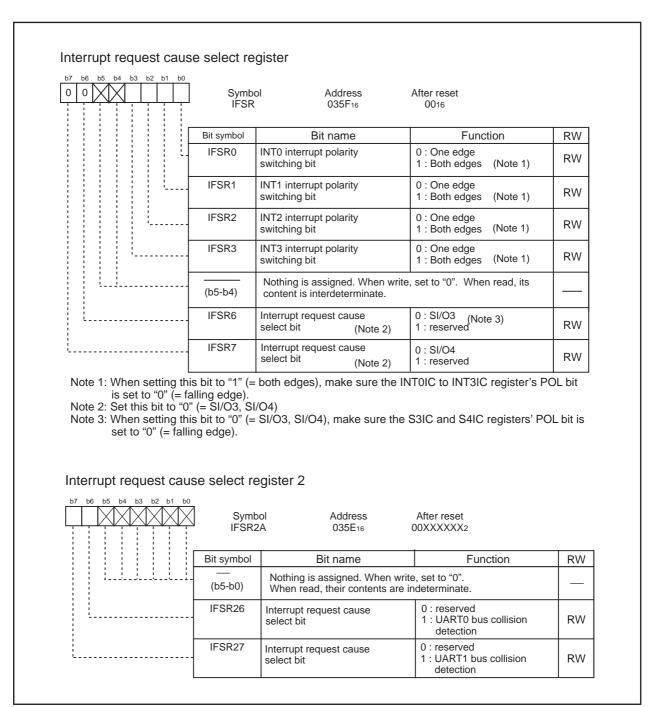

Figure 1.9.10. IFSR Register and IFSR2A Register

## **Address Match Interrupt**

An address match interrupt is generated immediately before executing the instruction at the address indicated by the RMADi register (i=0 to 3). Set the start address of any instruction in the RMADi register. Use the AIER register's AIER0 and AIER1 bits and the AIER2 register's AIER20 and AIER21 bits to enable or disable the interrupt. Note that the address match interrupt is unaffected by the I flag and IPL. For address match interrupts, the value of the PC that is saved to the stack area varies depending on the instruction being executed (refer to **Saving Registers**).

(The value of the PC that is saved to the stack area is not the correct return address.) Therefore, follow one of the methods described below to return from the address match interrupt.

- · Rewrite the content of the stack and then use the REIT instruction to return.
- Restore the stack to its previous state before the interrupt request was accepted by using the POP or similar other instruction and then use a jump instruction to return.

Table 1.9.6 shows the value of the PC that is saved to the stack area when an address match interrupt request is accepted.

Figure 1.9.11 shows the AIER, AIER2, and RMAD0 to RMAD3 registers.

Table 1.9.6. Value of the PC that is saved to the stack area when an address match interrupt request is accepted

Instruction at the Address Indicated by the RMADi Register						Value of the PC that is saved to the stack area

Address match interrupt 3	AIER21	RMAD3

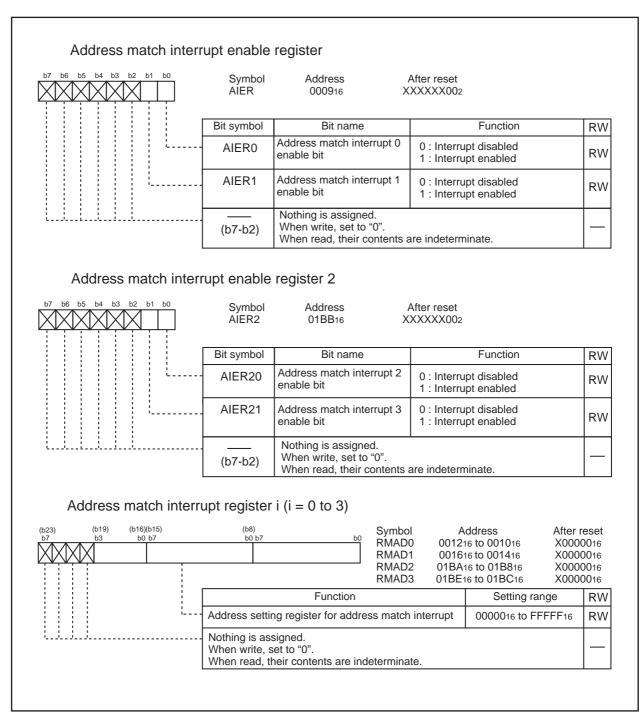

Figure 1.9.11. AIER Register, AIER2 Register and RMAD0 to RMAD3 Registers

## **Precautions for Interrupts**

## (1) Reading Address 0000016

• Do not read the address 0000016 in a program. When a maskable interrupt request is accepted, the CPU reads interrupt information (interrupt number and interrupt request priority level) from the address 0000016 during the interrupt sequence. At this time, the IR bit for the accepted interrupt is cleared to "0". If the address 0000016 is read in a program, the IR bit for the interrupt which has the highest priority among the enabled interrupts is cleared to "0". This causes a problem that the interrupt is canceled, or an unexpected interrupt is generated.

## (2) SP Setting

• Set any value in the SP before accepting an interrupt. The SP is cleared to '000016' after reset. Therefore, if an interrupt is accepted before setting any value in the SP, the program may go out of control.

## (3) INT Interrupt

- Either an "L" level or an "H" level of at least 250 ns width is necessary for the signal input to the INTo through INT3 pins regardless of the CPU clock.
- When the polarity of the INTo to INTo pins is changed, the IR bit is sometimes set to "1" (=interrupt requested). After changing the polarity, set the IR bit to "0" (=interrupt not requested). Figure 1.9.12 shows the procedure for changing the INT interrupt generate factor.

## (4) Watchdog Timer Interrupt

• Initialize the watchdog timer after the watchdog timer interrupt occurs.

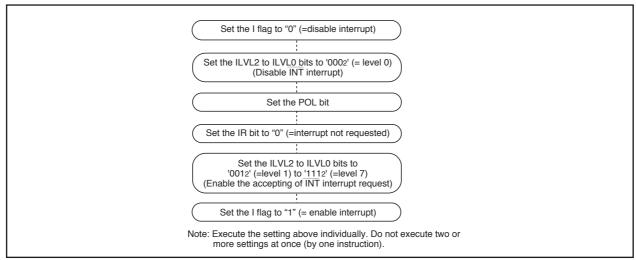

Figure 1.9.12. Switching Procedure for INT Interrupt Request

## (5) Modifying Interrupt Control Register

• Each interrupt control register can only be modified while no interrupt requests corresponding to that register are generated. If interrupt requests managed by any interrupt control register are likely to occur, disable the interrupts before modifying the register. A sample program is shown below.

To modify any interrupt control register after disabling interrupts, be careful with the instructions used.

#### Modifying other than the IR bit

If an interrupt request corresponding to that register is generated while executing the instruction, the IR bit may not be set to "1" (= interrupt requested), with the result that the interrupt request is ignored. If this presents a problem, use the following instructions to modify the register.

Instructions to use: AND, OR, BCLR, BSET

#### Modifying the IR bit

Even when the IR bit is cleared to "0" (= interrupt not requested), it may not actually be cleared to "0" depending on the instruction used. Therefore, use the MOV instruction to clear the IR bit.

```
Example 1:
INT_SWITCH1:
```

FCLR I ; Disable interrupts.

AND.B #00h, 0055h ; Set the TA0IC register to "0016".

NOP ; Four NOP instructions are required when using HOLD function.
NOP

FSET I ; Enable interrupts.

#### Example 2:

INT\_SWITCH2:

FCLR I ; Disable interrupts.

AND.B #00h, 0055h; Set the TAOIC register to "0016".

MOV.W MEM, RO ; Dummy read. FSET I ; Enable interrupts.

#### Example 3:

INT\_SWITCHS:

PUSHC FLG ; Push Rag register on to stack

FCLR | ; Disable interrupts.

AND.B #00h, 0055h ; Set the TAOIC register to "0016".

POPC FLG ; Enable interrupts.

Why the FSET linstruction is preceded by two NOP instructions (four when using HOLD function) in Example 1 and why the FSET linstruction is preceded by a dummy read in Example 2. This is to prevent the I flag from being set to "1" before writing to the interrupt control register for reasons of the instruction gives buffer.

M16C/6S Group Watchdog Timer

# **Watchdog Timer**

The watchdog timer is the function of detecting when the program is out of control. Therefore, we recommend using the watchdog timer to improve reliability of a system. The watchdog timer contains a 15-bit counter which counts down the clock derived by dividing the CPU clock using the prescaler. Whether to generate a watchdog timer interrupt request or apply a watchdog timer reset as an operation to be performed when the watchdog timer underflows after reaching the terminal count can be selected using the PM12 bit of PM1 register. The PM12 bit can only be set to "1" (reset). Once this bit is set to "1", it cannot be set to "0" (watchdog timer interrupt) in a program.

The pin, CPU and SFR initialized where the monitor timer underflows when the PM12 bit is "1" are the same as in software reset.

When the main clock is selected for CPU clock, the divide-by-N value for the prescaler can be chosen to be 16 or 128. The period of watchdog timer can be calculated as given below. The period of watchdog timer is, however, subject to an error due to the prescaler.

With main clock chosen for CPU clock

Prescaler dividing (16 or 128) X Watchdog timer count (32768)

Watchdog timer period =

CPU clock

For example, when CPU clock = 16 MHz and the divide-by-N value for the prescaler= 16, the watchdog timer period is approx. 32.8 ms.

The watchdog timer is initialized by writing to the WDTS register. The prescaler is initialized after reset. Note that the watchdog timer and the prescaler both are inactive after reset, so that the watchdog timer is activated to start counting by writing to the WDTS register.

In stop mode and wait mode, the watchdog timer and prescaler are stopped. Counting is resumed from the held value when the modes or state are released.

Figure 1.10.1 shows the block diagram of the watchdog timer. Figure 1.10.2 shows the watchdog timer-related registers.

#### · Count source protective mode

In this mode, a On-chip Oscillator clock is used for the watchdog timer count source. The watchdog timer can be kept being clocked even when CPU clock stops as a result of run-away.

Before this mode can be used, the following register settings are required:

- (1) Set the PRC1 bit of PRCR register to "1" (enable writes to PM1 and PM2 registers).
- (2) Set the PM12 bit of PM1 register to "1" (reset when the watchdog timer underflows).
- (3) Set the PM22 bit of PM2 register to "1" (On-chip Oscillator clock used for the watchdog timer count source).
- (4) Set the PRC1 bit of PRCR register to "0" (disable writes to PM1 and PM2 registers).
- (5) Write to the WDTS register (watchdog timer starts counting).

M16C/6S Group Watchdog Timer

Setting the PM22 bit to "1" results in the following conditions

 The On-chip Oscillator starts oscillating, and the On-chip Oscillator clock becomes the watchdog timer count source.

Watchdog timer period = Watchdog timer count (32768)
on-chip oscillator clock

- The CM10 bit of CM1 register is disabled against write. (Writing a "1" has no effect, nor is stop mode entered.)
- The watchdog timer does not stop when in wait mode.

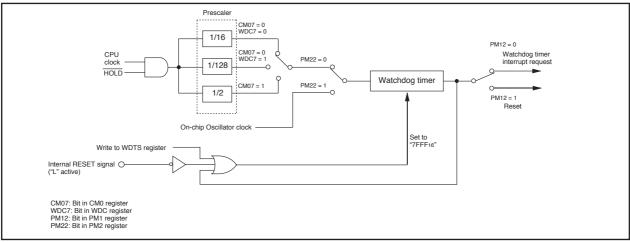

Figure 1.10.1. Watchdog Timer Block Diagram

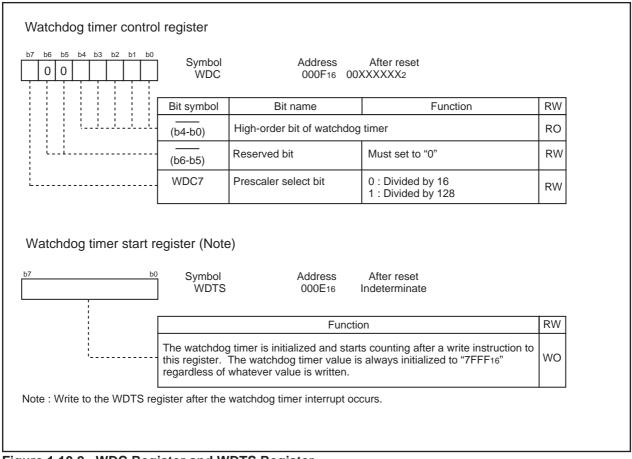

Figure 1.10.2. WDC Register and WDTS Register

## **DMAC**

The DMAC (Direct Memory Access Controller) allows data to be transferred without the CPU intervention. Two DMAC channels are included. Each time a DMA request occurs, the DMAC transfers one (8 or 16-bit) data from the source address to the destination address. The DMAC uses the same data bus as used by the CPU. Because the DMAC has higher priority of bus control than the CPU and because it makes use of a cycle steal method, it can transfer one word (16 bits) or one byte (8 bits) of data within a very short time after a DMA request is generated. Figure 1.11.1 shows the block diagram of the DMAC. Table 1.11.1 shows the DMAC specifications. Figures 1.11.2 to 1.11.4 show the DMAC-related registers.

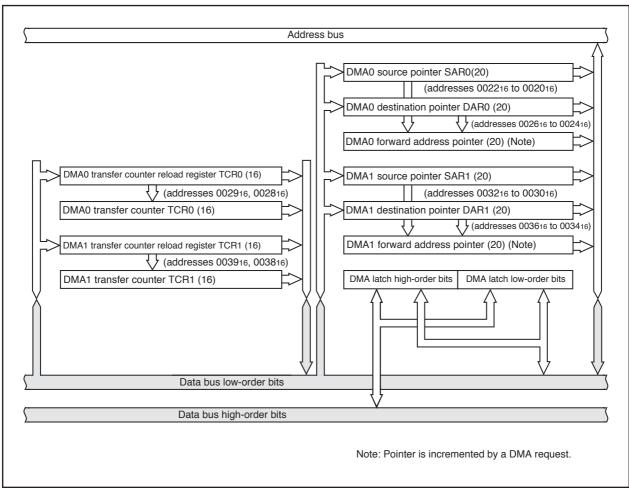

Figure 1.11.1. DMAC Block Diagram

A DMA request is generated by a write to the DMiSL register (i = 0-1)'s DSR bit, as well as by an interrupt request which is generated by any function specified by the DMiSL register's DMS and DSEL3–DSEL0 bits. However, unlike in the case of interrupt requests, DMA requests are not affected by the I flag and the interrupt control register, so that even when interrupt requests are disabled and no interrupt request can be accepted, DMA requests are always accepted. Furthermore, because the DMAC does not affect interrupts, the interrupt control register's IR bit does not change state due to a DMA transfer.

A data transfer is initiated each time a DMA request is generated when the DMiCON register's DMAE bit = "1" (DMA enabled). However, if the cycle in which a DMA request is generated is faster than the DMA transfer cycle, the number of transfer requests generated and the number of times data is transferred may not match. For details, refer to "DMA Requests".

M16C/6S Group **DMAC** 

Table 1.11.1. DMAC Specifications

Item		Specification	
No. of channels		2 (cycle steal method)	
Transfer memory space		From any address in the 1M bytes space to a fixed address	
		<ul> <li>From a fixed address to any address in the 1M bytes space</li> </ul>	
		From a fixed address to a fixed address

counter		SARi or the DARi pointer whichever is specified to be in the forward	
		direction and the DMAi transfer counter is reloaded with the value of the	
		DMAi transfer counter reload register.	

## Notes:

- 1. DMA transfer is not effective to any interrupt. DMA transfer is affected neither by the I flag nor by the interrupt control register.
- 2. The selectable causes of DMA requests differ with each channel.
- 3. Make sure that no DMAC-related registers (addresses 002016-003F16) are accessed by the DMAC.

RENESAS

## DMAi control register(i=0,1)

Note 1: The DMAS bit can be set to "0" by writing "0" in a program (This bit remains unchanged even if "1" is written). Note 2: At least one of the DAD and DSD bits must be "0" (address direction fixed).

Figure 1.11.3. DM1SL Register, DM0CON Register, and DM1CON Registers

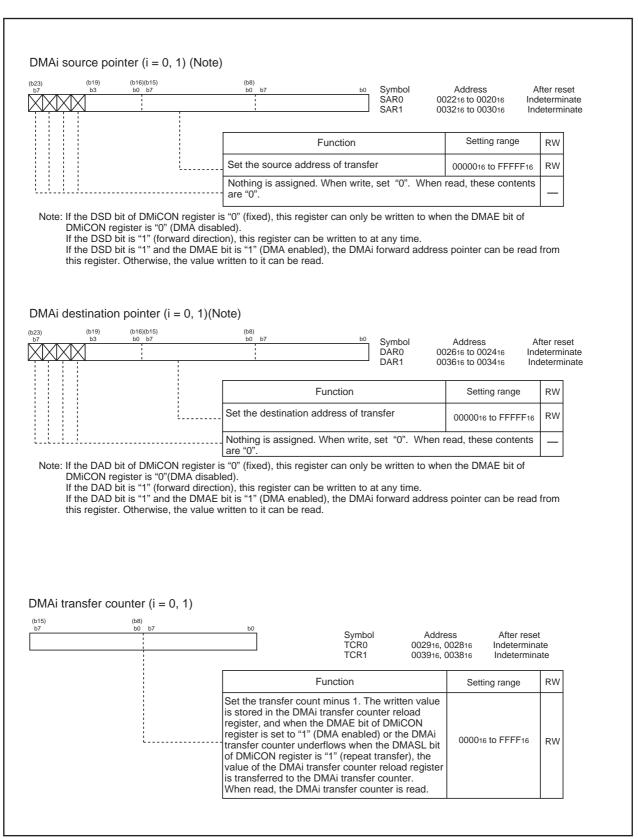

Figure 1.11.4. SAR0, SAR1, DAR0, DAR1, TCR0, and TCR1 Registers

# 1. Transfer Cycles

The transfer cycle consists of a memory or SFR read (source read) bus cycle and a write (destination write) bus cycle. The number of read and write bus cycles is affected by the source and destination addresses of transfer. Furthermore, the bus cycle itself is extended by a software wait or  $\overline{RDY}$  signal.

### (a) Effect of Source and Destination Addresses

If the transfer unit and data bus both are 16 bits and the source address of transfer begins with an odd address, the source read cycle consists of one more bus cycle than when the source address of transfer begins with an even address.

Similarly, if the transfer unit and data bus both are 16 bits and the destination address of transfer begins with an odd address, the destination write cycle consists of one more bus cycle than when the destination address of transfer begins with an even address.

# (b) Effect of Software Wait

For memory or SFR accesses in which one or more software wait states are inserted, the number of bus cycles required for that access increases by an amount equal to software wait states.

Figure 1.11.5 shows the example of the cycles for a source read. For convenience, the destination write cycle is shown as one cycle and the source read cycles for the different conditions are shown. In reality, the destination write cycle is subject to the same conditions as the source read cycle, with the transfer cycle changing accordingly. When calculating transfer cycles, take into consideration each condition for the source read and the destination write cycle, respectively. For example, when data is transferred in 16 bit units using an 8-bit bus ((2) in Figure 1.11.5), two source read bus cycles and two destination write bus cycles are required.

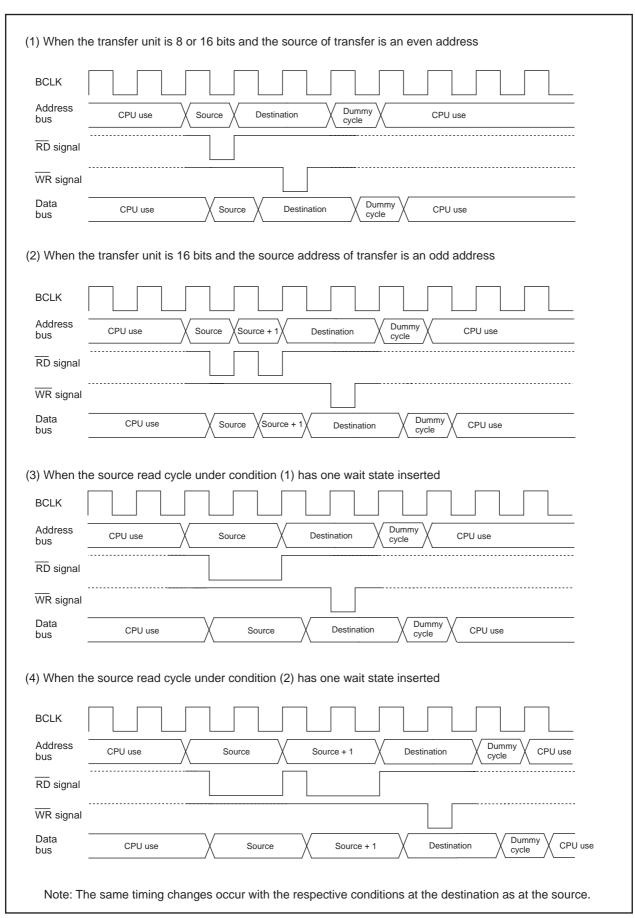

Figure 1.11.5. Transfer Cycles for Source Read

# 2. DMA Transfer Cycles

Any combination of even or odd transfer read and write addresses is possible. Table 1.11.2 shows the number of DMA transfer cycles. Table 1.11.3 shows the Coefficient j, k.

The number of DMAC transfer cycles can be calculated as follows:

No. of transfer cycles per transfer unit = No. of read cycles x j + No. of write cycles x k

Table 1.11.2. DMA Transfer Cycles

Transfer unit	Access address	No. of read	No. of write
		cycles	cycles
8-bit transfers	Even	1	1
(DMBIT= "1")	Odd	1	1
16-bit transfers	Even	1	1
(DMBIT= "0")	Odd	2	2

Table 1.11.3. Coefficient j, k

	Internal R	OM, RAM	SFR	
	No wait With wait		1-wait <sup>2</sup>	2-wait <sup>2</sup>
j	1	2	2	3
k	1	2	2	3

### Notes:

1. Depends on the set value of CSE register

2. Depends on the set value of PM20 bit in F

### 3. DMA Enable

When a data transfer starts after setting the DMAE bit in DMiCON register (i = 0, 1) to "1" (enabled), the DMAC operates as follows:

- (1) Reload the forward address pointer with the SARi register value when the DSD bit in DMiCON register is "1" (forward) or the DARi register value when the DAD bit of DMiCON register is "1" (forward).
- (2) Reload the DMAi transfer counter with the DMAi transfer counter reload register value.

If the DMAE bit is set to "1" again while it remains set, the DMAC performs the above operation. However, if a DMA request may occur simultaneously when the DMAE bit is being written, follow the steps below. Step 1: Write "1" to the DMAE bit and DMAS bit in DMiCON register simultaneously.

Step 2: Make sure that the DMAi is in an initial state as described above (1) and (2) in a program. If the DMAi is not in an initial state, the above steps should be repeated.

# 4. DMA Request

The DMAC can generate a DMA request as triggered by the cause of request that is selected with the DMS and DSEL3 to DSEL0 bits of DMiSL register (i = 0, 1) on either channel. Table 1.11.4 shows the timing at which the DMAS bit changes state.

Whenever a DMA request is generated, the DMAS bit is set to "1" (DMA requested) regardless of whether or not the DMAE bit is set. If the DMAE bit was set to "1" (enabled) when this occurred, the DMAS bit is set to "0" (DMA not requested) immediately before a data transfer starts. This bit cannot be set to "1" in a program (it can only be set to "0").

The DMAS bit may be set to "1" when the DMS or the DSEL3 to DSEL0 bits change state. Therefore, always be sure to set the DMAS bit to "0" after changing the DMS or the DSEL3 to DSEL0 bits.

Because if the DMAE bit is "1", a data transfer starts immediately after a DMA request is generated, the DMAS bit in almost all cases is "0" when read in a program. Read the DMAE bit to determine whether the DMAC is enabled.

Table 1.11.4. Timing at Which the DMAS Bit Changes State

DMA factor	DMAS bit of the DMiCON register		
DIVIA Idoloi	Timing at which the bit is set to "1"	Timing at which the bit is set to "0"	
Software trigger	When the DSR bit of DMiCON register is set to "1"	Immediately before a data transfer starts     When set by writing "0" in a program	
Peripheral function	When the interrupt control register for the peripheral function that is selected by the DSEL3 to DSEL0 and DMS bits of DMiCON register has its IR bit set to "1"		

# **Channel Priority and DMA Transfer Timing**

If both DMA0 and DMA1 are enabled and DMA transfer request signals from DMA0 and DMA1 are detected active in the same sampling period (one period from a falling edge to the next falling edge of BCLK), the DMAS bit on each channel is set to "1" (DMA requested) at the same time. In this case, the DMA requests are arbitrated according to the channel priority, DMA0 > DMA1. The following describes DMAC operation when DMA0 and DMA1 requests are detected active in the same sampling period. Figure 1.11.6 shows an example of DMA transfer effected by external factors.

In Figure 1.11.6, because DMA0 and DMA1 requests occurred at the same time, DMA0 which has higher channel priority is accepted first and a DMA transfer on it starts. When DMA0 finishes one transfer unit, it relinquishes control of the bus to the CPU, and when the CPU finishes one bus access, DMA1 starts a transfer next and after completion of one transfer unit, returns control of the bus to the CPU.

Note that because there is only one DMAS bit on each channel, the number of times DMA is requested cannot be counted. Therefore, even if multiple DMA requests occurred before gaining control of the bus as in the case of DMA1 in Figure 1.11.6, the DMAS bit is set to "0" when control of the bus is gained and after completion of one transfer unit, control of the bus is returned to the CPU.

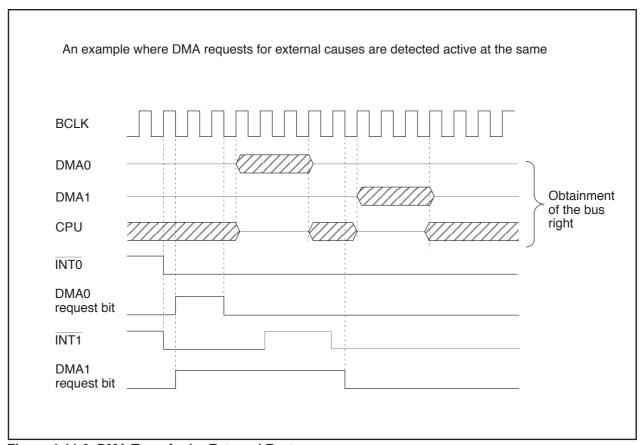

Figure 1.11.6. DMA Transfer by External Factors

# **Timers**

Five 16-bit timers, each capable of operating independently of the others. The count source for each timer acts as a clock, to control such timer operations as counting, reloading, etc. Figures 1.12.1 show block diagrams of timer A.

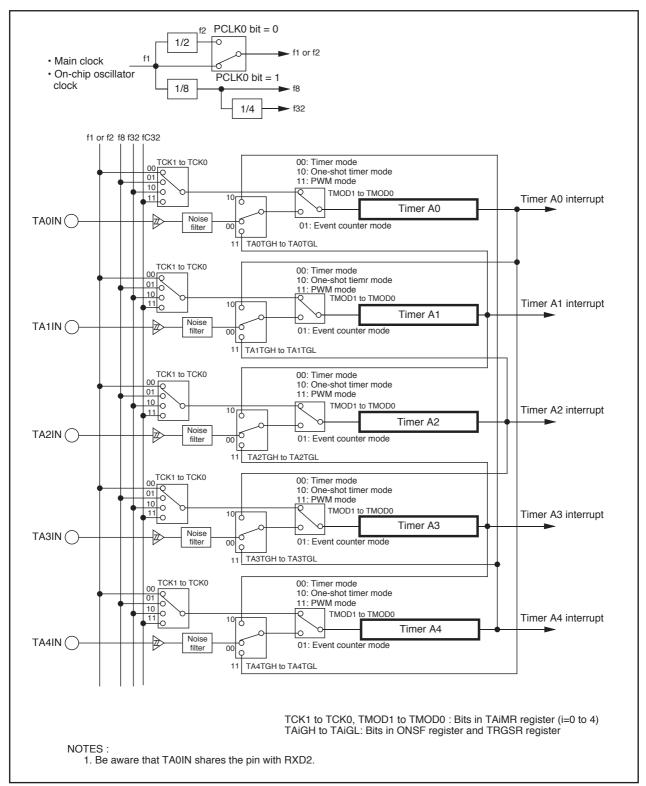

Figure 1.12.1. Timer A Configuration

### Timer A

Figure 1.12.2 shows a block diagram of the timer A. Figures 1.12.3 to 1.12.5 show registers related to the timer A.

The timer A supports the following four modes. Except in event counter mode, timers A0 to A4 all have the same function. Use the TMOD1 to TMOD0 bits of TAiMR register (i = 0 to 4) to select the desired mode.

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts pulses from an external device or overflows and underflows of other timers.
- One-shot timer mode: The timer outputs a pulse only once before it reaches the minimum count "000016."
- Pulse width modulation (PWM) mode: The timer outputs pulses in a given width successively.

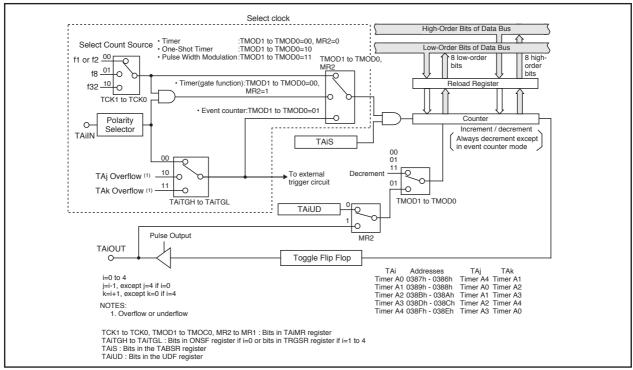

Figure 1.12.2. Timer A Block Diagram

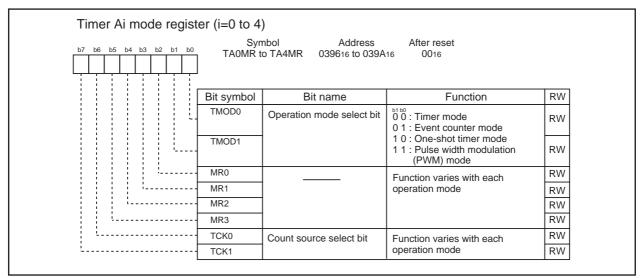

Figure 1.12.3. TA0MR to TA4MR Registers

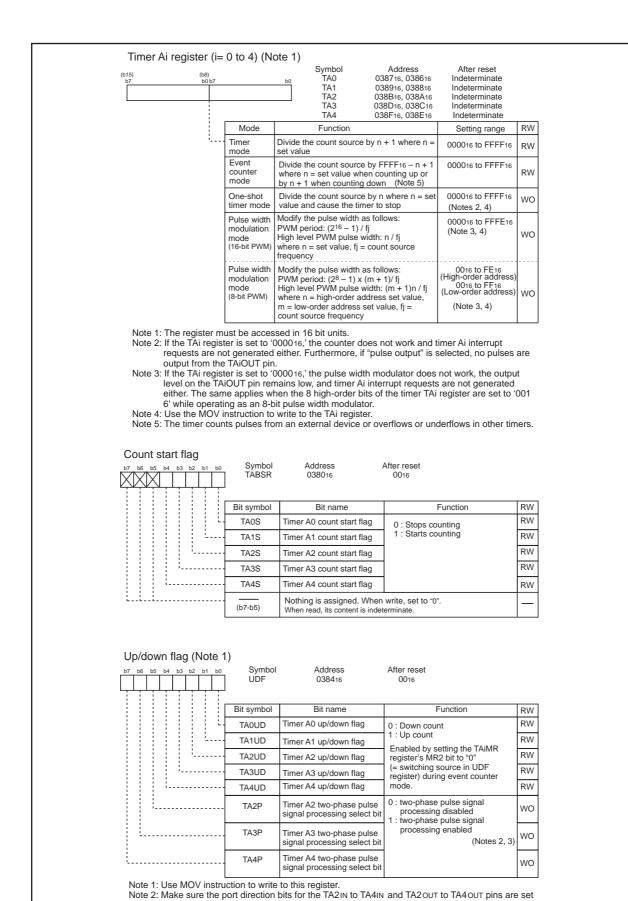

Figure 1.12.4. TA0 to TA4 Registers, TABSR Register, and UDF Register

to "0" (input mode).

Note 3: When not using the two-phase pulse signal processing function, set the corresponding bit to "0" (TA2P and TA3P must be set "0").

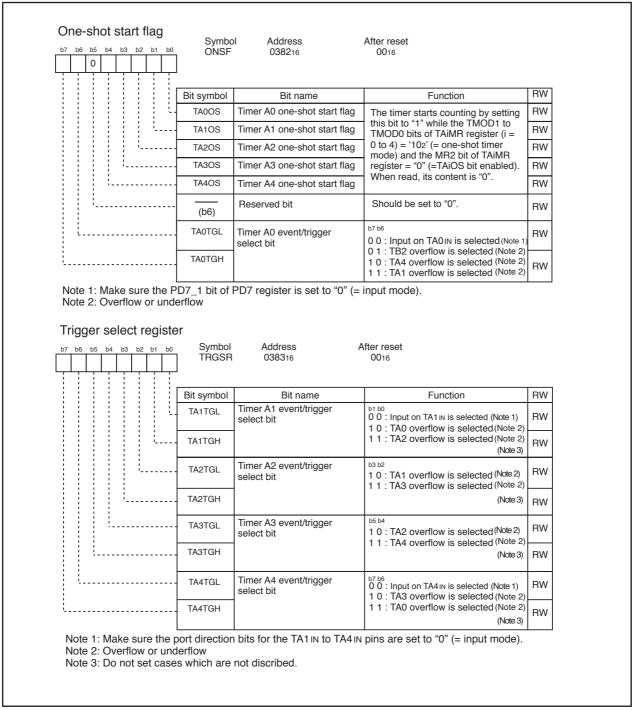

Figure 1.12.5. ONSF Register, TRGSR Register, and CPSRF Register

# 1. Timer Mode

In timer mode, the timer counts a count source generated internally (see Table 1.12.1). Figure 1.12.6 shows TAiMR register in timer mode.

Table 1.12.1. Specifications in Timer Mode

Item	Specification			
Count source	f1, f2, f8, f32			
Count operation	Down-count			
	When the timer underflows, it reloads the reload register contents and continues counting			
Divide ratio	1/(n+1) n: set value of TAiMR register (i= 0 to 4) 000016 to FFFF16			
Count start condition	Set TAiS bit of TABSR register to "1" (= start counting)			
Count stop condition	Set TAiS bit to "0" (= stop counting)			
Interrupt request generation timing	Timer underflow			
TAilN pin function	I/O port or gate input i≠2, 3			
TAiout pin function	I/O port or pulse output			
Read from timer	Count value can be read by reading TAi register			
Write to timer	When not counting and until the 1st count source is input after counting start			
	Value written to TAi register is written to both reload register and counter			
	When counting (after 1st count source input)			
	Value written to TAi register is written to only reload register			
	(Transferred to counter when reloaded next)			
Select function	Gate function			
	Counting can be started and stopped by an input signal to TAiIN pin			
	Pulse output function			
	Whenever the timer underflows, the output polarity of TAio∪T pin is inverted.			
	When not counting, the pin outputs a low.			

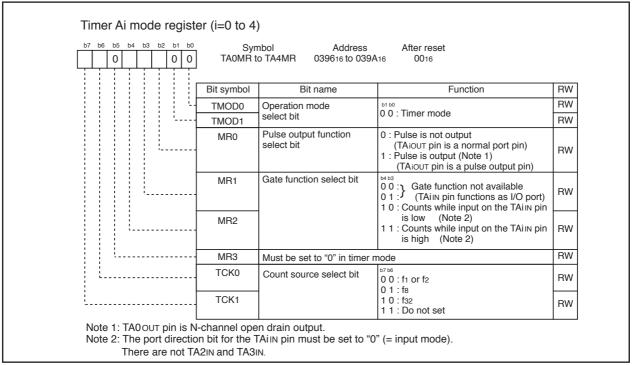

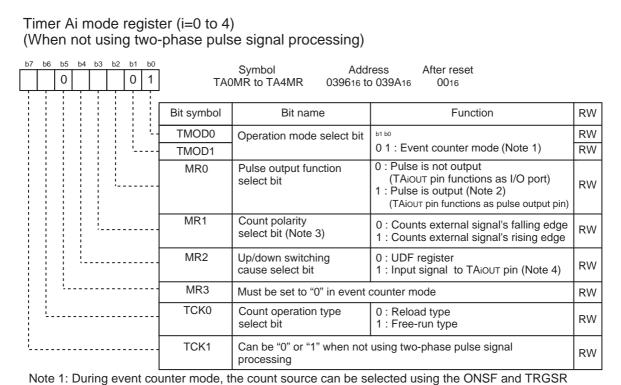

Figure 1.12.6. Timer Ai Mode Register in Timer Mode

# 2. Event Counter Mode

In event counter mode, the timer counts pulses from an external device or overflows and underflows of other timers. Timer A4 can count two-phase external signals. Table 1.12.2 lists specifications in event counter mode (when <u>not</u> processing two-phase pulse signal). Table 1.12.3 lists specifications in event counter mode (when processing two-phase pulse signal with the timer A4). Figure 1.12.7 shows TAiMR register in event counter mode (when <u>not</u> processing two-phase pulse signal). Figure 1.12.8 shows TA4MR registers in event counter mode (when processing two-phase pulse signal with the timer A4).

Table 1.12.2. Specifications in Event Counter Mode (when not processing two-phase pulse signal)

Item	Specification				
Count source	• External signals input to TAim pin (i=0 to 4) (effective edge can be selected				
	in program)				
	timer Aj (j=i-1, except j=4 if i=0) overflows or underflows,				
	timer Ak (k=i+1, except k=0 if i=4) overflows or underflows				
Count operation	Up-count or down-count can be selected by external signal or program				
	When the timer overflows or underflows, it reloads the reload register con-				
	tents and continues counting. When operating in free-running mode, the				
	timer continues counting without reloading.				
Divided ratio	1/ (FFFF <sub>16</sub> - n + 1) for up-count				
	1/ (n + 1) for down-count n : set value of TAi register 000016 to FFFF16				
Count start condition	Set TAiS bit of TABSR register to "1" (= start counting)				
Count stop condition	Set TAiS bit to "0" (= stop counting)				
Interrupt request generation timing	Timer overflow or underflow				
TAilN pin function	I/O port or count source input i≠2, 3				
TAiout pin function	I/O port, pulse output, or up/down-count select input				
Read from timer	Count value can be read by reading TAi register				
Write to timer	When not counting and until the 1st count source is input after counting start				
	Value written to TAi register is written to both reload register and counter				
	When counting (after 1st count source input)				
	Value written to TAi register is written to only reload register				
	(Transferred to counter when reloaded next)				
Select function	Free-run count function				
	Even when the timer overflows or underflows, the reload register content is				
	not reloaded to it				
	Pulse output function				
	Whenever the timer underflows or underflows, the output polarity of TAiout				
	pin is inverted . When not counting, the pin outputs a low.				

registers.

Figure 1.12.7. TAiMR Register in Event Counter Mode (when not using two-phase pulse signal processing)

Note 2: TA0out pin is N-channel open drain output.

Note 3: Effective when the TAiGH and TAiGL bits of ONSF or TRGSR register are '002' (TAIIN pin input).

Note 4: Count down when input on TAioUT pin is low or count up when input on that pin is high. The port direction bit for TAiout pin must be set to "0" (= input mode).

Table 1.12.3. Specifications in Event Counter Mode (when processing two-phase pulse signal with timer A4)

Item	Specification				
Count source	• Two-phase pulse signals input to TAiIN or TAiOUT pins (i = 4)				
Count operation	<ul> <li>Up-count or down-count can be selected by two-phase pulse signal</li> <li>When the timer overflows or underflows, it reloads the reload register contents and continues counting. When operating in free-running mode, the</li> </ul>				
	timer continues counting without reloading.				
Divide ratio	1/ (FFFF16 - n + 1) for up-count				
0	1/ (n + 1) for down-count n : set value of TAi register 000016 to FFFF16				
Count start condition	Set TAIS bit of TABSR register to "1" (= start counting)				
Count stop condition	Set TAiS bit to "0" (= stop counting)				
Interrupt request generation timing	Timer overflow or underflow				
TAilN pin function	Two-phase pulse input				
TAiout pin function	Two-phase pulse input				
Read from timer	Count value can be read by reading timer A4 register				
Write to timer	<ul> <li>When not counting and until the 1st count source is input after counting start Value written to TAi register is written to both reload register and counter</li> <li>When counting (after 1st count source input) Value written to TAi register is written to reload register (Transferred to counter when reloaded next)</li> </ul>				
Select function	• Multiply-by-4 processing operation (timer A4)  If the phase relationship is such that TAkin(k=4) pin goes "H" when the input signal on TAkout pin is "H", the timer counts up rising and falling edges on TAkout and TAkin pins. If the phase relationship is such that TAkin pin goes "L" when the input signal on TAkout pin is "H", the timer counts down rising and falling edges on TAkout and TAkin pins.  TAkout  Count up all edges  TAkin  (k=3,4)  Count up all edges  Count down all edges  Count down all edges				

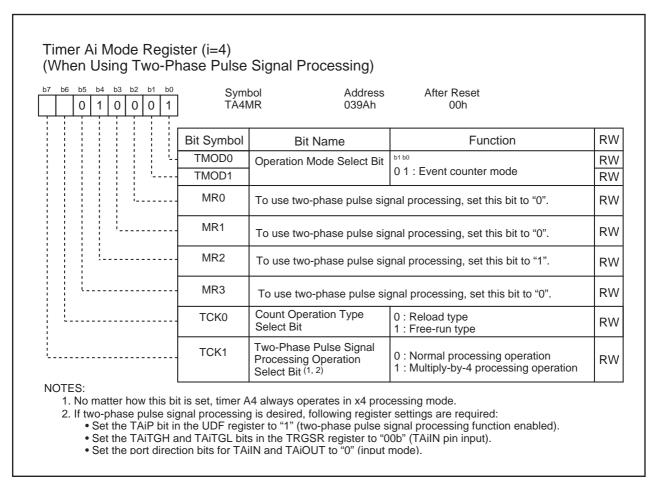

Figure 1.12.8. TA4MR Registers in Event Counter Mode (when using two-phase pulse signal processing with timer A4)

# 3. One-shot Timer Mode

In one-shot timer mode, the timer is activated only once by one trigger. (See Table 1.12.4.) When the trigger occurs, the timer starts up and continues operating for a given period. Figure 1.12.9 shows the TAIMR register in one-shot timer mode.

Table 1.12.4. Specifications in One-shot Timer Mode

Item	Specification			
Count source	f1, f2, f8, f32			
Count operation	Down-count			
	When the counter reaches 000016, it stops counting after reloading a new value			
	If a trigger occurs when counting, the timer reloads a new count and restarts counting			
Divide ratio	1/n n : set value of TAi register 000016 to FFFF16			
	However, the counter does not work if the divide-by-n value is set to 000016.			
Count start condition	TAiS bit of TABSR register = "1" (start counting) and one of the following trig-			
	gers occurs.			
	• External trigger input from the TAilN pin			
	timer Aj (j=i-1, except j=4 if i=0) overflow or underflow,			
	timer Ak (k=i+1, except k=0 if i=4) overflow or underflow			
	• The TAiOS bit of ONSF register is set to "1" (= timer starts)			
Count stop condition	When the counter is reloaded after reaching "000016"			
	• TAiS bit is set to "0" (= stop counting)			
Interrupt request generation timing	When the counter reaches "000016"			
TAin pin function	I/O port or trigger input			
TAio∪⊤ pin function	I/O port or pulse output			
Read from timer	An indeterminate value is read by reading TAi register			
Write to timer	When not counting and until the 1st count source is input after counting start			
	Value written to TAi register is written to both reload register and counter			
	When counting (after 1st count source input)			
	Value written to TAi register is written to only reload register			
	(Transferred to counter when reloaded next)			
Select function	Pulse output function			
	The timer outputs a low when not counting and a high when counting.			

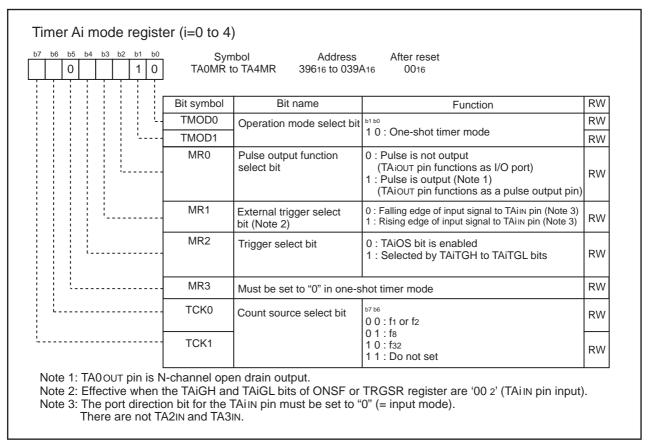

Figure 1.12.9. TAIMR Register in One-shot Timer Mode

# 4. Pulse Width Modulation (PWM) Mode

In PWM mode, the timer outputs pulses of a given width in succession (see Table 1.12.5). The counter functions as either 16-bit pulse width modulator or 8-bit pulse width modulator. Figure 1.12.10 shows TAiMR register in pulse width modulation mode. Figures 1.12.11 and 1.12.12 show examples of how a 16-bit pulse width modulator operates and how an 8-bit pulse width modulator operates.

Table 1.12.5. Specifications in PWM Mode

Item	Specification			
Count source	f1, f2, f8, f32			
Count operation	Down-count (operating as an 8-bit or a 16-bit pulse width modulator)			
	The timer reloads a new value at a rising edge of PWM pulse and continues counting			
	The timer is not affected by a trigger that occurs during counting			
16-bit PWM	High level width			
	Cycle time (2 <sup>16</sup> -1) / fj fixed fj: count source frequency (f1, f2, f8, f32)			
8-bit PWM	• High level width nx (m+1)/fj n: set value of TAiMR register high-order address			
	Cycle time (28-1) x (m+1) / fj m : set value of TAiMR register low-order address			
Count start condition	TAiS bit of TABSR register is set to "1" (= start counting)			
	The TAiS bit = 1 and external trigger input from the TAiIN pin			
	The TAiS bit = 1 and one of the following external triggers occurs			
	Timer Aj (j=i-1, except j=4 if i=0) overflow or underflow,			
	Timer Ak (k=i+1, except k=0 if i=4) overflow or underflow			
Count stop condition	TAiS bit is set to "0" (= stop counting)			
Interrupt request generation timing	PWM pulse goes "L"			
TAilN pin function	I/O port or trigger input			
TAiout pin function	Pulse output			
Read from timer	An indeterminate value is read by reading TAi register			
Write to timer	When not counting and until the 1st count source is input after counting start			
	Value written to TAi register is written to both reload register and counter			
	When counting (after 1st count source input)			
	Value written to TAi register is written to only reload register			
	(Transferred to counter when reloaded next)

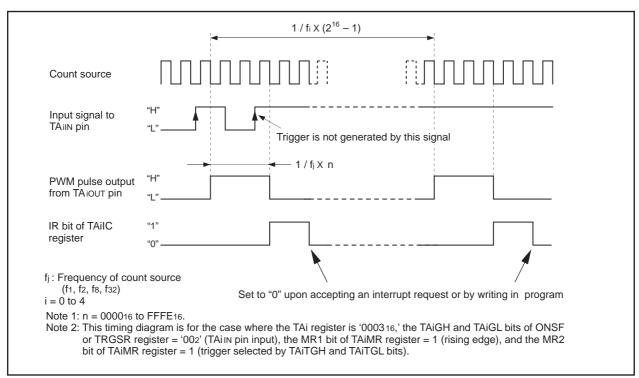

Figure 1.12.11. Example of 16-bit Pulse Width Modulator Operation

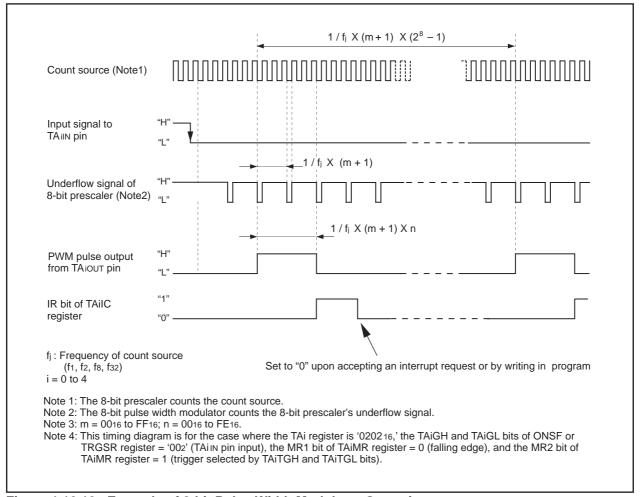

Figure 1.12.12. Example of 8-bit Pulse Width Modulator Operation

# Serial I/O

Serial I/O is configured with five channels: UART0 to UART2, SI/O3 and SI/O4.

# UARTi (i=0 to 2)

UARTi each have an exclusive timer to generate a transfer clock, so they operate independently of each other.

Figure 1.13.1 shows the block diagram of UARTi. Figure 1.13.2 shows the block diagram of the UARTi transmit/receive unit.

UARTi has the following modes:

- Clock synchronous serial I/O mode
- Clock asynchronous serial I/O mode (UART mode).
- Special mode 1 (I<sup>2</sup>C mode)
- · Special mode 2

Figures 1.13.3 to 1.13.8 show the UARTi-related registers.

Refer to tables listing each mode for register setting.

# Clock Synchronous serial I/O Mode

The clock synchronous serial I/O mode uses a transfer clock to transmit and receive data. Table 1.14.1 lists the specifications of the clock synchronous serial I/O mode. Table 1.14.2 lists the registers used in clock synchronous serial I/O mode and the register values set. UART2 is not available in this mode.

Table 1.14.1. Clock Synchronous Serial I/O Mode Specifications

Item	Specification		
Transfer data format	Transfer data length: 8 bits		
Transfer clock	• UiMR(i=0 to 1) register's CKDIR bit = "0" (internal clock) : fj/ 2(n+1)		
	fj = f1SIO, f2SIO, f8SIO, f32SIO. n: Setting value of UiBRG register 0016 to FF16		
	CKDIR bit = "1" (external clock) : Input from CLKi pin		
Transmission, reception control	Selectable from CTS function, RTS function or CTS/RTS function disable		
Transmission start condition	Before transmission can start, the following requirements must be met (Note 1)		
	- The TE bit of UiC1 register= 1 (transmission enabled)		
	- The TI bit of UiC1 register = 0 (data present in UiTB register)		
	- If CTS function is selected, input on the CTSi pin = "L"		
Reception start condition	Before reception can start, the following requirements must be met (Note 1)		
	- The RE bit of UiC1 register= 1 (reception enabled)		
	- The TE bit of UiC1 register= 1 (transmission enabled)		
	- The TI bit of UiC1 register= 0 (data present in the UiTB register)		
Interrupt request	For transmission, one of the following conditions can be selected		
generation timing	- The UiIRS bit (Note 3) = 0 (transmit buffer empty): when transferring data from the		
	UiTB register to the UARTi transmit register (at start of transmission)		
	- The UiIRS bit =1 (transfer completed): when the serial I/O finished sending data from		
	the UARTi transmit register		
	For reception		
	When transferring data from the UARTi receive register to the UiRB register (at		
	completion of reception)		
Error detection	Overrun error (Note 2)		
	This error occurs if the serial I/O started receiving the next data before reading the		
	UiRB register and received the 7th bit of the next data		
Select function	CLK polarity selection		
	Transfer data input/output can be chosen to occur synchronously with the rising or		
	the falling edge of the transfer clock		
	LSB first, MSB first selection		
	Whether to start sending/receiving data beginning with bit 0 or beginning with bit 7		
	can be selected		
	Continuous receive mode selection		
	Reception is enabled immediately by reading the UiRB register		
	Switching serial data logic		
	This function reverses the logic value of the transmit/receive data		
	Transfer clock output from multiple pins selection (UART1)		
	The output pin can be selected in a program from two UART1 transfer clock pins that		
	have been set		
	Separate CTS/RTS pins (UART0)		
	CTSo and RTSo are input/output from separate pins		

Note 1: When an external clock is selected, the conditions must be met while if the UiC0 register's CKPOL bit = "0" (transmit data output at the falling edge and the receive data taken in at the rising edge of the transfer clock), the external clock is in the high state; if the UiC0 register's CKPOL bit = "1" (transmit data output at the rising edge and the receive data taken in at the falling edge of the transfer clock), the external clock is in the low state.

Note 2: If an overrun error occurs, the value of UiRB register will be indeterminate. The IR bit of SiRIC register does not change. Note 3: The U0IRS and U1IRS bits respectively are the UCON register bits 0 and 1.

Table 1.14.2. Registers to Be Used and Settings in Clock Synchronous Serial I/O Mode

Register	Bit	Function		
UiTB(Note3)	0 to 7	Set transmission data		
UiRB(Note3)	0 to 7	Reception data can be read		
	OER	Overrun error flag		
UiBRG	0 to 7	Set a transfer rate		
UiMR(Note3)	SMD2 to SMD0	Set to "0012"		
	CKDIR	Select the internal clock or external clock		
	IOPOL	Set to "0"		
UiC0	CLK1 to CLK0	Select the count source for the UiBRG register		
	CRS	Select CTS or RTS to use		
	TXEPT	Transmit register empty flag		
	CRD	Enable or disable the CTS or RTS function		
	NCH	Select TxDi pin output mode		
	CKPOL	Select the transfer clock polarity		
	UFORM	Select the LSB first or MSB first		
UiC1	TE	Set this bit to "1" to enable transmission/reception		
	TI	Transmit buffer empty flag		
	RE	Set this bit to "1" to enable reception		
	RI	Reception complete flag		
	U2IRS (Note 1)	Select the source of UART2 transmit interrupt		
	U2RRM (Note 1)	Set this bit to "1" to use continuous receive mode		
	UiLCH	Set this bit to "1" to use inverted data logic		
UiERE Set to "0"		Set to "0"		
UiSMR	0 to 7	Set to "0"		
UiSMR2	0 to 7	Set to "0"		
UiSMR3	0 to 2	Set to "0"		
	NODC	Select clock output mode		
	4 to 7	Set to "0"		
UiSMR4	0 to 7	Set to "0"		
UCON	U0IRS, U1IRS	Select the source of UART0/UART1 transmit interrupt		
	U0RRM, U1RRM Set this bit to "1" to use continuous receive mode			
		Select the transfer clock output pin when CLKMD1 = 1		
		Set this bit to "1" to output UART1 transfer clock from two pins		
	RCSP	Set this bit to "1" to accept as input the UART0 CTSo signal from the P64 pin		
	7	Set to "0"		
Note 1: Cot	·	Set to "0"		

Note 1: Set the U0C1 and U1C1 register bit 4 and bit 5 to "0". The U0IRS, U1IRS, U0RRM and U1RRM bits are in the UCON register.

Note 2: Not all register bits are described above. Set those bits to "0" when writing to the registers in clock synchronous serial I/O mode.

i=0 to 1

Table 1.14.3 lists the functions of the input/output pins during clock synchronous serial I/O mode. Table 1.14.3 shows pin functions for the case where the multiple transfer clock output pin select function is deselected. Table 1.14.4 lists the P64 pin functions during clock synchronous serial I/O mode. Note that for a period from when the UARTi operation mode is selected to when transfer starts, the TxDi pin outputs an "H". (If the N-channel open-drain output is selected, this pin is in a high-impedance state.)

Table 1.14.3. Pin Functions (When Not Select Multiple Transfer Clock Output Pin Function)

Pin name	Function	Method of selection		
TxDi (i = 0 to 2) (P63, P67)	Serial data output	(Outputs dummy data when performing reception only)		
RxDi (P62, P66)	Serial data input	PD6 register's PD6_2 bit=0, PD6_6 bit=0 (Can be used as an input port when performing transmission only)		
CLKi	Transfer clock output	UiMR register's CKDIR bit=0		
(P61, P65)	Transfer clock input	UiMR register's CKDIR bit=1 PD6 register's PD6_1 bit=0, PD6_5 bit=0		
CTSi/RTSi (P60, P64)	CTS input	UiC0 register's CRD bit=0 UiC0 register's CRS bit=0 PD6 register's PD6_0 bit=0, PD6_4 bit=0		
	RTS output	UiC0 register's CRD bit=0 UiC0 register's CRS bit=1		
	I/O port	UiC0 register's CRD bit=1		

Table 1.14.4. P64 Pin Functions

Pin function	Bit set value					
	U1C0	U1C0 register UCON register		PD6 register		
	CRD	CRS	RCSP	CLKMD1	CLKMD0	PD6_4
P64	1	_	0	0	_	Input: 0, Output: 1
CTS <sub>1</sub>	0	0	0	0		0
RTS <sub>1</sub>	0	1	0	0		_
CTS <sub>0</sub> (Note1)	0	0	1	0	_	0
CLKS <sub>1</sub>	<u></u>			1(Note 2)	1	

Note 1: In addition to this, set the U0C0 register's CRD bit to "0" (CTSo/RTSo enabled) and the U0 C0 register's CRS bit to "1" (RTSo selected).

Note 2: When the CLKMD1 bit = 1 and the CLKMD0 bit = 0, the following logic levels are output:

- High if the U1C0 register's CLKPOL bit = 0
- Low if the U1C0 register's CLKPOL bit = 1

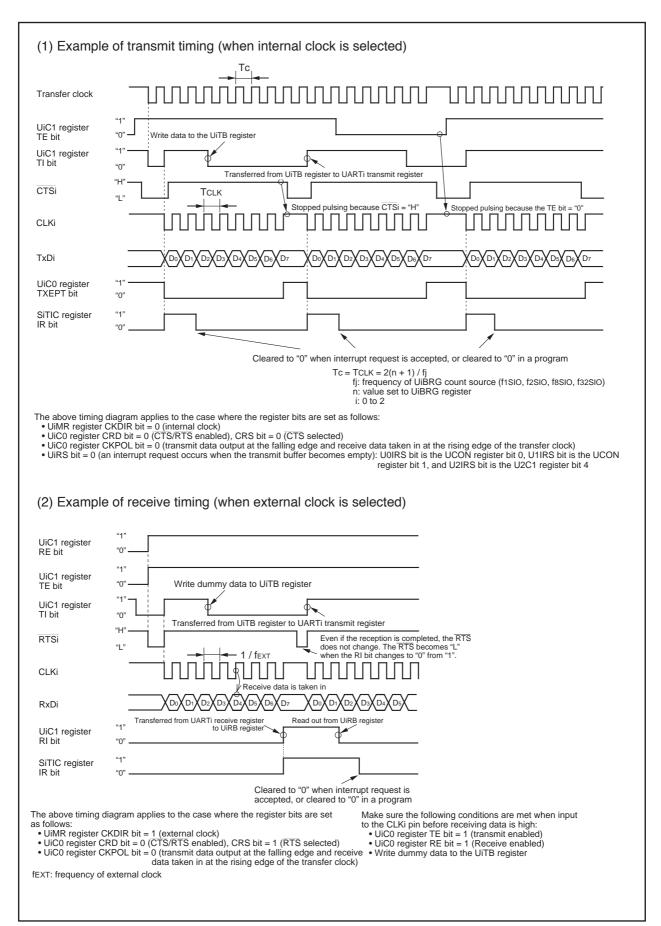

Figure 1.14.1. Transmit and Receive Operation

# **Counter Measure for Communication Error Occurs**

If a communication error occurs while transmitting or receiving in clock synchronous serial I/O mode, follow the procedures below.

- · Resetting the UiRB register (i=0 to 2)
- (1) Set the RE bit in the UiC1 register to "0" (reception disabled)
- (2) Set the SMD2 to SMD0 bits in the UiMR register to "000b" (Serial I/O disabled)
- (3) Set the SMD2 to SMD0 bits in the UiMR register to "001b" (Clock synchronous serial I/O mode)
- (4) Set the RE bit in the UiC1 register to "1" (reception enabled)
- Resetting the UiTB register (i=0 to 2)
- (1) Set the SMD2 to SMD0 bits in the UiMR register "000b" (Serial I/O disabled)
- (2) Set the SMD2 to SMD0 bits in the UiMR register "001b" (Clock synchronous serial I/O mode)
- (3) "1" is written to RE bit in the UiC1 register (reception enabled), regardless of the TE bit in the UiCi register

# (a) CLK Polarity Select Function

Use the UiC0 register (i = 0 to 1)'s CKPOL bit to select the transfer clock polarity. Figure 1.14.2 shows the polarity of the transfer clock.

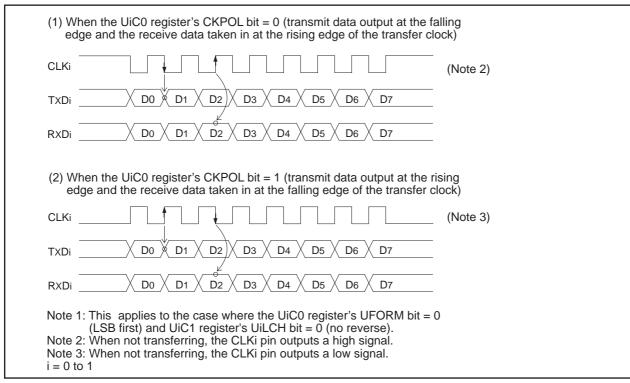

Figure 1.14.2. Transfer Clock Polarity

### (b) LSB First/MSB First Select Function

Use the UiC0 register (i = 0 to 1)'s UFORM bit to select the transfer format. Figure 1.14.3 shows the transfer format.

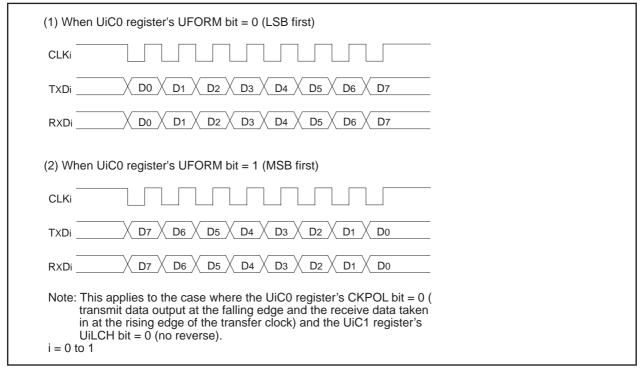

Figure 1.14.3. Transfer Format

# (c) Continuous Receive Mode

In continuous receive mode, receive operation becomes enable when the receive buffer register is read. It is not necessary to write dummy data into the transmit buffer register to enable receive operation in this mode. However, a dummy read of the receive buffer register is required when starting the operation mode.

When the UiRRM bit (i = 0 to 1) = 1 (continuous receive mode), the UiC1 register's TI bit is set to "1" (data present in the UiTB register) by reading the UiRB register. In this case, i.e., UiRRM bit = 1, do not write dummy data to the UiTB register in a program. The U0RRM and U1RRM bits are the UCON register bit 2 and bit 3, respectively.

# (d) Serial Data Logic Switching Function

When the UiC1 register (i = 0 to 1)'s UiLCH bit = 1 (reverse), the data written to the UiTB register has its logic reversed before being transmitted. Similarly, the received data has its logic reversed when read from the UiRB register. Figure 1.14.4 shows serial data logic.

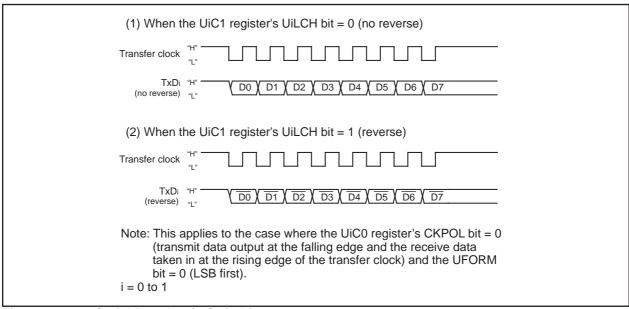

Figure 1.14.4. Serial Data Logic Switching

### (e) Transfer Clock Output From Multiple Pins (UART1)

Use the UCON register's CLKMD1 to CLKMD0 bits to select one of the two transfer clock output pins. (See Figure 1.14.5.) This function can be used when the selected transfer clock for UART1 is an internal clock.

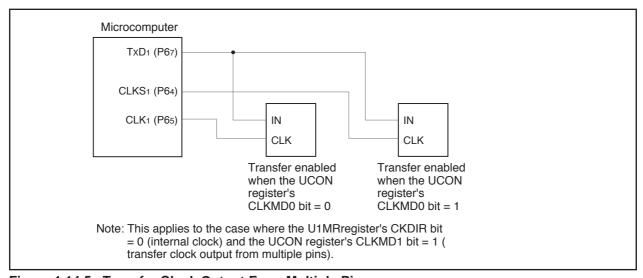

Figure 1.14.5. Transfer Clock Output From Multiple Pins

### **CTS/RTS** Function

When the  $\overline{\text{CTS}}$  function is used transmit and receive operation start when "L" is applied to the  $\overline{\text{CTSi}}/\overline{\text{RTSi}}$  (i=0 to 2) pin. Transmit and receive operation begins when the  $\overline{\text{CTSi}}/\overline{\text{RTSi}}$  pin is held "L". If the "L" signal is switched to "H" during a transmit or receive operation, the operation stops before the next data

When the RTS function is used, the CTSi/RTSi pin outputs on "L" signal when the microcomputer is ready to receive. The output level becomes "H" on the first falling edge of the CLKi pin.

CRD bit in UiC0 register = 1 ( CTS/RTS function disabled)

CTSi/RTSi pin is programmable I/O function

- CRD bit = 0, CRS bit = 0 (CTS function is selected) CTSi/RTSi pin is CTS function
- CRD bit = 0, CRS bit = 1 ( $\overline{RTS}$  function is selected)  $\overline{CTSi}/\overline{RTSi}$  pin is  $\overline{RTS}$  function

# (f) CTS/RTS Separate Function (UART0)

This function separates  $\overline{\text{CTSo}}/\overline{\text{RTSo}}$ , outputs  $\overline{\text{RTSo}}$  from the P60 pin, and accepts as input the  $\overline{\text{CTSo}}$  from the P64 pin. To use this function, set the register bits as shown below.

- U0C0 register's CRD bit = 0 (enables UART0 CTS/RTS)
- U0C0 register's CRS bit = 1 (outputs UART0 RTS)
- U1C0 register's CRD bit = 0 (enables UART1 CTS/RTS)
- U1C0 register's CRS bit = 0 (inputs UART1 CTS)
- UCON register's RCSP bit = 1 (inputs CTSo from the P64 pin)
- UCON register's CLKMD1 bit = 0 (CLKS1 not used)

Note that when using the  $\overline{CTS}/\overline{RTS}$  separate function, UART1  $\overline{CTS}/\overline{RTS}$  separate function cannot be used.

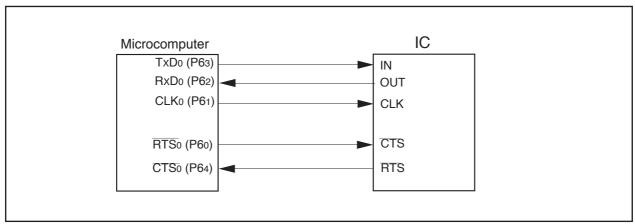

Figure 1.14.6. CTS/RTS Separate Function

### Clock Asynchronous Serial I/O (UART) Mode

The UART mode allows transmitting and receiving data after setting the desired transfer rate and transfer data format. Table 1.15.1 lists the specifications of the UART mode.

Table 1.15.1. UART Mode Specifications

Item	Specifications Specification			
Transfer data format	Character bit (transfer data): Selectable from 7, 8 or 9 bits			
	Start bit: 1 bit			
	Parity bit: Selectable from odd, even, or none			
	Stop bit: Selectable from 1 or 2 bits			
Transfer clock	• UiMR(i=0 to 2) register's CKDIR bit = 0 (internal clock) : fj/ 16(n+1)			
	fj = f1SIO, f2SIO, f8SIO, f32SIO. n: Setting value of UiBRG register 0016 to FF16			
	• CKDIR bit = "1" (external clock) : fEXT/16(n+1) (Note 3)			
	fext: Input from CLKi pin. n :Setting value of UiBRG register 0016 to FF16			
Transmission, reception control	· · · · · · · · · · · · · · · · · · ·			
Transmission start condition	Before transmission can start, the following requirements must be met			
	- The TE bit of UiC1 register= 1 (transmission enabled)			
	- The TI bit of UiC1 register = 0 (data present in UiTB register)			
	- If CTS function is selected, input on the CTSi pin = "L"			
Reception start condition	Before reception can start, the following requirements must be met			
	- The RE bit of UiC1 register= 1 (reception enabled)			
	- Start bit detection			
Interrupt request	For transmission, one of the following conditions can be selected			
generation timing	- The UiIRS bit (Note 2) = 0 (transmit buffer empty): when transferring data from the			
	UiTB register to the UARTi transmit register (at start of transmission)			
	The UiIRS bit =1 (transfer completed): when the serial I/O finished sending data from			
	the UARTi transmit register			
	• For reception			
	When transferring data from the UARTi receive register to the UiRB register (at			
	completion of reception)			
Error detection	Overrun error (Note 1)			
Endi detection	This error occurs if the serial I/O started receiving the next data before reading the			
	UiRB register and received the bit one before the last stop bit of the next data			
	• Framing error			
	This error occurs when the number of stop bits set is not detected			
	• Parity error			
	This error occurs when if parity is enabled, the number of 1's in parity and			
	character bits does not match the number of 1's set			
	• Error sum flag			
	This flag is set (= 1) when any of the overrun, framing, and parity errors is encountered			
Select function	• LSB first, MSB first selection			
	Whether to start sending/receiving data beginning with bit 0 or beginning with bit 7			
	can be selected			
	Serial data logic switch			
	This function reverses the logic of the transmit/receive data. The start and stop bits			
	are not reversed.			
	TxD, RxD I/O polarity switch			
	This function reverses the polarities of hte TxD pin output and RxD pin input. The			
	logic levels of all I/O data is reversed.			
	Separate CTS/RTS pins (UART0)			
Note 1: If an overrun error occurs	CTSo and RTSo are input/output from separate pins			

Note 1: If an overrun error occurs, the value of UiRB register will be indeterminate. The IR bit of SiRIC register does not change. Note 2: The U0IRS and U1IRS bits respectively are the UCON register bits 0 and 1; the U2IRS bit is the U2C1 register bit 4.

Note 3: CKDIR of U2MR must be set "0" to select internal clock.

Table 1.15.2. Registers to Be Used and Settings in UART Mode

Register	Bit	Function		
UiTB	0 to 8	Set transmission data (Note 1)		
UiRB	0 to 8	Reception data can be read (Note 1)		
	OER,FER,PER,SUM	Error flag		
UiBRG	0 to 7	Set a transfer rate		
UiMR	SMD2 to SMD0	Set these bits to '1002' when transfer data is 7 bits long		
		Set these bits to '1012' when transfer data is 8 bits long		
		Set these bits to '1102' when transfer data is 9 bits long		
	CKDIR	Select the internal clock or external clock		
	STPS	Select the stop bit		
	PRY, PRYE	Select whether parity is included and whether odd or even		
	IOPOL	Select the TxD/RxD input/output polarity		
UiC0	CLK0, CLK1	Select the count source for the UiBRG register		
	CRS	Select CTS or RTS to use		
	TXEPT	Transmit register empty flag		
	CRD	Enable or disable the CTS or RTS function		
	NCH	Select TxDi pin output mode (Note 2)		
	CKPOL	Set to "0"		
	UFORM	LSB first or MSB first can be selected when transfer data is 8 bits long. Set this		
		bit to "0" when transfer data is 7 or 9 bits long.		
UiC1	TE	Set this bit to "1" to enable transmission		
	TI	Transmit buffer empty flag		
	RE	Set this bit to "1" to enable reception		
	RI	Reception complete flag		
	U2IRS (Note 2)	Select the source of UART2 transmit interrupt		
	U2RRM (Note 2)	Set to "0"		
	UiLCH	Set this bit to "1" to use inverted data logic		
	UiERE	Set to "0"		
UiSMR	0 to 7	Set to "0"		
UiSMR2	0 to 7	Set to "0"		
UiSMR3	0 to 7	Set to "0"		
UiSMR4	0 to 7	Set to "0"		
UCON	U0IRS, U1IRS	Select the source of UART0/UART1 transmit interrupt		
	U0RRM, U1RRM	Set to "0"		
	CLKMD0	Invalid because CLKMD1 = 0		
	CLKMD1	Set to "0"		
	RCSP	Set this bit to "1" to accept as input the UARTO CTSo signal from the P64 pin		
	7	Set to "0"		

Note 1: The bits used for transmit/receive data are as follows: Bit 0 to bit 6 when transfer data is 7 bits long; bit 0 to bit 7 when transfer data is 8 bits long; bit 0 to bit 8 when transfer data is 9 bits long.

Note 2: Set the U0C1 and U1C1 registers bit 4 to bit 5 to "0". The U0IRS, U1IRS, U0RRM and U1RRM bits are included in the UCON register.

Note 3: TxD2 pin is N channel open-drain output. Set the U2C0 register's NCH bit to "0". i=0 to 2

Table 1.15.3 lists the functions of the input/output pins during UART mode. Table 1.15.4 lists the P64 pin functions during UART mode. Note that for a period from when the UARTi operation mode is selected to when transfer starts, the TxDi pin outputs an "H". (If the N-channel open-drain output is selected, this pin is in a high-impedance state.)

Table 1.15.3. I/O Pin Functions

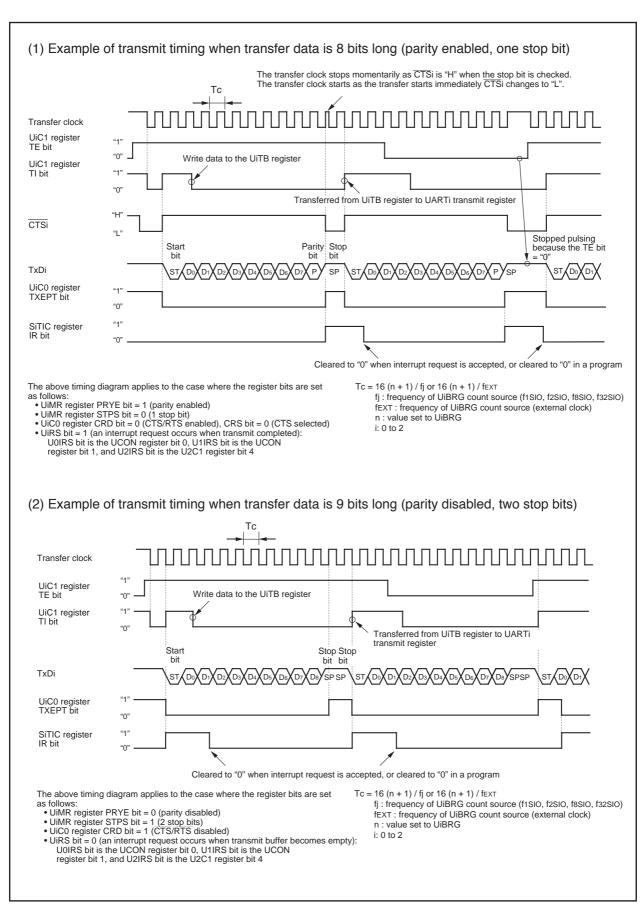

Pin name	Function	Method of selection
TxDi (i = 0 to 2) (P63, P67, P70)	Serial data output	(Outputs dummy data when performing reception only)
RxDi (P62, P66, P71)	Serial data input	PD6 register's PD6_2 bit=0, PD6_6 bit=0, PD7 register's PD7_1 bit=0 (Can be used as an input port when performing transmission only)
CLKi	Input/output port	UiMR register's CKDIR bit=0
(P61, P65)	Transfer clock input	UiMR register's CKDIR bit=1 PD6 register's PD6_1 bit=0, PD6_5 bit=0, PD7 register's PD7_2 bit=0
CTSi/RTSi (P60, P64, P73)	CTS input	UiC0 register's CRD bit=0 UiC0 register's CRS bit=0 PD6 register's PD6_0 bit=0, PD6_4 bit=0, PD7 register's PD7_3 bit=0
	RTS output	UiC0 register's CRD bit=0 UiC0 register's CRS bit=1
	Input/output port	UiC0 register's CRD bit=1

Table 1.15.4. P64 Pin Functions

Pin function	Bit set value				
	U1C0 register		UCON	register	PD6 register
	CRD	CRS	RCSP	CLKMD1	PD6_4
P64	1		0	0	Input: 0, Output: 1
CTS <sub>1</sub>	0	0	0	0	0
RTS <sub>1</sub>	0	1	0	0	
CTS <sub>0</sub> (Note)	0	0	1	0	0

Note: In addition to this, set the U0C0 register's CRD bit to "0" (CTSo/RTSo enabled) and the U0C0 register's CRS bit to "1" (RTSo selected).

RENESAS

Figure 1.15.1. Transmit Operation

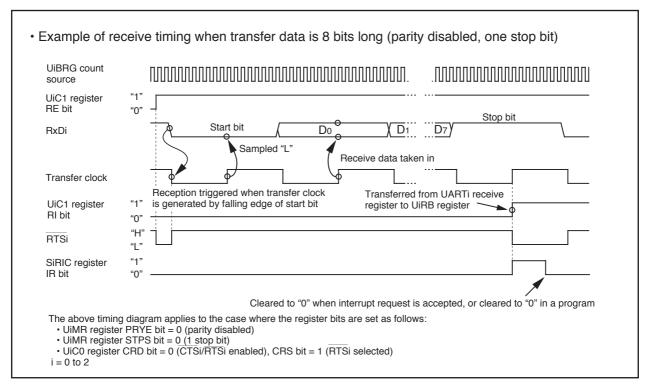

Figure 1.15.2. Receive Operation

#### **Bit Rates**

In UART mode, the frequency set by the UiBRG register (i=0 to 2) divided by 16 become the bit rates. Table 1.15.5 lists example of bit rates and settings.

Table 1.15.5. Example of Bit Rates and Settings

Bit Rate	Count Source	Peripheral Functio	n Clock : 16MHz	Peripheral Functio	n Clock : 24MHz
(bps)	of BRG	Set Value of BRG : n	Actual Time (bps)	Set value of BRG : n	Actual Time (bps)
1200	f8	103 (67h)	1202	155 (96h)	1202
2400	f8	51 (33h)	2404	77 (46h)	2404
4800	f8	25 (19h)	4808	38 (26h)	4808
9600	f1	103 (67h)	9615	155 (96h)	9615
14400	f1	68 (44h)	14493	103 (67h)	14423
19200	f1	51 (33h)	19231	77 (46h)	19231
28800	f1	34 (22h)	28571	51 (33h)	28846
31250	f1	31 (1Fh)	31250	47 (2Fh)	31250
38400	f1	25 (19h)	38462	38 (26h)	38462
51200	f1	19 (13h)	50000	28 (1Ch)	51724

#### **Counter Measure for Communication Error Occurs**

If a communication error occurs while transmitting or receiving in UART mode, follow the procedures below.

- Resetting the UiRB register (i=0 to 2)
- (1) Set the RE bit in the UiC1 register to "0" (reception disabled)
- (2) Set the RE bit in the UiC1 register to "1" (reception enabled)
- Resetting the UiTB register (i=0 to 2)
- (1) Set the SMD2 to SMD0 bits in the UiMR register "000b" (Serial I/O disabled)
- (2) Set the SMD2 to SMD0 bits in the UiMR register "001b", "101b", "110b".
- (3) "1" is written to RE bit in the UiC1 register (reception enabled), regardless of the TE bit in the UiCi register

### (a) LSB First/MSB First Select Function

As shown in Figure 1.15.3, use the UiC0 register's UFORM bit to select the transfer format. This function is valid when transfer data is 8 bits long.

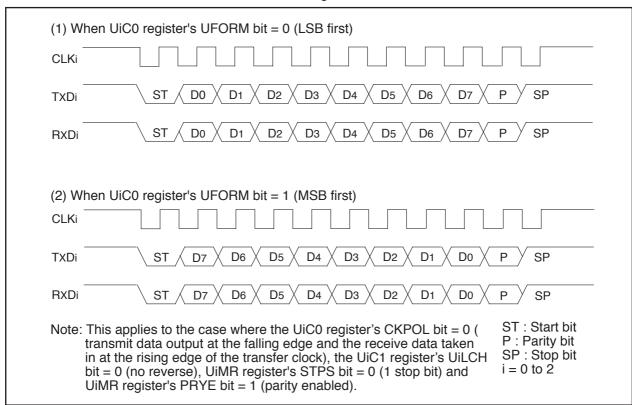

Figure 1.15.3. Transfer Format

### (b) Serial Data Logic Switching Function

The data written to the UiTB register has its logic reversed before being transmitted. Similarly, the received data has its logic reversed when read from the UiRB register. Figure 1.15.4 shows serial data logic.

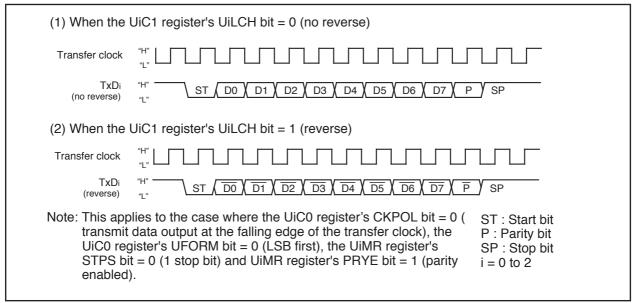

Figure 1.15.4. Serial Data Logic Switching

### (c) TxD and RxD I/O Polarity Inverse Function

This function inverses the polarities of the TxDi pin output and RxDi pin input. The logic levels of all input/output data (including the start, stop and parity bits) are inversed. Figure 1.15.5 shows the TxD pin output and RxD pin input polarity inverse.

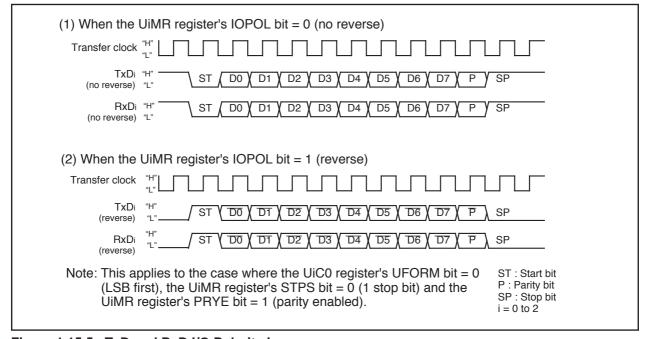

Figure 1.15.5. TxD and RxD I/O Polarity Inverse

#### **CTS/RTS** Function

When the CTS function is used transmit operation start when "L" is applied to the CTSi/RTSi (i=0 to 2) pin. Transmit operation begins when the CTSi/RTSi pin is held "L". If the "L" signal is switched to "H" during a transmit operation, the operation stops before the next data.

When the RTS function is used, the CTSi/RTSi pin outputs on "L" signal when the microcomputer is ready to receive. The output level becomes "H" on the first falling edge of the CLKi pin.

CRD bit in UiC0 register = 1 (disable CTS/RTS function of UART0)

CTSi/RTSi pin is programmable I/O function

- CRD bit = 0, CRS bit = 0 (CTS function is selected) CTSi/RTSi pin is CTS function
- CRD bit = 0, CRS bit = 1 ( $\overline{RTS}$  function is selected)  $\overline{CTSi}/\overline{RTSi}$  pin is  $\overline{RTS}$  function

### (d) CTS/RTS Separate Function (UART0)

This function separates  $\overline{\text{CTS0/RTS0}}$ , outputs  $\overline{\text{RTS0}}$  from the P60 pin, and accepts as input the  $\overline{\text{CTS0}}$  from the P64 pin. To use this function, set the register bits as shown below.

- U0C0 register's CRD bit = 0 (enables UART0 CTS/RTS)
- U0C0 register's CRS bit = 1 (outputs UART0 RTS)
- U1C0 register's CRD bit = 0 (enables UART1 CTS/RTS)
- U1C0 register's CRS bit = 0 (inputs UART1 CTS)
- UCON register's RCSP bit = 1 (inputs CTSo from the P64 pin)
- UCON register's CLKMD1 bit = 0 (CLKS1 not used)

Note that when using the  $\overline{\text{CTS}/\text{RTS}}$  separate function, UART1  $\overline{\text{CTS}/\text{RTS}}$  separate function cannot be used.

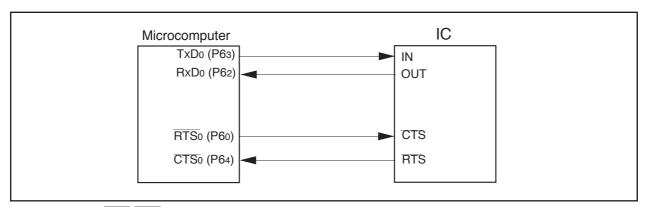

Figure 1.15.6. CTS/RTS Separate Function

## Special Mode 1 (I<sup>2</sup>C mode)

 $I^2C$  mode is provided for use as a simplified  $I^2C$  interface compatible mode. Table 1.16.1 lists the specifications of the  $I^2C$  mode. Table 1.16.2 lists the registers used in the  $I^2C$  mode and the register values set. Figure 1.16.1 shows the block diagram for  $I^2C$  mode. Figure 1.16.2 shows SCLi timing.

As shown in Table 1.16.4, the microcomputer is placed in I<sup>2</sup>C mode by setting the SMD2 to SMD0 bits to '0102' and the IICM bit to "1". Because SDAi transmit output has a delay circuit attached, SDAi output does not change state until SCLi goes low and remains stably low.

Table 1.16.1. I<sup>2</sup>C Mode Specifications

Item	Specification
Transfer data format	Transfer data length: 8 bits
Transfer clock	During master
	UiMR(i=0 to 2) register's CKDIR bit = "0" (internal clock) : fj/ 2(n+1)
	fj = f1SIO, f2SIO, f8SIO, f32SIO. n: Setting value of UiBRG register 0016 to FF16
	During slave
	CKDIR bit = "1" (external clock) : Input from CLKi pin
Transmission start condition	Before transmission can start, the following requirements must be met (Note 1)
	- The TE bit of UiC1 register= 1 (transmission enabled)
	- The TI bit of UiC1 register = 0 (data present in UiTB register)
Reception start condition	Before reception can start, the following requirements must be met (Note 1)
	- The RE bit of UiC1 register= 1 (reception enabled)
	- The TE bit of UiC1 register= 1 (transmission enabled)
	<ul> <li>The TI bit of UiC1 register= 0 (data present in the UiTB register)</li> </ul>
Interrupt request	When start or stop condition is detected, acknowledge undetected, and acknowledge
generation timing	detected
Error detection	Overrun error (Note 2)
	This error occurs if the serial I/O started receiving the next data before reading the
	UiRB register and received the 8th bit of the data
Select function	Arbitration lost
	Timing at which the UiRB register's ABT bit is updated can be selected
	SDAi digital delay
	No digital delay or a delay of 2 to 8 UiBRG count source clock cycles selectable
	Clock phase setting
	With or without clock delay selectable

Note 1: When an external clock is selected, the conditions must be met while the external clock is in the high state.

Note 2: If an overrun error occurs, the value of UiRB register will be indeterminate. The IR bit of SiRIC register does not change.

i = 0 to 2					

i = 0 to 2NOTES:

1. If the source or cause of any interrupt is changed, the IR bit in the interrupt control register for the changed interrupt may inadvertently be set to "1" (interrupt requested). (Refer to Changing the Interrupt Generate Factor.)

If one of the bits shown below is changed, the interrupt source, the interrupt timing, etc. change. Therefore, always be sure to clear the IR bit to "0" (interrupt not requested) after changing those bits.

SMD2 to SMD0 bits in the UiMR register, IICM bit in the UiSMR register, IICM2 bit in the UiSMR2 register, CKPH bit in the UiSMR3 register

- 2. Set the initial value of SDAi output while the SMD2 to SMD0 bits in the UiMR register = 000b (serial I/O disabled).
- 3. Second data transfer to UiRB register (Rising edge of SCLi 9th bit)
- 4. First data transfer to UiRB register (Falling edge of SCLi 9th bit)
- 5. See Figure 1.16.4 STSPSEL Bit Functions.
- 6. See Figure 1.16.2 Transfer to UiRB Register and Interrupt Timing
  7. When using UARTO, be sure to set the IFSR26 bit in the IFSR2A register to "1" (factor of interrupt: UARTO bus collision). When using UART1, be sure to set the IFSR27 bit to "1" (factor of interrupt: UART1 bus collision).

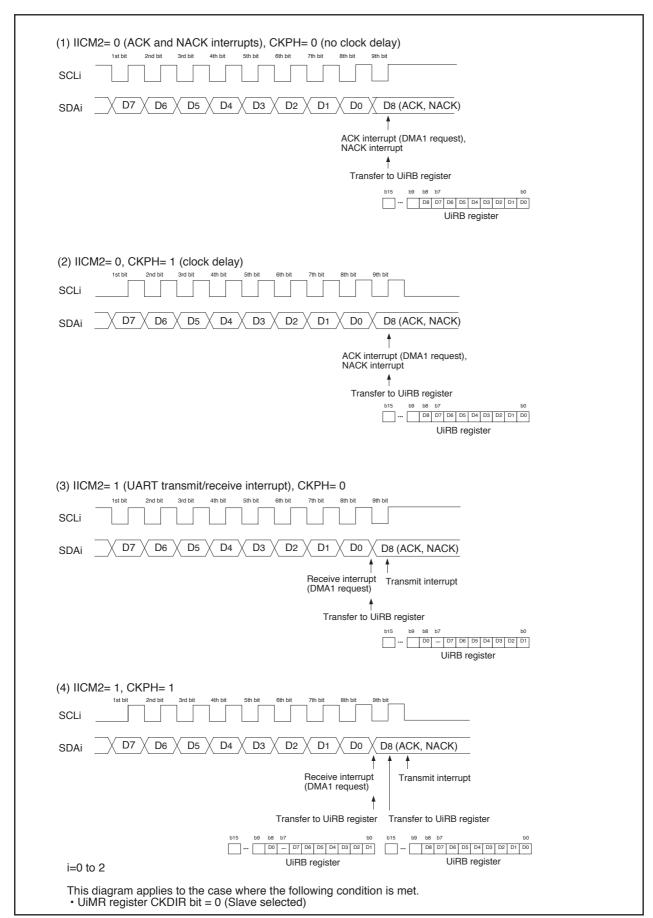

Figure 1.16.2. Transfer to UiRB Register and Interrupt Timing

### • Detection of Start and Stop Condition

Whether a start or a stop condition has been detected is determined.

A start condition-detected interrupt request is generated when the SDAi pin changes state from high to low while the SCLi pin is in the high state. A stop condition-detected interrupt request is generated when the SDAi pin changes state from low to high while the SCLi pin is in the high state.

Because the start and stop condition-detected interrupts share the interrupt control register and vector, check the UiSMR register's BBS bit to determine which interrupt source is requesting the interrupt.

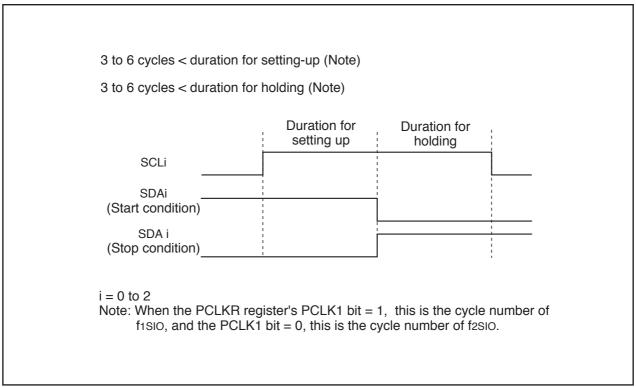

Figure 1.16.3. Detection of Start and Stop Condition

#### Output of Start and Stop Condition

A start condition is generated by setting the STAREQ bit in the UiSMR4 register (i = 0 to 2) to "1" (start).

A restart condition is generated by setting the RSTAREQ bit in the UiSMR4 register to "1" (start).

A stop condition is generated by setting the STPREQ bit in the UiSMR4 register to "1" (start).

The output procedure is described below.

- (1) Set the STAREQ bit, RSTAREQ bit or STPREQ bit to "1" (start).
- (2) Set the STSPSEL bit in the UiSMR4 register to "1" (output).

The function of the STSPSEL bit is shown in Table 1.16.5 and Figure 1.16.4.

Table 1.16.5. STSPSEL Bit Functions

request generation timing		tion

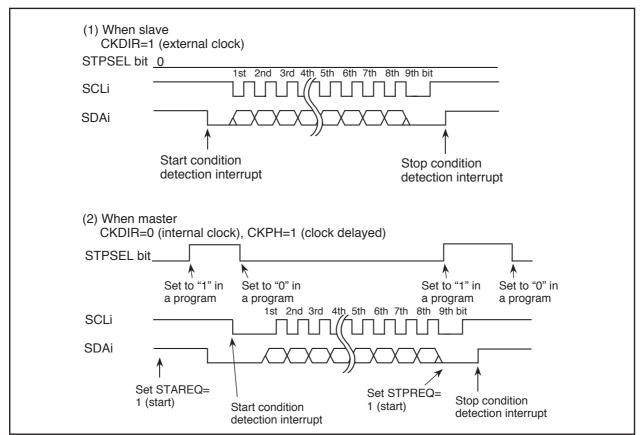

Figure 1.16.4. STSPSEL Bit Functions

### Arbitration

Unmatching of the transmit data and SDAi pin input data is checked synchronously with the rising edge of SCLi. Use the UiSMR register's ABC bit to select the timing at which the UiRB register's ABT bit is updated. If the ABC bit = 0 (updated bitwise), the ABT bit is set to "1" at the same time unmatching is detected during check, and is cleared to "0" when not detected. In cases when the ABC bit is set to "1", if unmatching is detected even once during check, the ABT bit is set to "1" (unmatching detected) at the falling edge of the clock pulse of 9th bit. If the ABT bit needs to be updated bytewise, clear the ABT bit to "0" (undetected) after detecting acknowledge in the first byte, before transferring the next byte.

Setting the UiSMR2 register's ALS bit to "1" (SDA output stop enabled) causes arbitration-lost to occur, in which case the SDAi pin is placed in the high-impedance state at the same time the ABT bit is set to "1" (unmatching detected).

#### Transfer Clock

Data is transmitted/received using a transfer clock like the one shown in Figure 1.16.4.

The UiSMR2 register's CSC bit is used to synchronize the internally generated clock (internal SCLi) and an external clock supplied to the SCLi pin. In cases when the CSC bit is set to "1" (clock synchronization enabled), if a falling edge on the SCLi pin is detected while the internal SCLi is high, the internal SCLi goes low, at which time the UiBRG register value is reloaded with and starts counting in the low-level interval. If the internal SCLi changes state from low to high while the SCLi pin is low, counting stops, and when the SCLi pin goes high, counting restarts.

In this way, the UARTi transfer clock is comprised of the logical product of the internal SCLi and SCLi pin signal. The transfer clock works from a half period before the falling edge of the internal SCLi 1st bit to the rising edge of the 9th bit. To use this function, select an internal clock for the transfer clock. The UiSMR2 register's SWC bit allows to select whether the SCLi pin should be fixed to or freed from low-level output at the falling edge of the 9th clock pulse.

If the UiSMR4 register's SCLHI bit is set to "1" (enabled), SCLi output is turned off (placed in the high-impedance state) when a stop condition is detected.

Setting the UiSMR2 register's SWC2 bit = 1 (0 output) makes it possible to forcibly output a low-level signal from the SCLi pin even while sending or receiving data. Clearing the SWC2 bit to "0" (transfer clock) allows the transfer clock to be output from or supplied to the SCLi pin, instead of outputting a low-level signal.

If the UiSMR4 register's SWC9 bit is set to "1" (SCL hold low enabled) when the UiSMR3 register's CKPH bit = 1, the SCLi pin is fixed to low-level output at the falling edge of the clock pulse next to the ninth. Setting the SWC9 bit = 0 (SCL hold low disabled) frees the SCLi pin from low-level output.

### SDA Output

The data written to the UiTB register bit 7 to bit 0 (D7 to D0) is sequentially output beginning with D7. The ninth bit (D8) is ACK or NACK.

The initial value of SDAi transmit output can only be set when IICM = 1 ( $I^2C$  mode) and the UiMR register's SMD2 to SMD0 bits = '0002' (serial I/O disabled).

The UiSMR3 register's DL2 to DL0 bits allow to add no delays or a delay of 2 to 8 UiBRG count source clock cycles to SDAi output.

Setting the UiSMR2 register's SDHI bit = 1 (SDA output disabled) forcibly places the SDAi pin in the high-impedance state. Do not write to the SDHI bit synchronously with the rising edge of the UARTi transfer clock. This is because the ABT bit may inadvertently be set to "1" (detected).

#### SDA Input

When the IICM2 bit = 0, the 1st to 8th bits (D7 to D0) of received data are stored in the UiRB register bit 7 to bit 0. The 9th bit (D8) is ACK or NACK.

When the IICM2 bit = 1, the 1st to 7th bits (D7 to D1) of received data are stored in the UiRB register bit 6 to bit 0 and the 8th bit (D0) is stored in the UiRB register bit 8. Even when the IICM2 bit = 1, providing the CKPH bit = 1, the same data as when the IICM2 bit = 0 can be read out by reading the UiRB register after the rising edge of the corresponding clock pulse of 9th bit.

#### ACK and NACK

If the STSPSEL bit in the UiSMR4 register is set to "0" (start and stop conditions not generated) and the ACKC bit in the UiSMR4 register is se to "1" (ACK data output), the value of the ACKD bit in the UiSMR4 register is output from the SDAi pin.

If the IICM2 bit = 0, a NACK interrupt request is generated if the SDAi pin remains high at the rising edge of the 9th bit of transmit clock pulse. An ACK interrupt request is generated if the SDAi pin is low at the rising edge of the 9th bit of transmit clock pulse.

If ACKi is selected for the cause of DMA1 request, a DMA transfer can be activated by detection of an acknowledge.

#### • Initialization of Transmission/Reception

If a start condition is detected while the STAC bit = 1 (UARTi initialization enabled), the serial I/O operates as described below.

- The transmit shift register is initialized, and the content of the UiTB register is transferred to the transmit shift register. In this way, the serial I/O starts sending data synchronously with the next clock pulse applied. However, the UARTi output value does not change state and remains the same as when a start condition was detected until the first bit of data is output synchronously with the input clock
- The receive shift register is initialized, and the serial I/O starts receiving data synchronously with the next clock pulse applied.
- The SWC bit is set to "1" (SCL wait output enabled). Consequently, the SCLi pin is pulled low at the falling edge of the ninth clock pulse.

Note that when UARTi transmission/reception is started using this function, the TI does not change state. Note also that when using this function, the selected transfer clock should be an external clock.

### **Special Mode 2**

Multiple slaves can be serially communicated from one master. Synchronous clock polarity and phase are selectable. Table 1.16.6 lists the specifications of Special Mode 2. Table 1.16.7 lists the registers used in Special Mode 2 and the register values set. Figure 1.16.5 shows communication control example for Special Mode 2. UART2 is not available in this mode.

Table 1.16.6. Special Mode 2 Specifications

Item	Specification
Transfer data format	Transfer data length: 8 bits
Transfer clock	Master mode
	UiMR(i=0 to 1) register's CKDIR bit = "0" (internal clock) : fj/ 2(n+1)
	fj = f1SIO, f2SIO, f8SIO, f32SIO. n: Setting value of UiBRG register 0016 to FF16
	Slave mode
	CKDIR bit = "1" (external clock selected) : Input from CLKi pin
Transmit/receive control	Controlled by input/output ports
Transmission start condition	Before transmission can start, the following requirements must be met (Note 1)
	<ul> <li>The TE bit of UiC1 register= 1 (transmission enabled)</li> </ul>
	<ul><li>The TI bit of UiC1 register = 0 (data present in UiTB register)</li></ul>
Reception start condition	Before reception can start, the following requirements must be met (Note 1)
	<ul><li>The RE bit of UiC1 register= 1 (reception enabled)</li></ul>
	<ul> <li>The TE bit of UiC1 register= 1 (transmission enabled)</li> </ul>
	<ul> <li>The TI bit of UiC1 register= 0 (data present in the UiTB register)</li> </ul>
Interrupt request	For transmission, one of the following conditions can be selected
generation timing	- The UiIRS bit of UiC1 register = 0 (transmit buffer empty): when transferring data
	from the UiTB register to the UARTi transmit register (at start of transmission)
	- The UiIRS bit =1 (transfer completed): when the serial I/O finished sending data from
	the UARTi transmit register
	For reception
	When transferring data from the UARTi receive register to the UiRB register (at
	completion of reception)
Error detection	Overrun error (Note 2)
	This error occurs if the serial I/O started receiving the next data before reading the
	UiRB register and received the 7th bit of the next data
Select function	Clock phase setting
	Selectable from four combinations of transfer clock polarities and phases

Note 1: When an external clock is selected, the conditions must be met while if the UiC0 register's CKPOL bit = "0" (transmit data output at the falling edge and the receive data taken in at the rising edge of the transfer clock), the external clock is in the high state; if the UiC0 register's CKPOL bit = "1" (transmit data output at the rising edge and the receive data taken in at the falling edge of the transfer clock), the external clock is in the low state.

Note 2: If an overrun error occurs, the value of UiRB register will be indeterminate. The IR bit of SiRIC register does not change.

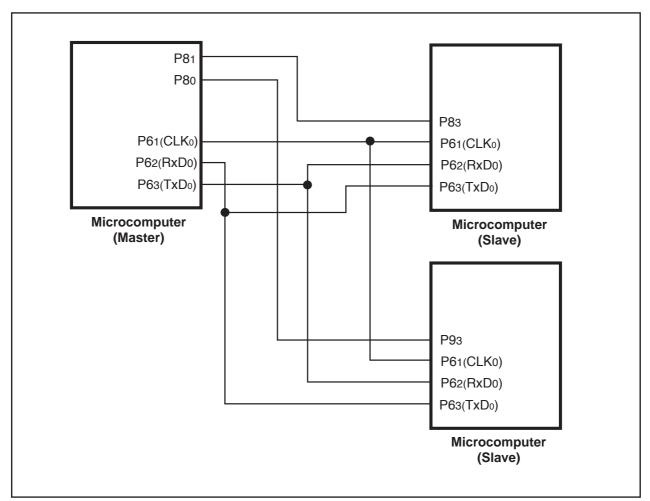

Figure 1.16.5. Serial Bus Communication Control Example (UART0)

Table 1.16.7. Registers to Be Used and Settings in Special Mode 2

Register	Bit	Function		
UiTB(Note2)	0 to 7	Set transmission data		
UiRB(Note2)	0 to 7	Reception data can be read		
	OER	Overrun error flag		
UiBRG	0 to 7	Set a transfer rate		
UiMR(Note2)	SMD2 to SMD0	Set to '0012'		
	CKDIR	Set this bit to "0" for master mode or "1" for slave mode		
	IOPOL	Set to "0"		
UiC0	CLK1, CLK0	Select the count source for the UiBRG register		
	CRS	Invalid because CRD = 1		
	TXEPT	Transmit register empty flag		
	CRD	Set to "1"		
	NCH	Select TxDi pin output format		
	CKPOL	Clock phases can be set in combination with the UiSMR3 register's CKPH bit		
	UFORM	Set to "0"		
UiC1	TE	Set this bit to "1" to enable transmission		
	TI	Transmit buffer empty flag		
	RE	Set this bit to "1" to enable reception		
	RI	Reception complete flag		
	U2IRS (Note 1)	Select UART2 transmit interrupt cause		
	U2RRM(Note 1),	Set to "0"		
	U2LCH, UiERE			
UiSMR	0 to 7	Set to "0"		
UiSMR2	0 to 7	Set to "0"		
UiSMR3	CKPH	Clock phases can be set in combination with the UiC0 register's CKPOL bit		
	NODC	Set to "0"		
	0, 2, 4 to 7	Set to "0"		
UiSMR4	0 to 7	Set to "0"		
UCON	U0IRS, U1IRS	Select UART0 and UART1 transmit interrupt cause		
	U0RRM, U1RRM	Set to "0"		
	CLKMD0	Invalid because CLKMD1 = 0		
	CLKMD1, RCSP, 7	Set to "0"		

Note 1: Set the U0C0 and U1C1 register bit 4 and bit 5 to "0". The U0IRS, U1IRS, U0RRM and U1RRM bits are in the UCON register.

Note 2: Not all register bits are described above. Set those bits to "0" when writing to the registers in Special Mode 2.

i = 0 to 1

### Clock Phase Setting Function

One of four combinations of transfer clock phases and polarities can be selected using the UiSMR3 register's CKPH bit and the UiC0 register's CKPOL bit.

Make sure the transfer clock polarity and phase are the same for the master and salves to be communicated.

Figure 1.16.6 shows the transmission and reception timing in master (internal clock).

Figure 1.16.7 shows the transmission and reception timing (CKPH=0) in slave (external clock) while Figure 1.16.8 shows the transmission and reception timing (CKPH=1) in slave (external clock).

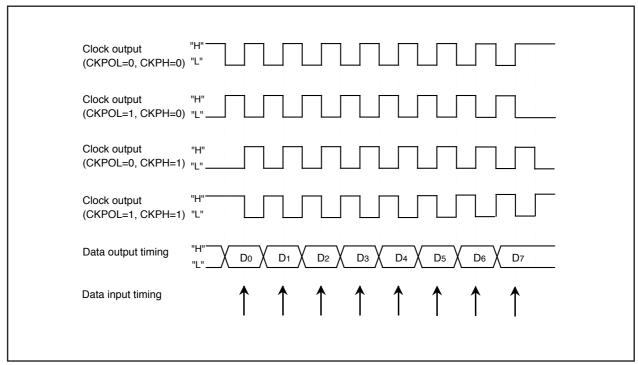

Figure 1.16.6. Transmission and Reception Timing in Master Mode (Internal Clock)

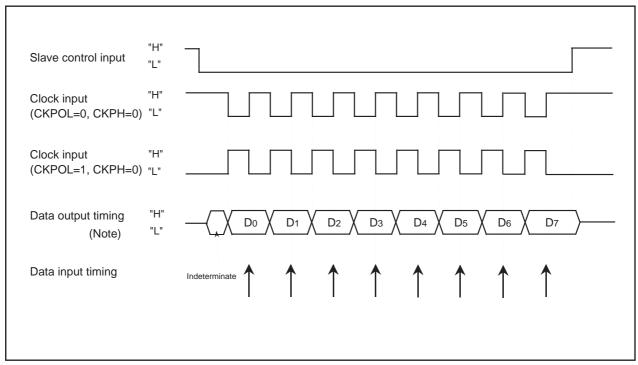

Figure 1.16.7. Transmission and Reception Timing (CKPH=0) in Slave Mode (External Clock)

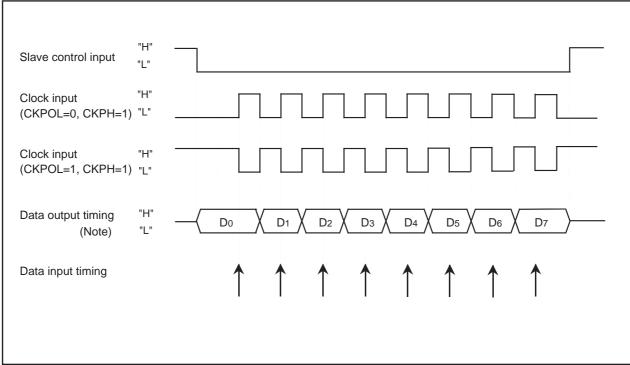

Figure 1.16.8. Transmission and Reception Timing (CKPH=1) in Slave Mode (External Clock)

# SI/O3 and SI/O4

SI/O3 and SI/O4 are exclusive clock-synchronous serial I/Os.

Figure 1.17.1 shows the block diagram of SI/O3 and SI/O4, and Figure 1.17.2 shows the SI/O3 and SI/O4-related registers. SI/O4 is derectly connected to IT800 internally.

Table 1.17.1 shows the specifications of SI/O3 and SI/O4.

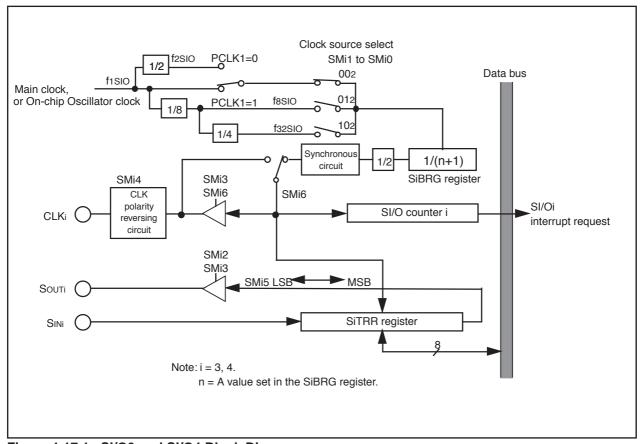

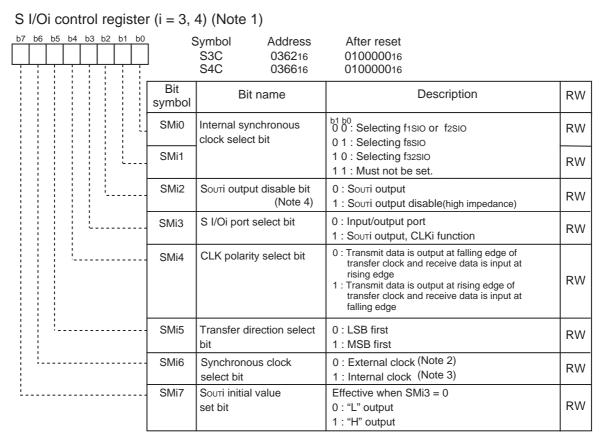

Figure 1.17.1. SI/O3 and SI/O4 Block Diagram

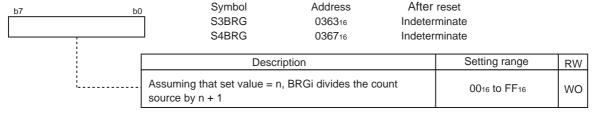

Note 1: Make sure this register is written to by the next instruction after setting the PRCR register's PRC2 bit to "1" (write enable).

Note 2: Set the SMi3 bit to "1" (SouTi output, CLKi function).

Note 3: Set the SMi3 bit to "1" and the corresponding port direction bit to "0" (input mode).

Note 4: Effective when SMi3 bit = 1.

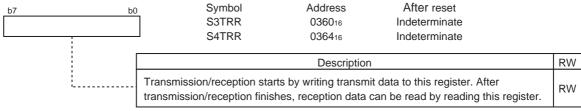

### SI/Oi bit rate generator (i = 3, 4) (Notes 1, 2)

Note 1: Write to this register while serial I/O is neither transmitting nor receiving.

Note 2: Use MOV instruction to write to this register.

### SI/Oi transmit/receive register (i = 3, 4) (Note 1, 2)

Note 1: Write to this register while serial I/O is neither transmitting nor receiving.

Note 2: To receive data, set the corresponding port direction bit for Sıni to "0" (input mode).

Figure 1.17.2. S3C and S4C Registers, S3BRG and S4BRG Registers, and S3TRR and S4TRR Registers

Table 1.17.1. SI/O3 and SI/O4 Specifications

Item	Specification
Transfer data format	Transfer data length: 8 bits
Transfer clock	• SiC (i=3, 4) register's SMi6 bit = "1" (internal clock) : fj/ 2(n+1)
	fj = f1SIO, f8SIO, f32SIO. n=Setting value of SiBRG register 0016 to FF16.
	• SMi6 bit = "0" (external clock) : Input from CLKi pin (Note 1)
Transmission/reception	Before transmission/reception can start, the following requirements must be met
start condition	Write transmit data to the SiTRR register (Notes 2, 3)
Interrupt request	When SiC register's SMi4 bit = 0
generation timing	The rising edge of the last transfer clock pulse (Note 4)
	• When SMi4 = 1
	The falling edge of the last transfer clock pulse (Note 4)
CLKi pin function	I/O port, transfer clock input, transfer clock output
Souti pin function	I/O port, transmit data output, high-impedance
SINi pin function	I/O port, receive data input
Select function	LSB first or MSB first selection
	Whether to start sending/receiving data beginning with bit 0 or beginning with bit 7
	can be selected
	<ul> <li>Function for setting an Souti initial value set function</li> </ul>
	When the SiC register's SMi6 bit = 0 (external clock), the Souti pin output level while
	not transmitting can be selected.
	CLK polarity selection
	Whether transmit data is output/input timing at the rising edge or falling edge of
	transfer clock can be selected.

Note 1: To set the SiC register's SMi6 bit to "0" (external clock), follow the procedure described below.

- If the SiC register's SMi4 bit = 0, write transmit data to the SiTRR register while input on the CLKi pin is high. The same applies when rewriting the SiC register's SMi7 bit.
- If the SMi4 bit = 1, write transmit data to the SiTRR register while input on the CLKi pin is low. The same applies when rewriting the SMi7 bit.
- Because shift operation continues as long as the transfer clock is supplied to the SI/Oi circuit, stop the transfer clock after supplying eight pulses. If the SMi6 bit = 1 (internal clock), the transfer clock automatically stops.
- Note 2: Unlike UART0 to UART2, SI/Oi (i = 3 to 4) is not separated between the transfer register and buffer. Therefore, do not write the next transmit data to the SiTRR register during transmission.
- Note 3: When the SiC register's SMi6 bit = 1 (internal clock), Souti retains the last data for a 1/2 transfer clock period after completion of transfer and, thereafter, goes to a high-impedance state. However, if transmit data is written to the SiTRR register during this period, Souti immediately goes to a high-impedance state, with the data hold time thereby reduced.
- Note 4: When the SiC register's SMi6 bit = 1 (internal clock), the transfer clock stops in the high state if the SMi4 bit = 0, or stops in the low state if the SMi4 bit = 1.

### (a) SI/Oi Operation Timing

Figure 1.17.3 shows the SI/Oi operation timing

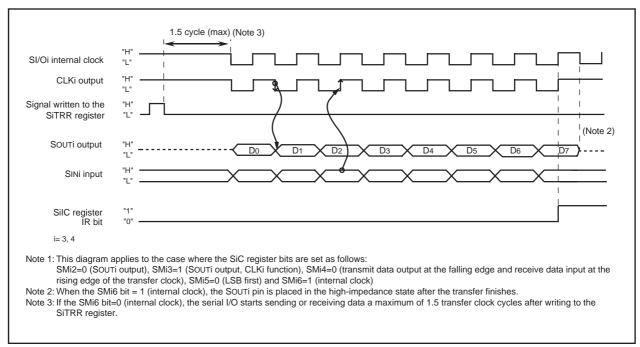

Figure 1.17.3. SI/Oi Operation Timing

### (b) CLK Polarity Selection

The SiC register's SMi4 bit allows selection of the polarity of the transfer clock. Figure 1.17.4 shows the polarity of the transfer clock.

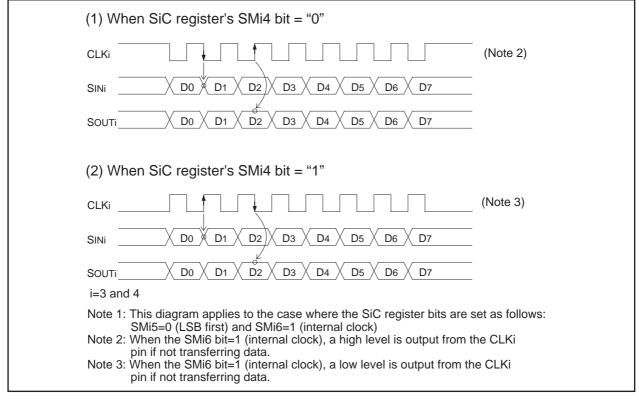

Figure 1.17.4. Polarity of Transfer Clock

### (c) Functions for Setting an Souti Initial Value

If the SiC register's SMi6 bit = 0 (external clock), the SOUTi pin output can be fixed high or low when not transferring. Figure 1.17.5 shows the timing chart for setting an SOUTi initial value and how to set it.

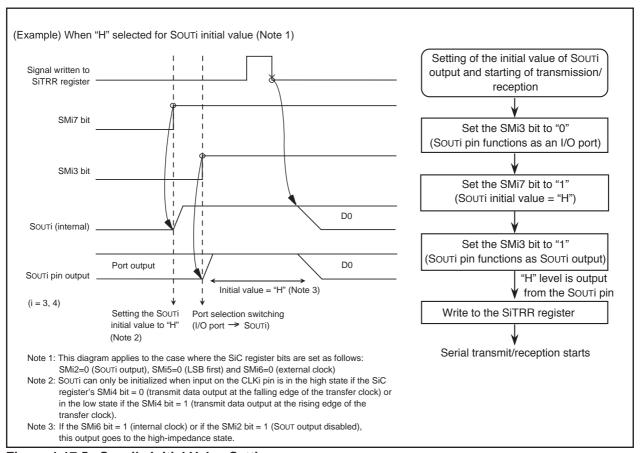

Figure 1.17.5. Souti's Initial Value Setting

# Programmable I/O Ports

The programmable input/output ports (hereafter referred to simply as "I/O ports") consist of 55 lines P1, P4 to P9 (except P85). Each port can be set for input or output every line by using a direction register, and can also be chosen to be or not be pulled high every 4 lines. P85 is an input-only port and does not have a pull-up resistor. There is no external connections for port P1\_0 to P1\_4, P1\_6 to P1\_7, P4\_0 to P4\_7, P5\_0 to P5\_7, P7\_2, P7\_5, P7\_7, P8\_2, P8\_6 to P8\_7, P9\_3 to P9\_7.

Figures 1.18.1 to 1.18.4 show the I/O ports. Figure 1.18.5 shows the I/O pins.

Each pin functions as an I/O port, a peripheral function input/output.

For details on how to set peripheral functions, refer to each functional description in this manual. If any pin is used as a peripheral function input, set the direction bit for that pin to "0" (input mode). Any pin used as an output pin for peripheral functions is directed for output no matter how the corresponding direction bit is set.

### (1) Port Pi Direction Register (PDi Register, i, 4 to 9)

Figure 1.18.6 shows the direction registers.

This register selects whether the I/O port is to be used for input or output. The bits in this register correspond one for one to each port.

No direction register bit for P85 is available.

### (2) Port Pi Register (Pi Register, i = 1, 4 to 9)

Figure 1.18.7 show the Pi registers.

Data input/output to and from external devices are accomplished by reading and writing to the Pi register. The Pi register consists of a port latch to hold the input/output data and a circuit to read the pin status. For ports set for input mode, the input level of the pin can be read by reading the corresponding Pi register, and data can be written to the port latch by writing to the Pi register.

For ports set for output mode, the port latch can be read by reading the corresponding Pi register, and data can be written to the port latch by writing to the Pi register. The data written to the port latch is output from the pin. The bits in the Pi register correspond one for one to each port.

# (3) Pull-up Control Register 0 to Pull-up Control Register 2 (PUR0 to PUR2 Registers)

Figure 1.18.8 shows the PUR0 to PUR2 registers.

The PUR0 to PUR2 register bits can be used to select whether or not to pull the corresponding port high in 4 bit units. The port chosen to be pulled high has a pull-up resistor connected to it when the direction bit is set for input mode.

### (4) Port Control Register

Figure 1.18.9 shows the port control register.

When the P1 register is read after setting the PCR register's PCR0 bit to "1", the corresponding port latch can be read no matter how the PD1 register is set.

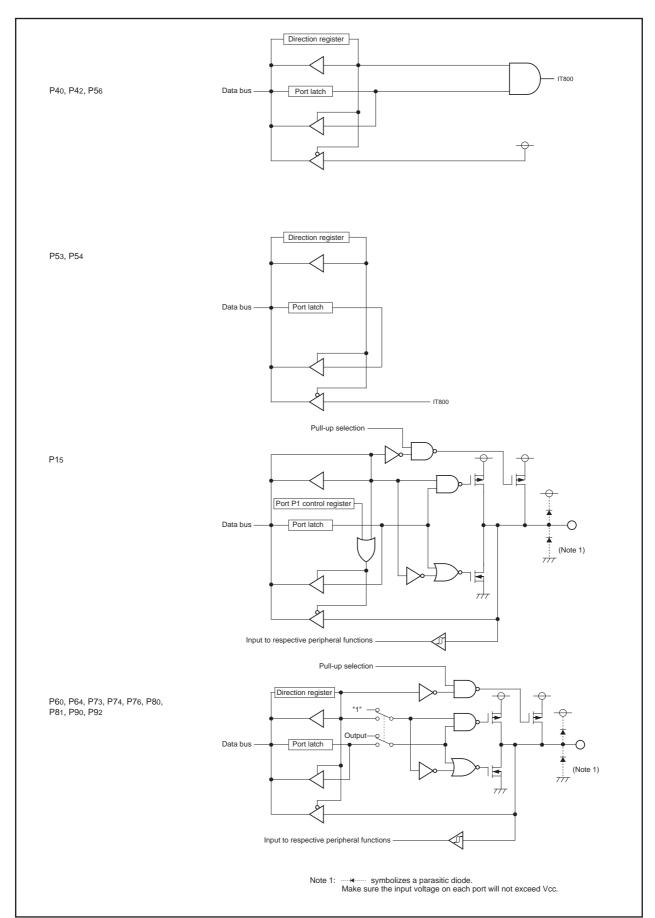

Figure 1.18.1. I/O Ports (1)

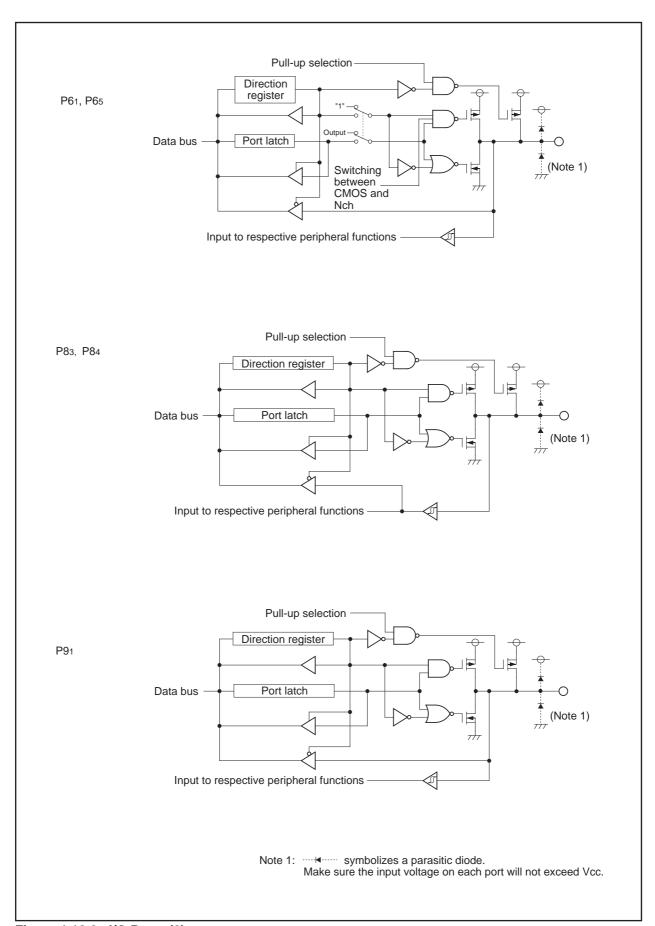

Figure 1.18.2. I/O Ports (2)

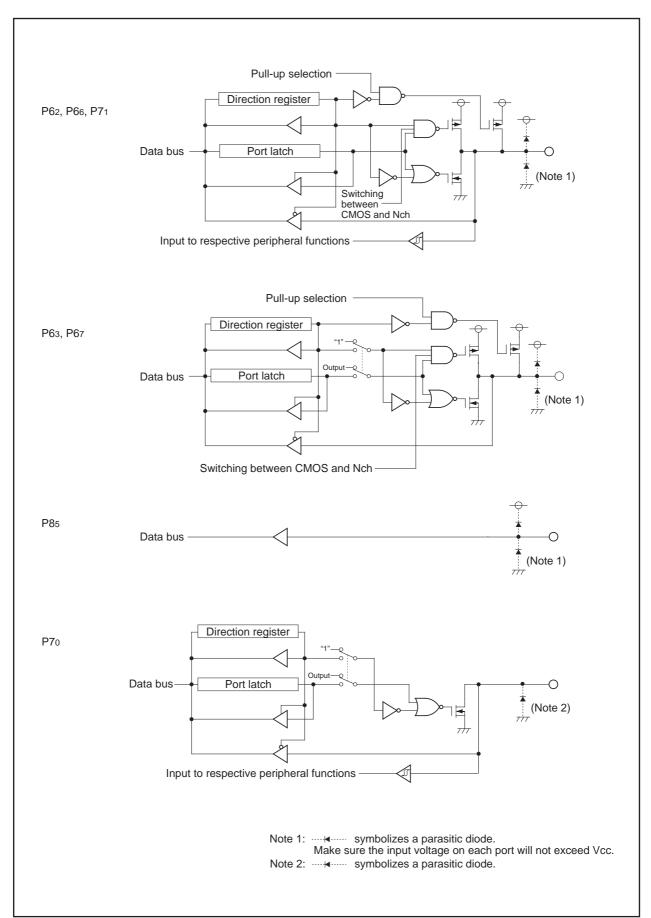

Figure 1.18.3. I/O Ports (3)

### Port P8 direction register

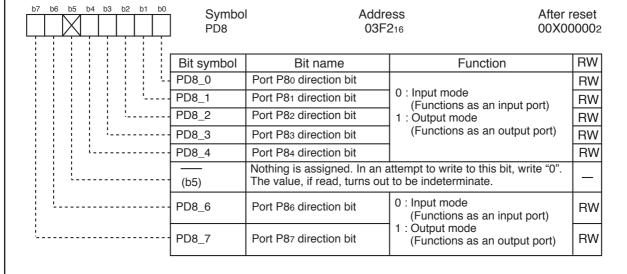

Figure 1.18.6. PD1, PD4 to PD9 Registers

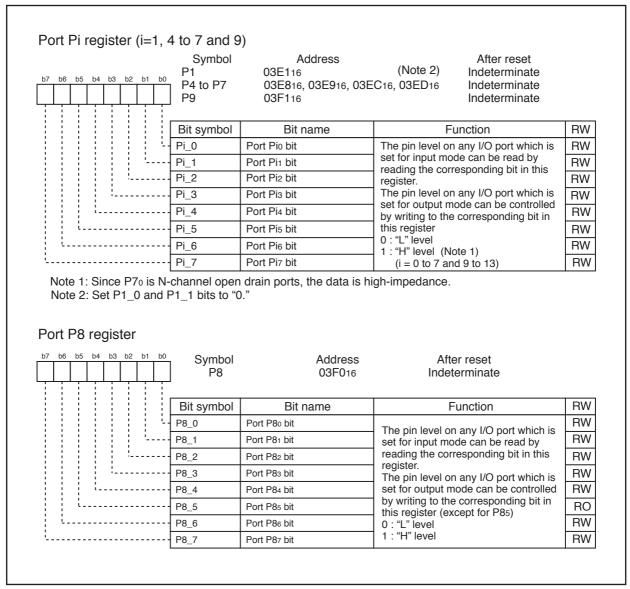

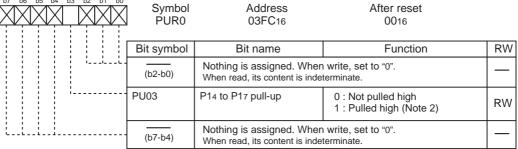

Figure 1.18.7. P1, P4 to P9

M16C/6S Group Programmable I/O Ports

# Pull-up control register 0 (Note 1)

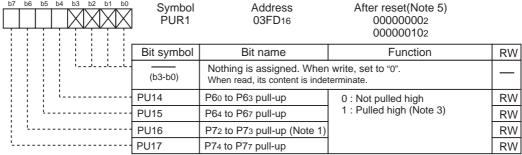

Note 1: During memory extension and microprocessor modes, the pins are not pulled high although their

corresponding register contents can be modified.

Note 2: The pin for which this bit is "1" (pulled high) and the direction bit is "0" (input mode) is pulled high.

#### Pull-up control register 1

Note 1: The P70 and P71 pins do not have pull-ups.

Note 2: During memory extension and microprocessor modes, the pins are not pulled high although the contents of these bits can be modified.

Note 3: The pin for which this bit is "1" (pulled high) and the direction bit is "0" (input mode) is pulled high. Note 4: If the PM01 to PM00 bits are set to "012" (memory expansion mode) or "112" (microprocessor mode) in a program during single-chip mode, the PU11 bit becomes "1".

Note 5: The values after hardware reset 1 and 2 are as follows:

• 000000002 when input on CNVss pin is "L'

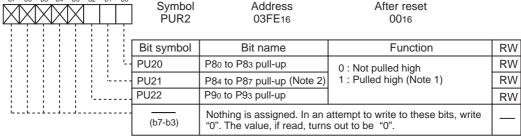

• 000000102 when input on CNVss pin is "H"

The values after software reset, watchdog timer reset and oscillation stop detection reset are as follows:

• 000000002 when PM 01 to PM00 bits of PM0 register are "002" (single-chip mode)

• 000000102 when PM 01 to PM00 bits of PM0 register are "012" (memory expansion mode) or "112" (microprocessor mode)

#### Pull-up control register 2

Note 1: The pin for which this bit is "1" (pulled high) and the direction bit is "0" (input mode) is pulled high. Note 2: The P85 pin does not have pull-up.

Table 1.18.1. Unassigned Pin Handling in Single-chip Mode (Excluding Analog Pins)

Pin name	Connection
Ports P1, P6 to P9 (excluding P85)	After setting for input mode, connect every pin to Vss via a resistor(pull-down); or after setting for output mode, leave these pins open. (2, 3, 4)
XOUT (Note 1)	Open
P85	Connect via resistor to VCC (pull-up)
VccA	Connect to Vcc
VssA	Connect to Vss

#### NOTES:

- 1. With external clock input to XIN pin.
- 2. When setting the port for output mode and leave it open, be aware that the port remains in input mode until it is switched to output mode in a program after reset. For this reason, the voltage level on the pin becomes indeterminate, causing the power supply current to increase while the port remains in input mode. Furthermore, by considering a possibility that the contents of the direction registers could be changed by noise or noise-induced runaway, it is recommended that the contents of the direction registers be periodically reset in software, for the increased reliability of the program.
- 3. Make sure the unused pins are processed with the shortest possible wiring from the microcomputer pins (within 2 cm).
- 4. When the port P7\_0 is set for output mode, make sure a low-level signal is output from the pin. The port P7\_0 is N-channel open-drain output.

Note 3: The total IoL (peak) for all ports must be 80mA max, the total IoH (peak) for all ports must be -40mA max.

Table 1.19.3. Flash Memory Version Electrical Characteristics (Note 1)

Symbol	Dor	Parameter		Standard			
Symbol	Pai	ametei	Min.	Typ. (Note 2)	Max	Unit	
_	Erase/Write cycle (N	ote 3)	100/1000 (No	ote 4, 6 )		cycle	
_	Word program time (Vcc=3.3V, Topr=25°C)		75		600	μs	
-	Block erase time	8Kbyte block		0.4	9	s	
		16Kbyte block		0.7	9	s	
		32Kbyte block		1.2	9	s	
tPS	Flash Memory Circui	t Stabilization Wait Time			15	μs	
_	Data retention time (I	Note 5)	20			year	

Note 1: When not otherwise specified, Vcc = 3.0 to 3.6V; Topr = 0 to 60 °C.

Note 2: VCC = 3.3V; Topr = 25 °C.

Note 3: Program and Erase Endurance refers to the number of times a block erase can be performed. If the program and erase endurance is n (n=100, 1,000), each block can be erased n times. For example, if a 8Kbytes block 0 is erased after writing 1 word data 4096 times, each to a different address, this counts as one program and erase endurance. Data cannot be written to the same address more than once without erasing the block. (Rewrite prohibited)

Note 4: Maximum number of E/W cycles for which opration is guaranteed.

Note 5: Topr = 55°C.

Note 6: The program area for U3 and U5 is 100 E/W cycles; the program area for U7 and U9 is 1,000 E/W cycles.

Note 7: Customers desiring E/W failure rate information should contact their Renesas technical support representative.

## **Flash Memory Version**

## **Flash Memory Performance**

The flash memory version has three modes—CPU rewrite, standard serial input/output, and parallel input/output modes—in which its internal flash memory can be operated on.

Note: About the parallel programmer of exclusive use, there is no schedule of development at the present time.

Table 1.20.1 shows the outline performance of flash memory version (see Table 1.1.1 for the items not listed in Table 1.20.1.).

**Table 1.20.1. Flash Memory Version Specifications** 

Item		Specification	
Flash memory oper	ating mode	2 modes (CPU rewrite, standard serial I/O)	
Erase block		See Figure 1.20.1 Flash Memory Block Diagram	
Program method		In units of word	
Erase method		Block erase	
Program, erase control method		Program and erase controlled by software command	
Protect method		The block 0 and block 1 are write protected by bit FMR02.	
Number of comman	ds	5 commands	
Program/Erase Endurance(Note)	Block 0 to 4 (program area)	100 times or 1,000 times (See Tables 1.1.5 and 1.1.6 Product code.)	
Data Retention		20 years (Topr = 55°C)	
ROM code protection	on	Standard serial I/O mode is supported.	

Note: Program and erase endurance definition

Program and erase endurance are the erase endurance of each block. If the program and erase endurance are n times (n=100,1,000), each block can be erased n times. For example, if a 8-Kbyte block 0 is erased after writing 1 word data 4096 times, each to different addresses, this is counted as one program and erasure. However, data cannot be written to the same address more than once without erasing the block. (Rewrite disabled)

**Table 1.20.2. Flash Memory Rewrite Modes Overview** 

Flash memory rewrite mode	CPU rewrite mode	Standard serial I/O mode
Function	The user ROM area is rewritten by executing software commands from the CPU. EW0 mode: Can be rewritten in any area other than the flash memory EW1 mode: Can be rewritten in the flash memory	The user ROM area is rewritten by using a dedicated serial programmer. Standard serial I/O mode 1: Clock sync serial I/O Standard serial I/O mode 2: UART
Areas which can be rewritten	User ROM area	User ROM area
Operation mode	Single chip mode Memory expansion mode (EW0 mode) Boot mode (EW0 mode)	Boot mode
ROM programmer	None	Serial programmer

## 1. Memory Map

The ROM in the flash memory version is separated between a user ROM area and a boot ROM area. Figures 1.20.1 and 1.20.2 show the block diagram of flash memory.

The user ROM area is divided into several blocks, so that memory can be erased one block at a time. The user ROM area can be rewritten in all of CPU rewrite, standard serial input/output, and parallel input/output modes.

The boot ROM area is reserved. The rewrite control program for standard serial I/O mode is stored in this area before shipment, so that the area cannot be rewritten.

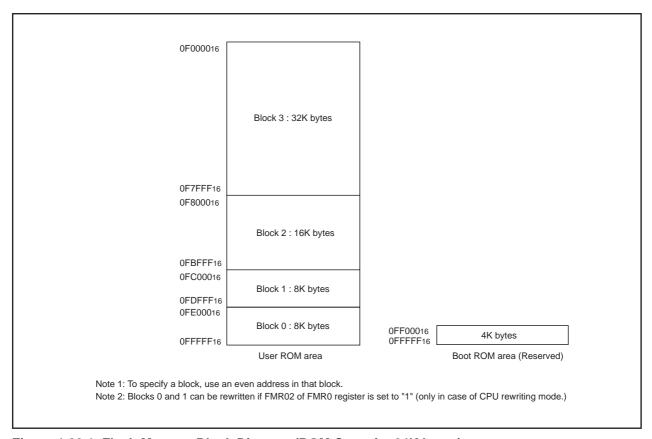

Figure 1.20.1. Flash Memory Block Diagram (ROM Capacity 64K bytes)

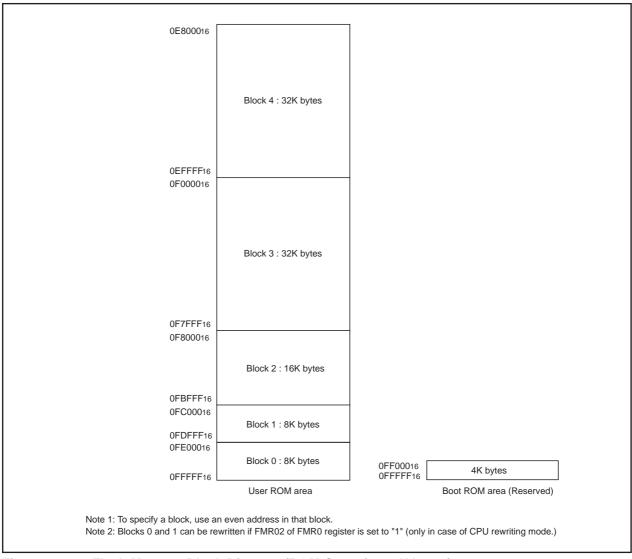

Figure 1.20.2. Flash Memory Block Diagram (ROM Capacity 96K bytes)

#### **Boot Mode**

After a hardware reset which is performed by applying a high-level signal to the CNVss and P15 pins, the microcomputer is placed in boot mode, thereby executing the program in the boot ROM area.

The boot ROM area contains a standard serial input/output mode based rewrite control program which was stored in it when shipped from the factory.

## **Functions To Prevent Flash Memory from Rewriting**

To prevent the flash memory from being read or rewritten easily, parallel input/output mode has a ROM code protect and standard serial input/output mode has an ID code check function.

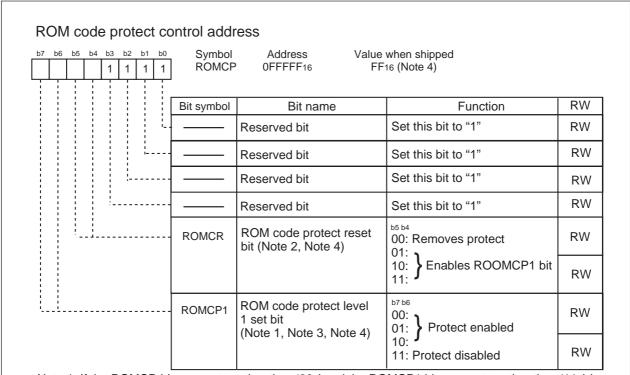

#### ROM Code Protect Function

The ROM code protect function inhibits the flash memory from being read or rewritten during parallel input/output mode. Figure 1.20.3 shows the ROMCP register.

The ROMCP register is located in the user ROM area. The ROMCP1 bit consists of two bits. The ROM code protect function is enabled by clearing one or both of two ROMCP1 bits to "0" when the ROMCR bits are not '002,' with the flash memory thereby protected against reading or rewriting. Conversely, when the ROMCR bits are '002' (ROM code protect removed), the flash memory can be read or rewritten. Once the ROM code protect function is enabled, the ROMCR bits cannot be changed during parallel input/output mode. Therefore, use standard serial input/output or other modes to rewrite the flash memory.

#### ID Code Check Function

Use this function in standard serial input/output mode. Unless the flash memory is blank, the ID codes sent from the programmer and the ID codes written in the flash memory are compared to see if they match. If the ID codes do not match, the commands sent from the programmer are not accepted. The ID code consists of 8-bit data, the areas of which, beginning with the first byte, are 0FFFDF16, 0FFFE316, 0FFFE316, 0FFFF316, and 0FFFFB16. Prepare a program in which the ID codes are preset at these addresses and write it in the flash memory.

- Note 1: If the ROMCR bits are set to other than '002' and the ROMCP1 bits are set to other than '112' ( ROM code protect enabled), the flash memory is disabled against reading and rewriting in parallel input/output mode.
- Note 2: If the ROMCR bits are set to '002' when the ROMCR bits are other than '002' and the ROMCP1 bits are other than '112,' ROM code protect level 1 is removed. However, because the ROMCR bits cannot be modified during parallel input/output mode, they need to be modified in standard serial input/output or other modes.
- Note 3: The ROMCP1 bits are effective when the ROMCR bits are '012,' '102,' or '112.' Note 4: Once any of these bits is cleared to "0", it cannot be set back to "1". If a memory block that contains the ROMCP register is erased, the ROMCP register is set to 'FF16.'

Figure 1.20.3. ROMCP Register

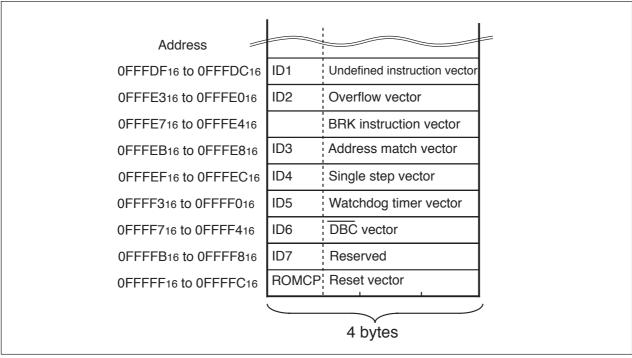

Figure 1.20.4. Address for ID Code Stored

## **CPU Rewrite Mode**

In CPU rewrite mode, the user ROM area can be rewritten by executing software commands from the CPU. Therefore, the user ROM area can be rewritten directly while the microcomputer is mounted on-board without having to use a ROM programmer, etc.

Make sure the Program and the Block Erase commands are executed only on each block in the user ROM area.

During CPU rewrite mode, the user ROM area be operated on in either Erase Write 0 (EW0) mode or Erase Write 1 (EW1) mode. Table 1.21.1 lists the differences between Erase Write 0 (EW0) and Erase Write 1 (EW1) modes.

Table 1.21.1. EW0 Mode and EW1 Mode

Item	EW0 mode	EW1 mode
Operation mode	Single chip mode	Single chip mode
Areas in which a	User ROM area	User ROM area
rewrite control		
program can be located		
Areas in which a	Must be transferred to any area other	Can be executed directly in the user

	command to read the status	
	register's SR7, SR5, and SR4 flags.	

Note: Make sure no interrupts (except \overline{NMI} and watchdog timer interrupts) and DMA transfers will occur.

## • EW0 Mode

The microcomputer is placed in CPU rewrite mode by setting the FMR0 register's FMR01 bit to "1" (CPU rewrite mode enabled), ready to accept commands. In this case, because the FMR1 register's FMR11 bit = 0, EW0 mode is selected. The FMR01 bit can be set to "1" by writing "0" and then "1" in succession. Use software commands to control program and erase operations. Read the FMR0 register or status register to check the status of program or erase operation at completion.

#### EW1 Mode

EW1 mode is selected by setting FMR11 bit to "1" (by writing "0" and then "1" in succession) after setting the FMR01 bit to "1" (by writing "0" and then "1" in succession).

Read the FMR0 register to check the status of program or erase operation at completion. The status register cannot be read during EW1 mode.

When an erase/program operation is initiated the CPU halts all program execution until the operation is completed.

Figure 1.21.1 shows the FMR0 and FMR1 registers.

#### FMR00 Bit

This bit indicates the operating status of the flash memory. The bit is "0" when the Program or Erase is running; otherwise, the bit is "1".

#### FMR01 Bit

The microcomputer is made ready to accept commands by setting the FMR01 bit to "1" (CPU rewrite mode).

#### FMR02 Bit

When FMR02 bit is "0" (rewriting is disable), block 0 and block 1 do not receive the command of a program and block erase.

#### **FMSTP Bit**

This bit is provided for initializing the flash memory control circuits, as well as for reducing the amount of current consumed in the flash memory. The internal flash memory is disabled against access by setting the FMSTP bit to "1". Therefore, the FMSTP bit must be written to by a program in other than the flash memory.

In the following cases, set the FMSTP bit to "1":

• When flash memory access resulted in an error while erasing or programming in EW0 mode (FMR00 bit not reset to "1" (ready))

#### FMR06 Bit

This is a read-only bit indicating the status of auto program operation. The bit is set to "1" when a program error occurs; otherwise, it is cleared to "0". For details, refer to the description of the full status check.

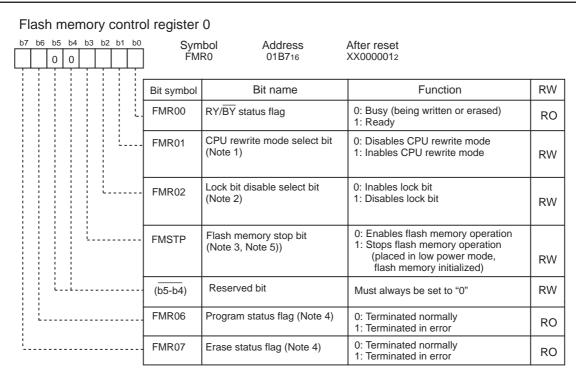

#### FMR07 Bit

This is a read-only bit indicating the status of auto erase operation. The bit is set to "1" when an erase error occurs; otherwise, it is cleared to "0". For details, refer to the description of the full status check.

Figure 1.21.2 and 1.21.3 show the setting and resetting of EW0 mode and EW1 mode, respectively.

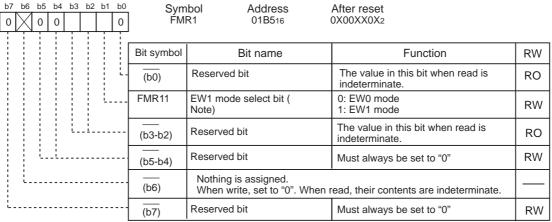

#### FMR11 Bit

Setting this bit to "1" places the microcomputer in EW1 mode.

- Note 1: To set this bit to "1", write "0" and then "1" in succession. Make sure no interrupts or DMA transfers will occur before writing "1" after writing "0". Also, while in EW0 mode, write to this bit from a program in other than the flash memory.
- Note 2: To set this bit to "1", write "0" and then "1" in succession when the FMR01 bit = 1. Make sure no interrupts or no DMA transfers will occur before writing "1" after writing "0".
- Note 3: Write to this bit from a program in other than the flash memory.
- Note 4: This flag is cleared to "0" by executing the Clear Status command.
- Note 5: Effective when the FMR01 bit = 1 (CPU rewrite mode). If the FMR01 bit = 0, although the FMR03 bit can be set to "1" by writing "1" in a program, the flash memory is neither placed in low power mode nor initialized.

#### Flash memory control register 1

Note: To set this bit to "1", write "0" and then "1" in succession when the FMR01 bit = 1. Make sure no interrupts or no DMA transfers will occur before writing "1" after writing "0".

The FMR01 and FMR11 bits both are cleared to "0" by setting the FMR01 bit to "0".

Figure 1.21.1. FIDR Register and FMR0 and FMR1 Registers

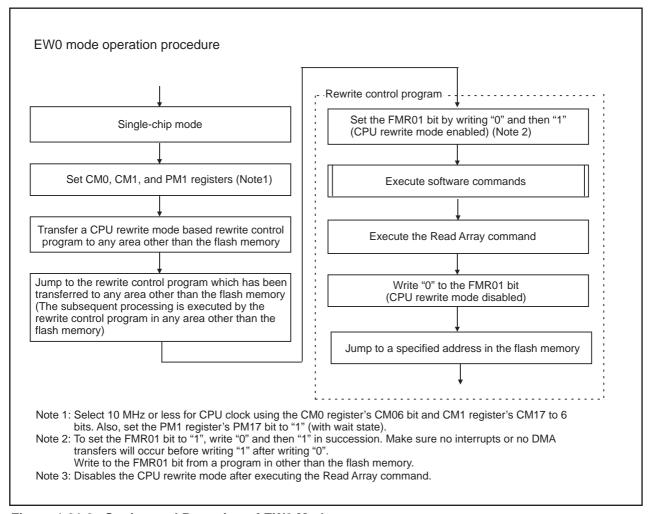

Figure 1.21.2. Setting and Resetting of EW0 Mode

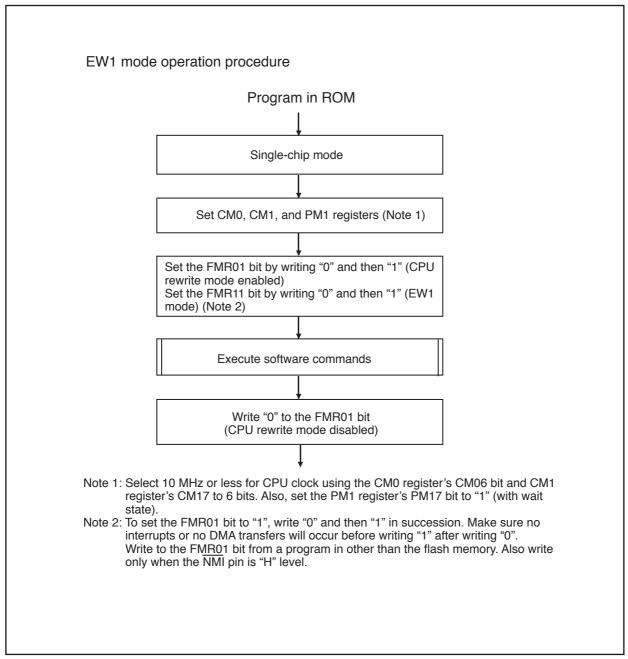

Figure 1.21.3. Setting and Resetting of EW1 Mode

#### **Precautions on CPU Rewrite Mode**

Described below are the precautions to be observed when rewriting the flash memory in CPU rewrite mode.

#### (1) Operation Speed

Before entering CPU rewrite mode (EW0 or EW1 mode), select 10 MHz or less for BCLK using the CM06 bit in the CM0 register and the CM17 to CM16 bits in the CM1 register. Also, set the PM17 bit in the PM1 register to "1" (with wait state).

## (2) Instructions to Prevent from Using

The following instructions cannot be used in EW0 mode because the flash memory's internal data is referenced: UND instruction, INTO instruction, JMPS instruction, JSRS instruction, and BRK instruction

#### (3) Interrupts

#### EW0 Mode

- Any interrupt which has a vector in the variable vector table can be used providing that its vector is transferred into the RAM area.
- The NMI and watchdog timer interrupts can be used because the FMR0 register and FMR1 register are initialized when one of those interrupts occurs. The jump addresses for those interrupt service routines should be set in the fixed vector table.
- Because the rewrite operation is halted when a NMI or watchdog timer interrupt occurs, the rewrite program must be executed again after exiting the interrupt service routine.
- The address match interrupt cannot be used because the flash memory's internal data is referenced.

#### EW1 Mode

- Make sure that any interrupt which has a vector in the variable vector table or address match interrupt will not be accepted during the auto program or auto erase period.
- Avoid using watchdog timer interrupts.
- The WDT interrupt can be used because the FMR0 register and FMR1 register are initialized when this interrupt occurs. The jump address for the interrupt service routine should be set in the fixed vector table.

Because the rewrite operation is halted when a WDT interrupt occurs, the rewrite program must be executed again after exiting the interrupt service routine.

#### (4) How to Access

To set the FMR01, FMR02, or FMR11 bit to "1", write "0" and then "1" in succession. This is necessary to ensure that no interrupts or DMA transfers will occur before writing "1" after writing "0".

#### (5) Writing in the User ROM Space

EW0 Mode

• If the power supply voltage drops while rewriting any block in which the rewrite control program is stored, a problem may occur that the rewrite control program is not correctly rewritten and, consequently, the flash memory becomes unable to be rewritten thereafter. In this case, standard serial I/O or parallel I/O mode should be used.

## EW1 Mode

• Avoid rewriting any block in which the rewrite control program is stored.

## (6) DMA Transfer

In EW1 mode, make sure that no DMA transfers will occur while the FMR0 register's FMR00 bit = 0 (during the auto program or auto erase period).

#### (7) Writing Command and Data

Write the command code and data at even addresses.

#### (8) Wait Mode

When shifting to wait mode, set the FMR01 bit to "0" (CPU rewrite mode disabled) before executing the WAIT instruction.

#### (9) Stop Mode

When shifting to stop mode, the following settings are required:

- Set the FMR01 bit to "0" (CPU rewrite mode disabled) and disable DMA transfers before setting the CM10 bit to "1" (stop mode).
- Execute the JMP.B instruction subsequent to the instruction which sets the CM10 bit to "1" (stop mode)

Example program BSET 0, CM1 ; Stop mode JMP.B L1 L1:

Program after returning from stop mode

#### **Software Commands**

Software commands are described below. The command code and data must be read and written in 16-bit units, to and from even addresses in the user ROM area. When writing command code, the 8 high-order bits (D1t–D8) are ignored.

Table 1.21.2. Software Commands

	First bus cycle			Second bus cycle			
Command	Modo		Data (D <sub>0</sub> to D <sub>7</sub> )	Mode	Address	Data (D <sub>0</sub> to D <sub>7</sub> )	
Read array	Write	Х	xxFF16				
Read status register	Write	X	xx7016	Read	X	SRD	
Clear status register	Write	X	xx5016				
Program	Write	WA	xx4016	Write	WA	WD	
Block erase	Write	X	xx2016	Write	ВА	xxD016	

SRD: Status register data (D7 to D0)

WA: Write address (Make sure the address value specified in the the first bus cycle is the same even address as the write address specified in the second bus cycle.)

WD: Write data (16 bits)

BA: Uppermost block address (even address, however)

X: Any even address in the user ROM area

x: High-order 8 bits of command code (ignored)

## Read Array Command (FF16)

This command reads the flash memory.

Writing 'xxFF<sub>16</sub>' in the first bus cycle places the microcomputer in read array mode. Enter the read address in the next or subsequent bus cycles, and the content of the specified address can be read in 16-bit units.

Because the microcomputer remains in read array mode until another command is written, the contents of multiple addresses can be read in succession.

However, when you use Read array command immediately after a program command, please read data in the following procedure.

- (1) FF16, FF16, and FF16 are written to 4 arbitrary continuous addresses.
- (2) The head address of (1) is specified in Read array mode.
- (3) (2) is repeated until the read value and FFFF16 are in agreement.
- (4) The head address +2 of (1) is specified.
- (5) (4) is repeated until the read value and FFFF16 are in agreement.
- (6) Arbitrary addresses are specified.

### Read Status Register Command (7016)

This command reads the status register.

Write 'xx7016' in the first bus cycle, and the status register can be read in the second bus cycle. (Refer to "Status Register.") When reading the status register too, specify an even address in the user ROM area.

Do not execute this command in EW1 mode.

#### Clear Status Register Command (5016)

This command clears the status register to "0".

Write 'xx50<sub>16</sub>' in the first bus cycle, and the FMR06 to FMR07 bits in the FMR0 register and SR4 to SR5 in the status register will be cleared to "0".

#### **Program Command (4016)**

This command writes data to the flash memory in 1 word (2 byte) units.

Write 'xx4016' in the first bus cycle and write data to the write address in the second bus cycle, and an auto program operation (data program and verify) will start. Make sure the address value specified in the first bus cycle is the same even address as the write address specified in the second bus cycle.

Check the FMR00 bit in the FMR0 register to see if auto programming has finished. The FMR00 bit is "0" during auto programming and set to "1" when auto programming is completed.

Check the FMR06 bit in the FMR0 register after auto programming has finished, and the result of auto programming can be known. (Refer to "Full Status Check.")

Writing over already programmed addresses is inhibited.

Moreover, when FMR02 bit of FMR0 register is "0" (rewriting is disable), the program command to block 0 and block 1 is not received. Just behind a program command, when you execute commands other than a program command, please make it the address value which was specified by the 2nd bus cycle of a program command and which writes in and specifies the same address as an address by the 1st bus cycle of the following command.

In EW1 mode, do not execute this command on any address at which the rewrite control program is located.

In EW0 mode, the microcomputer goes to read status register mode at the same time auto programming starts, making it possible to read the status register. The status register bit 7 (SR7) is cleared to "0" at the same time auto programming starts, and set back to "1" when auto programming finishes. In this case, the microcomputer remains in read status register mode until a read command is written next. The result of auto programming can be known by reading the status register after auto programming has finished.

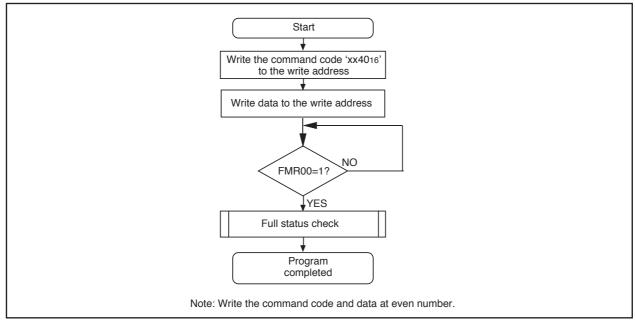

Figure 1.21.4. Program Command

#### **Block Erase**

Write 'xx2016' in the first bus cycle and write 'xxD016' to the uppermost address of a block (even address, however) in the second bus cycle, and an auto erase operation (erase and verify) will start. Check the FMR0 register's FMR00 bit to see if auto erasing has finished.

The FMR00 bit is "0" during auto erasing and set to "1" when auto erasing is completed.

Check the FMR0 register's FMR07 bit after auto erasing has finished, and the result of auto erasing can be known. (Refer to "Full Status Check.")

Moreover, when FMR02 bit of FMR0 register is "0" (rewriting is disable), the block erase command to block 0 and block 1 is not received.

Figure 1.21.5 shows an example of a block erase flowchart.

Each block can be protected against erasing by a lock bit. (Refer to "Data Protect Function.")

Writing over already programmed addresses is inhibited.

In EW1 mode, do not execute this command on any address at which the rewrite control program is located.

In EW0 mode, the microcomputer goes to read status register mode at the same time auto erasing starts, making it possible to read the status register. The status register bit 7 (SR7) is cleared to "0" at the same time auto erasing starts, and set back to "1" when auto erasing finishes. In this case, the microcomputer remains in read status register mode until the Read Array or Read Lock Bit Status command is written next.

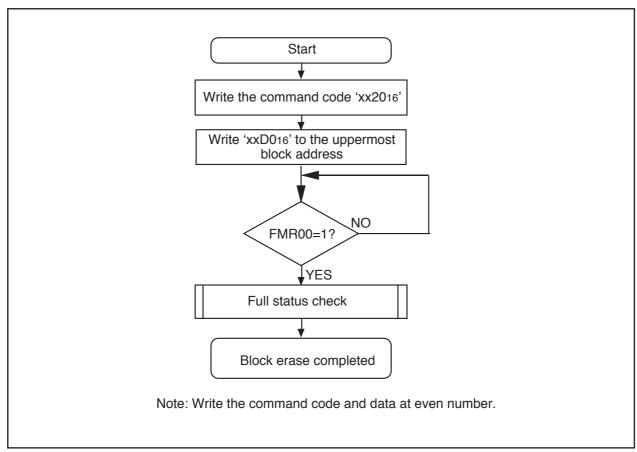

Figure 1.21.5. Block Erase Command

## **Status Register**

The status register indicates the operating status of the flash memory and whether an erase or programming operation terminated normally or in error. The status of the status register can be known by reading the FMR0 register's FMR00, FMR06, and FMR07 bits.

Table 1.21.3 shows the status register.

In EW0 mode, the status register can be read in the following cases:

- (1) When a given even address in the user ROM area is read after writing the Read Status Register command
- (2) When a given even address in the user ROM area is read after executing the Program, Block Erase, Erase All Unlocked Block, or Lock Bit Program command but before executing the Read Array command.

#### Sequencer Status (SR7 and FMR00 Bits )

The sequence status indicates the operating status of the flash memory. SR7 = 0 (busy) during auto programming and auto erase is set to "1" (ready) at the same time the operation finishes.

#### Erase Status (SR5 and FMR07 Bits)

Refer to "Full Status Check."

### **Program Status (SR4 and FMR06 Bits)**

Refer to "Full Status Check."

Table 1.21.3. Status Register

Do to D7: Indicates the data bus which is read out when the Read Status Register command is executed.

Status register	FMR0 register	Status name	Con	tents	Value after
bit	bit	Otatus Harrie	"0"	"1"	reset
SR7 (D7)	FMR00	Sequencer status	Busy	Ready	1
SR6 (D6)		Reserved	-	-	
SR5 (D5)	FMR07	Erase status	Terminated normally	Terminated in error	0
SR4 (D4)	FMR06	Program status	Terminated normally	Terminated in error	0
SR3 (D3)		Reserved	-	-	
SR2 (D2)		Reserved	-	-	
SR1 (D1)		Reserved	-	-	
SR0 (D0)		Reserved	-	-	

- The FMR07 bit (SR5) and FMR06 bit (SR4) are cleared to "0" by executing the Clear Status Register command.
- When the FMR07 bit (SR5) or FMR06 bit (SR4) = 1, the Program and Block Erase are not accepted.

## **Full Status Check**

When an error occurs, the FMR0 register's FMR06 to FMR07 bits are set to "1", indicating occurrence of each specific error. Therefore, execution results can be verified by checking these status bits (full status check). Table 1.21.4 lists errors and FMR0 register status. Figure 1.21.6 shows a full status check flowchart and the action to be taken when each error occurs.

Table 1.21.4. Errors and FMR0 Register Status

FMR00	register		
(SRD register)			
status		Error	Error occurrence condition
FMR07	FMR06		
(SR5)	(SR4)		
1	1	Command	When any commands are not written correctly
		sequence error	• A value other than 'xxD016' or 'xxFF16' is written in the second
			bus cycle of the block erase command (Note 1)
			When the block erase command is executed on protected blocks
			When the program command is executed on protected blocks
1	0	Erase error	When the block erase command is executed on unprotected
			blocks but the blocks are not automatically erased correctly
0	1	Program error	When the program command is executed on unprotected blocks
			but the blocks are not automatically programmed correctly.

Note 1: The flash memory enters read array mode by writing command code 'xxFF16' in the second bus cycle of these commands. The command code written in the first bus cycle becomes invalid.

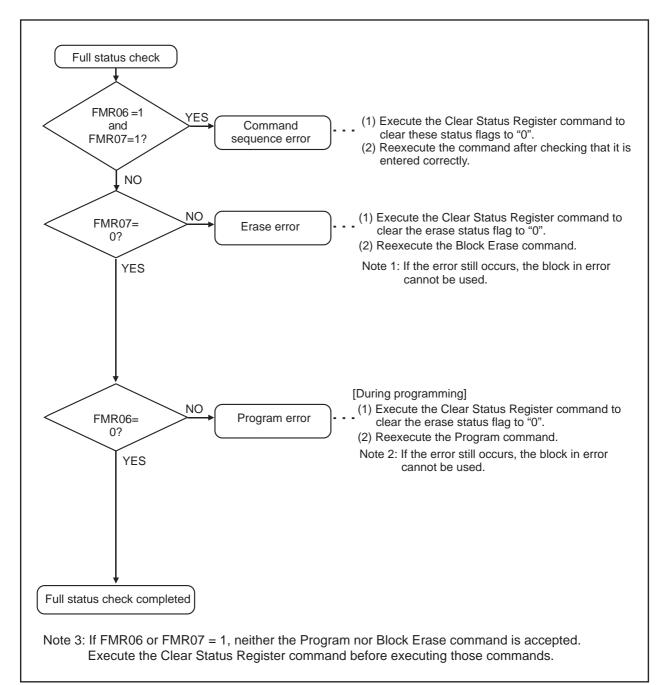

Figure 1.21.6. Full Status Check and Handling Procedure for Each Error

#### Standard Serial I/O Mode

The standard serial I/O mode inputs and outputs the software commands, addresses and data needed to operate (read, program, erase, etc.) the internal flash memory using the serial I/O port UART1. The serial I/O mode transfers the data serially in 8-bit units.

In the standard serial I/O mode the CPU executes a control program for flash memory rewrite (using the CPU's rewrite mode), rewrite data input and so forth. It is started when both the P15 (CE) pin and the CNVss pin are in "H" level after the reset is released. (In normal operation mode, set CNVss pin to "L" level.) The main clock f1 is 5.12 MHz in this mode.

This control program is written in the boot ROM area when the product is shipped.

There are actually two standard serial I/O modes: mode 1, which is clock synchronized, and mode 2, which is asynchronized. Standard serial I/O switches between mode 1 (clock synchronous) and mode 2 (clock asynchronous) depending on the level of CLK1 pin when the reset is released.

To use standard serial I/O mode 1 (clock synchronous), set the CLK1 pin to "H" level and release the reset. The operation uses the four UART1 pins CLK1, RxD1, TxD1 and RTS1 (BUSY). The CLK1 pin is the transfer clock input pin through which an external transfer clock is input. The TxD1 pin is for CMOS output. The RTS1 (BUSY) pin outputs an "L" level when ready for reception and an "H" level when reception starts. In mode 1, be sure the TxD1 (P67) pin is at high before reset being deasserted.

To use standard serial I/O mode 2 (clock asynchronous), set the CLK1 pin to "L" level and release the reset. The operation uses the two UART1 pins RxD1 and TxD1.

In standard serial input/output mode, the user ROM area can be rewritten while the microcomputer is mounted on-board by using a serial programmer suitable for the M16C/62P group. For more information about serial programmers, contact the manufacturer of your serial programmer. For details on how to use, refer to the user's manual included with your serial programmer.

Table 1.22.1 lists pin functions (flash memory standard serial input/output mode). Figures 1.22.1 to 1.22.2 show pin connections for serial input/output mode.

## **ID Code Check Function**

This function determines whether the ID codes sent from the serial programmer and those written in the flash memory match. (Refer to the description of the functions to inhibit rewriting flash memory version.)

Table 1.22.1. Functional explanation of pin (flash memory standard serial I/O mode)

Pin	Signal name	I/O	Description
Vcc,Vss	Power supply input		Apply the voltage guaranteed for Program and Erase to Vcc pin. Apply 0 V to Vss pin.
CNVss	CNVss	ı	Connect to Vcc pin.
RESET	Reset input	I	Reset input pin. While RESET pin is "L" level, input a 20 cycle or longer clock to XIN pin.
XIN	Clock input	ı	Connect a ceramic resonator or crystal oscillator between XIN and
Xout	Clock output	0	XOUT pins. To input an externally generated clock, input it to XIN pin and open XOUT pin.
VDCCN			Input "H" level signal.
VccA, VssA	Analog power supply input	ı	Please connect AVcc to Vcc and connect AVss to Vss.
VREF	Standard voltage input	I	Input the standard voltage of a preamplifier and an operational amplifier.
P60 to P63	Input port P6	ı	Input "H" or "L" level signal or open.
P64/RTS1	BUSY output	0	Standard serial I/O mode 1: BUSY signal output pin Standard serial I/O mode 2: Monitors the boot program operation check signal output pin.
P65/CLK1	SCLK input	I	Standard serial I/O mode 1: Serial clock input pin Standard serial I/O mode 2: Input "L."
P66/RxD1	RxD input	I	Serial data input pin.
P67/TxD1	TxD output	0	Serial data output pin. (Note 1)
P70, P71, P73, P74, P76	Input port P7	I	Input "H" or "L" level signal or open.
P80, P81, P83, P84, P85	Input port P8	I	Input "H" or "L" level signal or open.
P15	CE input	l	Input "H" level signal.
P90 to P92	Input port P11	ļ	Input "H" or "L" level signal or open.

Note 1: When using standard serial input/output mode 1, the TxD pin must be held high while the RESET pin is pulled low.

Therefore, connect this pin to Vcc1 via a resistor. Because this pin is directed for data output after reset, adjust the pull-up resistance value in the system so that data transfers will not be affected.

M16C/6S Group Flash Memory Version

# **Example of Circuit Application in the Standard Serial I/O Mode**

Figure 1.22.1 and 1.22.2 show example of circuit application in standard serial I/O mode 1 and mode 2, respectively. Refer to the user's manual for serial programmer to handle pins controlled by a serial programmer.

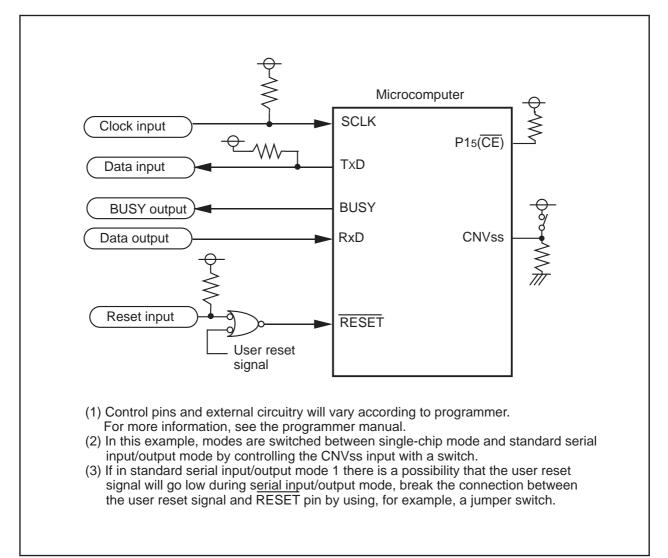

Figure 1.22.1. Circuit Application in Standard Serial I/O Mode 1

M16C/6S Group Flash Memory Version

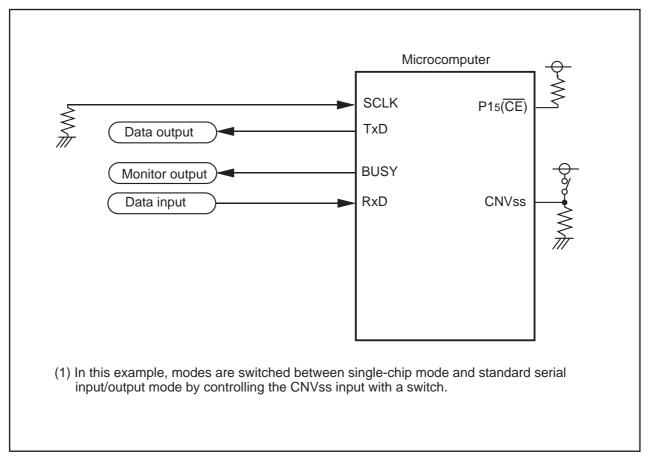

Figure 1.22.2. Circuit Application in Standard Serial I/o Mode 2

M16C/6S Group Flash Memory Version

# **ROM Code Protect Function**

The ROM code protect function inhibits the flash memory from being read or rewritten. (Refer to the description of the functions to inhibit rewriting flash memory version.)

# IT800AFE (Analog Front End)

# 1. The block diagram of analog front end

Analog front end (AFE) part is the circuit located between M16C/6S and a power line, and M16C/6S build in DAC, preamplifier, and ADC. There are the following two signal circuits in AFE.

- (1)Transmitting circuit:It drives with the signal from the logic of M16C/6S inside, and this is consists of DAC with a differential output, Output filter for spectrum adjustment, Differential line driver amplifier and line coupling circuit which drive power line.
- (2) Receiving circuit: This is consists of Line coupling circuit, Differential preamplifier, Input filter group and ADC. Line coupling circuit is common to both transmission and reception.

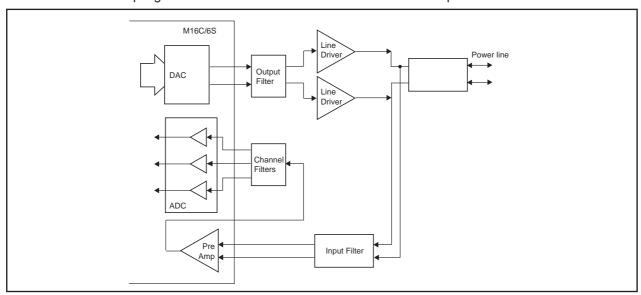

Figure 1.23.1 Analog Front End circuit block diagram

## (1)Transmitting path

The characteristics required for transmitting path are as follows.

- (a) A suitable output signal level is obtained on specific load.
- (b)Frequency characteristic is flat in signal bandwidth.
- (c)The signal level outside a zone: It is less than each regulation.

This system assumes operation in the following three fundamental signal zones.

- (a)The U.S., Japan: 120k to 400kHz
- (b) Europe in door: 95k to 125kHz(CENELEC B Band)
- (c) Europe out door: 20k to 80kHz(CENELEC A Band)

It is necessary to perform the change of a signal zone by change of adjustment of change of the configuration of IT800, the analog filter to a signal zone, or output electric power, and the output impedance of the line driver stage (notes).

Note. Please refer to the following standard and style about the conditions outside a signal level or a zone.

- (a) The U.S.: FCC standard, part 15
- (b) Europe: CENELEC standard, EN 50065-1
- (c)Japan:ARIB STD-T84

M16C/6S Group IT800AFE (Analog Front End)

# About DAC (Digital to Analog Converter)

DAC of built-in in M16C/6S is current output type 10 bit DAC. The standard level of output current can be set up by the external resistance linked to a built-in standard power supply. A DAC circuit and a load circuit are shown in Figure 1.23.2. The typical characteristic is shown in Table 1.23.1.

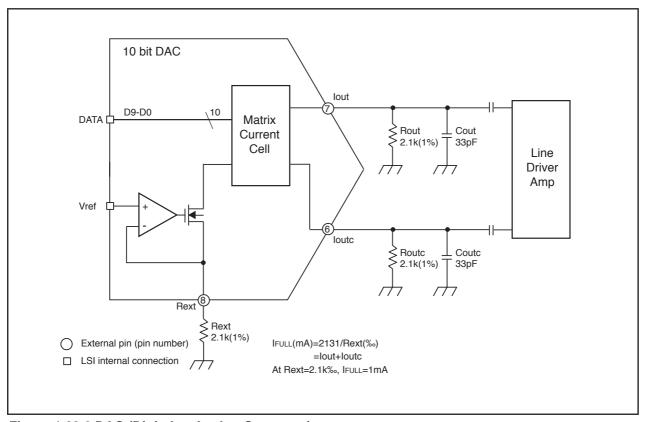

Figure 1.23.2 DAC (Digital to Analog Converter)

Table 1.23.1 DAC Electrical Characteristics (Vdd=3.3±0.3V, Ta = -20 to 85°C/-40 to 85°C/-40 to 105°C unless otherwise specified)

Б		Condition	Electrical Characteristics			11.7
Parameter	Symbol		Min	Тур	Max	Unit
Standard voltage	Vref	Rext=2.1k		0.3		V
Standard current	Iref	Rext=2.1k		0.14		mA
External standard register	Rext			2.1		k
DAC output register	Rout/Routc	Rext=2.1k			2.0	k
Full-scale current	IFULL	Rext=2.1k	0.9	1	1.1	mA
Maximum output voltage	Voutmax	Rout/Routc=2.1k			Vdd-1	V

In the circumference of a DAC circuit, it is cautious of the following point and a constant is set up.

# (a)Full-scale output current of DAC

Although the current by which DAC is outputted to a pin (lout/loutc) according to the change width of an internal bit changes, total is fixed and serves as full-scale output current (IFULL). This IFULL can be set up by the following formula.

IFULL=2131/Rext(mA)

The unit of Rext is  $\Omega$ 

Since about 1mA of an IFULL value is the optimal value, Rext is  $2.1k\Omega$ .

DAC is total and lout/loute changes between 0 to IFULL at 1024 steps by the full range for a change width of 10 bits.

The value of lout/loutc is expressed with the following formula if the step value which converted the 10-bit binary input into decimal is set to d. (d=0 to 1023)

lout=IFULL/1023\*d

loutc=IFULL/1023\*(1023-d)

#### (b) About DAC load resistance

Resistance (Rout/Routc) is connected to a DAC output pin.In this resistance, signal voltage occurs by the current (lout/loutc) which flows, respectively. In order to maintain the linearity of lout/loutc, it is necessary to set up Rout/Routc so that this potential may not exceed maximum 2V. Since lout/loutc is mostly set to one half of IFULL(s) at the time of a non-signal (balanced state), the signal voltage (Vout/Voutc) of a DAC output pin is set to below:

Vout=Rout X lout

Voutc=Routc X Ioutc

Since the recommendation value of Vout/Voutc at the time of a non-signal is about 1V, in Rext=2.1k $\Omega$ , Rout/Routc serves as 2.1k $\Omega$ .

The capacitor (Cout/Coutc) for output filters cuts the high frequency ingredient of DAC, and sets it up on balance with necessary zone frequency.

M16C/6S Group

# (2) Receiving circuit

# (a)Preamplifier

A preamplifier circuit consists of two CMOS operational amplifiers as shown in Figure 1.23.3, the first opamp is connected as gain stage with gain of 20dB and the second opamp is connected as a voltage follower for driving of external filter.

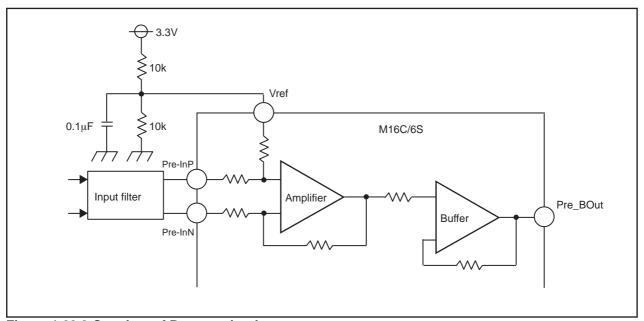

Figure 1.23.3 Consists of Preamp circuit

Table 1.23.2 Preamp Electrical Characteristics (Ta = 25°C unless otherwise specified)

D	0		Electrical Characteristics			
Parameter	Symbol	Condition	Min	Тур	Max	Unit
Standard voltage	Vdd		3.0	3.3	3.6	V
Input off-set voltage	Vof				15	mV
Open loop gain	Gvo	No-load	70			dB
Gain band width	BW	Gvo=0dB	5			MHz
Common mode input range	CMIR	DC to 1MHz	0.7		Vdd-0.7	V
Common mode rejection ratio	CMRR	DC to 1MHz	40			dB
Power supply rejection ratio	PSRR	DC to 1MHz	30			dB

### (b)ADC (Analog to Digital Converter)

The output of the channel filter (maximum of three) connected outside is connected to 1 bit ADC which consists of an operational amplifier and a comparator.

M16C/6S build in ADC of three equivalent performances. The circuit of one ADC has composition shown in the following figure.

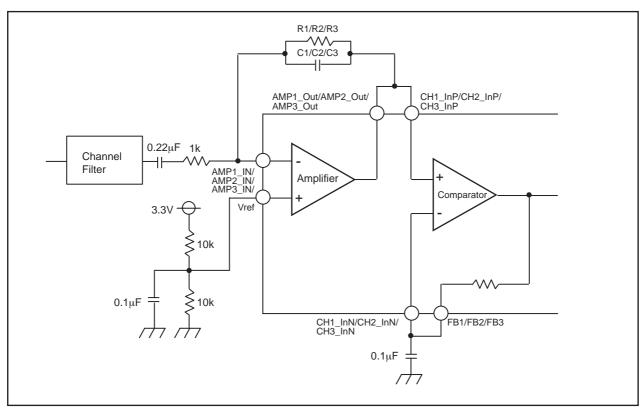

Figure 1.23.4 ADC block diagram

Three ADC use all three by the signal zone to be used. The constant of a filter is set up as shown in the following table.

Table 1.23.3 The example of an ADC part constant setting

Parts	Application characteristic	C1	C2	C3	Unit
0	FCC/ARIB	33	22	10	pF
Capacitor	CECLEC-B	33			pF
Parts	Application characteristic	R1	R2	R3	Unit
Pogiator	FCC/ARIB	10	10	12	kΩ
Register	CECLEC-B	10			kΩ

# **Usage Notes**

# **Register Setting**

Immediate values should be set in the registers containing write-only bits. When establishing a new value by modifying a previous value, write the previous value into RAM as well as the register. Change the contents of the RAM and then transfer the new value to the register.

#### **Power Control**

When entering wait mode, insert a JMP.B instruction before a WAIT instruction. Do not excute any instructions which can generate a write to RAM between the JMP.B and WAIT instructions. Disable the DMA transfers, if a DMA transfer may occur between the JMP.B and WAIT instructions. After the WAIT instruction, insert at least 4 NOP instructions. When entering wait mode, the instruction queue reads ahead the instructions following WAIT, and depending on timing, some of these may execute before the MCU enters wait mode.

Program example when entering wait mode

```
Program Example: JMP.B L1 ; Insert JMP.B instruction before WAIT instruction L1:

FSET I ;
WAIT ; Enter wait mode
NOP ; More than 4 NOP instructions
NOP
NOP
NOP
```

When entering stop mode, insert a JMP.B instruction immediately after executing an instruction which sets the CM10 bit in the CM1 register to 1, and then insert at least 4 NOP instructions. When entering stop mode, the instruction queue reads ahead the instructions following the instruction which sets the CM10 bit to 1 (all clock stops), and, some of these may execute before the MCU enters stop mode or before the interrupt routine for returning from stop mode.

Program example when entering stop mode

```
Program Example: FSET I
BSET CM10 ; Enter stop mode
JMP.B L2 ; Insert JMP.B instruction
L2:
NOP ; More than 4 NOP instructions
NOP
NOP
NOP
```

Stop mode and wait mode is cancelled by a hardware reset or an interrupt. if an interrupt is to be used to cancel stop mode and wait mode that interrupt must first have been enabled, and the priority level of the interrupt which is not used to cancel must have been changed to 0.

# **Changing the Interrupt Generate Factor**

If the interrupt generate factor is changed, the IR bit in the interrupt control register for the changed interrupt may inadvertently be set to 1 (interrupt requested). If you changed the interrupt generate factor for an interrupt that needs to be used, be sure to clear the IR bit for that interrupt to 0 (interrupt not requested). "Changing the interrupt generate factor" referred to here means any act of changing the source, polarity or timing of the interrupt assigned to each software interrupt number. Therefore, if a mode change of any peripheral function involves changing the generate factor, polarity or timing of an interrupt, be sure to clear the IR bit for that interrupt to 0 (interrupt not requested) after making such changes. Refer to the description of each peripheral function for details about the interrupts from peripheral functions.

Figure 1.24.1 shows the procedure for changing the interrupt generate factor.

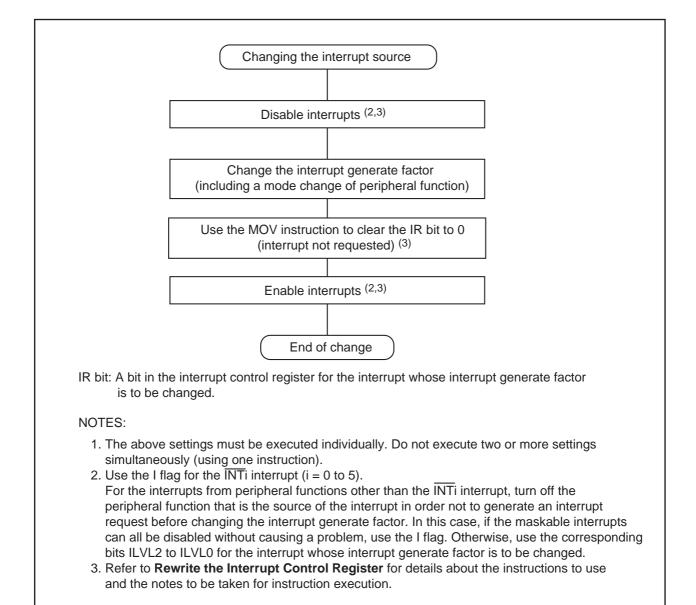

Figure 1.24.1 Procedure for Changing the Interrupt Generate Factor

# **Watchdog Timer Interrupt**

Initialize the watchdog timer after the watchdog timer interrupt occurs.

#### **DMAC**

# Write to DMAE Bit in DMiCON Register (i = 0 to 1)

When both of the conditions below are met, follow the steps below.

- (a) Conditions
  - The DMAE bit is set to 1 again while it remains set (DMAi is in an active state).
  - A DMA request may occur simultaneously when the DMAE bit is being written.
- (b) Procedure
  - (1) Write 1 to the DMAE bit and DMAS bit in DMiCON register simultaneously (1).
  - (2) Make sure that the DMAi is in an initial state (2) in a program.

If the DMAi is not in an initial state, the above steps should be repeated.

#### NOTES:

- 1. The DMAS bit remains unchanged even if 1 is written. However, if 0 is written to this bit, it is set to 0 (DMA not requested). In order to prevent the DMAS bit from being modified to 0, 1 should be written to the DMAS bit when 1 is written to the DMAE bit. In this way the state of the DMAS bit immediately before being written can be maintained.
  - Similarly, when writing to the DMAE bit with a read-modify-write instruction, 1 should be written to the DMAS bit in order to maintain a DMA request which is generated during execution.
- 2. Read the TCRi register to verify whether the DMAi is in an initial state. If the read value is equal to a value which was written to the TCRi register before DMA transfer start, the DMAi is in an initial state. (If a DMA request occurs after writing to the DMAE bit, the value written to the TCRi register is 1.) If the read value is a value in the middle of transfer, the DMAi is not in an initial state.

#### **Timers**

### Timer A

# Timer A (Timer Mode)

The timer remains idle after reset. Set the mode, count source, counter value, etc. using the TAiMR (i = 0 to 4) register and the TAi register before setting the TAiS bit in the TABSR register to 1 (count starts). Always make sure the TAiMR register is modified while the TAiS bit remains 0 (count stops) regardless whether after reset or not.

While counting is in progress, the counter value can be read out at any time by reading the TAi register. However, if the TAi register is read at the same time the counter is reloaded, the read value is always FFFF16. If the TAi register is read after setting a value in it, but before the counter starts counting, the read value is the one that has been set in the register.

# Timer A (Event Counter Mode)

The timer remains idle after reset. Set the mode, count source, counter value, etc. using the TAiMR (i = 0 to 4) register, the TAi register, the UDF register, bits TAZIE, TA0TGL, and TA0TGH in the ONSF register and the TRGSR register before setting the TAiS bit in the TABSR register to 1 (count starts).

Always make sure bits TAZIE, TA0TGL, and TA0TGH in the TAiMR register, the UDF register, the ONSF register, and the TRGSR register are modified while the TAiS bit remains 0 (count stops) regardless whether after reset or not.

While counting is in progress, the counter value can be read out at any time by reading the TAi register. However, if the TAi register is read at the same time the counter is reloaded, the read value is always FFFF16 when the timer counter underflows and 000016 when the timer counter overflows. If the TAi register is read after setting a value in it, but before the counter starts counting, the read value is the one that has been set in the register.

# Timer A (One-shot Timer Mode)

The timer remains idle after reset. Set the mode, count source, counter value, etc. using the TAiMR (i = 0 to 4) register, the TAi register, bits TA0TGL and TA0TGH in the ONSF register and the TRGSR register before setting the TAiS bit in the TABSR register to 1 (count starts).

Always make sure bits TA0TGL and TA0TGH in the TAiMR register, the ONSF register, and the TRGSR register are modified while the TAiS bit remains 0 (count stops) regardless whether after reset or not.

When setting TAiS bit to 0 (count stop), the followings occur:

- A counter stops counting and a content of reload register is reloaded.
- · TAiOUT pin outputs "L".
- After one cycle of the CPU clock, the IR bit in TAilC register is set to 1 (interrupt request).

Output in one-shot timer mode synchronizes with a count source internally generated. When the external trigger has been selected, a maximun delay of one cycle of the count source occurs between the trigger input to TAilN pin and output in one-shot timer mode.

The IR bit is set to 1 when timer operation mode is set with any of the following procedures:

- · Select one-shot timer mode after reset.
- Change an operation mode from timer mode to one-shot timer mode.
- Change an operation mode from event counter mode to one-shot timer mode.

To use the timer Ai interrupt (the IR bit), set the IR bit to 0 after the changes listed above have been made.

When a trigger occurs while the timer is counting, the counter reloads the reload register value, and continues counting after a second trigger is generated and the counter is decremented once. To generate a trigger while counting, space more than one cycle of the timer count source from the first trigger and generate again.

When selecting the external trigger for the count start conditions in timer A one-shot timer mode, do generate an external trigger 300ns before the count value of timer A is set to 000016. The one-shot timer does not continue counting and may stop.

# Timer A (Pulse Width Modulation Mode)

The timer remains idle after reset. Set the mode, count source, counter value, etc. using bits TA0TGL and TA0TGH in the TAiMR (i = 0 to 4) register, the TAi register, the ONSF register and the TRGSR register before setting the TAiS bit in the TABSR register to 1 (count starts).

Always make sure bits TA0TGL and TA0TGH in the TAiMR register, the ONSF register and the TRGSR register are modified while the TAiS bit remains 0 (count stops) regardless whether after reset or not.

The IR bit is set to 1 when setting a timer operation mode with any of the following procedures:

- · Select the PWM mode after reset.
- Change an operation mode from timer mode to PWM mode.
- Change an operation mode from event counter mode to PWM mode.

To use the timer Ai interrupt (interrupt request bit), set the IR bit to 0 by program after the above listed changes have been made.

When setting TAiS register to 0 (count stop) during PWM pulse output, the following action occurs:

- · Stop counting.
- When TAiOUT pin is output "H", output level is set to "L" and the IR bit is set to 1.
- When TAiOUT pin is output "L", both output level and the IR bit remains unchanged.

#### Serial I/O

# Clock-Synchronous Serial I/O

# Transmission/reception

With an external clock selected, and choosing the  $\overline{\text{RTS}}$  function, the output level of the  $\overline{\text{RTS}}$  ipin goes to "L" when the data-receivable status becomes ready, which informs the transmission side that the reception has become ready. The output level of the  $\overline{\text{RTS}}$  ipin goes to "H" when reception starts. So if the  $\overline{\text{RTS}}$  ipin is connected to the  $\overline{\text{CTS}}$  ipin on the transmission side, the circuit can transmission and reception data with consistent timing. With the internal clock, the  $\overline{\text{RTS}}$  function has no effect.

### **Transmission**

When an external clock is selected, the conditions must be met while if the CKPOL bit in the UiC0 register is set to 0 (transmit data output at the falling edge and the receive data taken in at the rising edge of the transfer clock), the external clock is in the high state; if the CKPOL bit in the UiC0 register is set to 1 (transmit data output at the rising edge and the receive data taken in at the falling edge of the transfer clock), the external clock is in the low state.

- The TE bit in UiC1 register is set to 1 (transmission enabled)
- The TI bit in UiC1 register is set to 0 (data present in UiTB register)
- · If CTS function is selected, input on the CTSi pin is set to "L"

# Reception

In operating the clock-synchronous serial I/O, operating a transmitter generates a shift clock. Fix settings for transmission even when using the device only for reception. Dummy data is output to the outside from the TxDi pin when receiving data.

When an internal clock is selected, set the TE bit in the UiC1 register (i = 0 to 2) to 1 (transmission enabled) and write dummy data to the UiTB register, and the shift clock will thereby be generated. When an external clock is selected, set the TE bit in the UiC1 register (i = 0 to 2) to 1 and write dummy data to the UiTB register, and the shift clock will be generated when the external clock is fed to the CLKi input pin.

When successively receiving data, if all bits of the next receive data are prepared in the UARTi receive register while the RE bit in the UiC1 register (i = 0 to 2) is set to 1 (data present in the UiRB register), an overrun error occurs and the UiRB register OER bit is set to 1 (overrun error occurred). In this case, because the content of the UiRB register is undefined, a corrective measure must be taken by programs on the transmit and receive sides so that the valid data before the overrun error occurred will be retransmitted. Note that when an overrun error occurred, the SiRIC register IR bit does not change state.

To receive data in succession, set dummy data in the lower-order byte of the UiTB register every time reception is made.

When an external clock is selected, make sure the external clock is in high state if the CKPOL bit is set to 0, and in low state if the CKPOL bit is set to 1 before the following conditions are met:

- The RE bit in the UiC1 register is set to 1 (reception enabled)
- The TE bit in the UiC1 register is set to 1 (transmission enabled)
- The TI bit in the UiC1 register= 0 (data present in the UiTB register)

#### **UART Mode**

# Special Mode 1 (I<sup>2</sup>C bus Mode)

When generating start, stop and restart conditions, set the STSPSEL bit in the U2SMR4 register to 0 and wait for more than half cycle of the transfer clock before setting each condition generate bit (STAREQ, RSTAREQ and STPREQ) from 0 to 1.

## SI/O3, SI/O4

The SOUTi default value which is set to the SOUTi pin by the SMi7 bit approximately 10ns may be output when changing the SMi3 bit from 0 (I/O port) to 1 (SOUTi output and CLKfunction) while the SMi2 bit in the SiC (i=3 and 4) to 0 (SOUTi output) and the SMi6 bit is set to 1 (internal clock). And then the SOUTi pin is held high-impedance.

If the level which is output from the SOUTi pin is a problem when changing the SMi3 bit from 0 to 1, set the default value of the SOUTi pin by the SMi7 bit.

# Programmable I/O Ports

The input threshold voltage of pins differs between programmable input/output ports and peripheral functions.

Therefore, if any pin is shared by a programmable input/output port and a peripheral function and the input level at this pin is outside the range of recommended operating conditions VIH and VIL (neither "high" nor "low"), the input level may be determined differently depending on which side—the programmable input/output port or the peripheral function—is currently selected.

# **Flash Memory Version**

# **Functions to Inhibit Rewriting Flash Memory Rewrite**

ID codes are stored in addresses 0FFFDF16, 0FFFE316, 0FFFEB16, 0FFFEF16, 0FFFF316, 0FFFF716, and 0FFFFB16. If wrong data are written to theses addresses, the flash memory cannot be read or written in standard serial I/O mode.

The ROMCP register is mapped in address 0FFFF16. If wrong data is written to this address, the flash memory cannot be read or written in parallel I/O mode.

In the flash memory version of MCU, these addresses are allocated to the vector addresses ("H") of fixed vectors. The b3 to b0 in address 0FFFFF16 are reserved bits. Set these bits to 11112.

# Regarding Programming/Erasure Times and Execution Time

As the number of programming/erasure times increases, so does the execution time for software commands (Program, and Block Erase).

The software commands are aborted by hardware reset 1, brown-out detection reset (hardware reset 2), and watchdog timer interrupt. If a software command is aborted by such reset or interrupt, the affected block must be erased before reexecuting the aborted command.

# **Definition of Programming/Erasure Times**

"Number of programs and erasure" refers to the number of erasure per block.

If the number of program and erasure is n (n=100 1,000) each block can be erased n times. For example, if a 8K byte block A is erased after writing 1 word data 4096 times, each to a different address, this is counted as one program and erasure. However, data cannot be written to the same address more than once without erasing the block. (Rewrite prohibited)

# **Boot Mode**

An undefined value is sometimes output in the I/O port until the internal power supply becomes stable when "H" is applied to the CNVss pin and "L" is applied to the RESET pin.

When setting the CNVss pin to "H", the following procedure is required:

- (1) Apply an "L" signal to the RESET pin and the CNVss pin.
- (2) Bring Vcc to more than 2.7V, and wait at least 2 msec. (Internal power supply stable waiting time)
- (3) Apply an "H" signal to the CNVss pin.
- (4) Apply an "H" signal to the RESET pin.

When the CNVss pin is "H" and RESET pin is "L", P67 pin is connected to the pull-up resister.

### **APPENDIX**

#### **IT800DLL Explanatory Note**

June 2, 2005

# IT800 Data Link Layer - Functionality and Advantages

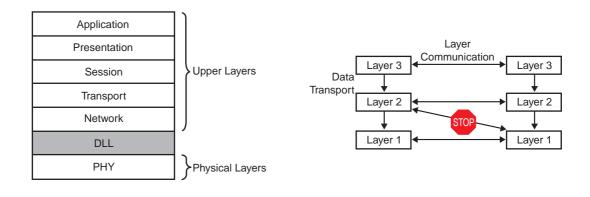

# 1. Scope

This document describes the functionality of the Data Link Layer (DLL) implemented in the products based on Yitran's IT800 technology for narrowband networking using the power line wiring.

The purpose of this document is to emphasize the advantages of the embedded algorithms and mechanisms of the DLL and to analyze the scenarios of using other implementations of a Data Link Layer.

#### 2. Network Reference Module

The DLL is the 2nd layer of the 7 layers in the OSI network reference model illustrated in Figure 1(a). According to this model, data is transported upstream and downstream between subsequent layers, where the communication between layers of different communication nodes is basically carried out between the same layers [Figure 1(b)].

**Figure 1: Network Reference Model** 

(b) Data Transport and Layer Communication

The Physical Layer (PHY) defines the electrical specifications for activating, the physical link between the communicating network system nodes. The DLL algorithms are designed to establish and manage a unique access channel between any two nodes as optimally and fairly as possible while minimizing the probability of collisions.

The IT800 DLL was developed by Yitran especially for the IT800 PHY and using the DLL optimize the utilization of the PHY and thus optimizes the overall performance.

The IT800 DLL implementation manages the time critical sessions of the interface with the PHY and uses the knowledge of the PHY implementation for optimal interrupt decoding and efficient interface interactions. The DLL takes advantage of various PHY features such as multiple transportation modes and the ability to create special packets and signals, enabling optimal utilization of the media channel while providing the most reliable data transfer.

(a) OSI 7 Layers Model

M16C/6S Group APPENDIX

### **IT800DLL Explanatory Note**

June 2, 2005

### 3. IT800DLL Main functions

The DLL main functions and mechanisms are described in the following table:

Function	Description
Carrier sense	Provides the carrier detection (CD) signal for triggering the media access algorithms as a function of the PHY correlator output, which indicates the probability of a signal on the line.
Channel access prioritization	Determines the sequence and time of packet transmissions for a PLC node, where the highest priority packet nodes participate in the DLL contention for the media access.
Adaptive back-off	Spreads the time over which a PLC node contends for the channel using a uniform distribution of the transmissions number over a given period of time (Yitran patent pending). This mechanism provides high efficiency of the network functionality, optimal utilization of the channel and sustains a viable network even in cases where many nodes contend for the channel simultaneously.
Acknowledgement	Serves for informing the transmitting node about the success or failure of a packet delivery to a target node by means of a traffic-free acknowledgement window.
Repetitive un- acknowledgement	This mechanism is used for transmitting packets a pre-determined number of times without requiring a reception acknowledgement from the target node.
Multiple hop broadcast	Retransmits single-network broadcast packets and CNC (Control Network Channel) messages to all the nodes participating in the same logical network.
Fragmentation and reassembly	Transfers packets longer than the maximal packet size allowed by the PHY by means of fragmentation in the transmitting node and reassembly in the receiving node
Packet filtering	Filters received packets according to their type for transferring only pre-defined types of messages to the upper layers and rejecting impostor node or other types of messages that are not required.

As can be seen from the table above, the IT800 DLL implements enhanced functionality, provides best performance in terms of channel access and throughput (based on Carrier Sense signaling, Adaptive Back-off algorithm and packet prioritization), reliable data transfer (using acknowledgement and repetition mechanisms, multi-hop transmissions and packet filtering) and allows easy integration of IT800 based solution with different protocol stacks. Another important advantage of using IT800DLL is assuring the co-existence between different IT800 based products operating in the same environment.

M16C/6S Group APPENDIX

#### **IT800DLL Explanatory Note**

June 2, 2005

### 4. Other DLL implementations

In case of using other implementations of the DLL or considering such implementations, please be advised to consider the following issues:

- 1. Co-existence: Implementing a different channel access scheme, prioritization levels, packet formats and so forth, will not allow your product to co-exist with other IT800 based products that may share the same medium. Using the IT800 will enable such co-existence regardless of the product, the vendor, the application and the protocol used in top of the DLL.
- 2. Required Knowledge, Time to Market and Cost: Interfacing the DLL is much easier than interfacing the PHY. Physical layer interface includes handling of a several interrupts, critical timing sections and so forth. To be able to do so you require very good understanding of the both the power line medium and the PHY internal mechanisms and will significantly increase the development resources and schedule and as a result the time to market and product cost. In addition note that not all the PHY internal mechanism can be disclosed as some are in the status of patent-pending.
- 3. Overall performance: IT800DLL has been tested and integrated into different Control and Automation products over many years. The implementation has showed the best performance for Narrowband Power Line communication modem, when all the algorithms implemented in it were verified using the networking simulations and in real systems.

# 5. Summary

As a conclusion, we highly recommend to using IT800 DLL implementation in all type of products using the IT800 PHY, rather than using the latter by itself.

In case you still wish to self implement the DLL layer, please be sure to consult RENESAS support engineers.

		148	Figure 1.18.10 title "(Excluding Analog Pins)" is added.		
		149	Table 1.19.1 Topr is revised, Note 1 is revised.		
		150	Table 1.19.2 "Vcc1" → "Vcc", Note 1 is revised.		
		152	Table 1.19.5 Note is deleted.		
		153	Table 1.19.6 Note is revised.		
		154	Table 1.19.7 Standard "95" is added. Note is revised.		
		155 to 157	Timing Requirements "-20 to 85°C" $\rightarrow$ "-20 to 85°C/-40 to 85°C/-40 to 105°C"		
		160	parallel writer → parallel programmer		
			Table 1.20.1 "Block 0 to 5" → "Block 0 to 4"		
			"See Figure 20.2.1 to 20.2.3" → "See Figure 1.20.1"		
		161	"The boot ROM area is located in parallel input/output mode." $\rightarrow$ "The bo		
			$\ensuremath{ROM}$ area is reserved. The rewrite control program the area cannot be rewrite		
		164	"In CPU mode, only the user ROM area the boot ROM area cannot be rewritten." is deleted.		
		178	Standard Serial I/O Mode "The main clock f1 is 5.12 MHz in this mode." is add		
		180	serial writer → serial programmer		
		183	1)Transmitting path is revised.		
		184	Table 1.23.1 title "-20 to $85^{\circ}$ C" $\rightarrow$ "-20 to $85^{\circ}$ C/-40 to $85^{\circ}$ C/-40 to $105^{\circ}$ C"		
		186	Table 1.23.2 title "-25°C" → "25°C"		
		187	Figure 1.23.4 is revised.		
		188 to 197	"Usage Notes" is added.		
		200	4. Other DLL implementations "the last three years" → "many years"		
5.01	Dec 10, 2009	2	Table 1.1.1 Memory Capacity; ROM is revised		
		5	Table 1.1.4 "M306S0F8DGP" is added,		
			Figure 1.1.2 ROM capacity "8: 64K bytes" is added		
		10	Figure 1.2.1 Internal ROM "64K bytes" is added, Note 1 is revised		
		26	Figure 1.6.4 Internal ROM "64K bytes" is added		
		161	Figure 1.20.1 is added		
		162	Figure 1.20.2 title "(ROM Capacity 96K bytes)" is added.
