

CS8190

Precision Air-Core Tach/Speedo Driver with Return to Zero

The CS8190 is specifically designed for use with air-core meter movements. The IC provides all the functions necessary for an analog tachometer or speedometer. The CS8190 takes a speed sensor input and generates sine and cosine related output signals to differentially drive an air-core meter.

Many enhancements have been added over industry standard tachometer drivers such as the CS289 or LM1819. The output utilizes differential drivers which eliminates the need for a zener reference and offers more torque. The device withstands 60 V transients which decreases the protection circuitry required. The device is also more precise than existing devices allowing for fewer trims and for use in a speedometer.

Features

- Direct Sensor Input
- High Output Torque
- Low Pointer Flutter
- High Input Impedance
- Overvoltage Protection
- Return to Zero
- Internally Fused Leads in PDIP-16 and SO-20W Packages
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

CIRCUIT DESCRIPTION and APPLICATION NOTES

The CS8190 is specifically designed for use with air-core meter movements. It includes an input comparator for sensing an input signal from an ignition pulse or speed sensor, a charge pump for frequency to voltage conversion, a bandgap voltage regulator for stable operation, and a function generator with sine and cosine amplifiers to differentially drive the meter coils.

From the partial schematic of Figure 7, the input signal is applied to the $FREQ_{IN}$ lead, this is the input to a high impedance comparator with a typical positive input threshold of 2.0 V and typical hysteresis of 0.5 V. The output of the comparator, SQ_{OUT} , is applied to the charge pump input $CP+$ through an external capacitor C_{CP} . When the input signal changes state, C_{CP} is charged or discharged through $R3$ and $R4$. The charge accumulated on C_{CP} is mirrored to $C4$ by the Norton Amplifier circuit comprising of $Q1$, $Q2$ and $Q3$. The charge pump output voltage, F/V_{OUT} , ranges from 2.0 V to 6.3 V depending on the input signal frequency and the gain of the charge pump according to the formula:

$$F/V_{OUT} = 2.0\text{ V} + 2.0 \times \text{FREQ} \times C_{CP} \times R_T \times (V_{REG} - 0.7\text{ V})$$

R_T is a potentiometer used to adjust the gain of the F/V output stage and give the correct meter deflection. The F/V output voltage is applied to the function generator which generates the sine and cosine output voltages. The output voltage of the sine and cosine amplifiers are derived from the

on-chip amplifier and function generator circuitry. The various trip points for the circuit (i.e., 0°, 90°, 180°, 270°) are determined by an internal resistor divider and the bandgap voltage reference. The coils are differentially driven, allowing bidirectional current flow in the outputs, thus providing up to 305° range of meter deflection. Driving the coils differentially offers faster response time, higher current capability, higher output voltage swings, and reduced external component count. The key advantage is a higher torque output for the pointer.

The output angle, θ , is equal to the F/V gain multiplied by the function generator gain:

$$\theta = AF/V \times AFG,$$

where:

$$AFG = 77^\circ/V(\text{typ})$$

The relationship between input frequency and output angle is:

$$\theta = AFG \times 2.0 \times \text{FREQ} \times C_{CP} \times R_T \times (V_{REG} - 0.7\text{ V})$$

or,

$$\theta = 970 \times \text{FREQ} \times C_{CP} \times R_T$$

The ripple voltage at the F/V converter's output is determined by the ratio of C_{CP} and $C4$ in the formula:

$$\Delta V = \frac{C_{CP}(V_{REG} - 0.7\text{ V})}{C4}$$

Figure 7. Partial Schematic of Input and Charge Pump

Figure 8. Timing Diagram of $FREQ_{IN}$ and I_{CP}

Ripple voltage on the F/V output causes pointer or needle flutter especially at low input frequencies.

The response time of the F/V is determined by the time constant formed by R_T and C_4 . Increasing the value of C_4 will reduce the ripple on the F/V output but will also increase the response time. An increase in response time causes a very slow meter movement and may be unacceptable for many applications.

The CS8190 has an undervoltage detect circuit that disables the input comparator when V_{CC} falls below 8.0 V(typical). With no input signal the F/V output voltage decreases and the needle moves towards zero. A second undervoltage detect circuit at 6.0 V(typical) causes the function generator to

generate a differential SIN drive voltage of zero volts and the differential COS drive voltage to go as high as possible. This combination of voltages (Figure 2) across the meter coil moves the needle to the 0° position. Connecting a large capacitor(> 2000 μF) to the V_{CC} lead (C_2 in Figure 9) increases the time between these undervoltage points since the capacitor discharges slowly and ensures that the needle moves towards 0° as opposed to 360° . The exact value of the capacitor depends on the response time of the system, the maximum meter deflection and the current consumption of the circuit. It should be selected by breadboarding the design in the lab.

CS8190

Notes:

1. C2 (> 2000 μF) is needed if return to zero function is required.
2. The product of C_{CP} and R_T have a direct effect on the transfer function (f to V conversion) and therefore directly affect temperature compensation.
3. C_{CP} Range; 20 pF to 0.2 μF.
4. R_T Range; 100 kΩ to 500 kΩ.
5. The IC must be protected from transients above 60 V and reverse battery conditions.
6. Additional filtering on the FREQ_{IN} lead may be required.
7. Gauge coil connections to the IC must be kept as short as possible (≤ 3.0 inch) for best pointer stability.

Figure 9. Speedometer or Tachometer Application

Design Example

Maximum meter Deflection = 270°

Maximum Input Frequency = 350 Hz

1. Select R_T and C_{CP}

$$\theta = 970 \times \text{FREQ} \times C_{CP} \times R_T = 270^\circ$$

Let C_{CP} = 0.0033 μF, find R_T

$$R_T = \frac{270^\circ}{970 \times 350 \text{ Hz} \times 0.0033 \mu\text{F}}$$

$$R_T = 243 \text{ k}\Omega$$

R_T should be a 250 kΩ potentiometer to trim out any inaccuracies due to IC tolerances or meter movement pointer placement.

2. Select R3 and R4

Resistor R3 sets the output current from the voltage regulator. The maximum output current from the voltage regulator is 10 mA. R3 must ensure that the current does not exceed this limit.

Choose R3 = 3.3 kΩ

The maximum charge current for C_{CP} is worst case estimated at:

$$\frac{V_{REG} - 0.7 \text{ V}}{3.3 \text{ k}\Omega} = 1.90 \text{ mA}$$

C_{CP} must charge and discharge fully during each cycle of the input signal. Time for one cycle at maximum frequency

is 2.85 ms. To ensure that C_{CP} is charged, assume that the (R3 + R4) C_{CP} time constant is less than 10% of the minimum input period.

$$T = 10\% \times \frac{1}{350 \text{ Hz}} = 285 \mu\text{s}$$

Choose R4 = 1.0 kΩ.

$$\text{Discharge time: } t_{DCHG} = R4 \times C_{CP} = 3.3 \text{ k}\Omega \times 0.0033 \mu\text{F} = 3.3 \mu\text{s}$$

$$\text{Charge time: } t_{CHG} = (R3 + R4)C_{CP} = 4.3 \text{ k}\Omega \times 0.0033 \mu\text{F} = 14.2 \mu\text{s}$$

3. Determine C4

C4 is selected to satisfy both the maximum allowable ripple voltage and response time of the meter movement.

$$C4 = \frac{C_{CP}(V_{REG} - 0.7 \text{ V})}{\Delta V_{MAX}}$$

With C4 = 0.47 μF, the F/V ripple voltage is 44 mV.

The last component to be selected is the return to zero capacitor C2. This is selected by increasing the input signal frequency to its maximum so the pointer is at its maximum deflection, then removing the power from the circuit. C2 should be large enough to ensure that the pointer always returns to the 0° position rather than 360° under all operating conditions.

Figure 10 shows how the CS8190 and the CS8441 are used to produce a Speedometer and Odometer circuit.

CS8190

Notes:

1. C₂ = 10 μF with CS8441 application.
2. The product of C_{CP} and R_T have a direct effect on the transfer function (f to V conversion) and therefore directly affect temperature compensation.
3. C_{CP} Range; 20 pF to 0.2 μF.
4. R_T Range; 100 kΩ to 500 kΩ.
5. The IC must be protected from transients above 60 V and reverse battery conditions.
6. Additional filtering on the FREQ_{IN} lead may be required.
7. Gauge coil connections to the IC must be kept as short as possible (≤ 3.0 inch) for best pointer stability.

Figure 10. Speedometer With Odometer or Tachometer Application

CS8190

In some cases a designer may wish to use the CS8190 only as a driver for an air-core meter having performed the F/V conversion elsewhere in the circuit.

Figure 11 shows how to drive the CS8190 with a DC voltage ranging from 2.0 V to 6.0 V. This is accomplished by forcing a voltage on the F/V_{OUT} lead. The alternative scheme shown in Figure 12 uses an external op amp as a buffer and operates over an input voltage range of 0 V to 4.0 V.

Figure 11. Driving the CS8190 from an External DC Voltage

Figures 11 and 12 are not temperature compensated.

Figure 12. Driving the CS8190 from an External DC Voltage Using an Op Amp Buffer
