Functional Description

CY62147GN and CY621472GN are high-performance CMOS low-power (MoBL) SRAM devices organized as 256K Words by 16-bits. Both devices are offered in single and dual chip enable options and in multiple pin configurations.

Devices with a single chip enable input are accessed by asserting the chip enable ($\overline{CE}$) input LOW. Dual chip enable devices are accessed by asserting both chip enable inputs – $\overline{CE}_1$ as low and $\overline{CE}_2$ as HIGH.

Data writes are performed by asserting the Write Enable ($\overline{WE}$) input LOW, while providing the data on I/O₀ through I/O₁₅ and address on A₀ through A₁₇ pins. The Byte High Enable ($\overline{BHE}$) and Byte Low Enable ($\overline{BLE}$) inputs control write operations to the upper and lower bytes of the specified memory location. $\overline{BHE}$ controls I/O₈ through I/O₁₅ and $\overline{BLE}$ controls I/O₀ through I/O₇.

Data reads are performed by asserting the Output Enable ($\overline{OE}$) input and providing the required address on the address lines. Read data is accessible on the I/O lines (I/O₀ through I/O₁₅).

Byte accesses can be performed by asserting the required byte enable signal ($\overline{BHE}$ or $\overline{BLE}$) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O₀ through I/O₁₅) are placed in a HI-Z state when the device is deselected ($\overline{CE}$ HIGH for a single chip enable device and $\overline{CE}_1$ HIGH/ $\overline{CE}_2$ LOW for a dual chip enable device), or control signals are de-asserted ($\overline{OE}$, $\overline{BLE}$, $\overline{BHE}$).

The device also has a unique Byte Power down feature, where, if both the Byte Enables ($\overline{BHE}$ and $\overline{BLE}$) are disabled, the devices seamlessly switch to standby mode irrespective of the state of the chip enables, thereby saving power.

The logic block diagram is provided in page 2.

Notes

15. Test conditions assume a signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use output loading shown in AC Test Loads and Waveforms section, unless specified otherwise.
16. These parameters are guaranteed by design.
17. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.
18. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.
19. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, $\overline{BHE}$ or $\overline{BLE}$, or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
20. The minimum pulse width in Write Cycle No. 3 ($\overline{WE}$ Controlled, $\overline{OE}$ LOW) should be equal to sum of t_{SD} and t_{HZWE} .
