| GND | This pin is connected to GND in the slot. |
| N.C. | This pin is left unconnected. |

How to Connect Output Signals

The output circuit of interface is illustrated in the below figure. Signal outputs are open-collector outputs; individual output signals are sent to the external device as negative logic signals. Note that each signal output must be pulled up at the external device as it is not pulled up internally.

Output Circuit

* O-xx represents an output pin.
One polyswitch is connected for Vcc(+5V) terminal.

CAUTION

When the PC is turned on, all output are reset to OFF.

Connecting to the LED

When "1" is output to a relevant bit, the corresponding LED comes on.
When "0" is output to the bit, in contrast, the LED goes out.

A Protection Function of the +5V Outputs

A protection function, which prevents excessive current flow from the +5V outputs, is attached to this board. In case of accidental short of the +5V output and GND, for example, the function works, and the board operation may become impossible temporarily. In such a case, you should turn the PC off and wait for several minutes before you use the board again.
