

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory

SST34HF1681

Advance Specifications

FEATURES:

- **Flash Organization: 1M x16**
- **Dual-Bank Architecture for Concurrent Read/Write Operation**
 - 16 Mbit: 12 Mbit + 4 Mbit
- **SRAM Organization:**
 - 8 Mbit: 512K x16
- **Single 2.7-3.3V Read and Write Operations**
- **Superior Reliability**
 - Endurance: 100,000 Cycles (typical)
 - Greater than 100 years Data Retention
- **Low Power Consumption:**
 - Active Current: 25 mA (typical)
 - Standby Current: 20 μ A (typical)
- **Hardware Sector Protection (WP#)**
 - Protects 4 outer most sectors (4 KWord) in the larger bank by holding WP# low and unprotects by holding WP# high
- **Hardware Reset Pin (RST#)**
 - Resets the internal state machine to reading data array
- **Sector-Erase Capability**
 - Uniform 1 KWord sectors
- **Block-Erase Capability**
 - Uniform 32 KWord blocks
- **Read Access Time**
 - Flash: 70 and 90 ns
 - SRAM: 70 and 90 ns
- **Latched Address and Data**
- **Fast Erase and Word-Program:**
 - Sector-Erase Time: 18 ms (typical)
 - Block-Erase Time: 18 ms (typical)
 - Chip-Erase Time: 70 ms (typical)
 - Word-Program Time: 14 μ s (typical)
 - Chip Rewrite Time: 8 seconds (typical)
- **Automatic Write Timing**
 - Internal V_{PP} Generation
- **End-of-Write Detection**
 - Toggle Bit
 - Data# Polling
 - Ready/Busy# pin
- **CMOS I/O Compatibility**
- **JEDEC Standard Command Set**
- **Conforms to Common Flash Memory Interface (CFI)**
- **Packages Available**
 - 56-ball LFBGA (8mm x 10mm)

PRODUCT DESCRIPTION

The SST34HF1681 ComboMemory devices integrate a 1M x16 CMOS flash memory bank with a 512K x16 CMOS SRAM memory bank in a Multi-Chip Package (MCP). These devices are fabricated using SST's proprietary, high-performance CMOS SuperFlash technology incorporating the split-gate cell design and thick oxide tunneling injector to attain better reliability and manufacturability compared with alternate approaches. The SST34HF1681 devices are ideal for applications such as cellular phones, GPSs, PDAs and other portable electronic devices in a low power and small form factor system.

The SST34HF1681 features dual flash memory bank architecture allowing for concurrent operations between the two flash memory banks and the SRAM. The devices can read data from either bank while an Erase or Program operation is in progress in the opposite bank. The two flash memory banks are partitioned into 4 Mbit and 12 Mbit with top or bottom sector protection options for storing boot code, program code, configuration/parameter data and user data.

The SuperFlash technology provides fixed Erase and Program times, independent of the number of Erase/Program cycles that have occurred. Therefore, the system software or hardware does not have to be modified or de-rated as is necessary with alternative flash technologies, whose Erase and Program times increase with accumulated Erase/Program cycles. The SST34HF1681 devices offer a guaranteed endurance of 10,000 cycles. Data retention is rated at greater than 100 years. With high performance Word-Program, the flash memory banks provide a typical Word-Program time of 14 μ sec. The entire flash memory bank can be erased and programmed word-by-word in typically 8 seconds for the SST34HF1681, when using interface features such as Toggle Bit or Data# Polling to indicate the completion of Program operation. To protect against inadvertent flash write, the SST34HF1681 devices contain on-chip hardware and software data protection schemes.

The flash and SRAM operate as two independent memory banks with respective bank enable signals. The memory bank selection is done by two bank enable signals. The

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory SST34HF1681

Advance Specifications

SRAM bank enable signal, BES1# and BES2, selects the SRAM bank. The flash memory bank enable signal, BEF#, has to be used with Software Data Protection (SDP) command sequence when controlling the Erase and Program operations in the flash memory bank. The memory banks are superimposed in the same memory address space where they share common address lines, data lines, WE# and OE# which minimize power consumption and area.

Designed, manufactured, and tested for applications requiring low power and small form factor, the SST34HF1681 are offered in both commercial and extended temperatures and a small footprint package to meet board space constraint requirements.

Device Operation

The SST34HF1681 uses BES1#, BES2 and BEF# to control operation of either the flash or the SRAM memory bank. When BEF# is low, the flash bank is activated for Read, Program or Erase operation. When BES1# is low, and BES2 is high the SRAM is activated for Read and Write operation. BEF# and BES1# cannot be at low level, and BES2 cannot be at high level at the same time. **If all bank enable signals are asserted, bus contention will result and the device may suffer permanent damage.** All address, data, and control lines are shared by flash and SRAM memory banks which minimizes power consumption and loading. The device goes into standby when BEF# and BES1# bank enables are raised to V_{IHC} (Logic High) or when BEF# is high and BES2 is low.

Concurrent Read/Write Operation

Dual bank architecture of SST34HF1681 devices allows the Concurrent Read/Write operation whereby the user can read from one bank while program or erase in the other bank. This operation can be used when the user needs to read system code in one bank while updating data in the other bank. See Figure 1 for Dual-Bank Memory Organization.

CONCURRENT READ/WRITE STATE TABLE

Flash		SRAM
Bank 1	Bank 2	
Read	Write	No Operation
Write	Read	No Operation
Write	No Operation	Read
No Operation	Write	Read
Write	No Operation	Write
No Operation	Write	Write

Note: For the purposes of this table, write means to Block-, Sector, or Chip-Erase, or Word-Program as applicable to the appropriate bank.

Flash Read Operation

The Read operation of the SST34HF1681 is controlled by BEF# and OE#, both have to be low for the system to obtain data from the outputs. BEF# is used for device selection. When BEF# is high, the chip is deselected and only standby power is consumed. OE# is the output control and is used to gate data from the output pins. The data bus is in high impedance state when either BEF# or OE# is high. Refer to the Read cycle timing diagram for further details (Figure 6).

Flash Word-Program Operation

The SST34HF1681 are programmed on a word-by-word basis. Before Program operations, the memory must be erased first. The Program operation consists of three steps. The first step is the three-byte load sequence for Software Data Protection. The second step is to load word address and word data. During the Word-Program operation, the addresses are latched on the falling edge of either BEF# or WE#, whichever occurs last. The data is latched on the rising edge of either BEF# or WE#, whichever occurs first. The third step is the internal Program operation which is initiated after the rising edge of the fourth WE# or BEF#, whichever occurs first. The Program operation, once initiated, will be completed typically within 10 μ s. See Figures 7 and 8 for WE# and BEF# controlled Program operation timing diagrams and Figure 21 for flowcharts. During the Program operation, the only valid reads are Data# Polling and Toggle Bit. During the internal Program operation, the host is free to perform additional tasks. Any commands issued during the internal Program operation are ignored.

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory SST34HF1681

Advance Specifications

Flash Sector/Block-Erase Operation

The Sector/Block-Erase operation allows the system to erase the device on a sector-by-sector or block-by-block basis. The SST34HF1681 offer both Sector-Erase and Block-Erase mode. The sector architecture is based on uniform sector size of 1 KWord. The Block-Erase mode is based on uniform block size of 32 KWord. The Sector-Erase operation is initiated by executing a six-byte command sequence with Sector-Erase command (30H) and sector address (SA) in the last bus cycle. The Block-Erase operation is initiated by executing a six-byte command sequence with Block-Erase command (50H) and block address (BA) in the last bus cycle. The sector or block address is latched on the falling edge of the sixth WE# pulse, while the command (30H or 50H) is latched on the rising edge of the sixth WE# pulse. The internal Erase operation begins after the sixth WE# pulse. See Figures 12 and 13 for timing waveforms. Any commands issued during the Sector- or Block-Erase operation are ignored.

Flash Chip-Erase Operation

The SST34HF1681 provide a Chip-Erase operation, which allows the user to erase all unprotected sectors/blocks to the "1" state. This is useful when the device must be quickly erased.

The Chip-Erase operation is initiated by executing a six-byte command sequence with Chip-Erase command (10H) at address 5555H in the last byte sequence. The Erase operation begins with the rising edge of the sixth WE# or BEF#, whichever occurs first. During the Erase operation, the only valid read is Toggle Bits or Data# Polling. See Table 4 for the command sequence, Figure 11 for timing diagram, and Figure 24 for the flowchart. Any commands issued during the Chip-Erase operation are ignored.

Flash Write Operation Status Detection

The SST34HF1681 provide one hardware and two software means to detect the completion of a Write (Program or Erase) cycle, in order to optimize the system Write cycle time. The hardware detection uses the Ready/Busy# (RY/BY#) pin. The software detection includes two status bits: Data# Polling (DQ₇) and Toggle Bit (DQ₆). The End-of-Write detection mode is enabled after the rising edge of WE#, which initiates the internal Program or Erase operation.

The actual completion of the nonvolatile write is asynchronous with the system; therefore, either a Ready/Busy# (RY/BY#), Data# Polling (DQ₇) or Toggle Bit (DQ₆) read may be simultaneous with the completion of the Write cycle. If this occurs, the system may possibly get an erroneous result,

i.e., valid data may appear to conflict with either DQ₇ or DQ₆. In order to prevent spurious rejection, if an erroneous result occurs, the software routine should include a loop to read the accessed location an additional two (2) times. If both reads are valid, then the device has completed the Write cycle, otherwise the rejection is valid.

Ready/Busy# (RY/BY#)

The SST34HF1681 includes a Ready/Busy# (RY/BY#) output signal. During any SDP initiated operation, e.g., Erase, Program, CFI or ID Read operation, RY/BY# is actively pulled low, indicating a SDP controlled operation is in Progress. The status of RY/BY# is valid after the rising edge of fourth WE# (or CE#) pulse for Program operation. For Sector-, Block- or Bank-Erase, the RY/BY# is valid after the rising edge of sixth WE# or (CE#) pulse. RY/BY# is an open drain output that allows several devices to be tied in parallel to V_{DD} via an external pull up resistor. Ready/Busy# is in high impedance whenever OE# or CE# is high or RST# is low. There is a 1 μ s bus recovery time (T_{BR}) required before valid data can be read on the data bus. New commands can be entered immediately after RY/BY# goes high.

Flash Data# Polling (DQ₇)

When the SST34HF1681 are in the internal Program operation, any attempt to read DQ₇ will produce the complement of the true data. Once the Program operation is completed, DQ₇ will produce true data. Note that even though DQ₇ may have valid data immediately following the completion of an internal Write operation, the remaining data outputs may still be invalid: valid data on the entire data bus will appear in subsequent successive Read cycles. During internal Erase operation, any attempt to read DQ₇ will produce a '0'. Once the internal Erase operation is completed, DQ₇ will produce a '1'. The Data# Polling (DQ₇) is valid after the rising edge of fourth WE# (or BEF#) pulse for Program operation. For Sector-, Block- or Chip-Erase, the Data# Polling (DQ₇) is valid after the rising edge of sixth WE# (or BEF#) pulse. See Figure 9 for Data# Polling (DQ₇) timing diagram and Figure 22 for a flowchart. There is a 1 μ s bus recovery time (T_{BR}) required before valid data can be read on the data bus. New commands can be entered immediately after DQ₇ becomes true data.

Flash Toggle Bits (DQ₆)

During the internal Program or Erase operation, any consecutive attempts to read DQ₆ will produce alternating 1s and 0s, i.e., toggling between 1 and 0. When the internal Program or Erase operation is completed, the DQ₆ bit will stop toggling. The device is then ready for the next oper-

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory

SST34HF1681

Advance Specifications

ation. The Toggle Bit (DQ₆) is valid after the rising edge of fourth WE# (or BEF#) pulse for Program operation. For Sector-, Block- or Chip-Erase, the Toggle Bit (DQ₆) is valid after the rising edge of sixth WE# (or BEF#) pulse. See Figure 10 for Toggle Bit timing diagram and Figure 22 for a flowchart. There is a 1 μ s bus recovery time (T_{BR}) required before valid data can be read on the data bus. New commands can be entered immediately after DQ₆ no longer toggles.

Data Protection

The SST34HF1681 provide both hardware and software features to protect nonvolatile data from inadvertent writes.

Hardware Data Protection

Noise/Glitch Protection: A WE# or BEF# pulse of less than 5 ns will not initiate a Write cycle.

V_{DD} Power Up/Down Detection: The Write operation is inhibited when V_{DD} is less than 1.5V.

Write Inhibit Mode: Forcing OE# low, BEF# high, or WE# high will inhibit the Write operation. This prevents inadvertent writes during power-up or power-down.

Hardware Block Protection

The SST34HF1681 provide a hardware block protection which protects the outermost 4 KWord in Bank 1. The block is protected when WP# is held low. See Figure 1 for Block-Protection location.

A user can disable block protection by driving WP# high thus allowing erase or program of data into the protected sectors. WP# must be held high prior to issuing the write command and remain stable until after the entire Write operation has completed.

Hardware Reset (RST#)

The RST# pin provides a hardware method of resetting the device to read array data. When the RST# pin is held low for at least T_{RP}, any in-progress operation will terminate and return to Read mode (see Figure 18). When no internal Program/Erase operation is in progress, a minimum period of T_{RHR} is required after RST# is driven high before a valid Read can take place (see Figure 17).

The Erase operation that has been interrupted needs to be reinitiated after the device resumes normal operation mode to ensure data integrity. See Figures 17 and 18 for timing diagrams.

Software Data Protection (SDP)

The SST34HF1681 provide the JEDEC standard Software Data Protection scheme for all data alteration operations, i.e., Program and Erase. Any Program operation requires the inclusion of the three-byte sequence. The three-byte load sequence is used to initiate the Program operation, providing optimal protection from inadvertent Write operations, e.g., during the system power-up or power-down. Any Erase operation requires the inclusion of six-byte sequence. The SST34HF1681 are shipped with the Software Data Protection permanently enabled. See Table 4 for the specific software command codes. During SDP command sequence, invalid commands will abort the device to Read mode within T_{RC}. The contents of DQ₁₅-DQ₈ are "Don't Care" during any SDP command sequence.

Common Flash Memory Interface (CFI)

The SST34HF1681 also contain the CFI information to describe the characteristics of the device. In order to enter the CFI Query mode, the system must write three-byte sequence, same as Software ID Entry command with 98H (CFI Query command) to address 555H in the last byte sequence. Once the device enters the CFI Query mode, the system can read CFI data at the addresses given in Tables 5 through 7. The system must write the CFI Exit command to return to Read mode from the CFI Query mode.

Product Identification

The Product Identification mode identifies the device as the SST34HF1681 and manufacturer as SST. This mode may be accessed by software operations only. The hardware device ID Read operation, which is typically used by programmers cannot be used on this device because of the shared lines between flash and SRAM in the multi-chip package. Therefore, application of high voltage to pin A₉ may damage this device. Users may use the software Product Identification operation to identify the part (i.e., using the device ID) when using multiple manufacturers in the same socket. For details, see Tables 3 and 4 for software operation, Figure 14 for the Software ID Entry and Read timing diagram and Figure 23 for the ID Entry command sequence flowchart.

T1.0 561

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory SST34HF1681

Advance Specifications

Product Identification Mode Exit/ CFI Mode Exit

In order to return to the standard Read mode, the Software Product Identification mode must be exited. Exit is accomplished by issuing the Software ID Exit command sequence, which returns the device to the Read mode. This command may also be used to reset the device to the Read mode after any inadvertent transient condition that apparently causes the device to behave abnormally, e.g., not read correctly. Please note that the Software ID Exit/CFI Exit command is ignored during an internal Program or Erase operation. See Table 4 for software command codes, Figure 16 for timing waveform and Figure 23 for a flowchart.

SRAM Operation

With BES1# low, BES2 and BEF# high, the SST34HF1681 operates as 512K x16 CMOS SRAM, with fully static operation requiring no external clocks or timing strobes. The SST34HF1681 SRAM is mapped into the first 512 KWord address space. When BES1#, BEF# are high and BES2 is low, all memory banks are deselected and the device enters standby. Read and Write cycle times are equal. The control signals UBS#

and LBS# provide access to the upper data byte and lower data byte. See Table 3 for SRAM Read and Write data byte control modes of operation.

SRAM Read

The SRAM Read operation of the SST34HF1681 is controlled by OE# and BES1#, both have to be low with WE# and BES2 high for the system to obtain data from the outputs. BES1# and BES2 are used for SRAM bank selection. OE# is the output control and is used to gate data from the output pins. The data bus is in high impedance state when OE# is high. Refer to the Read cycle timing diagram, Figure 3, for further details.

SRAM Write

The SRAM Write operation of the SST34HF1681 is controlled by WE# and BES1#, both have to be low, BES2 have to be high for the system to write to the SRAM. During the Word-Write operation, the addresses and data are referenced to the rising edge of either BES1#, WE#, or the falling edge of BES2 whichever occurs first. The write time is measured from the last falling edge of BES1# or WE# or the rising edge of BES2 to the first rising edge of BES1#, or WE# or the falling edge of BES2. Refer to the Write cycle timing diagram, Figures 4 and 5, for further details.

16 Mbit Concurrent SuperFlash + 8 Mbit SRAM ComboMemory

SST34HF1681

Advance Specifications

Absolute Maximum Stress Ratings (Applied conditions greater than those listed under “Absolute Maximum Stress Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions or conditions greater than those defined in the operational sections of this data sheet is not implied. Exposure to absolute maximum stress rating conditions may affect device reliability.)

Operating Temperature -20°C to +85°C
Storage Temperature -65°C to +125°C
D. C. Voltage on Any Pin to Ground Potential -0.5V to $V_{DD}^1+0.3V$
Transient Voltage (<20 ns) on Any Pin to Ground Potential -1.0V to $V_{DD}^1+1.0V$
Package Power Dissipation Capability ($T_a = 25^\circ C$) 1.0W
Output Short Circuit Current² 50 mA

1. $V_{DD} = V_{DDF}$ and V_{DDS}

2. Outputs shorted for no more than one second. No more than one output shorted at a time.

OPERATING RANGE

Range	Ambient Temp	V_{DD}
Commercial	0°C to +70°C	2.7-3.3V
Extended	-20°C to +85°C	2.7-3.3V

AC CONDITIONS OF TEST

Input Rise/Fall Time	5 ns
Output Load	$C_L = 30$ pF
See Figures 19 and 20
