Bits	Field Name	Description	Type	Reset
12	CLKACTIVITY_COREAON_32K_GFCLK	This field indicates the state of the COREAON_32K_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
11	CLKACTIVITY_SR_CORE_SYS_GFCLK	This field indicates the state of the SR_CORE_SYS_GFCLK clock input of the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
10	CLKACTIVITY_SR_GPU_SYS_GFCLK	This field indicates the state of the SR_GPU_SYS_GFCLK clock input of the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
9	CLKACTIVITY_SR_MPU_SYS_GFCLK	This field indicates the state of the SR_MPU_SYS_GFCLK clock input of the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_COREAON_L4_GICLK	This field indicates the state of the COREAON_L4_GICLK clock of the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED			
1:0	CLKTRCTRL	Controls the clock state transition of the COREAON clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x3

3.12.20.2 CM_CORE__CORE Register Description

Table 3-878. CM_L3MAIN1_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4A00 8700	**Instance**	CM_CORE__CORE
Description	This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						CLKACTIVITY_L3MAIN1_L4_GICLK	CLKACTIVITY_L3MAIN1_L3_GICLK	RESERVED						CLKTRCTRL	

Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	CLKACTIVITY_L3MAIN1_L4_GICLK	This field indicates the state of the L3MAIN1_L4_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_L3MAIN1_L3_GICLK	This field indicates the state of the L3MAIN1_L3_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the L3MAIN1 clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: Reserved 0x2: Reserved 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

Bits	Field Name	Description	Type	Reset
1:0	MODULEMODE	Control the way mandatory clocks are managed. 0x0: Module is disabled by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: Module is managed automatically by HW according to clock domain transition. A clock domain sleep transition put module into idle. A wakeup domain transition put it back into function. If CLKTRCTRL=3, any OCP access to module is always granted. Module clocks may be gated according to the clock domain state. 0x2: Reserved 0x3: Reserved	RW	0x0

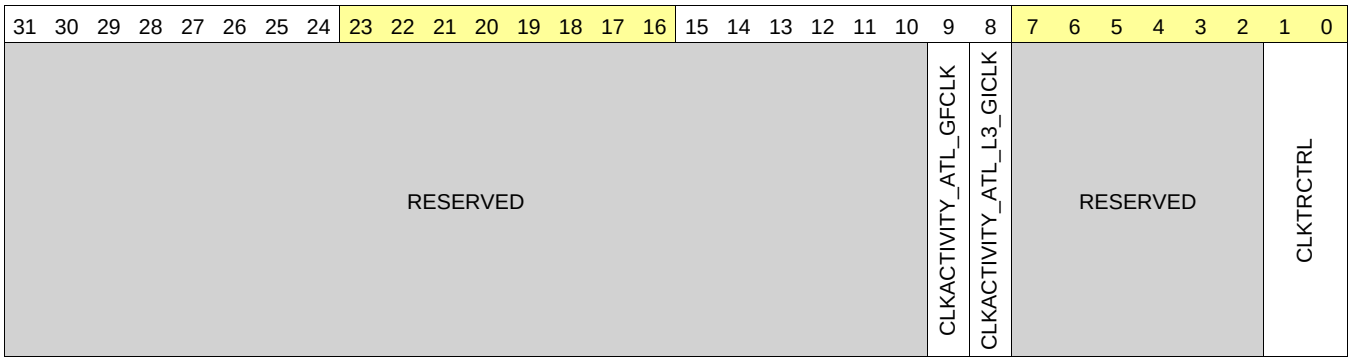
Table 3-948. CM_ATL_CLKSTCTRL

Address Offset	0x0000 0520		
Physical Address	0x4A00 8C20	**Instance**	CM_CORE__CORE
Description	This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	CLKACTIVITY_ATL_GFCLK	This field indicates the state of the ATL_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_ATL_L3_GICLK	This field indicates the state of the ATL_L3_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the ATL clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x3

3.12.24.2 CM_CORE__IVA Register Description

Table 3-1031. CM_IVA_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4A00 8F00	**Instance**	CM_CORE__IVA
Description	This register enables the IVA domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLKACTIVITY_IVA_GCLK	RESERVED						CLKTRCTRL	

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	CLKACTIVITY_IVA_GCLK	This field indicates the state of the IVA_ROOT_CLK clock input of the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the IVA clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: SW_SLEEP: Start a software forced sleep transition on the domain. 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x3

Bits	Field Name	Description	Type	Reset
1:0	MODULEMODE	Control the way mandatory clocks are managed. **Note:** In order to disable the APLL_PCIE, the user needs to disable PCIe_SSx (where x = 1 or 2) using the CM_PCIE_ PCIESSx_CLKCTRL[1:0] MODULEMODE registers. When PCIe_SS is disabled, the PRCM module automatically disables the APLL_PCIE. Please note that setting CM_CLKMODE_APLL_PCIE [1:0] MODE_SELECT bitfield to 0x0 does not disable the APLL_PCIE. 0x0: Module is disabled by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: Reserved 0x2: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guaranteed to stay present. As long as in this configuration, power domain sleep transition cannot happen. 0x3: Reserved	RW	0x0

3.12.26.2 CM_CORE__L4PER Register Description

Table 3-1087. CM_L4PER_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4A00 9700	**Instance**	CM_CORE__L4PER
Description	This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
23	CLKACTIVITY_MMC4_GFCLK	This field indicates the state of the MMC4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
22	CLKACTIVITY_MMC3_GFCLK	This field indicates the state of the MMC3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
21	CLKACTIVITY_PER_96M_GFCLK	This field indicates the state of the PER_96M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
20	CLKACTIVITY_PER_48M_GFCLK	This field indicates the state of the PER_48M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
19	CLKACTIVITY_PER_12M_GFCLK	This field indicates the state of the PER_12M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
18	CLKACTIVITY_UART4_GFCLK	This field indicates the state of the UART4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
17	CLKACTIVITY_UART3_GFCLK	This field indicates the state of the UART3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
16	CLKACTIVITY_UART2_GFCLK	This field indicates the state of the UART2_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
15	CLKACTIVITY_UART1_GFCLK	This field indicates the state of the UART1_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
14	CLKACTIVITY_TIMER9_GFCLK	This field indicates the state of the DMT9_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
13	CLKACTIVITY_TIMER4_GFCLK	This field indicates the state of the DMT4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
12	CLKACTIVITY_TIMER3_GFCLK	This field indicates the state of the DMT3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
11	CLKACTIVITY_TIMER2_GFCLK	This field indicates the state of the DMT2_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
10	CLKACTIVITY_TIMER11_GFCLK	This field indicates the state of the DMT11_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
9	CLKACTIVITY_TIMER10_GFCLK	This field indicates the state of the DMT10_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_L4PER_L3_GICLK	This field indicates the state of the L4PER_L3_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the L4PER clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: SW_SLEEP: Start a software forced sleep transition on the domain. 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

17:16	IDLEST	Module idle status. [warm reset insensitive] 0x0: Module is fully functional, including OCP 0x1: Module is performing transition: wakeup, or sleep, or sleep abortion 0x2: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 0x3: Module is disabled and cannot be accessed	R	0x3
15:2	RESERVED		R	0x0
1:0	MODULEMODE	Control the way mandatory clocks are managed. 0x0: Module is disabled by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 0x1: Reserved 0x2: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guaranteed to stay present. As long as in this configuration, power domain sleep transition cannot happen. 0x3: Reserved	RW	0x0

Table 3-1261. CM_COREAON_IO_SRCOMP_CLKCTRL_RESTORE

Address Offset	0x0000 0060		
Physical Address	0x4A00 9E60	**Instance**	CM_CORE__RESTORE
Description	Second address map for register CM_COREAON_IO_SRCOMP_CLKCTRL. Used only by automatic restore upon wakeup from device OFF mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESTORE																															

Bits	Field Name	Description	Type	Reset
31:0	RESTORE	See CCM_DYN_DEP_PRESCAL register.	RW	0x20

Table 3-1262. CM_DMA_STATICDEP_RESTORE

Address Offset	0x0000 006C		
Physical Address	0x4A00 9E6C	**Instance**	CM_CORE__RESTORE
Description	Second address map for register CM_DMA_STATICDEP. Used only by automatic restore upon wakeup from device OFF mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESTORE																															

Bits	Field Name	Description	Type	Reset
31:0	RESTORE	See CM_DMA_STATICDEP register.	RW	0xb0f0

3.12.29.2 SMARTREFLEX Register Description

Table 3-1266. SRCONFIG

Address Offset	0x0000 0000
Physical Address	None **Instance**
Description	Configuration bits for the Sensor Core and the Digital Processing
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACCUMDATA								SRCLKLENGTH								SRENABLE	SENENABLE	ERRORGENERATORENABLE	MINMAXAVGENABLE	RESERVED										SENNENABLE	SENPENABLE

Bits	Field Name	Description	Type	Reset
31:22	ACCUMDATA	Number of values to accumulate.	RW	0x80
21:12	SRCLKLENGTH	Determines the frequency of SRClk.	RW	0x200
11	SRENABLE	0: Syncronously resets MinMaxAvgAccumValid, MinMaxAvgValid, ErrorGeneratorValid, AccumData sensor, SRClk counter, and MinMaxAvg registers. Also gates the clock for power savings and disables all of the digital logic. 1: Enables the module	RW	0x0
10	SENENABLE	0: Both N and P sensors disabled (SVT) 1: Sensors enabled per SenNEnable SenPEnable	RW	0x1
9	ERRORGENERATORENABLE	0: Error Generator Module disabled 1: Error Generator Module enabled	RW	0x0
8	MINMAXAVGENABLE	0: Min/Max/Avg Detector Module disabled 1: Min/Max/Avg Detector Module enabled	RW	0x0
7:2	RESERVED		R	0x0
1	SENNENABLE	0: Disables SenN sensor 1: Enables SenN sensor	RW	0x1
0	SENPENABLE	0: Disables SenP sensor 1: Enables SenP sensor	RW	0x0

Table 3-1267. SRSTATUS

Address Offset	0x0000 0004		
Physical Address	None	**Instance**	
Description	Status bits that indicate that the values in the register are valid or events have occurred		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												AVGERRVALID	MINMAXAVGVALID	ERRORGENERATORVALID	MINMAXAVGACCUMVALID

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0
3	AVGERRVALID	0: AvgError registers are not valid 1: AvgError registers are valid	R	0x0
2	MINMAXAVGVALID	0: SenVal, SenMin, SenMax, SenAvg registers are not valid 1: SenVal, SenMin, SenMax, SenAvg registers are valid, but not necessarily fully accumulated	R	0x0
1	ERRORGENERATORVALID	0: SenError register do not have valid data 1: SenError registers have valid data	R	0x0
0	MINMAXAVGACCUMVALID	0: SenVal, SenMin, SenMax, SenAvg registers are not valid 1: SenVal, SenMin, SenMax, SenAvg registers have valid, final data	R	0x0

Table 3-1268. SENVAL

Address Offset	0x0000 0008		
Physical Address	None	**Instance**	
Description	The current sensor values from the Sensor Core(SVT)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENPVAL																SENNVAL															

Bits	Field Name	Description	Type	Reset
31:16	SENPVAL	The latest value of the SenPVal from the SVT sensor core	R	0x0
15:0	SENNVAL	The latest value of the SenNVal from the SVT sensor core	R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Table 3-1269. SENMIN

Address Offset	0x0000 000C		
Physical Address	None	**Instance**	
Description	The minimum sensor values(SVT)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENPMIN																SENNMIN															

Bits	Field Name	Description	Type	Reset
31:16	SENPMIN	The minimum value of the SenPVal from the SVT sensor core since the last restart operation	R	0xffff
15:0	SENNMIN	The minimum value of the SenNVal from the SVT sensor core since the last restart operation	R	0xffff

Table 3-1270. SENMAX

Address Offset	0x0000 0010		
Physical Address	None	**Instance**	
Description	The maximum sensor values(SVT)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENPMAX																SENNMAX															

Bits	Field Name	Description	Type	Reset
31:16	SENPMAX	The maximum value of the SenPVal from the SVT sensor core since the last restart operation	R	0x0
15:0	SENNMAX	The maximum value of the SenNVal from the SVT sensor core since the last restart operation	R	0x0

Table 3-1271. SENAVG

Address Offset	0x0000 0014		
Physical Address	None	**Instance**	
Description	The average sensor values(SVT)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENPAVG																SENNAVG															

Bits	Field Name	Description	Type	Reset
31:16	SENPAVG	The running average of the SenPVal from the SVT sensor core since the last restart operation	R	0x0
15:0	SENNAVG	The running average of the SenNVal from the SVT sensor core since the last restart operation	R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Table 3-1272. AVGWEIGHT

Address Offset	0x0000 0018		
Physical Address	None	**Instance**	
Description	The weighting factor in the average computation		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENPAVGWEIGHT1																SENNAVGWEIGHT															

Bits	Field Name	Description	Type	Reset
31:16	SENPAVGWEIGHT1	The weighting factor for the SenP averager	RW	0x0
15:0	SENNAVGWEIGHT	The weighting factor for the SenN averager	RW	0x0

Table 3-1273. NVALUERECIPROCAL

Address Offset	0x0000 001C		
Physical Address	None	**Instance**	
Description	The reciprocal of the SenN and SenP values used in error generation(SVT)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SENPGAIN				SENNGAIN				SENPRN								SENNRN							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED		R	0x0
23:20	SENPGAIN	The gain value for the SVT SenP reciprocal	RW	0x0
19:16	SENNGAIN	The gain value for the SVT SenN reciprocal	RW	0x0
15:8	SENPRN	The scale value for the SVT SenP reciprocal	RW	0x0
7:0	SENNRN	The scale value for the SVT SenN reciprocal	RW	0x0

Table 3-1274. IRQ_EOI

Address Offset	0x0000 0020		
Physical Address	None	**Instance**	
Description	EOI protocol re-trigger		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															EOI

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	EOI	The value read is always '0' Write: 0: re-evaluate pending sources re-send intr* 1: No change to interrupt	RW	0x0

17:16	VIP_BANK_ONSTATE	VIP_BANK memory state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3:2	RESERVED		R	0x0
1:0	POWERSTATE	Power state control 0x0: OFF state Note: Power domain is always on domain and does not support OFF state 0x1: Reserved 0x2: INACTIVE state 0x3: ON State	RW	0x0

Bits	Field Name	Description	Type	Reset
31:26	RESERVED		R	0x0
25:24	OCP_NRET_BANK_ONSTATE	OCP_WP bank and DMM bank2 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
23:22	IPU_UNICACHE_ONSTATE	IPU UNICACHE bank state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
21:20	IPU_L2RAM_ONSTATE	IPU L2 bank state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
19:18	CORE_OCMRAM_ONSTATE	OCMRAM bank state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
17:16	CORE_OTHER_BANK_ONSTATE	DMA/ICR bank and DMM bank1 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:13	RESERVED		R	0x0
12	OCP_NRET_BANK_RETSTATE	OCP_WP bank and DMM bank2 state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state.	R	0x0
11	IPU_UNICACHE_RETSTATE	IPU UNICACHE bank state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state. 0x1: Memory bank is retained when domain is in RETENTION state.	RW	0x1
10	IPU_L2RAM_RETSTATE	IPU L2 bank state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state. 0x1: Memory bank is retained when domain is in RETENTION state.	RW	0x1
9	CORE_OCMRAM_RETSTATE	OCMRAM bank state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
8	CORE_OTHER_BANK_RETSTATE	DMA/ICR bank and DMM bank1 state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1
7:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Only retention registers are retained and remaing logic is off when the domain is in RETENTION state. 0x1: Whole logic is retained when domain is in RETENTION state.	RW	0x1
1:0	POWERSTATE	Power state control 0x0: Reserved 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x3

3.12.35.2 DEVICE_PRM Register Description

Table 3-1509. PRM_RSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 7D00	**Instance**	DEVICE_PRM
Description	Global software cold and warm reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														RST_GLOBAL_COLD_SW	RST_GLOBAL_WARM_SW

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0
1	RST_GLOBAL_COLD_SW	Global COLD software reset control. This bit is reset only upon a global cold source of reset. 0x0: Global COLD software reset is cleared. 0x1: Triggers a global COLD software reset. The software must ensure the SDRAM is properly put in sef-refresh mode before applying this reset.	RW	0x0
0	RST_GLOBAL_WARM_SW	Global WARM software reset control. This bit is reset upon any global source of reset (warm and cold). 0x0: Global warm software reset is cleared. 0x1: Triggers a global warm software reset.	RW	0x0

Table 3-1522. PRM_IO_PMCTRL

Address Offset	0x0000 0020		
Physical Address	0x4AE0 7D20	**Instance**	DEVICE_PRM
Description	This register allows controlling power management features of the IOs.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															GLOBAL_WUEN	RESERVED						WUCLK_STATUS	WUCLK_CTRL	RESERVED		IO_ON_STATUS	ISOOVR_EXTEND	RESERVED		ISOCLK_STATUS	ISOCLK_OVERRIDE

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0
16	GLOBAL_WUEN	Global IO wakeup enable. This is a gating condition to all individual IO WUEN coming from control module. Gating is done in the Spinner logic. 0x0: All individual IO WUEN are gated in the Spinner logic (overriden to 0). 0x1: All individual IO WUEN from control module are going to IOs.	RW	0x0
15:10	RESERVED		R	0x0
9	WUCLK_STATUS	Gives value of WUCLKOUT signal coming back from IO pad ring.	R	0x0
8	WUCLK_CTRL	Direct control on WUCLKIN signal to IO pad ring. 0x0: WUCLKIN signal is driven to 0. IO wakeup daisy chain is functional as well as IO whose wakeup feature is enabled. 0x1: WUCLKIN signal is driven to 1. IO wakeup daisy chain is reset and is latching current pad states and WUEN inputs.	RW	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
7:6	RESERVED		R	0x0
5	IO_ON_STATUS	Gives the functional status of the IO ring. 0x0: Part or all of the IOs are not in the ON state, that is are in isolation state. 0x1: All IOs are in the ON state.	R	0x1
4	ISOOVR_EXTEND	Control non-EMIF IO isolation extension upon a device wakeup from OFF mode. 0x0: Non-EMIF IO isolation is not extended. 'EMIF_ON' IO transition happens as soon as automatic restore is completed. 0x1: Non-EMIF IO isolation is extended. 'EMIF_ON' IO transition is stalled.	RW	0x0
3:2	RESERVED		R	0x0
1	ISOCLK_STATUS	Gives value of ISOCLKOUT signal coming back from IO pad ring.	R	0x0
0	ISOCLK_OVERRIDE	Override control on ISOCLKIN signal to IO pad ring. Used at boot time when it is needed to change the mode of an IO from 1.8V default mode to 1.2V mode. When not overriden, this signal is controlled by hardware only. 0x0: ISOCLKIN signal is not overriden. 0x1: ISOCLKIN signal is overriden to active value ('1').	RW	0x0

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17:16	DSS_MEM_ONSTATE	DSS_MEM state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:9	RESERVED		R	0x0
8	DSS_MEM_RETSTATE	DSS_MEM state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state.	R	0x0
7:5	RESERVED		R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Whole logic is off when the domain is in RETENTION state.	R	0x0
1:0	POWERSTATE	Power state control 0x0: OFF state 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x0

3.12.39.2 EMU_CM Register Description

Table 3-1650. CM_EMU_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 7A00	**Instance**	EMU_CM
Description	This register enables the EMU domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. [warm reset insensitive]		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLKACTIVITY_EMU_SYS_CLK	RESERVED						CLKTRCTRL	

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	CLKACTIVITY_EMU_SYS_CLK	This field indicates the state of the EMU_SYS_CLK clock in the domain. 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the EMU clock domain. 0x0: Reserved 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							LOSTMEM_L3INIT_BANK1	RESERVED						LOSTCONTEXT_RFF	RESERVED

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	LOSTMEM_L3INIT_BANK1	Specify if memory-based context in L3INIT_BANK1 memory bank has been lost due to a previous power transition or other reset source. 0x0: Context has been maintained 0x1: Context has been lost	RW	0x1
7:2	RESERVED		R	0x0
1	LOSTCONTEXT_RFF	Specify if RFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of L3INIT_RET_RST signal) 0x0: Context has been maintained 0x1: Context has been lost	RW	0x1

3.12.50.2 L4PER_PRM Register Description

Table 3-1833. PM_L4PER_PWRSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 7400	**Instance**	L4PER_PRM
Description	This register controls the L4PER power state to reach upon a domain sleep transition		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												NONRETAINED_BANK_ONSTATE		RETAINED_BANK_ONSTATE		RESERVED							NONRETAINED_BANK_RETSTATE	RETAINED_BANK_RETSTATE	RESERVED			LOWPOWERSTATECHANGE	RESERVED	LOGICRETSTATE	POWERSTATE	

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19:18	NONRETAINED_BANK_ONSTATE	NONRETAINED_BANK state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
17:16	RETAINED_BANK_ONSTATE	RETAINED_BANK state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:10	RESERVED		R	0x0
9	NONRETAINED_BANK_RETSTATE	NONRETAINED_BANK state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state.	R	0x0
8	RETAINED_BANK_RETSTATE	RETAINED_BANK state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1
7:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Only retention registers are retained and remaing logic is off when the domain is in RETENTION state. 0x1: Whole logic is retained when domain is in RETENTION state.	RW	0x1
1:0	POWERSTATE	Power state control 0x0: Reserved 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x3

Table 3-1834. PM_L4PER_PWRSTST

PRCM Register Manual • L4PER_PRM Register Summary: [9]

Table 3-1856. RM_L4PER_TIMER9_CONTEXT

Address Offset	0x0000 0054		
Physical Address	0x4AE0 7454	**Instance**	L4PER_PRM
Description	This register contains dedicated TIMER9 context statuses. [warm reset insensitive]		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															LOSTCONTEXT_DFF

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	LOSTCONTEXT_DFF	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of L4PER_RST signal) 0x0: Context has been maintained 0x1: Context has been lost	RW	0x1

Copyright © 2018–2019, Texas Instruments Incorporated

Table 3-1857. RM_L4PER_ELM_CONTEXT

Address Offset	0x0000 005C		
Physical Address	0x4AE0 745C	**Instance**	L4PER_PRM
Description	This register contains dedicated ELM context statuses. [warm reset insensitive]		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															LOSTCONTEXT_DFF

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	LOSTCONTEXT_DFF	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of L4PER_RST signal) 0x0: Context has been maintained 0x1: Context has been lost	RW	0x1

Table 3-1858. PM_L4PER_GPIO2_WKDEP

Address Offset	0x0000 0060		
Physical Address	0x4AE0 7460	**Instance**	L4PER_PRM
Description	This register controls wakeup dependency based on GPIO2 service requests.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3.12.51.2 MPU_PRM Register Description

Table 3-1986. PM_MPU_PWRSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 6300	**Instance**	MPU_PRM
Description	This register controls the MPU domain power state to reach upon a domain sleep transition. If the value programmed in this register correspond to a lower power state than the one programmed in MPU-SS for CPU0 and/or CPU1, then value of this register is overwritten in PRCM logic to limit the power state to enter. **Notes:** Even if value of this register is overwritten in PRCM logic, value of this register remains unchanged. If user programs MPU power domain to go to CSWRET, then he can not program L2 cache to OFF mode. **Note:** Only the MPU Subsystem supports memory retention. MPU subsystem does not support OFF state.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 3-1988. PM_MPU_PWRSTST

Address Offset	0x0000 0004		
Physical Address	0x4AE0 6304	**Instance**	MPU_PRM
Description	This register provides a status on the MPU domain current power state. [warm reset insensitive]		
Type	RW		

31 30 29 28 27 26	25 24	23 22 21	20	19 18 17 16	15 14 13 12 11 10	9 8	7 6	5 4 3	2	1 0
RESERVED	LASTPOWERSTATEENTERED	RESERVED	INTRANSITION	RESERVED		MPU_RAM_STATEST	MPU_L2_STATEST	RESERVED	LOGICSTATEST	POWERSTATEST

Bits	Field Name	Description	Type	Reset
31:26	RESERVED		R	0x0
25:24	LASTPOWERSTATEENTERED	Last low power state entered. Set to 0x3 upon write of the same only. This register is intended for debug purpose only. 0x0: Power domain was previously OFF Note: Power domain is always on domain and does not support OFF state 0x1: Power domain was previously in RETENTION 0x2: Power domain was previously ON-INACTIVE 0x3: Power domain was previously ON-ACTIVE	RW	0x0
23:21	RESERVED		R	0x0
20	INTRANSITION	Domain transition status 0x0: No on-going transition on power domain 0x1: Power domain transition is in progress.	R	0x0
19:10	RESERVED		R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9:8	MPU_RAM_STATEST	MPU_RAM memory state status 0x0: Memory is OFF 0x1: Memory is RETENTION 0x2: Reserved 0x3: Memory is ON	R	0x3
7:6	MPU_L2_STATEST	MPU_L2 memory state status 0x0: Memory is OFF 0x1: Memory is RETENTION 0x2: Reserved 0x3: Memory is ON	R	0x3
5:3	RESERVED		R	0x0
2	LOGICSTATEST	Logic state status 0x0: Logic in domain is OFF 0x1: Logic in domain is ON	R	0x1
1:0	POWERSTATEST	Current power state status 0x0: Power domain is OFF 0x1: Power domain is in RETENTION 0x2: Power domain is ON-INACTIVE 0x3: Power domain is ON-ACTIVE	R	0x3

Table 3-2007. PRM_IRQSTATUS_DSP1

Address Offset	0x0000 0030		
Physical Address	0x4AE0 6030	**Instance**	OCP_SOCKET_PRM
Description	This register provides status on DSP1 interrupt events. Any event is logged independently of the corresponding IRQENABLE value. SW is required to clear a set bit by writing a '1' into the bit-position to be cleared.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31	ABB_MPU_DONE_ST	MPU ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
30	ABB_IVA_DONE_ST	IVA ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
29	ABB_DSPEVE_DONE_ST	DSPEVE ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
28	ABB_GPU_DONE_ST	GPU ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
27:13	RESERVED		R	0x0
12	DPLL_EVE_RECAL_ST	EVE DPLL recalibration interrupt status. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0

3.12.55.2 WKUPAON_CM Register Description

Table 3-2062. CM_WKUPAON_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 7800	**Instance**	WKUPAON_CM
Description	This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19	CLKACTIVITY_ADC_L3_GICLK	This field indicates the state of the ADC_L3_GICLK clock in the domain(it includes profiling, EMU_SYS_GCLK and all functional SYS_CLK. [warm reset insensitive] **Note: ADC_L3_GICLK is used as Interface clock for the MCAN module** 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
18	CLKACTIVITY_UART10_GFCLK	This field indicates the state of the UART10_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
17	CLKACTIVITY_TIMER1_GFCLK	This field indicates the state of the TIMER1_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
16	CLKACTIVITY_DCAN1_SYS_CLK	This field indicates the state of the DCAN1_SYS_CLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
15	CLKACTIVITY_SYS_CLK_ALL	This field indicates the state of the SYS_CLK runing at SCRM level because of any SCRM clock request. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
14	CLKACTIVITY_SYS_CLK_FUNC	This field indicates the state of the functional SYS_CLK clocks in the domain (this exclude activity of EMU_GCLK clock). [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
13	CLKACTIVITY_WKUPAON_IO_SRCOMP_GFCLK	This field indicates the state of the WKUPAON_IO_SRCOMP_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
12	CLKACTIVITY_WKUPAON_GICLK	This field indicates the state of the WKUPAON_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
11	CLKACTIVITY_WKUPAON_SYS_GFCLK	This field indicates the state of the WKUPAON_SYS_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
10	CLKACTIVITY_ADC_GFCLK	This field indicates the state of the ADC_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
9	CLKACTIVITY_ABE_LP_CLK	This field indicates the state of the ABE_LP_CLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_SYS_CLK	This field indicates the state of the SYS_CLK clock in the domain(it includes profiling, EMU_SYS_GCLK and all functional SYS_CLK. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the WKUPAON clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

Table 3-2064. CM_WKUPAON_L4_WKUP_CLKCTRL

Address Offset	0x0000 0020		
Physical Address	0x4AE0 7820	**Instance**	WKUPAON_CM
Description	This register manages the WKUPAON clocks.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														IDLEST		RESERVED														MODULEMODE	

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17:16	IDLEST	Module idle status. [warm reset insensitive] 0x0: Module is fully functional, including OCP 0x1: Module is performing transition: wakeup, or sleep, or sleep abortion 0x2: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 0x3: Module is disabled and cannot be accessed	R	0x3
15:2	RESERVED		R	0x0
1:0	MODULEMODE	Control the way mandatory clocks are managed. 0x1: Module is managed automatically by HW according to clock domain transition. A clock domain sleep transition put module into idle. A wakeup domain transition put it back into function. If CLKTRCTRL=3, any OCP access to module is always granted. Module clocks may be gated according to the clock domain state.	R	0x1

4.1 Dual Cortex-A15 MPU Subsystem Overview

4.1.1 Introduction

The dual Cortex®-A15 microprocessor unit (MPU) subsystem serves the applications processing role by running the high-level operating system (HLOS) and application code. The MPU subsystem is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management, debug, and emulation capabilities.

The MPU subsystem incorporates two Cortex-A15 MPU cores (MPU_C0 and MPU_C1), individual level 1 (L1) caches, level 2 (L2) cache (MPU_L2CACHE) shared between them, and various other shared peripherals. To aid software development, the processor cores can be kept cache-coherent with each other and with the L2 cache.

The MPU subsystem provides a high-performance computing platform with high peak-computing performance and low memory latency.

NOTE: Neither MPU_C0 nor MPU_C1 can be put in OFF power state.

Figure 4-1 is a high-level block diagram of the MPU subsystem.

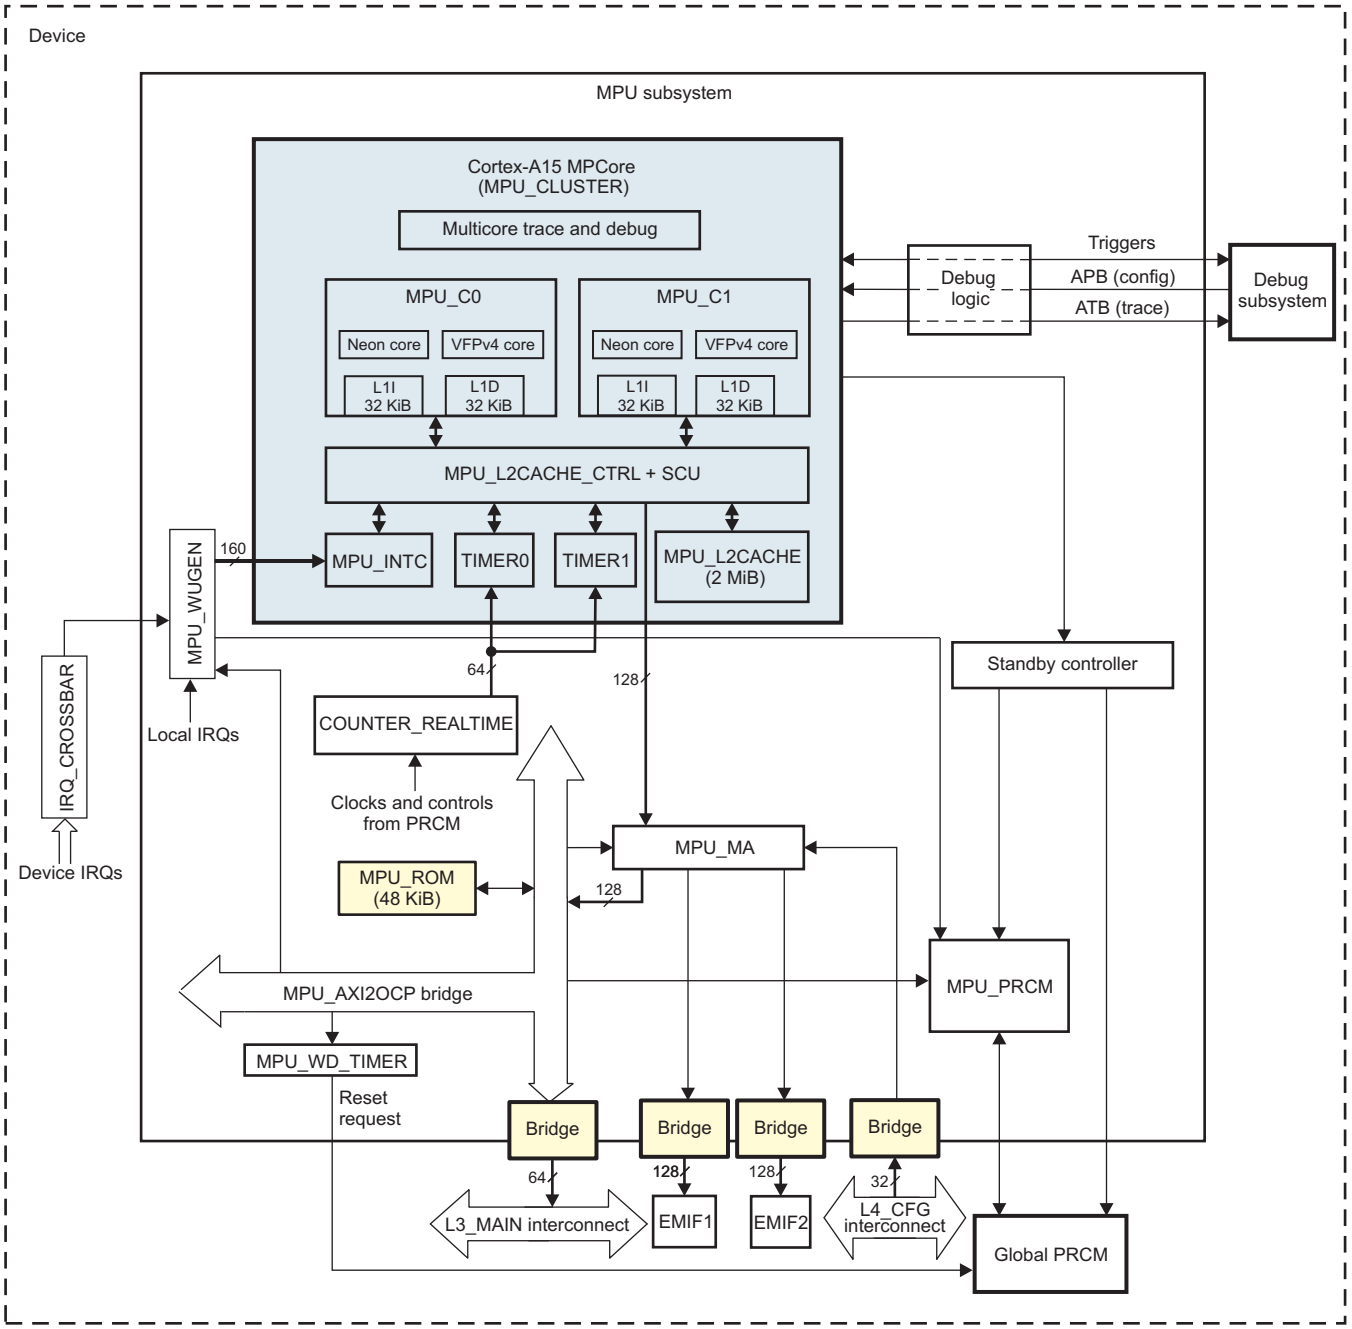
Figure 4-1. MPU Subsystem Overview



Copyright © 2018–2019, Texas Instruments Incorporated

4.1.2 Features

The MPU subsystem integrates the following:

- Arm®Cortex-A15 MPCore (MPU_CLUSTER)
  - Two Cortex-A15 MPU cores (revision r2p2, SMP architecture), each of them having the following features:
    - Superscalar, dynamic multi-issue technology
      - Out-of-order (OoO) instruction dispatch and completion
      - Dynamic branch prediction with branch target buffer (BTB), global history buffer (GHB), and 48-entry return stack
      - Continuous fetch and decoding of three instructions per clock cycle
      - Dispatch of up to four instructions and completion of eight instructions per clock cycle
      - Provides optimal performance from binaries compiled for previous Arm processors
      - Five execution units handle simple instructions, branch instructions, Neon™ and floating point instructions, multiply instructions, and load and store instructions.
      - Simple instructions take two cycles from dispatch, while complex instructions take up to 11 cycles.
      - Can issue two simple instructions in a cycle
      - Can issue a load and a store instruction in the same cycle
    - Integrated Neon processing engine to include the Arm Neon Advanced SIMD (single instruction, multiple data) support for accelerated media and signal processing computation
    - Includes VFPv4-compatible hardware to support single- and double-precision add, subtract, divide, multiply and accumulate, and square root operations
    - Extensive support to accelerate virtualization using a hypervisor
    - 32-KiB L1 instruction (L1I) and 32-KiB L1 data (L1D) cache:
      - 64-byte line size
      - 2-way set associative
    - Memory management unit (MMU):
      - Two-level translation lookaside buffer (TLB) organization
        - First level is an 32-entry, fully associative micro-TLB implemented for each of instruction fetch, load, and store.
        - Second level is a unified, 4-way associative, 512-entry main TLB
      - Supports hardware TLB table-walk for backward-compatible and new 64-bit entry page table formats
      - New page table format can produce 40-bit physical addresses
      - Two-stage translation where first stage is HLOS-controlled and the second level may be controlled by a hypervisor. Second stage always uses the new page table format
  - Integrated L2 cache (MPU_L2CACHE) and snoop control unit (SCU):
    - 2-MiB of unified (instructions and data) cache organized as 16 ways of 2048 sets of 64-byte lines
    - Redundant L1 data (cache) tags to perform snoop filtering (L1 instruction cache tags are not duplicated)
    - Operates at Cortex-A15 MPU core clock rate
    - Integrated L2 cache controller (MPU_L2CACHE_CTRL):
      - Sixteen 64-byte line buffers that handle evictions, line fills and snoop transfers
      - One 128-bit AMBA4 Coherent Bus (AXI4-ACE) port
      - Auto-prefetch buffer for up to 16 streams per core and detecting forward and backward strides
      - L1 cache coherency between the MPU cores is maintained by the L2 cache controller, which

Copyright © 2018–2019, Texas Instruments Incorporated

also serves as a snoop controller.
    - SCU ensures memory coherency between the two MPU cores
  - Generalized interrupt controller (GIC, also referred to as MPU_INTC): An interrupt controller supplied by Arm. The single GIC in the MPU_CLUSTER routes interrupts to each of the MPU cores. The GIC supports:
    - Number of shared peripheral interrupts (SPI): 160
    - Number of software generated interrupts (SGI): 16
    - Number of CPU interfaces: 2
    - Virtual CPU interface for virtualization support. This allows the majority of guest operating system (OS) interactions with the GIC to be handled in hardware, but with physical interrupts still requiring hypervisor intervention to assign them to the appropriate virtual machine.
  - Integrated timer counter and one timer block per MPU core
  - Arm CoreSight™ debug and trace modules. For more information, see Chapter 35, *On-Chip Debug Support*.
- MPU_AXI2OCP bridge (local interconnect):
  - Connected to Memory Adapter (MPU_MA), which routes the non-EMIF address space transactions to MPU_AXI2OCP
  - Single request multiple data (SRMD) protocol on L3_MAIN port
  - Multiple targets:
    - 64-bit port to the L3_MAIN interconnect. Interface frequency is 1/4 or 1/8 of core frequency
    - MPU_ROM
    - Internal MPU subsystem peripheral targets, including Memory Adapter LISA Section Manager (MA_LSM), wake-up generator (MPU_WUGEN), watchdog timer (MPU_WD_TIMER), and local PRCM module (MPU_PRCM) configuration
    - Internal AXI target, CoreSight System Trace Module (CS_STM)
- Memory adapter (MPU_MA): Helps decrease the latency of accesses between the MPU_L2CACHE and the two EMIFs (EMIF0 and EMIF1) by providing a direct path between the MPU subsystem and the EMIFs:
  - Connected to 128-bit AMBA4 interface of MPU_CLUSTER
  - Direct 128-bit interface to each of EMIF0 and EMIF1
  - Interface speed between MPU_CLUSTER and MPU_MA is at half-speed of MPU_CLUSTER internal core frequency
  - Quarter-speed interface to EMIF
  - Performs interleaving functions to optimize EMIF interface bandwidth
  - Uses firewall logic to check access rights of incoming addresses
- Local PRCM (MPU_PRCM):
  - Handles MPU_C0 and MPU_C1 power domains
  - Supports SR3-APG (SmartReflex3 Automatic Power Gating) power management technology inside the MPU_CLUSTER
  - MPU subsystem has six power domains
- Wake-up generator (MPU_WUGEN)
  - Responsible for waking up the MPU cores
  - Used by the ROM code and OS during SMP boot
- Standby controller: Handles the power transitions inside the MPU subsystem
- Realtime (master) counter (COUNTER_REALTIME): Produces the count used by the private timer peripherals in the MPU_CLUSTER
- Watchdog timer (MPU_WD_TIMER): Used to generate a chip-level watchdog reset request to global PRCM
- On-chip ROM (MPU_ROM): Both MPU_C0 and MPU_C1 can boot from this memory. The MPU_ROM

Copyright © 2018–2019, Texas Instruments Incorporated

size is 48-KiB, and the address range is from 0x4003 8000 to 0x4004 3FFF. For more information, see Chapter 34, *Initialization*.

- Interfaces:
  - 128-bit interface to each of EMIF0 and EMIF1
  - 64-bit master port to the L3_MAIN interconnect
  - 32-bit slave port from the L4_CFG_EMU interconnect (debug subsystem) for configuration of the MPU subsystem debug modules
  - 32-bit slave port from the L4_CFG interconnect for memory adapter firewall (MPU_MA_NTTP_FW) configuration
  - 32-bit ATB output for transmitting debug and trace data
  - 160 peripheral interrupt inputs
- Unsupported features of the Cortex-A15 MPU cores
  - Neither of the two Cortex-A15 MPU cores has a power switch, making both subsystem-level MPU core power domains Always-On. For more information on the power domain, see Section 3.7.5, *PD_MPU Description*.

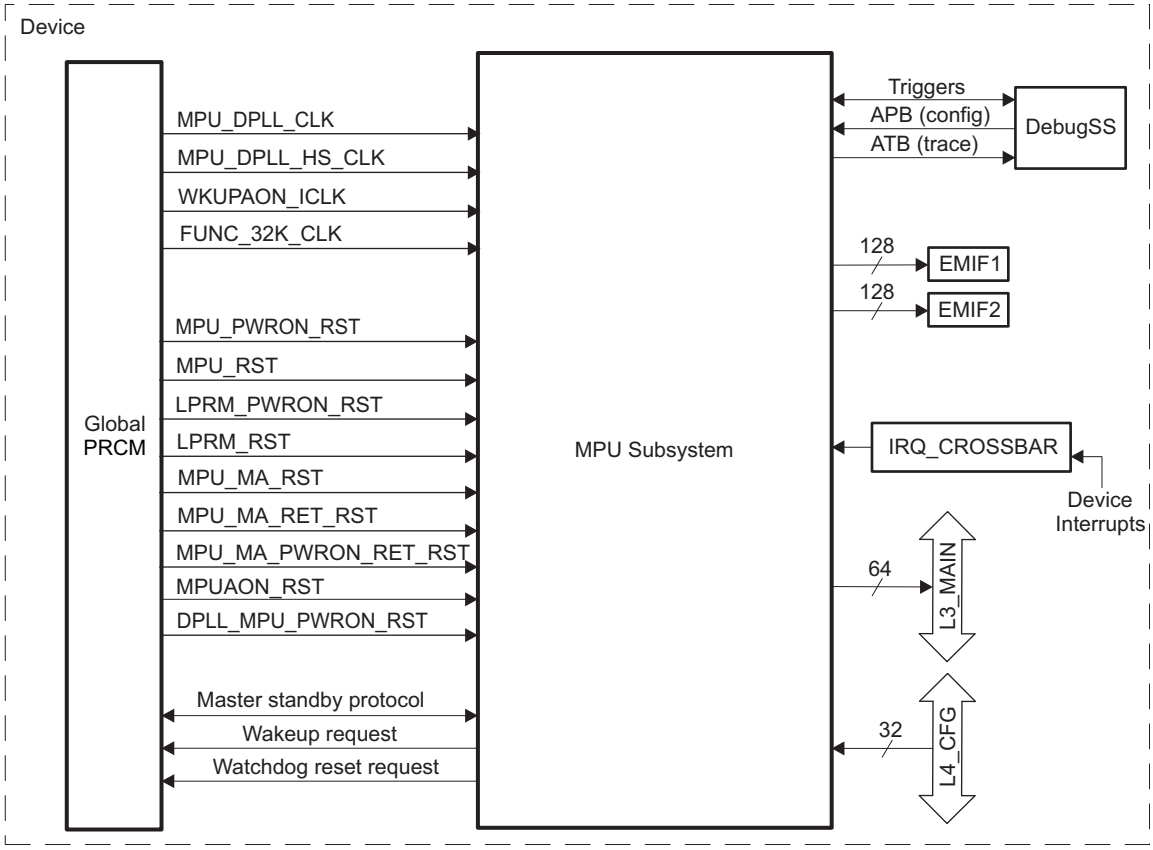
Copyright © 2018–2019, Texas Instruments Incorporated

4.2 Dual Cortex-A15 MPU Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 4-2 shows the MPU subsystem integration.

Figure 4-2. MPU Subsystem Integration



NOTE: For more information about:

- Clock distribution inside MPU subsystem, see Section 4.2.1, *Clock Distribution*.
- Reset distribution inside MPU subsystem, see Section 4.2.2, *Reset Distribution*.
- MPU_INTC default interrupt mapping, and IRQ_CROSSBAR mapping, see Chapter 18, *Interrupt Controllers*.
- MPU watchdog timer reset request, see Section 4.3.6, *MPU Watchdog Timer*.
- MPU trace and cross-triggering with Debug Subsystem, see Chapter 35, *On-Chip Debug Support*.
- Master standby protocol and wakeup request, see Section 3.1.1.1.2, *Module-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

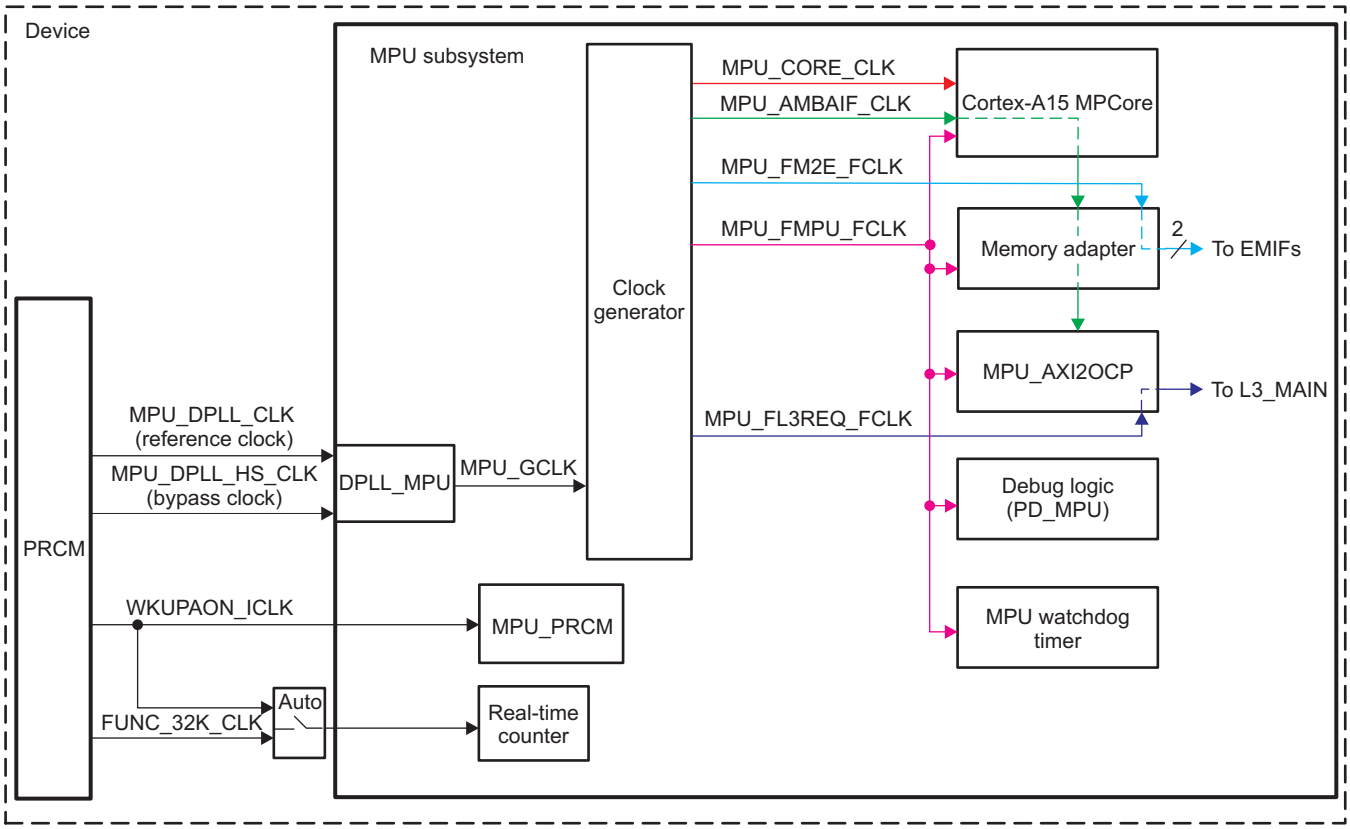
4.2.1 Clock Distribution

The Cortex-A15 MPU clock generator is fed by the MPU digital phase-locked loop (DPLL), which can be gated off by the global power, reset, and clock management (PRCM) module. There is a global clock gating for each MPU core. Because of the DPLL_MPU, the MPU subsystem is asynchronous from the rest of the device.

Figure 4-3 shows the MPU subsystem clocking scheme.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 4-3. MPU Subsystem Clocking Scheme



The clock generator generates the following clocks from the DPLL_MPU output clock (MPU_GCLK):

- MPU_CORE_CLK
- MPU_AMBAIF_CLK
- MPU_FMPU_FCLK
- MPU_FL3REQ_FCLK
- MPU_FM2E_FCLK

MPU_CORE_CLK is directly derived (no hardware dividing) from the DPLL_MPU output clock (that is, MPU_CORE_CLK = MPU_GCLK). The other clocks are derived via dividers.

Table 4-1 shows the supported frequency values for MPU subsystem clocks at different OPPs.

Table 4-1. MPU Subsystem Clocks Frequency Value Versus OPP

Clocks (Derived From DPLL_MPU)	OPP_LOW	OPP_NOM	OPP_OD	OPP_HIGH	OPP_PLUS
MPU_CORE_CLK (f)	See (1)	See (1)	See (1)	See (1)	See (1)
MPU_AMBAIF_CLK	f/2	f/2	f/2	f/2	f/2
MPU_FMPU_FCLK	f/4	f/4	f/4	f/4	f/4
MPU_FL3REQ_FCLK	f/4	f/4	f/4	f/8	f/8
MPU_FM2E_FCLK	f/4	f/4	f/4	f/4	f/4

(1) See device *Data Manual* for information about frequency value

Copyright © 2018–2019, Texas Instruments Incorporated

Some of the OPPs listed in Table 4-1 may not be supported for some devices.

NOTE: For more information about the supported OPPs, see the "*Operating Performance Points*" section of the device Data Manual.

NOTE: For more information about the DPLL_MPU, see Section 3.6.3.7, *DPLL_MPU Description*, in Chapter 3, *Power, Reset, and Clock Management*.

The two MPU cores cannot be clocked at different frequencies.

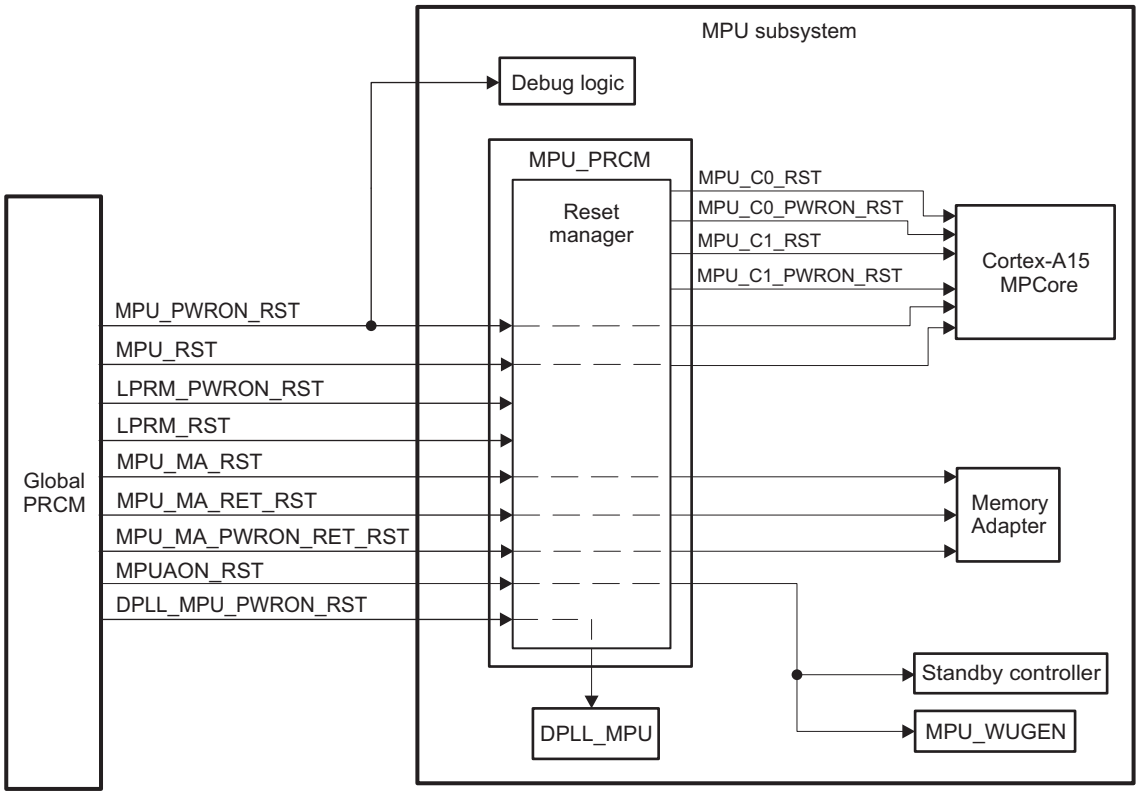
The realtime counter (COUNTER_REALTIME) is clocked by either WKUPAON_ICLK or FUNC_32K_CLK clocks, provided by the global PRCM module. By default, WKUPAON_ICLK is used as a COUNTER_REALTIME clock. When the MPU subsystem goes to standby mode, the counter automatically switches to a low-power mode using the FUNC_32K_CLK (SYS_CLK1/610).

4.2.2 Reset Distribution

Resets to the MPU subsystem are provided by the global PRCM module and controlled by the local MPU_PRCM module.

Figure 4-4 shows the reset scheme of the MPU subsystem.

Figure 4-4. MPU Subsystem Reset Scheme



All external resets that are input to the local PRCM signals are active low. All external reset input signals are driven by the global PRCM. Four internal reset signals are generated by the local PRCM module.

The LPRM_PWRON_RST reset signal is a global cold reset for the wake-up logic and resets the wake-up domain logic (the PSCON modules) in the local PRCM module. A cold reset is typically asserted when power is initially applied to the system. The user can check whether this reset event has occurred by reading the PRM_RSTST[0] GLOBAL_COLD_RST bit.

Copyright © 2018–2019, Texas Instruments Incorporated

The LPRM_RST reset signal is a global warm reset that resets the wake-up domain logic (the PSCON modules) in the local PRCM module. Warm reset is typically used to reset a system that has been operating for some time. The user can check whether this reset event has occurred by reading the PRM_RSTST[1] GLOBAL_WARM_RST bit.

The DPLL_MPU_PWRON_RST reset signal resets the DPLL_MPU.

The MPUAON_RST reset signal resets the MPU always-on domain: the standby controller and the MPU_WUGEN. The user can check whether the reset has occurred by reading the WKG_CONTROL_0[15] DOMAIN_RST bit for MPU_C0 and the WKG_CONTROL_1[15] DOMAIN_RST bit for MPU_C1.

The MPU_MA has three incoming reset signals:

- MPU_MA_RST
- MPU_MA_RET_RST
- MPU_MA_PWRON_RET_RST

The local PRCM module provides two reset signals for each CPU:

- The MPU_C0_RST and MPU_C1_RST reset signals are warm reset events. These reset signals initialize most of the Arm MPU cores, except the debug logic (breakpoints and watchpoints are retained during this reset). The user can check whether these reset events have occurred by reading the RM_CPUx_RSTCTRL[0] RST bit.
- The MPU_C0_PWRON_RST and MPU_C1_PWRON_RST reset signals are cold and debug reset events.

For more information about clocks, resets, and power domains, and the MPU_PWRON_RST and MPU_RST reset signals, see Chapter 3, *Power, Reset, and Clock Management*.

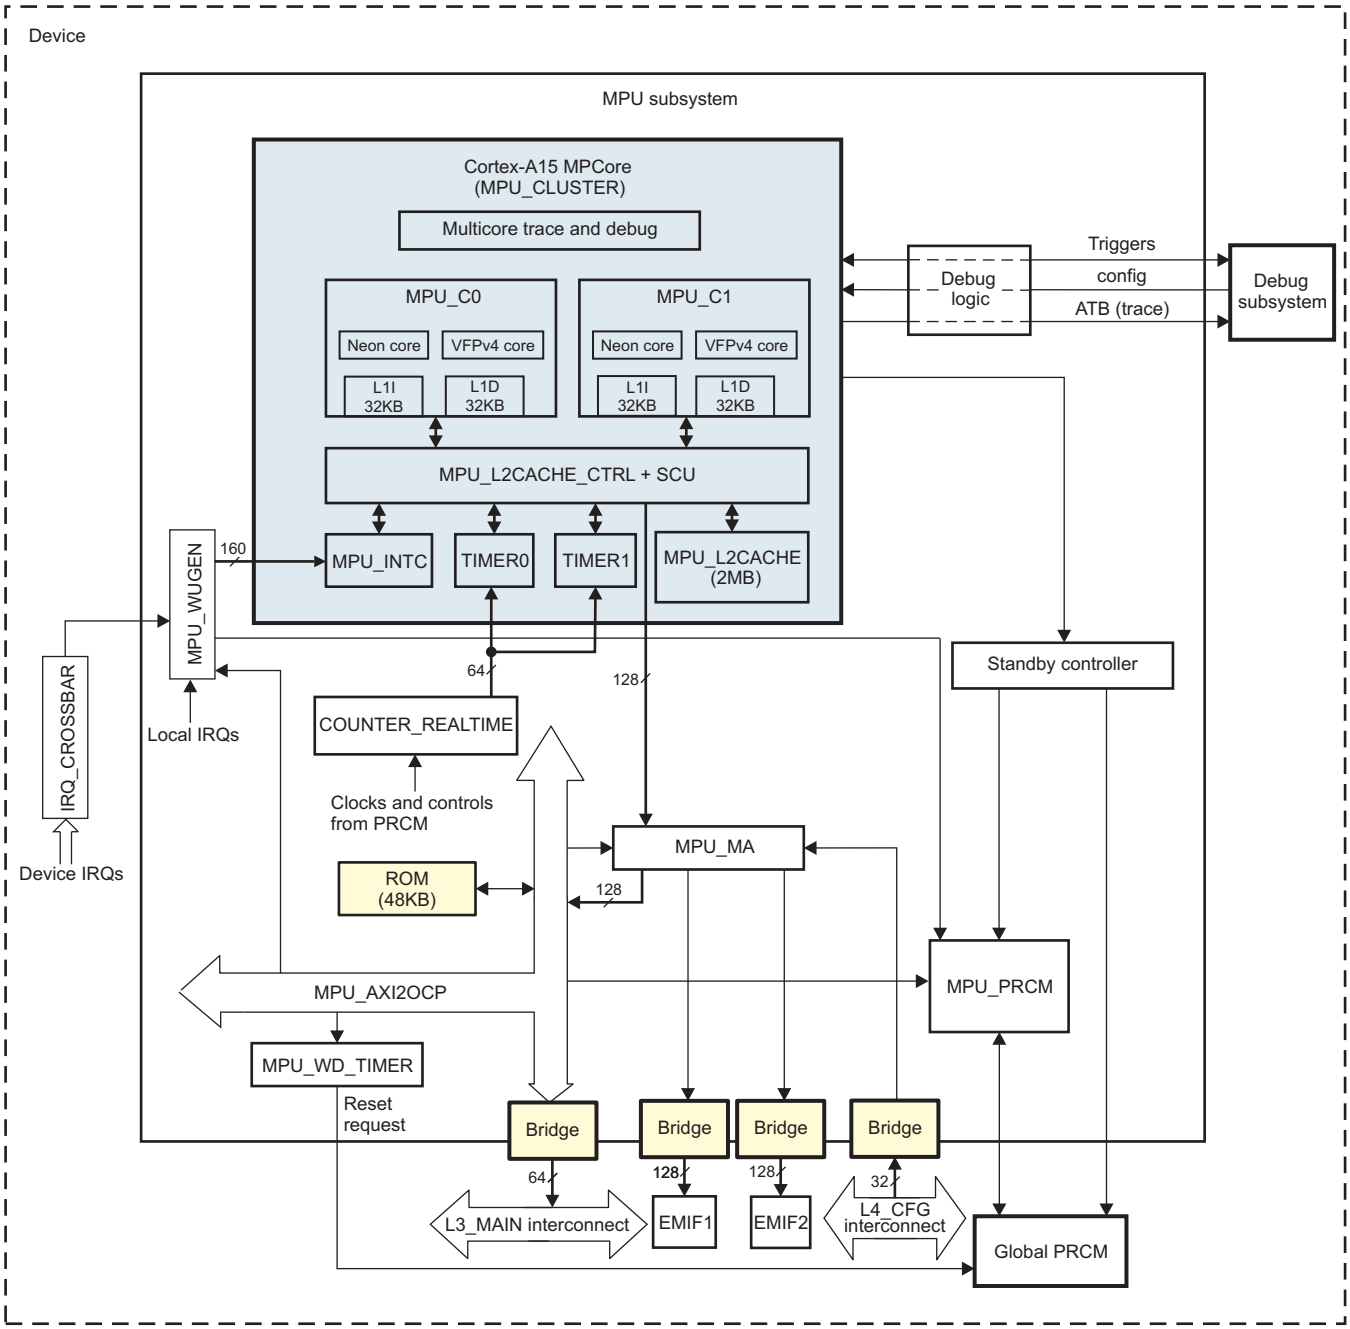
4.3 Dual Cortex-A15 MPU Subsystem Functional Description

4.3.1 MPU Subsystem Block Diagram

Figure 4-5 shows the block diagram of the MPU subsystem.

Figure 4-5. MPU Subsystem Block Diagram



4.3.2 Cortex-A15 MPCore (MPU_CLUSTER)

The MPU_CLUSTER consists of:

- Two CPUs (dual-core configuration), including:
  - Arm version 7 ISA: Standard Arm instruction set plus Thumb®-2 , Jazelle® RCT, and Jazelle DBX Java™ accelerator

Copyright © 2018–2019, Texas Instruments Incorporated

  - Neon SIMD coprocessor and VFPv4
  - 12-stage in-order MPU core pipeline
  - 128-bit-wide instruction fetch allows fetching up to four instructions/cycle
  - 32 KiB/32 KiB instruction and data cache for each MPU core
  - Complex Execution Unit (FPU) per MPU core
  - 32-entry fully-associative micro-TLB each for instruction and data per MPU core
  - 512-entry 4-way set-associative unified TLB per MPU core
- Unified L2 cache control including tags
- Interrupt controller (MPU_INTC)
  - Supports 160 hardware interrupts. For more information about interrupt mapping, see Chapter 18, *Interrupt Controllers*.
- One timer and watchdog timer per MPU core
- Internal APB bridge that connects to the APB port of each MPU core

The major interfaces of the MPU_CLUSTER are:

- Single AXI master supporting 128-bit interface
- System coherency supported through the AXI4 ACE interface
- An ATB port (for processor trace)
- An APB port
- Interrupt request lines

NOTE: The following hardware restrictions/limitations are applied to the Cortex-A15 MPCore in this device:

- Not implemented features:
  - ACP port to support hardware coherency with external master
  - ECC/parity support for the L1 or L2 caches
- Supported ACE configurations:
  - **AXI3** mode (default). In this configuration, barrier transactions are not issued on the AMBA4 interface.
  - **ACE non-coherent, no L3** mode. In this configuration, barrier transactions are issued on the AMBA4 interface.

For more information about AMBA4 interface configuration, see Section 4.3.8, *MPU Subsystem AMBA Interface Configuration*.

For more information about Cortex-A15 MPCore, see the Arm *Cortex-A15 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

4.3.2.1 MPU L2 Cache Memory System

The MPU subsystem implements an L2 memory system. This memory system consists of an L2 cache (MPU_L2CACHE) and associated L2 cache controller (MPU_L2CACHE_CTRL). The MPU L2 cache controller runs at full-CPU speed and is configured to have one 128-bit master port. The L2 cache controller is configurable via CP15 registers and is tightly coupled to the L1 memory system. The MPU L2 memory system supports Arm Instruction Set Architecture (v7).

MPU L2 supports hardware cache coherency, but is used in a limited way in the device. Because the rest of the system does not support coherency with the MPU L2 cache, software coherence is required.

The L2 cache size on the MPU subsystem is 2 MiB. The cache is configured as 16-way set associative, with 64-B line size. The L2 cache controller performs critical word-first-refilling with a random or pseudo-random cache replacement policy.

Copyright © 2018–2019, Texas Instruments Incorporated

The L2 includes logic to support cache event monitoring. The events being monitored are routed to the hardware debug (MPUHWDBGOUT[31:0]) port. The mapping of these events to the MPUHWDBGOUT[31:0] port is described in the *Control Module* chapter.

The L2 can be configured to generate interrupts on error conditions or event counter overflow/increment. The L2 interrupt (MPU_CLUSTER_IRQ_AXIERR) is mapped to interrupt line MPU_IRQ_3. When an interrupt occurs, software may look at corresponding interrupt register to determine the source of the interrupt.

4.3.2.1.1 MPU L2 Cache Architecture

The main features of the MPU_L2CACHE are:

- 2048-KiB 16-way set-associative unified instruction/data cache
- 9-stage L2 pipeline
- L2 hit latency of 12 cycles
- Fixed line length of 64-bytes (16 words)
- L1 inclusive
- Physically indexed and tagged
- 16-way set-associative (maximum)
- Bank partitions to support streaming Neon loads and simultaneous (two) L2 requests
- Exclusive-D L2 cache fill policy
- Global-random replacement strategy
- Four dirty bits per cache line to minimize traffic to L3
- Low-leakage sleep mode (retention until accessed)
- Cache redundancy and repair

4.3.2.1.2 MPU L2 Cache Controller

The main features of the MPU_L2CACHE_CTRL are:

- Single 128-bit AXI4 master port interface
- Tightly coupled L2/SCU for better L2 hit latency
- Nonblocking: Supports hit-under-miss and miss-under-miss for Neon requests
- Performs critical data first refilling
- Supports the following cache modes:
  - Write-through, read allocate
  - Write-back, read allocate, and write allocate
- Supports write-combining to two independently tagged quad-words
- 12 × 128-bit write buffers to buffer subblock writes (per MPU core)
- 12 × 128-bit ACP write buffer (shared across MPU cores)
- 16-entry × 512-bit victim buffers (shared across MPU cores)
- Separate 128-bit interfaces to the I-side and the D-side:
  - Four beat (128-bit) transfers to refill L1 from L2 (or 128-bit AXI)
  - Eight beat (64-bit) transfers to refill L1 from AXI
- 128-bit subblock write and copy-back interface on the D-side
- Outstanding transactions on the AXI4 master port:
  - 16 read
  - 16 write
- Performs hardware table walk using the L2 unified TLB

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: The Cortex-A15 processor memory system treats all write-through (WT) accesses as 'write-through, no-allocate'. This means that no cache line from any write-through page allocates in any L1 data or L2 cache. This implies that write-through lines are implemented as non-cacheable in Cortex-A15. Memory requests for write-through cache lines are not looked-up in the L1D or L2, and are sent directly to the AXI master interface. Not caching WT lines was done primarily to avoid back-and-forth L1/L2 snoop invalidations and increasing interconnect traffic when more than one CPU attempts to write to the same WT line. Coherency traffic is greatly reduced in an MP configuration when WT data is treated as 'write-through, no-allocate'.

For non-cacheable and WT memory, all Cortex-A15 memory read requests are 64 bytes. A15 over-reads and then allows forwarding of the data to multiple load instructions. If there is only a single load request for that line, there is no latency hit (since Cortex-A15 does critical word first) although there is potentially an increase in bus power. If there are multiple hits due to consecutive loads of data within the same line, there is a possibility of significant performance gains.

4.3.3 MPU_AXI2OCP

MPU_AXI2OCP provides a protocol bridge between buses and also serves as a small local interconnect to:

- Handle traffic to the L3_MAIN interconnect
- Configure local configuration registers in the MPU subsystem

Main features of MPU_AXI2OCP:

- Connects to the L3_MAIN interconnect through a 64-bit port. The interface frequency is configurable between one fourth (default value) and one eighth of the MPU_DPLL_CLK clock signal frequency. This is programmable in the global PRCM register CM_MPU_MPU_CLKCTRL[25:24] CLKSEL_EMIF_DIV_MODE bit. For CM_MPU_MPU_CLKCTRL register description, see Chapter 3, *Power, Reset, and Clock Management*
- Connects to the CS_STM module through a 32-bit AXI interface (for software instrumentation)
- Connection to the following modules for register configuration:
  - MPU_MA
  - MPU_PRCM
  - MPU_WUGEN
  - MPU_WD_TIMER
- Contains internal configuration register related to the MPU_MA function (MA_PRIORITY)
- Supports memory barrier instruction
- Supports single-request-multiple-data (data handshaking) burst mode to pipeline requests
- Supports multiple outstanding requests
- Supports posted and nonposted write transactions, based on the attributes of the transactions coming from the Cortex-A15 processor. Software can override all writes from the MPU_AXI2OCP to the L3_MAIN interconnect to be nonposted, regardless of the attributes of the transactions coming from the Arm Cortex-A15 processor, by setting the Control Module register CTRL_CORE_MPU_FORCEWRNP[0] MPU_FORCEWRNP bit to 0x1. This bit must not be changed until the transfer completes. For CTRL_CORE_MPU_FORCEWRNP register description, see Chapter 19, *Control Module*.

4.3.4 Memory Adapter

4.3.4.1 MPU_MA Overview

To decrease the latency of accesses between the MPU L2 cache, and the two EMIF modules, a direct path between the MPU subsystem and the EMIFs is created. This direct path is supported by a memory adapter (MPU_MA) module. The MPU_MA splits the incoming (from L2 cache) AXI4 traffic into MPU_AXI2OCP and EMIF accesses. The MPU_AXI2OCP accesses are sent to the memory adapter A2O ports. The EMIF accesses are optionally interleaved between the two EMIF ports. Mandatory firewall checks are performed on all accesses to the EMIFs.

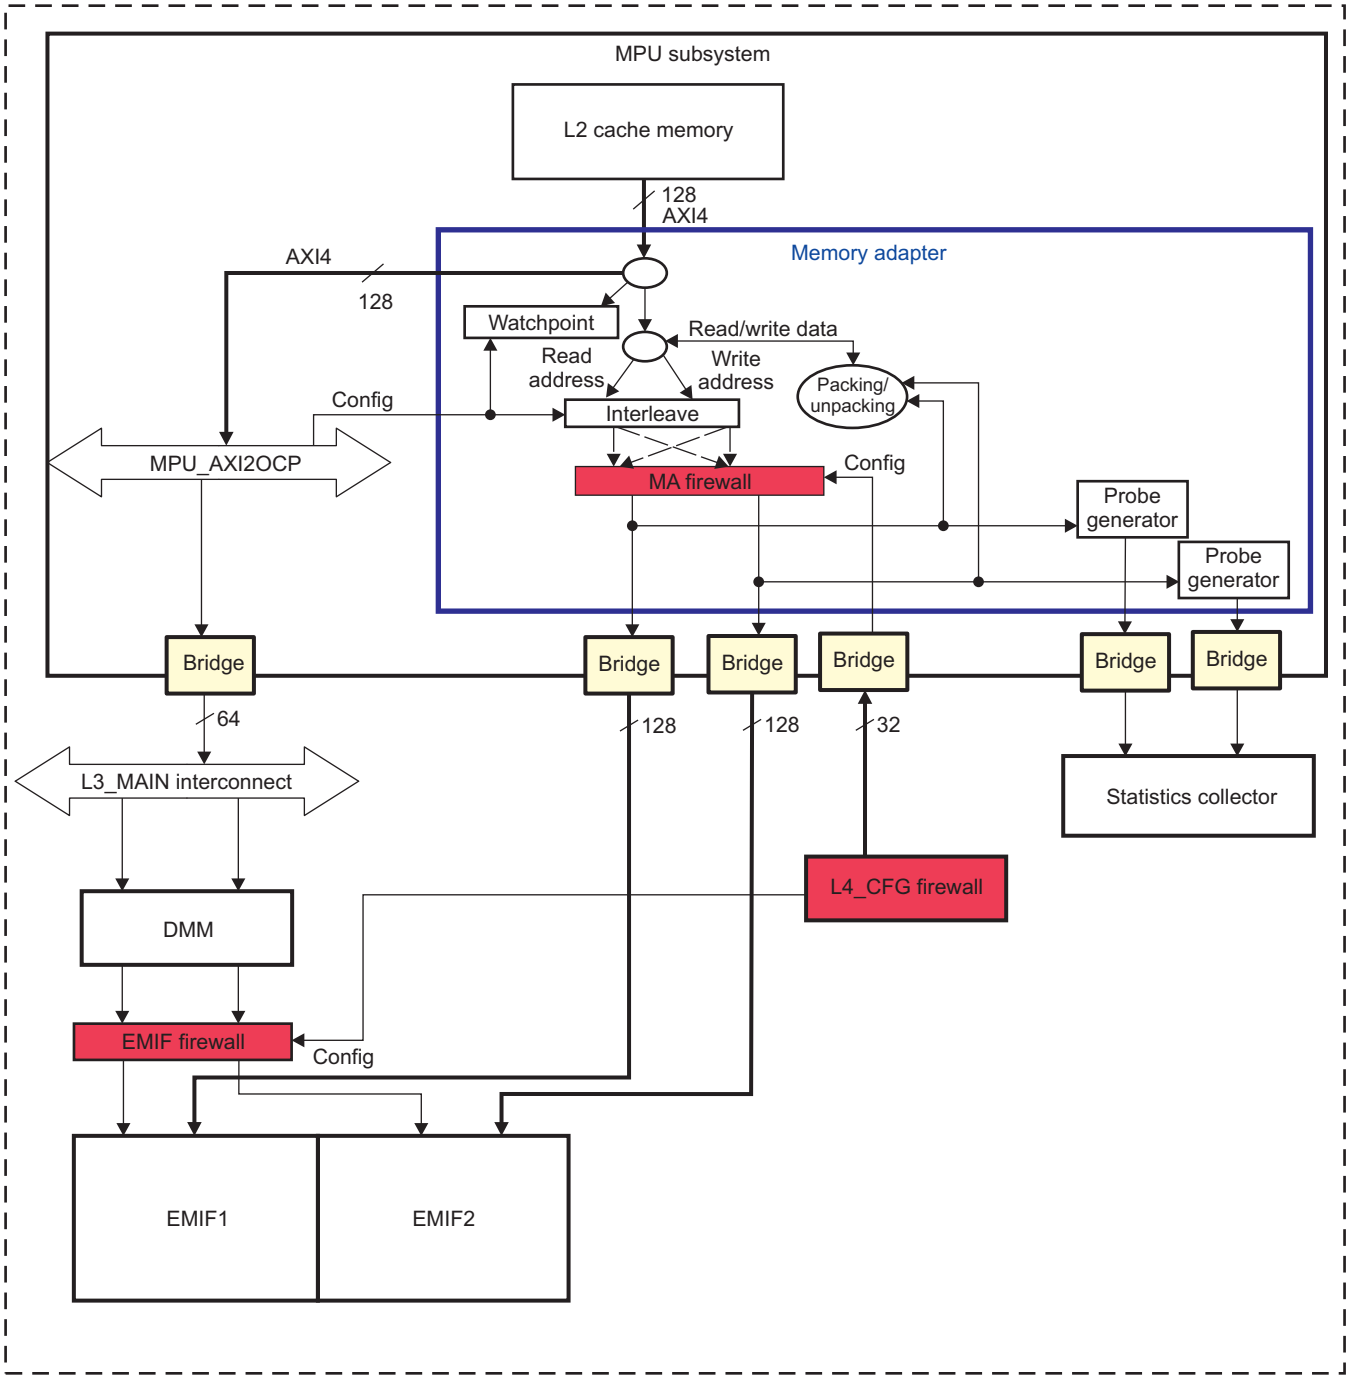
The main features of the MPU_MA are:

- Splits accesses between the MPU_AXI2OCP and the EMIF
- Input from L2 cache and output to MPU_AXI2OCP is AMBA4-compatible and runs at half the Cortex-A15 CPU frequency
- Supported read response interleaving on A2O port
- Parallel processing of reads and writes
- Support for narrow bursts
- Supports 4 × 128-bit line fills and eviction with critical word first
- Supports barrier instructions on normal read and write channels
- Direct 128-bit interfaces to each of EMIF1 and EMIF2:
  - Single request multiple data
  - No write response on posted writes
- Performs interleaving functions to load-balance the activities across the two EMIFs
- Uses firewall logic to check access rights of incoming addresses. The firewall on both EMIFs supports:
  - Configurable number of regions with fixed priority
  - Access support for up to eight execution domains
  - Busy indicator during reconfiguration
- Blocked read and write access to the EMIF for all accesses failing authorization checks
- Burst wrap for single cache line fills
- Supports boot from EMIF space
- Supports 8 GiB of memory. 6GiB accessible only by the MPU (MPU-only memory) and 2GiB shared among the system. Only 4 GiB are physically available on this device. 2GiB accessible only by the MPU and 2 GiB shared among the system.
- MA_LSM supports programmable interleaving for 2 GiB of shared memory:
  - Programmable multizone DRAM mapping and interleaving configuration
  - Supports four prioritized sections for defining configuration regions within the external memory
  - Supports interleaving at 128-, 256-, and 512-byte boundaries
- Fixed interleaving for extended 6 GiB of MPU-only memory
- Supports standard disconnect and idle protocols for independent powering down of the MPU_MA and both EMIFs (the EMIF must be powered down or up as a pair)
- Probe interface for performance monitoring of the EMIF ports
- 11 outstanding reads and 16 outstanding writes
- Supports exclusive accesses used for MPU internal synchronization
- Provides watchpoint capability on AXI bus. For more information, see Section 4.3.4.7.

Figure 4-6 shows the integration of the MPU_MA in the device.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 4-6. MPU_MA Overview



4.3.4.2 AXI Input Interface

The AXI input is driven from the single external port of the L2 cache. The incoming accesses are directed to the MPU_AXI2OCP module through the A2O port or begin their processing for a potential EMIF access. The routing of accesses is based on the AXI address and the EMIF boot input (pi_emifboot).

Table 4-2 lists the AXI access memory mapping. If the accesses are targeted for the MPU_AXI2OCP, then they are registered and sent to the A2O port without any alterations in its attributes (size, ID, etc.). The reserved space in the lower order memory area is a result of providing 8 GiB of continuous space for all the nonaliased regions.

Copyright © 2018–2019, Texas Instruments Incorporated

The EMIF memory space is broken into eight 1-GiB sections, which are denoted *emif(a)* through *emif(h)*. This partitioning helps to specify the aliasing of several memory ranges. It also aids in the discussion of how the MPU memory space is mapped into the physical EMIF space.

NOTE: Although the MPU has 8-GiB EMIF dedicated memory space, only 4 GiB are used. 4 GiB is the total of physically available SDRAM for this device.

It is expected that the OS uses either the lower 2-GiB space and the lower aliased address of emif(a) and (b), or the continuous 8-GiB space and the upper aliasing of the emif(a) and (b) for all EMIF accesses.

Table 4-2. AXI Access Memory Mapping

Region Name	Start Address	End Address	Interleaving	MPU_MA Action
Boot space	0x00 0000 0000	0x00 000F FFFF	Default	Sent to Firewall/EMIF, if pi_emifboot = 1
			N/A	Sent to A2O port, if pi_emifboot = 0
Non-emif	0x00 0010 0000	0x00 7FFF FFFF	N/A	Sent to A2O port
Emif(a)	0x00 8000 0000	0x00 BFFF FFFF	Programmable	Aliased to address range 0x02 8000 0000–0x02 FFFF FFFF
Emif(b)	0x00 C000 0000	0x00 FFFF FFFF	Programmable	
Reserved	0x01 0000 0000	0x01 FFFF FFFF	N/A	DECERR returned
Emif(c)	0x02 0000 0000	0x02 3FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(d)	0x02 4000 0000	0x02 7FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(a)	0x02 8000 0000	0x02 BFFF FFFF	Programmable	Sent to Firewall/EMIF
Emif(b)	0x02 C000 0000	0x02 FFFF FFFF	Programmable	Sent to Firewall/EMIF
Emif(g)	0x03 0000 0000	0x03 3FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(h)	0x03 4000 0000	0x03 7FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(e)	0x03 8000 0000	0x03 BFFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(f)	0x03 C000 0000	0x03 FFFF FFFF	Fixed	Sent to Firewall/EMIF
Reserved	0x04 0000 0000	0xFF FFFF FFFF	N/A	DECERR returned

4.3.4.3 Interleaving

To load-balance the activities across the two EMIFs, interleaving is used. For the lower 2-GiB address space, which is shared between the system and the MPU, a wide range of interleaving options are provided using the MA_LISA_MAP_i registers. Because the EMIF memories are accessible by the MPU subsystem through MPU_MA and by the L3_MAIN interconnect through the DMM, the same interleaving scheme must be used in both paths. To ensure compatibility, the interleaving function is implemented by a scaled down version of the LISA Section Manager (LSM), which implements the interleaving function in the DMM.

The high-order memory space, which is accessible only from the MPU subsystem, uses a simple fixed-interleaving scheme, which can be disabled. Heavy use in high memory space under noninterleaved configuration affects the balancing of the system access in lower-order memory.

4.3.4.3.1 High-Order Fixed Interleaving Model

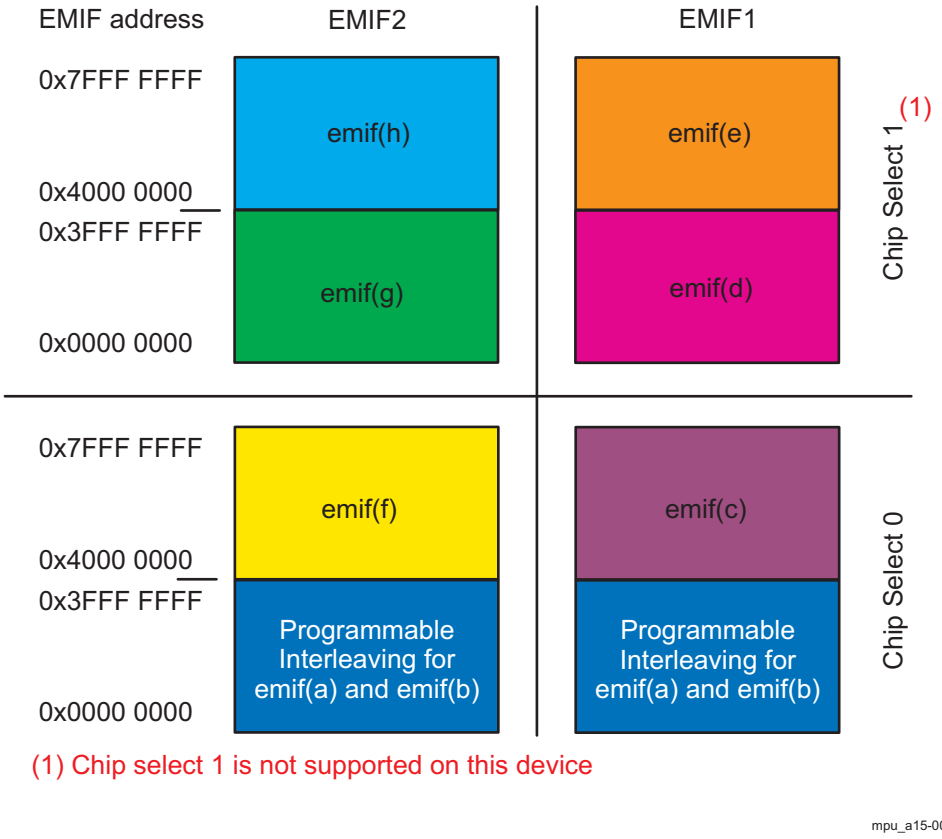
The memory address ranges *emif(c)* through *emif(h)* can be interleaved between the two EMIFs by setting the MA_PRIORITY[8] HIMEM_INTERLEAVE_UN bit to 0x1. If enabled, this high-order interleaving occurs on a fixed 256-byte boundary, unlike emif(a) and emif(b) programmable interleaving which can be configured to 128-, 256-, and 512-byte boundary through the MA_LISA_MAP_i[19:18] SDRC_INTL bit field and is enabled through the MA_LISA_MAP_i [9:8] SDRC_MAP bit field.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 4-7 and Figure 4-8 show how sections emif(a) through emif(h) are mapped into the EMIF1 and EMIF2 address spaces. The MA_LISA_MAP_i registers can be programmed to allow emif(a) and emif(b) address ranges to be remapped anywhere in EMIF1 or EMIF2 address spaces. Restricting EMIF1 and EMIF2 address spaces to the locations 0x0000 0000–0x7FFF FFFF allows the fully programmable emif(a) and emif(b) regions to co-exist with the fixed interleaving regions (emif(c) through emif(h)) without overlap. Although it is not recommended, the user can program the interleaver to map the emif(a) and emif(b) address ranges to the EMIF 0x8000 0000–0xFFFF FFFF location. If this is done, then additional address aliasing exists between emif sections (a/b) and sections (c) through (h).

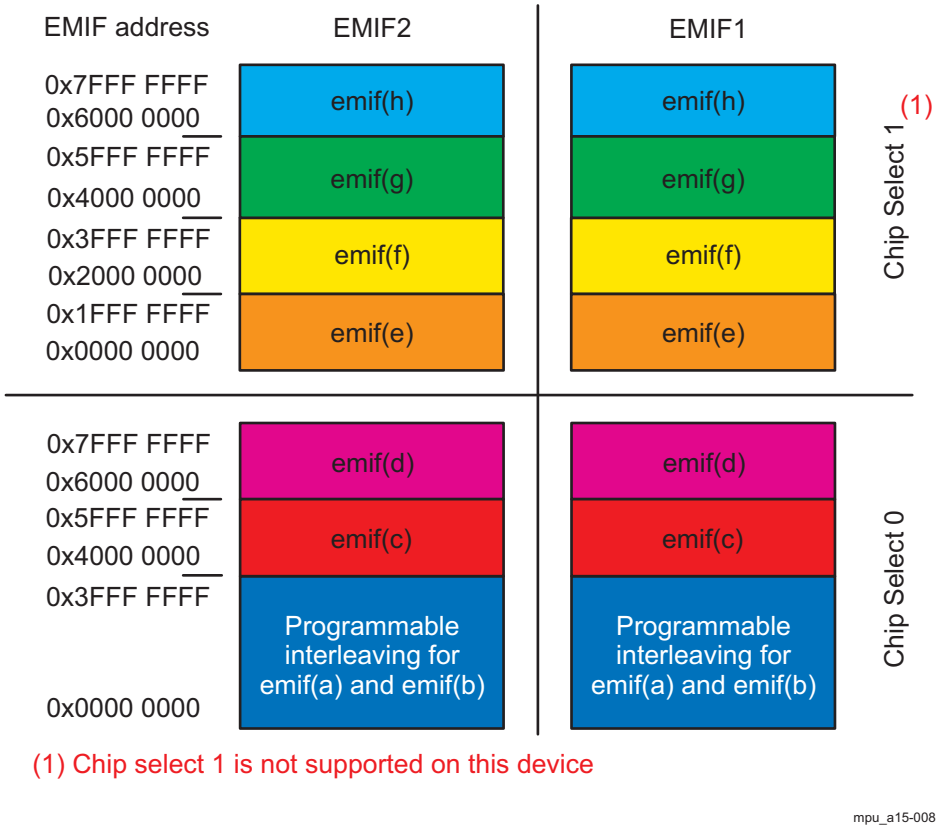
NOTE: In fixed interleaving, memory address space 0 is always used.

Figure 4-7. Fixed MPU-to-EMIF Address Mapping Without High-Order Interleaving



Copyright © 2018–2019, Texas Instruments Incorporated

Figure 4-8. Fixed MPU-to-EMIF Address Mapping With High-Order Interleaving



4.3.4.3.2 Lower 2-GiB Programmable Interleaving Model

For more information about the lower 2-GiB programmable interleaving model of the MA_LSM, see the *Dynamic Mapping*, and *Address Mapping* sections in Section 16.2, *Dynamic Memory Manager*. When reading, replace DMM with MA_LSM.

NOTE: The MA_LSM is associated with the lower 2GiB shared memory space, that is, emif(a) and emif(b). In this case there is programmable interleaving (128B, 256B and 512B) and programmable MPU-to-EMIF address mapping configured trough the MA_LISA_MAP_i registers.

The MA_LSM is NOT associated with the 6GiB of MPU-only memory, that is, Emif(c) through Emif(h). In this case there is fixed interleaving (256B only) and fixed MPU-to-EMIF address mapping which cannot be programmed using the MA_LISA_MAP_i registers because MA_LSM is not used with address ranges greater than 2GiB. The fixed MPU-to-EMIF address mapping is shown in Figure 4-7 and Figure 4-8.

4.3.4.3.3 Local Interconnect and Synchronization Agent (LISA) Section Manager

The LSM module in the MPU_MA contains one set of registers and two ports. Each port can handle one address translation, provide the interface size, and determine the EMIF mapping. The two ports process read and write addresses simultaneously. The MA_LSM supports four sections.

4.3.4.3.4 MA_LSM Registers

Table 4-3 lists the DMM registers that are duplicated locally in the MPU_MA. These registers have the same names except that DMM is replaced by MPU_MA. Software must keep the content of these registers equal to the content of their counterparts in the DMM.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 4-3. MPU_MA Registers Duplicated From the DMM Register Map

Register	Type	Width (Bits)	Base Address
MA_LISA_LOCK	RW	32	0x482A F01C
MA_LISA_MAP_i (where i = 0 to 3)	RW	32	0x482A F040–0x482A F04C

For descriptions of the registers, see Section 16.2, *Dynamic Memory Manager*. The only differences are the following reset values of the MA_LISA_MAP_0 register:

- MA_LISA_MAP_0[22:20] SYS_SIZE = 0x1 (32-MiB section)
- MA_LISA_MAP_0[17:16] SDRC_ADDRSPC = 0x1
- MA_LISA_MAP_0[9:8] SDRC_MAP = 0x1

The configuration of the MPU_MA must be programmed by the Cortex-A15 MPU to match the configuration of the DMM during boot. The registers must be locked after initial programming to avoid corruption by application software. When the SM configuration registers are being programmed, there are no interlocks or safeguards to prevent accesses from being processed at the same time.

If an access is made to a region marked as having unused address space or an unmapped SDRC map, no access is made to the EMIF and an error is returned. If an access is made to a region marked as accesses-SDRC-internal-registers, no access occurs to the EMIF and an error is returned. This is because the internal registers are not accessible from this port.

If an access is made to a region that is not mapped to any LISA section, or selects a section with one of the following programmations, then no access is made to the EMIF and an error is returned on the AXI port:

- SDRC_MAP field equal to UNMAPPED
- SDRC_ADDRSPC field equal to UNUSED

4.3.4.3.5 Posted and Nonposted Writes

On posted writes, a response is returned after all write data is accepted by the MPU_MA and one of the following occurs:

- The request is canceled, because of an interleaving error.
- The request is pushed into the firewall FIFO.

On nonposted writes, a response is not returned until after all write data is accepted by the MPU_MA and one of the following occurs:

- The request is canceled, because of an interleaving error.
- The request has a firewall violation.
- The associated response is received from the EMIF (access is completed in the EMIF).

When the FORCEWRNP[0] MPUFORCEWRNP bit is set to 0x1, all writes are forced to be converted to nonposted writes (prevents posted writes).

4.3.4.3.6 Errors

If the region is marked as unmapped, o targets EMIF internal registers or reserved space, access is blocked and an error response is returned. Such an error occurs on the first half of a potential split access and aborts the entire access at that time. DECERR errors ultimately generate Arm aborts. See the Arm Fault Status Register for more information.

To avoid undefined results, the following program rules must be followed:

- A section cannot be mapped as interleaving (MA_LISA_MAP_i[9:8] SDRC_MAP = 0x3), and the MA_LISA_MAP_i[19:18] SDRC_INTL bit field must be equal to 0x0.
- If the section maps to a single EMIF (MA_LISA_MAP_i[9:8] SDRC_MAP = 0x1 or 0x2), the MA_LISA_MAP_i[7:0] SDRC_ADDR bit field must be aligned to the MA_LISA_MAP_i[22:20] SYS_SIZE bit field (that is, the lower SDRC_ADDR bits must be 0).
- If the section maps to both EMIFs (MA_LISA_MAP_i[9:8] SDRC_MAP = 0x3), the

Copyright © 2018–2019, Texas Instruments Incorporated

MA_LISA_MAP_i[7:0] SDRC_ADDR bit field must be aligned to MA_LISA_MAP_i[22:20] SYS_SIZE – 1, because the addressable space for each EMIF is half.

- If the section maps to both EMIFs (MA_LISA_MAP_i[9:8] SDRC_MAP = 0x3), the MA_LISA_MAP_i[22:20] SYS_SIZE bit field cannot be 0.

4.3.4.4 Statistics Collector Probe Ports

To enable performance monitoring by the debug subsystem, a subset of interconnect signals must be monitored and sent to a statistics collector in the CORE domain. For more information about the statistics collector, see Chapter 35, *On-Chip Debug Support* chapter.

4.3.4.5 MPU_MA Firewall

A firewall (MA_MPU_NTTP_FW) exists between the interleaving logic and each EMIF port. The firewall checks the address and access qualifiers against the permission attributes for the highest priority region to which the address belongs. If the access fails to get permission, a violation occurs and the fw_func_error or fw_debug_error output is asserted. The failing access is blocked and a slave error response is returned on the MPU_MA port for read and nonposted accesses. For more information about the MPU_MA firewall, see Chapter 15, *Interconnect*.

4.3.4.6 MPU_MA Power and Reset Management

The MA_LSM supports only smart-idle mode.

4.3.4.7 MPU_MA Watchpoint

The MPU_MA implements a Watchpoint unit (MPU_MA_WP) attached to its AXI input interface and thus allowing the user to track certain AXI transactions. The MPU_MA_WP can be programmed to generate a trigger when a specified AXI transaction (or a chain of AXI transactions) satisfies a set of user-defined attributes. Upon triggering (that is, upon transaction match), additional information about the target transaction is captured in dedicated log registers.

4.3.4.7.1 Watchpoint Types

The MPU_MA_WP supports three types of watchpoints:

- Data watchpoint
- Memory barrier watchpoint
- Chained watchpoint (combination of data watchpoint and memory barrier)

Two types of chaining are supported based on the configuration of the DBG_HWWP0_CHAIN_CNTL[1] CHAIN_TYPE bit:

- Data watchpoint match *followed* by memory barrier match
- Data watchpoint match *preceded* by memory barrier match

Chaining is enabled by setting the DBG_HWWP0_CHAIN_CNTL[0] CHAIN_WP_EN bit to '1'. Note that both the data watchpoint and the memory barrier must also be subsequently enabled (by setting the DBG_HWWP0_MAIN_CNTL[0] WP_EN and DBG_HWWP0_MEM_CNTL[0] MEM_BAR_WP_EN bits, respectively) for chaining to work. To avoid race conditions and partial matches, no chained match may occur until the complete chain of watchpoints has been fully enabled.

4.3.4.7.2 Transaction Filtering Options

The following filtering options can be specified for a **data watchpoint match** condition (via the DBG_HWWP0_MAIN_CNTL and DBG_HWWP0_AUX_CNTL registers):

- Address within or outside a specific range
- Various access types:
  - Read or Write (non-posted/posted/either) or any (no preference)
  - Supervisor or User or any (no preference)

Copyright © 2018–2019, Texas Instruments Incorporated

  - Data or Instruction or any (no preference)
- MPU_MA target: AXI2OCP bridge or EMIF or any (no preference)
- Initiator: CPU0 or CPU1 or unknown source (ACP, FEQ, etc.) or any (no preference)

The following filtering options can be specified for a **memory barrier match** condition (via the DBG_HWWP0_MEM_CNTL register):

- Type of memory barrier instruction: DSB or DMB or any (no preference)
- Type of memory barrier access: Read or Write or any (no preference)

4.3.4.7.3 Transaction Match Effects

The following information concerns transaction attributes logging depending on the transaction match:

- **Data watchpoint match**: When a data watchpoint matches, the following transaction attributes are logged irrespective of the target of the transaction (not all attributes may be applicable for all targets):
  - 40-bit AXI physical address of the transaction
    - Related log registers: DBG_HWWP0_HG_ADDR0_LOG and DBG_HWWP0_LW_ADDR0_LOG
  - 128-bit data associated to the *n*-th beat of the burst transaction, where *n* is configured by the user (before enabling the watchpoint) in the DBG_HWWP0_MAIN_CNTL[23:20] BEAT_SEL bit field
    - Related log registers: DBG_HWWP0_DATA0_LOG, DBG_HWWP0_DATA1_LOG, DBG_HWWP2_DATA0_LOG, and DBG_HWWP3_DATA0_LOG
  - Byte Enable: Specifies the 16 data byte enables associated with the up to 128-bit data captured
    - Related log register: DBG_HWWP0_DATA_TRANS_ATTR0_LOG[15:0] BYTE_EN
  - Initiator Info: Specifies which initiator generated the transaction
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[22:20] INIT_INFO
  - Response Info: Specifies whether the response indicates transaction success or failure
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[25:24] RESP_INFO
  - Target Info: Specifies the target of the access
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[18:16] TARGET_INFO
  - Transaction Type: Specifies the type of the transaction which matches
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[12:10] TRANS_TYPE
  - Burst Length (1..63)
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[9:4] BURST_LENGTH
  - Burst Type: Specifies the type of the burst (only relevant if Burst Length > 1)
    - Related log register: DBG_HWWP0_TRANS_ATTR0_LOG[2:0] BURST_TYPE
  - Additional attributes, such as:
    - Data/Instruction access (DBG_HWWP0_TRANS_ATTR1_LOG[2] DATA)
    - Supervisor/User access (DBG_HWWP0_TRANS_ATTR1_LOG[1] SUPERVISOR)
- **Memory barrier watchpoint match**: When a memory barrier watchpoint matches, transaction attributes logged are those of the transaction immediately following the memory barrier
- **Chained watchpoint match**: When a chained watchpoint matches (which implies that both memory barrier and data watchpoint have matched), transaction attributes logged are those of the transaction of the matching data watchpoint

4.3.4.7.4 Trigger Generation

The user can configure the MPU_MA_WP unit to generate a trigger upon watchpoint match. The MPU_MA_WP has a single trigger output (MA_WP_TRIGGER) which is mapped to the CTITRIGIN[6] input of the CS_CTI_S module and is shared by the following trigger sources:

- **Data watchpoint trigger**: Upon data watchpoint match, the DBG_HWWP0_MAIN_CNTL[31] TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the DBG_HWWP0_MAIN_CNTL[0] WP_EN bit

Copyright © 2018–2019, Texas Instruments Incorporated

- **Memory barrier watchpoint trigger**: Upon memory barrier match, the DBG_HWWP0_MEM_CNTL[31] MEM_BAR_TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the DBG_HWWP0_MEM_CNTL[0] MEM_BAR_WP_EN bit
- **Chained watchpoint trigger**: Upon chained watchpoint match, the DBG_HWWP0_CHAIN_CNTL[31] CHAIN_WP_TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the DBG_HWWP0_CHAIN_CNTL[0] CHAIN_WP_EN bit

Note that the MPU_MA_WP module supports only a global enable (by setting the TRIG_CTRL[0] TRIG_EN bit) for all three sources listed above. It is SW responsibility to identify the source of the trigger generation by checking the corresponding trigger status bits.

4.3.4.7.5 Programming Options Summary

Below is a summary of the MPU_MA_WP programmable options:

- Match on a data watchpoint only:
  - Configure the DBG_HWWP0_MAIN_CNTL register
  - Configure the DBG_HWWP0_AUX_CNTL register
  - Set the DBG_HWWP0_MAIN_CNTL[0] WP_EN bit to enable data watchpoint
- Match on a memory barrier only:
  - Configure the DBG_HWWP0_MEM_CNTL register
  - Set the DBG_HWWP0_MEM_CNTL[0] MEM_BAR_WP_EN bit to enable memory barrier
- Match on a data watchpoint chained with a memory barrier:
  - Configure the DBG_HWWP0_CHAIN_CNTL[1] CHAIN_TYPE bit to chain data watchpoint *before* memory barrier or data watchpoint *after* memory barrier.
  - Set the DBG_HWWP0_CHAIN_CNTL[0] CHAIN_WP_EN bit to enable the chain (but both the memory and data watchpoints must also be subsequently enabled)
  - Configure the DBG_HWWP0_MAIN_CNTL register
  - Configure the DBG_HWWP0_AUX_CNTL register
  - Set the DBG_HWWP0_MAIN_CNTL[0] WP_EN bit to enable data watchpoint
  - Configure the DBG_HWWP0_MEM_CNTL register
  - Set the DBG_HWWP0_MEM_CNTL[0] MEM_BAR_WP_EN bit to enable memory barrier

4.3.5 Realtime Counter (Master Counter)

4.3.5.1 Counter Operation

The real-time counter (COUNTER_REALTIME) is a free-running counter which produces the count used by the private timer peripherals in the MPU_CLUSTER. For this reason, it is also called Master Counter.

COUNTER_REALTIME supports two modes of operation:

- **Active (FUNC)**: This is the normal mode in which the counter runs
- **Sleep / Low-Power (LP)**: The counter automatically switches to this mode when the MPU subsystem goes to standby mode

COUNTER_REALTIME has two clock inputs:

- **32K (slow) clock**: This is the FUNC_32K_CLK (SYSCLK1/610) clock
- **System (fast) clock**: This is the WKUPAON_ICLK clock (coming from the global PRCM). The two sources for this clock are:
  - SYS_CLK1: Main system clock of the SoC. Supported frequencies are: 19.2, 20, and 27 MHz
  - ABE_LP_CLK: Clock derived from DPLL_ABE, used in some low-power use cases; runs at 12.288 MHz (DPLL cascading)

COUNTER_REALTIME implements two internal counters: a 40-bit coarse counter, and a 48-bit system counter.

Copyright © 2018–2019, Texas Instruments Incorporated

The coarse counter is driven by the FUNC_32K_CLK clock. The coarse counter is the only one running in LP mode (the system counter is off in LP mode) and it is also used in FUNC mode as a timebase reference for the system counter. During active mode, the coarse counter value is multiplied by 375/2. This effectively shifts left the base counter value. This initial value is output to the CPUs and is also fed back into the circuit.

The system clock is running in parallel to the 32K clock and it drives the active mode circuit of COUNTER_REALTIME, which includes the following basic blocks:

- 48-bit system counter
- 12-bit fractional incrementor. It has the following input parameters:
  - Numerator (N) for SYS mode: PRM_FRAC_INCREMENTER_NUMERATOR [11:0] SYS_MODE_NUMERATOR
  - Numerator for ABE_LP mode: PRM_FRAC_INCREMENTER_NUMERATOR [27:16] ABE_LP_MODE_NUMERATOR
  - Common Denominator (D): PRM_FRAC_INCREMENTER_DENUMERATOR_RELOAD [11:0] DENOMINATOR
- Fine alignment circuit

At each system clock rising edge, the system counter value is compared to the shifted (x375/2) coarse counter value and based on this comparison, the system counter is either incremented or unchanged.

NOTE: COUNTER_REALTIME is designed for a count rate of 6.144 million counts per second (32768Hz x 375/2). Since the SoC does not use a true 32768Hz source (instead uses SYS_CLK1/610, which is ~32787Hz for 20MHz SYS_CLK1), the resulting timer rate is not 6.144 and timer drift can accumulate. To minimize error in active mode, the adjustable fine increment rate MUST equal the fixed coarse increment rate.

Table 4-4 shows suggested COUNTER_REALTIME increment values.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 4-4. COUNTER_REALTIME Increment Values

COUNTER_ REALTIME Clock Mode	COUNTER_ REALTIME Clock Name	COUNTER_ REALTIME Fast Source Rate (Hz)	Numerator (N) for Fast Source	Denominator (D) for Fast Source	COUNTER_REALTIME Fine Rate (Hz)	COUNTER_REALTIME 32K Source Rate (Hz)	COUNTER_REALTIME Fixed Coarse Rate (Hz)
			Target 32K*(375/2)		(Sys clock)*(N/D)	(SYSCLK1/610)	32K*(375/2)
System (SYS)	SYS_CLK1	19,200,000	75	244	5,901,639.3	31,475	5,901,639.3
		20,000,000	75	244	6,147,541.0	32,787	6,147,541.0
		27,000,000	75	244	8,299,180.3	44,262	8,299,180.3

		NA	NA	NA	NA	32,787	6,147,541.0
		NA	NA	NA	NA	44,262	8,299,180.3

4.3.5.2 Frequency Change Procedure

The change between the system clock (SYS_CLK1) and the ABE low-power clock (ABE_LP_CLK) is performed within global PRCM. A software-controllable bit (CM_CLKSEL_WKUPAON[0] CLKSEL) controls this change. A glitch-free clock multiplexer produces the resulting clock (WKUPAON_ICLK), which is used as the functional clock of the master counter. The CM_CLKSEL_WKUPAON[0] CLKSEL bit is exported from global PRCM to the master counter to control simultaneously the mode (SYS or ABE_LP).

The transition from SYS to ABE_LP mode (DPLL cascading entry) is done under software control as follows:

- DPLL_ABE must be locked before (under software control, global PRCM register CM_CLKMODE_DPLL_ABE[2:0] DPLL_EN = 0x7).
- Software writes 1 in the global PRCM register CM_CLKSEL_WKUPAON[0] CLKSEL bit to choose DPLL_ABE clock.

The transition from ABE_LP to SYS mode (DPLL cascading exit) is done under software control as follows:

- Software writes 0 in the global PRCM register CM_CLKSEL_WKUPAON[0] CLKSEL bit to choose SYS CLK.
- DPLL_ABE may be unlocked after.

Transition from FUNC (ABE_LP or SYS) to LP mode is done by hardware upon MPU subsystem standby entry sequence.

Transition from LP to FUNC (ABE_LP or SYS) mode is done by hardware upon MPU subsystem standby exit sequence.

The frequency change involves some uncertainty on the counter due to a glitch-free clock MUX in global PRCM. In order not to accumulate them, a free-running coarse counter on the FUNC_32K_CLK clock holds the reference count, used for realignment when necessary. To load and reload the reference count value (x375/2) from the coarse counter, the user must write 1 in the PRM_FRAC_INCREMENTER_DENUMERATOR_RELOAD[16] RELOAD bit (but it must be 0 prior to that).

Once configured (at first boot time), the counter is running in all modes without any action required by software.

4.3.6 MPU Watchdog Timer

The MPU watchdog timer (MPU_WD_TIMER) implements two channels, one per MPU core (MPU_WD_TIMER_C0 and MPU_WD_TIMER_C1, respectively; an unified name MPU_WD_TIMER_Cx is used hereafter in the chapter). The MPU_WD_TIMER operates on MPU subsystem clock (MPU_DPLL_CLK).

Each MPU_WD_TIMER_Cx channel implements:

- A 32-bit decrementing counter which has a period set by the value loaded into the counter (via the WDT_LOAD_REGISTER_i[31:0] NEWCOUNT bit field) and the prescaler ratio (set via the WDT_PRESCALER_REGISTER_i[9:0] PRESCALER bit field). The period is calculated as follows: $T_{MPU_WD_TIMER_Cx}$ = (PRESCALER + 1) x (NEWCOUNT + 1) / f(MPU_DPLL_CLK).
- Two interrupt output signals (WARN, INTR)
- One reset request output (MPUSSRST)

The counter starts decrementing when the WDT_CONTROL_REGISTER_i[0] ENABLE bit is set to 0x1. The current count value can be monitored by reading the WDT_COUNT_REGISTER_i[31:0] CURRENTCOUNT bit field. When the counter reaches zero, a timeout condition occurs. In the timeout condition, the counter stops counting and:

- MPU_WD_TIMER_Cx_IRQ interrupt is generated to the MPU_INTC, if enabled by setting the WDT_CONTROL_REGISTER_i[1] INTREN bit to 0x1.
- Reset request is generated to the global PRCM, if enabled by setting the WDT_CONTROL_REGISTER_i[3] MPUSSRSTEN bit to 0x1.

NOTE: If the MPU core corresponding to the MPU_WD_TIMER_Cx channel is in debug state, the counter does not decrement until the MPU core returns to non-debug state. Debug state is inferred by monitoring the DBGACK signal corresponding to this core.

Additionally, the user can also setup a warning condition which can be used to signal an interrupt that gives software a notice when the MPU_WD_TIMER_Cx is getting close to a timeout. The threshold value is set in the WDT_WARNING_REGISTER_i[31:0] WARNING_WATERMARK bit field. The current count value is then compared to the threshold (warning watermark) level value and when CURRENTCOUNT = WARNING_WATERMARK, a warning interrupt (MPU_WD_TIMER_Cx_IRQ_WARN) is generated to the MPU_INTC (if enabled by setting the WDT_CONTROL_REGISTER_i[1] WARNEN bit to 0x1).

The mapping of the four MPU_WD_TIMER interrupts is as follows:

- MPU_WD_TIMER_C0_IRQ_WARN mapped to MPU_IRQ_5
- MPU_WD_TIMER_C1_IRQ_WARN mapped to MPU_IRQ_6
- MPU_WD_TIMER_C0_IRQ mapped to MPU_IRQ_139
- MPU_WD_TIMER_C1_IRQ mapped to MPU_IRQ_140

The user can also poll the following status bits:

- WDT_RESET_STATUS_REGISTER_i[0] TO, to know when the timeout condition has occured. This bit might also be used to figure out which MPU_WD_TIMER_Cx signalled a reset request.
- WDT_RESET_STATUS_REGISTER_i[1] WARN, to know when the warning condition has occured.

The following programming guidelines should be taken into account:

- The WDT_PRESCALER_REGISTER_i register should be written (if needed) before the WDT_LOAD_REGISTER_i register is written. This is

Copyright © 2018–2019, Texas Instruments Incorporated

because when the WDT_LOAD_REGISTER_i register is written, the WDT_COUNT_REGISTER_i register is immediately updated with this value and at the same time, the PRESCALER value is sampled to be used by the decrement logic which controls the WDT_COUNT_REGISTER_i register.

- The WDT_WARNING_REGISTER_i and WDT_LOAD_REGISTER_i registers should be written before the MPU_WD_TIMER_Cx is enabled (WDT_CONTROL_REGISTER_i[0] ENABLE = 0x1). Otherwise, interrupts and reset request may be asserted immediately depending on the state of these registers. For example, after reset these registers have '0' and if the WDT_CONTROL_REGISTER register is configured to enable the corresponding interrupts and reset request, and then MPU_WD_TIMER_Cx is enabled, interrupts and reset request are immediately asserted.

The suggested programming order is as follows:

1. Set the warning watermark level (WDT_WARNING_REGISTER_i), if needed
2. Set the prescaler ratio (WDT_PRESCALER_REGISTER_i[9:0] PRESCALER)
3. Set the new count value (WDT_LOAD_REGISTER_i)
4. Enable corresponding interrupts and reset request in WDT_CONTROL_REGISTER_i, if needed
5. Enable MPU_WD_TIMER_Cx (WDT_CONTROL_REGISTER_i[0] ENABLE = 0x1)

NOTE: When the MPU cores are going to low power state, the MPU_WD_TIMER may need to be disabled. If it is not disabled, then the MPU_WD_TIMER may timeout (since the MPU core is not refreshing the timeout counters) and will generate MPUSS reset request which will reset the MPU domain, including both MPU cores.

4.3.7 MPU Subsystem Power Management

The MPU subsystem implements a local PRCM (MPU_PRCM) module to handle the local Cortex-A15 CPU power domains, along with the corresponding L1 cache. The MPU_PRCM module includes two power-management control (PSCON) modules to control the power chains for MPU_C0 and MPU_C1. The PRM_PSCON_COUNT register is used for that control purpose.

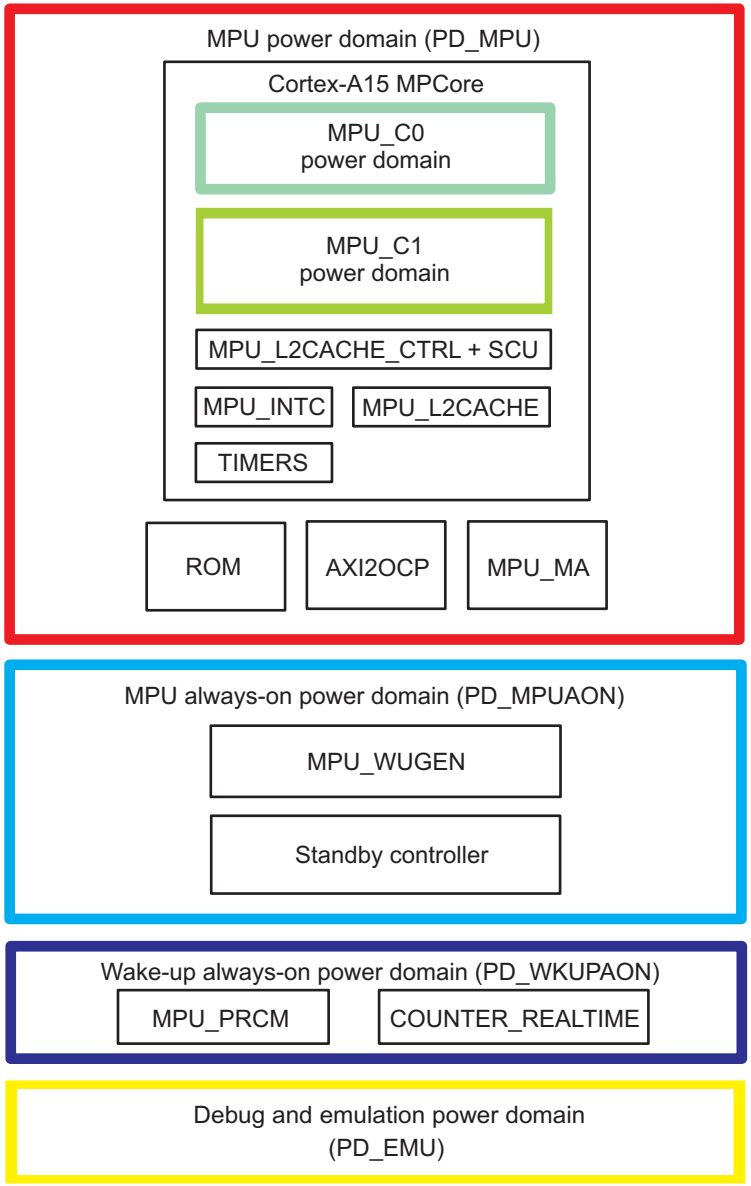
In addition to the standard power-management technique supported in the device, the MPU subsystem also employs an SR3-APG (SmartReflex3 automatic power gating) power-management technology to reduce leakage. This technology allows for full logic and memories retention on MPU_C0 and MPU_C1 and is controlled by the MPU_PRCM. The SR3-APG power-management can be enabled by setting the PRM_PSCON_COUNT[24] HG_EN bit. For more information about how to enable SR3-APG fast-wakeup, see Section 4.3.7.6, *SR3-APG Technology Fail-Safe Mode*.

4.3.7.1 Power Domains

The MPU subsystem is divided into six power domains controlled by the local or global PRCM module, as shown in Figure 4-9.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 4-9. MPU Subsystem Power Domains Overview



Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: The MPU debug and trace modules are implemented in various power domains. For more information, see Chapter 35, *On-Chip Debug Support*.

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross-reference to the different voltage domains.

For information about the physical power domains (PD_MPU, PD_MPUAON, PD_WKUPAON, and PD_EMU) and the related voltage domains, see Chapter 3, *Power, Reset, and Clock Management*.

4.3.7.2 Power States of MPU_Cx

MPU_Cx (where x = 0 or 1) changes power states only when the StandbyWFI signal is asserted. There is no signal coming from the MPU cores, or the MPU_CLUSTER to define in which power state MPU_Cx can go. Software must program such information by writing to the PM_CPUx_PWRSTCTRL[1:0] POWERSTATE bit field before executing the WFI instruction. Table 4-5 provides the software requirements before executing the WFI instruction, and the condition to return to RUN mode.

NOTE: Neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 4-5. MPU_Cx State Transitions

Low-Power State	Software Sequence Before Executing WFI	Wakeup (Transition Back to Run Mode)
WFI/ON Logic ON L1$ ON	Execute a Data Synchronization Barrier (DSB) instruction.	Managed locally to MPU_Cx upon one of the following sources: • An interrupt, masked or unmasked (important: masked does not mean disabled) • An imprecise data abort, regardless of the value of the CPSRA bit • A debug request generated by writing 1 to the HALTING DEBUG MODE bit of the Cortex-A15 DBGSCR register, or the assertion of the Cortex-A15 EDBGRQ pin • Global device cold or warm reset source
WFI/INACT Logic ON L1$ ON	Execute a DSB instruction.	Managed locally by MPU_PRCM upon following source: • An interrupt, enabled at MPU_WUGEN level • A forced wakeup (sw_wkup) • A full debug wake-up request sequence: ForceActive from the DAP_PC, a debug request (as explained previously), assert block reset, wait for processor to halt and clear the block reset • Global device cold or warm reset source
WFI/RETENTION Logic RET L1$ ON L1$ peripheral OFF	1. Set the PM_CPUx_PWRSTCTRL[1:0] POWERSTATE bit field to 0x1 (RETENTION state). 2. Execute a DSB instruction.	Managed locally by MPU_PRCM upon following source: • An interrupt, enabled at MPU_WUGEN level • A forced wakeup (sw_wkup) • A full debug wake-up request sequence: ForceActive from the DAP_PC, a debug request (as explained previously), assert block reset, wait for processor to halt and clear the block reset • Global device cold or warm reset source MPU_PRCM does not need to reset MPU_Cx.
WFI/FORCED_OFF Logic OFF L1$ OFF Note: Neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On.	1. Save MPU_INTC configuration for MPU_C1 interrupts. 2. Disable SGI and PPI toward MPU_C1 in MPU_INTC. 3. Save all Arm registers, including CPSR and SPSR. 4. Save all CP15 registers. 5. Save all debug-related states. 6. Set the PM_CPU1_PWRSTCTRL[1:0] POWERSTATE bit field to 0x0 (OFF state). 7. Set the PM_CPU1_PWRSTCTRL[7] FORCED_OFF bit to 0x1. 8. Clear the C-bit in the SCTLR to prevent further data cache allocation. 9. Clean/invalidate L1$ content on an as-needed basis. 10. Clear SMP bit to take CPU out of coherency. 11. Execute an ISB instruction to ensure that all of the above CP15 register changes have been committed. 12. Execute a DSB instruction.	Managed locally by MPU_PRCM upon following source: • A forced wakeup (sw_wkup) • A full debug wake-up request sequence (as previously mentioned). Block reset is not supported. • Global device cold or warm reset source MPU_PRCM must reset MPU_C1 to make it reboot and restore its context, including MPU_INTC.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: For the description of the Cortex-A15 CPU registers and the DSB/ISB instructions, see the Arm *Cortex-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

The RETENTION low-power state is not natively supported by the MPU_CLUSTER. This mode is implemented with SR3-APG power-management technology. The MPU subsystem power-management hardware is designed to ensure that the system does not have an L1 cache coherency problem when putting both MPU cores in retention mode. In this mode, the MPU_Cx logic is in full retention with all memory content preserved by keeping the array of memories fully powered and the logic of the memory peripheries shut down. In slow wake-up mode, memories are put into retention to prevent more leakage.

In FORCED_OFF and RETENTION low-power states, the standby controller gates the clock to the MPU_CLUSTER by deasserting the CLKEN signal before signaling the MPU_PRCM to perform a power transition. In these low-power states, the MPU core can be wakened only by the MPU_PRCM. A number of important actions must be performed by software before entering such a state.

NOTE: The private peripheral interrupts (PPIs) cannot wake up an MPU core in INACT, RETENTION, or FORCED_OFF low-power state. Software-generated interrupts (SGI) cannot wake up an MPU core in the same low-power state. However, it is possible to work around the issue by applying the following method:

- When MPU_Cx wants to send an SGI to MPU_Cy (that is, the other MPU core), it must first systematically set the CM_CPUy_CLKSTCTRL[1:0] CLKTRCTRL bit field to 0x2 (software-forced wake-up transition),
- The MPU_Cy corresponding ISR must write back the CM_CPUy_CLKSTCTRL[1:0] CLKTRCTRL bit field to 0x3 (HW_AUTO, automatic transition).

NOTE: FORCED_OFF mode is not supported on this device.

Table 4-6 gives details of the power state of the supported MPU_Cx and the corresponding values of the MPU_PRCM register.

Table 4-6. MPU_Cx Supported Power States

Hardware Conditions		MPU_Cx Programming Model		Resulting MPU_Cx State			
StandbyWFI StandbyWFE	**State of L2/Other MPU core**	**MPU_PRCM Power State PM_CPUx_PWRSTCTRL[1:0] POWERSTATE**	**MPU_PRCM Clock Transition Control CM_CPUx_CLKSTCTRL[1:0] CLKTRCTRL**	**Logic**	**L1 Cache**	**Arm Cortex-A15 Internal Clock**	**Power State at MPU_PRCM**

Table 4-6. MPU_Cx Supported Power States (continued)

Hardware Conditions		MPU_Cx Programming Model		Resulting MPU_Cx State			
StandbyWFI StandbyWFE	State of L2/Other MPU core	MPU_PRCM Power State PM_CPUx_PWRSTCTRL[1:0] POWERSTATE	MPU_PRCM Clock Transition Control CM_CPUx_CLKSTCTRL[1:0] CLKTRCTRL	Logic	L1 Cache	Arm Cortex-A15 Internal Clock	Power State at MPU_PRCM
MPU_Cx in WFI	!= (IDLE/WFI /WFI)	Any	HW_AUTO	ON	ON	OFF	ON
MPU_Cx in WFI	IDLE/WFI/ WFI	INACT	HW_AUTO	ON	ON	OFF	INACT
MPU_Cx in WFI	IDLE/WFI/ WFI	RETENTION	HW_AUTO	SR3-APG/ ON(1)	ON/RETENTION(2)	OFF	CSWRET

(1) If PRM_PSCON_COUNT[24] HG_EN = 1, MPU core logic is put in SR3-APG state. If not, MPU core logic is kept ON.

(2) L1$ state depends on the values of the PRM_PSCON_COUNT[25] HG_RAMPUP and PRM_PSCON_COUNT[24] HG_EN bits. When CPU PD is in the CSWRET state, if HG_ENABLE = 0x1 and HG_RAMPUP = 0x1, then L1$ memory is in ON state, else L1$ memory is in the RETENTION state. For more information, see Section 4.3.7.6, *SR3-APG Technology Fail-Safe Mode*.

The PM_CPUx_PWRSTCTRL register is static over any power transition. That is, software programs it before executing the WFI instruction and does not change it until MPU_Cx is again in running mode. In other words, when MPU_Cx reaches a low-power state, it cannot move to another low-power state. It must be woken up to reach another low-power state. To wake up MPU_Cx, the user must:

1. Execute a forced wake-up transition to the MPU_Cx: CM_CPUx_CLKSTCTRL[1:0] CLKTRCTRL = 0x2.
2. The MPU_Cx interrupt handler must write back the automatic hardware transition: CM_CPUx_CLKSTCTRL[1:0] CLKTRCTRL = 0x3.

Table 4-7 shows the available MPU_Cx power states in single and coherency mode. For coherency, software must ensure that both MPU cores are in the same power state.

Table 4-7. Available MPU_Cx Power States in Single and Coherency Mode

MPU_C0 Power State	MPU_C1 Power State	Mode
Running/ON or WFI/ON	Running/ON or WFI/ON	SMP mode (coherent mode)
WFI/INACT	WFI/INACT	
WFI/CSWRET	WFI/CSWRET	
Running/ON or WFI/ON	FORCED_OFF NOTE: Neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On.	Single mode (MPU_C1 is out of coherency)
WFI/INACT	FORCED_OFF NOTE: Neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On.	
WFI/CSWRET	FORCED_OFF NOTE: Neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On	

4.3.7.3 Power States of MPU Subsystem

The MPU subsystem power domain (PD_MPU) must be at a higher or equal power state (a state that consumes more power) than the higher of the two MPU cores. For example, it is illegal for the MPU subsystem power state to be RETENTION, while the power state of one or both of the MPU cores is ON.

Software must ensure that only legal power states are programmed. When an illegal state is entered, the behavior of the hardware is unpredictable.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 4-8 lists the MPU subsystem legal power states.

Table 4-8. MPU Subsystem Legal Power States

Hardware Conditions		MPU/System Programming Model				Resulting MPU/System State			
MPU_Cx States	State of L2	PRCM Power State PM_MPU_PWRSTCTRL[1:0] POWERSTATE	PRCM Logic Retention State PM_MPU_PWRSTCTRL[2] LOGICRETSTATE	PRCM L2 Memory Retention State PM_MPU_PWRSTCTRL[9] MPU_L2_RETSTATE	PRCM Clock Transition Control CM_MPU_CLKSTCTRL[1:0] CLKTRCTRL	Logic	L2 Cache	DPLL Clock	Power State (at PRCM)
At least one is ON	Any	Any	Any	Any	Any	ON	ON	ON	ON
Any	!= (IDLE / WFI)	Any	Any	Any	Any	ON	ON	ON	ON
Power state of both MPU cores is less than or equal to INACT	IDLE / WFI	Any	Any	Any	NO_SLEEP/SW_WKUP	ON	ON	ON	ON
	IDLE / WFI	ON	Any	Any	HW_AUTO	ON	ON	ON	ON
	IDLE / WFI	INACT	Any	Any	HW_AUTO	ON	ON	OFF	INACT
Power state of both MPU cores is equal to CSWRET	IDLE / WFI	RETENTION	CSWRET	RETENTION	HW_AUTO	ON	RETENTION	OFF	CSWRET
	IDLE / WFI	RETENTION	CSWRET	OFF	HW_AUTO	ON	OFF	OFF	CSWRET

NOTE: All the transitions presented in Table 4-8, except for the first line, are handled by the MPU_PRCM and the global PRCM.

Once the MPU subsystem reaches a low-power state (INACT, CSWRET), it cannot move to another low-power state. It must be woken up to reach another low-power state.

4.3.7.4 MPU_WUGEN

The MPU_WUGEN belongs to the MPU always-on power domain (PD_MPUAON) and is responsible for generating wake-up events from the incoming interrupts (external and local to the MPU subsystem) according to the MPU_WUGEN 160-bit enable field (from WKG_ENB_A_x to WKG_ENB_E_x for MPU_Cx, where x = 0 or 1), which defines the interrupt that wakes up the MPU cores.

All interrupts are enabled after reset, except MPU_IRQ_8. The Cortex-A15 MPU can access the MPU_WUGEN internal configuration registers through the MPU_AXI2OCP.

Software must program interrupt enabling and disabling coherently in the MPU_INTC and in the MPU_WUGEN enable registers. That is, a given interrupt for a given MPU core is either enabled at both MPU_INTC and MPU_WUGEN, or disabled at both; no combination is allowed.

MPU_WUGEN includes two registers (AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1) which can be used by the ROM code and OS during SMP boot. The AUX_CORE_BOOT_0 register is intended to indicate boot status to MPU_C1, the second core (also known as aux core); the AUX_CORE_BOOT_1 register can be used to store execution start address of the MPU_C1. For more information, see Section 34.3.4, *Startup and Configuration*, in Chapter 34, *Initialization*.

Figure 4-10 is a functional overview of the MPU_WUGEN in the MPU subsystem.

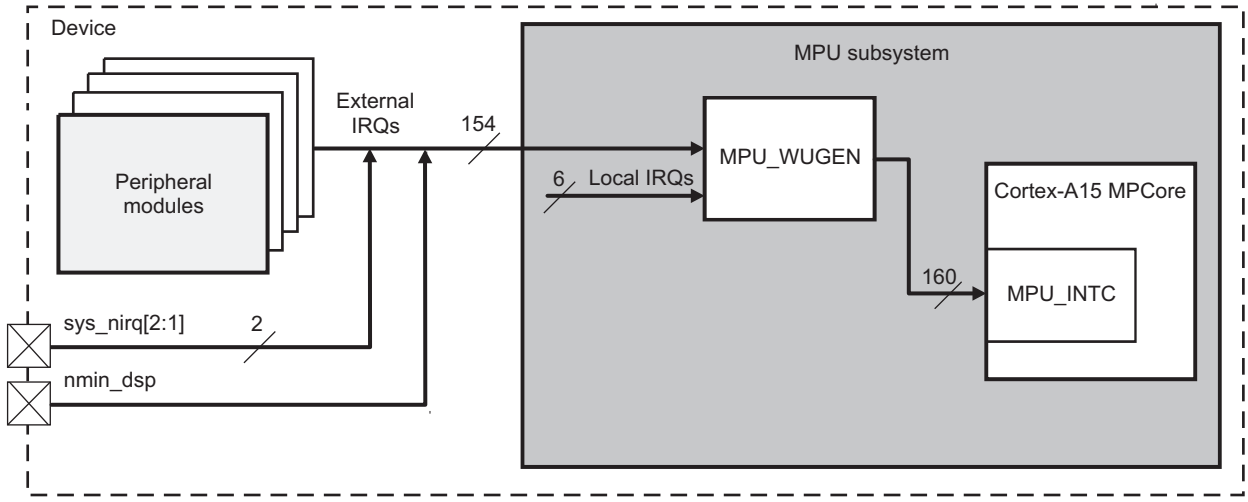
Figure 4-10. MPU_WUGEN Overview



4.3.7.5 Power Transition Sequence

At power-on-reset (POR), or global warm reset, both MPU cores are powered on. Software can determine the appropriate power mode for both MPU cores and program the MPU_PRCM accordingly.

There are three types of power transitions:

- Power transitions that do not involve the local or global PRCM module
  - MPU_Cx transition to WFE/ON - corresponds to line 2 of Table 4-6
  - MPU_Cx transition to WFI/ON - corresponds to lines 3, 4, and 6 of Table 4-6
- Power transitions handled by the local PRCM module
  - MPU_C1 cannot transition to WFI/FORCED_OFF; neither of the two Cortex-A15 MPU cores has a power switch, making both MPU power domains Always-On.
  - MPU_Cx transition to WFI/INACT, or WFI/RET - corresponds to line 7, 8 and 9 of Table 4-6. Requires software to program the MPU_PRCM with INACT/RET mode.
- Power transitions handled by the local and global PRCM modules

4.3.7.6 SR3-APG Technology Fail-Safe Mode

The SR3-APG power-management technology implements a fast power ramp-up technology. To take advantage of the fast ramp-up feature in SR3-APG, software must first enable it by setting the PRM_PSCON_COUNT[25] HG_RAMPUP bit to 1.

A fail-safe mechanism is put in place to revert back to the standard power ramp-up time by setting the PRM_PSCON_COUNT[25] HG_RAMPUP bit to 0.

The slow ramp-up time can be set through the PRM_PSCON_COUNT[23:16] HG_PONOUT_2_PGDOODIN_TIME bit field when the HG weak chain is used (in other words, the PRM_PSCON_COUNT[25] HG_RAMPUP bit is set to 0x0).

This applies only when SR3-APG is enabled (PRM_PSCON_COUNT[24] HG_EN = 1).

The L1 cache memory state depends on the values of the PRM_PSCON_COUNT[25] HG_RAMPUP and PRM_PSCON_COUNT[24] HG_EN bits. When CPU PD is in CSWRET state and HG_ENABLE and HG_RAMPUP are set to 0x1, L1 cache is in the ON state.

If SR3-APG is disabled (PRM_PSCON_COUNT[24] HG_EN = 0), the L1 cache array can be put in RETENTION during CSWRET regardless of the PRM_PSCON_COUNT[25] HG_RAMPUP bit.

4.3.8 MPU Subsystem AMBA Interface Configuration

There are some inputs at the MPU core (MPU_Cx) boundary which can be tied off to disable certain kind of transactions appearing on the AMBA4 interface:

- SYSBARDISABLE (SBD): This controls whether:
  - Barriers are handled internal to MPU core (SBD = 1), or
  - Barriers are issued on the AMBA4 interface (SBD = 0).
- BROADCASTINNER (BI), BROADCASTOUTER (BO), BROADDCASTMAINTENANCE (BCM): These control whether external snoops are issued on AMBA4 interface or not:
  - BI=BO=BCM=0: No external snoops issued.
  - BI=BO=BCM=1: External snoops can be issued. Not supported in the device.

For detailed description on these inputs, see the Arm *Cortex-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

To give flexibility and mitigate risk, a programmable register (AMBA_IF_MODE) is added to control the tie-off value of these MPU_Cx inputs. Once this register is programmed, MPU power domain has to go through OSWRET transition for the programmed values in bits AMBA_IF_MODE [3:0] to take effect. This is because the MPU_Cx non-cpu logic latches the value on the corresponding inputs when it is coming out of reset.

These are the only legal combinations of [BI, BO, BCM, SBD] allowed:

- BI, BO, BCM, SBD = 0001 – Corresponds to **AXI3** mode. Barriers not issued on AMBA4 interface. External snoops not issued. This is the default mode.
- BI, BO, BCM, SBD = 0000 – Corresponds to **ACE non-coherent, no L3** mode. Barriers issued on AMBA4 interface. External snoops not issued.

The ROM code provides specific API for configuring the AMBA_IF_MODE register. For more information, see section *Wakeup Generator*, in Chapter 34, *Initialization*.

Description	Wake-up generator control and status register for MPU_C1		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DOMAINRESET	MPU_WARM_RESET	MPU_COLD_RESET	RESERVED		EVENTO	STANDBYWFE	STANDBYWFI	RESERVED							

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x00000
15	DOMAINRESET	MPU always-on power domain (PD_MPUAON) reset status bit. It shows if the reset occurred previously. 0x0: No reset occurred. 0x1: Reset occurred.	R	0x0
14	MPU_WARM_RESET	This bit is set when the MPU_WARM_RESET signal is asserted. 0x0: MPU_WARM_RESET reset signal has not been asserted. 0x1: MPU_WARM_RESET reset request has been asserted.	RW	0x0
13	MPU_COLD_RESET	This bit is set when the MPU_COLD_RESET signal is asserted. 0x0: MPU_COLD_RESET reset signal has not been asserted. 0x1: MPU_COLD_RESET reset request has been asserted.	RW	0x0
12:11	RESERVED	Reserved	R	0x0
10	EVENTO	EVENTO status bit. The event output signal is active, when one SEV instruction is executed. This bit is set when a rising edge of EVENTO from CPU is detected. 0x0: Rising edge of EVENTO is not detected. 0x1: Rising edge of EVENTO is detected.	RW	0x0
9	STANDBYWFE	This bit gives software the visibility to track whether WFE mode have been entered. 0x0: WFE mode has not been entered. 0x1: WFE mode has been entered.	RW	0x0
8	STANDBYWFI	This bit gives software the visibility to track whether WFI mode have been entered. 0x0: WFI mode has not been entered. 0x1: WFI mode has been entered.	RW	0x0

Table 4-81. AUX_CORE_BOOT_1

Address Offset	0x804		
Physical Address	0x4828 1804	**Instance**	MPU_WUGEN
Description	This register is used by the ROM code and OS during SMP boot. It is intended to store the execution start address of MPU_C1. When needed, the SMP OS (executing on MPU_C0) stores the execution start address of MPU_C1 in AUX_CORE_BOOT_1, and then wakes up MPU_C1 by executing a SEV command. When MPU_C1 receives an event (caused by the SEV command), it executes the event handler in the ROM Code, which eventually branches to the address stored in AUX_CORE_BOOT_1.

Table 4-94. WDT_COUNT_REGISTER_i

Address Offset	0x0000 0004 + (0x20 * i)	**Index**	i = 0 to 1
Physical Address	0x482A 0004 + (0x20 * i)	**Instance**	MPU_WD_TIMER
Description	This register is a 32-bit decrementing counter. The decrement rate is programmed in the WDT_PRESCALER_REGISTER_i. The WDT_COUNT_REGISTER_i can be read to get the current count. It decrements if the MPU_WD_TIMER_Cx is enabled (WDT_CONTROL_REGISTER_i[0] ENABLE = 0x1). If the processor related to the corresponding watchdog channel is in debug state, the counter does not decrement until the processor returns to non-debug state. The WDT_COUNT_REGISTER_i decrements down to zero and stops. The only way to update the WDT_COUNT_REGISTER_i is to write to the WDT_LOAD_REGISTER_i. If a software failure prevents the WDT_COUNT_REGISTER_i from being refreshed, the WDT_COUNT_REGISTER_i reaches zero, the watchdog timeout status flag is set and all interrupt requests or reset requests enabled in the WDT_CONTROL_REGISTER_i are signalled. If a reset request is enabled, the global PRCM is then responsible for resetting the MPUSS. Debug state is inferred by monitoring the DBGACK signal corresponding to this core. This register is reset by warm reset of the corresponding MPU core.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 4-96. WDT_WARNING_REGISTER_i

Address Offset	0x0000 0008 + (0x20 * i)	**Index**	i = 0 to 1
Physical Address	0x482A 0008 + (0x20 * i)	**Instance**	MPU_WD_TIMER
Description	The WDT_COUNT_REGISTER_i is compared to the WDT_WARNING_REGISTER_i. If WDT_COUNT_REGISTER_i is less than or equal to the WDT_WARNING_REGISTER_i and WDT_CONTROL_REGISTER_i[8] WARNEN = 0b1, a warning interrupt is signalled to the MPU_INTC. The warning condition can be used to signal an interrupt that gives software a notice that the MPU_WD_TIMER_Cx is getting close to a timeout, when a more serious action should be taken.

Table 4-98. WDT_PRESCALER_REGISTER_i

Address Offset	0x0000 000C + (0x20 * i)	**Index**	i = 0 to 1
Physical Address	0x482A 000C + (0x20 * i)	**Instance**	MPU_WD_TIMER
Description	This register is used to set the count rate of the MPU_WD_TIMER_Cx counter.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						PRESCALER									

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x00 0000
9:0	PRESCALER	Sets the prescaler ratio. WDT_COUNT_REGISTER_i decrements every (PRESCALER + 1) MPU_DPLL_CLK clocks. Note: If the prescaler is set to (MPU_DPLL_CLK [in MHz] - 1), the MPU_WD_TIMER_Cx counter counts at a 1 microsecond rate.	RW	0x000

Table 4-100. WDT_CONTROL_REGISTER_i

Address Offset	0x0000 0010 + (0x20 * i)	**Index**	i = 0 to 1
Physical Address	0x482A 0010 + (0x20 * i)	**Instance**	MPU_WD_TIMER
Description	This register controls the behavior of the MPU_WD_TIMER_Cx. This register is reset by warm reset of the corresponding MPU core.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							WARNEN	RESERVED				MPUSSRSTEN	RESERVED	INTREN	ENABLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x00 0000
8	WARNEN	Warning Interrupt Enable. If this bit is set and the warning watermark test is true, a warning interrupt is generated to the MPU_INTC.	RW	0
7:4	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x0
3	MPUSSRSTEN	MPUSS Reset Enable. If this field is 0b1 when the timer reaches zero, a request is sent to the global PRCM to begin a global warm reset.	RW	0
2	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0
1	INTREN	Interrupt Enable. If this field is 0b1 when the timer reaches zero, an interrupt request is sent to the MPU_INTC.	RW	0
0	ENABLE	Enable for MPU_WD_TIMER_Cx. 0: MPU_WD_TIMER_Cx is disabled. It will not count down and it will not generate a reset request. All MPU_WD_TIMER_Cx registers may be accessed. 1: MPU_WD_TIMER_Cx is enabled. It will count down and generate a reset request if it reaches 0. This bit is reset by warm or power-on reset.	RW	0

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x0000 0000
1	WARN	Warning. Indicates that the count has passed the warning watermark level while the WDT_CONTROL_REGISTER_i[8] WARNEN bit was set. Write a '1' to this bit to reset it.	RW W1toClr	0
0	TO	Timeout. Indicates the WDT_COUNT_REGISTER_i has reached zero (timed out) and the signalling enabled in the WDT_CONTROL_REGISTER_i has occurred. Can be used to determine which MPU_WD_TIMER_Cx instance caused a reset. Write a '1' to this bit to reset it.	RW W1toClr	0

5.1 DSP Subsystems Overview

The device includes two identical instances (DSP1 and DSP2) of a digital signal processor (DSP) subsystem, based on the TI's standard TMS320C66x™ DSP CorePac core.

The TMS320C66x DSP core enhances the TMS320C674x™ core, which merges the C674x™ floating point and the C64x+™ fixed-point instruction set architectures. The C66x DSP is object-code compatible with the C64x+/C674x DSPs.

For more information on the TMS320C66x core CPU, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, (SPRUGH7).

Each of the two DSP subsystems integrated in the device includes the following components:

- A TMS320C66x™ CorePac DSP core that encompasses :
  - L1 program-dedicated (L1P) cacheable memory
  - L1 data-dedicated (L1D) cacheable memory
  - L2 (program and data) cacheable memory
  - Extended Memory Controller (XMC)
  - External Memory Controller (EMC)
  - DSP CorePac located interrupt controller (INTC)
  - DSP CorePac located power-down controller (PDC)
- Dedicated enhanced data memory access engine - EDMA, to transfer data from/to memories and peripherals external to the DSP subsystems and to local DSP memory (most commonly L2 SRAM). The external DMA requests are passed through DSP system level (SYS) wakeup logic, and collected from the DSP1 / DSP2 dedicated outputs of the device DMA Events Crossbar for each of the two subsystems.
- A level 2 (L2) interconnect network (DSP NoC) to allow connectivity between different modules of the subsystem or the remainder of the device via the device L3_MAIN interconnect.
- Two memory management units (on EDMA L2 interconnect and DSP MDMA paths) for accessing the device L3_MAIN interconnect address space
- Dedicated system control logic (DSP_SYSTEM) responsible for power management, clock generation, and connection to the device power, reset, and clock management (PRCM) module

Figure 5-1 is the DSP subsystem top-level architecture.

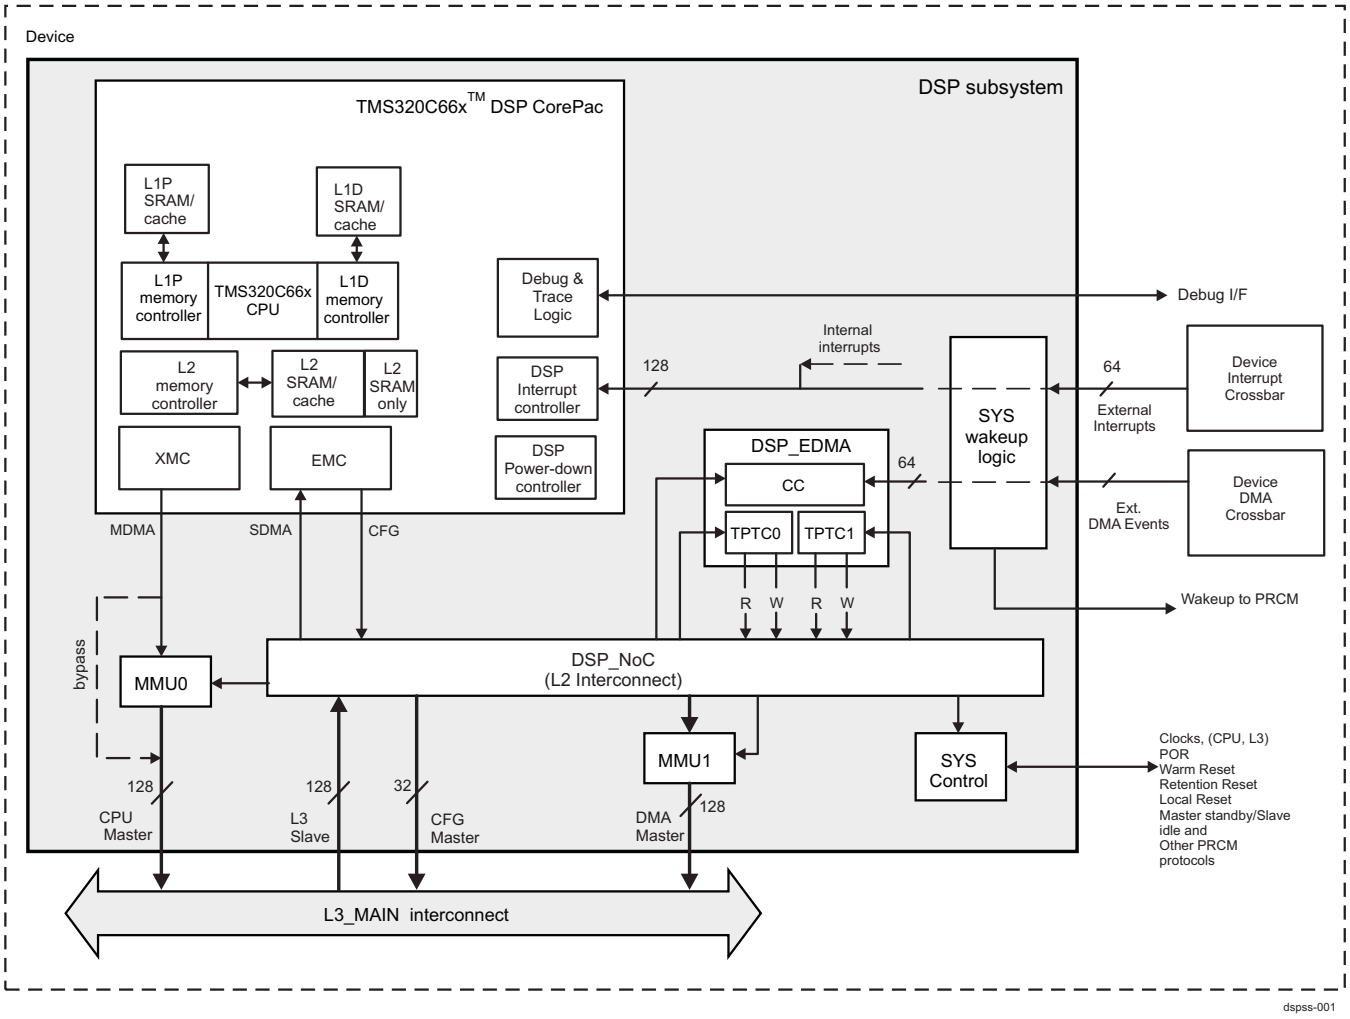
Figure 5-1. DSP Subsystem Highlight



5.1.1 DSP Subsystems Key Features

The TMS320C66x Instruction Set Architecture (ISA) is the latest for the C6000 family. As with its predecessors (C64x, C64x+ and C674x), the C66x is an advanced VLIW architecture with 8 functional units (two multiplier units and six arithmetic logic units) that operate in parallel. The C66x CPU has a total of 64 general-purpose 32-bit registers.

Some features of the DSP C6000 family devices are :

- Advanced VLIW CPU with eight functional units (two multipliers and six ALUs) which:
  - Executes up to eight instructions per cycle for up to ten times the performance of typical DSPs
  - Allows designers to develop highly effective RISC-like code for fast development time
- Instruction packing
  - Gives code size equivalence for eight instructions executed serially or in parallel
  - Reduces code size, program fetches, and power consumption
- Conditional execution of most instructions
  - Reduces costly branching
  - Increases parallelism for higher sustained performance
- Efficient code execution on independent functional units
  - Industry's most efficient C compiler on DSP benchmark suite

Copyright © 2018–2019, Texas Instruments Incorporated

  - Industry's first assembly optimizer for fast development and improved parallelization
- 8-/16-/32-bit/64-bit data support, providing efficient memory support for a variety of applications
- 40-bit arithmetic options which add extra precision for vocoders and other computationally intensive applications
- Saturation and normalization to provide support for key arithmetic operations
- Field manipulation and instruction extract, set, clear, and bit counting support common operation found in control and data manipulation applications.

The C66x CPU has the following additional features :

- Each multiplier can perform two 16 × 16-bit or four 8 × 8 bit multiplies every clock cycle.
- Quad 8-bit and dual 16-bit instruction set extensions with data flow support
- Support for non-aligned 32-bit (word) and 64-bit (double word) memory accesses
- Special communication-specific instructions have been added to address common operations in error-correcting codes.
- Bit count and rotate hardware extends support for bit-level algorithms.
- Compact instructions: Common instructions (AND, ADD, LD, MPY) have 16-bit versions to reduce code size.
- Protected mode operation: A two-level system of privileged program execution to support higher-capability operating systems and system features such as memory protection.
- Exceptions support for error detection and program redirection to provide robust code execution
- Hardware support for modulo loop operation to reduce code size and allow interrupts during fully-pipelined code
- Each multiplier can perform 32 × 32 bit multiplies
- Additional instructions to support complex multiplies allowing up to eight 16-bit multiply/add/subtracts per clock cycle

The TMS320C66x has the following key improvements to the ISA :

- 4x Multiply Accumulate improvement for both fixed and floating point
- Improvement of the floating point arithmetic
- Enhancement of the vector processing capability for fixed and floating point
- Addition of domain-specific instructions for complex arithmetic and matrix operations

On the C66x ISA, the vector processing capability is improved by extending the width of the SIMD instructions. The C674x DSP supports 2-way SIMD operations for 16-bit data and 4-way SIMD operations for 8-bit data. C66x enhances this capabilities with the addition of SIMD instructions for 32-bit data allowing operation on 128-bit vectors. For example the QMPY32 instruction is able to perform the element to element multiplication between two vectors of four 32-bit data each.

C66x ISA includes a set of specific instructions to handle complex arithmetic and matrix operations.

- **TMS320C66x DSP CorePac memory components :**
  - A 32-KiB L1 program memory (L1P) configurable as cache and / or SRAM:
    - When configured as a cache, the L1P is a 1-way set-associative cache with a 32-byte cache line
    - The DSP CorePac L1P memory controller provides bandwidth management, memory protection, and power-down functions
    - The L1P is capable of cache block and global coherence operations
    - The L1P controller has an Error Detection (ED) mechanism, including necessary SRAM
    - The L1P memory can be fully configured as a cache or SRAM
    - Page size for L1P memory is 2KB
  - A 32-KiB L1 data memory (L1D) configurable as cache and / or SRAM:
    - When configured as a cache, the L1D is a 2-way set-associative cache with a 64-byte cache line

Copyright © 2018–2019, Texas Instruments Incorporated

        - The DSP CorePac L1D memory controller provides bandwidth management, memory protection, and power-down functions
        - The L1D memory can be fully configured as a cache or SRAM
        - The L1D controller has an Error Correction Code (ECC) mechanism, including necessary SRAM
        - Page size for L1D memory is 2KB
    - A 288-KiB (program and data) L2 memory, only part of which is cacheable:
        - When configured as a cache, the L2 memory is a 4-way set associative cache with a 128-byte cache line
        - Only 256 KiB of L2 memory can be configured as cache or SRAM
        - 32 KiB of the L2 memory is always mapped as SRAM
        - The L2 memory controller has an Error Correction Code (ECC) and ED mechanism, including necessary SRAM
        - The L2 memory controller supports hardware prefetching and also provides bandwidth management, memory protection, and power-down functions.
        - Page size for L2 memory is 16KB
- The **External Memory Controller (EMC)** is a bridge from the C66x CorePac to the rest of the DSP subsystem and device. It has :
    - a 32-bit configuration port (CFG) providing access to local subsystem resources (like DSP_EDMA, DSP_SYSTEM, etc) or to L3_MAIN resources accessible via the CFG address range.
    - a 128-bit slave-DMA port (SDMA) which provides accesses of system masters outside the DSP subsystem to resources inside the DSP subsystem or C66x DSP CorePac memories, i.e. when the DSP subsystem is the slave in a transaction.
- The Extended Memory Controller (XMC) processes requests from the L2 Cache Controller (which are a result of CPU instruction fetches, load/store commands, cache operations) to device resources via the C66x DSP CorePac 128-bit master DMA (MDMA) port :
    - Memory protection for addresses outside C66x DSP CorePac generated over device L3_MAIN on the MDMA port
    - Prefetch, multi-in-flight requests
- A DSP local **Interrupt Controller (INTC)** in the DSP C66x CorePac, interfaces the system events to the DSP C66x core CPU interrupt and exceptions inputs. Each DSP subsystem C66x CorePac interrupt controller supports up to 128 system events of which 64 interrupts are external to DSP subsystems, collected from the DSP1 /DSP2 dedicated outputs of the device Interrupt Crossbar.
- **Local Enhanced Direct Memory Access (EDMA) controller feaures:**
    - Channel controller (CC) : 64-channel, 128 PaRAM, 2 Queues
    - 2 x Third-party Transfer Controllers (TPTC0 and TPTC1):
        - Each TC has a 128-bit read port and a 128-bit write port
        - 2KiB FIFOs on each TPTC
    - 1-dimensional/2-dimensional (1D/2D) addressing
    - Chaining capability
- **DSP subsystems integrated MMUs**:
    - Two MMUs are integrated:
        - The MMU0 is located between DSP MDMA master port and the device L3_MAIN interconnect and can be optionally bypassed
        - The MMU1 is located between the EDMA master port and the device L3_MAIN interconnect
- A DSP local **Power-Down Controller (PDC)** is responsible to power-down various parts of the DSP C66x CorePac, or the entire DSP C66x CorePac.
- The DSP subsystems **System Control logic** provides:
    - Slave idle and master standby protocols with device PRCM for powerdown
    - OCP Disconnect handshake for init and target busses

Copyright © 2018–2019, Texas Instruments Incorporated

  - Asynchronous reset
  - Power-down modes :
    - "Clockstop" mode featuring wake-up on interrupt event. The DMA event wake-up is managed in software.
- The device DSP subsystems are supplied by a PRCM DPLL, but each DSP1/2 **has integrated its own PLL module** outside the C66x CorePac for clock gating and division.
- **Each of the two device DSP subsystems has following port instances** to connect to remaining part of the device. See also Figure 5-1:
  - A 128-bit initiator (DSP MDMA master) port for MDMA/Cache requests
  - A 128-bit initiator (DSP EDMA master) port for EDMA requests
  - A 32-bit initiator (DSP CFG master) port for configuration requests
  - A 128-bit target (DSP slave) port for requests to DSP memories and various peripherals
- **C66x DSP subsystems (DSPSS) safety aspects** :
  - Above mentioned memory ECC/ED mechanisms
  - MMUs enable mapping of only the necessary application space to the processor
  - Memory Protection Units internal to the DSPSS (in L1P,L1D and L2 memory controllers) and external to DSPSS (firewalls) to help define legal accesses and raise exceptions on illegal accesses
  - Exceptions: Memory errors, various DSP errors, MMU errors and some system errors are detected and cause exceptions. The exceptions could be handled by the DSP or by a designated safety processor at the chip level. Note that it may not be possible for the safety processor to completely handle some exceptions

Unsupported features on the C66x DSP core for the device are:

- The Extended Memory Controller MPAX (memory protection and address extension) 36-bit addressing is NOT supported
- Neither of the two DSP subsystems has a power switch, making both power domains Always-On. For more information on the power domains, see Section 3.7.2, PD_DSP1 Description, and Section 3.7.3, PD_DSP2 Description.

Known DSP subsystem powermode restrictions for the device are:

- No power down modes are supported.

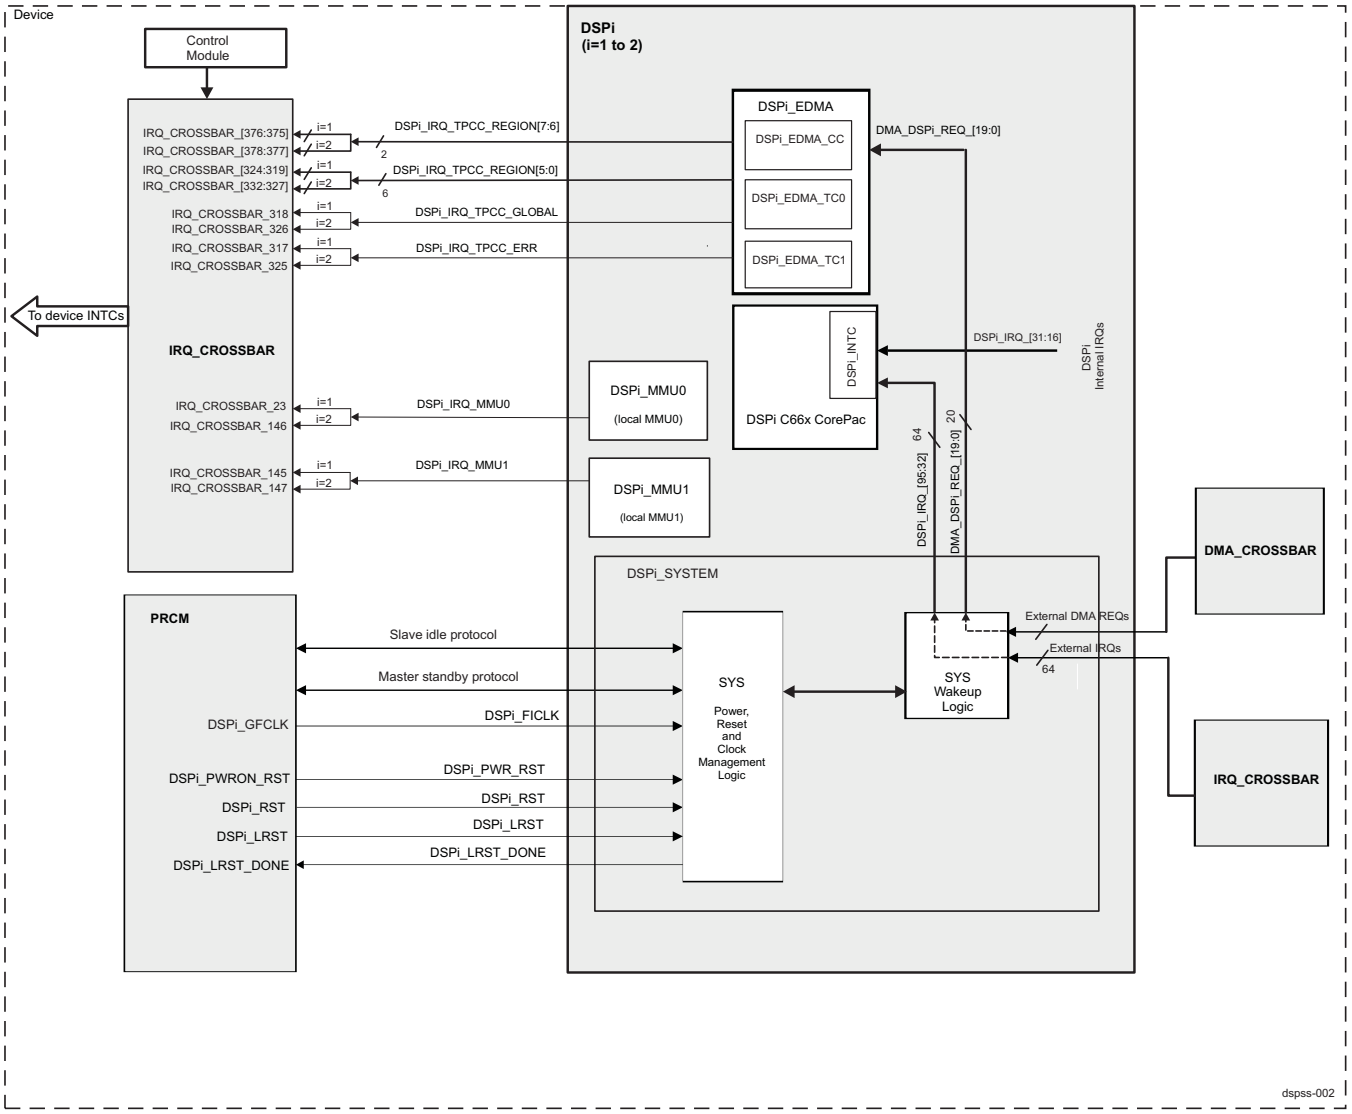
5.2 DSP Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 5-2 shows the integration of the DSP subsystem.

Figure 5-2. DSP Subsystem Integration



NOTE: For more information about the slave idle protocol and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 5-1 through Table 5-3 summarize the integration of the module in the device.

Table 5-3. DSP Hardware Requests (continued)

	DSP1_IRQ_TPCC_REGION3	IRQ_CROSSBAR_322	-	DSP1 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION4	IRQ_CROSSBAR_323	-	DSP1 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION5	IRQ_CROSSBAR_324	-	DSP1 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION6	IRQ_CROSSBAR_375	-	DSP1 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION7	IRQ_CROSSBAR_376	-	DSP1 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2	DSP2_IRQ_MMU0	IRQ_CROSSBAR_146	-	DSP2 subsystem local MMU0 (DSP2_MMU0CFG) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_MMU1	IRQ_CROSSBAR_147	-	DSP2 subsystem local MMU1 (DSP2_MMUCFG1) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_ERR	IRQ_CROSSBAR_325	-	DSP2 subsystem aggregated ("OR-ed") error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_GLOBAL	IRQ_CROSSBAR_326	-	DSP2 subsystem EDMA channel controller global interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_REGION0	IRQ_CROSSBAR_327	-	DSP2 subsystem EDMA channel controller REGION0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 5-3. DSP Hardware Requests (continued)

DSP2_IRQ_TPCC_REGION1	IRQ_CROSSBAR_328	-	DSP2 subsystem EDMA channel controller REGION1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION2	IRQ_CROSSBAR_329	-	DSP2 subsystem EDMA channel controller REGION2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION3	IRQ_CROSSBAR_330	-	DSP2 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION4	IRQ_CROSSBAR_331	-	DSP2 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION5	IRQ_CROSSBAR_332	-	DSP2 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION6	IRQ_CROSSBAR_377	-	DSP2 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION7	IRQ_CROSSBAR_378	-	DSP2 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The DSP1 / DSP2 does NOT generate any DMA requests towards other device DMA controllers outside DSP1 / DSP2 (EDMA, DMA_SYSTEM, etc.).

NOTE: The "**Default Mapping**" column in Table 5-3, *DSP Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 19, *Control Module*.
For more information about the device interrupt controllers, see Chapter 18, *Interrupt Controllers*.

NOTE:

- For a description of the interrupt source controls at DSP subsystem level, see Section 5.3.4, *DSP Interrupt Requests*.

Copyright © 2018–2019, Texas Instruments Incorporated

DSP1/DSP2 subsystem external interrupt sources: The default interrupt sources mapped by the device IRQ_CROSSBAR to the DSP1 / DSP2 interrupt controller lines are described in the Chapter 18, *Interrupt Controllers*. The programmable muxing of various external interrupt sources to the DSP1_INTC.DSP1_IRQ_x and DSP2_INTC.DSP2_IRQ_x input lines (where x=32 to 95) is covered in the Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, of the Chapter 19, *Control Module*.

DSP1/DSP2 subsystem internal interrupt sources: The mapping of DSP subsystem internal IRQ sources to DSP1_IRQ_x / DSP2_IRQ_x lines (where x=0 to 31 and x=96 to 127 for DSP subsystem internal event sources) is described in the Section 5.3.4, *DSP Interrupt Requests*.

DSP1/DSP2 subsystem external DMA request sources: The Table 5-6 and Table 5-7 lists the default DSP1 and DSP2 external DMA request sources, respectively, routed via the device DMA_CROSSBAR to the DSP1_EDMA / DSP2_EDMA channel controller inputs (DMA_DSP1_DREQ_i / DMA_DSP2_DREQ_i).

Copyright © 2018–2019, Texas Instruments Incorporated

5.3 DSP Subsystems Functional Description

5.3.1 DSP Subsystems Block Diagram

Each of the device two DSP subsystems - DSP1 and DSP2 is composed of a DSP C66x CorePac coupled with several other submodules that enable its integration in the device architecture. Device DSP subsystem provides :

- a 128-bit master data port (MDMA) on device L3_MAIN with a dedicated DSP subsystem local MMU (MMU0) on the path.
- a 32-bit master configuration port (CFG) on device L3_MAIN through which DSP host configures various device located peripherals (external to the DSP subsystem).
- a 128-bit slave DMA port (SDMA) on device L3_MAIN which allows external initiators (masters) to DSP to manipulate some portion of its config / status registers (those which are mapped in the L3_MAIN space) in the device
- a 128-bit master EDMA port - which allows the DSP_EDMA traffic controllers to initiate transfers on L3_MAIN.

The C66x DSP subsystem is illustrated in the Figure 5-1.

Copyright © 2018–2019, Texas Instruments Incorporated

5.3.2 DSP Subsystem Components

5.3.2.1 C66x DSP Subsystem Introduction

The key component of the C66x DSP subsystem is built on the TI's high performance TMS320C66x DSP CorePac which consists of a single TMS320C66x CPU (DSP_C0) processor along with a level 1 (L1P and L1D) cacheable SRAM and a level 2 (L2) cacheable SRAM memories interfaced via associated local L1P, L1D and L2 memory controllers, respectively. A DSP C66x CorePac includes also some other internal peripheral components, see Section 5.3.2.2.3 for details.

This chapter provides an overview of the DSP subsystem and the following considerations associated with it :

- DSP C66x CorePac Core and L1 / L2 Memories
- DSP System control and configuration :
  - clock management
  - wake-up event generation
  - interrupt masking
- DSP Booting
- DSP subsystem internal memory and external memory (L3_MAIN) space views
- DSP INTC interrupts mapping, event combining and exception generation
- DMA requests mapping to EDMA channels and EDMA traffic routing
- Others

For more information on the TMS320C66x DSP CorePac, refer to the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C), the *TMS320C66x DSP Cache User Guide*, (SPRUGY8) and the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, (SPRUGH7).

Copyright © 2018–2019, Texas Instruments Incorporated

5.3.2.2 DSP TMS320C66x CorePac

The TMS320C66x DSP CorePac is illustrated on Figure 5-1. It consists of a single DSP C66x CPU (DSP_C0) processor tightly coupled with level 1 - L1P (program), L1D (data) cacheable SRAM memories and level 2 (L2) cacheable SRAM memories. The C66x CorePac integrated memories are interfaced via associated local L1P, L1D and L2 memory controllers, respectively.

Additionally, the DSP C66x CorePac contains the following internal peripherals:

- an interrupt controller (DSP_INTC) to service DSP C66x CorePac internal and external interrupt events
- a power-down controller (DSP_PDC)
- an external memory controller - DSP_EMC
- an extended memory controller - DSP_XMC_CTRL
- a bandwidth manager - BWM with local controls to the L1P-, L1D- and L2-memories
- an internal direct memory access controller - IDMA

The C66x CorePac DSP also instantiates Debug and Trace logic, part of which is implemented in the DSP core C66x CPU. For more details, refer to the Chapter 35, *On-Chip Debug Support* .

5.3.2.2.1 DSP TMS320C66x CorePac CPU

The DSP C66x CorePac CPU includes following key components :

- A program fetch unit
- 16-/32-bit instruction dispatch unit, advanced instruction packing
- Instruction decode unit
- Two data paths, each with four functional units
- 64 x 32-bit general purpose registers
- Control logic and associated registers
- An internal interrupt and exception controller
- Test, emulation logic
- Internal DMA (IDMA) for transfers between internal memories

For more information on the TMS320C66x central processing unit, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, (SPRUGH7).

5.3.2.2.2 DSP TMS320C66x CorePac Internal Memory Controllers and Memories

The TMS320C66x DSP CorePac implements a two-level internal cache-based memory architecture.

5.3.2.2.2.1 Level 1 Memories

Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). Each of the memories can be split into static RAM (normal addressable on-chip memory) and cache.

L1P memory is dedicated to TMS320C66x CPU program words storage and is interfaced via a dedicated L1P memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1P memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1P features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1P controller configuration register - L1PCFG[2:0] L1PMODE bitfield. **Note that, the L1P controller maps the cache space by starting at the top of the L1P memory map (i.e. from most significant address) and working downwards. The L1P mapped SRAM size is 32 KiB minus the configured cache size.**

NOTE: The L1P cache / SRAM is ONLY read-accessible by the C66x CPU processor. The DSP C66x CorePac external DMAs (SDMA and EDMA) and internal DMA (IDMA) are the only initiators which can write to the L1P memory. The CPU may however write access and modify certain L1P cache/SRAM controller registers if such access is allowed for the register.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: In the device integrated DSP, at reset, the entire 32 KiB- L1P memory is initialized as a cache (reset value of L1PMODE=0x7).

For more information on the L1P cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, (SPRUGY8).

L1D memory is used for level 1 CPU data storage and is interfaced via a dedicated L1D memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1D memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1D features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1D configuration register - L1DCFG[2:0] L1DMODE bitfield. **Note that, the L1D controller maps the cache space by starting at the top of the L1D memory map (i.e. from most significant address) and working downwards. The L1D mapped SRAM size is 32 KiB minus the configured cache size.**

NOTE: In the device integrated DSP, at reset, the entire 32 KiB- L1D memory is initialized as a cache (i.e. reset value of L1DMODE = 0x7).

For more information on the L1D cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, (SPRUGY8).

5.3.2.2.2 Level 2 Memory

The L2 memory can also be split into L2 RAM (normal addressable on-chip memory) and L2-cache for caching external to the DSP meagmodule memory locations. The on-chip integrated L2 memory total size is 288 KiB. The L2 memory is shared between data and program word sources within and outside the DSP C66x CorePac. The L2 memory is divided into two physical 128 bit-wide banks, accesses to which are interleaved on address LSB. Each of the two L2 banks is further split into 4 subbanks.

NOTE: Only 256 KiB of the L2 memory are cacheable in the device DSP. The remaining 32 KiB are always mapped as static RAM.

The L2 memory features a dynamically configurable cache size (32 KiB, 64 KiB, 128 KiB and 256 KiB) defined via L2 configuration register - L2CFG[2:0] L2MODE bitfield. The additional (to the 32KiB fixed SRAM L2) SRAM available is 256-KiB minus the cache size.

L2 memory controller is responsible for MDMA bus error events reporting. The DSP C66x CorePac MDMA bus error event is exported outside the C66x DSP CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"MDMAERREVT"** event in the Table 5-5.

NOTE: The MDMA bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

5.3.2.2.3 DSP C66x CorePac Internal Peripherals

The DSP C66x CorePac includes the following internal peripherals:

- DSP interrupt controller (DSP_INTC)
- DSP power-down controller (DSP_PDC)
- Bandwidth manager (DSP_BWM)
- Memory Protection Hardware
- Internal DMA (DSP_IDMA) controller

Copyright © 2018–2019, Texas Instruments Incorporated

- External Memory Controller (DSP_EMC)
- Extended Memory Controller (DSP_XMC_CTRL) including prefetch buffer logic
- Error Detection logic for the L1P memory
- Error Detection and Correction (ECC) logic for the L2 memory

This section briefly describes the DSP_INTC, DSP_PDC, DSP_BWM, DSP_IDMA, DSP_EMC, DSP_XMC_CTRL controller, L1P Error detection and L2 ECC logic. For more information on the TMS320C66x DSP CorePac, see the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.2.3.1 DSP C66x CorePac Interrupt Controller (DSP INTC)

The DSP C66x CorePac includes an interrupt controller (DSP_INTC) and can receive a total of 128 system events as inputs. They include DSP-generated events and chip-level events.

In addition to these 128 events, a non-maskable (NMI) event (see the Section 5.3.4.1.1) and reset events are mapped to the DSP_INTC as well, and are routed straight through to the DSP CPU core.

For more details on the DSP_INTC functionalities and its corresponding control / status registers (part of the DSP_ICFG local configuration space), refer to the section *Interrupt Controller* within the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

For more details on input interrupt mappings and associated IRQ wake-up events, refer to the Section 5.3.4.1.

For more information about the device DSP_INTC, see Chapter 18, *Interrupt Controllers*. For more information on chip level IRQ mapping via the device IRQ_CROSSBAR module, see Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 19, *Control Module*.

5.3.2.2.3.2 DSP C66x CorePac Power-Down Controller (DSP PDC)

The DSP C66x CorePac includes a power-down controller (PDC). The PDC can power-down all of the following components of the DSP C66x CorePac and internal memories of the DSP subsystem:

- C66x CPU
- L1P Memory
- L2 Memory
- Cache controllers
- Entire TMS320C66x DSP CorePac

Refer to the *Power-Down Controller* in the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C) for detailed descriptions of the DSP C66x CorePac components power-down control.

5.3.2.2.3.3 DSP C66x CorePac Bandwidth Manager (BWM)

The DSP C66x CorePac implements a bandwidth manager (BWM) to assure that some requestors do NOT block resources in the C66x CorePac DSP for extended periods of time.

Refer to the *Bandiwdth Management Architecture* in the*TMS320C66x DSP CorePac User Guide*, (SPRUGW0C) for detailed descriptions of the DSP C66x CorePac components power-down control.

5.3.2.2.3.4 DSP C66x CorePac Memory Protection Hardware

The C66x Core Pac memory protection architecture introduces in the DSP a combination of DSP privilege levels and a memory system permission structure. This provides several benefits to the system, as follows:

The DSP C66x CorePac MP events are exported outside the DSP C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **memory protection fault** events listed in the Table 5-5.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: The memory protection exception events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

NOTE: IDMA, DMA or System initiators should not issue read/write requests to regions of DSP L1P, L1D, or L2 memory configured as cache. In such cases the corresponding MPPA register should be set to 0x0 to disallow external read/write accesses.

Refer to the section *Memory Protection* in the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C) for detailed descriptions of the DSP C66x CorePac components power-down control.

5.3.2.2.3.5 DSP C66x CorePac Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the DSP C66x CorePac. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port.

The IDMA configuration / status registers themselves are part of the DSP_ICFG and are visible only to C66x CPU.

NOTE: **The IDMA cannot transfer data to or from the internal DSP memory-mapped register space (DSP_ICFG).**

The IDMA exception is mapped to the system level ERRINT_IRQ interrupt event. For more details, refer to the Section 5.3.4.2.2 and the Table 5-5.

The DSP C66x CorePac IDMA error event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"EMC_IDMAERR"** event in the Table 5-5.

NOTE: The IDMA exception error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

The IDMA is fully described in the section *Internal Direct Memory Access (IDMA) Controller* of the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.2.3.6 DSP C66x CorePac External Memory Controller

The DSP C66x CorePac has an embedded External Memory Controller which acts as a bridge between the DSP C66x CorePac CPU and the remaining part of DSP subsystem. It implements two ports interfacing the DSP C66x CorePac environment:

- An external peripheral 32-bit CFG port which acts as an (DSP CPU cfg) initiator on the DSP_NoC L2 interconnect. It is the root source of all C66x CPU external configuration traffic **(excluding the DSP_ICFG traffic which takes place only within the DSP C66x CorePac)** towards the subsystem.
- An SDMA slave port which is a target on the L2 DSP_NoC interconnect. It generally accepts traffic initiated on DSP_NoC by the:
  - DSP_EDMA_TC0 and DSP_EDMA_TC1
  - DSP external slave port on the L3_MAIN

In summary:

- The CPU CFG port provides access to the memory-mapped registers which control various peripherals

Copyright © 2018–2019, Texas Instruments Incorporated

and resources within the DSP subsystem, such as the MMUs, DSP_EDMA controllers, DSP system control and wakeup logic, DSP NoC itself, DSP external peripherals, etc.

- The DSP system masters found outside the DSP C66x CorePac such as the DSP_EDMA controllers (TC0 and TC1) or L3_MAIN masters (device MPU, IPU1, IPU2, etc.) access the SDMA slave port to reach resources inside the DSP C66x CorePac. In respect to the SDMA port, the DSP C66x CorePac is the slave in the transaction.

The DSP_EMC controller adds following functionalities to the DSP C66x CorePac:

- Reporting errors related to the C66x CPU external peripheral configuration bus (associated registers)

NOTE: Regarding PrivID versus AID mapping functionality of the EMC, the C66x DSP CorePac is able to distinguish ONLY "local" vs "external" requests. The device integrated C66x DSP CorePac has the SDMA PrivID input tied-off to a value of 0x0. On DSP C66x CorePac SDMA port, this means that no distinguishing can be made between external requests which come over DSP_NoC interconnect from local DSP_EDMA and those coming from other initiators accesing DSP via the device L3_MAIN interconnect.

This limits the funcitionality of the internal memory protection registers.

The DSP C66x CorePac EMC error event is exported outside the DSP C66x CorePac in the subsystem, and is capable to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **EMC_BUSERR** event in the Table 5-5.

NOTE: The EMC configuration bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

For various DSP_NoC initiator vs target mappings, refer to the Table 5-8.

Note that, there are DSP_NoC pressure (Mflag bus) controls in DSP_SYSTEM logic related to the C66x CPU CFG and DSP_NoC SDMA init traffic. They are described in the Section 5.3.8.3.

The EMC functionalities / registers are fully described in the section *External Memory Controller (EMC)* of the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.2.3.7 DSP C66x CorePac Extended Memory Controller

The DSP C66x CorePac located extended memory controller (DSP_XMC_CTRL) implements a local DMA master port (MDMA) which provides the primary path for C66x CPU and cache requests to the device level memories such as (DDR or L3 SRAM) and peripheral / memory mapped register space. Via some additional logic, including DSP_SYSTEM controls and a local DSP MMU - DSP_MMU0 on the path (with option to bypass), C66x local MDMA port is mapped to the DSP subsystem CPU master port (i.e. MDMA master port of the DSP CPU on L3_MAIN). The DSP C66x Corepac MDMA port is mapped to the DSP Subsystem CPU Master Port (with DSP_MMU0 involved or not involved) to allow fast accesses (DSP_NoC not involved) to the external SDRAM (via the L3_MAIN and DMM) or to L3 SRAM (via the L3_MAIN).

The memory protection settings in MPAX defines types of the memory accesses permitted on various address ranges within DSP C66x CorePac 32-bit address map.

The DSP_XMC_CTRL also instantiates program and data prefetch buffer logic to reduce time during servicing read requests from the L1D, L1P and L2 memory controllers. The aim is to buffer program and data fetches from external L3_MAIN memory locations. While the program prefetch buffer is organized as 4 entry x 32 byte, the data prefetch buffer is organized in 8 slots, with 128 bytes per slot. The DSP_XMC_CTRL prefetch reduces the penalty associated with accesses to the L3_MAIN SDRAM upon L1P, L1D and L2-cache read-misses.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: the DSP_XMC_CTRL registers are part of the DSP_ICFG space, hence they are not accessible outside the DSP C66x CorePac (visible only to the C66x CPU).

In summary the DSP_XMC_CTRL provides :

- a master path from the DSP C66x CorePac level 2 cache / SRAM memory to device memory such as SDRAM or L3 SRAM or peripheral / MMR address space.
- memory protection on external address ranges related to L3_MAIN RAMs (via MPAX unit) :
  - 16 user-defined address ranges (MPAX segments) can be used to divide external memory space
- Address translation
- Data and Program prefetch buffer logic
- 12- address candidate buffer that acts as a "stream detection filter"

NOTE: The device DSP subsystem does NOT use the DSP C66x CorePac multicore shared memory controller (MSMC) port to add more static RAM within subsystem boundaries, i.e. no additional SRAM is available in the DSP except for the L1P, L1D and L2 memories. Only the DSP_XMC_CTRL controller MDMA port on the L3_MAIN interconnect is used to extend DSP available RAM memory via a direct or DSP_MMU0 translated access to the device EMIF DDR memories and OCMC RAMs.

NOTE: **Only the memory protection function of the DSP_XMC_CTRL MPAX unit is intergated** and used in the device DSP subsystem. The MDMA port 32-bit to 36-bit address extension function is NOT used in the device DSP because L3_MAIN address bus width is 32-bit. The DSP_MMU0 does NOT perform an address size (32b -> 36b) extension as well.

The XMC functionalities / registers are fully described in the section *Extended Memory Controller (XMC)* of the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.2.3.7.1 XMC MDMA Accesses at DSP System Level

5.3.2.2.3.7.1.1 DSP System MPAX Logic

The default configuration of MPAX registers provides a 32-bit view of system memory on L3_MAIN.

In summary, each MPAX segment (mentioned above) is programmed with a starting virtual base address, segment sizes from 4 GiB down to 4 KiB, replacement address (i.e., physical address); and permission attributes. Provided that DSP_MMU0 can be used to perform address translation, in most cases the replacement address will equal the base address (i.e., virtual == physical from DSP C66x CorePac perespective).

The system level implementation of MPAX logic allows the C66x CPU to change permission without being required to flush the cache.

The C66x CPU subsystem relies on the MPAXn.PERM field to properly configure the permissions for remote address ranges. The MDMA.rperm[6:0] signals are tie-off to a fixed value of 0x7F on the DSP C66x CorePac boundary.

5.3.2.2.3.7.1.2 MDMA Non-Post Override Control

The C66x corepac submits writes denoted as either “cacheable” or non-cacheable. Write accesses that are non-cacheable will be submitted as interconnect (L3_MAIN) non-posted writes; whereas write accesses that are cacheable are submitted as interconnect posted writes. An exception for the cache writes to L3_MAIN is that in the case of a cache block write-back operation (when actual cache evict busrts are actually issued towards L3_MAIN connected memory), a non-posted write is submitted.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: In order to provide a safety net for interconnects that may do aggressive reordering, a memory-mapped register SW control is provided - DSP_SYS_BUS_CONFIG[24] NOPOSTOVERRIDE. When set, this results in all write commands being issued as non-posted. This bit defaults to set, and thus the default behavior is for non-posted writes to be used exclusively.

5.3.2.2.3.8 L1P Memory Error Detection Logic

The L1P memory detection logic (no correction is implemented) uses a 4-bit parity per 256-bit location (1-bit parity per 64-bit line quadrant).

The L1P error detection logic features:

- L1P error detection command, status and address controls (registers)
- L1P_ED error detection exception / interrupt to the DSP_INTC upon DMA / IDMA access
- a direct exception event to C66x CPU (DSP_INTC not involved) upon parity error during a program fetch from L1P-cache
- L1P-cache error recovery

The L1P parity error detection event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"PMC_ED"** event in the Table 5-5.

NOTE: The L1P error detection event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

For more details on L1P error detection logic, refer to the section *L1P Error Detection*, of the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.2.3.9 L2 Memory Error Detection and Correction Logic

The L2 Memory error detection and correction logic (ECC) implements a distance-3 “detect 2, correct 1” Hamming code based error correction / detection algorithm. A 12-bit hamming code per 256-bit is used.

The L2 error detection and correction logic features:

- L2 error detection command, status and address controls (registers)
- L2 EDC enable
- L2 error detection event counter
- 2x L2 EDC exception / interrupts mapped to the DSP_INTC :
  - L2_ED1 = "error corrected" event
  - L2_ED2 = "error-not-corrected" event

The two L2 memory error correction events are exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"UMC_ED1" and "UMC_ED2"** events in the Table 5-5.

NOTE: The L2 error detection events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

Copyright © 2018–2019, Texas Instruments Incorporated

For more details on L2 error detection and correction logic, refer to the section *L2 Error Detection and Correction* of the*TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.3.2.3 DSP Debug and Trace Support

The DSP subsystem offers full support for the native DSP C66x CorePac debug features. This includes Advanced Event Triggering (AET) and Trace.

5.3.2.3.1 DSP Advanced Event Triggering (AET)

AET capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

5.3.2.3.2 DSP Trace Support

Trace is a debug technology that provides a detailed, historical account of application code execution, timing, and data accesses. Trace collects, compresses, and exports debug information for analysis. Trace works in real-time and does not impact the execution of the system. Trace is supported via Code Composer Studio.

See also the Chapter 35, *On-Chip Debug Support* .

5.3.3 DSP System Control Logic

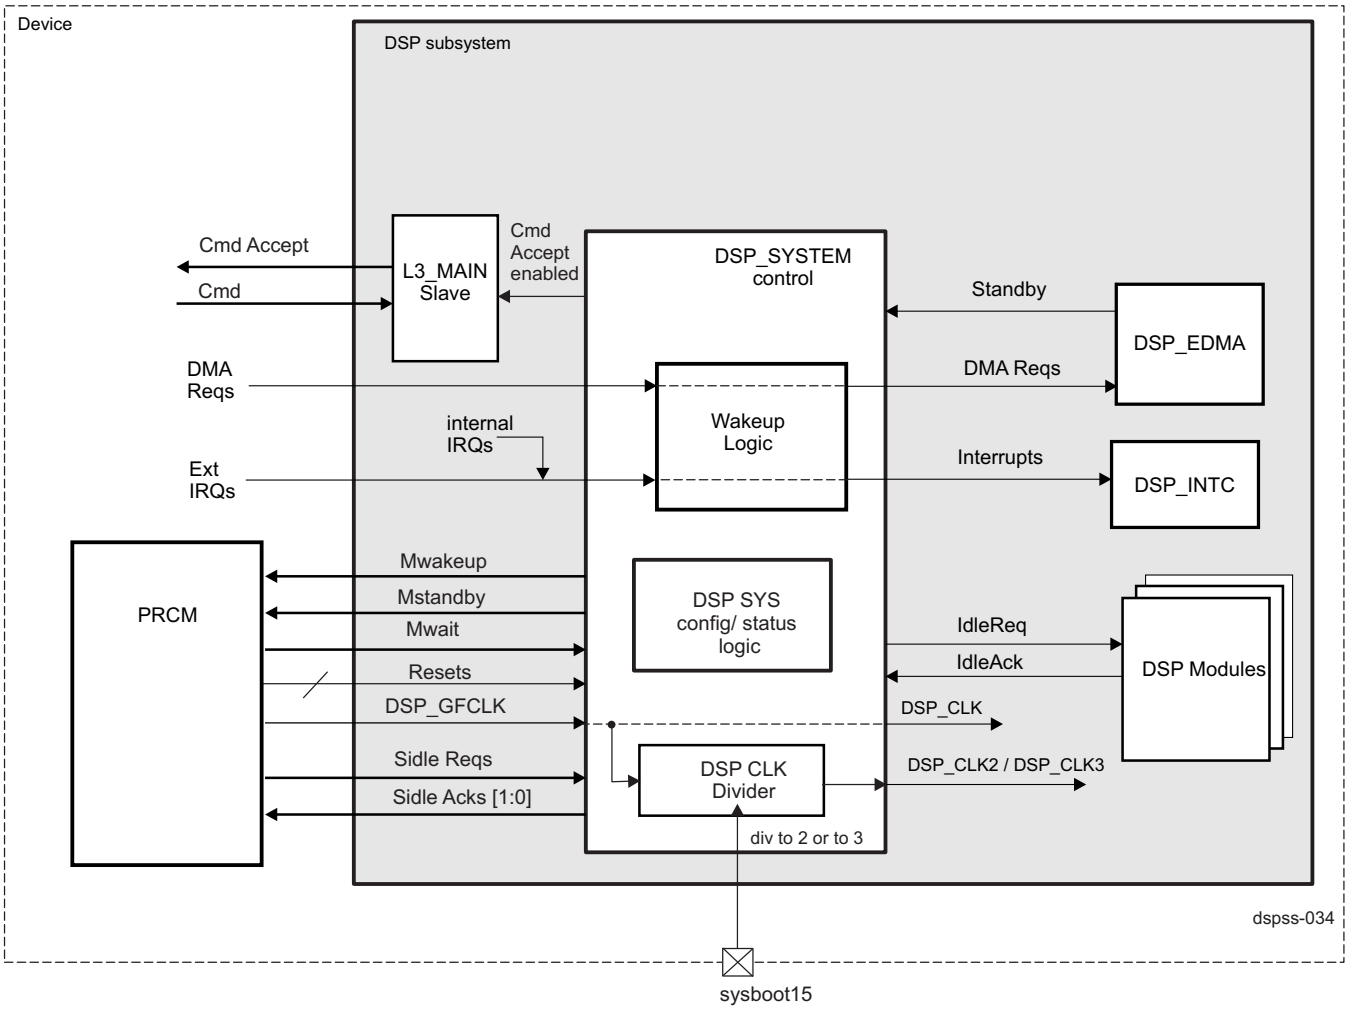
The DSP_SYSTEM module controls the following functions:

- Generation of the divided clocks (DSP_CLK2 or DSP_CLK3) to all components of the DSP subsystem
- Synchronization of the DSP divided clocks
- PRCM module power handshaking
- Reset input resynchronization of the active-to-inactive transition to the CD1_CLK clock
- DSP subsystem top level configuraiton registers and its access from the DSP core.

Figure 5-3 highlights the DSP_SYSTEM and its connectivities to the surrounding blocks within the subsystem and in the device.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 5-3. DSP_SYSTEM Block Diagram



5.3.3.1 DSP System Clocks

The DSP1 and DSP2 subsystems inputs a primary non-divided clock (DSP1_FICLK / DSP2_FICLK) and based on it (DSP_CLK1), internally generates either **a divided by 2 clock** (DSP_CLK2) version or **a divided by 3 clock** (DSP_CLK3). The divided clock determines the operation rate of the DSP subsystem logic and bus interfaces. The division is defined upon device boot time through signal level externally applied on the device **sysboot15** input. The actual bit configuration is latched upon power-on reset in Control Module register CTRL_CORE_BOOTSTRAP[15] SYS_BOOT_15_CLOCK_DIVIDER boot status bit. For more details, refer to the Section 19.4.6.14.1, *System Boot Status Settings* of the chapter, *Control Module*.

NOTE: Only DSP_CLK3 clock is supported on this family of devices. The DSP clock divider is internally tied-off (sysboot15 is not used for DSP clock selection).

The clock operating mode setting (DSP_CLK2 or DSP_CLK3) must be static just before and continually after reset deassertion. This signal will also drive the configuration to the DSP C66x CorePac for the XMC_MDMA_CLK, EMC_SDMA_CLK, and EMC_CFG_CLK configurations.

The DSPSS1 / DSPSS2 subsystem input clock frequency (DSP_CLK1) corresponds to the PRCM DSP1_GFCLK / DSP2_GFCLK frequency that is configured in the device PRCM registers.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: For valid DSP_CLK1 (and hence for DSP_CLK3 = DSP_CLK1 / 3) frequency range, see the Operating Performance Points section of the device Data Manual.

The Section 5.3.2 also shows the distribution of the different DSP subsystems blocks within the two DSP local clock domains CD0_CLK (running on DSP_CLK frequency) and CD1_CLK (running on DSP_CLK2 or DSP_CLK3 frequency).

5.3.3.2 DSP Hardware Resets

The DSP uses the same reset sources than those mapped to the DSP C66x CorePac; i.e. DSP C66x CorePac reset inputs will be pinned out as DSP system reset inputs.

The Table 5-4 summarizes the DSP hardware reset inputs and their functional descriptions.

Table 5-4. Summary of the DSP1 and DSP2 Hardware Resets

DSP1 reset input	DSP1 reset "done" output to PRCM	Description
DSP1_PWR_RST	-	This is power-on reset signal used inside DSP1 to reset mainly the emulation logic. It resets the entire DSP1 logic.
DSP1_RST	-	Reset signal used to reset all logic inside DSP1 except Emulation logic.
DSP1_LRST	-	Reset applied ONLY to the C66x CPU inside DSP1
-	DSP1_LRST_DONE	Indicates completion of the DSP1 local C66x CPU reset to device PRCM
DSP2 reset input	**DSP2 reset "done" output to PRCM**	**Description**
DSP2_PWR_RST	-	This is power-on reset signal used inside DSP2 to reset mainly the emulation logic. It resets the entire DSP2 logic.
DSP2_RST	-	Reset signal used to reset all logic inside DSP2 except Emulation logic.
DSP2_LRST	-	Reset applied ONLY to the C66x CPU inside DSP2
-	DSP2_LRST_DONE	Indicates completion of the DSP2 local C66x CPU reset to device PRCM

See also the Section 5.2 for more information on the PRCM reset sources to DSP reset inputs connectivity.

Refer to the Section 3.5.6.6, *DSP1 Subsystem Power-on Reset Sequence* and the Section 3.5.6.8, *DSP2 Subsystem Power-on Reset Sequence* in the chapter, *Power, Reset and Clock Manamgement* for more details on the DSP1 and DSP2 power-on reset sequence, respectively.

NOTE: In the case of DSP1 / DSP2 recovery from the “Powerdown-grid off”, a full power-on-reset sequence is required before re-booting and resuming functional operation.

The DSP host (device MPU) software must ensure that the PRCM functional clock DSP1_GFCLK / DSP2_GFCLK is enabled to the DSP1 / DSP2, respectively, prior to starting the DSP1 / DSP2 power-on reset sequence.

Copyright © 2018–2019, Texas Instruments Incorporated

5.3.3.3 DSP Software Resets

During a software reset on the DSP, all resets described in Table 5-4 are asserted, except for the power-on DSP_PWRON_RST signal which remains de-asserted in this case.

The DSP subsystem does NOT implement any local software reset controls. The software reset assertion and DSP_LRST completion monitoring is done in PRCM located registers (part of the DSP1_PRM / DSP2_PRM address space).

Refer to the Section 3.5.6.7, *DSP1 Subsystem Software Warm Reset Sequence* and the Section 3.5.6.9, *DSP2 Subsystem Software Warm Reset Sequence* in the chapter, *Power, Reset and Clock Manamgement* for more details on the DSP1 and DSP2 software reset sequence and related software controls, respectively.

5.3.3.4 DSP Power Management

The supported power-down modes are:

- Slave idle and master standby protocols for powerdown
- "Disconnect from interconnect" handshake for init and target busses
- Clock Stop mode - wakeup on interrupt or DMA event
- Grid OFF mode : No power supply is switched-on. (This mode is not supported on this device. Neither of the two DSP subsystems has a power switch, making both power domains Always-On.)

The DSP C66x CorePac natively supports “CLKSTOP/Static Powerdown” mode of operation. Once the device PRCM restores clocks and power supply, then the DSP C66x CorePac can exit static-powerdown.

The DSP_SYSTEM wakeup logic is implemented in the "always-on" clock / power supply domain. This logic monitors new interrupts / events and will drive the IDLE wakeup request when a new interrupt / event occurs.

5.3.3.4.1 DSP System Powerdown Protocols

For the Static powerdown mode, the device PRCM will control whether clocks are gated, or whether supplies are reduced or removed.

In the static powerdown modes - the DSP recognizes new level interrupts while in a clock-gated state (and drive wakeup request). During this powerdown mode all internal state will be retained, including DSP C66x CorePac, interconnect, EDMA, memories, etc.

The following protocols are implemented with PRCM:

- Slave idle protocol with device PRCM for powerdown (wake-up capable)
- Master standby protocol with device PRCM for powerdown
- Interconnect disconnect for master and slave ports

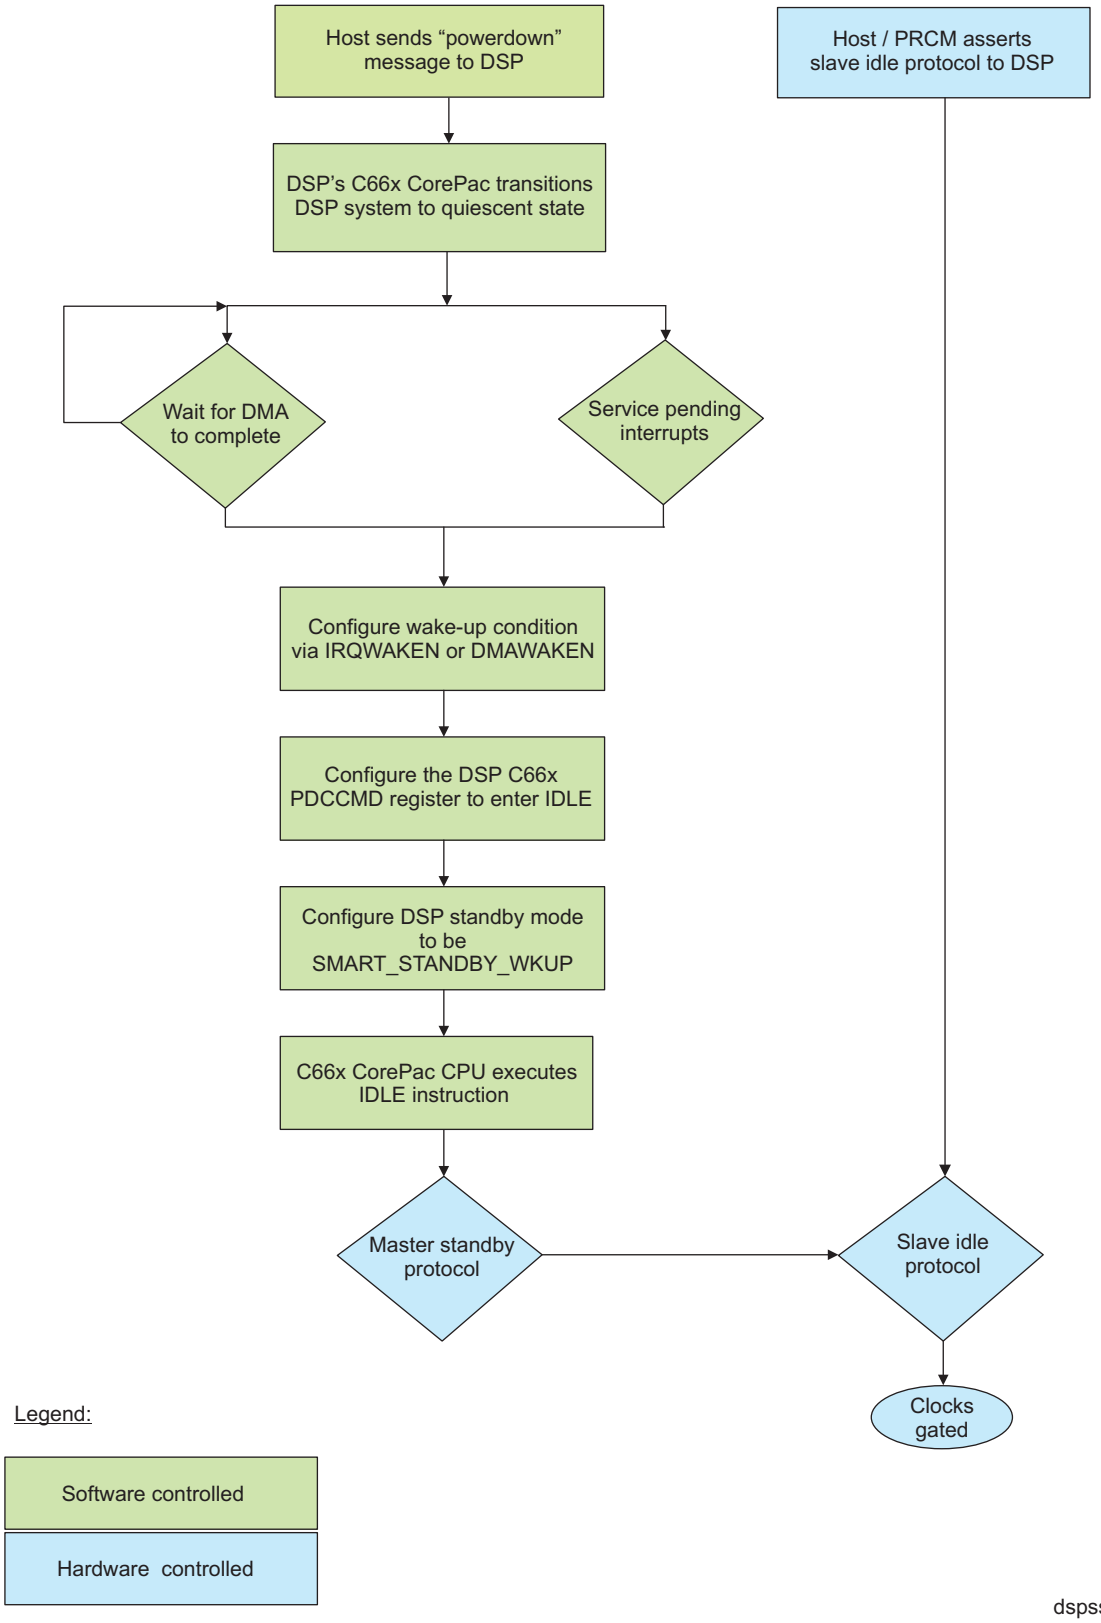
The Master standby and slave idle protocols behaviour is controlled in the DSP_SYS_SYSCONFIG register.

5.3.3.4.2 DSP Software and Hardware Power Down Sequence Overview

Figure 5-4 highlights the high level flow-chart for entry into any of the DSP powerdown modes. The system host (typically) first informs the DSP that it should enter a powerdown mode. The host (g.h. device MPU) sends a software message (normally via system level mailbox+interrupt). In parallel, the PRCM (via host or DSP programmation) will hardware assert an SIdleReq request to the DSP via the IDLE Protocol connection. At the next stage, the C66x CPU, in general, performs any software bookkeeping necessary to transition the DSP subsystem to a quiescent state. This may include : waiting for outstanding DMA transfers to complete, waiting for outstanding DMA transfers to complete, etc. The C66x processor should finally execute the IDLE instruction when it is ready to be powered-down. Assuming the DSP_SYS_SYSCONFIG[5:4] STANDBYMODE is enabled, then the hardware will transition to an idle state and notify to the system the intention to enter powerdown state to the system via the master standby and slave idle protocols. After IDLE and MSTANDBY handshake is completed, the DSP clocks are optionally gated.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 5-4. Extended Duration Sleep Software and Hardware Sequence



Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: The PM_DSPx_PWRSTCTRL[1:0] POWERSTATE bit field in device PRCM must be set to 0x3 (ON state) prior to performing the sequence shown in Figure 5-4 for the transition to be successful.

5.3.3.4.3 DSP IDLE Wakeup

In order to facilitate auto-wakeup of DSP C66x, the IDLE protocol's wakeup capability is used. Wakeup operation is enabled if DSP_SYS_SYSCONFIG[3:2] IDLEMODE is set to 0x3.

In this mode, while in IDLE state, if an external input interrupt source is asserted (if enabled via the DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1 mask) or if an external DMA event source is asserted (if enabled via the DSP_SYS_DMAWAKEEN0 / DSP_SYS_DMAWAKEEN1 mask) or if the DSP subsystem NMI input is asserted **(note that there is no wake enable mask for the non-maskable interrupt)** then the Mwakeup signal is asserted to the PRCM which is expected to observe the Mwakeup. Upon such assertion the PRCM enables the clocks, exiting the "Standby" and "Idle" states. at this point the C66x CPU is able to branch to the pending interrupt service routine. The MWakeup is deasserted when all IRQ or DMA requests enabled in the DSP_SYS_IRQWAKEEN0/1 and DSP_SYS_DMAWAKEEN0/1 are deasserted.

The Wakeup logic controlling assertion of the MWakeup request is completely asynchronous because in IDLE mode the clock may not be present. It relies on level sensitive interrupts.

NOTE: The DSP_EDMA must be manually removed from IDLE / Standby state. During that time, it is possible that the EDMA input event is no longer pending and may not have been recognized/latched as an EVENT to the EDMA. In that case, the user SW can enable the DSP EDMA_WAKE_INT (in associated DSP_SYS_EDMAWAKE0_IRQENABLE_SET register) to recognize in the (DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW /DSP_SYS_EDMAWAKE0_IRQSTATUS) which specific EDMA event was asserted and caused the wakeup condition. The DSP software can then trigger the corresponding DSP_EDMA channel manually (by setting the ESR) or by servicing the interrupt/event manually via reads and writes. For more details, refer to the Section 5.3.5.1.

5.3.3.4.4 DSP SYSTEM IRQWAKEEN registers

The DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1 masking bits must be appropriately set for any valid interrupt mapped from device IRQ_CROSSBAR to the DSP subsystem boundary, to enable its path (passing through the DSP_SYSTEM wakeup logic) to the DSP local interrupt controller - DSP_INTC.

CAUTION

In order for a given interrupt to be serviced by the DSP (even when the Idle Instruction is NOT being executed), the Interrupt must be enabled in the coresponding DSP_SYS_IRQWAKEEN0 or DSP_SYS_IRQWAKEEN1 register.

5.3.3.4.5 DSP Automatic Power Transition

This section provides register details for configuring the DSP1 subsystem in automatic power transition mode. The same should be considered for DSP2 in corresponding PRCM and DSP2 related registers.

The DSP1 module is supposed to be configured to automatic management in PRCM.DSP1_CM_CORE_AON via setting the register CM_DSP1_DSP1_CLKCTRL[1:0] MODULEMODE bitfield to 0x1. The DSP1 clock domain is supposed to be configured in automatic "HW_AUTO" transition (setting bitfield CM_DSP1_CLKSTCTRL[1:0] CLKTRCTRL=0x3).
The power state (controls are in the PRCM.DSP1_PRM instance) to reach upon a sleep transition is configured in the PM_DSP1_PWRSTCTRL[1:0]POWERSTATE bitfield.

Copyright © 2018–2019, Texas Instruments Incorporated

5.3.4 DSP Interrupt Requests

The DSP subsystem relies on the DSP C66x CorePac local interrupt controller - DSP_INTC for mapping the various input interrupts to the C66x CPU, that are :

- generated outside the DSP, by the device intergated modules and subsystems
- generated within the DSP subsystems but outside the DSP C66x CorePac
- generated by different components within the DSP C66x CorePac

In addition, a non-maskable input interrupt, direct mapped on a C66x processor NMI input is implemented. It is mapped via a register that resides within the device Control Module. Both the maskable interrupts and the non-maskable interrupts are synchronized internally.

Part of the DSP subsystem module generated interrupts which are output as follows:

- DSP_EDMA interrupts
- DSP_MMU0 and DSP_MMU1 interrupts
- Error interrupts

Figure 5-5 shows how are the interrupt sources organized. To manage and expand the interrupt capabilities of the DSP C66x CorePac (internal and external interrupt requests), the DSP subsystem includes two levels of interrupt control :

- The DSP C66x CorePac local Interrupt controller - DSP_INTC
- The System control logic - DSP_SYSTEM

Figure 5-5. DSP Subsystem Interrupt Management

5.3.4.1 DSP Input Interrupts

In summary, the DSP_INTC accepts up to 124 event inputs, and flexibly maps those down to 12 interrupt inputs to the DSP. The mapping can be 1:1 (input:output), or can use the event combiner to map multiple interrupts (within a 32-bit group) to one of the DSP interrupt inputs. In general, many of the 124 interrupt controller inputs are collected within the DSP C66x CorePac, and are NOT available at the DSP C66x CorePac boundaries.

The C66x CPU dropped event is exported outside the C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"INTERR" event** listed in the Table 5-5.

NOTE: The dropped CPU event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

Part of the input interrupts, generated by DSP peripherals that are located outside the DSP C66x CorePac - DSP_EDMA (DSP_EDMA_CC, DSP_EDMA_TC0, DSP_EDMA_TC1) , DSP_MMU0, DSP_MMU1 and DSP_NoC, are also mapped to outputs at the DSP subsystem boundary, such that they can be exported to system hosts (MPU, etc.) via the device IRQ_CROSSBAR.

Of particular interest, MMUs (DSP_MMU0 and DSP_MMU1) interrupts will typically be serviced by the device MPU instead of by the local DSP core.

Any interrupt input at DSP subsystem boundaries (i.e. excluding the DSP subsystem internal IRQ sources that reside in and outside the DSP C66x CorePac) can be used to wake-up the DSP subsystem from an IDLE state. This is described in the Section 5.3.3.4.3 and is controlled by the DSP_SYSTEM logic register DSP_SYS_SYSCONFIG [3:2] IDLEMODE bitfield along with the DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1 registers.

CAUTION

The DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1 bits MUST be enabled for externally mapped interrupts (DSP_INTC[95:32]) to be serviced by the DSP regardless of the DSP power state (IDLE or non-IDLE).

The DSP C66x CorePac DSP_INTC registers are NOT readable by any entity other than the C66x CPU, because they are part of the DSP_ICFG C66x CorePac internal configuration space (see also the Section 5.3.10). Hereby, only the C66x itself is able to service these interrupt events. The only way for these interrupts to be cleared is for the DSP CPU to clear the state in the EVTFLAGi (where i=0 to 3) register, or via reset assertion.

NOTE: For cases where the DSP maps an interrupt directly, the DSP is not strictly required to clear the EVTFLAGi register. User software must take the extra step of clearing the EVTFLAGi to cause the corresponding output interrupt to be cleared and re-asserted upon a new input event assertion.

5.3.4.1.1 DSP Non-maskable Interrupt Input

The device DSP also supports a non-maskable interrupt (NMI) directly mapped to the NMI input of the C66x CPU. This line is also mapped to the NMEVT input of the DSP local INTC, and can be used as an exception signal, too. At system level, the NMI interrupt mapping to the DSP_INTC is controlled via the **device core Control Module** register as follows:

- CTRL_CORE_NMI_DESTINATION_2 [15:8] DSP1 = 0x1 enables the DSP1 to receive the NMI coming from the device **nmin_dsp** input.
- CTRL_CORE_NMI_DESTINATION_2 [23:26] DSP2 = 0x1 enables the DSP2 to receive the NMI

Copyright © 2018–2019, Texas Instruments Incorporated

coming from the device **nmin_dsp** input.

For more details on the NMI receive enable bit mapping, refer to the Section 19.5, *Control Module Register Manual* in the chapter, *Control Module*.

5.3.4.2 DSP Event and Interrupt Generation Outputs

5.3.4.2.1 DSP MDMA and DSP EDMA Mflag Event Outputs

The Mflag events generated by DSP subsystem EVTOUT bus are represented in the Figure 5-5.

A couple of the DSP EVTOUT bus outputs - EVTOUT[31] and EVTOUT[30] are used for generation of MFLAGs dedicated to the DSP MDMA and EDMA ports, respectively. DSP MFLAGs are connected directly to DMM and EMIF. The DSP MFLAGs participate in the DMM Emergency and EMIF MFLAG prioritization schemes. At the L3 Level Bandwidth regulators connected to the DSP MDMA and EDMA ports can be used to control DSP traffic versus other device traffic.

The device DSP subsystem is able to generate the 2 output Mflag events via the following DSP_SYSTEM module located registers :

- DSP_SYS_EVTOUT_SET[31:30]
- DSP_SYS_EVTOUT_CLR[31:30]

The current state of the outputs can be detected by reading any of these "pseudo" register bits.

NOTE: Only EVTOUT[31:30] outputs are implemented in the device, hence only bits [31:30] of the mentioned DSP_SYS_EVTOUT_x registers are used.

The DSP_SYS_EVTOUT_SET register unconditionally drives the corresponding output event to '1'. The DSP_SYS_EVTOUT_CLR register unconditionally drives the corresponding output event to a '0'.

5.3.4.2.2 DSP Aggregated Error Interrupt Output

The aggregated error interrupt of the DSP subsystem is shown in the Figure 5-5.

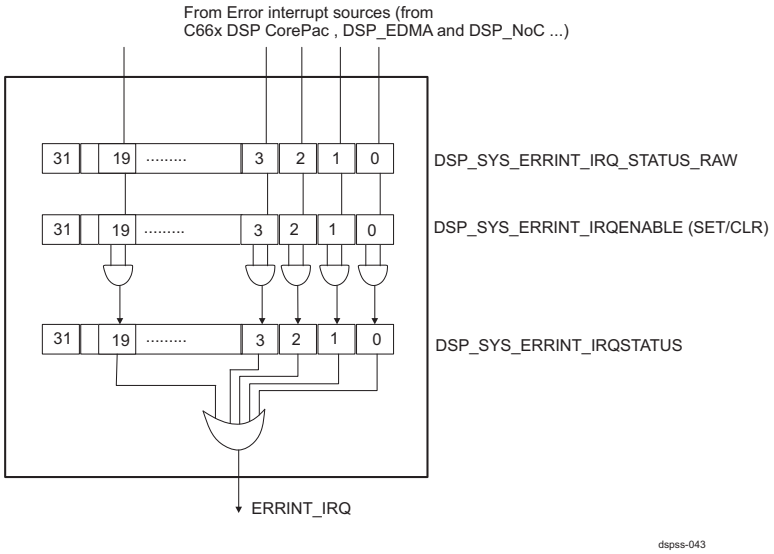
The subset of those events that correspond to: **DSP C66x CorePac generated error events**, **DSP_EDMA error interrupts** and **L2 DSP_NoC interconnect error interrupt**, is reduced by an OR-schematic to a single ERRINT_IRQ output interrupt which is made available on DSP subsystem boundary. It is expected that one of the DSP system hosts monitors the interrupts/error conditions in safety conscious systems.

Figure 5-6 shows a functional representation of the DSP error interrupt "OR"-reduction logic. In summary, there exists **an unmasked status** (DSP_SYS_ERRINT_IRQSTATUS_RAW) register, two complementary enable bit-vector registers (DSP_SYS_ERRINT_IRQENABLE_SET / DSP_SYS_ERRINT_IRQENABLE_CLR), and a masked status register (DSP_SYS_ERRINT_IRQSTATUS). The ERRINT event is asserted when any enabled error interrupt input is asserted.

NOTE: The ERRINT_IRQ output can be programmatically mapped as the DSPi_IRQ_TPCC_ERR (where i=1 to 2) interrupt to all device (dsp hosts) interrupt controllers via the device IRQ_CROSSBAR. For more information on the IRQ_CROSSBAR module, see Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 19, *Control Module*.
For more information about the device interrupt controllers, see Chapter 18, *Interrupt Controllers*.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 5-6. ERRINT Diagram



The Table 5-5 details the mapping of error event output sources to the bit positions within the following DSP error event related registers :

- DSP_SYS_ERRINT_IRQSTATUS_RAW
- DSP_SYS_ERRINT_IRQSTATUS
- DSP_SYS_ERRINT_IRQENABLE_SET
- DSP_SYS_ERRINT_IRQENABLE_CLR

Following functional descriptions are valid for the above registers :

- **IRQ status raw register -** This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register -** This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register -** This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register -** This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

NOTE: A DSP_SYS_ERRINT_IRQSTATUS_RAW bit is set even if the corresponding event is NOT enabled in the DSP_SYS_ERRINT_IRQENABLE_SET.

Table 5-5. DSP ERRINT Interrupt Mapping

Interrupt Number	Name	Description
0	tpcc_errint_level	DSP EDMA CC error interrupt
1	tptc_errint0_level	DSP EDMA TC0 error interrupt
2	tptc_errint1_level	DSP EDMA TC1 error interrupt
3	noc_errint_level	DSP L2 Interconnect (DSP_NoC) error interrupt

Copyright © 2018–2019, Texas Instruments Incorporated

Table 5-5. DSP ERRINT Interrupt Mapping (continued)

Interrupt Number	Name	Description
4	INTERR	DSP C66x CorePac Dropped CPU Interrupt event
5	EMC_IDMAERR	DSP C66x CorePac Invalid IDMA Parameters
6	MDMAERREVT	DSP C66x CorePac VbusM Error Event
7	PMC_ED	DSP C66x CorePac Single bit error detected during DMA read
8	UMC_ED1	DSP C66x CorePac Corrected bit error detected
9	UMC_ED2	DSP C66x CorePac Uncorrected bit error detected
10	SYS_CMPA	DSP C66x CorePac CPU memory protection fault
11	PMC_CMPA	DSP C66x CorePac CPU memory protection fault
12	PMC_DMPA	DSP C66x CorePac DMA memory protection fault
13	DMC_CMPA	DSP C66x CorePac CPU memory protection fault
14	DMC_DMPA	DSP C66x CorePac DMA memory protection fault
15	UMC_CMPA	DSP C66x CorePac CPU memory protection fault
16	UMC_DMPA	DSP C66x CorePac DMA memory protection fault
17	EMC_CMPA	DSP C66x CorePac CPU memory protection fault
18	EMC_BUSERR	DSP C66x CorePac Bus Error Interrupt
19	Reserved	-
20	Reserved	-
21	Reserved	-
22	Reserved	-

Note that neither of the events, listed in Table 5-5 , is exported as a separate hardware interrupt off the DSP boundary.

5.3.4.2.3 Non-DSP C66x CorePac Generated Peripheral Interrupt Outputs

The non-DSP C66x CorePac interrupts generated by peripherals within the DSP subsystem are also summarized in the Figure 5-5.

Besides the aggregated error event ERRINT_IRQ interrupts – DSPi_IRQ_TPCC_ERR (where i=1 to 2), interrupts (see also Figure 5-5) **generated individually by DSPSS peripherals located outside the DSP C66x CorePac**, are mapped as separate IRQ outputs at DSP boundaries. They are sourced by the DSP_EDMA_CC, DSP_EDMA_TC0, DSP_EDMA_TC1, DSP_MMU0, DSP_MMU1 and DSP_NoC and exported to other host INTCs via the device IRQ_CROSSBAR. Refer to the Section 5.2, for more information on these DSP interrupt outputs mapping.

5.3.5 DSP DMA Requests

The DSP_EDMA_CC (channel controller) supports 64 hardware event inputs, that can be used to synchronize the 64 DMA channels. These event inputs are provided at the DSP subsystem boundary via the device DMA_CROSSBAR and can be mapped to sources within the device.

Copyright © 2018–2019, Texas Instruments Incorporated

The DSP subsystem receives DMA requests from certain peripherals, such as the McASP modules. The DMA requests path through the DSP logic is shown in Figure 5-7.

Similar to the interrupts received at DSP subsystem boundary, the DSP EDMA requests are first routed through the wakeup generation logic of the DSP_SYSTEM module, hence, each DMA request received by the DSP subsystem can wakeup the system from DSP low power modes (including wakeup from DSP OFF mode). To enable the DMA requests mapped via the DMA_CROSSBAR to **DSP_EDMA_CC [19:0]** inputs, corresponding bits in range [19:0] of the register DSP_SYS_DMAWAKEEN0 must be enabled in software.

CAUTION

The DMA request corresponding DSP_SYS_DMAWAKEEN0 / DSP_SYS_DMAWAKEEN1 MUST be enabled, for the DMA requests to be serviced by the DSP regardless of the DSP being in IDLE or active state.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 5-7. DSP DMA Requests

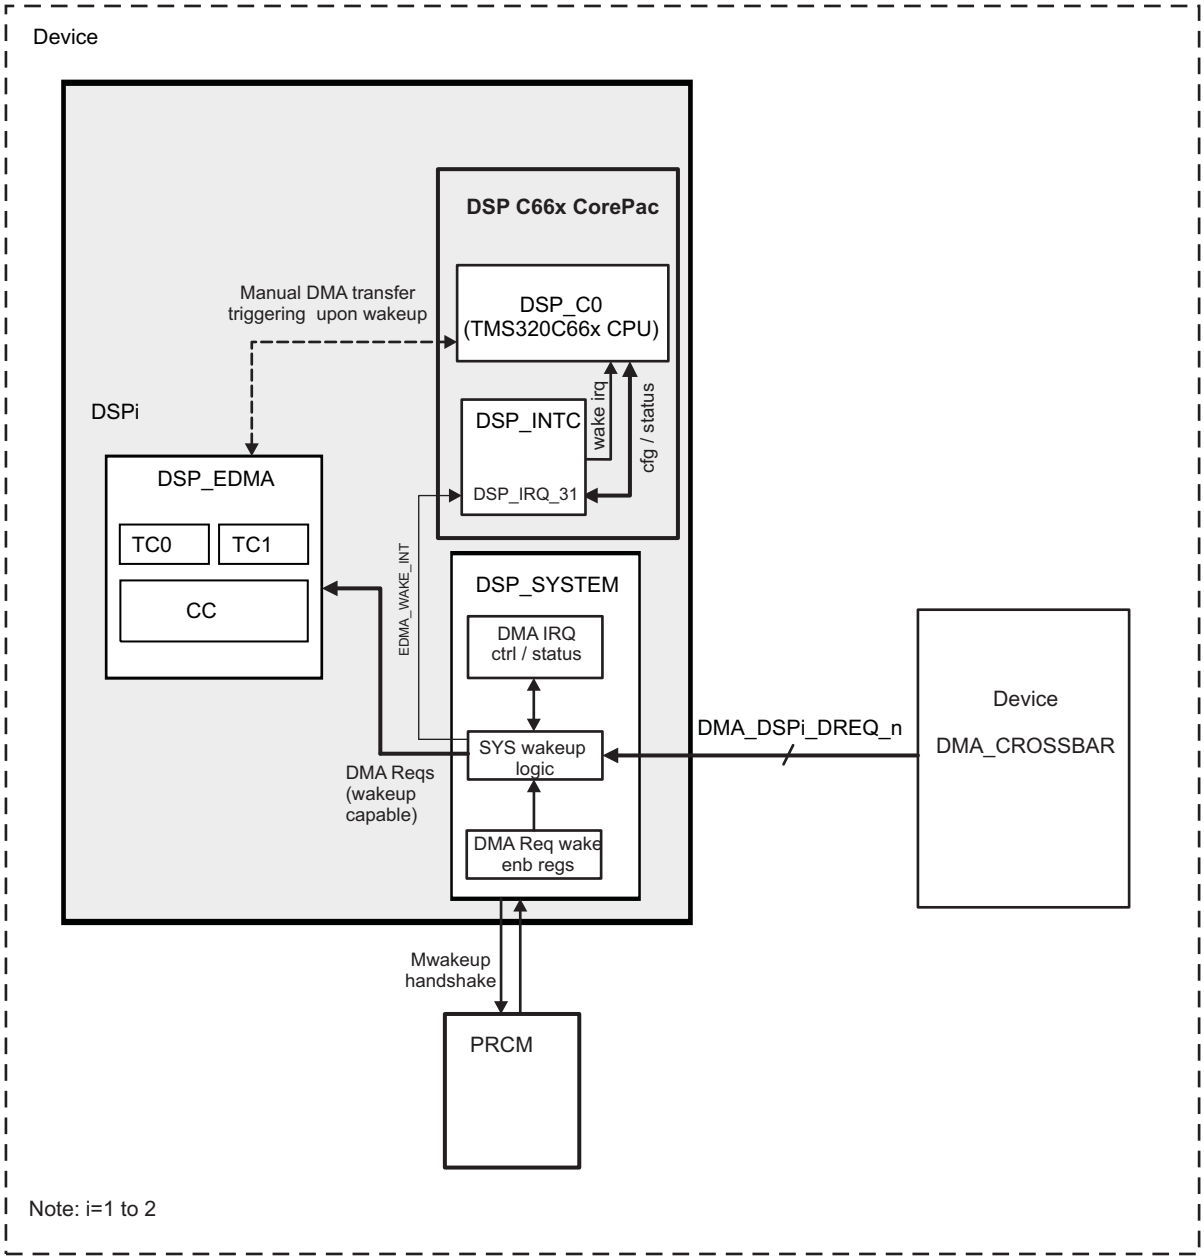


Table 5-6 and Table 5-7 list the default DMA sources for the DSP1_EDMA and DSP2_EDMA controllers. In addition, DSP1_EDMA / DSP2_EDMA inputs (DMA_DSP1_DREQ_[19:0] / DMA_DSP2_DREQ_[19:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 17-6. The CTRL_CORE_DMA_DSP1_DREQ_y_z / CTRL_CORE_DMA_DSP2_DREQ_y_z registers (where *y* and *z* are indexes of DSP1_EDMA / DSP2_EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

For more details on the device DMA_CROSSBAR multiplexing registers structure, refer to Section 19.4.6.5, *DMA_CROSSBAR Module Functional Description* of chapter, *Control Module*.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 5-6. DSP1_EDMA Default Request Mapping

DMA Request Line	DMA_ CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_ CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_DSP1_DREQ_0	1	CTRL_CORE_DMA_DSP1_DREQ_0_1[7:0]	128	McASP1_DREQ_RX	McASP1 receive event
DMA_DSP1_DREQ_1	2	CTRL_CORE_DMA_DSP1_DREQ_0_1[23:16]	129	McASP1_DREQ_TX	McASP1 transmit event

5.3.5.1 DSP EDMA Wakeup Interrupt

This section provides description of the registers used for the **EDMA wakeup interrupt** functionality, including the EDMA_WAKE_INT IRQ status and enable fields. The EDMA Wakeup Interrupt allows incoming EDMA events to be latched and an interrupt sent to the DSP (if enabled). This interrupt is generated in the DSP_SYSTEM as an single "OR-ed" output of all external DMA requests latched in DSP subsystem. This output is further synchronized to DSP_FCLK and mapped as the EDMA_WAKE_INT event to the DSP_IRQ_31 input of the C66x DSP CorePac DSP_INTC. The C66x CPU is expected to service the interrupt by triggering the corresponding EDMA channel manually, or by servicing the request via normal reads and writes (instead of using the EDMA). This functionality is required since the EDMA is not capable of following the smart wakeup protocol.

NOTE: The DSP_SYS_DMAWAKEEN0 / DSP_SYS_DMAWAKEEN1 registers are used for enabling the assertion of the 'Mwakeup' asynchronous wakeup request to the device PRCM upon DMA requests reception. The interrupt functionality of the registers: DSP_SYS_EDMAWAKE0_x covered in this subsection is specifically for generating **an wake interrupt** to the DSP. In most cases, the enable mask for the two sets of registers should be set to the same value.

The EDMAWAKE0 registers corresponding to the EDMA Events 19 thru 0 (msbit to lsbit) are as follows:

- DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW[19:0]
- DSP_SYS_EDMAWAKE0_IRQSTATUS[19:0]
- DSP_SYS_EDMAWAKE0_IRQENABLE_SET[19:0]
- DSP_SYS_EDMAWAKE0_IRQENABLE_CLR[19:0]

Following functional descriptions are valid for the above registers :

- **IRQ status raw register -** This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register -** This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register -** This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register -** This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

NOTE: A DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW bit is set even if the corresponding event is NOT enabled in the DSP_SYS_EDMAWAKE0_IRQENABLE_SET[19:0].

5.3.6 DSP Intergated Memory Management Units

5.3.6.1 DSP MMUs Overview

A standalone memory management unit (DSP_MMU0) is included within the DSP1 (DSP1_MMU0) and DSP2 (DSP2_MMU0) subsystems boundaries. The DSP_MMU0 is integrated on the C66x CPU MDMA path to the device L3_MAIN interconnect. This provides several benefits including protection of the system memories from corruption by DSP1 and DSP2 accidental accesses.

Copyright © 2018–2019, Texas Instruments Incorporated

A standalone memory management unit (DSP_MMU1) is included within the DSP1 (DSP1_MMU1) and DSP2 (DSP2_MMU1) subsystems boundaries. The DSP_MMU1 is integrated on the EDMA data path which starts from the L2 DSP_NoC interconnect and leaves the DSP subsystem on the DSP EDMA master port. This provides several benefits including protection of the device L3_MAIN memory space from corruption by DSP1 and DSP2 DMA (DSP1_EDMA and DSP2_EDMA, respectively) accidental accesses.

Both DSP MMUs generate interrupts which are internally mapped to the DSP C66x CorePac DSP_INTC and output to the device IRQ_CROSSBAR. See also the Section 5.2 and Section 5.3.4.

CAUTION

In the case of a page fault, a DSP C66x CorePac CPU is unable to service it's own DSP_MMU0 and DSP_MMU1 interrupts . The device MPU (Cortex-A15) is expected to manage any TLB patches as necessary.

Both DSP MMUs (on MDMA and EDMA paths respectively) have identical functionalities.

- 32-bit input and ouput address width (to match L3_MAIN address width)
- 32 TLB cache entries
- 32 + 1 tags
- 128-bit data bus for MDMA and EDMA

5.3.6.2 Routing MDMA Traffic through DSP MMU0

DSP C66x CPU traffic initiated on the DSP MDMA port can be optionally routed through the DSP_MMU0 on the 32-bit MDMA address path. This is controlled in two levels :

- **global** by the DSP_SYSTEM register DSP_SYS_MMU_CONFIG [0] MMU0_EN bit. This bit acts as a mux-select : setting it to 0b1 enables requests to use the DSP_MMU0; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP_MMU0 is disabled in DSP_SYSTEM and MDMA port traffic bypasses the DSP_MMU0.
- **local** by MMU enable control in a dedicated DSP_MMU0 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the Chapter 21, *Memory Management Units*.

NOTE: For the DSP_MMU0 to operate, SW should enable it both at the DSP_SYSTEM global level and DSP_MMU0 local register level.

When enabling the DSP_MMU0, software must take care that no transactions are in flight through that MMU. This is typically handled by issueing a DSP "MFENCE" instruction operation. Note that the local enable bit inside the DSP_MMU0 must be configured as normal (refer to the Chapter 21, *Memory Management Units*.)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set* of the *TMS320C66x DSP CPU and Instruction Set*).

In addition, the DSP_MMU0 traffic can be aborted in case of a lockup via the DSP_SYS_MMU_CONFIG [8] MMU0_ABORT bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP_MMU0 encounters a page fault that cannot be serviced.

For more information on device DSP_MMU0 functionality and register settings, refer to the Section 21.3, *MMU Functional Description* and Section 21.5, *MMU Register Manual*, in the chapter, *Memory Management Units*, respectively.

5.3.6.3 Routing EDMA Traffic thorugh DSP MMU1

The DSP_EDMA traffics initiated on the DSP EDMA master port can be optionally routed through the DSP_MMU1 on the EDMA address path. This is controlled in two levels :

- **global** by the DSP_SYSTEM register DSP_SYS_MMU_CONFIG [4] MMU1_EN bit. This bit acts as a

Copyright © 2018–2019, Texas Instruments Incorporated

mux-select : setting it to 0b1 enables requests to use the DSP_MMU1; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP_MMU1 is disabled in DSP_SYSTEM and EDMA traffic bypasses the DSP_MMU1.

- **local** by MMU enable control in a dedicated DSP_MMU1 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the Section 21.5, *MMU Register Manual*, in the Chapter 21,*Memory Management Units*.

NOTE: For the DSP_MMU1 to operate, SW should enable it both at the DSP_SYSTEM global level and DSP_MMU1 local register level.

When enabling the DSP_MMU1, software must take care that no transactions are in flight through that MMU. This is typically handled by disabling any EDMA transactions prior to enabling the MMU. Note that the local enable bit inside the DSP_MMU1 must be configured as normal (refer to the Chapter 21,*Memory Management Units*.)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set* of the *TMS320C66x DSP CPU and Instruction Set*).

In addition, the DSP_MMU1 traffic can be aborted in case of a lockup via the DSP_SYS_MMU_CONFIG [12] MMU1_ABORT bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP_MMU1 encounters a page fault that cannot be serviced.

For more information on device DSP_MMU1 functionality and settings, refer to the Section 21.3, *MMU Functional Description* and the Section 21.5, *MMU Register Manual*, in the chapter, *Memory Management Units*, respectively.

5.3.7 DSP Integrated EDMA Subsystem

This section represents an overview of the DSP integrated EDMA functionalities, as well as the subsystem level and device related register controls. For more details on the EDMA functionalities and programming registers, refer to the Section 17.2, *Enhanced DMA*.

5.3.7.1 DSP EDMA Overview

The enhanced-DMA subsystem which is part of the DSP1 (DSP1_EDMA) and the DSP2 (DSP2_EDMA) subsystems is the primary DMA engine for transfers between system memory (DDR and/or L3_MAIN SRAM) and DSP internal memories (L1s and L2).

The Channel Controller - DSP_EDMA_CC serves as the “user interface” of the DSP_EDMA. The two Transfer Controllers - DSP_EDMA_TC0 and DSP_EDMA_TC1 serve as the data transfer engines of the DSP_EDMA. The C66x CPU tipically programs the Channel Controller, which in turn submits Transfer Requests (TR) to the appropriate Transfer Controller. Interrupts are posted in the DSP_EDMA_CC upon transfer completion (if requested), and signaled to the C66x. The EDMA TC completion interrupt is not supported/connected.

The DSP_EDMA is primarily used to perform block transfers between DSP C66x CorePac memories (mostly L2 memory) and system memory (mostly DDR or L3 SRAM).

The DSP_EDMA is configured with 2 Queues (in the CC). Two DSP_EDMA traffic controllers (TC) offer high performance and preemptability of transfers. For typical use cases, it is expected that low latency/small payload transfers) use Queue0/TC0 and high bandwidth/large payload transfers (e.g., DDR on L3_MAIN or DSP local L2 SRAM) will use Queue1/TC1.

DSP_EDMA_CC configuration in the device features :

- 64x EDMA channels
- 8x QDMA channels
- 64x interrupt channels
- 128x PaRAM entries
- 2x Event Queues
- 2x Traffic controllers

Copyright © 2018–2019, Texas Instruments Incorporated

- memory protection support
- channel mapping capability
- 8x memory protected and Shadow Regions

DSP_EDMA_TC0/TC1 configuration in the device features :

- 2048 Byte FIFO support
- multitag support
- 16-bit data bus
- 4-level destination register depth
- 7-bit address for internal FIFOs
- 16 IDs for Read commands
- 16 IDs for Write commands

NOTE: The device DSP integrated EDMA controller instances (DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1) are functionally identical with the device EDMA controller instances (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1). The only difference is that the DSP_EDMA instances are located at different physical addresses.

For more details on the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 controllers functionalities, refer to Section 17.2.4, *EDMA Controller Functional Description*, in Section 17.2, *Enhanced DMA*.

The DSP_EDMA instances, their corresponding registers summary and descriptions are covered in the Section 17.2.7, *EDMA Register Manual* of the Section 17.2, *Enhanced DMA*.

5.3.7.2 DSP System and Device Level Settings of DSP EDMA

DSP_EDMA traffic TC0 and TC1 controllers "Active" or "Idle" status: can be monitored in DSP_SYSTEM located :

- DSP_SYS_STAT[1] TC0_STAT bit
- DSP_SYS_STAT[2] TC1_STAT bit

The **default** burst size for both the DSP_EDMA_TC0 and DSP_EDMA_TC1 can be defined in DSP_SYSTEM register. This is achieved via programming :

- DSP_SYS_BUS_CONFIG [1:0] TC0_DBS
- DSP_SYS_BUS_CONFIG [5:4] TC1_DBS

There are also other DSP_EDMA controls associated with DSP_NoC interconnect pressure settings. For more details, refer to the Section 5.3.8.

The 3 error events associated with the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 are exported outside the DSP C66x CorePac in the subsystem, and are able to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"tpcc_errint_level", "tptc_errint0_level" and "tptc_errint1_level"** events, respectively in the Table 5-5.

NOTE: The DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 events are NOT exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

The DSP_SYSTEM logic is assigned to route the external DMA requests to the EDMA hardware request inputs. Additionally, EDMA events can conditionally wake-up the DSP system from a low power mode, via software enabling DSP_SYSTEM MWakeup handshake with the device PRCM. This mechanism is described in the Section 5.3.5.

Copyright © 2018–2019, Texas Instruments Incorporated

The programmable muxing of various external DMA request sources to the DSP EDMA. DMA_DSP1_DREQ_x and DMA_DSP2_DREQ_x input lines (where x=0 to 19) is covered in the Section 19.4.6.5, *DMA_CROSSBAR Module Functional Description*, of the Chapter 19, *Control Module*.

DSP1/DSP2 subsystem external DMA request sources : For the default DSP1 / DSP2 external DMA request sources, routed via the device DMA_CROSSBAR to the DSP1_EDMA / DSP2_EDMA channel controller inputs (DMA_DSP1_DREQ_i / DMA_DSP2_DREQ_i), respectively, refer to the Section 5.3.5.

Copyright © 2018–2019, Texas Instruments Incorporated

5.3.8 DSP L2 interconnect Network

A 128-bit level 2 (L2) Interconnect from Arteris - FlexNoC® is instantiated in the DSP subsystem, outside the DSP C66x CorePac. It is signified as "DSP_NoC" throughout this chapter.

NOTE: The C66x master MDMA data does NOT flow through the DSP_NoC.

The system and local initiators on DSP_NoC are as follows :

- local C66x CPU 32-bit CFG master port which traffic is split via DSP_NoC fabric into several configuration target traffics inside and outside the DSP subsystem.
- SDMA initiator port on DSP_NoC which conveys accesses towards DSP Memories and memory-mapped registers initiated outside the DSP subsystem via the L3_MAIN interconnect.
- EDMA traffic controllers - TC0 read / write initiator ports
- EDMA traffic controllers - TC1 read / write initiator ports

NOTE: The DSP_ICFG space is not visible to SDMA initiators (DSP_EDMA or DSP hosts on L3_MAIN) with CFG traffic.

The targets on the DSP_NoC are as follows :

- DSP C66x CorePac SDMA port
- Internal CFG targets on the DSP_NoC :
  - DSP_MMU0 Cfg
  - DSP_MMU1 Cfg
  - DSP_SYSTEM Cfg
  - DSP_EDMA_CC Cfg
  - DSP_EDMA_TC0 Cfg
  - DSP_EDMA_TC1 Cfg
- 32-bit CFG port on L3_MAIN (it acts as master on the L3_MAIN)
- EDMA Target port which conveys EDMA bidi transfers outside the DSP (through or bypassing DSP_MMU1).

The Table 5-8 summarizes the interconnections which can be established between DSP initiators and targets over the L2 DSP_NoC in the device. In this table HW implemented interconnections are marked with an asterics.

Table 5-8. DSP_NoC Defined Connectivities

		DSP_NoC Initiators			
		DSP C66x CorePac CFG init	EDMA_TC0 init	EDMA_TC1 init	SDMA init (mapped to SDMA port on L3_MAIN)
DSP_NoC Targets	DSP C66x CorePac SDMA (slave) port	n.a.	*	*	*
	DSP_MMU0 Cfg	*	n.a.	n.a.	*
	DSP_MMU1 Cfg	*	n.a.	n.a.	*
	DSP_SYSTEM Cfg	*	n.a.	n.a.	*
	DSP_EDMA_CC Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC0 Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC1 Cfg	*	n.a.	n.a.	*
	DSP_NoC Cfg	*	n.a.	n.a.	*
	Cfg port (Cfg Init on L3_MAIN)	*	n.a.	n.a.	n.a.
	Master DMA port (DSP DMA init on L3_MAIN)	n.a.	*	*	n.a.

Copyright © 2018–2019, Texas Instruments Incorporated

A DSP_NoC error event (combination of several local to the interconnect events) is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **"noc_errint_level"** event in the Table 5-5.

NOTE: The DSP_NoC event is NOT exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and asscoiated event registers at DSP_SYSTEM level, refer to the Section 5.3.4.2.2.

5.3.8.1 DSP Public Firewall Settings

The DSP1 and DSP2 L2 Interconnect (DSP1_NoC and DSP2_NoC, respectively) implements two firewalls – dsp firewall0 (DSP_FW0) is used to protect DSP_MMU0's configuration space (which includes the TLB) and dsp firewall1 is used to protect DSP_MMU1's configuration space (which includes the TLB). Access permission is based on the privilege level, domain, ConnID, and access types of a request.

The default value of 0xFFFF_FFFF in the MRM region 0 permission registers:

- L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_MRM_PERMISSION_REGION_LOW_0
- L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_MRM_PERMISSION_REGION_HIGH_0
- L3_DSPSS_INIT_OCP_MMU1_CTRL_TARG_OCP_FW_504000_MRM_PERMISSION_REGION_LOW_0
- L3_DSPSS_INIT_OCP_MMU1_CTRL_TARG_OCP_FW_504000_MRM_PERMISSION_REGION_HIGH_0

permits any requestor to access the DSP_MMU0 and DSP_MMU1 configuration space.

For more information on the access region definitions, public privilege access, public user access and initiator permission settings, which are identical between DSP_NoC firewalls and L3_MAIN interconnect firewalls, refer to the Section 15.2.3.7.3, *L3_MAIN Firewall Functionality*, in the, Section 15.2, *L3_MAIN Interconnect*.

There are also several other DSP_NoC registers - L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_LOGICAL_ADDR_ERRLOG_0, L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_REGUPDATE_CONTROL used for error handling, firewall reset and other purposes. These are functionally identical with the corresponding L3_MAIN interconnect registers, described in the Section 15.2.3.8, *L3_MAIN Interconnect Error Handling*, in the Section 15.2, *L3_MAIN Interconnect*.

The various firewall access control registers are part of the C66x CPU local accessible - DSP_FW_L2_NOC_CFG address space, and L3_MAIN initiators accessible DSP1/2_FW_L2_NOC_CFG configuration space. The corresponding MMU0 and MMU1 configuration space firewall registers (DSP_FW0 starting at offset **0x0000_0000** , and DSP_FW1 starting at offset **0x0000_1000**) are summarized and described in the Section 5.4.4.

5.3.8.2 DSP NoC Flag Mux and Error Log Registers

The DSP_NoC registers (starting at offset >= 0x0000_4000) are used for error logging and flag muxing purposes. The status information stored in there can be used for example to resolve issues related to DSP_NoC access conflicts, for debug purposes, etc.

For more information, refer to the Section 15.2.3.5, *Flag Muxing*, in the Section 15.2, *L3_MAIN Interconnect*.

5.3.8.3 DSP NoC Arbitration

A pressure based arbitration is implemented for the DSP_NoC interconnect.

Copyright © 2018–2019, Texas Instruments Incorporated

A DSP_NoC local MFlag mechanism is used but it is SW controlled in the DSP_SYSTEM configuration space.

This is done via the register DSP_SYS_BUS_CONFIG bitfields :

- TC0_L2PRES - for DSP_EDMA_TC0 pressure control
- TC1_L2PRES - for DSP_EDMA_TC1 pressure control
- CFG_L2PRES - for the DSP C66x CorePac 32-bit CFG pressure control
- SDMA_L2PRES - for pressure control of the DSP system and L3_MAIN accesses targetting the DSP C66x CorePac SDMA slave port

The pressure for each port is signaled on a MFlag[1:0] bus and conveys a value of 0 (lowest), 1 (medium), or 3 (highest). A value of 0x2 is reserved/undefined.

NOTE: The default pressure level for all ports is 0x0 and is recommended for most systems. This results in round-robin arbitration across active requests.

5.3.9 DSP Boot Configuration

DSP1 subsystem boot vector input which defines the 22-bit DSP1 Boot Address is mapped to the device core control module register CTRL_CORE_CONTROL_DSP1_RST_VECT[21:0] DSP1_RST_VECT bitfield. DSP2 subsystem boot vector input which defines the 22-bit DSP2 Boot Address is mapped to the device core control module register CTRL_CORE_CONTROL_DSP2_RST_VECT[21:0] DSP2_RST_VECT bitfield.In general, the device MPU (Cortex-A15) host loads code to a given address location in the device system memory, sets the DSP1_RST_VECT / DSP2_RST_VECT bitfield to the address value, and then release the DSP1 / DSP2 from reset. At that point, the DSP1 / DSP2 will begin fetching code from that location.

NOTE: If the values of the control core module CTRL_CORE_CONTROL_DSP1_RST_VECT[21:0] / CTRL_CORE_CONTROL_DSP2_RST_VECT [21:0] register change, the values will be taken into account by DSP upon the next reset.

NOTE: Upon device boot time (a power-on reset applied), the device "sysboot15" input latched in the Control Module bootstrap register defines the value of DSP functional clock divider (2 or 3). For more details, refer to the Section 5.3.3.1

5.3.10 DSP Internal and External Memory Views

5.3.10.1 C66x CPU View of the Address Space

The **C66x CPU View** represents the view from the DSP, which result from program fetches, or load / store instructions. Accesses to DSP memories (L1P, L1D, L2) and to DSP Internal configuration space (DSP_ICFG) are intercepted within the DSP C66x CorePac (whether using local or global addresses).

The DSP C66x CorePac CFG (C66x CPU 32-bit master port) interface is strictly for non-cacheable loads and stores, and is intended to be used for I/O space or memory mapped registers (MMR) space. DSP C66x CorePac CFG accesses are routed / arbitrated by the DSP_NoC L2 inteconnect. DSP C66x CorePac CFG accesses are mapped between 0x01C0_0000 and 0x0FFF_FFFF.

NOTE: The DSP C66x CorePac CFG initiator interface is strictly for non-cacheable loads and stores within MMR and I/O spaces.

DSP configuration accesses to **external to DSP subsystem** peripherals can be issued on either the DSP subsystem CFG Master port which is mapped to the device L3_MAIN or DSP 32-bit CFG "system" interface is connected to the chip level L3_MAIN interconnect and used to access L3_MAIN addressses that are mapped between 0x01C0_0000 and 0x0FFF_FFFF.

Copyright © 2018–2019, Texas Instruments Incorporated

DSP **accesses (to non-DSP memories like SDRAM on L3_MAIN) for addresses above 0x1000_0000 are handled via the DSP (XMC) MDMA 128-bit master interface and are routed to the DSP subsystem MDMA Initiator port either through DSP_ MMU0 or bypassing MMU.**

NOTE: In some cases, L3_MAIN peripherals may be mapped to both the MDMA bus and the CFG bus. In that case, there may be a latency advantage of using the CFG address for those peripherals

Table 5-9 shows the DSP C66x CPU memory view of the various DSP C66x CorePac internal and external resources.

Table 5-9. C66x CPU View Map

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports)[1]		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x00E0_0000	0x00E0_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x00F0_0000	0x00F0_7FFF	32KiB	DSP_L1D	DSP L1D SRAM (local)
0x0180_0000	0x01BF_FFFF	4096 KiB	DSP_ICFG	DSP Internal CFG [2]
0x01D0_0000	0x01D0_0FFF	4 KiB	DSP_SYSTEM	DSP_SYSTEM Memory Mapped Registers block
0x01D0_1000	0x01D0_1FFF	4 KiB	DSP_MMU0CFG	DSP MMU0 configuration / registers
0x01D0_2000	0x01D0_2FFF	4 KiB	DSP_MMU1CFG	DSP MMU1 configuration / registers
0x01D0_5000	0x01D0_5FFF	4 KiB	DSP_EDMA_TC0	DSP_EDMA Transfer Controller 0
0x01D0_6000	0x01D0_6FFF	4 KiB	DSP_EDMA_TC1	DSP_EDMA Transfer Controller 1
0x01D0_7000	0x01D0_7FFF	4 KiB	DSP_NoC	DSP L2 interconnect registers
0x01D1_0000	0x01D1_7FFF	32 KiB	DSP_EDMA_CC	DSP_EDMA Channel Controller
0x0200_0000	0x020F_FFFF	1 MiB	EVE1	DSP configuration traffic to the EVE1 (mapped on the DSP CFG interface)
0x0210_0000	0x021F_FFFF	1 MiB	EVE2	DSP configuration traffic to the EVE2 (mapped on the DSP CFG interface)
0x0220_0000	0x022F_FFFF	1 MiB	EVE3[3]	DSP configuration traffic to the EVE3 (mapped on the DSP CFG interface)
0x0230_0000	0x023F_FFFF	1 MiB	EVE4[3]	DSP configuration traffic to the EVE4 (mapped on the DSP CFG interface)
0x0330_0000	0x033F_FFFF	1 MiB	EDMA_TPCC	DSP configuration traffic to the EDMA_TPCC (mapped on the DSP CFG interface)
0x0340_0000	0x034F_FFFF	1 MiB	EDMA_TC0	DSP configuration traffic to the EDMA_TC0 (mapped on the DSP CFG interface)
0x0350_0000	0x035F_FFFF	1 MiB	EDMA_TC1	DSP configuration traffic to the EDMA_TC1 (mapped on the DSP CFG interface)
0x0800_0000	0x0800_FFFF	64 KiB	DSP_XMC_CTRL MMRs	DSP internal MMRs for XMC controller (non-cache)

(1) Only the C66x CPU view of device implemented functional memory regions are shown. The remaining regions are reserved.
(2) The internal configuration space registers are visible ONLY to the C66x CPU (DSP_C0) within the DSP C66x CorePac, i.e. they are NOT visible to initiators outside the DSP C66x CorePac.
(3) EVE3 and EVE4 are not supported in this family of devices.

Table 5-9. C66x CPU View Map (continued)

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports)[1]		Size	DSP Memory Region	Function
Start Address	End Address			
0x0802_0000	0x080F_FFFF	896 KiB	MDMA non-cache	MDMA initiator (non-cache) to L3_MAIN (DSP_MMU0)
0x0810_0000	0x0BBF_FFFF	59 MiB		
0x1000_0000	0x10FF_FFFF	16 MiB	DSP1 L1P, L1D and L2 memories	An image of DSP1 C66x CorePac internal space - only L1P, L1D and L2 memories (global) [4]
0x1000_0000	0x10FF_FFFF	16 MiB	DSP2 MDMA (cached)	DSP2 MDMA initiator (cached) to L3_MAIN (through DSP2_MMU0)
0x1100_0000	0x11FF_FFFF	16 MiB	DSP2 L1P, L1D and L2 memories	An image of DSP2 C66x CorePac internal space - only L1P, L1D and L2 memories (global) [5]
			DSP1 MDMA (cached)	MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0)
0x1200_0000	0x1FFF_FFFF	224 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively)
0x2000_0000	0xFFFF_FFFF	3584 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively)

(4) The DSP1 CPU sees an image of its own memories in the 0x1000_0000 - 0x10FF_FFFF address range (the same mapped also at lower addresses 0x0080_0000 - 0x00F0_7FFF). On the other side, DSP2 CPU addresses, generated in the same range (with DSP2_MMU0 involved), are mapped to the DSP2 MDMA port (cached transfers to/from L3_MAIN connected system memories).

(5) The DSP2 CPU sees an image of its own memories in the 0x1100_0000 - 0x11FF_FFFF address range (the same mapped also at lower addresses 0x0080_0000 - 0x00F0_7FFF). On the other side, DSP1 CPU addresses, generated in the same range (with DSP1_MMU0 involved), are mapped to the DSP1 MDMA port (cached transfers to / from L3_MAIN connected system memories).

Refer to the Section 2.2, *L3_MAIN Memory Space Mapping*, in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the Section 2.7, *DSP Subsystem Memory Space Mapping* in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

5.3.10.2 DSP_EDMA View of the Address Space

EDMA is able to initiate internal accesses directly to the DSP memories via the DSP C66x CorePac SDMA bus. The access is conducted to the DSP C66x CorePac internal memories over the L2 DSP_NoC interconnect.

Table 5-10 shows the DSP integrated EDMA controller memory view of the various DSP C66x CorePac internal and external resources.

Table 5-10. DSP EDMA Controller View Map

DSP_EDMA Controller View (EDMA master internal / external port)		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x00E0_0000	0x00E0_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x00F0_0000	0x00F0_7FFF	32KiB	DSP_L1D	DSP L1D SRAM (local)
0x0802_0000	0x0BBF_FFFF	59 MiB	EDMA to L3_MAIN	EDMA initiator (DSP_MMU1)

Copyright © 2018–2019, Texas Instruments Incorporated

Table 5-10. DSP EDMA Controller View Map (continued)

DSP_EDMA Controller View (EDMA master internal / external port)		Size	DSP Memory Region	Function
Start Address	End Address			
0x1000_0000	0x10FF_FFFF	16 MiB	DSP L1/L2	An image of DSP C66x CorePac internal space - only L1P, L1D and L2 memories (global) (1)
0x2000_0000	0xFFFF_FFFF	3584 MiB	DMA OCP	L3_MAIN interconnect memory via MMU1 / DMA OCP Initiator

(1) The internal configuration space registers DSP_ICFG are visible ONLY to the C66x CPU (DSP_C0) within the DSP C66x CorePac , i.e. they are NOT visible to the DSP_EDMA.

Access from EDMA to external resources on L3_MAIN are routed via DSP subsystem **EDMA initiator port**. **Note that these accesses are transferred through the DSP_MMU1 memory management unit.**

NOTE: The DSP_EDMA can NOT access the DSP_ICFG (DSP C66x CorePac internal) addresses.

With the DSP_MMU1 disabled, the subset of the memory map used for DSP_EDMA internal accesses will NOT be visible. Thus only addresse which equal 0x2000_0000 and above will be considered as valid 32-bit addresses (i.e. L3_MAIN space accesses only).

Refer to the Section 2.2, *L3_MAIN Memory Space Mapping*, in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the Section 2.7, *DSP Subsystem Memory Space Mapping* in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

5.3.10.3 L3_MAIN View of the DSP Address Space

System initiated accesses (i.e. external-to-DSP accesses over device L3_MAIN) to DSP are issued over the DSP SDMA target port.

NOTE: The MSB-bits of the address are truncated to only provide an 8 MiB view of the memory map within the DSP subsystem. Notice that the relative offsets of the DSP CFG space is different for the OCP SDMA target port relative to the DSP internal initiators.

The SDMA target bus is able to access internal subsystem address space (such as DSP_EDMA, DSP_MMU0, DPS_MMU1, etc.), or the DSP local memory address space. The SDMA target bus **is NOT able to access the DSP ICFG space (such as DSP_INTC, DSP_BWM, etc)** or the other initiator ports on the DSP subsystem boundary (i.e., accesses cannot go through DSPSS to get to the DSP_EDMA initiator port, L3_MAIN CFG initiator port).

The DSP slave DMA port memory map - Table 5-11 shows an 8 MiB window (23-bit address) both from the SDMA Target bus (0x0000_0000 through 0x007F_FFFF), as well as the EDMA (0x0080_0000 through 0x00FF_FFFF). The DSP C66x CorePac internally views itself as a 16 MiB window where 0x0000_0000 through 0x007F_FFFF is reserved, L2 SRAM starts at 0x0080_0000, L1P SRAM starts at 0x00E0_0000, and L1D SRAM starts at 0x00F0_0000).

Table 5-11. SDMA Target Port Memory Map

System L3_MAIN View(1)		Size	DSP Memory Region	Function
Start Address	End Address			
0x0000_0000	0x0004_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x0050_0000	0x0050_0FFF	4 KiB	DSP_SYSTEM	DSP SYSTEM MMR Block
0x0050_1000	0x0050_1FFF	4 KiB	DSP_MMU0CFG	DSP MMU0 configuration / regs

(1) Only system (L3_MAIN) view over functionally used regions are shown. The remaining regions are reserved.

Table 5-11. SDMA Target Port Memory Map (continued)

System L3_MAIN View[1]		Size	DSP Memory Region	Function
Start Address	End Address			
0x0050_2000	0x0050_2FFF	4 KiB	DSP_MMU1CFG	DSP MMU1 configuration / regs
0x0050_5000	0x0050_5FFF	4 KiB	DSP_EDMA_TC0	DSP EDMA Transfer Controller 0
0x0050_6000	0x0050_6FFF	4 KiB	DSP_EDMA_TC1	DSP EDMA Transfer Controller 1
0x0050_7000	0x0050_7FFF	4 KiB	DSP_NoC	DSP L2 Interconnect registers
0x0051_0000	0x0051_7FFF	32 KiB	DSP_EDMA_CC	DSP EDMA Channel Controller
0x0060_0000	0x0060_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x0070_0000	0x0070_7FFF	32 KiB	DSP_L1D	DSP L1D SRAM (local)

Refer to the Section 2.2, *L3_MAIN Memory Space Mapping*, in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the Section 2.7, *DSP Subsystem Memory Space Mapping* in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

5.4 DSP Subsystem Register Manual

This section describes the DSP Subsystem instances registers.

5.4.1 DSP Subsystem Instance Summary

Table 5-12. DSP Subsystem Instance Summary

Module Name	Module Base Address	Size
DSP_ICFG	0x0180 0000[1]	4 KiB
DSP_SYSTEM	0x01D0 0000[1]	256 Bytes
DSP_FW_L2_NOC_CFG	0x01D0 3000[1]	8576 Bytes
DSP1_SYSTEM	0x40D0 0000	256 Bytes
DSP1_FW_L2_NOC_CFG	0x40D0 3000	8576 Bytes
DSP2_SYSTEM	0x4150 0000	256 Bytes
DSP2_FW_L2_NOC_CFG	0x4150 3000	8576 Bytes

(1) **The registers of DSP subsystem instances prefixed only with DSP in the name, and NOT DSP1 or DSP2, are NOT visible on the device L3_MAIN. They are visible only within the DSP_ICFG internal configuration space hence accessible only by the DSP C66x CPU.**

NOTE: For more details on the DSP_MMU0 and DSP_MMU1 registers, as well as their :

- DSP_MMU0CFG and DSP_MMU1CFG physical addresses accesible only by DSP_C0 CPU core in the DSP subsystem
- DSP1_MMU0CFG and DSP1_MMU1CFG physical addresses visible on L3_MAIN
- DSP2_MMU0CFG and DSP2_MMU1CFG physical addresses visible on L3_MAIN

refer to Section 21.5, *MMU Register Manual*, in Chapter 21, *Memory Management Units*.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: For more details on the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 registers, as well as their :

- DSP1_EDMA_CC, DSP1_EDMA_TC0 and DSP1_EDMA_TC1 physical addresses visible on L3_MAIN
- DSP2_EDMA_CC, DSP2_EDMA_TC0 and DSP2_EDMA_TC1 physical addresses visible on L3_MAIN

refer to Section 17.2.7, *EDMA Register Manual*, in Section 17.2, *Enhanced DMA*.

CAUTION

The L1P, L1D and L2 memory controller registers mapped in the L3_MAIN are limited to 32-bit data access; 16- and 8-bit access are not allowed and can corrupt register content.

5.4.2 DSP_ICFG Registers

5.4.2.1 DSP_ICFG Register Summary

NOTE: The DSP_ICFG addresses are visible only within the DSP core internal configuration space.

Table 5-13. DSP_ICFG Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	DSP_ICFG Physical Address	Register Reset Value[1]

5.4.2.2 DSP_ICFG Register Description

For bitfield descriptions of all registers which reside within the DSP_ICFG configuration address space, refer to the *TMS320C66x DSP CorePac User Guide*, (SPRUGW0C).

5.4.3 DSP_SYSTEM Registers

5.4.3.1 DSP_SYSTEM Register Summary

NOTE: While the DSP1_SYSTEM and DSP2_SYSTEM addresses are part of the device L3_MAIN memory space, **the DSP_SYSTEM addresses are visible only within the DSP_ICFG internal configuration space (visible only to C66x CPU and debug logic).**

Table 5-30. DSP_SYS_IRQWAKEEN0

Address Offset	0x0000 0020		
Physical Address	0x01D0 0020 0x40D0 0020 0x4150 0020	**Instance**	DSP_SYSTEM DSP1_SYSTEM DSP2_SYSTEM
Description	The register provides a global interrupt wakeup enable bit vector that defines which input interrupts are used to cause a wake from powerdown state (via the slave idle protocol). IRQWAKEEN0 is for interrupt inputs 63 thru 32, and IRQWAKEEN1 is for interrupt inputs 95 thru 64. Internal interrupts cannot cause a wake condition since in this state there is no guaranteed clock and all sub-modules should be in idle state. Software can write 1 to set and 0 to clear the corresponding bit (i.e., enable the corresponding interrupt for wakeup). Reads of this register return the actual state of the enable register.

5.4.4 DSP_FW_L2_NOC_CFG Registers

This section covers the DSPSS level defined public firewall (DSP_MMU0, DSP_MMU1) and L2 interconnect (DSP_NoC) functional registers.

5.4.4.1 DSP_FW_L2_NOC_CFG Register Summary

NOTE: While the DSP1_FW_L2_NOC_CFG and DSP2_FW_L2_NOC_CFG addresses are part of the device L3_MAIN memory space, **the DSP_FW_L2_NOC_CFG addresses are visible only within the DSP_ICFG internal configuration space (visible only to C66x CPU and debug logic).**

IVA Subsystem

NOTE: The IVA-HD subsystem is a set of video encoder and decoder hardware accelerators. The list of supported codecs can be found in the software development kit (SDK) documentation.

The IVA-HD subsystem availability is device part number dependent. Refer to device *Data Manual*, for more information.

Dual Cortex-M4 IPU Subsystem

This chapter describes the dual Cortex-M4 image processor unit (IPU) subsystem.

Topic **Page**

7.1 Dual Cortex-M4 IPU Subsystem Overview 1820
7.2 Dual Cortex-M4 IPU Subsystem Integration 1823
7.3 Dual Cortex-M4 IPU Subsystem Functional Description 1828
7.4 Dual Cortex-M4 IPU Subsystem Register Manual 1841

Copyright © 2018–2019, Texas Instruments Incorporated

7.1 Dual Cortex-M4 IPU Subsystem Overview

7.1.1 Introduction

The device instantiates two dual Cortex®-M4 image processor unit (IPU) subsystems available for general purpose usage.

NOTE: The two IPU subsystems are identical from functional point of view. Thus, a unified name **IPUx** shall be used throughout the chapter for simplification.

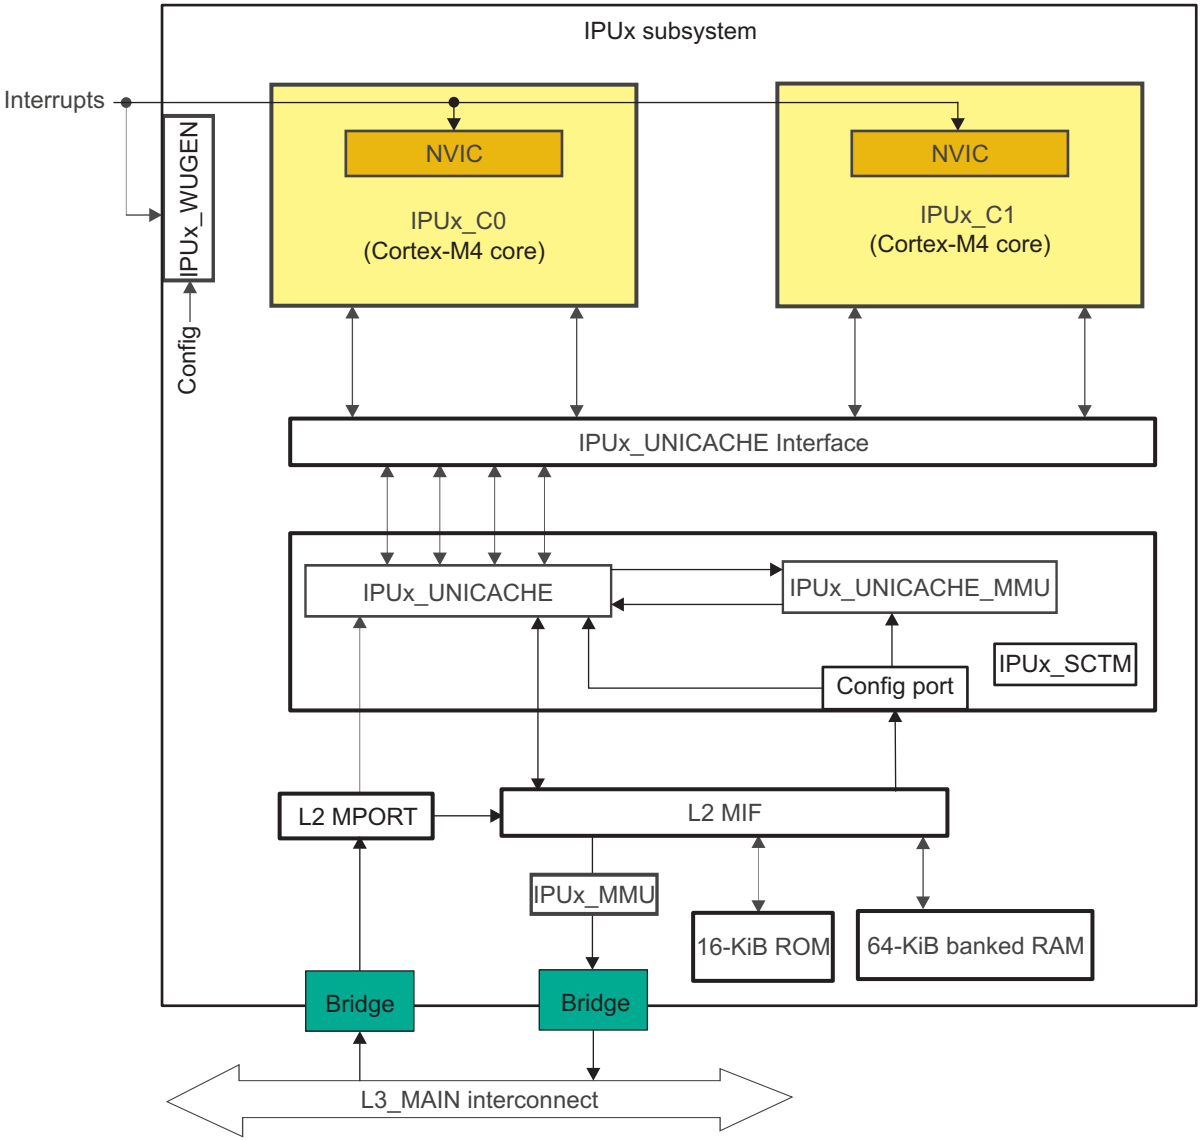
Each IPU subsystem contains two Arm® Cortex-M4 processors (IPUx_C0 and IPUx_C1) that share a common level 1 (L1) cache (called unicache [IPUx_UNICACHE]). The two Cortex-M4 cores are completely homogeneous to one another. Any task possible using one Cortex-M4 core is also possible using the other Cortex-M4 core. It is software responsibility to distribute the various tasks between each Cortex-M4 core for optimal performance.

The integrated interrupt handling of the IPUx subsystem allows it to function as an efficient control unit.

Figure 7-1 is a high-level block diagram of the IPUx subsystem.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 7-1. IPUx Subsystem Overview



Copyright © 2018–2019, Texas Instruments Incorporated

7.1.2 Features

Each IPU subsystem integrates the following:

- Two Arm Cortex-M4 microprocessors (IPUx_C0 and IPUx_C1):
  - Armv7-M and Thumb®-2 instruction set architecture (ISA)
  - Armv6 SIMD and digital signal processor (DSP) extensions
  - Single-cycle MAC
  - Integrated nested vector interrupt controller (NVIC) (also called IPUx_Cx_INTC, where x = 0, 1)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Unicache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- Level 2 (L2) master interface (MIF) splitter for access to memory or configuration port
- Configuration port: Used for unicache maintenance and unicache memory management unit (IPUx_UNICACHE_MMU) configuration
- Unicache:
  - 32 KiB divided into 16 banks
  - 4-way
  - Cache configuration lock/freeze/preload
  - Internal MMU:
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- Subsystem counter timer module (IPUx_UNICACHE_SCTM, or just SCTM)
- On-chip ROM (IPUx_ROM) and banked RAM (IPUx_RAM) memory
- Emulation/debug: Emulation feature embedded in Cortex-M4
- L2 MMU (IPUx_MMU): 32 entries with table walking logic
- Wake-up generator (IPUx_WUGEN): Generates wake-up request from external interrupts
- Power management:
  - Local power-management control: Configurable through the IPUx_WUGEN registers.
  - Three sleep modes supported, controlled by the local power-management module.
  - IPUx is clock-gated in all sleep modes.
  - IPUx_Cx_INTC interrupt interface stays awake.

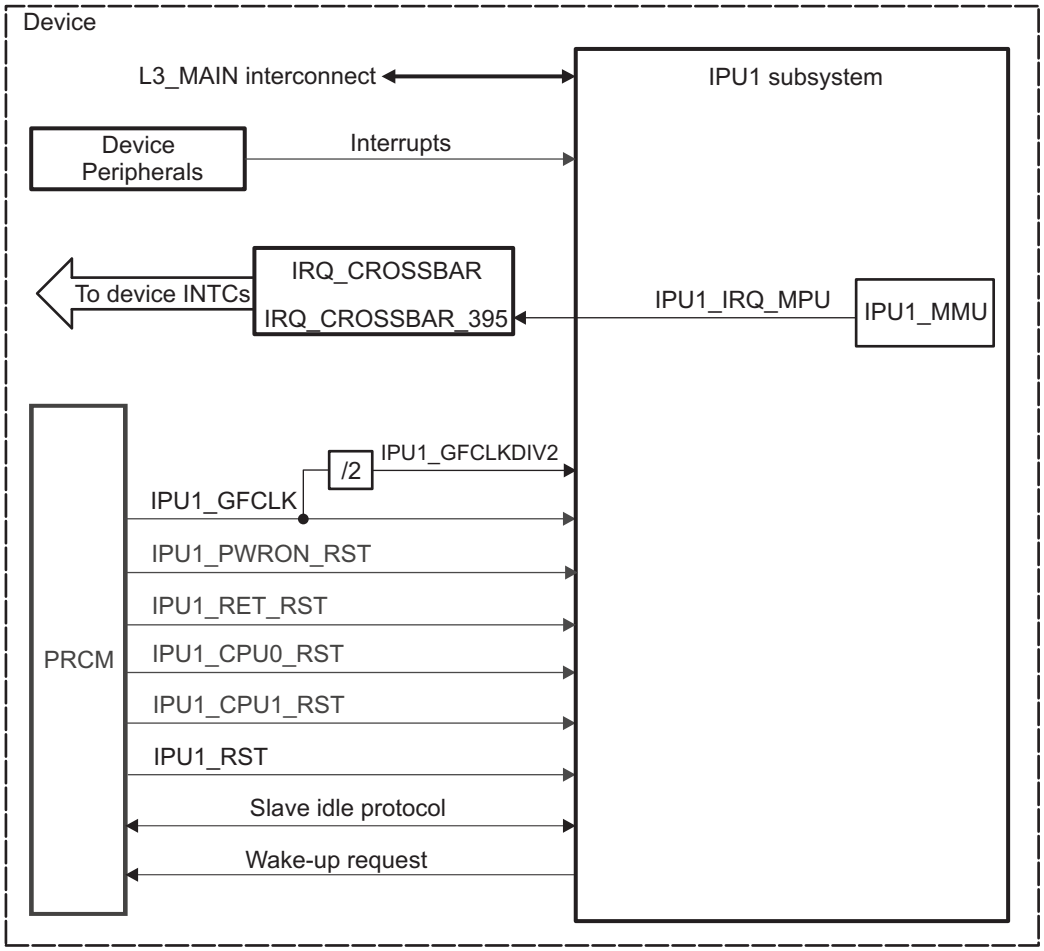
7.2 Dual Cortex-M4 IPU Subsystem Integration

Figure 7-2 and Figure 7-3 show the integration of IPU1 and IPU2 in the device.

Figure 7-2. IPU1 Subsystem Integration



Copyright © 2018–2019, Texas Instruments Incorporated

Figure 7-3. IPU2 Subsystem Integration

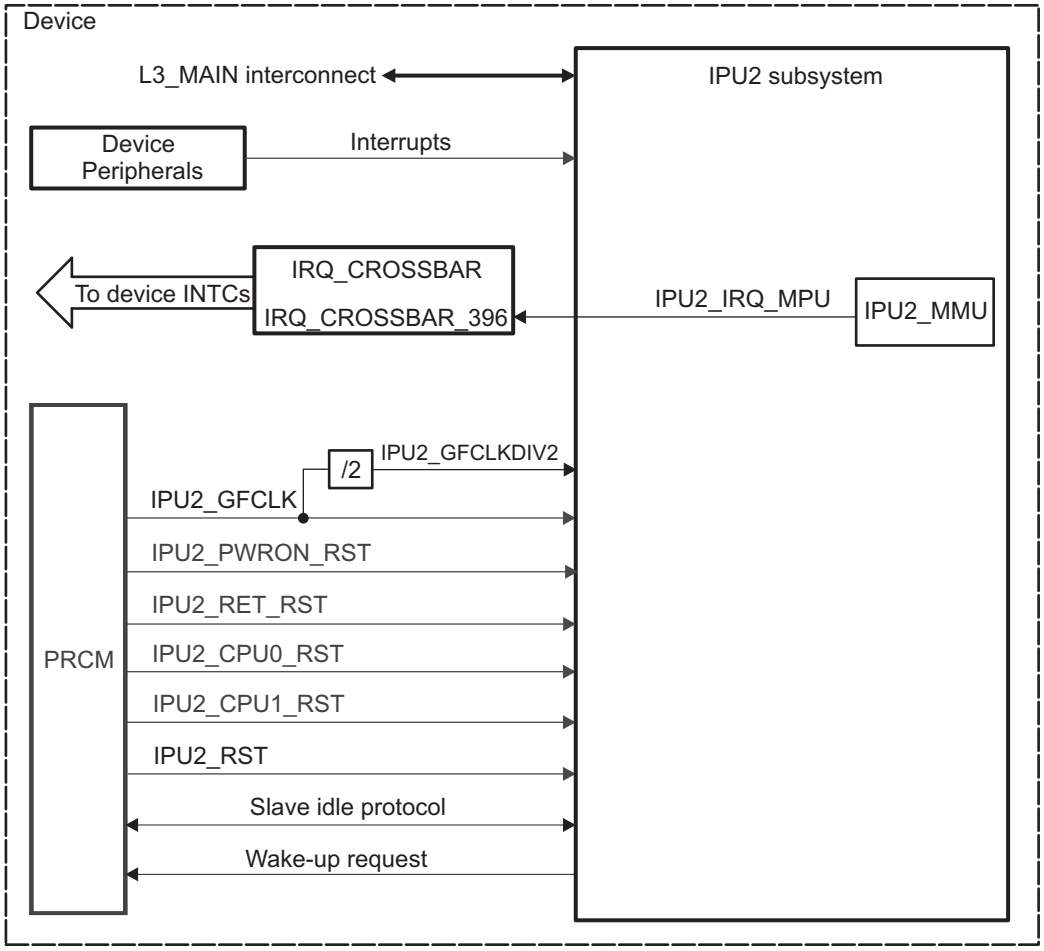


Table 7-1 through Table 7-3 summarize the integration of the module in the device.

Table 7-1. IPUx Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IPU1	PD_IPU	L3_MAIN
IPU2	PD_CORE	L3_MAIN

Table 7-2. IPUx Hardware Requests

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
IPU1	IPU1_IRQ_MPU	IRQ_CROSSBAR_395	MPU_IRQ_100	IPU1_MMU fault interrupt.
IPU2	IPU2_IRQ_MPU	IRQ_CROSSBAR_396	–	IPU2_MMU fault interrupt. This interrupt is not mapped by default to any device INTC.

	IPU2_RET_RST	IPU2_RET_RST	PRCM module	Retention reset to few retention logic inside the IPU2_UNICACHE
	IPU2_CPU0_RST	IPU2_CPU0_RST	PRCM module	Reset signal to IPU2_C0
	IPU2_CPU1_RST	IPU2_CPU1_RST	PRCM module	Reset signal to IPU2_C1
	IPU2_RST	IPU2_RST	PRCM module	Reset signal to the IPU2_UNICACHE and the IPU2_MMU

NOTE: The "**Default Mapping**" column in Table 7-2 shows the default mapping of module IRQ source signal. This IRQ source signal can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see Chapter 19, *Control Module*.

For more information about the device interrupt controllers, see Chapter 18, *Interrupt Controllers*.

For more information about clocks, resets, and power domains, see Chapter 3, *Power, Reset, and Clock Management*.

7.2.1 Dual Cortex-M4 IPU Subsystem Clock and Reset Distribution

7.2.1.1 Clock Distribution

The IPUx subsystem has two clock inputs:

- **IPUx_GFCLK**: Main source clock for IPUx; feeds most of IPUx internal modules:
  - IPUx Unicache & MMU, L2 MIF & MPORT (all running on (1x) IPUx_GFCLK)
  - Cortex-M4 cores, IPUx_RAM, IPUx_ROM (all running on (1/2x) IPUx_GFCLK via internal divider)
- **IPUx_GFCLKDIV2**: This is IPUx_GFCLK externally divided by two; feeds IPUx L2 MMU

The IPUx_GFCLK itself can be derived from either:

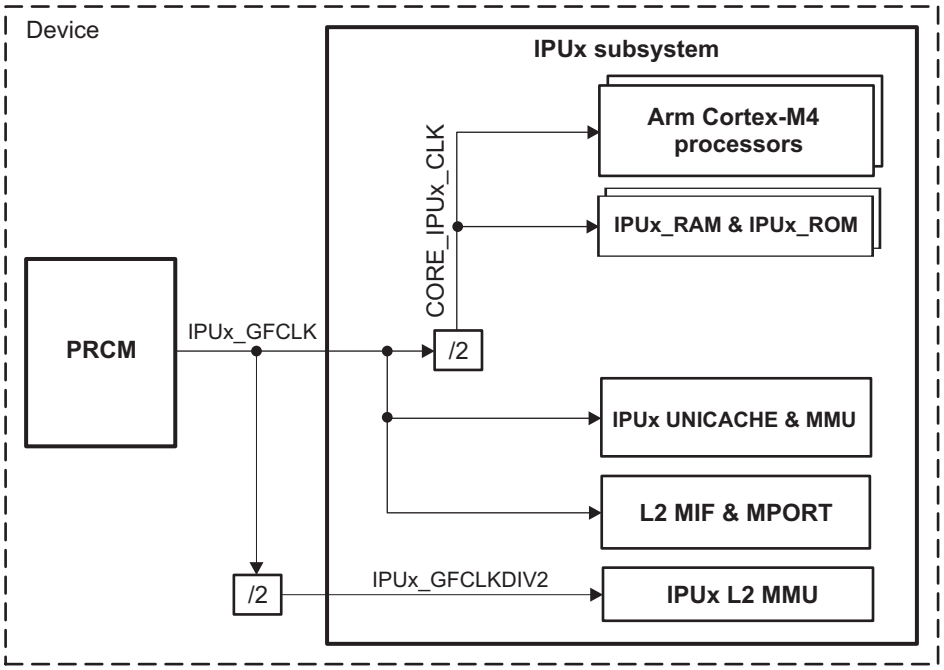
Copyright © 2018–2019, Texas Instruments Incorporated

- CORE_IPU_ISS_BOOST_CLK – main clock for IPUx from DPLL_CORE, or
- DPLL_ABE_X2_CLK – alternative clock from DPLL_DDR

For more information, see Chapter 3, *Power, Reset, and Clock Management*.

Figure 7-4 shows the clocking scheme of the IPUx subsystem.

Figure 7-4. IPUx Subsystem Clocking Scheme



7.2.1.2 Reset Distribution

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two Arm Cortex-M4 processors and the rest of the IPUx subsystem be reset independently. These three reset signals are: IPUx_CPU0_RST, IPUx_CPU1_RST, and IPUx_RST. The Arm Cortex-M4 processors must come out of reset one at a time:

- At IPUx_CPU0_RST, IPUx_C0 comes out of reset, but IPUx_C1 is held in reset.
- IPUx_C0 controls the reset for IPUx_C1 (through the PRCM RM_IPUx_RSTCTRL[1] RST2 bit).

Because IPUx_C0 controls the reset for IPUx_C1 (through the PRCM registers), the code running on IPUx_C0 decides the mode of operation, whether it is:

- Mode 1: One Arm Cortex-M4 processor is running, and the other processor is held on reset.
- Mode 2: The two Arm Cortex-M4 processors are running.

This decision of which mode to use is driven by the use case. If the software partitioning and performance requirement for a use case requires two Cortex-M4 processors to run simultaneously, the user must go to mode 2. If IPUx_C1 is not required for a particular use case, the user can remain in mode 1.

Figure 7-5 shows the reset scheme of the IPUx subsystem.

7.3 Dual Cortex-M4 IPU Subsystem Functional Description

7.3.1 IPUx Subsystem Block Diagram

The IPUx subsystem integrates the following group of submodules:

- Two Arm Cortex-M4 processors: Two cores (r0p1 revision), IPUx_C0 and IPUx_C1. For a description of the Arm Cortex-M4 processor, see the Arm *Cortex-M4 Technical Reference Manual*, available at infocenter.arm.com/help/index.jsp.
- Interrupt controller (IPUx_Cx_INTC): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M4 processor receives the same interrupts, except for a few internal interrupts. Every IRQ line is shared between the two Arm processors. By properly configuring the IPUx_Cx_INTC registers inside each Arm processor, it can be ensured that the shared IRQ is taken by only one of the Arm processors (for more information, see Chapter 18, *Interrupt Controllers*).
- IPUx_UNICACHE interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the Arm Cortex-M4 processors (two for each processor).The instruction and data connections from each Arm Cortex-M4 are multiplexed, but the Arm Cortex-M4 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cacheability is provided through the MMU inside the cache.
- IPUx_UNICACHE: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- IPUx_UNICACHE_MMU: Serves the role of an attribute MMU (AMMU) for the unicache. It provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the IPUx_UNICACHE_MMU is done only under privilege mode. The IPUx_UNICACHE_MMU can be programmed by the dual Cortex-A15 microprocessor unit (MPU) subsystem through the IPUx subsystem slave port.
- IPUx_UNICACHE_SCTM: Embedded in the IPUx_UNICACHE
- Interconnect configuration port: Cache maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the IPUx_UNICACHE_MMU. Interconnect accesses are generated from the L2 MIF.
- IPUx_MMU: Provides address translation for all the accesses done from the IPUx subsystem to the level 3 (L3_MAIN) interconnect. The IPUx_MMU can be programmed by the MPU subsystem through the IPUx subsystem slave port.
- L3_MAIN interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the IPUx subsystem, see Chapter 2, *Memory Mapping*.
- On-chip IPUx_ROM and banked IPUx_RAM memory. The IPUx_ROM memory is used for boot/initialization purposes. For more information about the initialization of the device, see Chapter 34, *Initialization*.

Figure 7-6 is a block diagram of the IPUx subsystem.

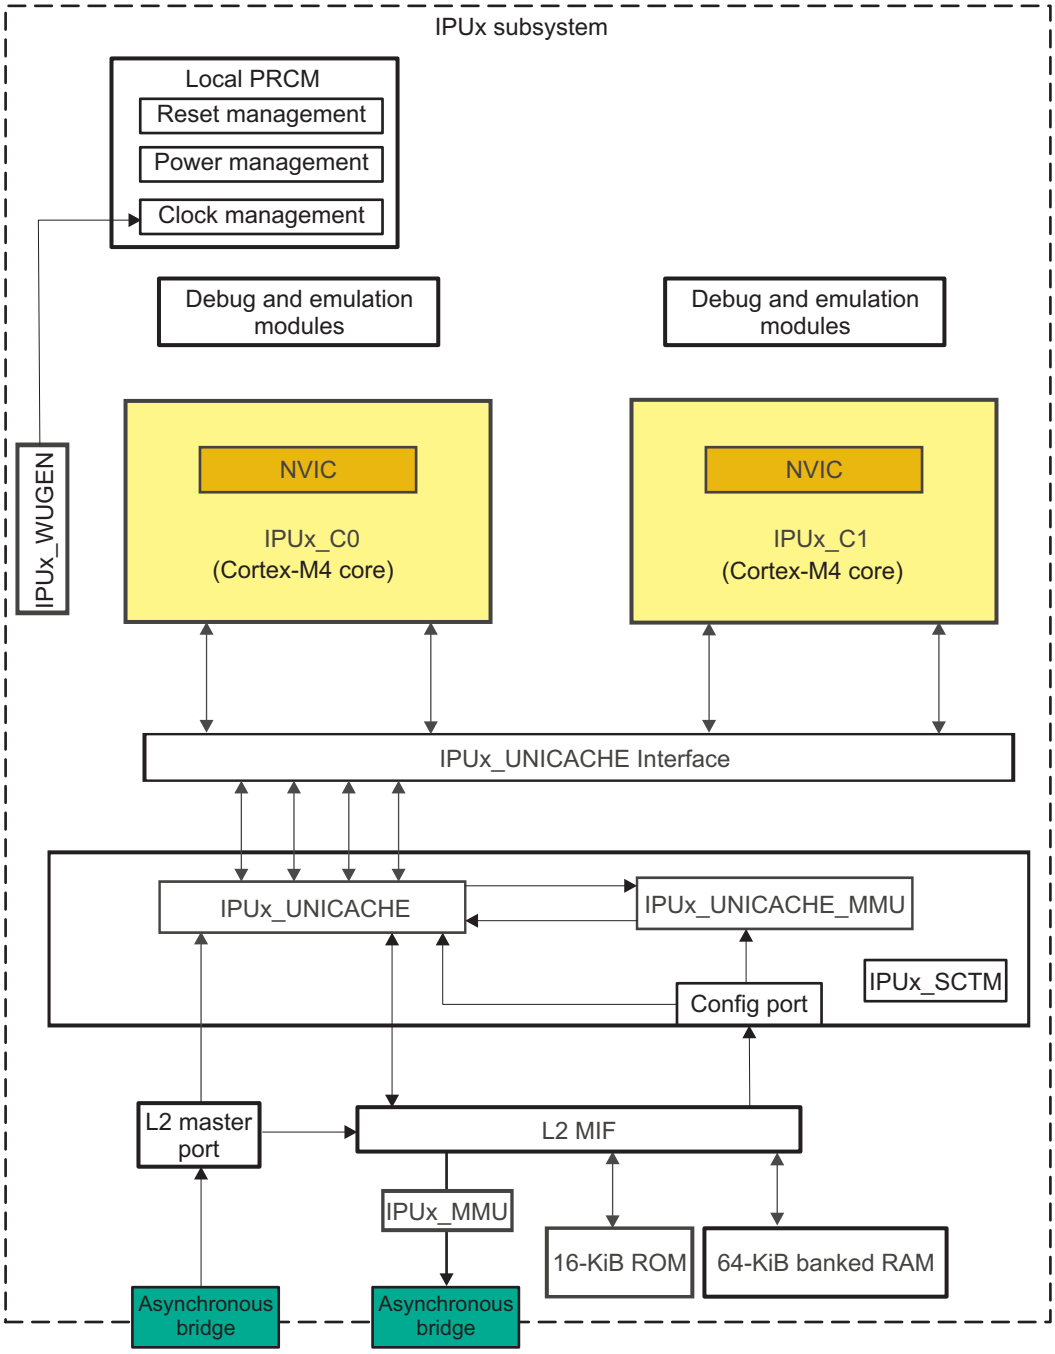
Figure 7-6. IPUx Subsystem Block Diagram



7.3.2 Power Management

7.3.2.1 Local Power Management

The user can configure the local power management through the STANDBY_CORE_SYSCONFIG, IDLE_CORE_SYSCONFIG, and WUGEN_IRQ_EN registers. The user can:

- Configure the different standby modes (the default is smart wake-up standby mode) through the STANDBY_CORE_SYSCONFIG[1:0] STANDBYMODE bit field
- Configure the different idle modes (the default is smart wake-up idle mode) through the IDLE_CORE_SYSCONFIG[1:0] IDLEMODE bit field

Copyright © 2018–2019, Texas Instruments Incorporated

- Control which interrupts will cause a wakeup by appropriately configuring the WUGEN_MEVT0 and WUGEN_MEVT1 registers (the default is ALL_MASKED)

The IPUx subsystem provides three sleep modes:

- On mode: Sleep on exit (wait for the interrupt service routine [ISR] to complete)
- Sleep mode: Wait for interrupt to wake up the processor
- Deep-sleep mode: Long duration sleep; phase-locked loop (PLL) can be stopped

During sleep mode, the system clock can be stopped, but the free-running clock input must still be running to allow the processor to be wakened by an interrupt or an event. The sleep modes are invoked by wait for interrupt (WFI) or wait for event (WFE) instructions. The processor clock is automatically stopped, waiting for an interrupt or an event. Deep-sleep mode also stops the processor clock, but this can also be supported by the PRCM module. A combined signal is generated from the two Cortex-M4 processors in deep-sleep mode to initiate another power state and let the PRCM module handle the next power states. At this time, software must ensure that all IPUx_UNICACHE background operations (for example, maintenance) are complete.

Table 7-4 describes local clock gating.

Table 7-4. Local Clock Gating

Cortex-M4 CPU Mode	IPUx_C1 On	IPUx_C1 Sleep	IPUx_C1 Deep Sleep
IPUx_C0 On	On	Functional clock 2 stopped locally	Functional clock 2 stopped locally
IPUx_C0 Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Functional clock 1 and clock 2 stopped locally
IPUx_C0 Deep Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Standby request to power-management module

NOTE: For information about source clock gating and for a description of the sleep/wake-up transitions, see Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.2 Power Domains

The IPUx subsystem is divided into two power domains (PD_IPU and PD_COREAON), which are controlled by the PRCM module.

The PD_IPU power domain is the main power domain and includes all the IPUx subsystem components (two Arm Cortex-M4 processors, IPUx_UNICACHE, IPUx_ROM and IPUx_RAM memories, and emulation\debug modules) except the IPUx_WUGEN.

The PD_COREAON power domain is an always-on power domain. The PD_COREAON power domain contains the IPUx_WUGEN, which generates a wake-up request from external interrupts. By this separate PD_COREAON power domain, the wake-up request can be generated even when the PD_IPU power domain is in OFF or RET state.

For information about the PD_IPU and PD_COREAON power domains, see Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.3 Voltage Domain

The IPUx subsystem is located within the CORE voltage domain (VD_CORE). All IPU logic (Cortex-M4 cores, IPUx_UNICACHE/MMU, IPUx_WUGEN, etc...) is fed by VD_CORE. All IPU memory arrays are fed by on-chip memory (SRAM) LDO dedicated to the CORE domain – SLDO_CORE.

For information about VD_CORE and SLDO_CORE, see Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.4 Power States and Modes

Table 7-5 lists the different power modes and the expected states for each power domain.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 7-5. IPUx Subsystem Power Modes

		Activity			Power Status	
	Functional Domain	Core		IPUx subsystem	PD_DSP Power Domain	PD_COREAON Power Domain
	Modules included	IPUx_C0	IPUx_C1	IPUx_WUGEN		
Power modes	Active	Active	Active	Active	ON	ON
	IPUx_C0 idle	Idle	Active	Active	ON	ON
	IPUx_C1 idle	Active	Idle	Active	ON	ON
	Core standby	Idle	Idle	Active	ON	ON
	Full idle	Idle	Idle	Idle	ON	ON
	CSWR	Idle	Idle	Idle	ON/LOWV	ON/LOWV
	OSWR	Idle	Idle	Idle	RET	ON
	Power off	Idle	Idle	Idle	OFF	OFF

Table 7-6 lists the power mode transitions in the IPUx subsystem.

Table 7-6. Power Mode Transitions

	Active	IPUx_C0 Idle	IPUx_C1 Idle	Standby	Full-Idle	Retention	Power Off
Active		WFE/WFI instruction	WFE/WFI instruction				
IPUx_C0 idle	Events/ interrupts			Deep sleep			
IPUx_C1 idle	Events/ interrupts			Deep sleep			
Standby	Wake-up IRQ				L1/L2/ IPUx_WUGEN functional domain idle		
Full idle	Wake-up IRQ			Wake-up (through interconnect)		PRCM module	PRCM module
CSWR/OSWR					PRCM module or wakeup		PRCM module
Power off					PRCM module or wakeup	PRCM module	

The different power modes and their features are:

- Active mode: All function domains are operative.
- IPUx_C0 and IPUx_C1 idle mode:
  - Only the CPU core is idled (when running WFE/WFI instructions).
  - Only one Cortex-M4 core can be in this mode. Interrupts or events can waken the core.
  - Can go into sleep or deep-sleep mode. Potentially, both cores can be in sleep mode.
  - When both cores are in deep-sleep mode, a standby request is sent to the PRCM module.
  - Software must ensure that all IPUx_UNICACHE background operations (for example, maintenance) are complete before the PRCM module asserts an IdleReq.
- Core standby mode
  - Both cores in the CORE functional domain are in idle mode (an interrupt cannot wake up either of the cores).
  - The PRCM module must have acknowledged its acceptance by an MWait signal.
  - After this handshake, all power management is under the control of the PRCM module.
- Full-idle mode:
  - The IPUx subsystem functional domain is also idled.

Copyright © 2018–2019, Texas Instruments Incorporated

  - After coming to this mode, power states can be moved deeper.
- Retention mode:
  - The voltage of the logic supply is lowered to reduce static power consumption by leakage current. The logic power switch in the PD_IPU power domain is still closed (ON); thus, all logic states are retained.
  - L1 and/or L2 memories can go independently into retention depending on the settings done at the PRCM level.
- Power off mode:
  - The voltage source is shut down. The logic states, including the retention logic, are lost.
  - The IPUx_WUGEN is not operating and only the PRCM module can trigger the IPUx subsystem wakeup.
  - Reset must be applied to the IPUx subsystem to restart the two Arm Cortex-M4 processors and the memory subsystem.

7.3.2.5 Wake-Up Generator (IPUx_WUGEN)

The IPUx_WUGEN in the IPUx subsystem enables efficient power management. The IPUx_WUGEN generates a wake-up signal to the PRCM module to enable the IPUx subsystem to recover its functional clocks, which are gated by the PRCM module when at least one request is active. The IPUx_WUGEN can be configured in standby mode or idle mode through the STANDBY_CORE_SYSCONFIG[1:0] STANDBYMODE and IDLE_CORE_SYSCONFIG[1:0] IDLEMODE bit fields.

7.3.2.5.1 IPUx_WUGEN Main Features

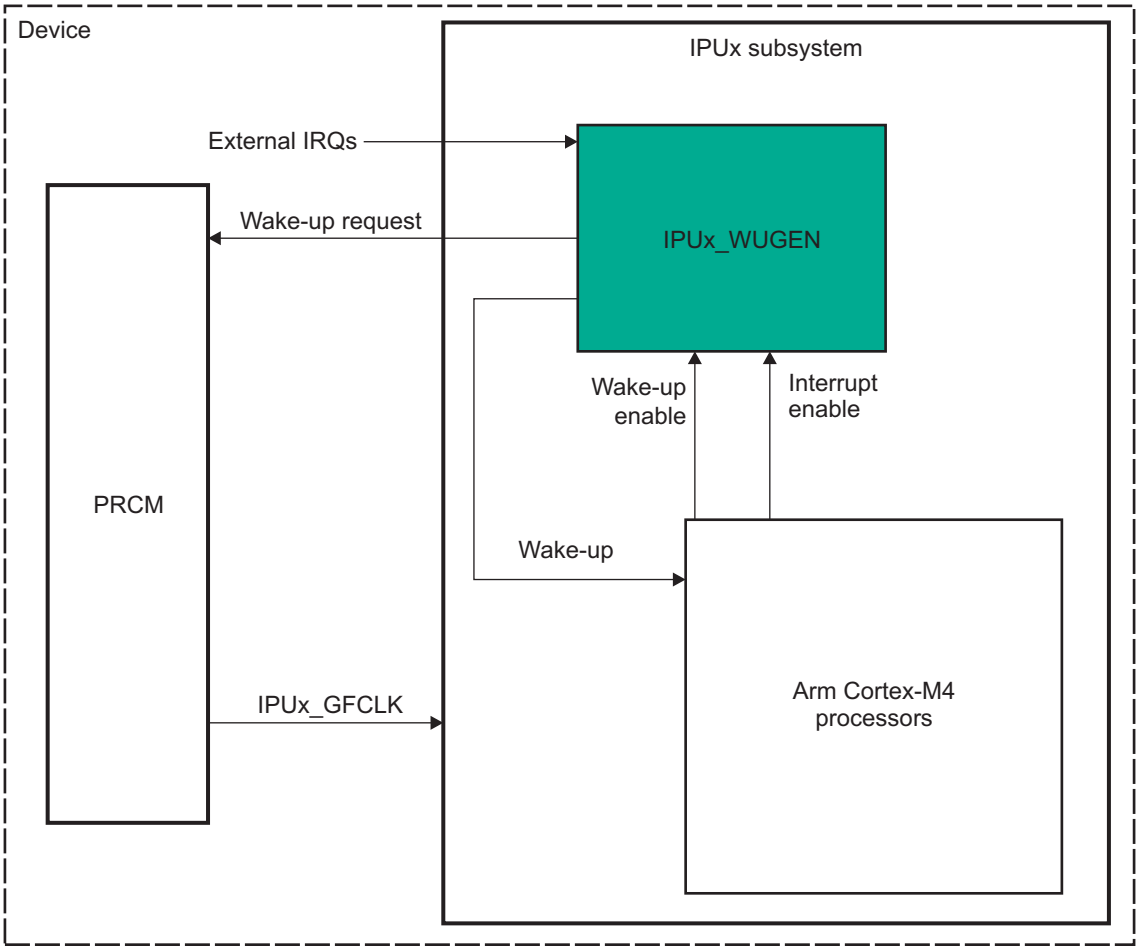
The IPUx_WUGEN allows:

- Gating of the IPUx subsystem clock dynamically, thus reducing power consumption
- Simplifying of dependencies in the PRCM module

Figure 7-7 is an overview of the IPUx_WUGEN.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 7-7. IPUx_WUGEN Overview



The wake-up signal to the PRCM module requests the IPUx subsystem functional clock (IPUx_GFCLK). The wake-up signal to the Arm Cortex-M4 processors indicates to them that at least one enabled request is active.

7.3.3 IPUx_UNICACHE

Table 7-7 describes the IPUx_UNICACHE configuration in the IPUx subsystem platform.

Table 7-7. IPUx_UNICACHE Configuration

Parameter	Value
Way	4
Size	32 KiB
Bank elements	32 bits
Bank number	16
Slave interface data size	32 bits
Master interface data size	64 bits
Line size	256 bits
MMU lookup	Included
Number of slaves	4
Number of masters	1
Number of fill/prefetch buffers	Four prefetch buffers
Slave types	IPUx_UNICACHE interface

Copyright © 2018–2019, Texas Instruments Incorporated

IPUx_UNICACHE allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

7.3.4 IPUx_UNICACHE_MMU

The IPUx_UNICACHE_MMU serves the role of an attribute MMU (AMMU) for the unicache. It provides the multi-access cache with region-based address translation, read/write control, access type control, and multi-level cache maintenance. Table 7-8 describes the IPUx_UNICACHE_MMU configuration in the device.

Table 7-8. IPUx_UNICACHE_MMU Configuration

Parameter	Values
Number of large pages	4 entries
Size of large pages	512 MiB or 32 MiB (configurable)
Number of medium pages	2 entries
Size of medium pages	256 KiB or 128 KiB (configurable)
Number of small pages	10 entries
Size of small pages	16 KiB or 4 KiB (configurable)
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of IPUx_UNICACHE maintenance interfaces	3
Size of entry address	32-bit

As can be seen in Table 7-8, IPUx_UNICACHE_MMU supports different page sizes: large, medium, and small. The number of large pages, number of medium pages, etc., is defined at design time. The size of the pages is configurable in the following IPUx_UNICACHE_MMU registers:

- CACHE_MMU_LARGE_POLICY_i[1] SIZE
- CACHE_MMU_MED_POLICY_j[1] SIZE
- CACHE_MMU_SMALL_POLICY_k[1] SIZE

The different MMU page sizes can be used to create smaller policies within a larger region.

The logical source address is configured in:

- CACHE_MMU_LARGE_ADDR_i[31:25] ADDRESS
- CACHE_MMU_MED_ADDR_j[31:17] ADDRESS
- CACHE_MMU_SMALL_ADDR_k[31:12] ADDRESS

The logical source translated address is configured in:

- CACHE_MMU_LARGE_XLTE_i[31:25] ADDRESS
- CACHE_MMU_MED_XLTE_j[31:17] ADDRESS
- CACHE_MMU_SMALL_XLTE_k[31:12] ADDRESS

Copyright © 2018–2019, Texas Instruments Incorporated

When the SIZE bit is set to 0, all the bits in the ADDRESS bit field of the corresponding logical source address and logical source translated address can be used.

When the SIZE bit is set to 1, the ADDRESS bit field of the corresponding logical source address and logical source translated address must be programmed only with addresses that can address the size of a second possible page.

7.3.5 IPUx_UNICACHE_SCTM

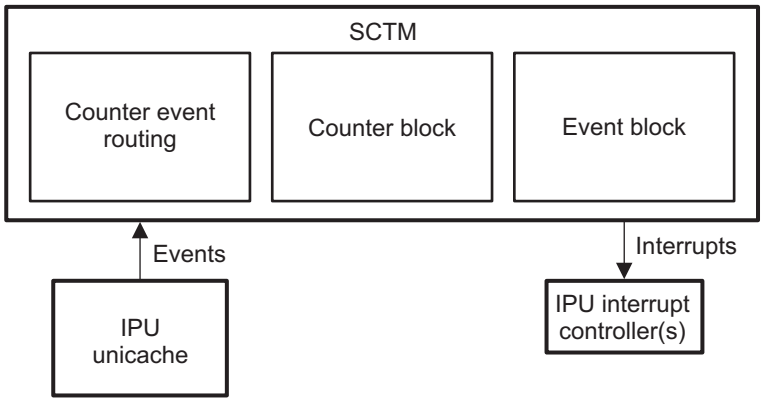
The Subsystem Counter Timer Module (SCTM) is a generic profile counter and timer module that provides the following functions:

- Counter functions:
  - Input events counting
  - Two counter modes:
    - Event counting
    - Duration counting
  - Counter chaining
- Timer functions:
  - Periodic intervals generation
  - Two timer modes:
    - Run-once mode
    - Restart mode
  - Events and/or interrupt generation

The SCTM has eight counters (two of which have timer functions). There are input events going into the SCTM and interrupt events going to the IPU INTC. For more information about the counter configuration and the SCTM input events, see Section 35.7.2, *IPU Subsystem Performance Monitoring*, in Chapter 35, *On-Chip Debug Support*. For more information about the mapping of the SCTM interrupt event signals to IPU INTC inputs, see Section 18.3.4, *Interrupt Requests to IPU1_Cx_INTC*, in Chapter 18, *Interrupt Controllers*.

Figure 7-8 shows the SCTM block diagram.

Figure 7-8. SCTM Block Diagram



7.3.5.1 Counter Functions

7.3.5.1.1 Input Events

Signals from within the subsystem are routed to the SCTM and used to control the counters and timers in the module. The routing of the input events from the module boundary to an individual counter is accomplished through an input event multiplexer and is controlled by the CACHE_SCTM_CTCR_WT_i[20:16] INPSEL and CACHE_SCTM_CTCR_WOT_j[20:16] INPSEL bit fields.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: For more information about input events to the module boundary, see Section 35.7.2.2, *Cache Events*, in Chapter 35, *On-Chip Debug Support*.

7.3.5.1.2 Counters

There are individual 32-bit counters in the SCTM. The counters count when the input event signals are asserted.

7.3.5.1.2.1 Counting Modes

The counters in the SCTM support two mutually exclusive counting modes:

- Event mode: The counter increments each time a rising edge is detected on the designated input event signal.
- Duration mode: The counter continually increments when the event input is asserted.

7.3.5.1.2.2 Counter Overflow

When the counter reaches the terminal value (0xFFFFFFF) it wraps and continues to increment. This is considered a timer overflow condition. The CACHE_SCTM_CTCR_WT_i[6] OVRFLW and CACHE_SCTM_CTCR_WOT_j[6] OVRFLW bits indicate that overflow has occurred. The overflow bit can be cleared by reading it. When chained, only the high-order counter overflows.

7.3.5.1.2.3 Counters and Processor State

The counters can be configured to alter their behavior based on the state of the CPU. The CACHE_SCTM_CTCR_WT_i[4] FREE and CACHE_SCTM_CTCR_WOT_j[4] FREE bits determine whether the counter will continue to operate when the processor enters debug halt state. When the FREE bit is set to 0, the counter stops incrementing while the debug halt input from the CPU is asserted. Normal operation resumes when the processor exits the debug halt state and the debug halt input is deasserted. When the FREE bit is set to 1, the state of the debug halt input is not used to control counter operation.

The CACHE_SCTM_CTCR_WT_i[5] IDLE and CACHE_SCTM_CTCR_WOT_j[5] IDLE bits determine whether the counter will continue to operate when the processor enters idle state (the processor is no longer executing instructions and is waiting for a wake-up event). When the IDLE bit is set to 0, the counter stops incrementing while the idle input from the CPU is asserted. Normal operation resumes when the processor exits the idle state and the idle input is deasserted. When the IDLE bit is set to 1, the state of the idle input is not used to control counter operation.

7.3.5.1.2.4 Chaining Counters

The individual 32-bit counters in the SCTM can be chained with an adjacent counter to form a 64-bit counter. Counters chained to a counter across an even-odd index boundary with the even counter contain the least-significant 32 bits of the 64-bit pairing. For example, counters 1 and 0 can be paired and counter 1 will contain bits 63:32 and counter 0 will contain bits 31:0. The high-order counter increments by 1 each time the low-order counter wraps.

Counters are chained by setting the CACHE_SCTM_CTCR_WT_i[2] CHAIN or CACHE_SCTM_CTCR_WOT_j[2] CHAIN bit for both counters. When chained, the counter control for both counters is taken from the CACHE_SCTM_CTCR_WT_i or CACHE_SCTM_CTCR_WOT_j register of the low-order counter. Other than the CHAIN bit, all other bits in the high-order CACHE_SCTM_CTCR_WT_i or CACHE_SCTM_CTCR_WOT_j register are ignored.

Chained counters can function only in counter mode. Timer mode is not supported.

The CACHE_SCTM_CTCR_WT_i[7] CHNSDW and CACHE_SCTM_CTCR_WOT_j[7] CHNSDW bits are used to indicate that a counter can provide atomics accessed when chained. These bits are valid only for counters with even indexes (the lower half of a 64-bit counter pair). When these bits are set, the counter can shadow the value of the lower half of the chained counter value at the same time the upper half of the counter is read. The shadowed value (not the current value) is returned when the value of the low-order

Copyright © 2018–2019, Texas Instruments Incorporated

counter is read. Therefore, when a chained counter has atomic read capability, an atomic counter value can be obtained simply by reading the high-order counter first, followed by the low-order counter. This order must always be observed to prevent reading stale counter values from the low-order counter. When counters are functioning independently, the shadow feature is deactivated and a read of the counter always returns the current value.

7.3.5.1.2.5 Enabling and Disabling Counters

After the counter is correctly configured, it can be started by setting the CACHE_SCTM_CTCR_WT_i[0] ENBL or CACHE_SCTM_CTCR_WOT_j[0] ENBL bit. At this point, the counter begins incrementing under the control of the configured event input. The counter can be disabled (counting stops) at any time by clearing the ENBL bit. Counters can be enabled and disabled dynamically during application flow.

Counters can also be enabled and disabled as groups through the CACHE_SCTM_CTGNBL register. This register provides control of the individual counter-enable in groups. This allows an application to enable or disable groups of counters in lockstep by setting corresponding bits to 1 (bit number corresponds to counter number).

7.3.5.1.2.6 Resetting Counters

The counters can be reset to their initial value (0x00000000) by writing 1 to the CACHE_SCTM_CTCR_WT_i[1] RESET or CACHE_SCTM_CTCR_WOT_j[1] RESET bit. If the counter is chained, the high-order and low-order counters are reset when the RESET bit is written for the low-order counter.

Counters can also be reset as groups through the CACHE_SCTM_CTGRST registers. These registers provide control of the individual counter reset in groups. This allows an application to reset groups of counters in lockstep.

7.3.5.2 Timer Functions

Counters 0 and 1 in the SCTM can function as timers. When operating as timers, interrupts and/or debug input events are generated when the value of the counter reaches a designated interval.

7.3.5.2.1 Periodic Intervals

The interval for a timer is contained in the CACHE_SCTM_TINTVLR_i register. There is a CACHE_SCTM_TINTVLR_i register for every timer-capable counter in the SCTM. Timers are initialized to 0. When the corresponding CACHE_SCTM_CTCNTR_k increments and matches the values designated in CACHE_SCTM_TINTVLR_i, the timer is considered to be triggered and events configured in CACHE_SCTM_CTCR_WT_i are generated.

Timers can function in one of two mutually exclusive modes:

- Run-once mode: The timer stops after the first interval match and is not re-enabled until the timer is reset to the initial value (0) by setting the CACHE_SCTM_CTCR_WT_i[1] RESET bit to 1.
- Restart mode: The timer automatically resets to the initial value (0) each time the designated interval is reached.

The CACHE_SCTM_CTCR_WT_i[10] RESTART bit is used to configure the timer mode.

7.3.5.2.2 Event Generation

Timers can generate interrupts and debug events. Interrupts are routed from the module boundary to the interrupt controller(s) in the subsystem. Debug events are routed as triggers to debug logic within the subsystem.

The generation of the interrupts is controlled by the CACHE_SCTM_CTCR_WT_i[8] INT bit. The generation of debug events is controlled by the CACHE_SCTM_CTCR_WT_i[9] DBG bit. The INT and DBG bits can be set simultaneously and both signals are generated on interval match.

If neither INT nor DBG is set, the timer function is disabled and the counter functions as a regular counter.

Copyright © 2018–2019, Texas Instruments Incorporated

7.3.6 IPUx_MMU

An additional MMU provides address translation for the accesses done from the IPUx subsystem to the L3_MAIN interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with Armv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion
- Two-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16 MiB, 1 MiB, 64 KiB, 4 KiB)
- Page table alignment on 128-byte boundary for Arm11® compatibility

The configuration of the MMU can be done from one of the Cortex-M4 cores or from the L3_MAIN interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access.

For more information about the IPUx_MMU, see Chapter 21, *Memory Management Units*.

7.3.6.1 IPUx_MMU Behavior on Page-Fault in IPUx Subsystem

Table 7-9. IPUx_MMU Behavior on Page-Fault

Application		Debug	
Table-Walker Enabled	**Table-Walker Disabled**	**Table-Walker Enabled**	**Table-Walker Disabled**
Use Table-Walker to find translation. Update TLB cache if successful, set TRANSLATIONFAULT bit and interrupt if not. The following bits are used for the purpose: MMU_IRQENABLE[1] TRANSLATIONFAULT and MMU_IRQSTATUS[1] TRANSLATIONFAULT.	Set TLBMISS bit and interrupt and stall. The following registers are used for the purpose: MMU_IRQENABLE[0] TLBMISS and MMU_IRQSTATUS[0] TLBMISS.	Use Table-Walker to find translation. Update TLB cache if successful (only if the MMU_CNTL[3] EMUTLBUPDATE bit is set), generate in-band bus error if not.	Set EMUMISS bit and interrupt and stall. The following bits are used for the purpose: MMU_IRQENABLE[2] EMUMISS and MMU_IRQSTATUS[2] EMUMISS.

The MMU fault interrupt line is connected to both Cortex-M4 cores (at IPUx_IRQ_16 interrupt line) and is also propagated outside of the IPUx subsystem and connected to an IRQ_CROSSBAR input (IRQ_CROSSBAR_395 for the IPU1 MMU interrupt, IRQ_CROSSBAR_396 for the IPU2 MMU interrupt). The user can route this interrupt to any device host processor by programming properly the corresponding Control Module registers. The host processor (typically, a Cortex-A15) receives the MMU fault and must clean up the fault to resume the execution of the code (or reset IPUx subsystem). It is not possible for one of the Cortex-M4 CPUs to clean up the fault caused by the other Cortex-M4 CPU. This is because both the slave port of the IPUx_MMU (which is stalled) and the configuration port of IPUx_MMU are connected (through a splitter) to the same IPUx_UNICACHE master port.

The default behavior of the IPUx_MMU previously described can be overridden by setting the MMU_GP_REG[0] BUS_ERR_BACK_EN bit to 1. Once this bit is set, all MMU faults (including TLB miss) return a bus error to the IPUx subsystem (interrupt event XLATE_MMU_FAULT). This allows the end user to quickly establish the cause of the MMU fault by having appropriate code in the ISR.

7.3.7 Interprocessor Communication (IPC)

7.3.7.1 Use of WFE and SEV

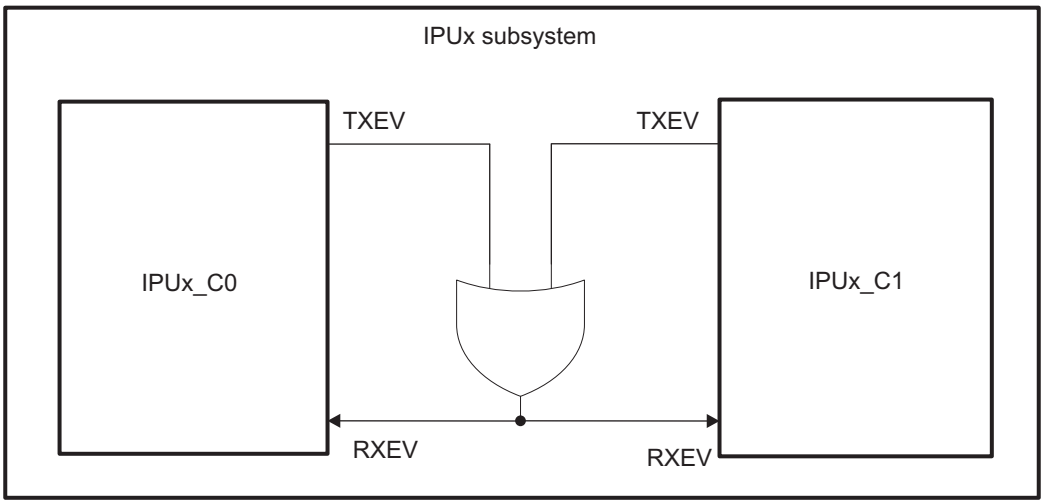
The IPUx subsystem provides a multiprocessor communication interface for synchronizing tasks. The Arm processors have one output signal, TXEV (transmit event), for sending events and one input signal, RXEV (receive event), for receiving events. Figure 7-9 shows how TXEV and RXEV are connected in the IPUx subsystem.

Copyright © 2018–2019, Texas Instruments Incorporated

When a WFE instruction is executed, the processor enters into sleep mode waiting for an event and continues instruction execution when an external event is received. With an SEV (send event) instruction, one processor can wake up the other processor, which is in sleep mode.

The WFE and SEV instructions can help reduce the number of iterations around a lock acquire loop (a spinlock), and thereby reduce power consumption. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction, which suspends execution on that observer until an asynchronous exception or an explicit event (sent by an observer using the SEV instruction) is seen by that observer. The observer that holds the lock uses the SEV instruction to send an event after a lock is released.

Figure 7-9. Event Communication Connection in IPUx Subsystem



7.3.7.2 Use of Interrupt for IPC

Each Cortex-M4 core can interrupt the other Cortex-M4 core by setting up an interrupt register (CORTEXM4_CTRL_REG). This register is used to trigger the corresponding 'per core' HWSEM_M4_IRQ interrupt (interrupt number 19). Because the priority level for that interrupt can be defined, it is possible to choose the task level at which the interrupt will run. For example, if IPUx_C0 was active and IPUx_C1 was idle (WFI state), when IPUx_C0 completes its task it sets the bit for IPUx_C1 in the control register (CORTEXM4_CTRL_REG[16] INT_CORTEX_2) and goes into sleep mode. IPUx_C1 wakes up seeing this interrupt, and starts running its task. After the completion of its task, IPUx_C1 sets the interrupt for IPUx_C0 (CORTEXM4_CTRL_REG[0] INT_CORTEX_1), and then goes into WFI state. This kind of handshake ensures that if IPUx_C0 and IPUx_C1 are accessing the same resources (memory, registers etc.), only one of the CPUs at a time is active.

7.3.7.3 Use of the Bit-Band Feature for Semaphore Operations

The two Cortex-M4 cores share the same memory system, and it is possible to use the bit-band feature to carry semaphore operations. Because the bit-band alias writes are locked read-modify-write transfers, provided that all tasks changed only the lock bit representing themselves, the lock bits of other tasks are not lost, even if two tasks try to write to the same memory location at the same time.

Each Cortex-M4 core supports two bit-band regions.

Bit-band 1 applies to the virtual address space 0x2000 0000–0x200F FFFF (1 MiB). This virtual address space can be mapped to any physical address and bit-banding will apply to that region. It is recommended that the user map the L2 IPUx_RAM (64 KiB) to this virtual space and use it only for bit-banding operations. If required, the user can define other available small and medium pages over and above the L2 IPUx_RAM virtual space and further extend the use of the bit-band feature.

Copyright © 2018–2019, Texas Instruments Incorporated

Bit-band 2 applies to the virtual address space 0x4000 0000–0x400F FFFF (1 MiB). The first 16 KiB of this space (0x4000 0000–0x4000 3FFF) are already reserved for small (one page) pages and cannot be remapped by software. The bit-band alias that corresponds to this 16-KiB region (0x4200 0000–0x4207 FFFF) must also be treated as reserved and no access should be made. The rest of bit-band 2 can be used by appropriately defining the available small and medium pages. In this device, because it is likely that during normal AMMU programming all of L3_MAIN is mapped to this region, it is highly recommended that the user use only bit-band 1 for all purposes and bit-band 2 only if it is necessary.

7.3.7.4 Private Memory Space

Each Arm Cortex-M4 processor has its own memory space, inaccessible by the other processor. In the private memory space are the IPUx_Cx_INTC and RW table registers: CORTEXM4_RW_PID1 and CORTEXM4_RW_PID2. CORTEXM4_RW_PID1 and CORTEXM4_RW_PID2 are accessible only by the respective Cortex-M4 cores (CORTEXM4_RW_PID1 is accessible only by IPUx_C0, while CORTEXM4_RW_PID2 is accessible only by IPUx_C1) . These registers are not accessible from the Cortex-A15 MPU. Because they are not shared, they do not require the bit-band feature (semaphore) to read and write to them.

7.3.8 IPU Boot Options

The IPU boot location is controlled via two Control Module registers:

- CTRL_CORE_CORTEX_M4_MMUADDRTRANSLTR[19:0] CORTEX_M4_MMUADDRTRANSLTR: Used to set the physical translated address for IPU AMMU
- CTRL_CORE_CORTEX_M4_MMUADDRLOGICTR[19:0] CORTEX_M4_MMUADDRLOGICTR: Used to set the logical source address for IPU AMMU

By default, two AMMU pages are enabled:

- Small page-0: Translates the 16KB address range from CORTEX_M4_MMUADDRLOGICTR to (CORTEX_M4_MMUADDRLOGICTR + 0x3FFF). If CORTEX_M4_MMUADDRLOGICTR is set to 0x00000, page-0 will control the boot location. If the boot location needs to be mapped to the L2 RAM (0x5502_0000), then CORTEX_M4_MMUADDRTRANSLTR needs to be set to 0x55020. This page is set as non-cacheable at reset.
- Small page-1: Loaded with the physical address of the IPU AMMU configuration registers (0x5508_0000 - 0x5508_0FFF), which is mapped to the virtual address range from 0x4000_0000 to 0x4000_0FFF. This page is also set as non-cacheable at reset.

NOTE: Small page-1 is by default 4KB. Software has to modify it to 16KB to cover L2MMU/WUGEN masks.

For IPU to boot from any location in L3:

1. Provide boot address through CORTEX_M4_MMUADDRTRANSLTR to AMMU page-0 (CORTEX_M4_MMUADDRLOGICTR set to 0x00000). Keep L2 MMU disabled (or enable L2 MMU but keep the same translation for 0x0; otherwise there will be L2-MMU page-walks / page-faults).
2. Set CORTEX_M4_MMUADDRTRANSLTR to 0x00000 (or any value). Host CPU re-programs AMMU page to map 0x0 virtual address to a physical L2 RAM / L3 location. Only after the programming is complete, Cortex-M4 reset is released. L2 MMU as described above.
3. Set CORTEX_M4_MMUADDRTRANSLTR to 0x00000 (no translation). Host CPU programs L2 MMU to do the address translation for 0x0.

For IPU to boot from L2 RAM:

1. This must be done through AMMU page-0. Use either (1) or (2) as described above.

Physical Address	0x5508 0500 + (0x4 * i) 0x5888 0500 + (0x4 * i) 0x5508 0500 + (0x4 * i) 0x5508 0500 + (0x4 * i)	**Instance**	IPU1_WUGEN_IPU IPU1_WUGEN_MAIN_L3 IPU2_WUGEN_IPU IPU2_WUGEN_MAIN_L3
Description	These registers contain the control and status settings for a single counter in the module. There will be a CTCR for every counter in the module (WT: with timer)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INPSEL								RESERVED					RESTART	DBG	INT	CHNSDW	OVRFLW	IDLE	FREE	DURMODE	CHAIN	RESET	ENBL

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:16	INPSEL	Counter Timer input selection 0: Constantly asserted input that results in a free-running counter/timer 1-31: Index of event input signal selected	RW	0x00
15:11	RESERVED	Reserved.	R	0x00
10	RESTART	Restart the timer after an interval match 0: The timer stops after the first interval match. It must be manually reset by software before it starts counting again (run-once timer mode). 1: The timer immediately resets to 0 and begins incrementing again based on the current input configuration (restart timer mode).	RW	0
9	DBG	Signal debug logic on interval match 0: No debug event is generated. 1: Upon interval match, generates a debug event on the corresponding debug output event signal	RW	0
8	INT	Generate interrupt on interval match 0: No interrupt is generated. 1: Upon interval match, generates an interrupt on the corresponding interrupt output event signal	RW	0
7	CHNSDW	Counter has a shadow register for chain reads. 0: The read of the corresponding counter register returns the current value. 1: Read of the high-order counter register, simultaneously loads the current value of the 32 LSBs into a shadow register. The read of the counter register that corresponds to this counter returns the value of the shadow register. This is applicable only when the counter is chained.	R	0
6	OVRFLW	Counter has wrapped since it was last read 0: The counter has not wrapped since the last read. 1: The counter has wrapped since the last read.	R	0
5	IDLE	Counter ignores processor IDLE state 0: The counter does not increment during IDLE state. 1: The counter continues to function during IDLE state; applicable if IDLEMODE = 1.	RW	0
4	FREE	Counter ignores processor debug halt state	RW	0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
		0: The counter does not increment (decrement) during the debug halt state. 1: The counter continues to function during debug halt state.		
3	DURMODE	Counter is in duration or occurrence mode 0: The counter operates in event mode. The counter increments by 1 each time a rising edge is seen on the designated input event signal. 1: The counter operates in duration mode. The counter increments every time a clock cycle is seen and the corresponding input event signal is asserted.	RW	0
2	CHAIN	Counter is chained to an adjacent counter 0: The counter is not chained. 1: Reserved	RW	0
1	RESET	Counter reset control 0: No effect 1: The corresponding counter is reset to the initial value and the OVERFLW bit is cleared. It continues to function if it is still enabled.	RW	0
0	ENBL	Counter enable control 0: The counter does not increment. 1: The counter increments as configured.	RW	0

Embedded Vision Engine

This chapter describes the Embedded Vision Engine (EVE) for the device.

NOTE: The Embedded Vision Engine (EVE) module is a programmable imaging and vision processing engine. Software support for the EVE module is available through OpenCL Custom Device model with fixed set of functions. The EVE module availability is device part number dependent. Refer to device Data Manual, for more information.

Camera Interface Subsystem

This chapter describes the Camera Interface Subsystem (CAL and CSI2_PHY) in the device.

NOTE: CAL and CSI2_PHY modules are not supported on the AM574x family of devices.

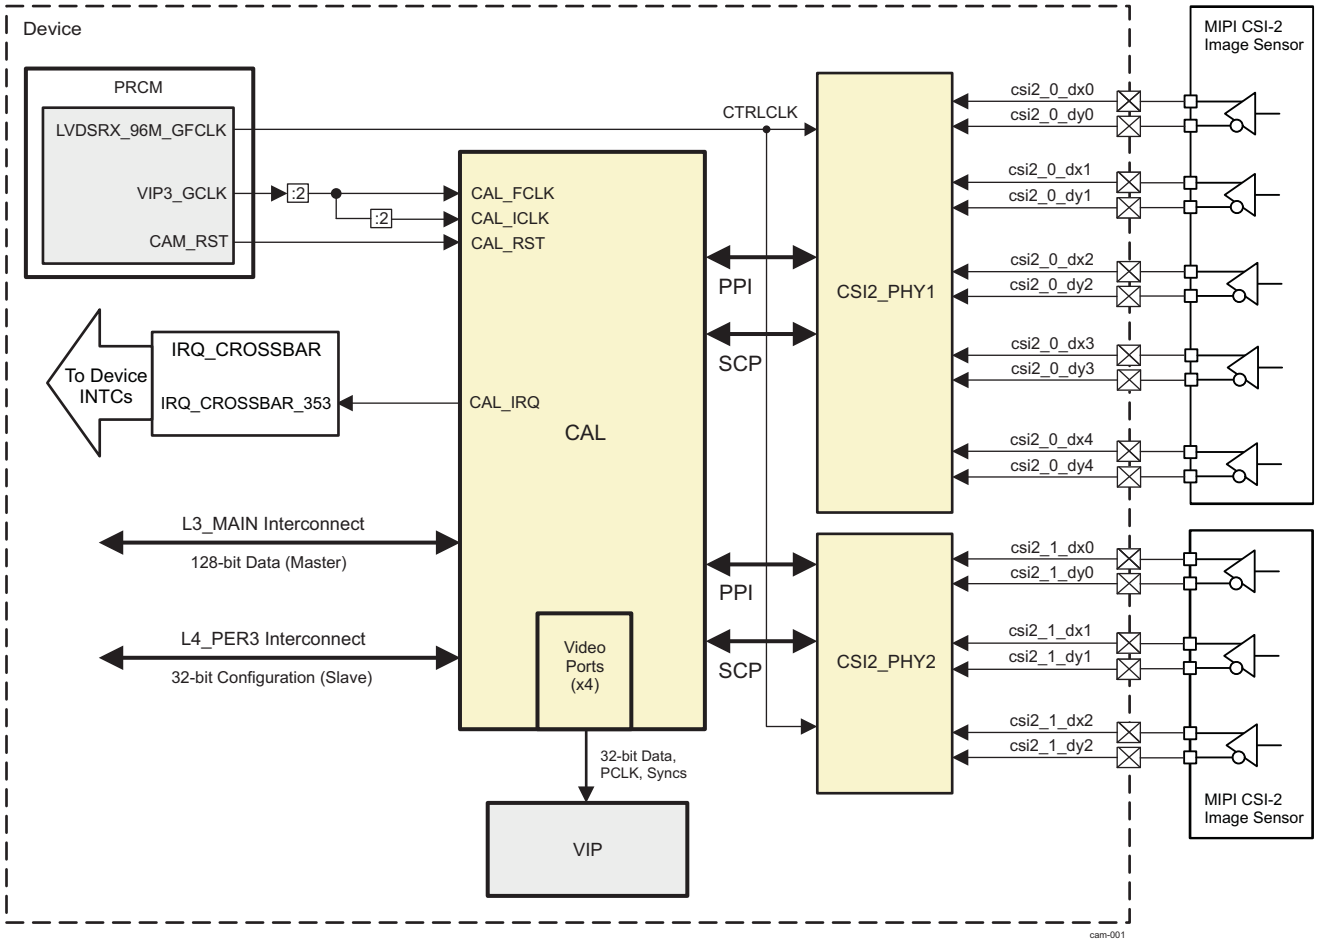
9.1 CAMSS Overview

9.1.1 CAMSS Block Diagram

Figure 9-1. CAMSS Overview



9.1.2 CAMSS Features

The device CAMSS provides:

- Camera Adapter Layer (CAL) module with up to 304 MHz processing clock rate
- CAL interfaces:
  - Two PHY Protocol Interfaces (PPI) to MIPI D-PHY compliant receivers (CSI2_PHY1 and CSI2_PHY2)
    - Byte clock for data transfers up to 187.5 MHz (that is, D-PHY with 1.5 Gbps per lane)
    - Programmable clock and data lane position
    - Serial Configuration Interface (SCP)
  - 32-bit slave configuration interface (OCPC) to the interconnect
  - 128-bit master data interface (OCPO) to the L3_MAIN interconnect and system memory
  - Video port:
    - Four video port interfaces
    - Up to 2 pixels per clock cycle
    - Pixel rate smoothing buffer
- On-the-fly functional mode: A byte stream received from a PPI is interpreted as a CSI-2 stream. Pixels

Copyright © 2018–2019, Texas Instruments Incorporated

are extracted and sent to the system memory and/or video port

- MIPI CSI-2 low level protocol support:
  - Up to 8 contexts (VCT + DT combinations)
  - Data lane merger
  - Error detection / correction (CRC/ECC)
  - Re-synchronization FIFO
- Up to four [4] independent pixel processing contexts:
  - All primary and secondary MIPI CSI-2 formats supported
  - Extract pixels from byte stream
  - DPCM decompression (4 pixels/cycle for predictor1; 1 pixel/cycle for predictor2)
  - DPCM compression (2 pixels/cycle for predictor1; predictor2 is not supported)
  - Pixel packing into a byte stream (for memory storage)
- Up to eight [8] independent write DMA contexts:
  - Write header, pixel, or attribute data
  - Horizontal cropping
  - Pack data from independent streams into efficient OCP transactions
  - 1D and 2D addressing modes (only INCR bursts)
  - Resynchronize on line boundaries (for TxBuffer overflows)
  - Linear, circular, and sub-sampled addressing modes
- Unsupported features of the CAMSS:
  - The CAMSS does not have a power switch, making the power domain (PD_CAM) Always-On. For more information on the power domain, see Section 3.7.14, *PD_CAM (Physical PD_COREAON) Description*.

9.2 CAMSS Environment

This section describes the CAMSS application fields from an environment point of view (external connections). It describes the CAMSS connectivity options and lists all possible interfaces.

9.2.1 CAMSS Interfaces Signal Descriptions

Figure 9-2. CAMSS Environment

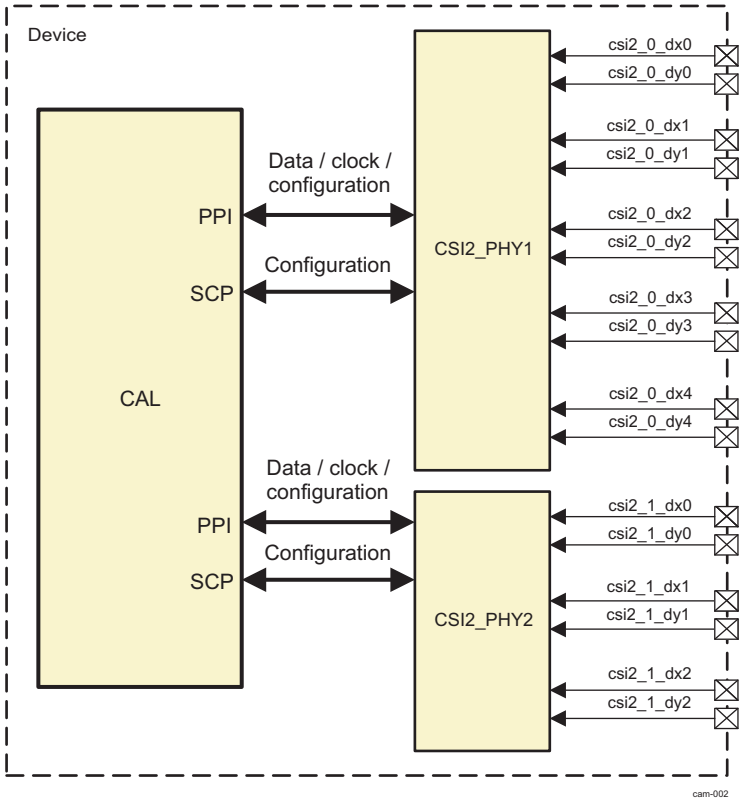

Table 9-1 summarizes the CAMSS I/O signals.

Table 9-1. CAMSS I/O Description

Signal Name	I/O[1]	Description
csi2_0_dx0	I	Serial CSI2 mode: Differential clock lane positive input
csi2_0_dy0	I	Serial CSI2 mode: Differential clock lane negative input
csi2_0_dx1	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy1	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx2	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy2	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx3	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy3	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx4	I	Serial CSI2 mode: Differential data lane positive input

(1) I = Input; O = Output

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-1. CAMSS I/O Description (continued)

Signal Name	I/O[1]	Description
csi2_0_dy4	I	Serial CSI2 mode: Differential data lane negative input
csi2_1_dx0	I	Serial CSI2 mode: Differential clock lane positive input
csi2_1_dy0	I	Serial CSI2 mode: Differential clock lane negative input
csi2_1_dx1	I	Serial CSI2 mode: Differential data lane positive input
csi2_1_dy1	I	Serial CSI2 mode: Differential data lane negative input
csi2_1_dx2	I	Serial CSI2 mode: Differential data lane positive input
csi2_1_dy2	I	Serial CSI2 mode: Differential data lane negative input

NOTE: The *Description* column in Table 9-1 shows only the default function (data or clock lane) of each CSI2 differential pair. Refer to Section 9.4.5, *CSI2 PHY Functional Description*, for more details on configurations available.

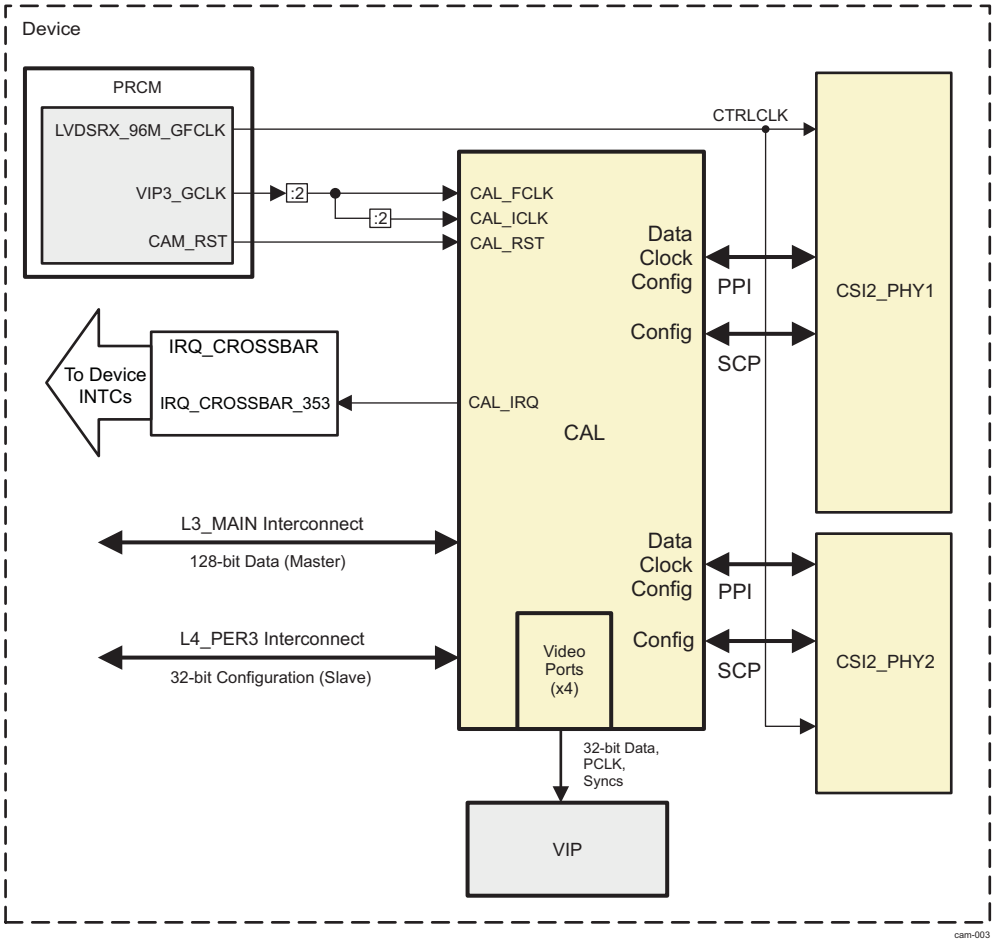
9.3 CAMSS Integration

This section describes the integration of CAMSS in the device, including information about clocks, resets, and hardware requests.

Figure 9-3. CAMSS Integration



NOTE: For more information about the slave idle protocol, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

9.3.1 CAMSS Main Integration Attributes

This section describes the CAMSS integration in the device, including information about clocks, resets, and hardware requests.

Table 9-2 through Table 9-4 summarize the integration of the module in the device.

Table 9-2. CAL Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
CAL	PD_COREAON PD_CAM (1)	No	L3_MAIN for data transfers to system memory; L4_PER3 for configuration

(1) CAL module is placed in PD_COREAON but its clocks and resets controls are associated with PD_CAM. In order to use the CAL module, PD_CAM needs to be turned on. For more information on the power domains, see Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-3. CAMSS Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CAL	CAL_FCLK	VIP3_GCLK	PRCM	Functional clock.
	CAL_ICLK	VIP3_GCLK / 2	PRCM	Configuration clock on L4_PER3 interconnect (OCPC port). Equal to 1/2 of the CAL_FLCK.
	CAL_BYTECLKHS	RXBYTECLKHS	CSI2 PHY	CSI2 High-Speed Receive Byte Clock.
CSI2_PHY1 and CSI2_PHY2	CTRLCLK	LVDSRX_96M_GFCLK	PRCM	Control clock for CSI2 PHY modules.
	SCPCLK	CAL_SCPCLK	CAL	Configuration clock for CSI2 PHY modules. Equal to 1/4 of CAL_FLCK.
	PWRCLK	CAL_PWRCLK	CAL	Power management clock for CSI2 PHY modules. Equal to 1/4 of CAL_FLCK.
-	-	VP_PCLK	CAL	Pixel clock provided on the CAL output video port(s). For more information, see Section 9.3.2, *CAL Integration - Video Port*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CAL	CAL_RST	CAM_RST	PRCM	CAL global hardware reset

Table 9-4. CAL Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
CAL	CAL_IRQ	IRQ_CROSSBAR_353	N/A	CAL interrupt request

NOTE: The "**Default Mapping**" column in Table 9-4 *CAL Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 19, *Control Module*. For more information about the device interrupt controllers, see Chapter 18, *Interrupt Controllers*.

9.3.2 CAL Integration - Video Port

CAL has two modes for video port operation: baseline mode and VPx4 mode.

- The baseline mode can be selected by setting CTRL_CORE_SMA_SW_3[31] CAL_BASELINE_EN register bit to 1 from RESET onwards. In baseline mode only Video Port 1 is active. The CTRL_CORE_SMA_SW_3 register is located in device Control Module, see Chapter 19.
- In VPx4 mode, CAL provides four identical video ports. The VPx4 mode (default) is selected when CAL_BASELINE_EN register bit is set to 0. All four video ports follow the same programming with the exception of CPORT. For more information, see Section 9.4.6.9, *CAL Video Port*.

The video ports can be used for data transfer to the device VIP modules. The mapping of CAL video ports signals to VIP modules is controlled via registers in the device Control Module. For more information, see Section 10.2, *VIP Environment*.

Table 9-5 summarizes the video port interface signals.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-5. CAL Video Port Signals

Signal name[1]	I/O	Description
VPn_PCLK	O	Output pixel clock. Synchronous to the functional clock. Mean clock rate defined by the CAL_VPORT_CTRL1[16:0] PCLK register bit-field.
VPn_VS	O	Active during the first pixel of the frame.
VPn_VE	O	Active during the last pixel of the frame.
VPn_HS	O	Active during the first pixel of any line.
VPn_HE	O	Active during the last pixel of any line.
VPn_DATA[15:0]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Pixel data for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 0 MSBs are padded with 0s when less than 16 bits are used.
VPn_DATA[31:16]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Stuffed with 0s for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 1 MSBs are padded with 0s when less than 16 bits are used.
VPn_STALL	I	Hardwired to 0. The video port cannot be stalled from outside CAL.

(1) n = 1 through 4 (video port number)

Software can control the minimum time between two consecutive VP_PCLK pulses using the CAL_VPORT_CTRL1[16:0] PCLK bit field. It can also impose minimum vertical and horizontal blanking using the CAL_VPORT_CTRL1[24:17] XBLK and CAL_VPORT_CTRL1[30:25] YBLK bit fields.

The video port can carry up to 2 pixels per VP_PCLK clock cycle.

For more details on the video port, see Section 9.4.6.9, *CAL Video Port*.

9.3.3 CAL Integration - PPI Interface

CAL does not connect directly to an image sensor but to a complex I/O (CSI2 PHY). CAL can connect to up to two CSI2 complex I/Os through PHY Protocol Interfaces (PPI) which can be used simultaneously. For more details on the PPI interface configuration, refer to Section 9.4.5, *CSI2 PHY Functional Description*, and Section 9.4.6.2.1, *CSI2 Physical Layer*.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4 CAMSS Functional Description

9.4.1 CAMSS Hardware and Software Reset

An active low asynchronous hardware reset is provided by the PRCM. It is internally resynchronized to the functional clock domain.

A software reset is triggered by setting the CAL_HL_SYSCONFIG[0] SOFTRESET bit to 0x1. The CAL hardware ensures that the software reset is performed on clean OCP transactions boundaries and that no OCP protocol violation can occur due to the software reset. Mainly, it finishes ongoing OCP transactions and prevents generation of new ones.

The CAL_HL_SYSCONFIG[0] SOFTRESET bit is automatically cleared by hardware when the software reset has completed. The software reset will never complete, if outstanding OCP responses are not returned. This situation is only expected when the slave with which CAL is communicating fails. A hardware reset is reset in that case.

A software reset is faster than a hardware reset controlled by the device PRCM module. In fact, to avoid OCP protocol violations, the PRCM module first puts the CAL into Idle mode. The PRCM can only perform a clean hardware reset once CAL has acknowledged the IDLE request. That only happens once the CAL has flushed all pending traffic. A software reset simply waits for the next clean OCP transaction boundary without finishing the frame.

OCPC is fully functional after a software reset.

9.4.2 CAMSS Clock Configuration

CAL receives one functional clock (CAL_FLCK) from PRCM that is also used for the OCP ports. The configuration port (OCPC) operates at half the functional clock speed (clock enable signal used).

In addition, CAL receives one asynchronous clock for each PPI interface. This clock is generated from the bit clock received from the image sensor and converted into a byte clock (CAL_BYTECLKHS) by the connected CSI2 PHY.

CAL also provides the PWRSCP clock used to configure the CSI2 PHY. It is equal to the CAL functional clock divided by 4 (CAL_FLCK / 4) and is gated depending on the functional needs.

9.4.3 CAMSS Power Management

CAL supports a IDLE protocol interface. It is used to ensure that the CAL clock / power can only be cut where there are no pending transactions. It is also used to ensure that CAL generates no more traffic before gating the functional clock. The PRCM sends an IDLE request to CAL when the software requests CAL shutdown.

When CAL receives an IDLE request, it performs the following actions:

1. Finishes pending transactions:
   a. All data has been flushed out from the write buffer.
   b. FE short packet has been received (but no new FS) on all enabled PPI virtual channels.
2. Disconnects the OCPC and OCPO ports on clean transaction boundaries.
3. Acknowledges the IDLE request.

On CAL level the IDLE protocol configuration is controlled via CAL_HL_SYSCONFIG[3:2] IDLEMODE register bit-field. For more information on CAL clock and power management on device level, see Section 3.6.4.24, *CD_CAM Clock Domain* and , *PD_CAM Description* in Chapter 3, *Power, Reset, and Clock Management*.

For more information on CSI2 PHY power management, refer to Section 9.4.5.2, *CSI2 PHY Configuration*.

9.4.4 CAMSS Interrupt Events

This section describes the interrupt events that can trigger the CAL_IRQ signal (see also Section 9.3.1, *CAL Main Integration Attributes*).

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: The CAL does not provide an event to detect Attribute Payload data at low level protocol level. Attribute data can only be sent to memory and therefore software can use the IRQ_WDMA_START / END events detected by the Write DMA block.

Table 9-6 lists the event generation and corresponding registers of the CSI2 Low Level Protocol engines.

Table 9-6. CSI2 Low Level Protocol Interrupts

Event and Register	Description
CAL_CSI2_COMPLEXIO_IRQENABLE_I[27] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered when a FIFO overflow is detected. An overflow can occur if there is a mismatch between the data input and output rates. In case of an overflow the module properly finishes the burst that has been started and does not issue any new OCP transactions on the master port. A reset of the module is required to restart correctly.
CAL_CSI2_COMPLEXIO_IRQENABLE_I[28] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types from 0x8 to 0xF are considered)
CAL_CSI2_COMPLEXIO_IRQENABLE_I[30] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CAL_CSI2_VC_IRQENABLE_I[] ECC_CORRECTION_IRQ_x, where x = [0...3]	ECC was used to correct a 1-bit error (short packet only).
CAL_CSI2_VC_IRQENABLE_I[] FS_IRQ_x, where x = [0...3]	Frame start: This interrupt is triggered when a frame-start synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] FE_IRQ_x, where x = [0...3]	Frame end: This interrupt is triggered when a frame-end synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] LS_IRQ_x, where x = [0...3]	Line start: This interrupt is triggered when a line-start synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] LE_IRQ_x, where x = [0...3]	Line end: This interrupt is triggered when a line-end synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] CS_IRQ_x, where x = [0...3]	CS error: This interrupt is triggered when a mismatch between the transmitter and receiver checksums (payload) is detected.

Table 9-7 lists CSI2 Complex I/O event generation. The events are checked and controlled from the CAL_CSI2_COMPLEXIO_IRQSTATUS_I and CAL_CSI2_COMPLEXIO_IRQENABLE_I registers.

Table 9-7. CSI2 Complex I/O Interrupts

Event and Register	Description
CAL_CSI2_COMPLEXIO_IRQENABLE_I[0] ERRSOTHS1	Start of transmission error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[1] ERRSOTHS2	Start of transmission error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[2] ERRSOTHS3	Start of transmission error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[3] ERRSOTHS3	Start of transmission error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[4] ERRSOTHS3	Start of transmission error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[8] ERRSOTSYNCHS3	Start of transmission sync error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[9] ERRSOTSYNCHS3	Start of transmission sync error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[10] ERRESC1	Escape entry error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[11] ERRESC2	Escape entry error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[12] ERRESC3	Escape entry error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[13] ERRESC4	Escape entry error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[14] ERRESC5	Escape entry error for lane 5

CAL_CSI2_COMPLEXIO_IRQENABLE_I[16] ERRCONTROL2	Control error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[17] ERRCONTROL3	Control error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[18] ERRCONTROL4	Control error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[19] ERRCONTROL5	Control error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[20] STATEULPM1	Lane 1 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I[21] STATEULPM2	Lane 2 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I[22] STATEULPM3	Lane 3 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I[23] STATEULPM4	Lane 4 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I[24] STATEULPM5	Lane 5 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I[25] STATEALLULPMENTER	All active lanes are entering the ULPM.
CAL_CSI2_COMPLEXIO_IRQENABLE_I[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

Table 9-8. CAL Write DMA Interrupts

Event	Description
IRQ_WDMA_STARTx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Frame start. Triggered by the Write DMA when a data word tagged as ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S or PIX_DAT_FS has been detected by the Write DMA. Typically used by SW to detect when shadowed registers can be updated for the next frame. Refer to Section 9.4.6.8, *CAL Write DMA*, for more details.
IRQ_WDMA_ENDx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Frame end. Triggered by the Write DMA when the FE tag has been received by the cropping stage and the last data of the last line has been sent to memory. Therefore, this event may be triggered after the last data has been written to memory when data has been discarded by the cropping feature. The FE corresponds to a data word tagged as ATT_HDR_E, ATT_DAT_E, CTRL_HDR_E, PIX_HDR_E, PIX_DAT_FE or FE_CODE. Typically used by SW to detect when all data of a header, attribute packet, control packet or pixel frame has been written to memory. This event is triggered when the last OCP transaction has been sent to memory but before the response for this OCP transaction has been received from the target. Therefore, there is a small delay between the moment where the event is triggered and the last data can be read back from the buffer. Typically that delay is compensated by IRQ detection latencies.
IRQ_WDMA_CIRCx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Circular event. Triggered when the number of lines defined by CAL_WR_DMA_OFST_k[23:22] CIRC_MODE has been sent to the OCP master port.

Table 9-9. CAL Line Number Interrupt

Event	Description
IRQ_LINE_NUMBER	Line number reached. The line number programmed in CAL_LINE_NUMBER_EVT[29:16] LINE register bit-field) is received on CPORT# CAL_LINE_NUMBER_EVT[4:0] CPORT.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-10. CAL Video Port EOF Interrupt

Event	Description
IRQ_VPORT_EOF	Event triggered when data tagged as PIX_DAT_FE is sent to the video port. Typically used by SW to detect when all data has been sent to the video port.

On CAL top level, the different events trigger IRQs, if they have been enabled using the CAL_HL_IRQENABLE_SET_j register. The status can be read from the CAL_HL_IRQSTATUS_j register. The event-to-register mapping is shown in Figure 9-4.

- IRQ_PPI1_VC and IRQ_PPI0_VC refer to events controlled by CAL_CSI2_VC_IRQENABLE_l register and described in Table 9-6, *CSI2 Low Level Protocol Interrupts*.
- IRQ_PPI1 and IRQ_PPI0 refer to events controlled by CAL_CSI2_COMPLEXIO_IRQENABLE_l and described in Table 9-6, *CSI2 Low Level Protocol Interrupts* and Table 9-7, *CSI2 Complex I/O Interrupts.*

All events are merged into a single CAL_IRQ signal available at CAL boundary.

NOTE: CAL_HL_IRQSTATUS_j does not refer to events, but is used to collect events tracked in CAL_CSI2_VC_IRQSTATUS_l and CAL_CSI2_COMPLEXIO_IRQSTATUS_l registers, and enabled by CAL_CSI2_VC_IRQENABLE_l and CAL_CSI2_COMPLEXIO_IRQENABLE_l registers. SW must use them to detect, if a Complex I/O or PPI event is pending and then get event details from the relevant second level IRQ status register. SW must only clear those events by setting the relevant bits in the CAL_CSI2_VC_IRQSTATUS_l and CAL_CSI2_COMPLEXIO_IRQSTATUS_l registers. CAL_HL_IRQSTATUS_j is automatically cleared by the HW when no more enabled Complex I/O or PPI events are pending

9.4.5 CSI2 PHY Functional Description

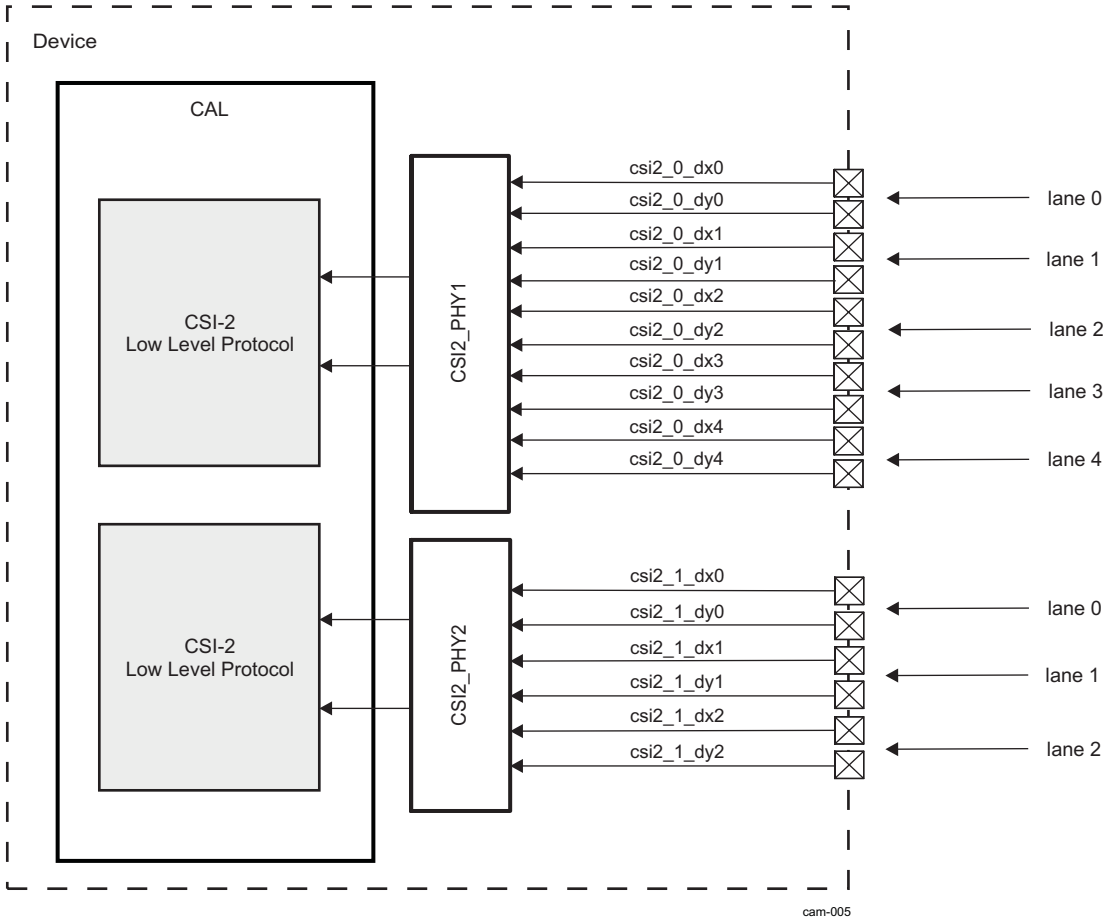
9.4.5.1 CSI2 PHY Overview

Two MIPI D-PHY compliant PHY receivers (CSI2_PHY1 and CSI2_PHY2, or generally referenced to as CSI2 PHY) immediately before the CAL module act as a physical connection and configuration of clock/data lanes with external sensors. A CSI2 PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receivers are compatible with the *MIPI D-PHY Specification v1.00.00*. The selection of a CSI2 PHY in D-PHY mode must be done before reset and not on the fly.

The CSI2 PHY is controlled and must be configured first from the device Control Module for pad configuration. The differential data/clock lanes coming into the CSI2 PHY1 and CSI2 PHY2 are configured from registers explained in Section 9.4.5.3, *CSI2 PHY Link Initialization Sequence*.

There are two CSI2 PHY instances integrated in the device. As shown in Figure 9-5, the CSI2_PHY1 contains four data lanes and CSI2_PHY2 has two data lanes. Figure 9-5 shows the two CSI2 PHY cases, with their signals further covered in Section 9.4.6.2.1, *CSI2 Physical Layer*.

Figure 9-5. CSI2 PHY Diagram



NOTE: LANE 4 of CSI2_PHY1 can be used only as a data lane, never as a clock lane. All other configurations are possible.

Copyright © 2018–2019, Texas Instruments Incorporated

CSI2_PHY1 and CSI2_PHY2 represent the overall PHY solution for connecting external sensors to feed the CAL module. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module (except otherwise notified), and the DX/DY data pad for each lane module can be configured as DP or DN pins defined. The configuration and the selection of D-PHY mode, data/clock are done through the device Control Module (see Chapter 19, *Control Module*). The only exception is the four-data-lane use case, in which one corner lane is allowed to be only a data lane. Both CSI2 PHY modules can be configured through serial configuration protocol (SCP) interface.

9.4.5.2 CSI2 PHY Configuration

The CSI2 PHY converts the bitstream, divided into 1 up to 4 serial data lanes, and one clock lane, into a bitstream compatible with the CSI2 low level protocol within the CAL module .

The CSI2 low level protocol engine only provides the SCP clock when CSI2 PHY registers are accessed and CAL_CTRL[21] PWRSCPCLK = 0. However, the CSI2 PHY needs at least 3 SCP clock cycles to come out of the reset state. Therefore, SW must perform a dummy read of a CSI2 PHY register (32 SCP clock pulses) to complete the CSI2 PHY reset sequence. Alternatively, the SCP clock can be programmed to be free-runnig by setting CAL_CTRL[21] PWRSCPCLK = 1 (not prefered).

The CAL_CSI2_COMPLEXIO_IRQSTATUS_I register logs complex I/O events of the following types:

- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

Some complex I/O parameters can be configured through the following registers:

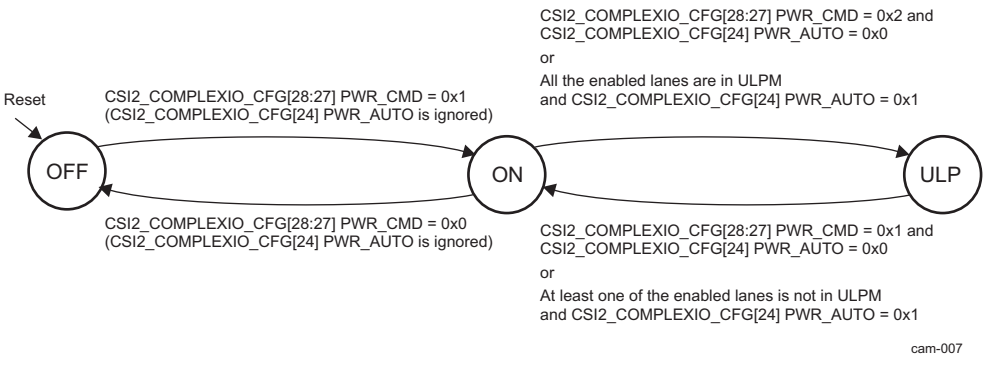
- The REG0 register detects clock miss with respect to the *MIPI D-PHY Specification v1.00.00* and control timing.
- The REG0 register reports completion of reset on the different parts of the module and configures the timing parameters.
- The CAL_CSI2_COMPLEXIO_CFG_I register contains the PWR_AUTO and PWR_CMD bit fields, which affect the power management of the complex I/Os.

The Complex I/O FSM has three power states: ON, OFF, and Ultralow Power (ULP). Two operation modes are available:.

- Automatic mode, when the CAL_CSI2_COMPLEXIO_CFG_I[24] PWR_AUTO bit is set to 1. The transitions between ON and ULP states is done automatically based on the received ULPM signals from the complex I/O for the active lanes defined in CAL_CSI2_COMPLEXIO_CFG_I[] DATAx_POSITION bit-field, where x = [1...4].
- Manual mode, when the CAL_CSI2_COMPLEXIO_CFG_I[24] PWR_AUTO bit is set to 0 (default). The complex I/O power state is controlled by the CAL_CSI2_COMPLEXIO_CFG_I[28:27] PWR_CMD bit field. The allowed transitions are: OFF <-> ON and ON <-> ULP.

Figure 9-6 shows the complex I/O power finite state-machine (FSM).

Figure 9-6. CSI2 Complex I/O Power FSM



Copyright © 2018–2019, Texas Instruments Incorporated

Another register, CAL_CSI2_TIMING_I, is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the three complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The CAL_CSI2_TIMING_I[15] FORCE_RX_MODE_IO1 bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bits (CAL_CSI2_TIMING_I[14] STOP_STATE_X16_IO1, CAL_CSI2_TIMING_I[13] STOP_STATE_X4_IO1, and the CAL_CSI2_TIMING_I[12:0] STOP_STATE_COUNTER_IO1 bit field) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock cycles and can be calculated as follows:

Total delay in functional clock cycles = CAL_CSI2_TIMING_I.STOP_STATE_COUNTER_IO1 x (1 + CAL_CSI2_TIMING_I.STOP_STATE_X16_IO1 x 15) x (1 + CAL_CSI2_TIMING_I.STOP_STATE_X4_IO1 x 3).

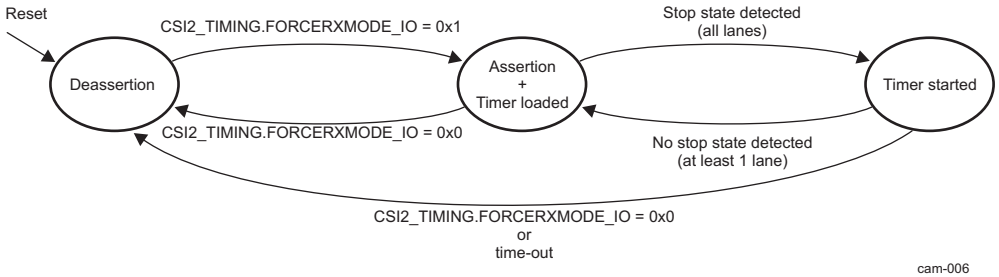
Table 9-11 lists the possible values of the delay, in terms of the functional clock cycles, depending on the values of the STOP_STATE_X16_IO1 and STOP_STATE_X4_IO1 bits.

Table 9-11. CSI2 PHY Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The FORCERXMODE signal is used at initialization time (complex I/O). Figure 9-7 describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

Figure 9-7. CSI2 PHY RxMode and StopState FSM



CAL asserts FORCERXMODE signal when the bit-field CAL_CSI2_TIMING_I[15] FORCE_RX_MODE_IO1 is set by the SW. It can be reset by SW or automatically by HW when the time out occurs. At the same time the signal is asserted, the logic starts monitoring the StopState[0:4] signals corresponding only to the enabled lanes. When all of StopState signals for only the enabled lanes are asserted by the complex IO, the timer starts. When one of the signals, for the enabled lanes only, is not in StopState, the timer is reloaded and the logic re-starts monitoring the stop state signals. When the timer period is finished, the ForceRxMode signal is de-asserted.

9.4.5.3 CSI2 PHY Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CSI2 PHY. The CAL CSI2 low level protocol coordinates the PHY initialization. The controller must ensure that the CSI2 PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CSI2 PHY for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state". One possible initialization sequence is:

To fully initialize the CSI2 PHY, perform the following steps:

1. Configure all CSI2 low level protocol registers to be ready to receive signals/data from the CSI2 PHY:

Copyright © 2018–2019, Texas Instruments Incorporated

i. Set CAL_CSI2_COMPLEXIO_CFG_I[18:16] DATA4_POSITION.
ii. Set CAL_CSI2_COMPLEXIO_CFG_I[14:12] DATA3_POSITION.
iii. Set CAL_CSI2_COMPLEXIO_CFG_I[10:8] DATA2_POSITION.
iv. Set CAL_CSI2_COMPLEXIO_CFG_I[6:4] DATA1_POSITION.
v. Set CAL_CSI2_COMPLEXIO_CFG_I[2:0] CLOCK_POSITION.
vi. Set the CTRL_CORE_CONTROL_CSI[10:9] CSI0_CAMMODE (for CSI2_PHY1) and CTRL_CORE_CONTROL_CSI[2:1] CSI1_CAMMODE (for CSI2_PHY2).

CAUTION

The above settings must be done before the CSI2 PHY is active.

vii. A dedicated internal clock gate control is present for each CSI2 PHY. Enable/disable the internal CTRLCLK from the CTRL_CORE_CONTROL_CSI register by setting the following bits:
- [8] CSI0_CTRLCLKEN for CSI2_PHY1
- [0] CSI1_CTRLCLKEN for CSI2_PHY2

2. CSI2 PHY and link initialization sequence:
a. Deassert the CSI2 PHY reset:
i. Set CAL_CSI2_COMPLEXIO_CFG_I[30] RESET_CTRL to 0x1.

CAUTION

For the CAL_CSI2_COMPLEXIO_CFG_I[29] RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must to be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSI2 PHY reset and before asserting the FORCERXMODE signal:
- REG0
- REG1
- REG2

b. Assert the FORCERXMODE signal:
i. Set CAL_CSI2_TIMING_I[15] FORCE_RX_MODE_IO1 to 0x1.
c. Connect pulldown on CSI2 PHY link (DP/DN) by asserting the respective PIPD signals (PIPD = 0):
For CSI2_PHY1 pulldown on signals through the SMA_SW_3[19] CSI2_0_XY_PIPD register bit.
For CSI2_PHY2 pulldown on signals through the SMA_SW_3[18] CSI2_1_XY_PIPD register bit.
d. Power up the CSI2 PHY:
a. Set CAL_CSI2_COMPLEXIO_CFG_I[28:27] PWR_CMD to 0x1.
e. Check whether the state status reaches the ON state:
- CAL_CSI2_COMPLEXIO_CFG_I[26:25] PWR_STATUS = 0x1

f. Wait for STOPSTATE = 1 (for all enabled lane modules):
a. The timer is set through the CAL_CSI2_TIMING_I[14:0] bit field. The reset value can be kept.
b. Wait until CAL_CSI2_TIMING_I[15] FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
g. Release PIPD signals (PIPD = 1):
For CSI2_PHY1 pulldown on signals through the SMA_SW_3[19] CSI2_0_XY_PIPD register bit.
For CSI2_PHY2 pulldown on signals through the SMA_SW_3[18] CSI2_1_XY_PIPD register bit.

3. The CSI2 PHY is initialized and ready/active in CSI-2 (D-PHY) mode.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4.5.4 CSI2 PHY Error Signals

In D-PHY mode, the CSI2 PHY supports the following error detection and signaling to the associated receiver:

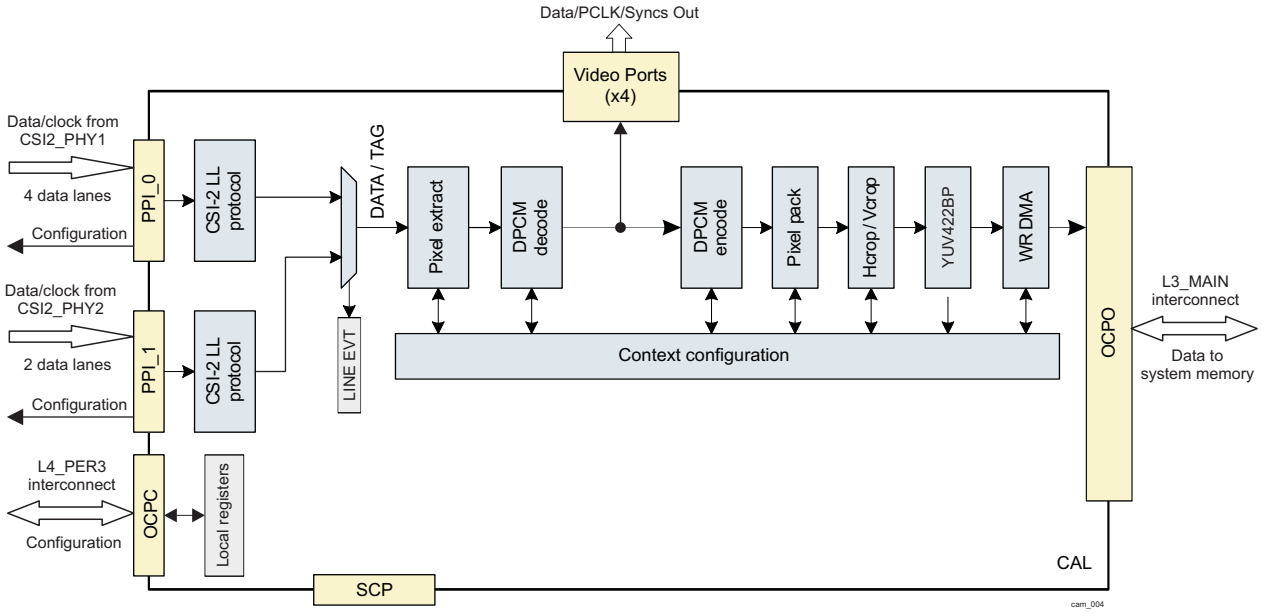
- ERRSOTHS: Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSI2 PHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS: Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSI2 PHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL: Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC: Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRSYNCESC: Flags the low-power data transmission synchronization error. This error is flagged if the number of bits received during a low-power data transmission is not a multiple of 8 bits. This signal, if asserted, is high until the next change in the state of the LP line. In case the number of received bits is 1 less than a multiple of 8, RXVALIDESC is also asserted together with ERRSYNCESC, and an erroneous data byte is output on RXDATAESC. In other cases of this error, RXVALIDESC is not asserted and an erroneous data byte is not sent out.

9.4.6 CAL Functional Description

9.4.6.1 CAL Block Diagram

Figure 9-8 shows a top-level overview diagram of the CAL module.

Figure 9-8. CAL Top-Level Diagram



The CAL module is composed of two possible data sources (two CSI-2 low level protocol decoders) plus a pixel data processing pipeline.

Copyright © 2018–2019, Texas Instruments Incorporated

The CSI-2 LL protocol block receives data from a D-PHY receiver (CSI2 PHY, up to four data pairs), merges data from multiple lanes, detects and correct errors, extracts the virtual channel ID, detects and extracts the synchronization codes and re-formats the data into a stream understood by the CAL processing pipeline. Each PPI interface has a small FIFO to accommodate latencies to access the CAL pipeline.

The data from all sources is multiplexed with 64-bit granularity and sent to the CAL pipeline for further processing. The data pipeline forwards 64-bit wide data words as well as a 5-bit wide data qualifier + 4-bit validity qualifier + 5-bit CPORT number referred as TAG in this chapter.

The TAG is set by the data source and controls how the different stages in the processing pipeline behave. Figure 9-9 summarizes possible values for the data qualifier and the corresponding behavior of the different processing stages:

Figure 9-9. CAL Data Pipeline TAGs

ID	Label	Description / generation	Pixel extraction	DPCM decode	DPCM encode	Pixel packing	Video Port	WRITE DMA
0	IDLE	Indicates no active data in the pipeline. Used to gate processing logic and save power	idle	idle	idle	idle	idle	idle
1	ATT_HDR_S	Attribute header (bytes 0~7)	bypass	bypass	bypass	bypass	idle	reset + write
2	ATT_HDR_E	Attribute header (bytes 8~15)	bypass	bypass	bypass	bypass	idle	write + flush

15	PIX_DAT_LE	Data paylod (bytes last-7 ~ last, line 2 ~ n-1)	process	process	process	process	output	write + flush
16	FE_CODE	Frame end short packet received. Used for data received from PPI when the number of lines per frame is not known	bypass	bypass	bypass	bypass	frame end	frame end

cam_009

NOTE: Figure 9-9 does not describe all possible configurations for the CAL pixel processing stages. Depending on the use case, each pixel processing stage (extraction, DPCM decoding/encoding, packing) can be individually configured or bypassed via a dedicated bit-field in the CAL_PIX_PROC_i register.

9.4.6.2 CSI2 Low Level Protocol

CAL has two PPI interfaces that connect directly to two D-PHY instances of up to 4 lanes each. It also implements an OCP to SCP bridge to access the complex IO internal registers.

9.4.6.2.1 CSI2 Physical Layer

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

The maximum CSI2 data transfer capacity is 1500 Mbps per data lane. The speed of the link is reconfigurable by SW only when the CSI2 PHY is in "stop state" or in ULPM (ulra-low power mode).

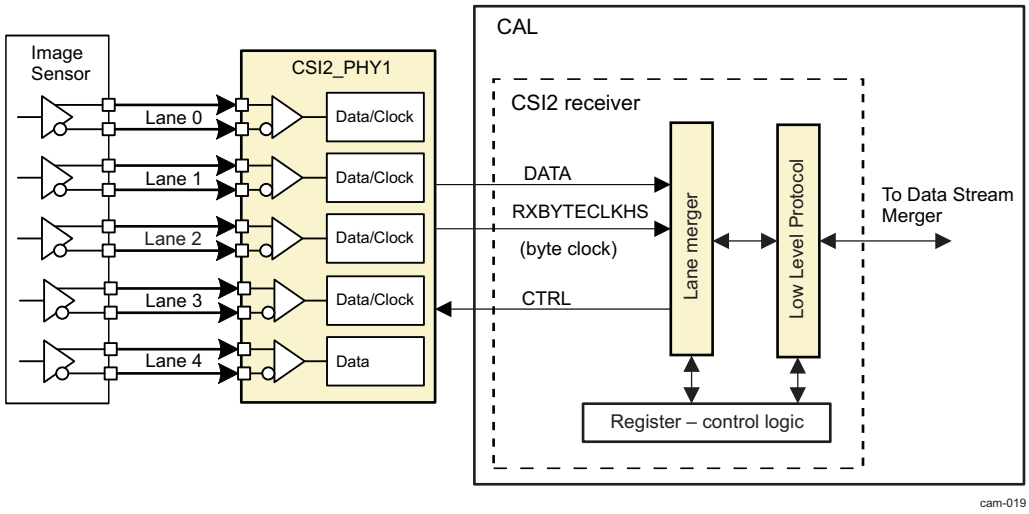
Copyright © 2018–2019, Texas Instruments Incorporated

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS (low speed) mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 LL protocol core.
- The clock signal carries the DDR clock signal.
- The SW has to configure the order of the data lanes to indicate the byte order while merging the received bytes for each CSI2 PHY into a byte stream.

Figure 9-10 is the CSI2 Low Level Protocol engine block diagram (it assumes there are four CSI2 image sensor data lanes). The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver (Figure 9-10 shows CSI2_PHY1 with up to four data pairs), converts the data to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and forwards it to the the CAL Data Stream Merger.

Figure 9-10. CSI2 Low Level Protocol Engine Block Diagram



Each physical lane can be a data or clock lane with a restriction to the fourth lane, which can only be data (see Section 9.4.5.1, *CSI2 PHY Overview*). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the CAL_CSI2_COMPLEXIO_CFG_I registers. The CAL_CSI2_COMPLEXIO_CFG_I[2:0] CLOCK_POSITION bit field and the CAL_CSI2_COMPLEXIO_CFG_I[3] CLOCK_POL bit configure which lane transmits the clock and define its polarity. The DATAx_POSITION and DATAx_POL bit-fields configure the data lanes and their polarity, where x is the number of the data lane (x = 1 to 4). When the DATAx_POSITION field is set to 0, data lane x is not used.

CAUTION

Lane 4 (position 5) supports only data. The CLOCK_POSITION must not be set at position 5.

csi2_0_dx4	lane 4 (position 5)	I	Serial data input only
csi2_0_dy4			

(1) I = Input

Table 9-13. CSI2_PHY2 I/O Description

Signal Name		I/O[1]	Description
csi2_1_dx0	lane 0 (position 1)	I	Serial data/clock input
csi2_1_dy0			
csi2_1_dx1	lane 1 (position 2)	I	Serial data/clock input
csi2_1_dy1			
csi2_1_dx2	lane 2 (position 3)	I	Serial data/clock input
csi2_1_dy2			

(1) I = Input

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

9.4.6.2.2 CSI2 Multi-lane Layer and Lane Merger

The layer consists of lane merger logic in order to merge the incoming serial stream into a byte stream. The bits are send with LSB first. The number of active lanes is configurable through register. The order of the lanes at the CSI-2 receiver core is also configurable. The number of lanes can be changed only in ULPM or when all data lanes are in "stop state" (OFF mode).

The lane merger can merge up to four lanes into a single byte stream, and is not used for a single lane.

Figure 9-11 to Figure 9-14 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

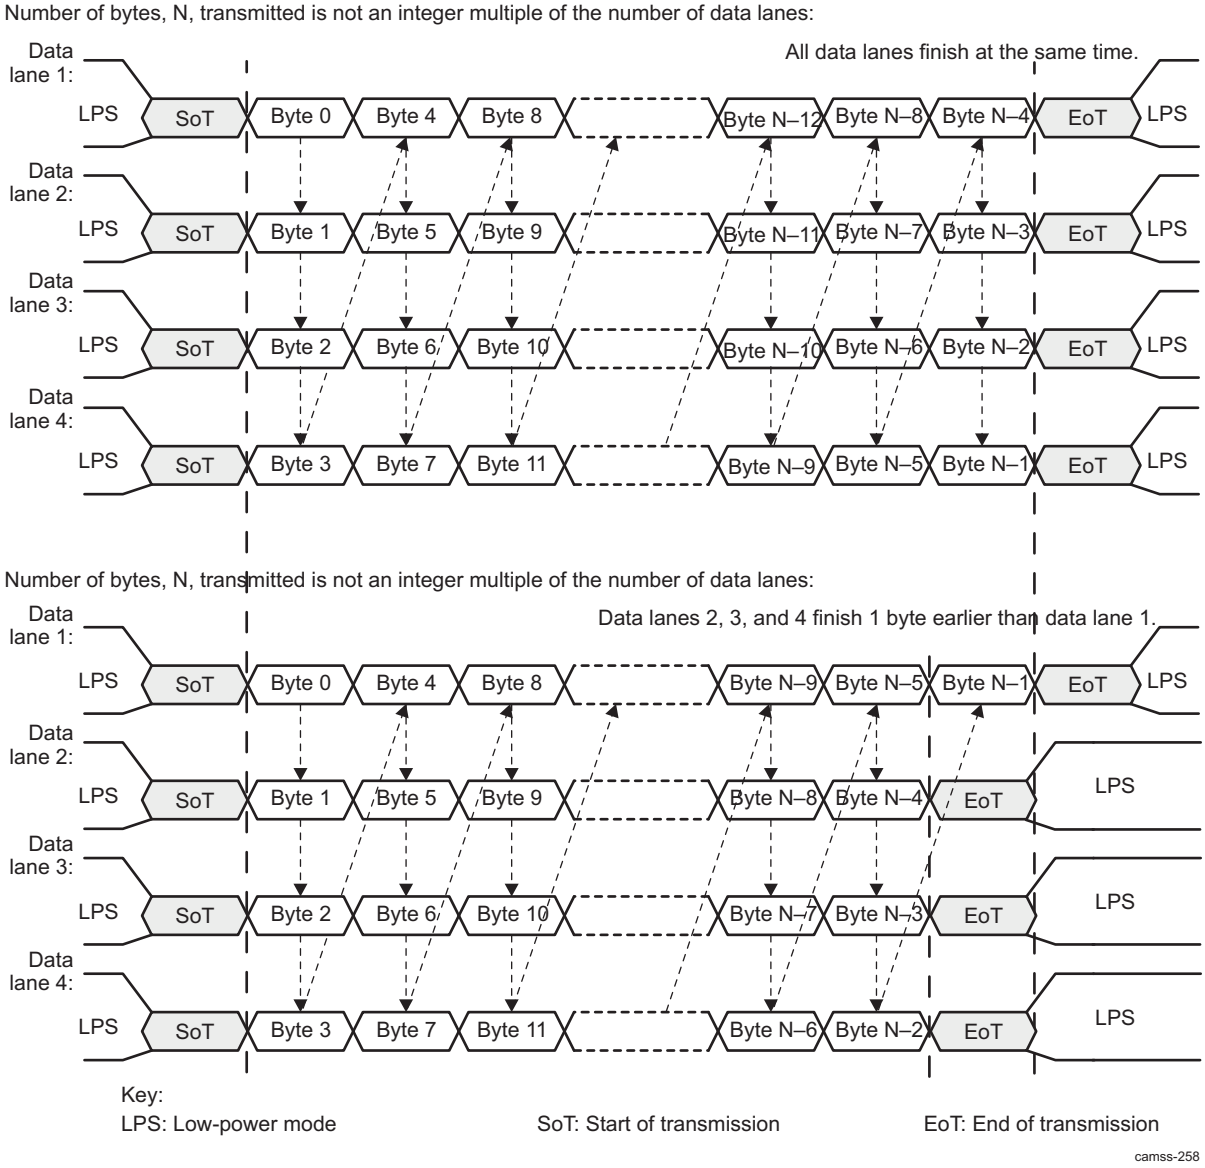
Figure 9-14. CSI2 Four Data-Lane Merger Configuration



9.4.6.2.3 CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

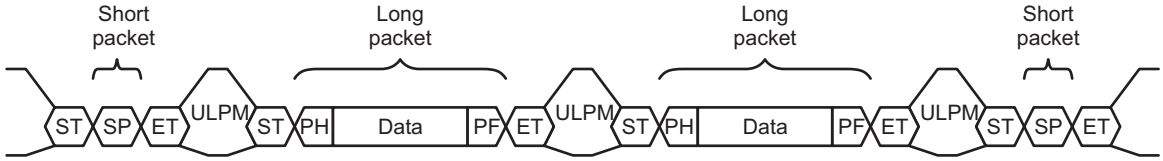
The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 9-15 shows the CSI2 protocol layer with short and long packets.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-15. CSI2 Protocol Layer With Short and Long Packets



Key:

ST: Start of transmission	ET: End of transmission
PH: Packet header	PF: Packet footer
ULPM: Ultralow-power mode	SP: Short packet

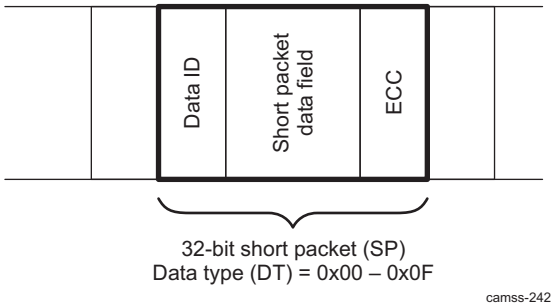
camss-241

Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

9.4.6.2.3.1 CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. A short packet contains only a Packet Header; a Packet Footer is not be present. Figure 9-16 shows the structure of a short packet.

Figure 9-16. CSI2 Short Packet Structure



camss-242

NOTE: CAL accepts but does not use the frame number or line numbers transmitted by the sensor as required by the MIPI CSI-2 standard.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID . The data type associated with the context is not used to distinguish which context is used when receiving short packets.

9.4.6.2.3.2 CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

The packet header is further composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 9-17 and Table 9-14 show the structure of a long packet.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-17. CSI2 Long Packet Structure

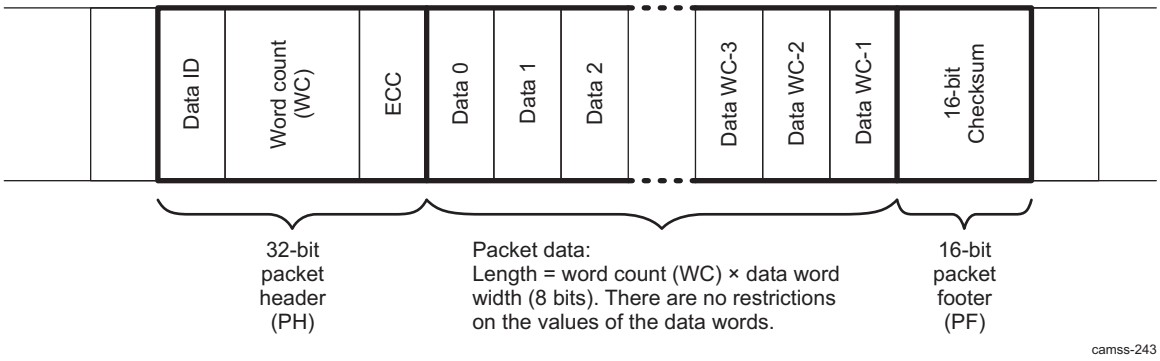


Table 9-14. CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bits)	Description
Header	Data ID	8	Contains the virtual channel identifier for data and the data-type for the application specific payload data
	Word count	16	Number of 8-bit data words in the Data Payload between the end of the Packet Header and the start of the Packet Footer. Neither the Packet Header nor the Packet Footer are included in the Word Count.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC-8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit CRC for packet data

There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

9.4.6.2.3.3 CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

9.4.6.2.3.3.1 CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet). It allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header.

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged. After the end of the Packet Header, the receiver reads the next Word Count * 8-bit data words of the Data Payload. While reading the Data Payload the receiver does not look for any embedded sync codes. Therefore, there are no limitations on the value of a data word.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered.

For long and short packets, the correction is always done, if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. Table 9-15 describes the field in which events are logged. Logging cannot be disabled, but SW can set the corresponding bit in the CAL_CSI2_VC_IRQENABLE_I register to prevent event generation at a higher level.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-15. CSI2 ECC Event Logging

	Short and Long Packet
With correction	Global CAL_CSI2_VC_IRQSTATUS_I[] ECC_CORRECTION_IRQ_x, where x = [0 to 3]
Without correction	Global CAL_CSI2_VC_IRQSTATUS_I[] ECC_NO_CORRECTION_IRQ_x, where x = [0 to 3]

The ECC check can be disabled (short and long packet) by setting the CAL_CSI2_PPI_CTRL_I[2] ECC_EN bit to 0. Setting the bit to 1 enables the ECC check.

Refer to the MIPI CSI-2 1.0 standard for more details on ECC generation.

9.4.6.2.3.3.2 CSI2 Checksum

Once the CSI2 receiver has read the Data Payload, it reads the checksum in the Packet Footer. In the generic case, the length of the Data Payload is a multiple of 8-bit data words. In addition, each data format may impose additional restrictions on the length of the payload data, e.g. multiple of four bytes. Each byte is transmitted LSB first.

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. The CSI2 receiver checksum is compared against the CSI-2 transmitter checksum. If the checksum does not match, an interrupt is triggered.

CRC errors are logged in the CAL_CSI2_VC_IRQSTATUS_I[] CS_IRQ_x (where x = [0 to 3]) register bit-fields. Logging cannot be disabled, but SW can configure the corresponding bit in the CAL_CSI2_VC_IRQENABLE_I register to prevent event generation at a higher level.

Since the payload has been already transferred into memory, it is not possible to discard the data but only to generate an interrupt.

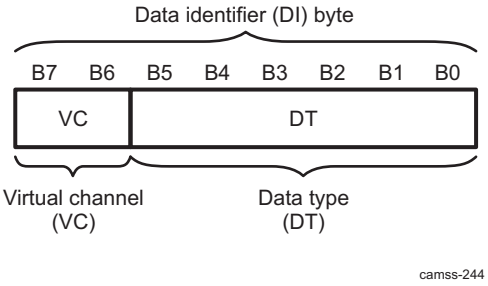
9.4.6.2.3.4 CSI2 Alignment Constraints

Payload data may be transmitted in any byte order restricted only by data format requirements. Multi-byte elements such as Word Count, Checksum and the Short packet 16-bit Data Field is transmitted LSB byte first.

9.4.6.2.3.5 CSI2 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in Figure 9-18. The VC value is contained in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 9-18. CSI2 Data Identifier Structure

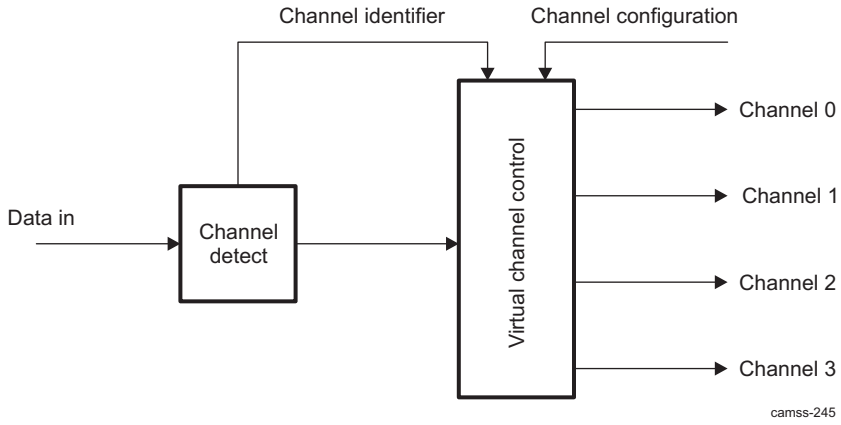


Copyright © 2018–2019, Texas Instruments Incorporated

9.4.6.2.3.6 CSI2 Virtual Channel ID

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data (embedded and image-sensor) separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 9-19 shows a virtual channel.

Figure 9-19. CSI2 Virtual Channel



9.4.6.2.3.7 CSI2 Synchronization Codes

Each frame is clearly identified by a synchronization code for the start of frame and the end of frame. The start of line and end of line can be sent by the image sensor but it is optional.

In order to send the synchronization codes, the camera uses the short packets. Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

Table 9-16 summarizes the synchronization code values.

Table 9-16. CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

9.4.6.2.3.8 CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

Copyright © 2018–2019, Texas Instruments Incorporated

An interrupt (logged in CAL_CSI2_COMPLEXIO_IRQSTATUS_I[28] SHORT_PACKET register bit) indicates to the application the short packet event. Logging cannot be disabled, but SW can set the corresponding bit in the CAL_CSI2_COMPLEXIO_IRQENABLE_I register to prevent event generation at a higher level. It is SW responsibility to read the register CAL_CSI2_SHORT_PACKET_I before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packets since there is no data type in it to be associated with context.

9.4.6.2.3.9 CSI2 Frame Structure and Data

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent by the image sensor as SOF and EOF information. It is decoded by the receiver and is sent to the system memory through the OCPO port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame contains embedded data and image-sensor data. Figure 9-20 shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in Figure 9-20 and Figure 9-21. The following definitions for a frame apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats. The image embedded data is carried using separate data types and virtual channels (see Section 9.4.6.2.3.10, *CSI2 Virtual Channel and Context*).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See Section 9.4.6.2.3.10, *CSI2 Virtual Channel and Context*.

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 9-20. CSI2 General Frame Structure (Informative)

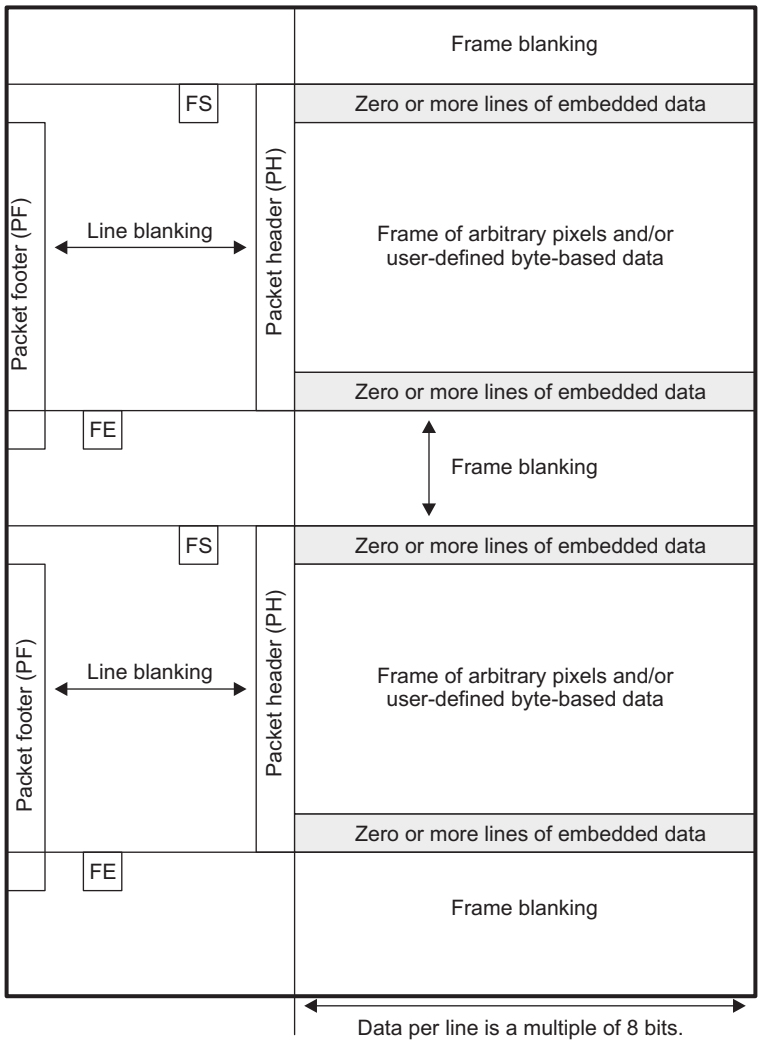

Figure 9-21 shows the frame structure of a YUV4:2:2 interlaced video frame without embedded data.

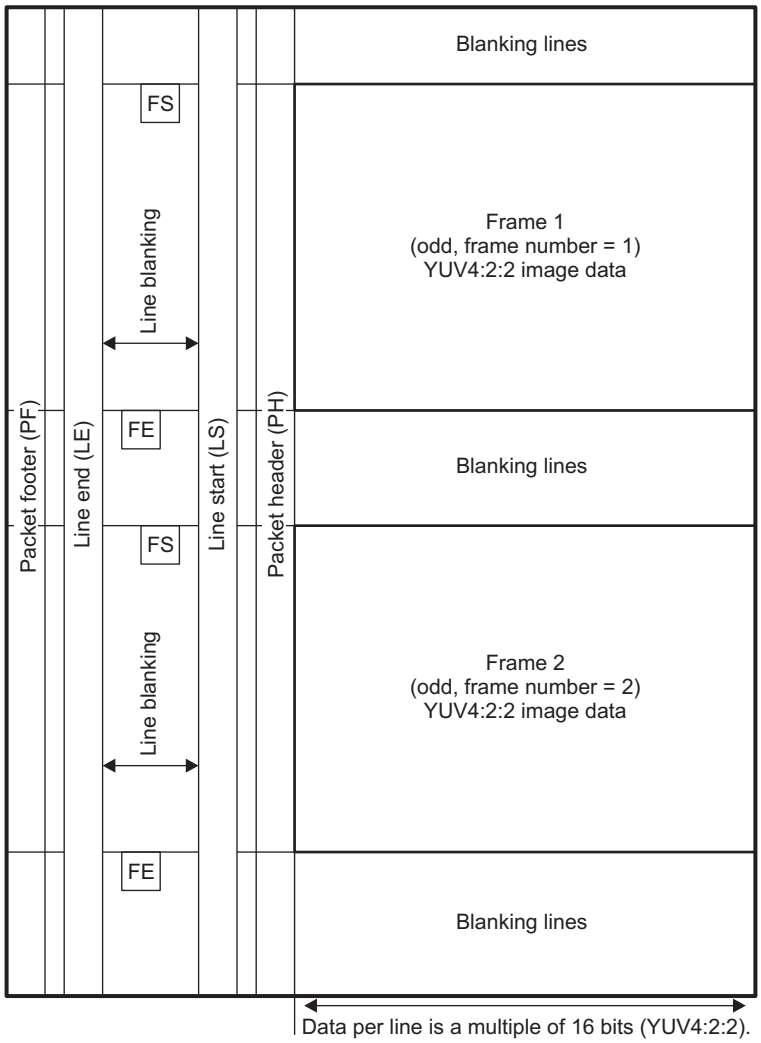
Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-21. CSI2 Digital Interlaced Video Frame (Informative)



The period between the LEC and the new LSC is called line blanking period. The time between the FEC and the new FSC is called frame blanking period. The receiver works with "near zero" line blanking period.

NOTE: The embedded information (SOF & EOF lines) is never compressed (no DPCM). The embedded information covers full lines. The embedded information is not encoded in the same data format as the pixel data. The CSI-2 receiver extracts the embedded information but does not modify the data format.

The pixel data can be compressed.

9.4.6.2.3.10 CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

Copyright © 2018–2019, Texas Instruments Incorporated

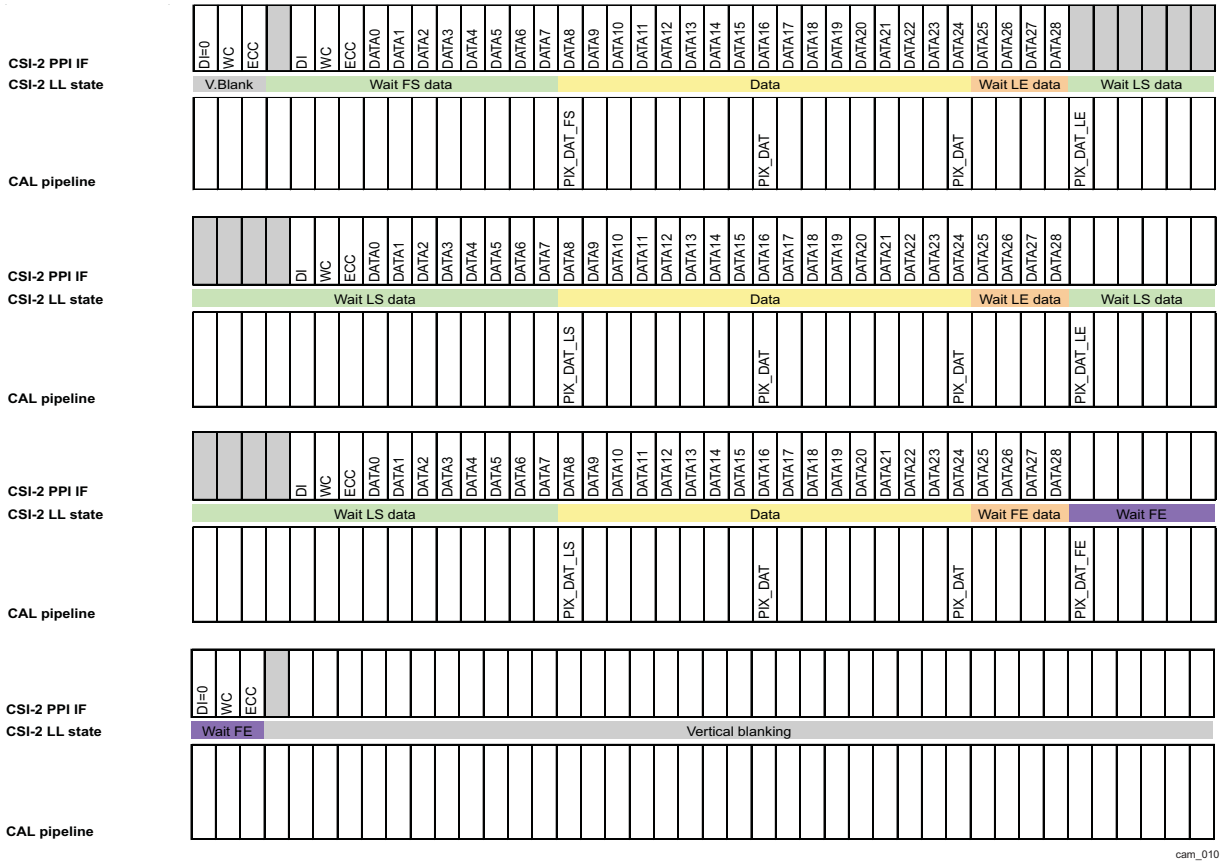
The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels. The virtual channel values used for each channel are as follows:

- Virtual channel 0 -> 0x0
- Virtual channel 1 -> 0x1
- Virtual channel 2 -> 0x2
- Virtual channel 3 -> 0x3

9.4.6.2.4 CSI2 TAG Generation FSM

Figure 9-22 shows how the synchronization codes for the CAL internal pipeline are extracted from the CSI-2 stream. CSI-2 PPI IF corresponds to the byte stream after lane merge and PHY LS -> HS transition detection. CSI-2 LL state corresponds to the internal state of the TAG generation engine. CAL pipeline corresponds to the tags sent to the CAL processing pipeline.

Figure 9-22. CSI-2 LL Tag Generation Example - Line Mode



Data is packed into words of 64-bits before it can be sent to the shared CAL processing pipeline. Each PPI has its own TAG generation & packing state machine. Both CSI2 PHYs are therefore independent and can operate simultaneously. Each PPI FSM has 8 copies of the CAL_CSI2_CTXy_I (y = [0 to 7], CAL_CSI2_CTX0_I through CAL_CSI2_CTX7_I) state registers (that is, contexts).

To use a context, SW must define:

- The used virtual channel (through CAL_CSI2_CTXy_I[7:0] VC register bit-field)
- The expected MIPI CSI-2 Data Type (through CAL_CSI2_CTXy_I[5:0] DT bit-field)
- The CPORT ID to use (through CAL_CSI2_CTXy_I[12:8] CPORT bit-field) for the data, and if it should be tagged as Attribute (that is, Embedded) data or as Pixel data (through CAL_CSI2_CTXy_I[13] ATT bit).

Copyright © 2018–2019, Texas Instruments Incorporated

Attribute data is tagged using ATT_DAT_S, ATT_DAT and ATT_E tags. Pixel data is tagged using PIX_DAT_FS, PIX_DAT, PIX_DAT_LE, PIX_DAT_LS, PIX_DAT_FE. Data reception is disabled by setting CAL_CSI2_CTXy_I[5:0] DT bit to 0.

The tag generation FSM accumulates words of up to 64-bits of data from the physical interface. Two SW selectable modes are supported:

- Line mode (set by CAL_CSI2_CTXy_I[14] PACK_MODE = 0). In this mode CAL generates frame (PIX_DAT_FS; PIX_DAT_FE) and line (PIX_DAT_LS, PIX_DAT_LE) synchronization codes using synchronization information provided by the CSI-2 transmitter. It pads words with 0's when the line end or frame end is reached and generates the adequate data validity qualifier (VQ). Line and frame starts always correspond to full 64-bit words (VQ=0x0). This is typically the mode to be used to receive pixel data.
- Frame mode (set by CAL_CSI2_CTXy_I[14] PACK_MODE = 1). In this mode CAL only generates PIX_DAT_FS and PIX_DAT_FE synchronization codes. PIX_DAT_LE and PIX_DAT_LS are replaced by PIX_DAT and adequate data validity qualifiers are generated to create a contiguous stream. This mode is typically used to receive a JPEG frame from a CSI-2 camera.

This appended dummy data can be cropped by the Write DMA, or the hardware accelerator attached to the Video port. The shared CAL processing pipeline therefore always receives full 64-bit words. The line length is detected from the CSI-2 long packet header and mismatches are detected through CRC errors.

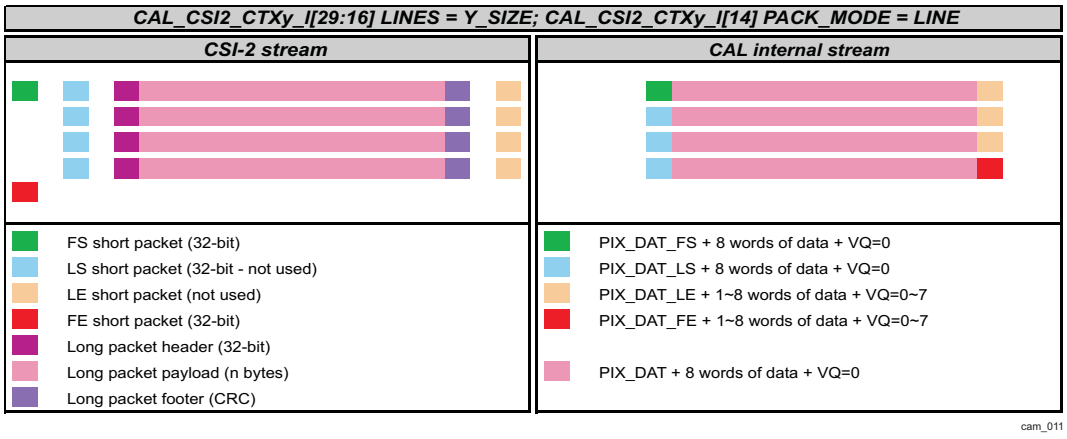
The tag generation FSM ensures that only valid TAG sequences can be provided to the shared CAL processing pipeline. FS, LS and LE codes are directly extracted from the CSI-2 stream. The FE code is not directly available and can be generated by two mechanisms:

- If SW knows the number of lines transmitted by the camera, it must write it into the CAL_CSI2_CTXy_I[29:16] LINES register bit-field. The tag generation FSM will send a FE TAG for the last received line of each frame instead of the LE TAG. This leads to regular video timings and avoids potential artifacts. CAL generates the FE_CODE tag when the FE short packet is received earlier than expected (for example, incorrect configuration or lines discarded due to transmission errors). The PIX_DATA_FE tag is generated at the end of the last line specified in CAL_CSI2_CTXy_I[29:16] LINES bit-field. Additional lines received for the same frame are discarded.
- If the number of lines is not known, SW must set the CAL_CSI2_CTXy_I[29:16] LINES register bit-field to 0. The tag generation FSM sends the PIX_DAT_LE TAG for the last line in the case and FE_CODE tag line when a FE short packet is received.

No LS/LE tags are generated when CAL_CSI2_CTXy_I[13] ATT = 1.

Figure 9-23 through Figure 9-26 illustrate the operation of the packing stage.

Figure 9-23. CSI-2 Packing – Example 1



Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-24. CSI-2 Packing – Example 2

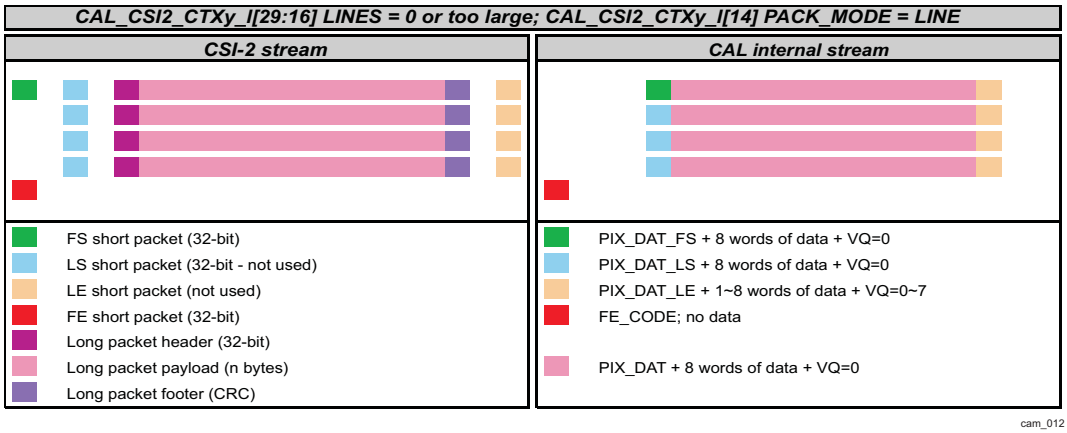


Figure 9-25. CSI-2 Packing – Example 3

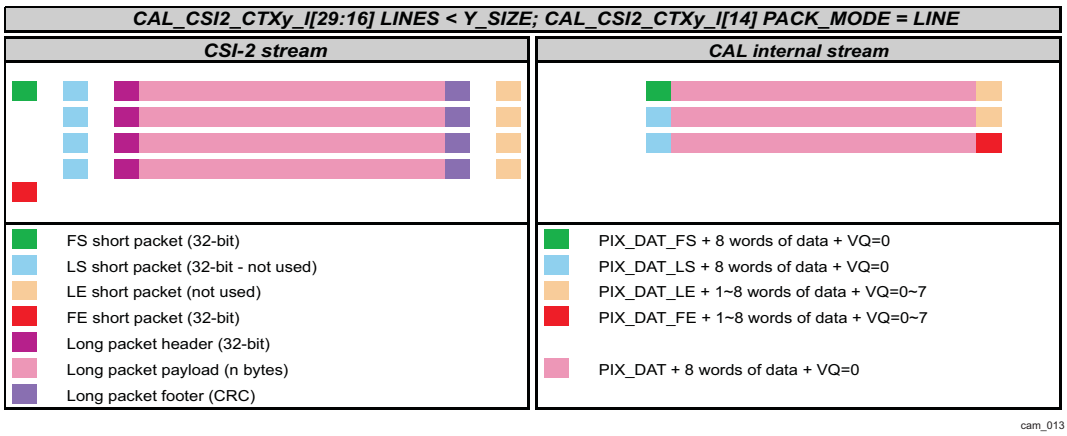

Figure 9-26. CSI-2 Packing – Example 4

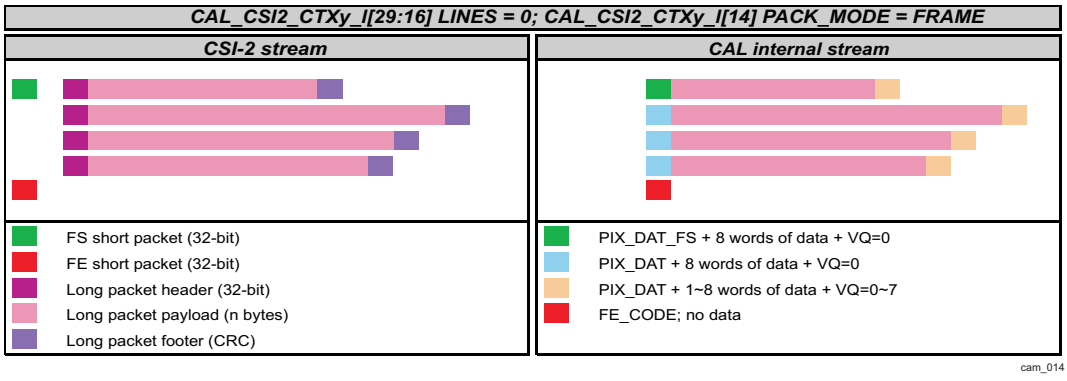


Data is discarded and an FIFO_OVR event is triggered when the CAL shared pipeline cannot accept the data from PPI interfaces fast enough. The tag generation FSM ensures however that only valid tag sequences can be generated:

- Only a few words are dropped in the middle of a line: corresponding data words are dropped and synchronization TAGs (LE or FE) are transmitted normally. The line where the overflow has occurred is therefore corrupted (that is, pixels shifted left), but synchronization is recovered from the next line start.
- The overflow condition persists over a line or frame boundary: one or multiple lines/frames are dropped. HW waits until one word becomes available in the PPI FIFO and inserts a data word with TAG FE. It then waits for the next FS to resume normal operation.

Copyright © 2018–2019, Texas Instruments Incorporated

No specific SW intervention is required to recover synchronization and the HW ensures that no protocol violations or accesses outside of allocated buffers could occur.

NOTE: Optional MIPI CSI-2 LS and LE short packets are ignored by CAL. They are allowed in the datastream from the camera, but are not used and not forwarded to the CAL shared processing pipeline.

CAL does not have a specific mechanism to ignore CRC checking. SW must simply disable the CS_IRQ event. CAL does not discard data with invalid CRC.

9.4.6.3 CAL Data Stream Merger

Two possible sources (2 x PPI) can produce data that is sent through the shared CAL processing pipeline. The shared processing pipeline is time multiplexed at 64-bit word level. Data from the PPI interfaces cannot be stalled. It is therefore stored in a FIFO (per PPI) to compensate shared pipeline access latencies.

A fixed priority arbitration scheme is used when data is ready from multiple sources. PPI_0 source is with highest priority, after that PPI_1.

PPI FIFOs are only intended to compensate internal pipeline access latencies. It is SW responsibility to ensure that the total pixel rates are compatible with CAL capabilities.

9.4.6.4 CAL Pixel Extraction

Software must configure which CPORT a given pixel processing context must process, by setting the CAL_PIX_PROC_i[23:19] CPORT register bit-field to the CPORT ID. The operation to perform is defined by the CAL_PIX_PROC_i[4:1] EXTRACT bit-field.

The data of a CPORT is forwarded without modification when pixel processing is disabled for that CPORT.

The pixel extraction stage receives up to 64 bits per cycle and can output either 64 bits (bypass) or 4 samples (6 ~ 16 bits per sample; 1 sample = 1 pixel for RAW data) per cycle.

Extracted pixels are left padded with 0's to fill 16-bit containers (for example, for RAW10: out[15:10]=0's and out[9:0]=data)

It only processes data tagged as DAT_PIX_FS, DAT_PIX_LS, DAT_PIX, DAT_PIX_FE, and DAT_PIX_LE (see Figure 9-9, *CAL Data Pipeline TAGs*, for definitions). All other data types are simply forwarded (that is, output = input).

DAT_PIX_FS and DAT_PIX_LS tags reset the pixel extraction state-machine. That ensures proper recovery in case the pixel decoder goes out of sync for some reason (for example, TxBuffer overflow in the transmitter, wrong configuration, bad synchronization between hardware and software).

Four samples do not necessarily align with a complete 64-bit word and several bits remain unused. They are stored locally until enough data is available to extract four additional samples or the end of a line has been reached (that is, TAG = PIX_DAT_LE or PIX_DAT_FE). The last 64-bit word can be padded with 0's, if there is not enough data to generate 4 pixels after all data tagged as PIX_DAT_LE or PIX_DAT_FE has been processed.

Contexts can be interleaved with 64-bit word granularity (that is, two consecutive words can have different TAGs).

The number of contexts is as defined in the CAL_HL_HWINFO[12:8] PCTX register bit-field

NOTE: The pixel extraction engine does not process the VQ (data validity qualifier) generated by the CSI-2 data packing stage. It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

The pixel extraction stage must be bypassed for JPEG data.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4.6.5 CAL DPCM Decoding and Encoding

The CAL DPCM decoder block only processes data tagged as DAT_PIX_FS, DAT_PIX_LS, DAT_PIX, DAT_PIX_LE and DAT_PIX_FE (as defined in Figure 9-9, *CAL Data Pipeline TAGs*). All other data types or data belonging to CPORTs where DPCM encode/decode is disabled, is simply forwarded. Software chooses which CPORT a given pixel processing context must process by setting the CAL_PIX_PROC_i[23:19] CPORT register bit-field to the CPORT ID. The DPCM decompression operation is selected though the CAL_PIX_PROC_i[9:5] DPCMD bit-field, and the DPCM compression operation is selected though the CAL_PIX_PROC_i[15:11] DPCME bit-field.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM encoder.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM decoder, except when the previous TAG received on that context was DPCM_INIT. DPCM_INIT copies the received word into the context status register of the DPCM decoder and discards the initialization word (that is, it is not forwarded to the next pipeline stage). The next word of four pixels received on that context is DPCM decoded and the usual initialization step is skipped. That feature is intended to enable DPCM decoding of an image in multiple vertical stripes without re-decoding each line from the beginning.

Table 9-17. CAL DPCM Formats

Codec	Predictor	Decode	Encode	Performance
10 - 8 - 10	Predictor 1	YES	YES	4 px/cyc
10 - 8 - 10	Predictor 2	-	-	-
10 - 7 - 10	Predictor 1	YES	-	4 px/cyc
10 - 7 - 10	Predictor 2	YES	-	1 px/cyc
10 - 6 - 10	Predictor 1	YES	-	4 px/cyc
10 - 6 - 10	Predictor 2	YES	-	1 px/cyc
12 - 8 - 12	Predictor 1	YES	YES	4 px/cyc
12 - 8 - 12	Predictor 2	-	-	-
12 - 7 - 12	Predictor 1	YES	-	4 px/cyc
12 - 7 - 12	Predictor 2	-	-	-
12 - 6 - 12	Predictor 1	YES	-	4 px/cyc
12 - 6 - 12	Predictor 2	-	-	-
14 - 10 - 14[(1)]	Predictor 1	YES	YES	4 px/cyc
14 - 10 - 14	Predictor 2	-	-	-
14 - 8 - 14	Predictor 1	YES	YES	4 px/cyc
14 - 8 - 14	Predictor 2	-	-	-
16 - 12 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 12 - 16	Predictor 2	-	-	-
16 - 10 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 10 - 16	Predictor 2	-	-	-
16 - 8 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 8 - 16	Predictor 2	-	-	-

(1) The WDR_DPCM_ENABLE eFuse must be enabled (CTRL_WKUP_STD_FUSE_CONF[27] CAL_WDCPM_DISABLE register bit = 0x0).

The DPCM encoder and decoder are independent. They preserve state for each of the pixel processing contexts (defined in CAL_HL_HWINFO[12:8] PCTX register bit-field), so that the encoder and the decoder context can be swapped with 4-pixel granularity.

The DPCM encoder and decoder can stall the incoming pixel from the pixel extraction block, if it arrives faster than what they can handle (that is, PREDICTOR2 selection or dataflow stalled by the pixel packing stage/Write DMA).

9.4.6.6 CAL Stream Interleaving

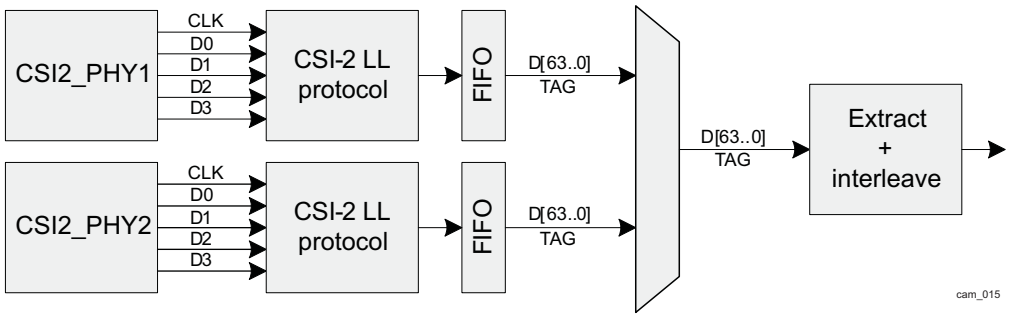
CAL supports interleaving at pixel level of data streams received from two cameras that are synchronized. These two cameras are typically CSI-2 cameras attached to the PPI_0 and PPI_1 interfaces.

Copyright © 2018–2019, Texas Instruments Incorporated

In order to use the stream interleaving feature, CAL_CTRL1[1:0] PPI_GROUPING register bit-field must be set to PPI_0 or PPI_1.

Figure 9-27 shows a physical view of the interleaving.

Figure 9-27. CAL PPI Interleaving - Physical View



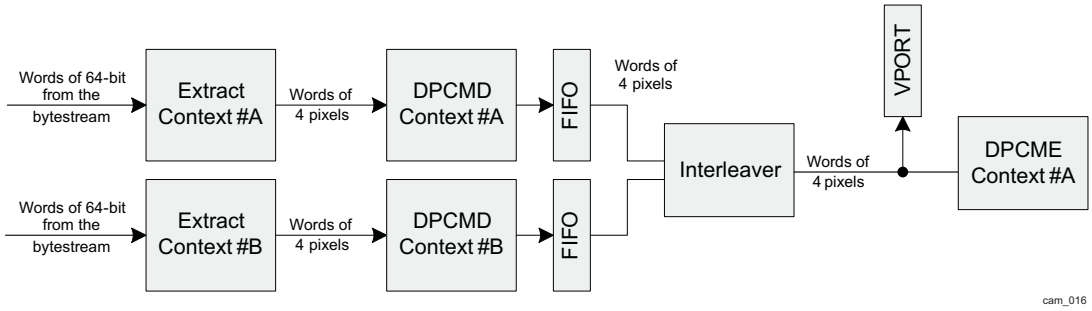
The actual interleaving is done after the DPCM decompression stage of the CAL processing pipeline and requires two linked pixel processing contexts. The interleaving feature is controlled by bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the CAL_CTRL1 register. CAL supports no interleaving, interleaving with 1 pixel granularity or interleaving with 4 pixel granularity.

Both PPI interfaces must be configured to forward the received bytestream to the internal processing pipeline using two separate CPORT IDs. The bytestream is then converted into words of 4 pixels by the two independent extraction contexts and DPCM decompressed. Up to this stage, the processing is identical to non interleaved mode.

Data generated by the two pixel processing contexts is stored in two small FIFOs when interleaving is enabled (that is, when bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the CAL_CTRL1 register are set to a value different than 0x0). Otherwise, the data is directly forwarded to the rest of the pipeline.

Figure 9-28 provides a logical view of a CAL stream interleaving.

Figure 9-28. CAL Stream Interleaving - Logical View



The interleaver reads blocks of 2 or 4 pixels from the 2 FIFOs (physically stored in 16-bit containers) and interleaves the data with 1 pixel or 4 pixel granularity. Figure 9-29 below shows when pixels are read from the respective FIFOs (the number in the cell is the pixel position)

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-29. CAL Interleave FIFO reads

cam_018

The datastream uses the pixel processing context #0 and its CPORT ID after interleaving.

NOTE: Bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the CAL_CTRL1 register must not be changed when the pixel processing contexts 0 or 1 are processing data.

Interleaving is not supported for JPEG data. Bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 must be set to 0x0 for JPEG data.

The stream sizes on both PPI_0 and PPI_1 are expected to be equal. However, if they are not, CAL will forward data from the longer stream without interleaving.

The PPI context IDs of interleaved streams must match. Therefore, it is possible to interleave context #0 from PPI_0 with context #0 from PPI_1. But it is not possible to interleave context #0 from PPI_0 with context #1 from PPI_1.

9.4.6.7 CAL Pixel Packing

Software selects which CPORT a given pixel processing context must process by setting the CAL_PIX_PROC_i[23:19] CPORT bit field to the CPORT ID. The operation to perform is defined by the CAL_PIX_PROC_i[18:16] PACK bit field.

Copyright © 2018–2019, Texas Instruments Incorporated

The pixel packing stage only processes data tagged as PIX_DAT_FS, PIX_DAT_LS, PIX_DAT, PIX_DAT_FE and PIX_DAT_LE. All other data types or data belonging to a CPORT where pixel packing is disabled is simply forwarded. The packing stage is reset by PIX_DAT_FS and PIX_DAT_LS to recover synchronization in case it has been lost.

The pixel packing stage is flushed by a PIX_DAT_FE, PIX_DAT_LE and PIX_DAT_LE TAG: the last generated 64-bit word may be padded with 0's

Pixel packing is a symmetrical processing step to the pixel extraction (see Section 9.4.6.4, *CAL Pixel Extraction*). However, the list of supported formats is different. The pixel packing stage also has buffering to preserve temporary (that is, incomplete) data when contexts are switched.

Supported packing modes are:

- RAW8 (8 bits per pixel)
- RAW10 (MIPI) (10 bits per pixel)
- RAW12 (linear) (12 bits per pixel)
- RAW12 (MIPI) (12 bits per pixel)
- RAW16 (16 bits per pixel)
- ARGB (32 bits per pixel)

The pixel packing engine does not process the VQ (data validity qualifier) generated by the CSI-2 data packing stage. It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

Figure 9-31 shows how the packing engine packs 32 consecutive pixels (equal to 8 active input cycles as 4 pixels are provided per cycle) into five 64-bit words ready to be sent to memory (REM).

9.4.6.8 CAL Write DMA

9.4.6.8.1 CAL Write DMA Overview

The memory Write DMA has WCTX (defined in CAL_HL_HWINFO[18:13] WCTX register bit-field) independent write contexts (that is, logical DMA channels). Each context receives a byte stream over a 64-bit wide bus as well as the TAG.

The Write DMA filters incoming data using the CPORT number and data type contained in the TAG. Data is only processed, if it matches the CPORT number defined in the CAL_WR_DMA_CTRL_k[13:9] CPORT register bit-field and the data type defined in the CAL_WR_DMA_CTRL_k[8:6] DTAG bit-field. It also uses the received TAG to lookup the adequate context information and control the address generation logic.

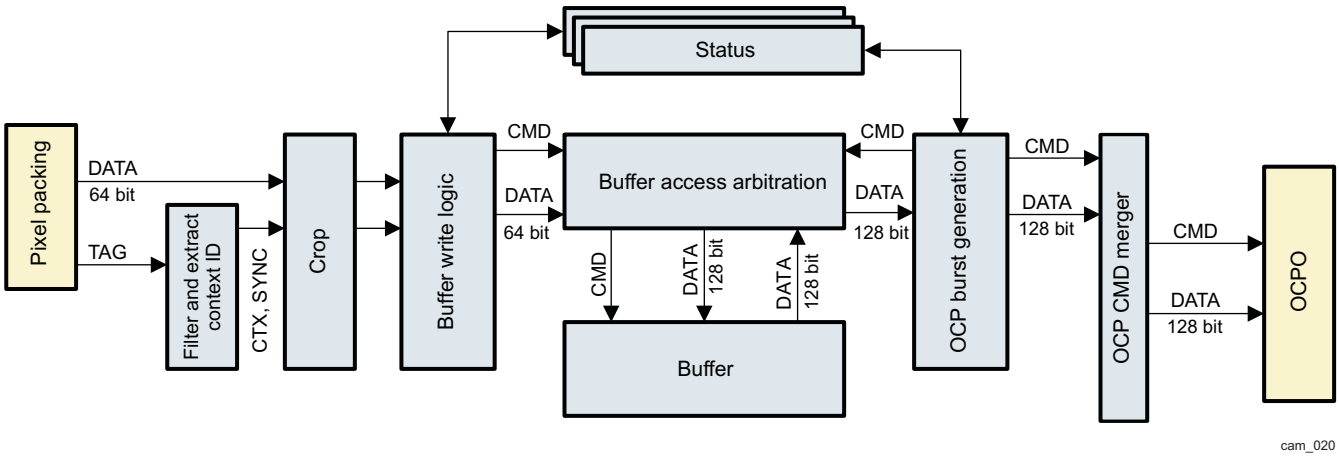
Copyright © 2018–2019, Texas Instruments Incorporated

Only one write context can process a given data word from the internal pipeline at the time. Said differently, the Write DMA cannot be used to write two copies of the same data into separate locations. Software must prevent that two active write contexts have the same settings for CAL_WR_DMA_CTRL_k[13:9] CPORT and CAL_WR_DMA_CTRL_k[8:6] DTAG bit-fields.

Data that is not processed by the Write DMA is discarded. Since the Write DMA is the last stage in the CAL processing pipeline, it cannot forward data to a next stage.

Figure 9-33 shows a simplified block diagram of the Write DMA engine.

Figure 9-33. CAL Pixel Packing – Data Storage in Memory



9.4.6.8.2 CAL Write DMA Data Cropping

SW can limit the maximum number of lines (defined in CAL_WR_DMA_CTRL_k[31:18] YSIZE register bit-field) to be written into memory for pixel formats (for which line start/end codes are provided). By default, all received lines are written to memory (when the value of [31:18] YSIZE = 0x0000). This feature is typically used to prevent writes outside of the allocated SDRAM buffer even when CAL and the external data transmitter get out of sync (for example, due to EMI on the link).

It is possible also SW to discard part of the received data for pixel and attribute data (that is, header and control data cannot be discarded). This is performed inside the Write DMA cropping block. The feature is enabled by configuring:

- The position of the 1st byte to preserve in each line in the CAL_WR_DMA_XSIZE_k[15:3] XSKIP register bit-field
- The number of bytes to preserve for each line in the CAL_WR_DMA_XSIZE_k[31:19] XSIZE bit-field

The cropping block discards unwanted data and modifies data TAG to preserve integrity. For example, when pixel data is processed:

- PIX_DAT_FS => 1st word of a frame
- PIX_DAT_LS => 1st word of a line, except for the 1st line
- PIX_DAT_LE => last word of a line, except for the last line
- PIX_DAT_FE => last word of a frame
- PIX_DAT => any other pixel data

Cropping is mainly intended to reduce storage requirements / power consumption when digital zoom is used. No dummy data will be written, if the programmed size is less than what is received.

Cropping may also be used for attribute data. It cannot be used for header data. It is SW responsibility to not use cropping for header data. HW does not perform any additional checks.

The Write DMA accumulates data independently for contexts until an OCP write transaction can be generated. That is the case when enough data is available to generate a full burst or when the end of an image line has been reached.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: Data cropping is performed after the DPCM encoder. Therefore, horizontal skipping cannot be used when data is DPCM encoded. Otherwise, it will be not possible to decode the data, unless reference samples have been stored to resume decode.

Cropping must be disabled for JPEG data.

9.4.6.8.3 CAL Write DMA YUV422 to YUV422BP Conversion

The Write DMA block can convert data in YUV422 format into YUV422BP format. The BP refers to "Bi-Planer", where Y and UV are split out onto two separate DMA channels (CAL does not perform the decimation). The format conversion to YUV422BP, when enabled, takes place after the cropping stage.

SW must program two adjacent Write DMA contexts for the YUV422BP conversion. The Y channel is always an even numbered context, while the UV channel is the next context (that is, Y is context #0 and UV is context #1). The Y context is the dominant and the UV is the slave. The YUV422BP register bits are set for both channels/contexts. Both Write DMA channels shall be programmed identically except for the destination address. Even the CAL_WR_DMA_CTRL_k[2:0] MODE register bit-field should be programmed identically for both channels. Internally, the slave channel will be disabled from capturing data from its programmed context and will rather accept the UV portion of the data from the dominant channel.

Only YUV422 data format can be converted to YUV422BP and it is the SW responsibility to program upstream modules of CAL to supply YUV422 data for conversion. True YUV420 format would decimate every other line of UV extracted from the YUV422, but CAL does not perform this aspect of the operation.

Internally, the YUV422BP conversion is using pairs of YUV422 bus transactions and separating out Y and UV portions. It then re-inserts these reformed data phases on the internal bus to the Write DMA assigning context n to the Y data and context n+1 to the UV data. The Write DMA treats these Y and UV data streams as two independent contexts. Up stream of the YUV422BP conversion, the CAL treats it as a single context.

cam-022

Figure 9-34. CAL YUV422 to YUV422BP Conversion (Internal Bus Format)

The DMA module extracts the two different contexts from the internal bus to the Write DMA module. As it does with other formats, it packs the data into a buffer per DMA context and writes this out onto the OCP bus once sufficient data is available for an efficient DMA burst.

The following DMA limitations apply to the YUV422BP conversion:

- Image lines less than 16 pixels are not supported.
- Filter/Cropping shall only be performed on (n x 2) pixel boundaries
- When CIRC_MODE is used, it shall be set identically for both Y and UV channels in the CAL_WR_DMA_OFST_k register. This means that both channels shall either be CIRC_MODE or not, and when in CIRC_MODE they are programmed for the same circular terminal count.

Copyright © 2018–2019, Texas Instruments Incorporated

- YUV422BP format is supported only for PIX_DAT. It is not supported for ATT_DAT, ATT_HDR, CTRL_HDR, PIX HDR.
- YUV422BP Y context can only be assigned to Even Context (that is, 0, 2, 4, 6).
- YUV422BP UV context must be the next context (that is, for example, if Y context is 2, then UV context is 3).
- Since YUV422BP consumes two DMA channels per CSI2 channel, the overall channel count is degraded by a factor of 2 (that is, maximum of four YUV422BP channels is simultaneously supported).
- JPEG is not supported for YUV422BP conversion.

9.4.6.8.4 CAL Write DMA Buffer Management

The DMA write buffer has two functions:

- Accumulate enough data to issue efficient OCP transactions
- Buffer data when it cannot be written to the OCPO port

Different write contexts do not have fixed locations in the write buffer to optimize the required buffer size. In fact, at a given point of time only some of the contexts are active while others are idle. There is no reserved space for unused contexts. Also, different contexts have different bandwidth requirements. Therefore, different amounts of data will pile up for different contexts when OCPO is stalled.

The buffer is divided into slots of $2^{(WDMA_SLOTSIZE+7)}$ bytes that are dynamically allocated to a context. CAL maintains some internal status information to manage the buffer:

- For each slot:
  - State (2 bits):
    - Empty
    - Open (ready to receive more data)
    - Closed (does not accept new data; ready for OCP burst generation)
  - Level (4 bits): amount of data currently stored in the data slot
    - Cleared when data has been sent to OCPO
    - Incremented by 8 bytes each time a new word of 64-bits is added
  - Destination Address (29 bits): destination address for an OCP burst
    - This value is computed when the 1st word of 64-bits is stored in the slot
    - All data of the slot is stored contagiously in memory. The HW allocates new slots to skip memory locations at line ends.
- For each context
  - Slot current in use (if applicable)
  - Destination address

The Write DMA uses the data qualifier provided along with data words to pack data in the local working memory. It has a barrel shifter to pack data when lines ends do not correspond to 64-bit word boundaries and CAL_CSI2_CTXy_l[14] PACK_MODE = 0x1 (Frame mode).

OCP bursts cannot span over multiple slots for design simplification. Refer to section OCP Transaction Generation for more details.

9.4.6.8.5 CAL Write DMA OCP Address Generation

NOTE: CAL can perfom TILER view memory access by configuring CTRL_CORE_SEC_EFUSE_SMA_SW_3[30] CAL_TILED_MEMORY_SPACE register bit. For more details, refer to Section 2.2, *L3_MAIN Memory Map*, and Chapter 19, *Control Module*.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4.6.8.5.1 Write DMA Buffer Base Address

The buffer base address (refered to as BASE, internal variable that cannot be read by SW) is automatically updated when an ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S or PIX_DAT_FS is received by the Write DMA using the following algorithm based around CAL_WR_DMA_CTRL_k[2:0] MODE register bit-field:

- MODE = 0x0 (Disable): DMA is disabled
- MODE = 0x1 (Ping/pong destination address on every frame):
  - BASE = CAL_WR_DMA_ADDR_k
  - CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD
  - CAL_WR_DMA_ADDR_OLD = BASE
- MODE = 0x3 (Initialize start address for continous mode. The first frame will be written at this address and consecutive frames will be appended):
  - BASE = CAL_WR_DMA_ADDR_k
  - CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD
  - CAL_WR_DMA_ADDR_OLD = LINE_START (See Section 9.4.6.8.5.2, *Write DMA Line Start Address*, for further details)
  - CAL_WR_DMA_CTRL_k[2:0] MODE = 0x2
- MODE = 0x2 (Continously write data to memory):
  - BASE = LINE_START + CAL_WR_DMA_OFST_k
- MODE = 0x4 (Use CAL_WR_DMA_ADDR_k as base address)
  - BASE = CAL_WR_DMA_ADDR_k

After reset, CAL_WR_DMA_ADDR_OLD = 0x00000000. Software must update the CAL_WR_DMA_ADDR_k register after the first FE event with a valid destination address. Otherwise, data will be sent to address 0 which is typically not a valid destination.

9.4.6.8.5.2 Write DMA Line Start Address

The line start address is set to the base address when the base address is updated (that is, LINE_NUMBER = 0 at frame start). Otherwise, the line start address is updated upon reception of the PIX_DAT_LS tag depending on the CAL_WR_DMA_OFST_k[23:22] CIRC_MODE register bit-field and CAL_WR_DMA_CTRL_k[4:3] WR_PATTERN bit-field. Table 9-18 summarizes how the line starts address (LINE_START) and line numbers are updated on every PIX_DAT_LS tag.

Table 9-18. Write DMA - Line Start Address Computation

CAL_WR_DMA_OFST_k [23:22] CIRC_MODE	CAL_WR_DMA_CTRL_k [4:3] WR_PATTERN	Description
0 (Disabled)	0 (Linear)	Linear buffer LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST

0 (Disabled)	2 (Write 2 lines, skip 2 lines)	Linear buffer + skip pattern
		if LINE_N #2 == 0:
		LINE_N = LINE_N + 1
		LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST
		else:
		LINE_N = LINE_N + 3
		LINE_START = LINE_START + 3*CAL_WR_DMA_OFST_k[18:4] OFST

0 (Disabled)	3 (Write 2 lines, skip 4 lines)	Linear buffer + skip pattern if LINE_N #2 == 0: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST else: LINE_N = LINE_N + 5 LINE_START = LINE_START + 5*CAL_WR_DMA_OFST_k[18:4] OFST

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-18. Write DMA - Line Start Address Computation (continued)

CAL_WR_DMA_OFST_k [23:22] CIRC_MODE	CAL_WR_DMA_CTRL_k [4:3] WR_PATTERN	Description

1 (1 Line)	0 (Linear)	Circular buffer
		if CIRC_MODE == 1:
		G = 1
		elif CIRC_MODE == 2:
		G = 4
		else:
		G = 64
		if LINE_N == G*CAL_WR_DMA_OFST_k[31:24] CIRC_SIZE:
		LINE_N = 0
		LINE_START = BASE
		else:
		LINE_N = LINE_N + 1
		LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST

2 (4 Lines)		
3 (64 Lines)		
different than 0	different than 0	Reserved. Do not use this combination.

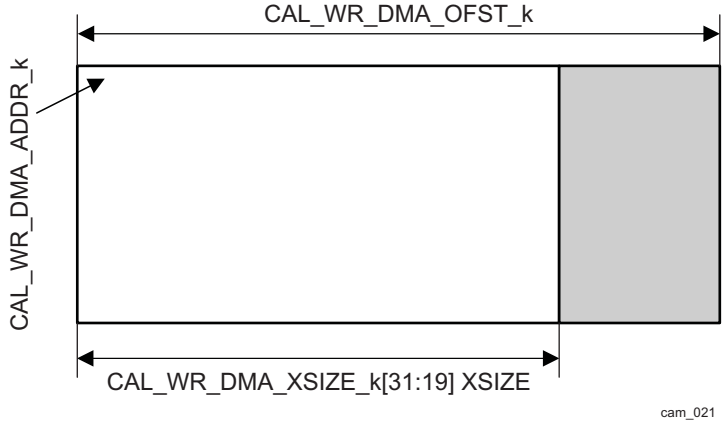
NOTE: CAL_WR_DMA_CTRL_k[2:0] MODE must be set to 0x0 (disabled) or 0x4 (use CAL_WR_DMA_ADDR_k as base address), when CAL_WR_DMA_OFST_k[23:22] CIRC_MODE !=0.

9.4.6.8.5.3 Write DMA Data Address

Data received together with the ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S, PIX_DAT_FS or PIX_DAT_LS tag is stored at the line start address (refer to section Line Start Address). For all other tags (ATT_HDR_E, ATT_DAT, ATT_DAT_E, PIX_HDR_E, CTRL_HDR_E, PIX_DAT, PIX_DAT_FE or PIX_DAT_LE), data is appended (that is, ADDR+ = 8, for each word of 64-bits).

Figure 9-35 illustrates how data is stored in memory when CAL_WR_DMA_OFST_k[23:22] CIRC_MODE = 0 (disabled) and CAL_WR_DMA_CTRL_k[4:3] WR_PATTERN = 0 (linear).

Figure 9-35. Write DMA - Framing



The Write DMA channel with the lowest ID has the highest priority when multiple channels are ready to send data simultaneously.

Software can use CAL_WR_DMA_XSIZE_k[31:19] XSIZE = 0 in case the stream size is not known or exceeds the maximum range of the XSIZE bitfield. CAL skips the cropping feature in that case and sends all data to memory. However, software must still ensure that enough memory space has been allocated.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4.6.8.6 CAL Write DMA OCP Transaction Generation

The Write DMA generates OCP write bursts of 1~8 x 16 bytes. A burst never crosses a 128 byte boundary. The maximum burst size is defined by the CAL_CTRL[6:5] BURSTSIZE register bit-field. The first and the last burst of a contiguous data block may use smaller burst sizes than defined in the BURSTSIZE bit-field. Bursts in the middle of the data block must use exactly the size defined in the BURSTSIZE bit-field.

9.4.6.8.7 CAL Write DMA Real Time Traffic

Traffic for which the pixel rate is imposed by the camera is qualified as hard real time traffic. Example of such hard real time traffic is data received from the camera (through PPI), optionally processed in the CAL and then sent to SDRAM using the OCPO port.

Hard real time traffic cannot be stalled for long periods of time. Indeed, the camera sends data at constant speed and it can only be stalled until FIFOs on the path are filled up. When FIFOs become full, data is discarded and the frame is therefore corrupted. To minimize the risk of real time data corruption, the device supports a mechanism that is activated by the MFlag generated by real time initiators.

MFlag generation must be disabled (through CAL_CTRL[20:13] MFLAGL = 0xFF and CAL_CTRL[31:24] MFLAGH = 0xFF), when CAL does not generate any real time traffic.

Static assertion of MFlag is only supported for debug purposes and must not be enabled for normal utilization (CAL_CTRL[20:13] MFLAGL = 0x00 -> MFlag=0x11; CAL_CTRL[20:13] MFLAGL = 0xFF and CAL_CTRL[30:24] MFLAGH = 0x00 -> MFlag=0x01).

Dynamic MFlag generation is to be used when the Write DMA operates on real time data. In that case, the MFlag value depends on the number of slots (n) ready to generate transactions in the Write DMA:

- MFlag = 00: SAFE (n < CAL_CTRL[20:13] MFLAGL)
- MFlag = 01: VULNERABLE (CAL_CTRL[20:13] MFLAGL <= n < CAL_CTRL[31:24] MFLAGH)
- MFlag = 11: ENDANGERED (CAL_CTRL[30:24] MFLAGH <= n)

Software must ensure that:

- CAL_CTRL[20:13] MFLAGL <= CAL_CTRL[30:24] MFLAGH (only 0x00 or 0x11 generated, when MFLAGL = MFLAGH)
- CAL_CTRL[20:13] MFLAGL = 0x00, 0xFF or less or equal to $2^{(CAL_HL_HWINFO[3:0]\ WFIFO\ -\ 3)}$
- CAL_CTRL[30:24] MFLAGH = 0x00, 0xFF or less or equal to $2^{(CAL_HL_HWINFO[3:0]\ WFIFO\ -\ 3)}$

9.4.6.9 CAL Video Port

9.4.6.9.1 CAL Video Port Overview

Figure 9-36 shows the CAL video port internal architecture. It is composed of a timing generator and a FIFO. All four video ports have same architecture and take same register inputs.

The video port receives data + TAGs from the DPCM decoder stage. It filters the received data and only processes:

- Data that matches the CPORT ID defined by the CAL_VPORT_CTRL2[4:0] CPORT register bit-field
- Data that is tagged as PIX_DAT_FS, PIX_DAT_LS, PIX_DAT, PIX_DAT_LE or PIX_DAT_FE

In addition, it uses the FE_CODE tag to enter the vertical blanking period after the end of the horizontal blanking period when the vertical blanking period is not already started.

Other data is ignored by the video port (this does not affect the operation of other pipeline stages).

Copyright © 2018–2019, Texas Instruments Incorporated

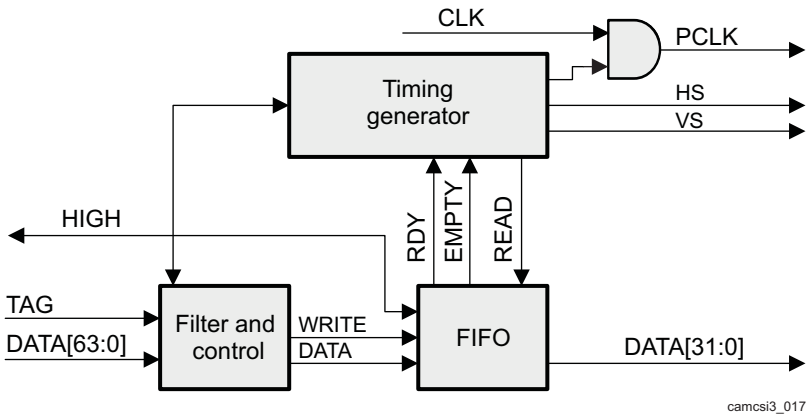
NOTE: Only one CPORT can use the video port and only pixel data can be sent to the video port (that is, control and attribute packets are ignored).

When the video port is configured in baseline mode (CTRL_CORE_SMA_SW_3[31] CAL_BASELINE_EN = 0x1), then only one CPORT can use Video Port 1 and only pixel data can be sent to Video Port 1 (that is, control and attribute packets are ignored).

When the video port is configured in VPx4 mode (CTRL_CORE_SMA_SW_3[31] CAL_BASELINE_EN = 0x0), then the video ports mapping is as follows:

- VP1: CAL_VPORT_CTRL2[4:0] CPORT
- VP2: CAL_VPORT_CTRL2[4:0] CPORT + 1
- VP3: CAL_VPORT_CTRL2[4:0] CPORT + 2
- VP4: CAL_VPORT_CTRL2[4:0] CPORT + 3

Figure 9-36. CAL Video Port and Timing Generator



The FIFO receives data from the internal processing pipeline at a variable rate (up to 4 pixels per cycle). The HIGH signal is asserted a few cycles before the FIFO becomes full. It is used to stall the incoming pixel flow . Therefore, no FIFO overflow can occur.

The timing generator is started after a PIX_DAT_FS tag, when the FIFO level exceeds the threshold defined in CAL_VPORT_CTRL2[31:18] RDY_THR bit field. This threshold is 0 by default but may be used to smooth the traffic on the video port .

The timing generator controls pixel reads from the FIFO. It only reads a pixel when:

- The current output position corresponds to an active location.
- Data is ready in the FIFO.

9.4.6.9.2 CAL Video Port Pixel Clock Generation

The video port pixel clock (VP_PCLK) is generated from the functional clock (CAL_FCLK). Software sets the peak pixel rate using the CAL_VPORT_CTRL1[16:0] PCLK register bit-field. The pixel rate is automatically controlled by the hardware, when data arrives from the RD_DMA.

The mean pixel clock rate on the video port can be given with the equation:
VP_PCLK = CAL_FCLK × CAL_VPORT_CTRL1[16:0] PCLK / 65536

As VP_PCLK is generated from the CAL functional clock, some clock pulses are gated to reach the selected frequency. The following algorithm is used to generate the internal PCLK_EN signal:

1. ACC = CAL_VPORT_CTRL1[16:0] PCLK
2. If (ACC + CAL_VPORT_CTRL1[16:0] PCLK >= 65536) then PCLK_EN=1 else PCLK_EN=0
3. ACC = (ACC + CAL_VPORT_CTRL1[16:0] PCLK) % 65536
4. Go back to step #2

The configured pixel clock is used for active as well as for blanking periods.

Copyright © 2018–2019, Texas Instruments Incorporated

9.4.6.9.3 CAL Video Port Video Timing Generator

The timing generator state-machine reuses the synchronization information received through TAGs to:

- Control state transitions
- Assert the VP_HS and VP_VS signals
- Detect when data is ready to be sent

For more details on the video port, refer to Section 9.3.2, *CAL Integration - Video Port*.

The timing generator can be unconditionally reset in the following ways:

- A general hardware (by CAL_RST signal) or software (through the CAL_HL_SYSCONFIG[0] SOFTRESET register bit) reset
- Setting the CAL_VPORT_CTRL2[17] FSM_RESET bit

It is also reset by data tagged as PIX_DAT_FS when the CAL_VPORT_CTRL2[16] FS_RESETS bit is set. This bit is enabled by default, but may be disabled when vertical blanking times are very short and there is no risk of TX data dropping/desynchronizing.

Four VP_PCLK cycles are sent before the first active pixel . The video port state-machine then waits until four VP_PCLK cycles are sent after the last blanking cycle of the frame.

Active data is sent to the video port only when at least 4 × CAL_VPORT_CTRL2[31:18] RDY_THR pixels are available. That mechanism can be used to smooth the pixel rate on the video port, if input data arrives at bursty rate. The video port FIFO accumulates 4 × CAL_VPORT_CTRL2[31:18] RDY_THR after frame start before it sends the first pixel, and signal VP_VS = VP_HS = 1.

The video port can generate horizontal and vertical blanking in addition to pixels received from the CAL pipeline. The amount of blanking is defined by the CAL_VPORT_CTRL1[24:17] XBLK and CAL_VPORT_CTRL1[30:25] YBLK bit fields. The pixel clock is active at the chosen speed during blanking. VP_HS pulses are provided during vertical blanking. The pixel clock is cut during the idle period.

The timing generator is stalled (VP_PCLK = 0, state-machine stalled) when the current position is in the active video region (waiting for data), but no data is available. VP_PCLK is free running (at the speed defined by CAL_VPORT_CTRL1[16:0] PCLK bit-field) during horizontal and vertical blanking periods. No line PIX_DAT_HS, PIX_DAT_HE, PIX_DAT_VS, PIX_DAT_VE tags are expected by the video port state-machine during blanking periods.

NOTE: Software does not need to configure the size of the image for the video port. This information is extracted from the received datastream. Generally, to generate the vertical blanking, CAL counts the number of active pixels from the last image line.

The VP_VE signal is not generated when data comes from PPI interfaces, and no line or a too large number of lines have been configured in the CAL_CSI2_CTXy_l[29:16] LINES register bit-field. However, the PPI provides the FE_CODE tag when the FE short packet is received from the camera. The state machine enters into vertical blanking generation mode upon reception, in case of this tag (if it is not already in vertical blanking mode: in that case it has no effect).

9.4.6.10 CAL Registers Shadowing

Table 9-19 summarizes which CAL registers are shadowed.

Table 9-19. CAL Registers Shadowing

Register	Shadowed	Trigger	Additional Information
CAL_HL_REVISION	No	N/A	
CAL_HL_HWINFO	No	N/A	
CAL_HL_SYSCONFIG	No	N/A	
CAL_HL_IRQ_EOI	No	N/A	
CAL_HL_IRQSTATUS_RAW_j	No	N/A	

Copyright © 2018–2019, Texas Instruments Incorporated

Table 9-19. CAL Registers Shadowing (continued)

Register	Shadowed	Trigger	Additional Information
CAL_HL_IRQSTATUS_j	No	N/A	
CAL_HL_IRQENABLE_SET_j	No	N/A	
CAL_HL_IRQENABLE_CLR_j	No	N/A	
CAL_PIX_PROC_i[0] EN	Yes	FS @ pixel processing input	Format received on CPORT may change (for example between viewfinder and full frame). However, utilization of separate CPORTs is preferred (if camera sensor permits).
CAL_PIX_PROC_i other bits	No	N/A	Use separate contexts and EN bits, if pixel processing for a given CPORT must be changed on a frame by frame basis
CAL_CTRL	No	N/A	Typically not changed while there is active traffic
CAL_LINE_NUMBER_EVT	No	N/A	
CAL_VPORT_CTRL1	Yes	FS @ video port input	Blanking / PCLK settings may need to be changed on each frame; for example when binning / digital zoom settings change.
CAL_VPORT_CTRL2[] FSRESET bit	No	N/A	Control bit for debug only
CAL_VPORT_CTRL2 other bits	Yes	FS @ video port input	Pixel rate and source CPORT may need to change on the fly (that is, switch between camera modes that use separate CPORTs)
CAL_RD_DMA_CTRL	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_OFST	No	N/A	One-shot-operation only
CAL_RD_DMA_XSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_YSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_OFST	No	N/A	One-shot-operation only
CAL_WR_DMA_CTRL_k[1:0] MODE	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k[13:9] CPORT	Resolution may change for a given CPORT. That is not preferred but some sensors may require this mode.
CAL_WR_DMA_CTRL_k other bits	No	N/A	Use separate contexts and MODE bits, if size changes for a given CPORT.
CAL_WR_DMA_ADDR_k	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k[13:9] CPORT	Output is typically double buffered so that CAL writes one buffer when the other buffer is read.

NOTE: Registers that are not shadowed are busy writable. Changes are immediately taken into account and may cause failure, if they are done while the hardware is using the register (that is, outside of the blanking periods).

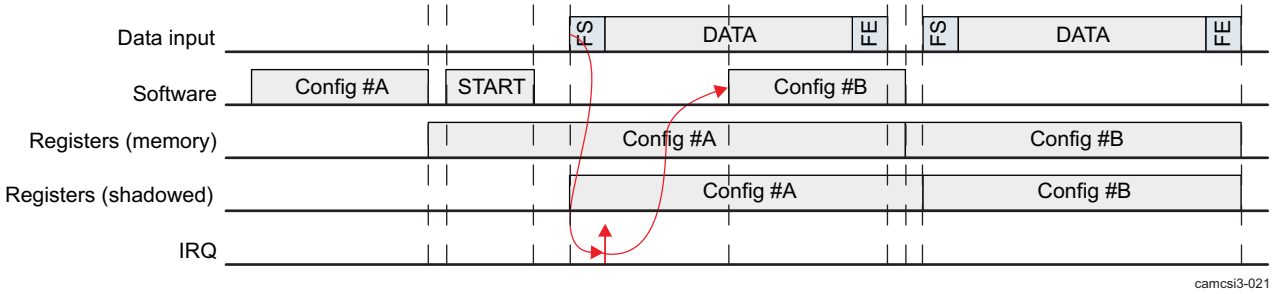
For all shadowed registers, except CAL_WR_DMA_ADDR_k, the content of the shadowed register is copied into the internal copy when the FS of the newly enabled stream is received by the corresponding engine. Said differently, new settings are taken into account just before they are needed. That maximizes time available to the software to change register settings. In particular, the first received FS copies initial settings into a shadow register.

The FS event is detected at the location in the pipeline where the setting applies. Said differently, the copy from shadow to working register does not occur exactly at the same time in all pipeline stages and there is no risk that the shadowing mechanism is activated too late or too early.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 9-37 shows an example. Software writes configuration #A and then starts the processing step. The value from the configuration register is copied into the shadowed register that is used by hardware when the PIX_DAT_FS tag is received by relevant pipeline stage. Software may use an IRQ to detect the frame start and provide the settings for the next frame. The frame start interrupt is triggered by the low-level protocol. This happens up to 8 cycles before the PIX_DAT_FS tag reaches the processing stage. Therefore, software must ensure that there is a delay of at least 8 functional clock cycles from the FS_IRQ to the configuration update. In a real world case, this delay is ensured by the IRQ controller plus software latency. Software must first read the CAL_HL_IRQSTATUS_j registers to detect which event has triggered the IRQ before it can update configuration registers.

Figure 9-37. CAL Registers Shadowing Example



The CAL_WR_DMA_ADDR_k register has a specific shadowing to avoid that multibuffer management is on the critical software path. For more details, see Section 9.4.6.8.5, *Write DMA OCP Address Generation*.

Table 9-54. CAL_RD_DMA_CTRL

Address Offset	0x0000 0140		
Physical Address	0x489B 0140	**Instance**	CAL
Description	Read DMA control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCLK																OCP_TAG_CNT				BW_LIMITER										INIT	GO

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:15	PCLK	Controls the data rate at which data is read from the read DMA FIFO and sent to the internal processing pipeline. Data rate = FCLK * 8 * PCLK / 2^16 Bytes/s HW guarantees that data is never sent at faster rate than defined by this register. The data may be sent at slower rate when the RD DMA FIFO is empty or the processing pipeline is busy (data from OCPI has higher priority) Missed slots are not cummulated. Valid range: 0 .. 2^16	RW	0x0 0000
14:11	OCP_TAG_CNT	Maximum allowed number of outstanding OCP read requests minus 1 (i.e. 0xF meand up to 16 outstanding requests)	RW	0x0
10:2	BW_LIMITER	Defines a minimum cycle count between to consecutive read requests issued by the RD DMA. Used to limit the SDRAM load in memory to memory mode. The pixel rate should be controlled at video port level when data read from memory is send to the video port. Valid range = 9..4095 cycles	RW	0x000
1	INIT	Enable reading of DPCM decoder initialization data from SDRAM 0x0: Disabled 0x1: Enabled	RW	0
0	GO	Start data read from memory. This bit is set by SW and automatically cleared by HW when the frame has been processed. Write 0x0: No effect Write 0x1: Start read DMA Read 0x1: Read DMA BUSY / it is currently fetching data from memory and sends it to the processing pipeline Read 0x0: Read DMA idle / ready to receive the next start trigger from SW	RW	0

YSIZE														RESERVED		YUV422BP	STALL_RD_DMA	CPORT						DTAG			ICM_PSTART	WR_PATTERN		MODE	

Bits	Field Name	Description	Type	Reset
31:18	YSIZE	Maximum number of lines the WR DMA can write to memory. That feature is typically used to prevent writes outside of an allocated memory buffer (may, for example, happen when sync information is lost). 0: No limitation. All received lines are written to memory. 1~2^14-1: maximum number of lines to write to memory	RW	0x0000
17:16	RESERVED	Reserved	R	0x0
15	YUV422BP	Activates YUV422BP conversion from YUV422. Requires two consecutive WrDMA channels where first channel is even and second is odd. Both channels shall be programmed identically except for DMA destination address. 0x0: YUV422BP conversion disabled 0x1: YUV422BP conversion enabled	RW	0x0
14	STALL_RD_DMA	Controls if a the RD DMA shall be stalled when the write context is stalled because it waits for the PSTART pulse. 0x0: Don't stall the read DMA 0x1: Stall the read DMA if the write DMA context is stalled.	RW	0x1
13:9	CPORT	Cport ID	RW	0x00
8:6	DTAG	Store data tagged as DTAG 0x6: reserved 0x1: Attribute data TAG=ATT_DAT_S; ATT_DAT; ATT_DAT_E 0x7: reserved 0x0: Attribute packet headers. TAG=ATT_HDR_S, ATT_HDR_E 0x2: Control packets TAG=CTRL_HDR_S; CTRL_HDR_E 0x4: Pixel data TAG=PIX_DAT_FS; PIX_DAT_LS; PIX_DAT; PIX_DAT_LE; PIX_DAT_FE; FE_CODE 0x5: reserved 0x3: Pixel packet headers TAG=PIX_HDR_S; PIX_HDR_E	RW	0x0
5	ICM_PSTART	Enables monitoring of the ICM_PSTART[x] signal 0x0: Disabled. Ignore PSTART input 0x1: Enabled. Write the number of lines defined by CAL_WR_DMA_OFST_k.CIRC_MODE for each received PSTART pulse.	RW	0x0

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4:3	WR_PATTERN	Data write pattern. The write pattern must be set to linear for formats that don't have a concept of lines. 0x0: Linear 0x1: Reserved 0x3: Write 2 lines Skip 4 lines 0x2: Write two lines Skip two lines	RW	0x0
2:0	MODE	Mode 0x1: Ping/pong destination address on every frame 0x0: Disable 0x2: Continously write data to memory 0x4: Use CAL_WR_DMA_ADDR_k as base address. 0x5: Reserved 0x3: Initialize start address for continous mode. The 1st frame will be written at this address and consecutive frames will be appended.	RW	0x0

9.5.3 CSI2 PHY Registers

9.5.3.1 CSI2 PHY Register Summary

Table 9-126 summarizes the CSI2 PHY registers mapping.

Copyright © 2018–2019, Texas Instruments Incorporated

NOTE: CAMERARX_CORE_0 is for CSI2_PHY1.

CAMERARX_CORE_1 is for CSI2_PHY2.

Table 9-126. CSI2 PHY Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	CAMERARX_CORE_0 L4_PER3 Physical Address	CAMERARX_CORE_1 L4_PER3 Physical Address
REG0	RW	32	0x0000 0000	0x489B 0800	0x489B 0900
REG1	RW	32	0x0000 0004	0x489B 0804	0x489B 0904
REG2	RW	32	0x0000 0008	0x489B 0808	0x489B 0908

9.5.3.2 CSI2 PHY Register Description

Table 9-127. REG0

Address Offset	0x0000 0000		
Physical Address	0x489B 0800 0x489B 0900	**Instance**	CAMERARX_CORE_0 CAMERARX_CORE_1
Description	First register. Note: For detailed description on parameter functionality, refer to MIPI D-PHY Specification v1.00.00.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							HSCLOCKCONFIG	RESERVED								THS_TERM								THS_SETTLE							

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Reserved fields	NA	0x00
24	HSCLOCKCONFIG	Disable clock missing detector	RW	0
23:16	RESERVED	Read returns zero	R	0x00
15:8	THS_TERM	THS_TERM timing parameter in multiples of DDR clock frequency. Effective time for enabling of termination = synchronizer delay + timer delay + LPRX delay + combinational routing delay ~ (1–2)* DDRCLK + THS-TERM + ~ (1 –15) ns. Programmed value = floor(20 ns/DDR_CLK), where DDR_CLK is the period of the CSI-2 I/O lane rate. Default value: 4 (for 400 MHz).	RW	0x04
7:0	THS_SETTLE	THS_SETTLE timing parameter in multiples of DDR clock frequency. Effective THS_SETTLE seen on line (starting to look for sync pattern) = synchronizer delay + timer delay + LPRX delay + combinational routing delay – pipeline delay in HS data path ~ (1–2)* DDRCLK + THS-SETTLE + ~ (1–15) ns –1*DDRCLK. Programmed value = floor(105 ns/DDR_CLK) + 4, where DDR_CLK is the period of the CSI-2 I/O lane rate. Default value: 39 (for 400 MHz). Minimum supported THS-SETTLE programmed value = 3.	RW	0x27

Table 9-129. REG1

Address Offset	0x0000 0004		
Physical Address	0x489B 0804 0x489B 0904	**Instance**	CAMERARX_CORE_0 CAMERARX_CORE_1
Description	Second register. Note: For detailed description on parameter functionality, refer to MIPI D-PHY Specification v1.00.00.		
Type	RW		

31 30	29 28	27 26	25	24	23 22 21 20 19 18 17 16	15 14 13 12 11 10	9 8	7 6 5 4 3 2 1 0
RESVD_READ_BIT	RESET_DONE_STATUS	RESERVED	CLOCK_MISS_DETECTOR_STATUS		TCLK_TERM	DPHY_HS_SYNC_PATTERN	CTRLCLK_DIV_FACTOR	TCLK_SETTLE

Bits	Field Name	Description	Type	Reset
31:30	RESVD_READ_BIT	Reserved bit	NA	0x0
29:28	RESET_DONE_STATUS	Reset done read bits. 28: RESETDONERXBYTECLK **Note:** BYTECLK is provided to the CSI2 low level protocol 29: RESETDONECTRLCLK **Note:** This is the CTRLCLK provided to the PHY from the PRCM module.	R	0x0
27:26	RESERVED	Write 0 for future compatibility.	RW	0x0
25	CLOCK_MISS_DETECTOR_STATUS	Clock missing detector status. Internal debug bit. 1: Error in clock missing detector. 0: Clock missing detector successful Note: CLKMISS detector is likely to malfunction, if tclk-trail section CAMSS Interrupt Events (60ns) is not honoured.	R	0
24:18	TCLK_TERM	TCLK_TERM timing parameter in multiples of CTRLCLK Effective time for enabling of termination = synchronizer delay + timer delay + LPRX delay + combinational routing delay ~ (1–2)* CTRLCLK + TCLK_TERM + ~ (1–15) ns Programmed value = ceil(9.5 / CTRLCLK period) – 1 Default value : 0 (for 96 MHz)	RW	0x00
17:10	DPHY_HS_SYNC_PATTERN	DPHY mode HS sync pattern in byte order (reverse of received order) See Section 9.4.5.4, *CSI2 PHY Error Signals.*	RW	0xB8

Copyright © 2018–2019, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9:8	TCLK_DIV	CTRLCLK_DIV_FACTOR Divide factor for CTRLCLK for CLKMISS detector Programmed value = ceil (15ns/CTRLCLK Period) - 1 Default value: 1 (for 96 MHz) CLKMISS detection time = (5*TCLK_DIV+1)*(CTRLCLK period) < 60ns Note: Only the CTRLCLK frequencies that satisfie above relationship are allowed. Typically, 96MHz will be used at CTRLCLK.	RW	0x1
7:0	TCLK_SETTLE	TCLK_SETTLE timing parameter in multiples of CTRLCLK Clock Effective TCLK_SETTLE = synchronizer delay + timer delay + LPRX delay + combinational routing delay ~ (1–2)* CTRLCLK + Tclk-settle + ~ (1 –15) ns Programmed value = max[3, ceil(155 ns/CTRLCLK period) –1] Default value: 14 (for 96 MHz)	RW	0x0E

Video Input Port

This chapter describes the Video Input Port (VIP) module for the device.

Topic **Page**

10.1 VIP Overview 1990
10.2 VIP Environment 1992
10.3 VIP Integration 1998

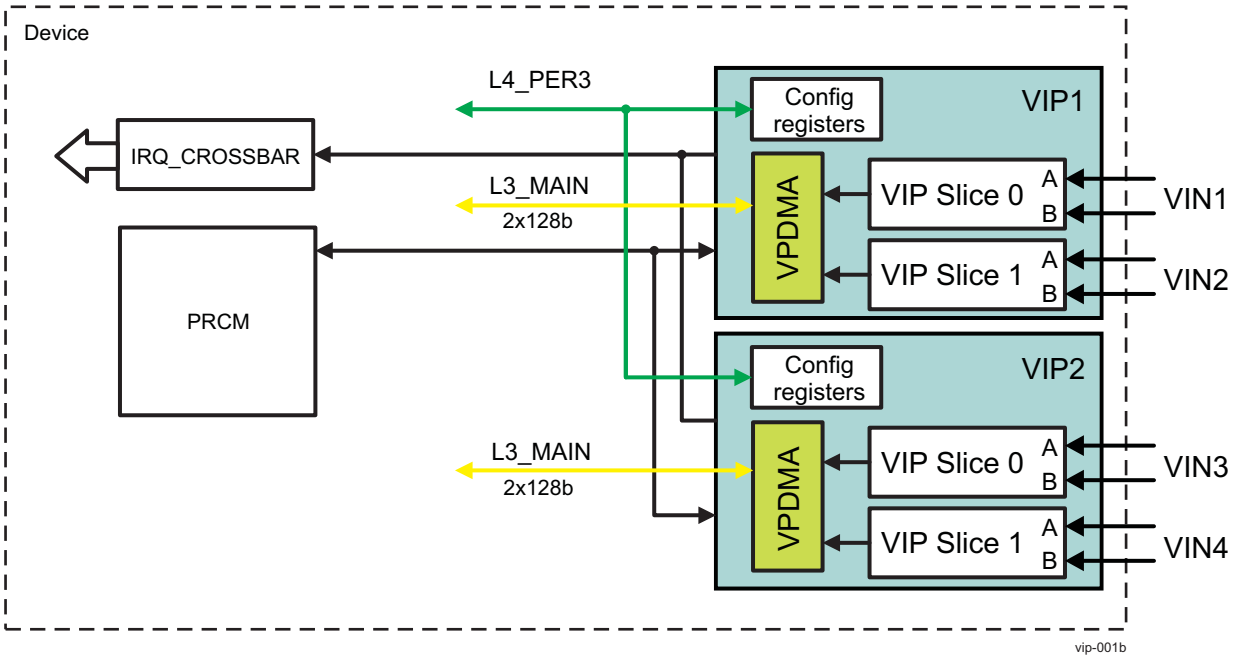
10.1 VIP Overview

The VIP module provides video capture functions for the device. VIP incorporates a multi-channel raw video parser, various video processing blocks, and a flexible Video Port Direct Memory Access (VPDMA) engine to store incoming video in various formats. The device integrates two instantiations of the VIP module giving the ability of capturing up to eight video streams.

Figure 10-1 shows a block diagram with the VIP modules within the device.

Figure 10-1. VIP Overview



A VIP module includes the following main features:

- Two independently configurable external video input capture slices (Slice 0 and Slice 1) each providing up to two video input ports, Port A and Port B:
  - Port A can be configured as a 24/16/8-bit port.
  - Port B is a fixed 8-bit port.
  - At device level, the same device pads may be shared between Port A and Port B of each slice. For more information, see the multiplexing characteristics in device Data Manual.
- Each video Port A can be operated as a port with clock independent input channels (with interleaved or separated Y/C data input). Embedded sync and external sync modes are supported for all input configurations.
- Support for a single external asynchronous pixel clock, up to 165MHz per port.
- Pixel Clock Input Domain Port A supports up to one 24-bit input data bus, including BT.1120 style embedded sync for 16-bit and 24-bit data.
- Embedded Sync data interface mode supports single or multiplexed sources
- Discrete Sync data interface mode supports only single source input
- 24-bit data input plus discrete syncs can be configured to include:
  - 8-bit YUV422 (Y and U/V time interleaved)
  - 16-bit YUV422 (CbY and CrY time interleaved)
  - 24-bit YUV444
  - 16-bit RGB565
  - 24-bit RGB888
  - 12/16-bit RAW Capture

Copyright © 2018–2019, Texas Instruments Incorporated

  - 24-bit RAW capture
- Discrete sync modes include:
  - VSYNC + HSYNC (FID determined by FID signal pin or HSYNC/VSYNC skew)
  - VSYNC + ACTVID + FID
  - VBLANK + ACTVID (ACTVID toggles in VBLANK) + FID
  - VBLANK + ACTVID (no ACTVID toggles in VBLANK) + FID
- Multichannel parser (embedded syncs only):
  - Embedded syncs only
  - Pixel (2x or 4x) or Line multiplexed modes supported
  - Performs demultiplexing and basic error checking
  - Supports maximum of 9 channels in Line Mux (8 normal + 1 split line)
- Ancillary data capture support:
  - For 16-bit or 24-bit input, ancillary data may be extracted from any single channel
  - For 8-bit time interleaved input, ancillary data can be chosen from the Luma channel, the Chroma channel, or both channels
  - Horizontal blanking interval data capture only supported when using discrete syncs (VSYNC + HSYNC or VSYNC + HBLANK)
  - Ancillary data extraction supported on multichannel capture as well as single source streams
- Format conversion and scaling:
  - Programmable color space conversion
  - YUV422 to YUV444 conversion
  - YUV444 to YUV422 conversion
  - YUV422 to YUV420 conversion
  - YUV444 Source: YUV444 to YUV444, YUV444 to RGB888, YUV444 to YUV422, YUV444 to YUV420
  - RGB888 Source: RGB888 to RGB888, RGB888 to YUV444, RGB888 to YUV422, RGB888 to YUV420
  - YUV422 Source: YUV422 to YUV422, YUV422 to YUV420, YUV422 to YUV444, YUV422 to RGB888
  - Supports RAW to RAW (no processing)
  - Scaling and format conversions do not work for multiplexed input
- Supports up to 2047 pixels wide input - when scaling is engaged
- Supports up to 3840 pixels wide input - when only chroma up/down sampling is engaged, without scaling
- Supports up to 4095 pixels wide input - without scaling and chroma up/down sampling
- The maximum supported input resolution is further limited by:
  - Pixel clock and feature-dependent constraints
  - For RGB24-bit format (RAW data), the maximum frame width is limited to 2730 pixels
- Unsupported features of the VIP modules
  - The VIP modules do not have a power switch, making the power domain (PD_CAM) Always-On. For more information on the power domain, see Section 3.7.14, PD_CAM (Physical PD_COREAON) Description.

A VPDMA module includes the following main features:

- VPDMA output buffer size restriction feature, which ensures that writes do not exceed allocated memory buffer size
- Support for Tiled (2D) and raster addressing without bandwidth penalty
- Dual clients per channel allows for capture of scaled and nonscaled versions of the data stream (non-multiplexed mode only)

Copyright © 2018–2019, Texas Instruments Incorporated

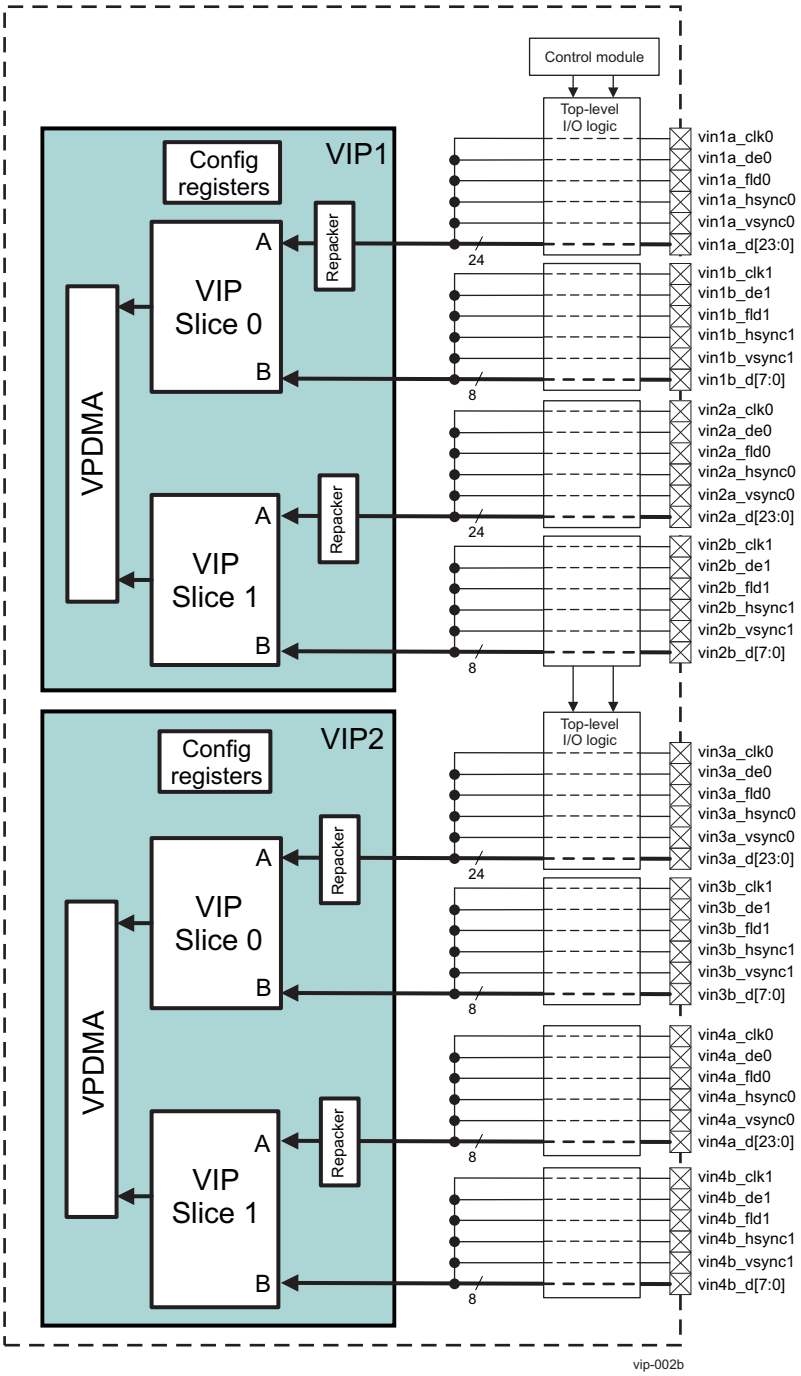
- Start on new frame capability
- Interrupt every X number of frames
- Interrupt every X lines (synced to frame start)
- Dynamic MFLAG generation

10.2 VIP Environment

This section describes the VIP modules from an environment point of view (external connections). It describes the VIP connectivity options and lists all possible interfaces. Figure 10-2 is a block diagram of the VIP environment.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-2. VIP Environment



NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to different pads of the device and is programmable in the device Control Module registers and/or dedicated module registers. For more information, see Section 19.4.6.1.1, *Pad Configuration Registers* in Chapter 19, *Control Module*.

Additionally, by configuring bits [12] VIP_SEL_4A, [11] VIP_SEL_3A, [10] VIP_SEL_2A and [9] VIP_SEL_1A of the CTRL_CORE_CONTROL_SPARE_RW register in the device Control Module it is possible to map the signals of CAL video ports (described in Section 9.3.2, *CAL Integration - Video Port*) to Port A of each VIP slice.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 10-1. VIP1 Interface Signals

Sub-module Name	Signal Name	Type[1]	Description
Slice 0	vin1a_d[23:0]	I	Pixel data.
Port A	vin1a_clk0	I	Pixel clock.
	vin1a_vsync0	I	Vertical synchronization.
	vin1a_hsync0[2]	I	Horizontal synchronization.
	vin1a_de0	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin1a_fld0[2]	I	The FID signal indicates the field identifier for the video input field: • 0 means even. • 1 means odd.
Slice 0	vin1b_d[7:0]	I	Pixel data.
Port B	vin1b_clk1	I	Pixel clock.
	vin1b_vsync1	I	Vertical synchronization.
	vin1b_hsync1	I	Horizontal synchronization.
	vin1b_de1	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin1b_fld1	I	The FID signal indicates the field identifier for the video input field: • 0 means even. • 1 means odd.
Slice 1	vin2a_d[23:0]	I	Pixel data.
Port A	vin2a_clk0	I	Pixel clock.
	vin2a_vsync0	I	Vertical synchronization.
	vin2a_hsync0[2]	I	Horizontal synchronization.
	vin2a_de0	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin2a_fld0[2]	I	The FID signal indicates the field identifier for the video input field: • 0 means even. • 1 means odd.
Slice 1	vin2b_d[7:0]	I	Pixel data.
Port B	vin2b_clk1	I	Pixel clock.
	vin2b_vsync1	I	Vertical synchronization.
	vin2b_hsync1	I	Horizontal synchronization.
	vin2b_de1	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.

(1) I = Input, O = Output, I/O = Input/Output
(2) Signal not used (tied low) when VIP1 is connected to CAL video ports.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 10-1. VIP1 Interface Signals (continued)

Sub-module Name	Signal Name	Type[1]	Description
	vin2b_fld1	I	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.

Table 10-2. VIP2 Interface Signals

Sub-module Name	Signal Name	Type[1]	Description
Slice 0	vin3a_d[23:0]	I	Pixel data.
Port A	vin3a_clk0	I	Pixel clock.
	vin3a_vsync0	I	Vertical synchronization.
	vin3a_hsync0[2]	I	Horizontal synchronization.
	vin3a_de0	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin3a_fld0[2]	I	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.
Slice 0	vin3b_d[7:0]	I	Pixel data.
Port B	vin3b_clk1	I	Pixel clock.
	vin3b_vsync1	I	Vertical synchronization.
	vin3b_hsync1	I	Horizontal synchronization.
	vin3b_de1	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin3b_fld1	I	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.
Slice 1	vin4a_d[23:0]	I	Pixel data
Port A	vin4a_clk0	I	Pixel clock
	vin4a_vsync0	I	Vertical synchronization.
	vin4a_hsync0[2]	I	Horizontal synchronization.
	vin4a_de0	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin4a_fld0[2]	I	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.
Slice 1	vin4b_d[7:0]	I	Pixel data.
Port B	vin4b_clk1	I	Pixel clock.

(1) I = Input, O = Output, I/O = Input/Output
(2) Signal not used (tied low) when VIP2 is connected to CAL video ports.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 10-2. VIP2 Interface Signals (continued)

Sub-module Name	Signal Name	Type[1]	Description
	vin4b_vsync1	I	Vertical synchronization.
	vin4b_hsync1	I	Horizontal synchronization.
	vin4b_de1	I	The DE signal acts as an Input-enable signal to indicate when data must be latched using the input clock. DE is also referred to as ACTVID throughout the VIP chapter. Both of these terms, ACTVID and DE, are the same and used interchangeably.
	vin4b_fld1	I	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.

NOTE: At device level, the same device pads may be shared between Port A and Port B of each slice. For more information, see the multiplexing characteristics in device Data Manual.

Copyright © 2018–2019, Texas Instruments Incorporated

Table 10-3 and Table 10-4 summarize the mapping of RGB and YUV color components to VIP input data signals, with corresponding settings of VIP_MAIN[1:0] DATA_INTERFACE_MODE register bit-field.

Table 10-3. VIP Port A Input Data Signals to RGB and YUV Color Components Mapping

VIP Port A Data Signals	24-bit RGB888 Input Mode	16-bit RGB565 Input Mode	24-bit YUV444 Input Mode	16-bit YUV422 Input Mode (1)	8-bit YUV422 Input Mode (2)
X = 1 to 6	DATA_INTERFACE_MODE = 00b	DATA_INTERFACE_MODE = 00b	DATA_INTERFACE_MODE = 00b	DATA_INTERFACE_MODE = 01b	DATA_INTERFACE_MODE = 10b

vinXa_d18	Red 2	-	Y2	-	-
vinXa_d17	Red 1	-	Y1	-	-
vinXa_d16	Red 0	-	Y0	-	-
vinXa_d15	Green 7	Green 5	Cb7	Y7 (MS bit)	-
vinXa_d14	Green 6	Green 4	Cb6	Y6	-
vinXa_d13	Green 5	Green 3	Cb5	Y5	-
vinXa_d12	Green 4	Green 2	Cb4	Y4	-
vinXa_d11	Green 3	Green 1	Cb3	Y3	-
vinXa_d10	Green 2	Green 0	Cb2	Y2	-
vinXa_d9	Green 1	-	Cb1	Y1	-
vinXa_d8	Green 0	-	Cb0	Y0	-
vinXa_d7	Blue 7	Blue 4	Cr7	Cb7/Cr7/...	Cb7/Y7/Cr7/... (MS bit)
vinXa_d6	Blue 6	Blue 3	Cr6	Cb6/Cr6/...	Cb6/Y6/Cr6/...
vinXa_d5	Blue 5	Blue 2	Cr5	Cb5/Cr5/...	Cb5/Y5/Cr5/...
vinXa_d4	Blue 4	Blue 1	Cr4	Cb4/Cr4/...	Cb4/Y4/Cr4/...
vinXa_d3	Blue 3	Blue 0 (LS bit)	Cr3	Cb3/Cr3/...	Cb3/Y3/Cr3/...
vinXa_d2	Blue 2	-	Cr2	Cb2/Cr2/...	Cb2/Y2/Cr2/...
vinXa_d1	Blue 1	-	Cr1	Cb1/Cr1/...	Cb1/Y1/Cr1/...
vinXa_d0	Blue 0 (LS bit)	-	Cr0 (LS bit)	Cb0/Cr0/... (LS bit)	Cb0/Y0/Cr0/... (LS bit)

(1) Chroma is time division multiplexed (interleaved). For more details, see Section 10.4.5.6.2, *16b Interface Mode*.
(2) Luma and Chroma are time division multiplexed (interleaved). For more details, see Section 10.4.5.6.1, *8b Interface Mode*.

NOTE: 16-bit RGB data can be captured also on the vinXa_d[15:0] input data bus of Port A. In this case, the 16-bit RGB data captured by the VIP_PARSER will be passed to VPDMA, as if it is a 16-bit YUV data. The VIP_MAIN[1:0] DATA_INTERFACE_MODE register bit-field must be configured for a 16-bit input mode. The VPDMA will then directly store this data in memory as a 16-bit data, provided that any 16-bit data type in the VPDMA outbound descriptor is set.

Table 10-4. VIP Port B Input Data Signals to YUV Color Components Mapping

VIP Port B Data Signals	8-bit YUV422 Input Mode (1)

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
VIP1	VIP1_IRQ1	IRQ_CROSSBAR_351	N/A	VIP1 interrupt requests. These IRQ source signals are not mapped by default to any device INTC.
	VIP1_IRQ2	IRQ_CROSSBAR_392	N/A	
VIP2	VIP2_IRQ1	IRQ_CROSSBAR_352	N/A	VIP2 interrupt requests. These IRQ source signals are not mapped by default to any device INTC.
	VIP2_IRQ2	IRQ_CROSSBAR_393	N/A	

Copyright © 2018–2019, Texas Instruments Incorporated

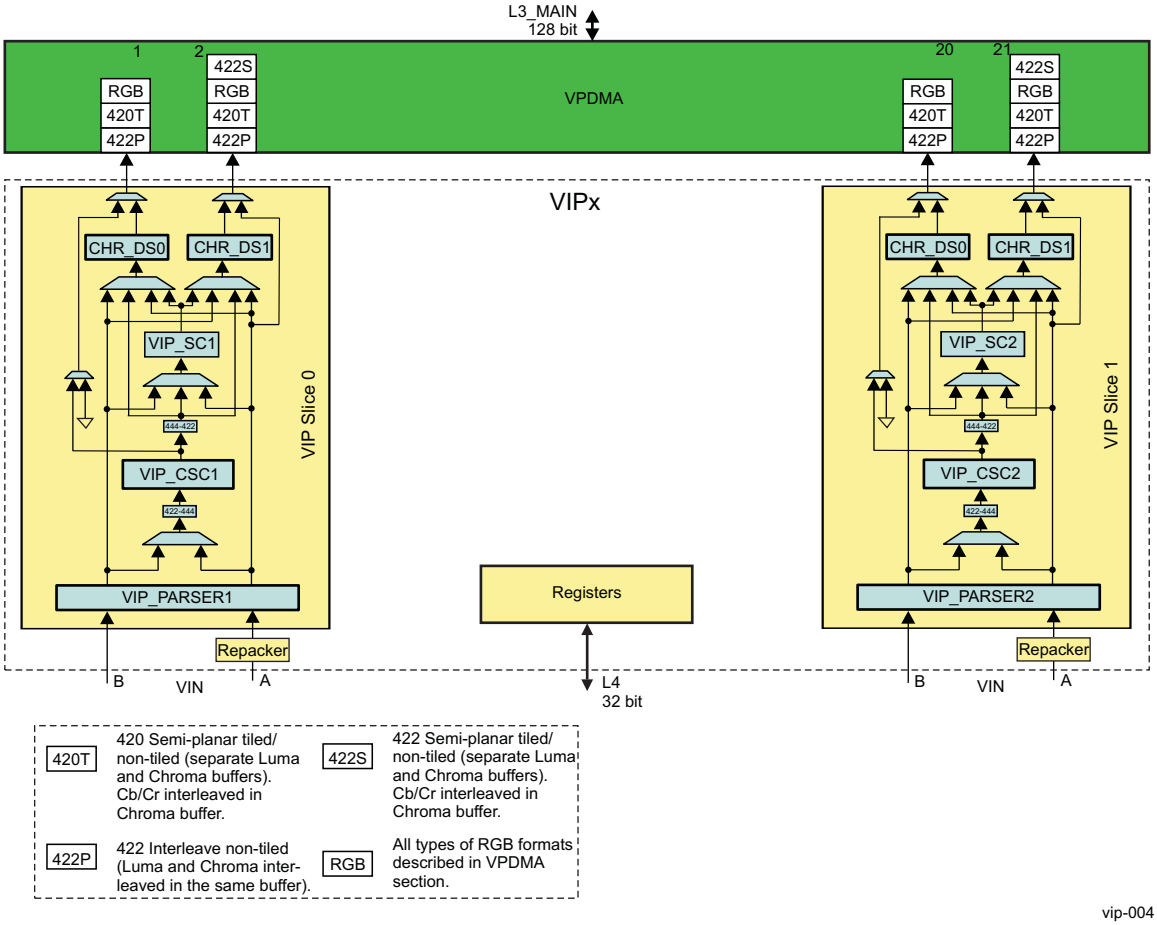
NOTE: The "**Default Mapping**" column in Table 10-7 *VIP Hardware Requests* shows the default mapping of module IRQ source signals. These module IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module, respectively.
For more information about the IRQ_CROSSBAR module, see Section 19.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 19, *Control Module*.
For more information about the device interrupt controllers, see Chapter 18, *Interrupt Controllers*.

10.4 VIP Functional Description

10.4.1 VIP Block Diagram

Figure 10-4 shows the internal structure of a single VIP module in the device.

Figure 10-4. VIP Block Diagram



10.4.2 VIP Software Reset

Software reset in the VIP module can be done by setting the VIP_CLKC_RST[16] VIP1_DP_RST for Slice 0, VIP_CLKC_RST[17] VIP2_DP_RST for Slice 1, VIP_CLKC_RST[0] VPDMA_RST for VIP VPDMA to 0x1. By setting VIP_CLKC_RST[31] MAIN_RST reset is performed for all modules within the instance. Software must ensure that the software reset completes before performing operations within the VIP module.

Copyright © 2018–2019, Texas Instruments Incorporated

10.4.3 VIP Power and Clocks Management

The VIP modules support the MStandby/Wait and IdleReq/SidleAck protocols as defined in Chapter 3, *Power, Reset, and Clock Management.*

Power Management within the VIP module can be accomplished in several ways:

- L4 MConnect/SConnect can disable the internal L4 clock network
- L3 MConnect/Sconnect can disable the internal L3 clock network

These items are accomplished using the standard slave idle (for L4) and master standby (for L3) protocols. When these modules are instructed to disable clocks for the internal L3 or L4 (MMR) clock domains, the internal clock networks will be shut down. This shut down applies to the clock signals - L3_CLK and L4_CLK.

10.4.3.1 VIP Clocks

The VIP internal clock domains can only be shut down by writing the appropriate register bit within the Clock Enable register - VIP_CLKC_CLKEN[16] VIP1_DP_EN for slice0, VIP_CLKC_CLKEN[17] VIP2_DP_EN for slice1 and VIP_CLKC_CLKEN[0] VPDMA_EN for the VPDMA engine

10.4.3.2 VIP Idle Mode

The VIP supports no-idle mode, force-idle mode, and smart-idle mode. The mode can be selected byprogramming the appropriate value in the VIP_SYSCONFIG[3:2] IDLEMODE bit field.

Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.

- Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements.
- No-idle mode: local target never enters idle state.
- Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA related requests) wakeup events

10.4.3.3 VIP StandBy Mode

The VIP supports no-standby mode and force-standby mode. The mode is set in the VIP_SYSCONFIG[5:4] STANDBYMODE bit field.

Configuration of the local initiator state management mode:

- Force-standby mode: local initiator is unconditionally placed in standby state.
- No-standby mode: local initiator is unconditionally placed out of standby state.

10.4.4 VIP Slice

10.4.4.1 VIP Slice Processing Path Overview

Figure 10-5 shows in details the internal processing path and output signals to VPDMA for a single VIP Slice. External video source drives the input side of the VIP Slice. Port A[x:y] can be in YUV422 format (A[15:0] in the diagram) or RGB/YUV444 format (A[23:0] in the diagram), depending on the external video input source and configuration options within the VIP_PARSER. Port B[x:y] can be in YUV422 format (B[15:0] in the diagram). When the VIP_PARSER is configured to capture 24bit RGB/444 data, A[23:0] is used and the data path inside VIP must be configured correctly for it. Multiplexer selections and controls shown in Figure 10-5 are described in register VIP_CLKC_VIP0DPS for Slice 0, and register VIP_CLKC_VIP1DPS for Slice 1. The outputs of each VIP Slice drive the VPDMA module, which sends the resulting data to DDR memory.

10.4.4.2 VIP Slice Processing Path Multiplexers

10.4.4.2.1 VIP_CSC Multiplexers

The following registers are controling the VIP Color Space Converter (CSC) multiplexers: VIP_CLKC_VIP0DPS[2:0] VIP1_CSC_SRC_SELECT for Slice 0 and VIP_CLKC_VIP1DPS[2:0] VIP2_CSC_SRC_SELECT for Slice 1.

The VIP_CSC block (for each slice within the VIP subsystem) receives data from one the following sources:

- VIP_PARSER Port A Output (422)
- VIP_PARSER Port B Output (422)
- VIP_PARSER Port A Output (RGB)

The default state for this multiplexer is disabled, so there is no VIP_CSC input.

10.4.4.2.2 VIP_SC Multiplexer

The multiplexer for Slice 0 and Slice 1 is controleld by VIP_CLKC_VIP0DPS[5:3] VIP1_SC_SRC_SELECT and VIP_CLKC_VIP1DPS[5:3] VIP2_SC_SRC_SELECT, respectively.

The scaler module (VIP_SC) within the VIP subsystem (for a single slice) receives data from one of the following sources:

- VIP_CSC
- VIP_PARSER Port A Output
- VIP_PARSER Port B Output

The default state for this multiplexer is disabled, so there is no VIP_SC input.

10.4.4.2.3 Output to VPDMA Multiplexers

This section is under development and is included as a placeholder for future updates.

10.4.4.3 VIP Slice Processing Path Examples

The following sections provide VIP Slice data path examples for different types of input data, and describe the corresponding multiplexer configurations. Refer to Table 10-8, *VIP Slice Processing Path Control*, for mapping of the multiplexer controls to registers.

In the block diagrams of the following sections:

- Output A refers to the result of processing Input A data.
- Output B refers to the result of processing Input B data.

10.4.5 VIP Parser

The VIP Parser (VIP_PARSER) module is used to capture the external video data into the VIP module.

Copyright © 2018–2019, Texas Instruments Incorporated

10.4.5.1 Features

Each VIP module contains two VIP_PARSER modules (one VIP_PARSER per slice).

For a single VIP_PARSER, the video capture functions include:

- Two Pixel Clock Input Domains are supported (Port A and Port B):
  - Each Pixel Clock Input Domain has separate clock and framing signals.
  - Each Pixel Clock Input Domain can support embedded (BT.656/1120 style in /24-bit, or BT.656 in 8-bit) or discrete (BT.601 style) sync.
  - Pixel Clock Input Domain Port B supports one 8-bit input data bus. Port A supports one 24-bit input data bus. At device level, the same device pads may be shared between Port A and Port B. For more information, see the multiplexing characteristics in device Data Manual.
- Embedded Sync data interface mode supports single or multiplexed sources;
- Discrete Sync data interface mode supports only single source input;
- The two Pixel Clock Input Domains can be individually configured in any combination of Embedded or Discrete Sync;
- Vertical Ancillary Data capture is supported for each input source;
- A maximum of 8 + 1 (8 normal line sources + 1 split-line source) multiplexed sources are supported for a single Pixel Clock Input Domain using TI Line Mux Mode;
- Multiplexed data can only appear in embedded sync mode;
- Where possible, blanking pixels that may contain embedded vertical ancillary data will be stored in a dedicated buffer per each video source;
- Optional selection of channel (Luma or Chroma, or both) from which Vertical Ancillary data is extracted for YUV422 source;
- For RGB source, Vertical Ancillary data can be found in one of the R, G, or B channels. The VIP_PARSER can select the channel from which Vertical Ancillary data is extracted;
- Ancillary Data can appear in the Horizontal Blanking as well as the Vertical Blanking. Typically, only Vertical Blanking Ancillary Data is captured. However, Horizontal Blanking Ancillary Data can be captured as well using HSYNC style discrete sync capture mode;
- Video up to WUXGA (1920 × 1200) can be supported using Port A in 16-bit or 24-bit mode.

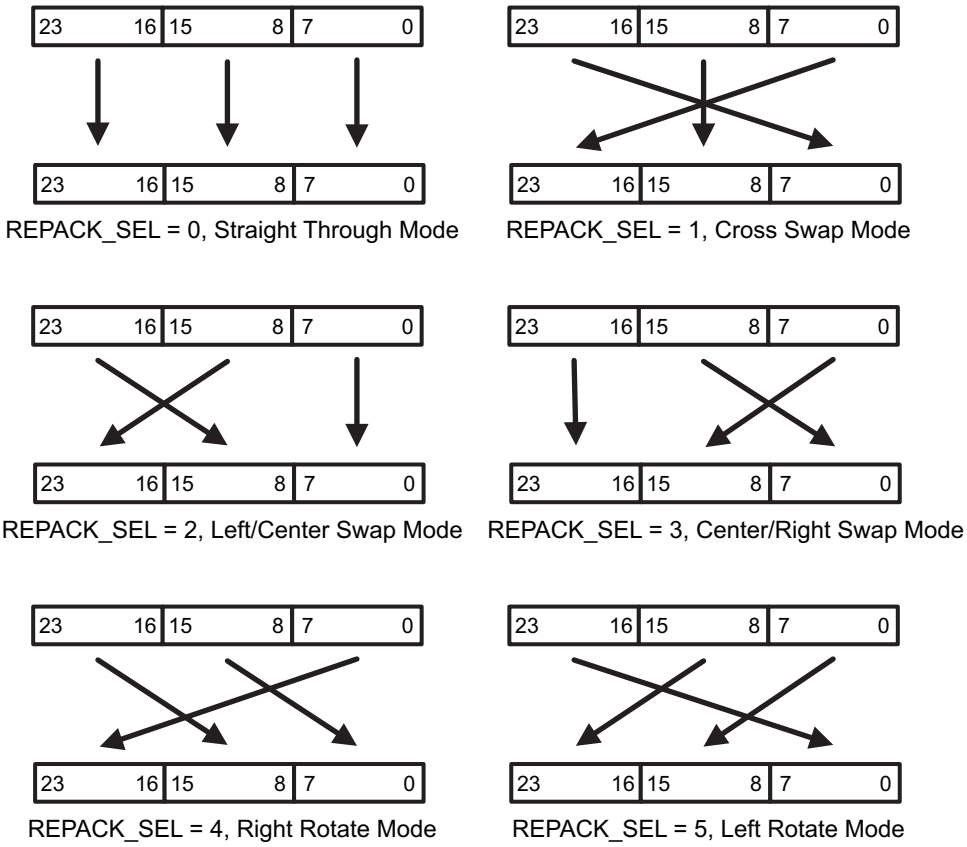
10.4.5.2 Repacker

The Repacker module rearranges the input bit ordering of the 24-bit data bus on Port A of each VIP slice. This module allows external input data to be presented to the datapath such that various data packing formats can be achieved in memory. As shown in Figure 10-15, a Repacker exists for each 24-bit input port.

The Repacker module is a simple multiplexer that serves to move input bits to different locations on the its output bus to VIP Parser. Figure 10-15 shows the supported bytelane swapping modes corresponding to different VIP_XTRA_PORT_A[30:28] REPACK_SEL settings.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-15. Bytelane Swapping Modes



16-bit RAW data entering the VIP subsystem is packed as a contiguous input bus from bits 15 to 0. This 16-bit RAW input must be remapped to the RGB565 format, so that it can be saved to DDR memory properly, because the VPDMA does not support the RAW16 input format natively. Instead, the RAW 16 format is first remapped as RGB565 data and then given to the VPDMA. Figure 10-16 describes the VIP_XTRA_PORT_A[30:28] REPACK_SEL = 6 option to remap a contiguous [15:0] RAW input data bus to a RGB565 compliant output bus. This RAW16 data will use RGB565 data types in the VPDMA Data Descriptors.

Figure 10-16. RAW16 to RGB565 Mapping

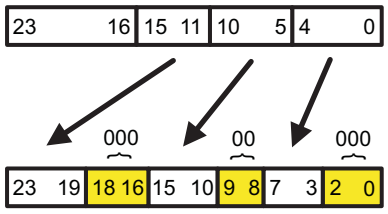


Figure 10-17 describes the mux configuration where 12 bit components are swapped. This mode may be useful when the input data is 12 bit per component YUV422 and is sent directly to memory.

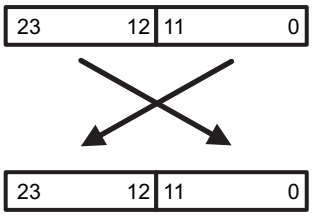
Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-17. RAW12 Swap



REPACK_SEL = 7, RAW12 Swapping Mode

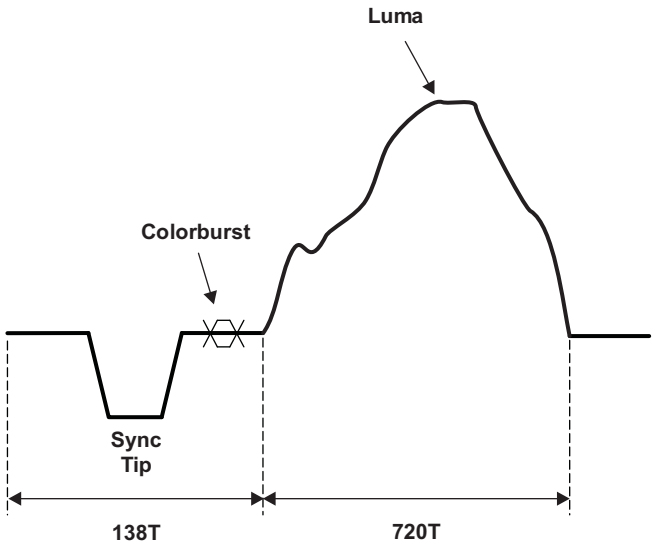
NOTE: There is no repacker for the 8-bit input port (Port B of each VIP slice).

The RAW16 and RAW12 mapping modes do not work for embedded sync streams.

10.4.5.3 Analog Video

A digital interface stream is based on analog video. The waveform for a line of NTSC analog video is shown in Figure 10-18.

Figure 10-18. NTSC Analog Video Waveform for One Horizontal Line



T is a time constant. For NTSC, T=1/13.5 MHz = 74ns.

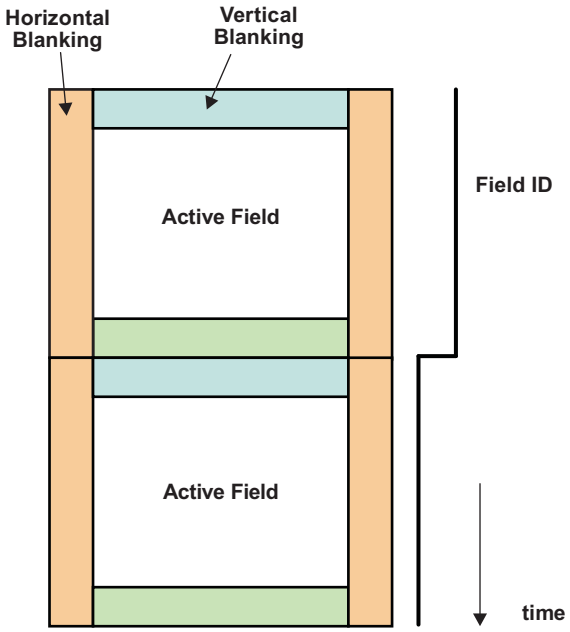
10.4.5.4 Digitized Video

Digitized video is based on scan lines in found in analog video. BT.601 uses various sync signals to specify when a new field and a new line starts. BT.656 and BT.1120 uses sync words embedded in the data stream to specify start of field and start of line.

An image can be digitized into regions shown in Figure 10-19.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-19. Digitized Video

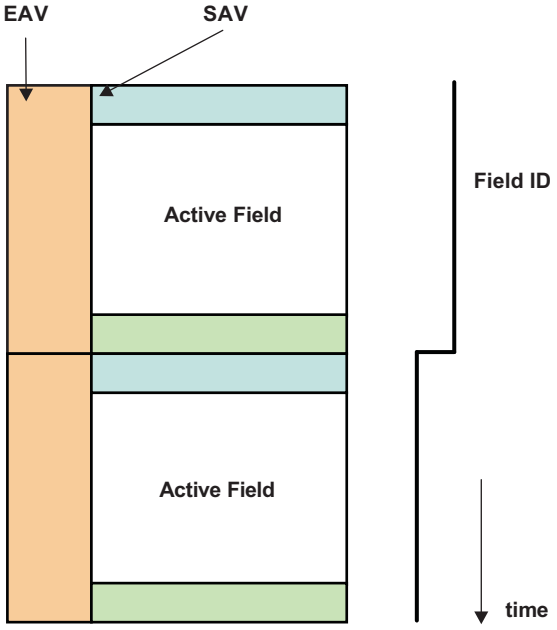


With the capability to encode sync words inside the data stream, there is more flexibility for adding non-video related data, called Ancillary Data. Also, code words embedded in the digital stream can be used as a type of identifier for multiplexing several sources of video into one data stream.

Figure 10-20 shows End-of-Active-Video (EAV) and Start-of-Active-Video (SAV) code words added to a video transmission. The period between the EAV and SAV is equivalent to Horizontal Blanking. The period between the SAV to the next EAV is active video or vertical blanking.

In the BT.656 or BT.1120 embedded code word scheme, three bits of the EAV/SAV code word are important: F (field), H (horizontal blanking), and V (vertical blanking).

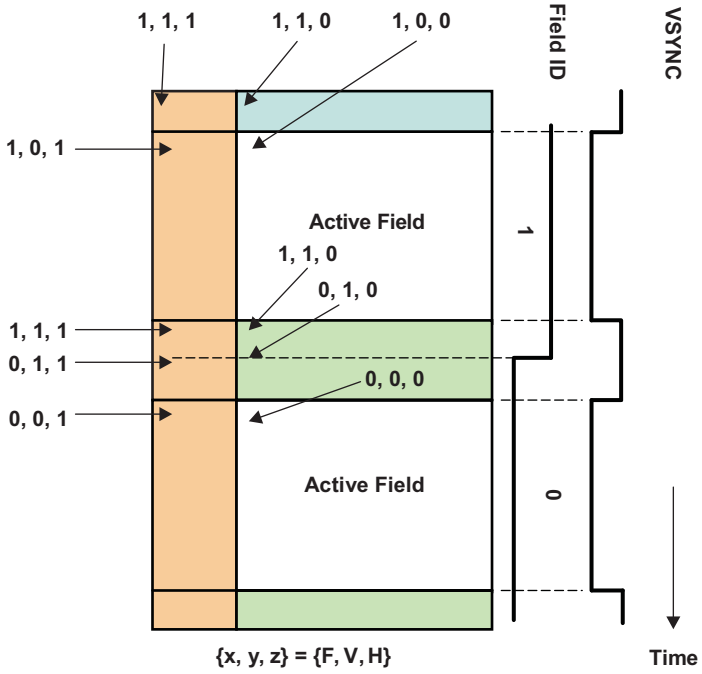
Figure 10-20. Code Word Embedded Video Format



Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-21 shows the values of F, V, and H flags at different locations in the picture. The Field flag represents the state of the Field ID for the picture. For progressive frames, F is always '0.' The V flag specifies vertical blanking areas. The H flag specifies horizontal blanking portions of the picture.

Figure 10-21. Digitized Video with F, V, and H Flags in EAV/SAV



10.4.5.5 Frame Buffers

The VIP/VPDMA support Frame Buffers in DDR memory for Active Video and Ancillary Data.

4:2:2 data is always saved in packed pixel buffers.

4:2:0 data is saved in Planar Luma buffers and Planar CbCr pair buffers.

A Luma Frame Buffer is a Planar storage area. Each line is the width in pixels (1Byte/pixel) of the output picture size format. The frame buffer contains the number of active video lines in the output picture size format.

A Chroma Pair Frame Buffer is Planar storage of CbCr pixel pairs, with each pixel being a byte. For 4:2:0 storage, N lines in the output picture active video results in N/2 lines of CbCr pairs being stored.

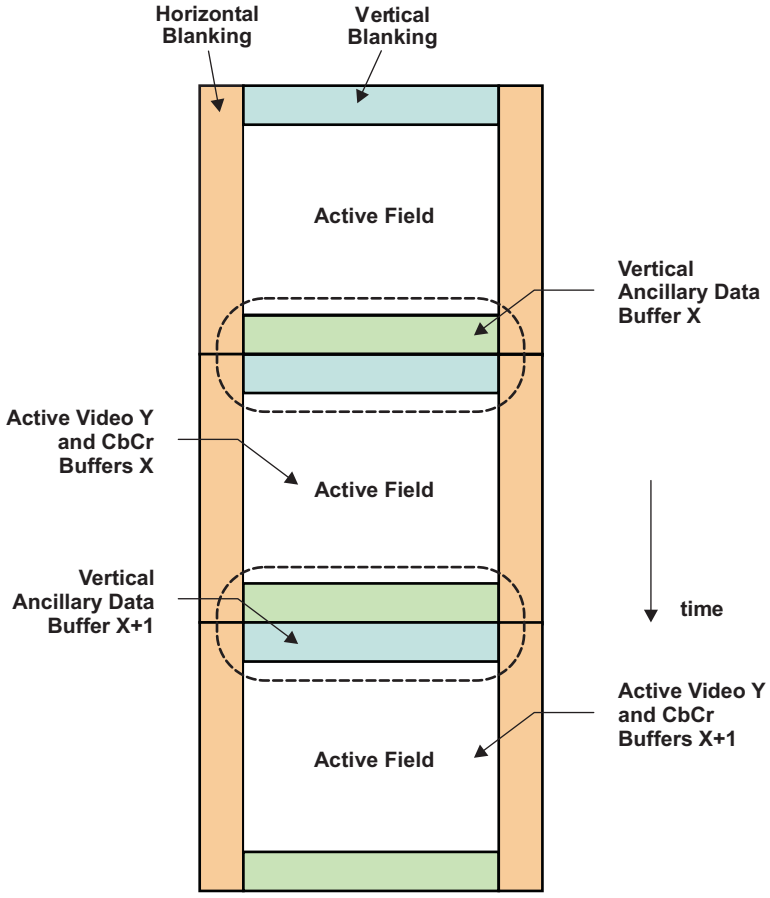
The Ancillary Data buffer is different than the Active Video Frame Buffers. The Ancillary Data buffer only stores Vertical Blanking Ancillary Data. The number of lines in the Ancillary Data buffer is the same as the number of Vertical Blanking lines. Typically, only one channel is extracted from the Vertical Blanking data, so the width of the Ancillary Data buffer is the same as the width of the Luma Buffer.

In 8-bit input mode, it is possible for both Luma and Chroma sites to be extracted for Vertical Ancillary data. Each color component is strobed on separate input clock cycles. In this case, the line width of the Ancillary data is twice the Luma line width of the picture. Both Luma and Chroma sites cannot be extracted for 16-bit input mode because both Luma and Chroma are sent on the same input clock cycle and the Ancillary port to the VPDMA VPI is only 8 bits wide.

Figure 10-22 shows how the planar data regions are stored in DDR memory. The vertical blanking data is stored in a set of Planar Buffers. Note that the bottom of the Vertical Ancillary Data from the previous field or frame is stored in the same buffer as the top of the Vertical Ancillary Data from the current field or frame.

Copyright © 2018–2019, Texas Instruments Incorporated

Figure 10-22. Planar Buffer Storage Description



The Luma representing Active Video is stored in a set of Planar Buffers. The CbCr Chroma Pairs are stored in a set of Planar Buffers.

10.4.5.6 Input Data Interface

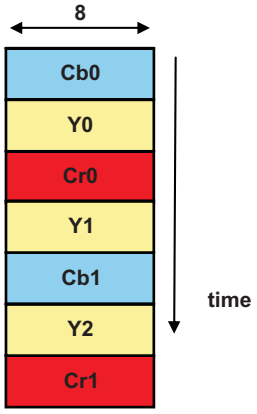
This section describes how the data (luma and chroma data for YUV422 format capture and R,G, and B data for RGB888 format capture) is muxed for the various interface modes.

10.4.5.6.1 8b Interface Mode

In 8-bit data interface mode, the input pixels are multiplexed according to Figure 10-23. The Chroma Format is 4:2:2. Sites with Cb/Cr pixels are known as Chroma sites. Those sites with Y pixels are known as Luma sites.

Copyright © 2018–2019, Texas Instruments Incorporated

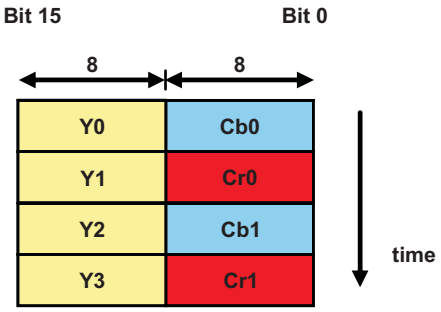
Figure 10-23. 8-bit Interface Discrete Sync Pixel Multiplexing



10.4.5.6.2 16b Interface Mode

In 16-bit interface mode, Luma is on 8 MSB bits of the data bus and Cb/Cr chroma pixels alternate on the other 8 bits of the data bus as shown in Figure 10-24.

Figure 10-24. 16-bit Interface Discrete Sync Pixel Multiplexing

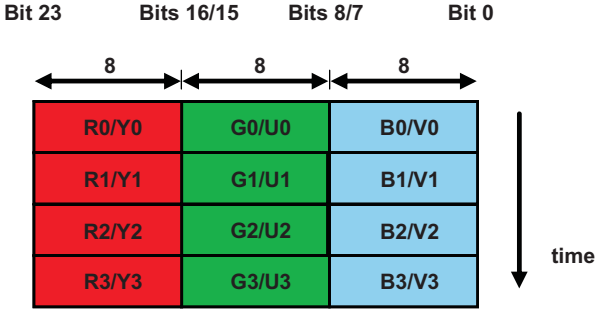


10.4.5.6.3 24b Interface Mode

RGB or YUV444 data is sent in 24b Interface Mode. The three components are packed into the data bus and sent to the VPDMA. The 24-bit Luma VPI client to the VPDMA carries all three components. This data is saved to the DDR in packed mode. That is, the three components are not separated by hardware. The 24-bit data bus is shown in Figure 10-25.

Ancillary data is saved in the Ancillary Data buffer. The VIP_PORT_A[5:4] CTRL_CHAN_SEL and VIP_PORT_B[5:4] CTRL_CHAN_SEL configuration register is used to select whether the ancillary data is from the R/Y, G/U, or B/V channels.

Figure 10-25. 24b Interface RGB Discrete Sync



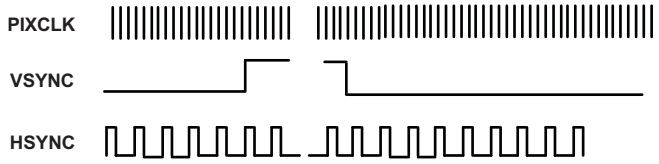
Copyright © 2018–2019, Texas Instruments Incorporated

In 24b interface mode YUV4:4:4 data is also supported. The flow for YUV4:4:4 data is the same as RGB data (Figure 10-25). Bits [23:16] of the input data bus are placed on bits [23:16] of the data bus going to VPDMA, bits [15:8] of the input bus are placed on bits [15:8] of the data bus going to VPDMA and finally bits [7:0] of the input data bus, are placed on bits [7:0] on the bus going to VPDMA.

10.4.5.6.4 Signal Relationships

A digital representation of video can be realized by using HSYNC and VSYNC signals to identify frame start and line start. Suppose HSYNC and VSYNC are active high, Figure 10-26 shows the general relationship of these signals.

Figure 10-26. Discrete Sync Signals



Every PIXCLK cycle carries either an active pixel or a blanking pixel. VSYNC pulses between two fields (or frames, in the case of progressive video). HSYNC pulses to signify the beginning of every line. An ACTVID signal can be used as a data valid to specify active video.

Discrete Sync cannot be used with any multi-camera multiplexed stream inputs. In the device, if Port A is configured for 24-bit discrete sync, then Port B must be disabled since there are no more data input pins left over for Port B.

If Port A is not 24 bits, then the 8-bit Port B can be configured and enabled for either discrete or embedded sync.

10.4.5.6.5 General 5 Pin Interfaces

Discrete Sync signal handling varies among different sending devices. The information that must be conveyed includes the pixel data value, field ID, horizontal blanking, and vertical blanking. Many devices can be configured to adjust the timing of the signals relative to each other.

In this section, DATA will be depicted as 8 bits. However, discrete sync does optionally support 16-bit and 24-bit data input. Type 1 is named after a generic five pin interface between the sending and receiving devices.

In Figure 10-27, P0 represents the first pixel in the horizontal blanking interval following the last vertical blanking line of the previous field or frame. HSYNC specifies the horizontal blanking region and VSYNC specifies that the P0 pixel is in the vertical sync area. HSYNC can be a strobe that is active one or more cycles and can deassert before the actual end of horizontal blanking or HSYNC may be active for the full duration of horizontal blanking.

Likewise, VSYNC can be a strobe that is active one or more cycles and can deassert before the actual end of vertical blanking or VSYNC may be active for the full duration of vertical blanking.

FID can change at this pixel or it may change later. For interlaced source, though, the FID will be inverted for this pixel at the same time point in the next field. So, it does not really matter when FID is captured. Many sending devices allow the location of FID changes to be programmable.

In this diagram and all others in this document, the active polarities of the interface signals can be either high or low. For the sake of uniformity in this document, all polarities are drawn active high. Also, different vendors have different datasheet names for the interface signals.

Figure 10-27. Type 1, First Horizontal Blanking Pixel

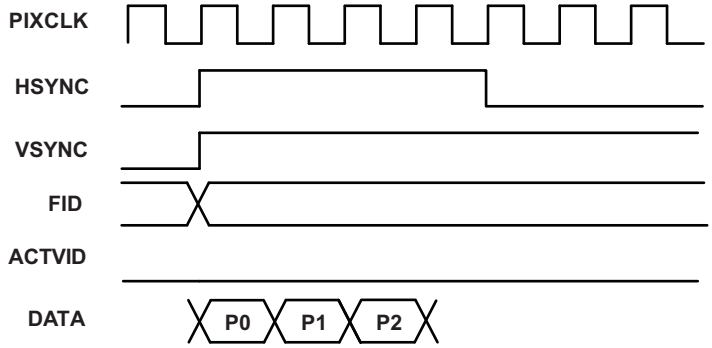

Figure 10-28 shows the P0 pixel being the first Chroma Channel data value in the Vertical Ancillary Data region. HSYNC is definitely de-asserted by now since P0 is no longer in horizontal blanking. ACTVID may or may not be active for Vertical Ancillary Data. Some devices consider these pixels to be Active (as in non-horizontal blanking). Other devices consider only video to be ACTIVE Video.

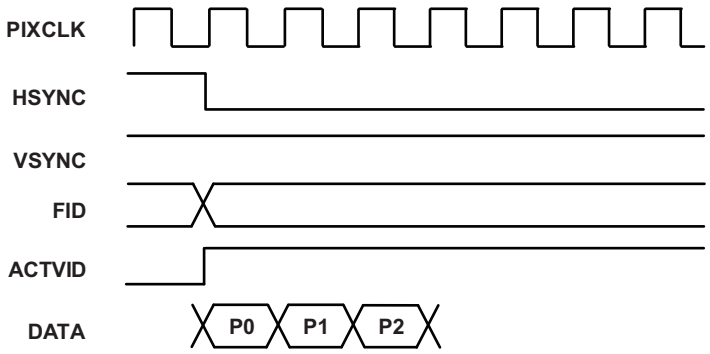
Figure 10-28. Type 1, First Vertical Ancillary Data Pixel



Following the vertical blanking region, the video portion of the field or frame starts. Figure 10-29 shows the horizontal blanking area in this video portion of the field or frame. P0 is the first pixel in the horizontal blanking. HSYNC is active for one or more pixel clocks. VSYNC is inactive in this video area. FID can change here. ACTVID is low since P0 is horizontal blanking.
