- **Device detection and parameters.** The ROM code first performs an initial wait for device auto initialization (with 250ms timeout) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100ms timeout). The ONFI Read ID (command 90h / address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent.
- If the parameters page does not have the ONFI signature, then the ONFI identification fails and the device falls back to using the look up table. If the parameter page contains the ONFI signature, the information shown in Table 4-13 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameters page stream are simply ignored.

**Table 4-13. ONFI Parameters Page Description**

| Offset | Description | Size (bytes) |
|---|---|---|
| 6 | Features supported | 2 |
| 80 | Number of data bytes per page | 4 |
| 84 | Number of spare bytes per page | 2 |
| 92 | Number of pages per block | 4 |
| 101 | Number of address cycles | 1 |

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 100ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM Code table. The list of supported devices is shown in Table 4-14.

**Table 4-14. Supported NAND Devices**

| Capacity | Device ID | Bus Width | Page size |
|---|---|---|---|
| 512 Mb | F0 | x8 | 2048 |
| 512 Mb | C0 | x16 | 2048 |

When the parameters are retrieved from the ROM table: page size and block size is updated based on 4th byte of NAND ID data. Due to inconsistency amongst different manufacturers, only devices which has been recognized to be at least 2Gb (included) have these parameters updated. Therefore, the ROM Code supports 4kB page devices but only if their size, according to the table, is at least 2Gb. Devices which are smaller than 2Gb have the block size parameter set to 128kB (when page size is 2KB). Table 4-15 shows the 4th ID Data byte encoding used in ROM Code.

- **Reading NAND geometry from I2C EEPROM.** ROM supports a special boot mode called NANDI2C to support NAND devices whose geometry cannot be detected by the ROM automatically using methods described in the previous section (Figure 4-12). If this boot mode is selected, the ROM code tries to read NAND geometry from an I2C EEPROM. If the read is successful, ROM code then proceeds to the next steps of NAND boot, beginning with reading bad blocks of information.

  The list of pins that are configured by the ROM in case of NANDI2C boot mode (this is in addition to the NAND boot pins) is described in Table 4-18).

**Table 4-16. Pins used for NANDI2C boot for I2C EEPROM access**

| Signal name | Pin used |
|---|---|
| I2C SCL | i2c0_scl |
| I2C SDA | i2c0_sda |

ROM accesses the I2C EEPROM at I2C slave address 50h and reads 7 bytes starting from address offset 80h. The format of this (NAND geometry information) is as follows:

**Table 4-17. NAND Geometry Information on I2C EEPROM**

| Byte address | Information | |
|---|---|---|
| | Upper nibble | Lower nibble |
| 80h | Magic Number – 10h | |
| 81h | Magic Number – B3h | |
| 82h | Magic Number – 57h | |
| 83h | Magic Number – A6h | |
| 84h | NAND column address (word/byte offset within a page) size in bytes, Example: 2 | NAND row address (page offset) size in bytes. Example: 3 |
| 85h | Page size (2N) exponent “N”. Example (for page size of 2048): 11 | Pages per block (2N) exponent “N” Example (for number of blocks 64): 6 |
| 86h | NAND bus width 0 → 8-bit, 1 → 16-bit | ECC Type 0→ No ECC, 1 → BCH8, 2 → BCH16 |

Copyright © 2011–2016, Texas Instruments Incorporated

- **ECC correction.** The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

  For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when manufacturer code (first ID byte) is 98h the cell type information is checked in the 4th byte of ID data. If it is equal to 10b then the ECC correction applied is BCH 16b/sector.

The detection procedure is described in Figure 4-12. Once the device has been successfully detected, the ROM code changes GPMC to 16-bit bus width if necessary.

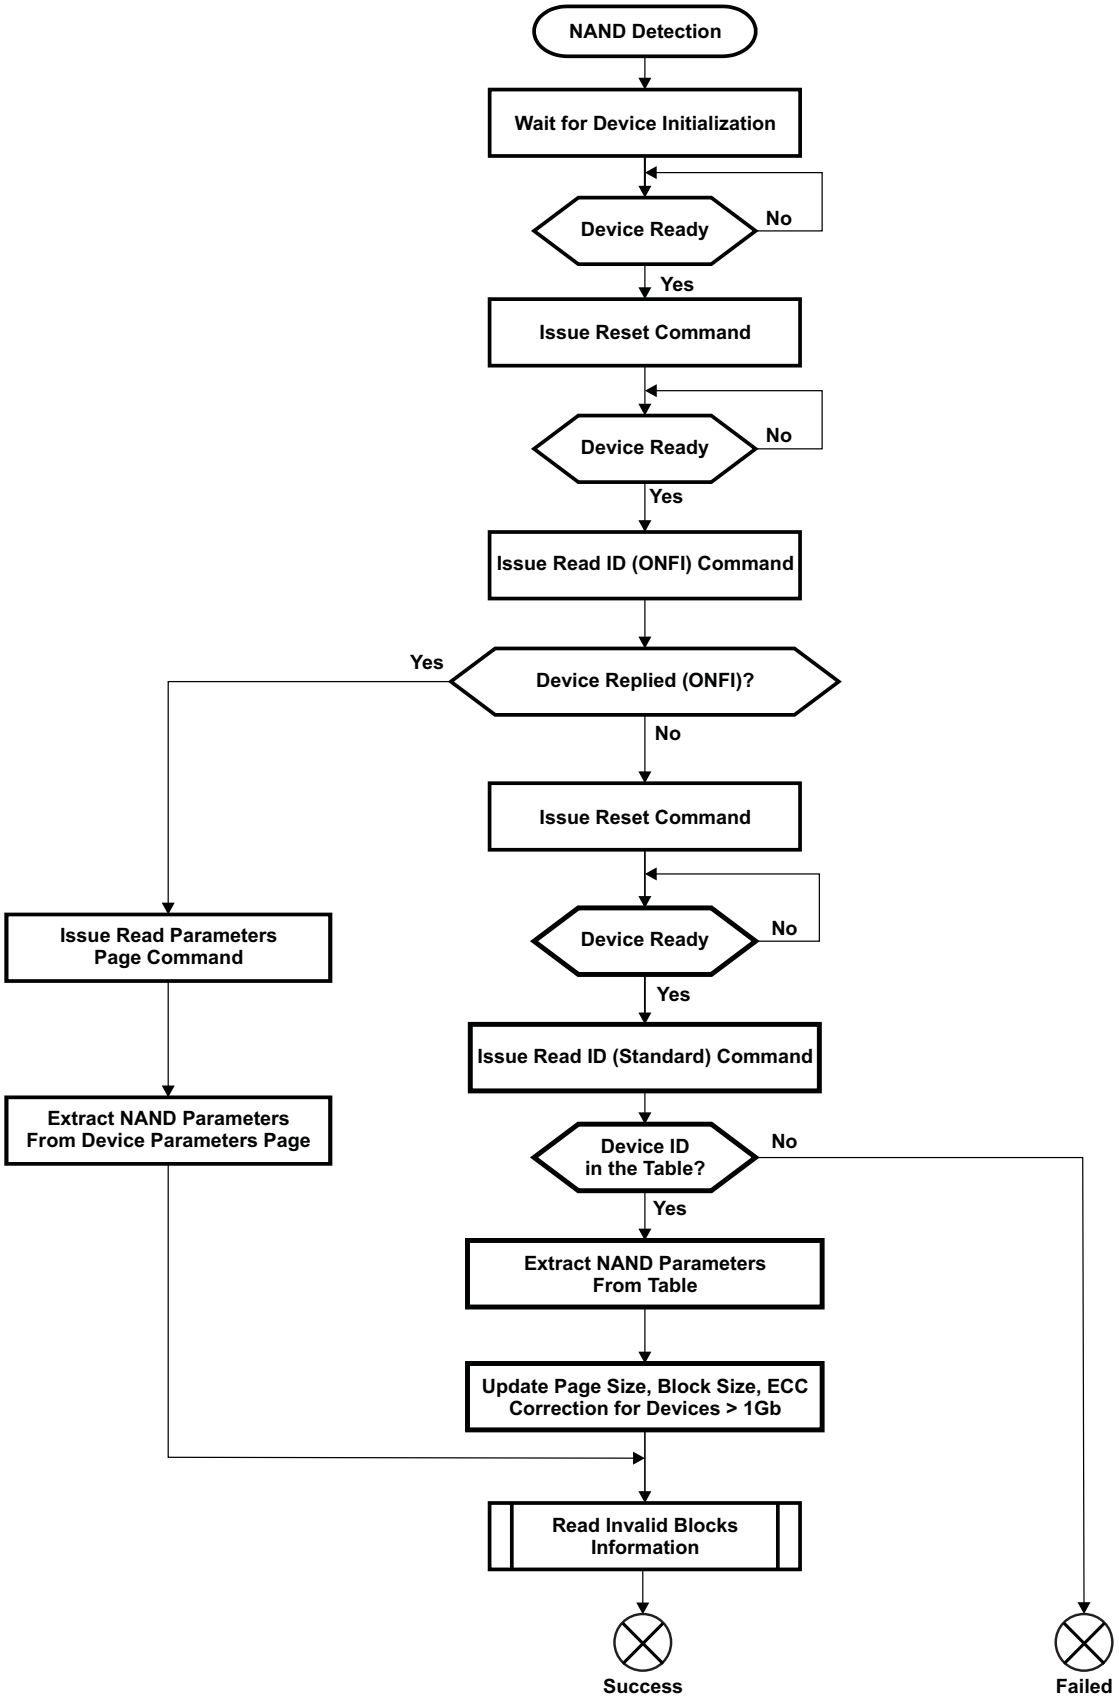
**Figure 4-12. NAND Device Detection**



Copyright © 2011–2016, Texas Instruments Incorporated

- **Bad block verification.** Invalid blocks are blocks which contain invalid bits whose reliability cannot be guaranteed by the manufacturer. Those bits are identified in the factory or during the programming and reported in the initial invalid block information located in the spare area on the 1st and 2nd page of each block. Since the ROM Code is looking for an image in the first four blocks, it must detect block validity status of these blocks. Blocks which are detected as invalid are not accessed later on. Blocks validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in 1st and 2nd pages for an 8 bits device / first word equal to FFFFh in 1st and 2nd page for a 16-bit device).

  Figure 4-13 depicts the invalid block detection routine. The routine consists in reading spare areas and checking validity data pattern.

**Figure 4-13. NAND Invalid Blocks Detection**

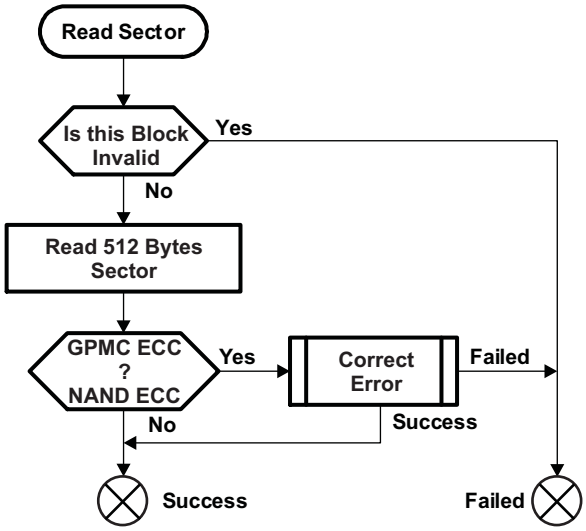
#### 4.7.3.3 NAND Read Sector Procedure

The ROM Code reads data from NAND devices in 512 bytes sectors. The read function fails in two cases:

- The accessed sector is within a block marked as invalid
- The accessed sector contains an error which cannot be corrected with ECC

Figure 4-14 shows the read sector routine for NAND devices. The ROM Code uses normal read (command 00h 30h) for reading NAND page data.

**Figure 4-14. NAND Read Sector Procedure**



Page data can contain errors due to memory alteration. The ROM Code uses an ECC correction algorithm to detect and possibly correct those errors. The ECC algorithm used is BCH with capability for correcting 8b or 16b errors per sector. The BCH data is automatically calculated by the GPMC on reading each 512 bytes sector. The computed ECC is compared against ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 4-15 and Figure 4-16 show the mapping of ECC data inside the spare area for respectively 2KB-page and 4KB- page devices. If both ECC data are equal then the Read Sector function returns the read 512 bytes sector without error. Otherwise, the ROM Code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

### 4.7.3.4 Pins Used for NAND Boot

The list of pins that are configured by the ROM in case of NAND boot mode are in Table 4-18. Note that all the pins might not be driven at boot time.

**Table 4-18. Pins Used for NAND Boot**

| Signal name | Pin used |
|---|---|
| cs0 | gpmc_cs0 |
| advn_ale | gpmc_advn_ale |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-18. Pins Used for NAND Boot (continued)**

| Signal name | Pin used |
|---|---|
| oen_ren | gpmc_oen_ren |
| be0n_cle | gpmc_be0n_cle |
| wen | gpmc_wen |
| wait | gpmc_wait |
| clk | gpmc_clk(1) |
| ad0 - ad15 | gpmc_ad0 - gpmc_ad15 |

(1) gpmc_clk is not configured in MBOOT[10] = 1b

#### 4.7.3.5 Sysboot Pins for NAND Boot

Some of the SYSBOOT pins have special meanings when NAND boot is selected.

**Table 4-19. Special SYSBOOT pins for NAND boot**

| SYSBOOT[n] | Description |
|---|---|
| [12] (CS0BW) | Must be 0 if 8-bit NAND is used |
| | Must be 1 if 16-bit NAND is used |
| [15] (CS0WAIT) | Must be 0 |
| [14:13] (CS0MUX[1:0]) | Must be 0 |

### *4.7.4 MMC/SD Cards*

#### 4.7.4.1 Overview

The ROM code supports booting from MMC/SD cards in the following conditions:

- MMC/SD Cards compliant to low and high capacities
- MMC/SD cards connected to MMC interface #1
- 3V VCC power supply, support for 3V or 1.8V I/O voltages
- Initial 1-bit MMC Mode, optional 4-bits or 8-bits mode
- Clock Frequency: identification mode: 400 KHz; data transfer mode up to 10 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from sectors in the user area
- File system mode (FAT12/16/32 supported with or without Master Boot Record), image data is read from a booting file

#### 4.7.4.2 System Interconnection

An MMC/SD card can be connected to the MMC1 interface typically through a card cage.

Notes:

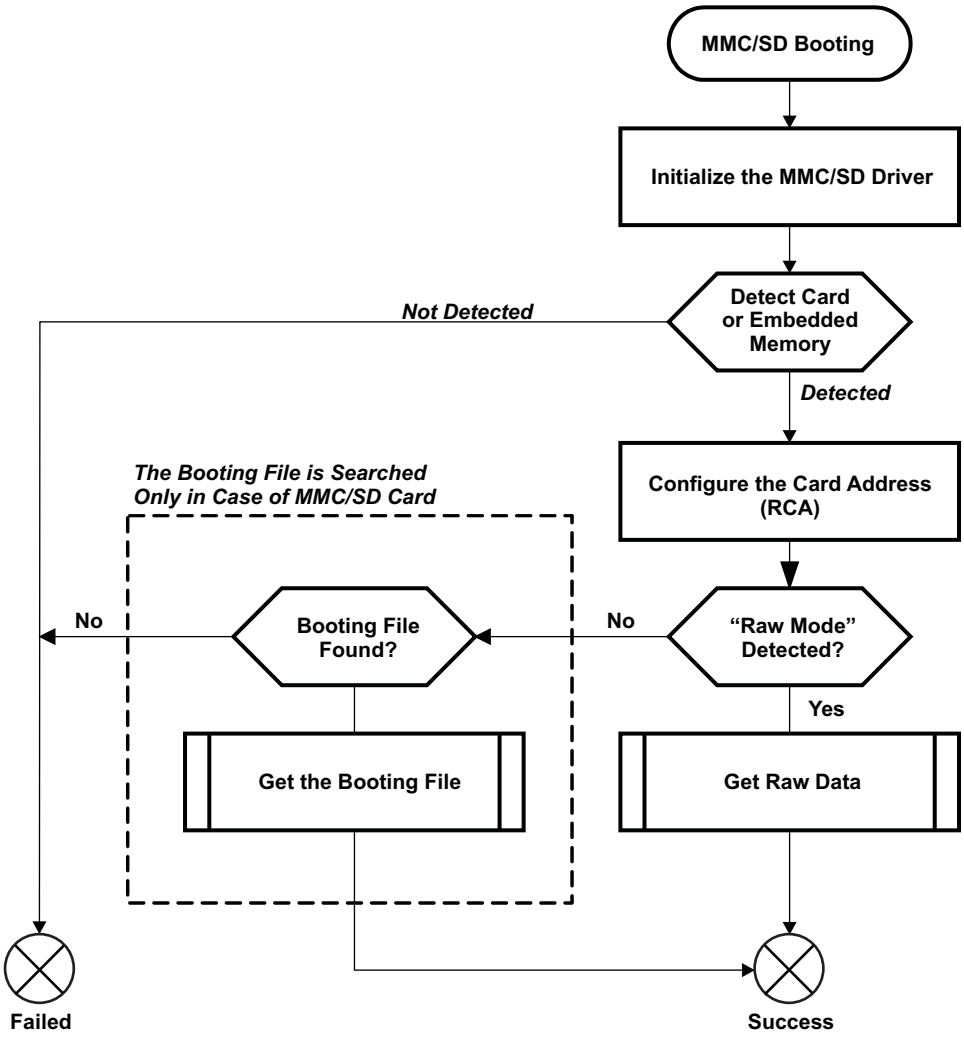
- It may be possible to design the system so that an eMMC/eSD memory type is connected to the MMC1 interface. However, the dual voltage IOs feature of MMC1 dedicates it preferably to cards.
- The ROM Code does not handle the card detection feature on card cage.

#### 4.7.4.3 Booting Procedure

The high level flowchart of the eMMC/eSD and MMC/SD booting procedure is depicted in Figure 4-17. The booting file is searched only in case of booting from a card. eMMC/eSD embedded memories only support raw mode.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-17. MMC/SD Booting**



### 4.7.4.4 Initialization and Detection

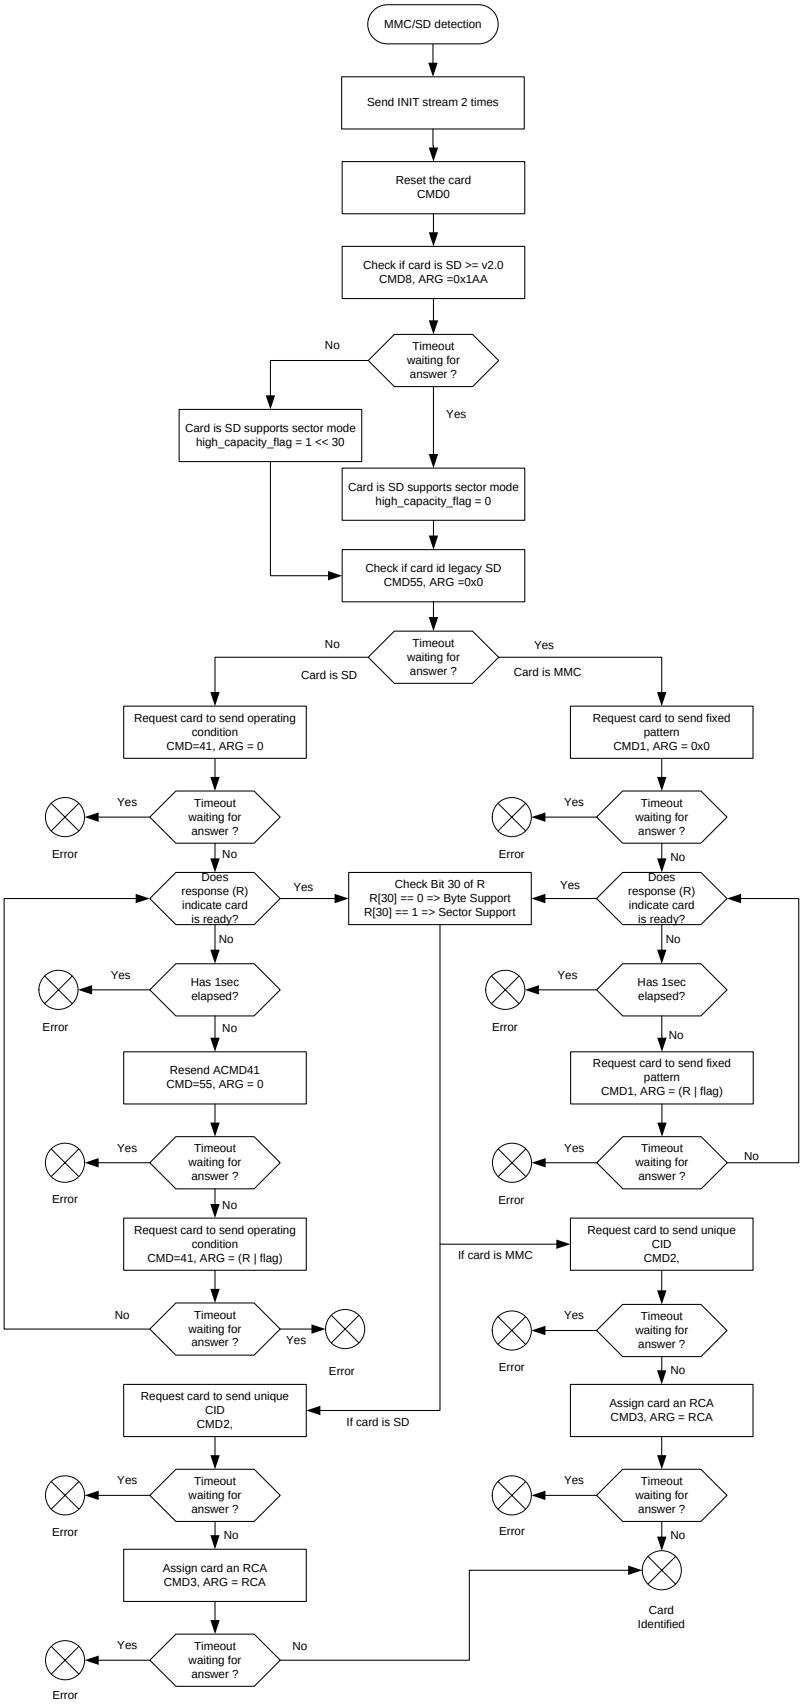
The ROM Code initializes the memory device or card connected on MMC interface using the standard High-Voltage range (3.0V). If neither memory device nor card is detected then the ROM code carries on to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM Code assumes that only one memory or card is present on the bus. This first sequence is done using the CMD signal that is common to SD and MMC devices.

MMC and SD standards detail this phase as initialization phase. Both standards differ in the first commands involved: CMD1 and ACMD41. The ROM code uses this difference in command set to discriminate between MMC and SD devices: CMD1 is supported only by the MMC standard whereas ACMD41 is only supported by SD standard. The ROM code first sends a CMD1 to the device and gets a response only if an MMC device is connected. If no response is received then ACMD41 (ACMD41 is made out of CMD55 and ACMD41) is sent and a response is expected from an SD device. If no response is received then it is assumed that no device is connected and the ROM Code exits the MMC/SD Booting procedure with FAIL. This is detection procedure is shown in Figure 4-18.

As previously mentioned, the contents of an MMC/D card may be formatted as raw binary or within a FAT filesystem. eMMC/SD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-18. MMC/SD Detection Procedure**



Copyright © 2011–2016, Texas Instruments Incorporated

As previously mentioned, the contents of an MMC/D card may be formatted as raw binary or within a FAT filesystem. eMMC/SD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

#### 4.7.4.5 MMC/SD Read Sector Procedure in Raw Mode

In raw mode the booting image can be located at one of the four consecutive locations in the main area: offset 0/20000h (128KB)/40000h (256KB)/60000h (384KB). For this reason a booting image shall not exceed 128KB in size. However it is possible to flash a device with an image greater than 128KB starting at one of the aforementioned locations. Therefore the ROM code does not check the image size. The only drawback is that the image will cross the subsequent image boundary.

The raw mode is detected by reading sectors #0, #256, #512, #768. The content of these sectors is then verified for presence of a TOC structure as described in Figure 4-26. A configuration header (CH) must be located in the first sector followed by a header. The CH might be void (only containing a CHSETTINGS item for which the Valid field is zero).

#### 4.7.4.6 MMC/SD Read Sector Procedure in FAT Mode

MMC/SD cards may hold a FAT file system which ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named “MLO.” This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any master boot record (MBR) holding a partition table
- When acting as hard-drive-like, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary and active.

The card should always hold an MBR except for MMC cards using floppy-like file system (refer to the CSD internal Register fields FILE_FORMAT_GRP and FILE_FORMAT). However, depending on the operating system, the MMC/SD card will be formatted either with partition(s) (using an MBR) or without. The ROM code supports both types; this is described in the following section.

The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512 byte sector within the booting file without involving ROM code FAT module.

The sector read procedure utilizes standard MMC/SD raw data read function. The sector address is generated based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

#### 4.7.4.7 FAT File System

This paragraph describes functionalities which are used by the ROM Code. It is not intended to fully describe the Master Boot Record and the FAT file system, but does include:

- How to recognize if a sector is the 1st sector of an MBR
- How to recognize if a sector is the 1st sector of a FAT12/16/32
- How to find the 1st cluster of the booting file
- How to buffer the booting file FAT entries

Some memory devices which support file systems can be formatted with or without MBR, therefore the first task of the ROM Code is to detect whether or not the device is holding an MBR in the first sector. If this is the case, an active FAT12/16/32 partition is searched in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no useable partition is found then the ROM Code returns to the Booting procedure with FAIL. The Extended partitions are not checked, the booting file must reside in a primary partition.

Copyright © 2011–2016, Texas Instruments Incorporated

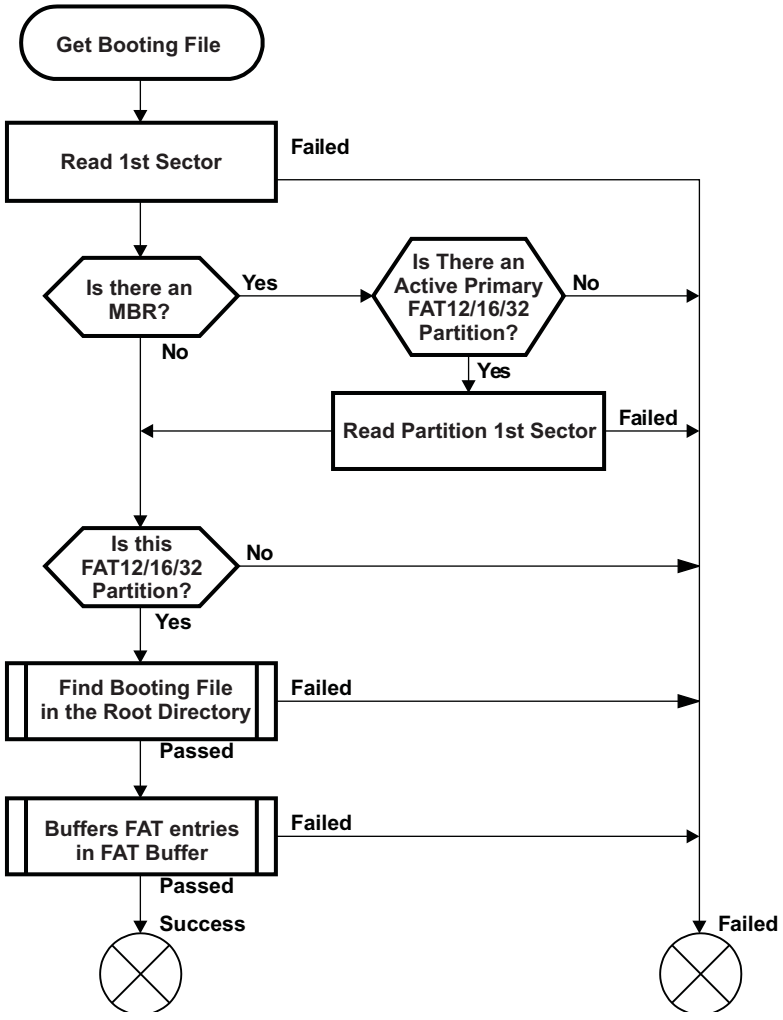
If a partition is found then its first sector is read and used further on. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used further on. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, in case another partition type is used (i.e., Linux FS or any other) or if the partition is not valid, the ROM Code returns with FAIL.

Otherwise, the Root Directory entries are searched for a file named depending on the booting device. The Long File Names (LFN) format is not used and only File Names in 8.3 Format are searched for. If no valid file is found, the ROM Code returns with FAIL.

Once the file has been found, the ROM Code reads the File Allocation Table (FAT) and buffers the singly-linked chain of clusters in a FAT Buffer which will be used by the Booting Procedure to access the file directly sector by sector. For FAT12/16 and for FAT32 (valid if a specific flag has been set in the FAT32 Boot Sector), there exist multiples copies of the FAT (ROM Code supports only two copies). When buffering FAT entries, the two FATs are compared. If they are not the same, only entries from the last FAT are used. The FAT Buffer holds sector numbers and not cluster numbers. The ROM Code converts each cluster entry to one or several sector entries if applicable.

The whole process is described in Figure 4-19. Every part related to MBR or FAT12/16/32 is described in the next paragraph.

**Figure 4-19. MMC/SD Booting, Get Booting File**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 4.7.4.7.1 Master Boot Record: MBR

The Master boot record is the 1st sector of a memory device. It is made out of some executable code and four partition entries. The aim of such a structure is to be able to divide the hard disk in partitions mostly used to boot different systems (Microsoft Windows™, Linux, …). Its structure is described in Table 4-20 and Table 4-21. The valid partition types searched by the ROM Code are described in Table 4-22.

**Table 4-20. Master Boot Record Structure**

| Offset | Length [bytes] | Entry Description | Value |
|---|---|---|---|
| 0000h | 446 | Optional Code | |
| 01BEh | 16 | Partition Table Entry | (see ) |
| 01CEh | 16 | Partition Table Entry | (see ) |
| 01DEh | 16 | Partition Table Entry | (see ) |
| 01EEh | 16 | Partition Table Entry | (see ) |
| 01FEh | 2 | Signature | AA55h |

**Table 4-21. Partition Entry**

| Offset | Length [bytes] | Entry Description | Value |
|---|---|---|---|
| 0000h | 1 | Partition State | 00h: Inactive<br>80h: Active |
| 0001h | 1 | Partition Start Head | $H_s$ |
| 0002h | 2 | Partition Start Cylinder and Sector | $C_s$[7:0]-$C_s$[9:8]-$S_s$[5:0] |
| 0004h | 1 | Partition Type | Refer to for partial partition types |
| 0005h | 16 | Partition End Head | $H_e$ |
| 0006h | 2 | Partition End Cylinder and Sector | $C_e$[7:0] - $C_e$[9:8] - $S_e$[5:0] |
| 0008h | 4 | First sector position relative to the beginning of media | $LBA_s = C_s.H.S + H_s.S + S_s - 1$ |
| 000Ch | 4 | Number of sectors in partition | $LBA_e = C_e.H.S + H_e.S + S_e - 1$<br>$Nb_s = LBA_e - LBA_s + 1$ |

**Table 4-22. Partition Types**

| Partition Type | Description |
|---|---|
| 01h | FAT12 |
| 04h, 06h, 0Eh | FAT16 |
| 0Bh, 0Ch, 0Fh | FAT32 |

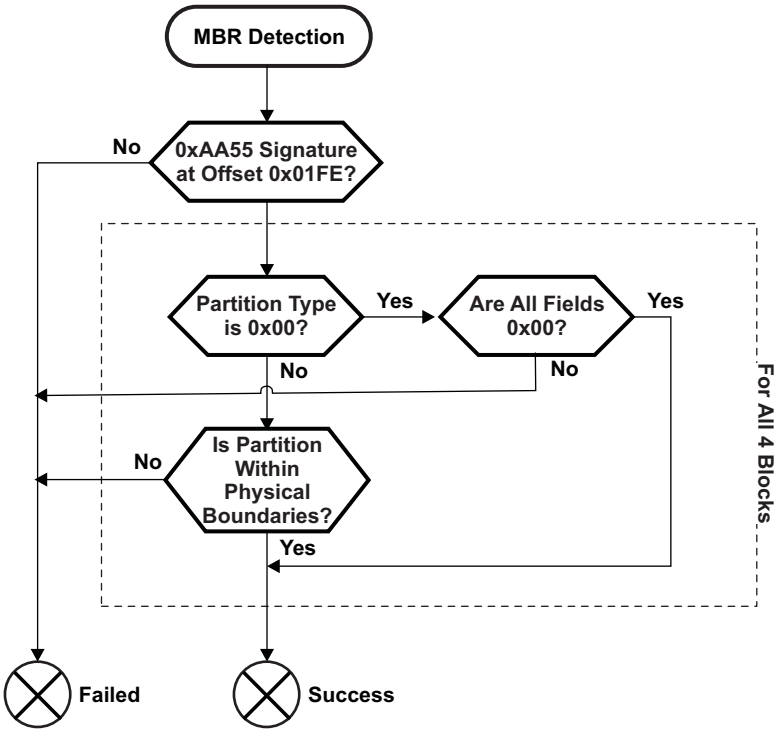
Copyright © 2011–2016, Texas Instruments Incorporated

The way the ROM Code detects whether a sector is the 1st sector of an MBR or not is described in Figure 4-20.

The ROM Code first checks if the signature is present. Each partition entry is checked:

- If its type is set to 00h then all fields in the entry must be 00h
- The partition is checked to be within physical boundaries, i.e. the partition is located inside and its size fits the total physical sectors.

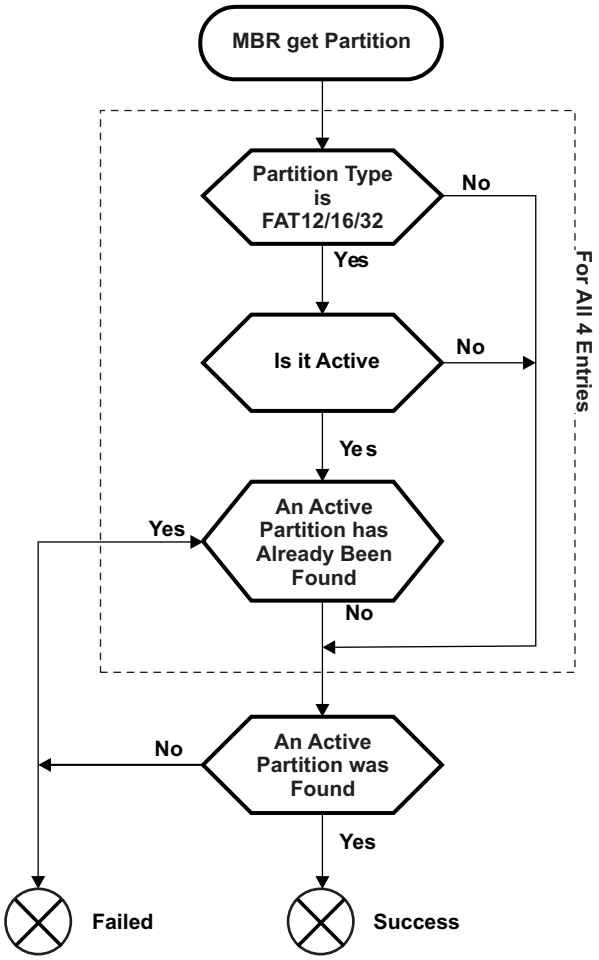
**Figure 4-20. MBR Detection Procedure**



Copyright © 2011–2016, Texas Instruments Incorporated

Once identified, the ROM Code gets the partition using the procedure described in Figure 4-21. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h or 80h (if there is more than one active partition the test fails). The ROM Code returns with FAIL if no active primary FAT12/16/32 could be found.

**Figure 4-21. MBR, Get Partition**



#### 4.7.4.7.2 FAT12/16/32 Boot Sector

The FAT file system is made out of several parts:

- Boot Sector which holds the BIOS Parameter Block (BPB)
- File Allocation Table (FAT) which describes the use of each cluster of the partition
- Data Area which holds the Files, Directories and Root Directory (for FAT12/16, the Root Directory has a specific fixed location)

The boot sector is described in Table 4-23. In the following description, all the fields whose names start with BPB_ are part of the BPB. All the fields whose names start with BS_ are part of the Boot Sector and not really part of the BPB (not mandatory); they are not used at all by the ROM Code.

**Table 4-23. FAT Boot Sector**

| | Offset | Length [bytes] | Name | Description |
|---|---|---|---|---|
| | 0000h | 3 | BS_jmpBoot | Jump Instruction to Boot Code (not used) |
| | 0003h | 8 | BS_OEMName | Name of the System which created the partition |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-23. FAT Boot Sector (continued)**

| | Offset | Length [bytes] | Name | Description |
|---|---|---|---|---|
| | 000Bh | 2 | BPB_BytsPerSec | Counts of Bytes per sector (usually 512) |
| | 000Dh | 1 | BPB_SecPerClus | Number of sectors per allocation unit |
| | 000Eh | 2 | BPB_RsvdSecCnt | Number of reserved sectors for the Boot Sector<br>For FAT12/16 is 1, for FAT32, usually 32 |
| | 0010h | 1 | BPB_NumFATs | Number of copies of FAT, usually 2 |
| | 0011h | 2 | BPB_RootEntCnt | For FAT12/16, number of 32 bytes entries in the Root Directory (multiple of BPB_BytsPerSec/32)<br>For FAT32 this value is 0 |
| | 0013h | 2 | BPB_TotSec16 | Total Count of sectors on the volume. If the size is bigger than 10000h or for FAT32, this field is 0 and BPB_TotSec32 holds the value |
| | 0015h | 1 | BPB_Media | Media Type, usually F8h: fixed, non-removable |
| | 0016h | 2 | BPB_FATSz16 | For FAT12/16, size in sectors of one FAT<br>For FAT32, holds 0 |
| | 0018h | 2 | BPB_SecPerTrk | Number of sectors per track, 63 for MMC/SD |
| | 001Ah | 2 | BPB_NumHeads | Number of heads, 255 for MMC/SD |
| | 001Ch | 4 | BPB_HiddSec | Number of sectors preceding the partition |
| | 0020h | 4 | BPB_TotSec32 | Total Count of sectors on the volume. If the size is smaller than 10000h (for FAT12/16), this field is 0 and BPB_TotSec16 is valid |
| **FAT12/16** | 0024h | 1 | BS_DrvNum | Drive Number |
| | 0025h | 1 | BS_Reserved1 | 00h |
| | 0026h | 1 | BS_BootSig | Extended Boot Signature 29h. Indicates that the following 3 fields are present |
| | 0027h | 4 | BS_VolID | Volume Serial Number |
| | 002Bh | 11 | BS_VolLab | Volume Label |
| | 0036h | 8 | BS_FilSysType | File system Type: “FAT12”, “FAT16”, “FAT32”.<br>Note: This field is not mandatory (i.e., BS_) therefore it cannot be used to indentify the partition type. |
| **FAT32** | 0024h | 4 | BPB_FATSz32 | Size in sectors of one FAT. Field BPB_FATSz16 must be 0 |
| | 0028h | 2 | BPB_ExtFlags | FAT Flags:<br>[7]: 0 = FAT is mirrored; 1 = Only one FAT is used<br>[3:0]: Number of used FAT if no mirroring used |
| | 002Ah | 2 | BPB_FSVer | File system Version Number |
| | 002Ch | 4 | BPB_RootClus | First Cluster number of the Root Directory |
| | 0030h | 2 | BPB_FSInfo | Sector number of FSINFO Structure in the reserved-area, usually 1 |
| | 0032h | 2 | BPB_BkBootSec | If non-zero, indicates the sector number in the reserved-area of a copy of the Boot Sector |

| | 01FEh | 2 | BPB_Signature | AA55h |

Copyright © 2011–2016, Texas Instruments Incorporated

To check whether or not a sector holds a valid FAT12/16/32 partition, only fields starting with BPB can be checked as they are mandatory. The fields starting from offset 0024h to 01FDh cannot be used for the check as they will differ if using FAT12/16 or FAT32. The procedure is described in Figure 22. First the ROM Code checks if the BPB_Signature is equal to AA55h. Then it checks some fields which must have some specific values (BPB_BytsPerSec, BPB_SecPerClus, BPB_RsvdSecCnt, BPB_NumFATs, BPB_RootEntCnt). If the geometry of the device is known then it is compared against BPB_SecPerTrk and BPB_NumHeads fields. If an MBR was found before, the partition size is also checked.

$$BPB_TotSec16 = MBR_Partition_Size$$

*or*

$$BPB_TotSec32 = MBR_Partition_Size$$

The field BPB_ToSec16 is used if the total number of sectors is below 65518 (in this case BPB_TotSec32=0), otherwise, BPB_TotSec32 is used (BPB_TotSec16=0). The partition sector offset is also checked: BPB_HiddSec = MBR_Partition_Offset (if this value is not 0 as some operating systems do not update this field correctly). The last step is to decide which type of FAT file system it is. The ROM Code computes the number of clusters in the Data Area part of the partition:

$$Nb_{clusters} < 4085 \Rightarrow \text{FAT12}$$

$$4085 \le Nb_{clusters} < 65525 \Rightarrow \text{FAT16}$$

$$65525 \le Nb_{clusters} \Rightarrow \text{FAT32}$$

Where Nbclusters is given by the size of the Data Area:

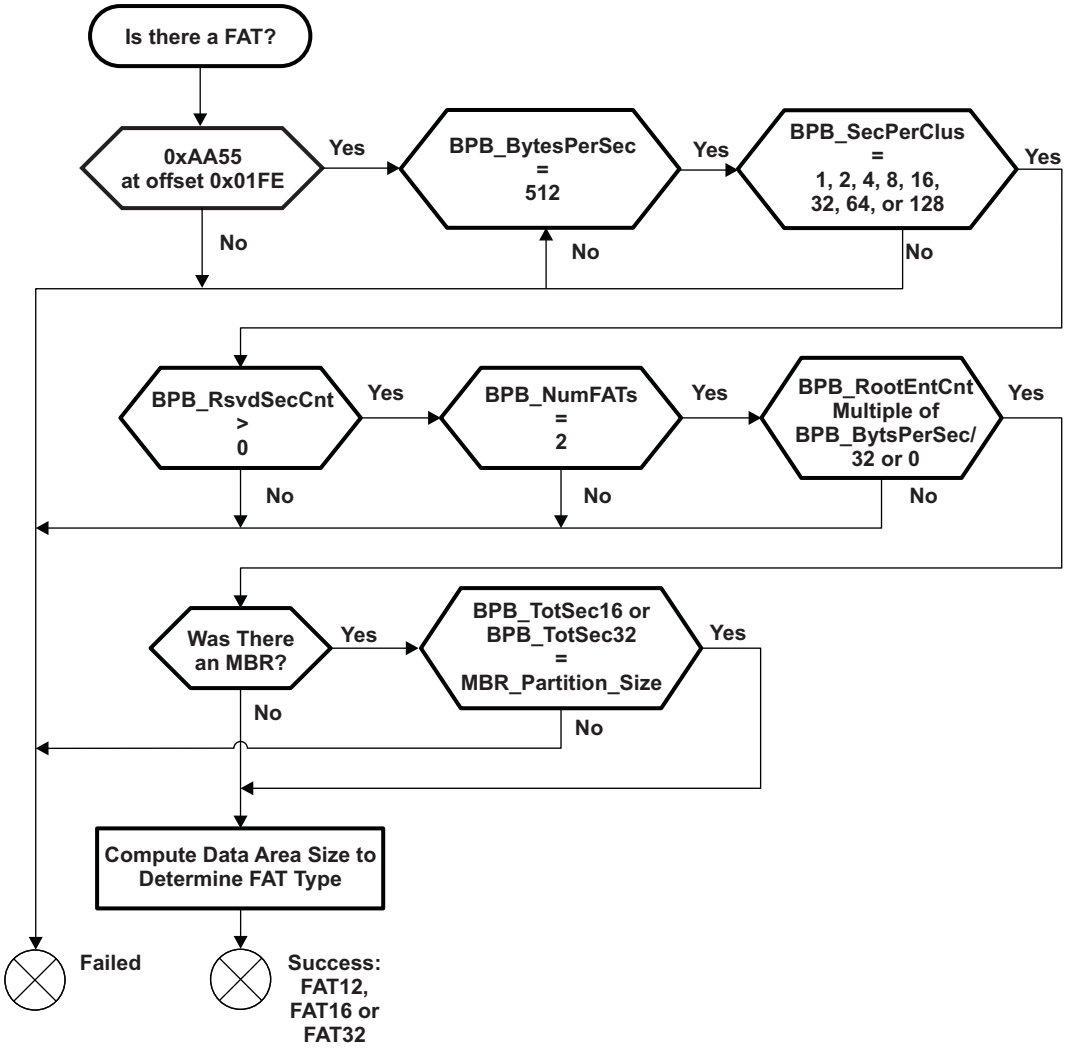
$$RootDirSectors = \frac{BPB_RootEntCnt * 32}{BPB_BytesPerSec}$$

$$DataSec = BPB_TotSec - (BPB_\text{Re}svdSecCnt + (BPB_NumFATs.BPB_FATSz) + RootDirSectors)$$

$$Nb_{clusters} = \frac{DataSec}{BPB_SecPerClus}$$

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-22. FAT Detection Procedure**



### 4.7.4.8 FAT12/16/32 Root Directory

The next task for the ROM Code is to find the booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The general formulae to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerClus$$

Note: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

Note: The BPB_HiddSec field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used.

Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e., filename, date of creation, rights, cluster location etc. This is described in Table 4-24.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-24. FAT Directory Entry**

| Offset | Length | Name | Description | |
|---|---|---|---|---|
| | [bytes] | | | |
| 0000h | 11 | DIR_Name | Short Name (8+3) | |
| 000Bh | 1 | DIR_Attr | File Attributes: | |
| | | | ATTR_READ_ONLY | 01h |
| | | | ATTR_HIDDEN | 02h |
| | | | ATTR_SYSTEM | 04h |
| | | | ATTR_VOLUME_ID | 08h |
| | | | ATTR_DIRECTORY | 10h |
| | | | ATTR_ARCHIVE | 20h |
| | | | ATTR_LONG_NAME | ATTR_READ_ONLY \| ATTR_HIDDEN \| ATTR_SYSTEM \| ATTR_VOLUME_ID |
| 000Ch | 1 | DIR_NTRes | Reserved, set to 00h | |
| 000Dh | 1 | DIR_CrtTimeTenth | Millisecond stamp at file creation | |
| 000Eh | 2 | DIR_CrtTime | Time file was created | |
| 0010h | 2 | DIR_CrtDate | Date file was created | |
| 0012h | 2 | DIR_LstAccDate | Last Access date | |
| 0014h | 2 | DIR_FstClusHi | High word of this entry's first cluster number | |
| 0016h | 2 | DIR_WrtTime | Time of last write | |
| 0018h | 2 | DIR_WrtDate | Date of last write | |
| 001Ah | 2 | DIR_FstClusLo | Low word of this entry's first cluster number | |
| 001Ch | 4 | DIR_FileSize | File size in bytes | |

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the next paragraph.

#### 4.7.4.9 FAT12/16/32 File Allocation Table

The ROM Code needs to read the FAT in order to retrieve sectors either for the booting file or for the Root Directory (in case the file system is FAT32).

There can be multiple copies of the FAT inside the file system (ROM Code supports only 2) located after the Boot Sector:

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_FatSz \cdot n$$

Its size is given by BPB_FATSz16 or BPB_FATSz32. The ROM Code checks each copy of the FAT if identical. In case the values are different, the ROM Code uses the value from the last FAT copy. With FAT32 file system, the copy system can be disabled according to a flag located in BPB_ExtFlags[7]. If this flag is set then FAT BPB_ExtFlags[3:0] is used. In this case no verification is made by the ROM Code with other copies of FAT.

Copyright © 2011–2016, Texas Instruments Incorporated

The FAT is a simple array of values each refering to a cluster located in the Data Area. One entry of the array is 12, 16 or 32 bits depending on the file system in use. The value inside an entry defines whether the cluster is being used or not and if another cluster has to be taken into account. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in Table 4-25.

Note: : For compatibility reasons, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); FFFFFF8h and FFFFFFFh (for FAT32).

**Table 4-25. FAT Entry Description**

| FAT12 | FAT16 | FAT32 | Description |
|---|---|---|---|
| 000h | 0000h | ?0000000h | Free Cluster |
| 001h | 0001h | ?0000001h | Reserved Cluster |
| 002h-FEFh | 0002h-FFEFh | 00000002h-?FFFFFEFh | Used Cluster; value points to next cluster |
| FF0h-FF6h | FFF0h-FFF6h | ?FFFFFF0h-?FFFFFF6h | Reserved values |
| FF7h | FFF7h | ?FFFFFF7h | Bad Cluster |
| FF8h-FFFh | FFF8h-FFFFh | ?FFFFFF8h-?FFFFFFFh | Last Cluster in File |

Note: FAT32 uses only bits [27:0], the upper 4 bits are usually 0 and should be left untouched. When accessing the Root Directory for FAT32, the ROM Code just starts from the Root Directory Cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM Code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later on by the booting procedure to access the file.

#### 4.7.4.10 Pins Used for MMC Boot

The list of pins that are configured by the ROM in case of MMC boot mode are as follows. Please note that all the pins might not be driven at boot time.

**Table 4-26. Pins Used for MMC Boot**

| Signal name | Pin used |
|---|---|
| clk | mmc1_clk |
| cmd | mmc1_cmd_mux0 |
| dat0 | mmc1_dat0 |
| dat1 | mmc1_dat1 |
| dat2 | mmc1_dat2 |
| dat3 | mmc1_dat3 |

### *4.7.5 SPI*

SPI EEPROMs or SPI flashes have an EEPROM or NOR flash backend and they connect to the device using the serial SPI protocol. These typically devices operate in three stages – the command stage, the address stage and the data transfer stage. The command is usually an 8 bit value followed by the address (depending on the size of the device) followed by the data to be read or written. Because of the need for fewer pins, these devices are comparatively inexpensive, easy for board layout, and are the devices of choice when cost, complexity and form factor are critical considerations.

#### 4.7.5.1 SPI Features

The following features are included in SPI:

- Supports 12 MHz clock (50% duty cycle)
- Supports only SPI Mode 3 (clock polarity = 1, clock phase = 1)
- Supports only 24 bit addressable EEPROMs

Copyright © 2011–2016, Texas Instruments Incorporated

- Supports only 4-pin SPI mode (CS, CLK, Serial Input, Serial Output)
- The boot devices must be connected to channel 0 and must support the read command (03h)
- The boot image is copied into internal memory and then executed

#### 4.7.5.2 Initialization and Detection

The ROM Code initializes the SPI controller, pin muxing and clocks for communicating with the SPI device. The controller is initialized in Mode 3 and the clock is setup to operate at 12 MHz. There is no specific device identification routine that is executed by the ROM code to identify whether a boot device is preset or not. If no SPI device is present, the sector read will return only 0xFFFFFFFF and the SPI boot will be treated as failed.

#### 4.7.5.3 SPI Read Sector Procedure

The ROM Code reads SPI data from the boot device in 512 byte sectors. For each call to the SPI Read Sector routine, the SPI Read Command (0x03) is sent along with the 24 bit start address of the data to be read.

From the next iteration onwards, a dummy value is transmitted on the master out line and the data is received on the master in line. This needs to be done because SPI protocol always operated in full duplex mode. The dummy data transmitted by the ROM is the Read Command appended to the start address. The data from the boot device is received MSB first.

As the A8 is a little-endian processor, and SPI operates in a big-endian format, this means that while writing to the flash, care needs to be taken to write the image in a big-endian format. This way we can avoid doing the endian conversion at boot time, thus improving boot performance

#### 4.7.5.4 Pins Used for SPI Boot

The list of device pins that are configured by the ROM in the case of SPI boot mode are shown in the table below. Please note that all the pins might not be driven at boot time.

The default state of the other SPI chip select pins could be low at POR, so care must be taken if any other devices are connected to CS[1], CS[2] or CS[3]. External logic must be used to ensure that the chip select to these devices are not enabled by default. .

**Table 4-27. Pins Used for SPI Boot**

| Signal name | Pin used |
|---|---|
| cs | spi0_cs0 |
| miso | spi0_d0 |
| mosi | spi0_d1 |
| clk | spi0_sclk |

### *4.7.6 Blocks and Sectors Search Summary*

Table 4-28 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NAND is organized with blocks, which are erasable units.

**Table 4-28. Blocks and Sectors Searched on non-XIP Memories**

| Memory | Maximum number of blocks checked | Number of sectors searched |
|---|---|---|
| NAND | first 4 | Number of sectors in one block (1) |
| SPI, eMMC/eSD and MMC/SD cards (raw mode) | first 4 | 1 |

(1) Depends on NAND geometry.

Regarding MMC/SD card booting in FAT mode, the file system area is searched for one file.

Copyright © 2011–2016, Texas Instruments Incorporated

## 4.8 Peripheral Booting

### 4.8.1 Overview

The ROM Code can boot from three different peripheral interfaces:

| | |
|---|---|
| EMAC | 1000/100/10 Mbps Ethernet, using standard TCP/IP network boot protocols BOOTP and TFTP |
| PCIe | One lane @250 MB/s |
| UART | 115.2Kbps, 8 bits, even parity, 1 stop bit, no flow control |

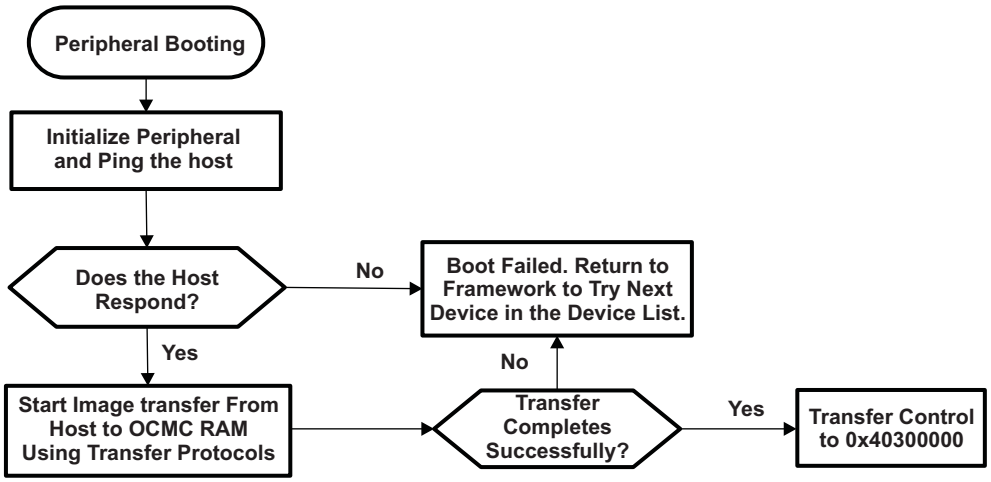
The purpose of booting from a peripheral interface is to download a boot image from an external host (typically a PC). This booting method is mostly used for programming flash memories connected to the device (e.g., in the case of initial flashing, firmware update or servicing).

### 4.8.2 Boot Image Location and Size

The boot image is downloaded directly into internal RAM at the location 40300000h. The maximum size of downloaded image is 110KB.

### 4.8.3 Peripheral Boot Procedure Overview

**Figure 4-23. Peripheral Booting Procedure**



### 4.8.4 EMAC Boot Procedure

#### 4.8.4.1 Device Initialization

- EMAC boot uses the CPGMAC0 subsystem of the device. It can be connected to external Ethernet PHY using the GMII0, RMII or RGMII interfaces and MDIO pins
- Device uses EFUSE register MAC_ID0 for Ethernet MAC address of the device.
- Device detects if the PHY is alive on the MDIO interface and
  - Reads the STATUS register to check if Ethernet link is active
  - Reads the CONTROL register to detect the auto-negotiated mode of operation
    - Is the mode full-duplex or half duplex
    - Speed of operation, 1000/100/10 Mbps

Copyright © 2011–2016, Texas Instruments Incorporated

#### 4.8.4.2 BOOTP (RFC 951)

The device then proceeds to obtain the IP and Boot information using BOOTP protocol. The device prepares and broadcasts the BOOTP message that has the following information:

- Device MAC address in “chaddr” field – to uniquely identify the device to the server.
- “Vender-class-identifier” option number 60 (RFC 1497, RFC 1533). Servers could use this information to identify the device type. The value present is "DM816x ROM v1.0"
- ”Client-identifier” option number 61 (RFC 1497, RFC 1533). This has the ASIC-ID structure which contains additional info for the device.

The device then expects a BOOTP response that provides the following information for the booting to proceed:

- Device IP address from “yiaddr” field
- Subnetmask from extended option 1 (RFC 1497, RFC 1533)
- Gateway IP from extended option number 3 (RFC 1497, RFC 1533) or from “giaddr” field of BOOTP response.
- Boot image filename from “file” field
- TFTP server IP address from the “siaddr” field

  Timeouts and retries
- Exponentially increasing timeouts starting from 4s
- Five retries

#### 4.8.4.3 FTP (RFC 1350)

After a successful BOOTP completion, the device initiates the TFTP download of the boot image into SRAM. The device has the capability to reach TFTP server within the local subnet or outside, though the gateway.

Timeouts and retries

- Timeout of 1s to receive a response for the READ request
- 5 retries for the READ request
- Retries are managed by server once data transfer starts (server re-sends a data packet if the ACK was not received within a timeout value)
- Device has a 60s timeout to complete the data transfer, to handle the scenario if the server dies in the middle of a data transfer

#### 4.8.4.4 Pins Used for EMAC Boot

The list of pins that are configured by the ROM in case of EMAC boot mode are in . Note that all the pins might not be driven at boot time.

**Table 4-29. Pins Used for EMAC Boot**

| Signal name | Pin used |
|---|---|

## *4.8.5 PCIe Boot Procedure*

### 4.8.5.1 Device Initialization

- ROM code configures the PCIe vendor ID as 104Ch

Copyright © 2011–2016, Texas Instruments Incorporated

- ROM code configures the PCIe device ID as B801h.
- The BAR window sizes for inbound translation are configurable as per the tables below
- Only legacy interrupt A is enabled. MSI is disabled
- The device is configured in the D0 power state
- The link and device capability is configured for maximum flexibility
- The PCIe settings used by the ROM can be overridden after boot by the Root Complex

**Figure 4-24. PCIe Peripheral Booting Procedure**

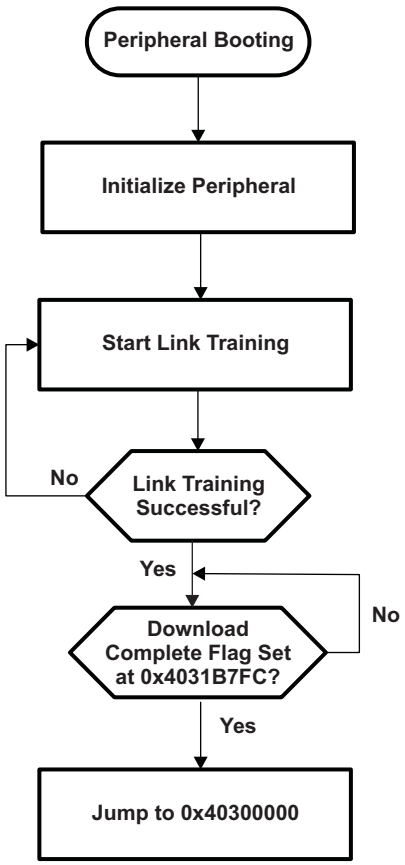

**Table 4-33. PCIe 32 BAR Window Size Configuration**

| PCIe32 | | | | | | | |
|---|---|---|---|---|---|---|---|
| BAR0 | BAR1 | BAR2 | | BAR3 | | BAR4 | |
| | | CS0BW | Size | CS0MUX[1:0] | Size | CS0WAIT | Size |

**Table 4-34. PCIe 64 BAR Window Size Configuration (continued)**

| PCIe64 | | | | |
|---|---|---|---|---|
| 4KB | 0 | 0 | 00 | 0 |
| | 01 | 256MB | 01 | 1GB |
| | 10 | 523MB | 10 | 2GB |
| | 11 | 1GB | 11 | 4GB |

**Table 4-35. PCIe BAR Window Base Address and Offset Configuration**

| BAR | Base Address | Offset | Comments |
|---|---|---|---|
| 0 | 0000 0000h | 0000 0000h | |
| 1 (64bit BAR0) | 4000 0000h | 4030 0000h | OCMC RAM |
| 2 | 6000 0000h | 5000 0000h | GPMC |
| 3 (64 Bit BAR2) | 8000 0000h | 8000 0000h | DDR 0 |
| 4 | A000 0000h | C000 0000h | DDR 1 |

Note that the base address and offset configurations can be changed from the host after the enumeration is complete.

### *4.8.6 UART Boot Procedure*

#### 4.8.6.1 Device Initialization

- UART boot uses UART0
- UART0 is configured to run at 115200 baud, 8-bits, even parity, 1 stop bit and no flow control.

#### 4.8.6.2 Boot Image Download

- UART boot uses x-modem client protocol to receive the boot image.
- Utilities like hyperterm, teraterm, minicom can be used on the PC side to download the boot image to the board
- With x-modem packet size of 1K throughout is roughly about 4KBytes/Sec.
- The ROM code will ping the host 10 times in 3s to start x-modem transfer. If host does not respond, UART boot will timeout.
- Once the transfer has started, if the host does not send any packet for 3s, UART boot will time out.
- If the delay between two consecutive bytes of the same packet is more than 2ms, the host is requested to re-transmit the entire packet again.
- Error checking using the CRC-16 support in x-modem. If an error is detected, the host is requested to re-transmit the packet again.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 4.8.6.3 Pins Used for UART Boot Mode

The list of pins that are configured by the ROM incase of UART boot mode are in Table 4-36. Note that all the pins might not be driven at boot time.

**Table 4-36. Pins Used for UART Boot**

| Signal name | Pin used |
|---|---|
| rx | uart0_rxd |
| tx | uart0_txd |

#### ASIC ID Structure

The ASIC ID size is 58 Bytes for UART and 81 Bytes for others.

## 4.9 Image Format

### *4.9.1 Overview*

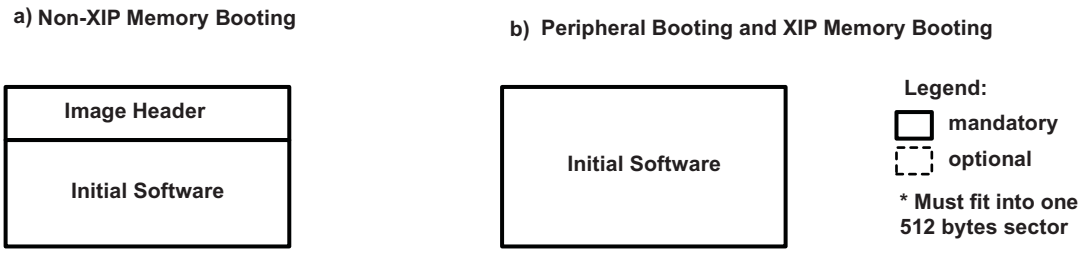
All preceding sections describe how the ROM Code searches and detects a boot image from a memory or a peripheral device type. This section describes the format of the boot image itself.

A boot image is basically made out of two major parts:

- The software to execute
- A header containing the destination address and size of the image for non-XIP memory devices

The mandatory section of a boot image contains the software which will be loaded into the memory and executed. An overview of the image formats is shown in Figure 4-25.

**Figure 4-25. Image Formats**



(a) Non - XIP Memory Booting
It is used for memories which require shadowing (for example, an MMC). The image must begin with a header which contains information on image size and destination address

(b) Peripheral Booting and XIP Memory Booting
When the memory device is of XIP type (e.g., NOR) the header is not needed and the image can contain code for direct execution. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

Copyright © 2011–2016, Texas Instruments Incorporated

#### 4.9.1.1 Image Formats

When the booting memory device is non-XIP (for example, an MMC), the image must contain a small header with the size of the software to load, and the destination address which tells where to store it.

The header is not needed when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

**Table 4-37. Image Formats**

| Field | non-XIP device (offset) | XIP device (offset) | Size (bytes) | Description |
|---|---|---|---|---|
| Size | 0000h | - | 4 | Size of the image |
| Destination | 0004h | - | 4 | Address where to store the image / code entry point |
| Image | 0008h | 0000h | x | Executable code |

**Note:** the “Destination” address field stands for both:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

In other words, the user must take care to locate the code entry point to the target address for image copy.

### *4.9.2 Table of Contents*

The TOC is 512 bytes long and consists of a maximum of 16 TOC items (32 bytes long each), located one after the other. If the number of TOC items is less than 16, the TOC item after the last used TOC item must be filled by FFh. Each TOC item contains information required by the ROM Code such as item location, size and name, as illustrated in Figure 4-26 and Table 4-38

**Figure 4-26. TOC Structure**

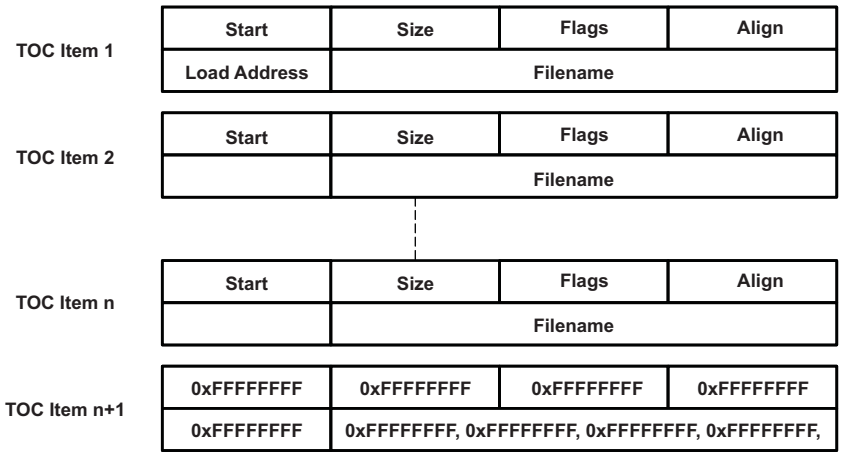


**Table 4-38. TOC Item Fields**

| Offset | Field | Size [bytes] | Description |
|---|---|---|---|
| 0h | Start | 4 | Offset from the start address of TOC to the actual address of sub image. |
| 4h | Size | 4 | Size of sub image. |
| 8h | Flags | 4 | Reserved |
| Ch | Align | 4 | Reserved |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-38. TOC Item Fields (continued)**

| Offset | Field | Size [bytes] | Description |
|---|---|---|---|
| 10h | Load Address | 4 | For an Initial SW TOC item during Memory Booting this field is the target address for item copy.<br>It is ignored in other cases. |
| 14h | Filename | 12 | 12 character long name of sub image, including the zero ('\0') terminator. |

The ROM Code recognizes sections pointed to by the TOC based on the filename as described in Table 4-39.

- The 'X-LOADER', '2ND', 'MLO', or 'ULO' section contains the Initial Software
- Optionally, the TOC may contain CH sections. CHSETTINGS is a mandatory section of CH and is used to recognize CH presence.

**Table 4-39. Filenames in TOC**

| Filename | Description |
|---|---|
| X-LOADER | Bootstrap |
| 2ND | Secondary loader (peripheral booting) |
| MLO | MMC/SD Loader (Memory booting) |
| ULO | Alternative filename used for Secondary Loader via USB (Peripheral booting) |
| CHSETTINGS | Configuration Header general setting item. this item is mandatory for CH |
| CHRAM | Configuration Header EMIF item |
| CHFLASH | Configuration Header GPMC item |
| CHMMCSD | Configuration Header MMD/SD item |

## 4.10 Execution

### *4.10.1 Overview*

One of the early steps of the public ROM code execution is to search for a boot image from the requested medium (configured by the MBOOT pins) and copy it to RAM if needed. If the boot interface is non-XIP then the image is simply copied to the provided destination address (internal or external RAM) and then executed. If the boot interface is of XIP type then the image copy is not needed and execution is directly given to the XIP memory.

### *4.10.2 Execution*

The image is executed at the time the ROM Code performs the branch to the first executable instruction inside the Initial SW. For a non-XIP device, the execution address is the first word after the header. The branch is performed in ARM supervisor mode. The R0 register points to the booting parameters structure (see Table 4-40) which contains details about the booting execution.

**Table 4-40. Booting Parameters Structure**

| Offset | Field | Size [bytes] | Description |

## 4.11 Services for HLOS Support

The TrustZone® architecture of the Cortex™-A8 core restricts accesses to secure mode only coprocessor registers. The Cortex-A8 core of the device is forbidden from entering the secure mode and hence cannot directly access any secure resources. However, a high-level OS needs to access secure registers for L2 cache maintenance and other operations.

For these purposes, the ROM Code provides different primitives that can be called. These services are implemented in monitor mode (service must be called by writing function ID into R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the MPU. The caller must take care of saving R0, R1, and R12 before using these APIs, as these get overwritten by the ROM code.

The services provided are:

- Write Auxiliary Control Register (WRITE_ACR).
- Write Nonsecure Access Control Register (WRITE_NACR).
- Write L2 Cache Auxiliary Control Register (WRITE_CACR).

**Table 4-41. Write Auxiliary Control Register (WRITE_ACR)**

| Function ID | Description | |
|---|---|---|
| R12 = 0x100 | This function writes the ARM CP15 Auxiliary Control Register with the input value in R0. | |

| Input | 32 bit unsigned integer – R0<br>32 bit unsigned integer – R1 | Value to set in the register<br>Don't care |
| Output | - | - |
| Return | - | - |

For more information about ARM registers, see the *Cortex™-A8 Technical Reference Manual*.

## 4.12 Tracing

Tracing in the Public ROM Code consist in three 32 bit vectors for which each bit corresponds to a particular “way point” in the ROM Code execution sequence (refer to Section 4.3.2.4). Tracing vectors are initialized at the very beginning of the startup phase and updated all along the boot process.

There are two sets of tracing vectors. The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM Code run after cold reset. As a consequence after a warm reset, it is possible to have visibility on the boot scenario that occurred during cold reset.

**Table 4-44. Tracing Vectors**

| Trace vector | Bit # | Group | Meaning |
|---|---|---|---|
| 1 | 0 | General | Passed the public reset vector |
| 1 | 1 | General | Entered main function |
| 1 | 2 | General | Running after the cold reset |

## 5.1 Overview

This chapter contains a general description of the DCAN Controller Area Network module, a high-integrity serial communications protocol for distributed real-time applications.

The DCAN module supports bit rates up to 1 Mbit/s and is compliant to the CAN 2.0B protocol specification. This device has two DCAN modules, referred to as DCAN0 and DCAN1 in this document.

### 5.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 MBit/s
- Dual clock source
- 64 message objects (see Section 5.1.2.3)
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- CAN Rx/Tx pins configurable as general purpose input/output (I/O) pins
- Support for two interrupt lines: Level 0 and Level 1
- Local power down and wakeup support
- Automatic RAM initialization
- Support for DMA access

### 5.1.2 Functional Description

The DCAN module consists of the components CAN Core, Message RAM, Message RAM Interface, Message Handler, Registers and Message Object access and Module Interface (see Figure 5-1). The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 MBit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

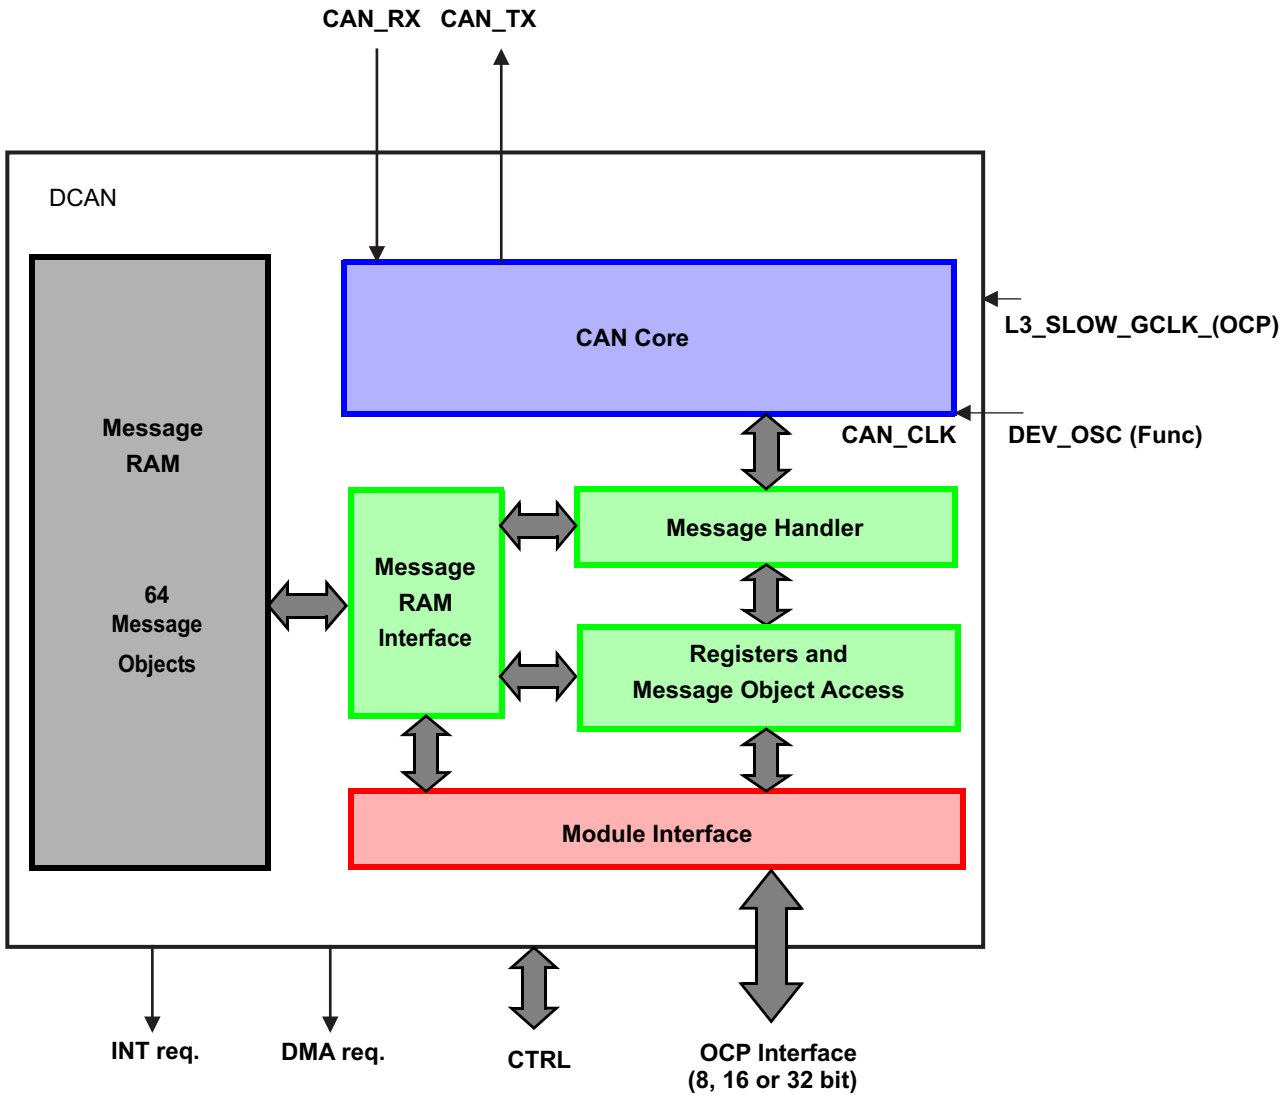
All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly by the CPU via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 5-1 shows the DCAN block diagram and its features are described below.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 5-1. DCAN Block Diagram**



#### 5.1.2.1 CAN Core

The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

#### 5.1.2.2 Message Handler

The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

#### 5.1.2.3 Message RAM

DCAN0 and DCAN1 enables the storage of 64 CAN messages.

#### 5.1.2.4 Message RAM Interface

Three interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 5.9.12.

Copyright © 2011–2016, Texas Instruments Incorporated

The interface registers have the same word-length as the message RAM.

#### 5.1.2.5 Registers and Message Object Access

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either CPU or DMA.

#### 5.1.2.6 Module Interface

The DCAN module registers are accessed by the CPU or user software through a 32-bit peripheral bus interface.

#### 5.1.2.7 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) and the peripheral asynchronous clock source domain (DEV_OSC) for CAN_CLK.

## 5.2 CAN Operation

After hardware reset, the Init bit in the CAN control register (DCAN CTL) is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 5-2 illustrates the basic initialization flow for the CAN module.

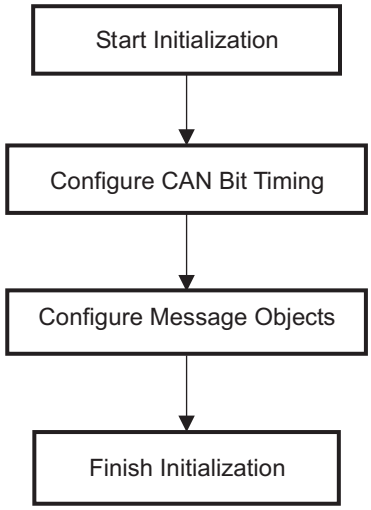
### *5.2.1 CAN Module Initialization*

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the CPU has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

**Figure 5-2. CAN Module General Initialization Flow**



#### 5.2.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 5-3.

**Step 1:** Enter *initialization mode* by setting the Init (Initialization) bit in the CAN control register.

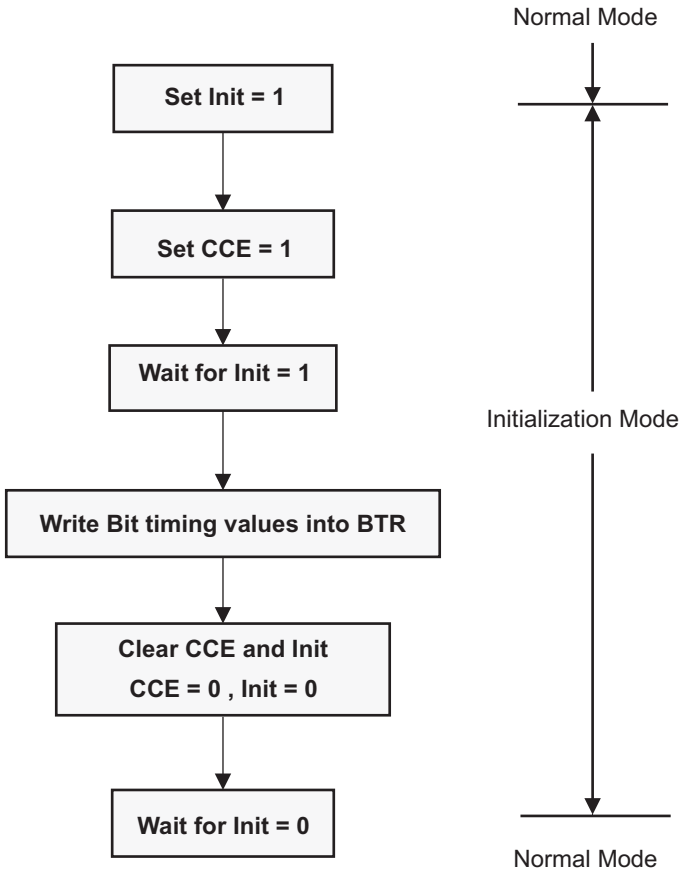
Copyright © 2011–2016, Texas Instruments Incorporated

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on hardware reset and during Bus-Off.

**Figure 5-3. CAN Bit-Timing Configuration**



**Step 2:** Set the Configure Change Enable ( CCE) bit in the CAN control register.

The access to the Bit Timing register (BTR) for the configuration of the bit timing is enabled when both Init and CCE bits in the CAN Control register are set.

**Step 3:** Wait for the Init bit to get set. This would make sure that the module has entered *Initialization mode*.

**Step 4:** Write the bit timing values into the bit timing register. See Section 5.10.2 for the BTR value calculation for a given bit timing.

**Step 5:** Clear the CCE and Init bit.

**Step 6:** Wait for the Init bit to clear. This would ensure that the module has come out of *initialization mode*.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

**NOTE:** The module will not come out of the *initialization mode* if any incorrect BTR values are written in step 4.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 5.2.1.

#### 5.2.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the CPU does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 5.11) and the message object structure (see Section 5.12) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 5.8. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

**NOTE:** The message objects initialization is independent of the bit-timing configuration.

#### 5.2.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control register, DCAN_RAMINIT, which initializes the RAM with zeros and sets parity bits accordingly. Wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on RAM hardware initialization, see the system module reference guide.

### *5.2.2 CAN Message Transfer (Normal Operation)*

Once the DCAN is initialized and Init bit is reset to zero, the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to ‘1’) at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The interrupt register points to those message objects with IntPnd = ‘1’. It is updated even if the interrupt lines to the CPU are disabled (IE0/IE1 are zero).

The CPU may poll all MessageObject’s NewDat and TxRqst bits in parallel from the NewData X registers and the Transmission Request X Registers (DCAN TXRQ X). Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to “don’t care” may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Copyright © 2011–2016, Texas Instruments Incorporated

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

#### 5.2.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission ( DAR) in the CAN Control register. Further details to this mode are provided in Section 5.9.3.

#### 5.2.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting the Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit ABO in the CAN control register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of L3_SLOW_GCLK cycles which can be defined in the Auto-Bus-On Time register (DCAN ABOTR).

**NOTE:** If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

### *5.2.3 Test Modes*

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the Test bit in the CAN control register needs to be set to 1. This enables write access to the test register (DCAN TEST).

**NOTE:** When using any of the Loop Back modes, it must be ensured by software that all message transfers are finished before setting the Init bit to 1.

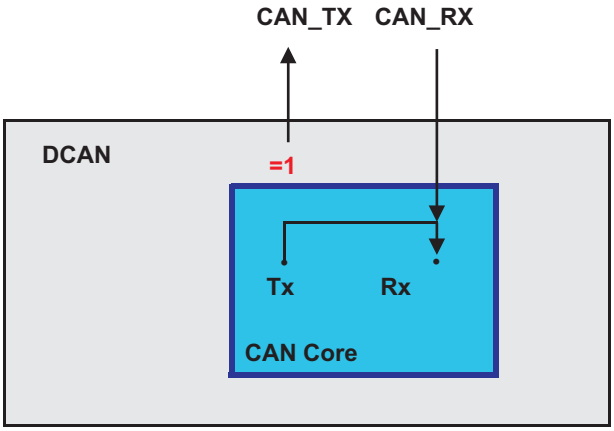
#### 5.2.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 5-4 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in the Test register to one. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 5-4. CAN Core in Silent Mode**



### 5.2.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

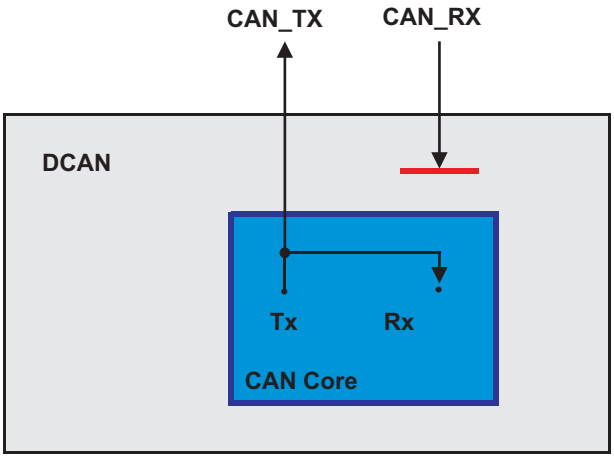
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 5-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit LBack in the test register to one.

**NOTE:** In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 5.2.3.3.

**Figure 5-5. CAN Core in Loopback Mode**



Copyright © 2011–2016, Texas Instruments Incorporated

### 5.2.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

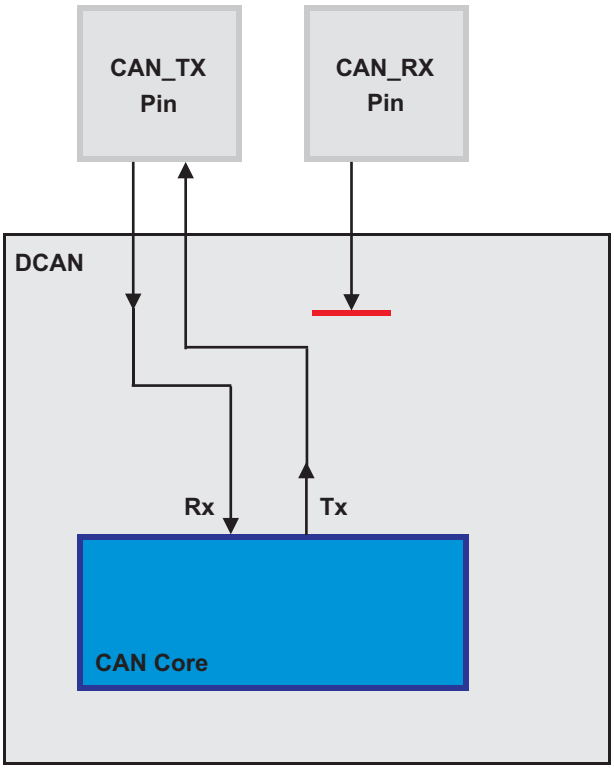
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit **ExL** in test register to one.

Figure 5-6 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

**NOTE:** When loopback mode is active (LBack bit set), the ExL bit will be ignored.

**Figure 5-6. CAN Core in External Loopback Mode**



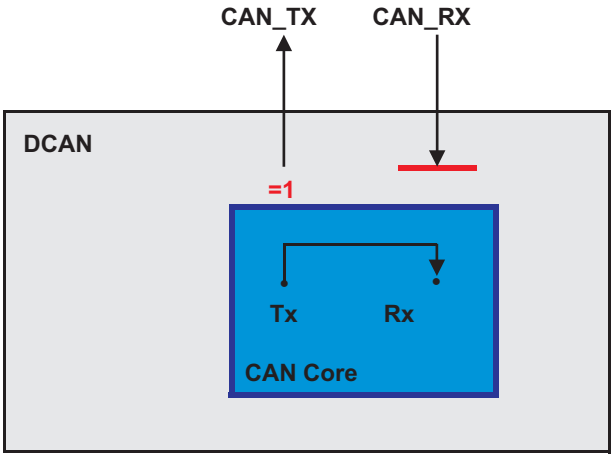
### 5.2.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest,” i.e., the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 5-7 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 5-7. CAN Core in Loop Back Combined With Silent Mode**



#### 5.2.3.5 Software Control of CAN_TX pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the test register bits Tx[1:0] as described in section Section 5.14.1.6.

**NOTE:** The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

## 5.3 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) as the general module clock source, and the peripheral asynchronous clock source domain (DEV_OSC) provided to the CAN core (as clock source CAN_CLK) for generating the CAN bit timing.

Both clock domains can be derived from the same clock source (so that L3_SLOW_GCLK = DEV_OSC).

For more information on how to configure the relevant clock source registers in the system module, see the system module reference guide and the device-specific data sheet.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

**NOTE:** If the dual clock functionality is used, then L3_SLOW_GCLK must always be higher or equal to CAN_CLK (DEV_OSC) (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated L3_SLOW_GCLK has to be considered:

$f_{0,\ L3_SLOW_GCLK}(OCP) \pm \Delta f_{FM,\ L3_SLOW_GCLK}(OCP) \geq f_{CANCLK}$

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK (DEV_OSC), an oscillator frequency of 8MHz or higher has to be used.

## 5.4 Interrupt Functionality

Interrupts can be generated on two interrupt lines: DCANINT0 and DCANINT1. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN control register. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 5-8 and Figure 5-9).

The source of an interrupt can be determined by the interrupt identifiers Int0ID/Int1ID in the interrupt register (see Section 5.14.1.5). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN ES and PARITYERR_EOI). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the error and status register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 command register). When IntPnd is cleared, the interrupt register will point to the next message object with a pending interrupt.

### *5.4.1 Message Object Interrupts*

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE that are described in Section 5.12.1.

Message object interrupts can be routed to either DCANINT0 or DCANINT1 line, controlled by the interrupt multiplexer register (DCAN INTMUX12 to DCAN INTMUX78), see Section 5.14.1.17.

### *5.4.2 Status Change Interrupts*

The events WakeUpPnd, RxOk, TxOk and LEC in error and status register ( DCAN ES) belong to the status change interrupts. The status change interrupt group can be enabled by SIEbit in the CAN control register.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN control register.

**NOTE:** Reading the error and status register will clear the WakeUpPnd flag. If in global power-down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.4.3 Error Interrupts

The events PER, BOff and EWarn, monitored in the Error and Status register, DCAN ES, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE in the CAN Control register.

Error interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN Control register.

**Figure 5-8. CAN Interrupt Topology 1**

## 5.5 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN control registers.

### 5.5.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the PDR bit in CAN Control register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Init bit in CAN control register to prevent any further CAN transfers, and it will also set the PDA bit in CAN error and status register. With setting the PDA bits, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 5.5.2) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

**NOTE:** In local low-power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the init bit, these messages may get sent.

### 5.5.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control register.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit ( WUBA) in the CAN control register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the PDR bit in the CAN Control register and also clear the PDA bit in the error and status register. The WakeUpPnd bit in CAN error and status register will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

**NOTE:** The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 5-10 shows a flow diagram about entering and leaving local power-down mode.

## 5.6 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 5.12.4.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by PMD bit field in the CAN control register.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 5.12.3) or in RDA mode (see Section 5.12.4). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

**NOTE:** The parity scheme is tied to even parity at the device level.

### 5.6.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the PER bit in the error and status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the host CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, e.g., by immediately checking the parity error code register (DCAN PERR) on parity error interrupt.

**NOTE:** During RAM initialization, no parity check will be done, but if the PMD bit is set, the parity bits will be generated.

### 5.6.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess ( RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

**NOTE:** If parity check was disabled, the application has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

Copyright © 2011–2016, Texas Instruments Incorporated

## 5.7 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via OCP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in the CAN control register.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 5.12.3).

**NOTE:** During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

**NOTE:** Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- Error and status register (clear of status flags by read)
- IF1/IF2 command registers (clear of DMAActive flag by read/write)

## 5.8 Configuration of Message Objects

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver library should offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

### 5.8.1 Configuration of a Transmit Object for Data Frames

Table 5-1 shows how a transmit object can be initialized.

**Table 5-1. Initialization of a Transmit Object**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 1 | 0 | 0 | 0 | appl. | 0 | appl. | 0 |

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 5.9.8. Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

### 5.8.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### 5.8.3 Configuration of a Single Receive Object for Data Frames

Table 5-2 shows how a receive object for data frames can be initialized.

**Table 5-2. Initialization of a single Receive Object for Data Frames**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 0 | 0 | 0 | appl. | 0 | 0 | 0 | 0 |

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.8.4 Configuration of a Single Receive Object for Remote Frames

Table 5-3 shows how a receive object for remote frames can be initialized.

**Table 5-3. Initialization of a Single Receive Object for Remote Frames**

| MsgVal | Arb | Data | Mask | EoB | Dir | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | appl. | appl. | appl. | 1 | 1 | 0 | 0 | appl. | 0 | 0 | 0 | 0 |

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 5.8.5).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 5.9.8.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

### 5.8.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

Copyright © 2011–2016, Texas Instruments Incorporated

## 5.9 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

### 5.9.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 5.9.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 5.9.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MsgVal bits in the Message Valid register (DCAN MSGVAL12 to DCAN MSGVAL78) and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

Copyright © 2011–2016, Texas Instruments Incorporated

After a successful transmission and if no new data was written to the message object (NewDat = ‘0’) since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

### 5.9.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither d nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN IF1DATA/DCAN IF2DATA) or IF1/IF2 Data B register (DCAN IF1DATB/DCAN IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN IF1CMD/DCAN IF2CMD) and then the number of the message object is written to bits [7:0] of the command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 5.9.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

### 5.9.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Before changing the configuration of a message object, MsgVal has to be reset.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register should be set to 0x87.

**NOTE:** After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.9.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

### 5.9.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the interrupt register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 5.9.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

### 5.9.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the command register. That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.9.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register.

### 5.9.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

### 5.9.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N –1 plus A FIFO buffer of length N will store –1 plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 5-11.

**NOTE:** All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

## 5.10 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods ($f_{osc}$) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

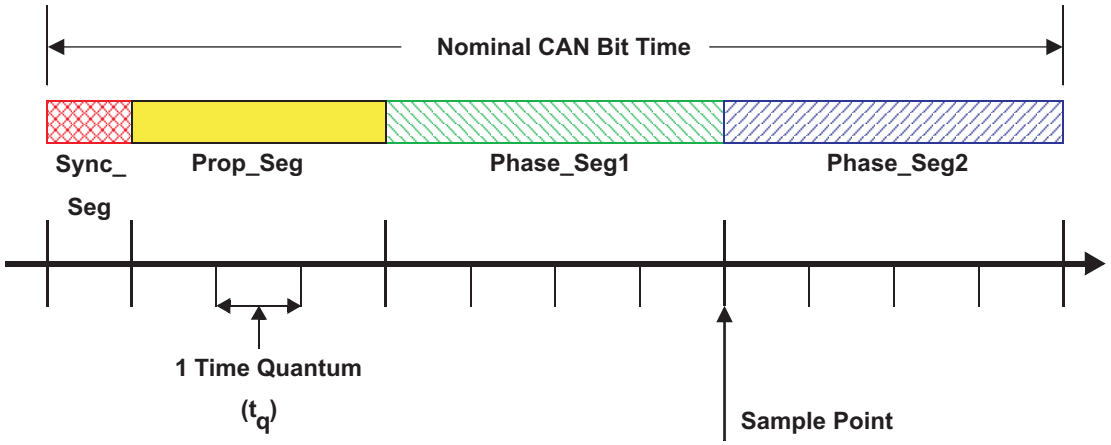
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### 5.10.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 5-12):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

**Figure 5-12. Bit Timing**



Each segment consists of a specific number of time quanta. The length of one time quantum ($t_q$), which is the basic time unit of the bit time, is given by the CAN_CLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

$t_q$ = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 5-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-4. Parameters of the CAN Bit Time**

| Parameter | Range | Remark |
|---|---|---|
| Sync_Seg | 1 $t_q$ (fixed) | Synchronization of bus input to CAN_CLK |
| Prop_Seg | [1 … 8] $t_q$ | Compensates for the physical delay times |
| Phase_Seg1 | [1 … 8] $t_q$ | May be lengthened temporarily by synchronization |
| Phase_Seg2 | [1 … 8] $t_q$ | May be shortened temporarily by synchronization |
| Synchronization Jump Width (SJW) | [1 … 4] $t_q$ | May not be longer than either Phase Buffer Segment |

**NOTE:** For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

#### 5.10.1.1 Synchronization Segment

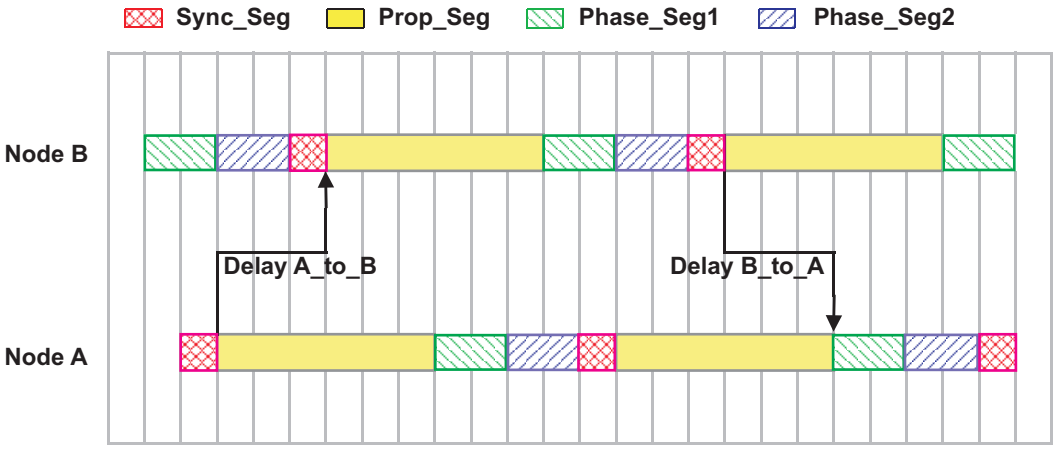
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

#### 5.10.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's non-destructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 5-13 shows the phase shift and propagation times between two CAN nodes.

**Figure 5-13. The Propagation Time Segment**



**Delay A_to_B >= node output delay(A) + bus line delay(AÆB) + node input delay(B)**

**Prop_Seg >= Delay A_to_B + Delay B_to_A**

**Prop_Seg >= 2 • [max(node output delay+bus line delay + node input delay)]**

Copyright © 2011–2016, Texas Instruments Incorporated

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3 Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 $t_q$, requiring a longer Prop_Seg.

#### 5.10.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

Copyright © 2011–2016, Texas Instruments Incorporated

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

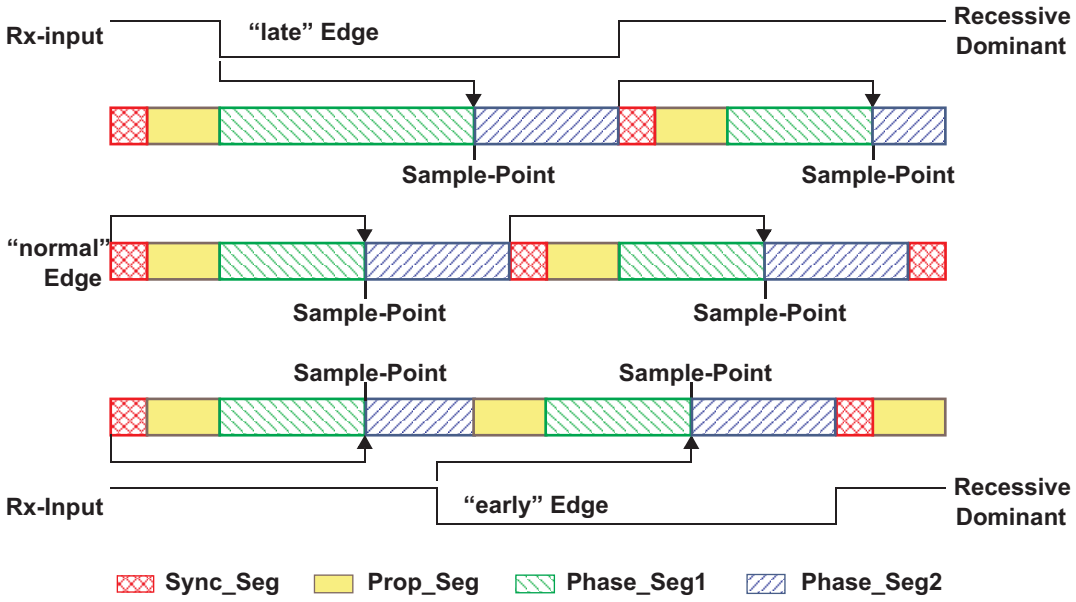
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 5-14 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

**Figure 5-14. Synchronization on Late and Early Edges**



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

Copyright © 2011–2016, Texas Instruments Incorporated

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

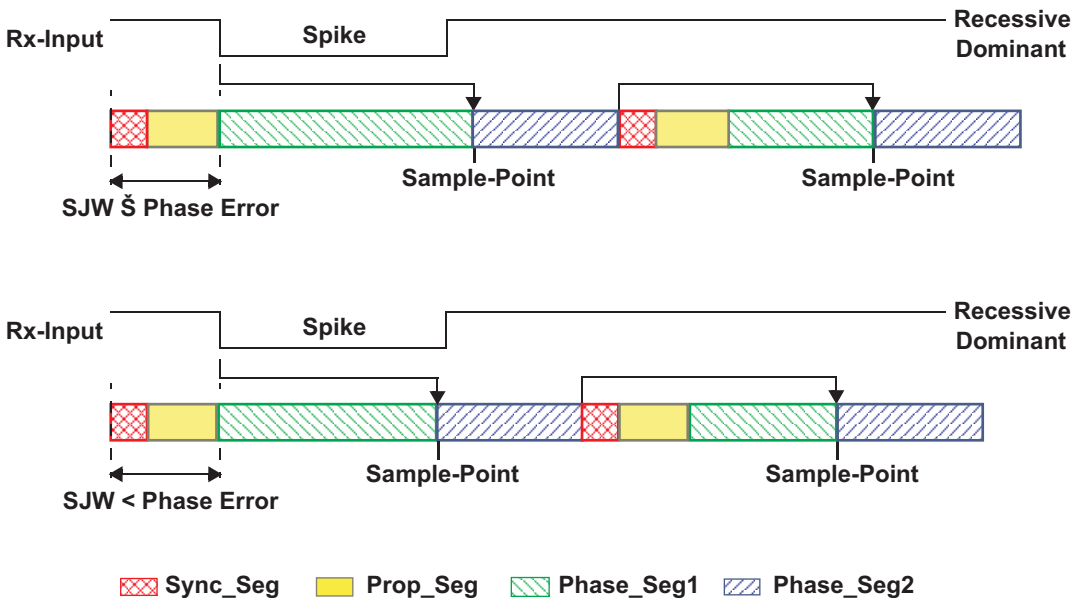
In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 5-15 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 5-15. Filtering of Short Dominant Spikes**



### 5.10.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency $f_{osc}$ around the nominal frequency $f_{nom}$ with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit_time}$$

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

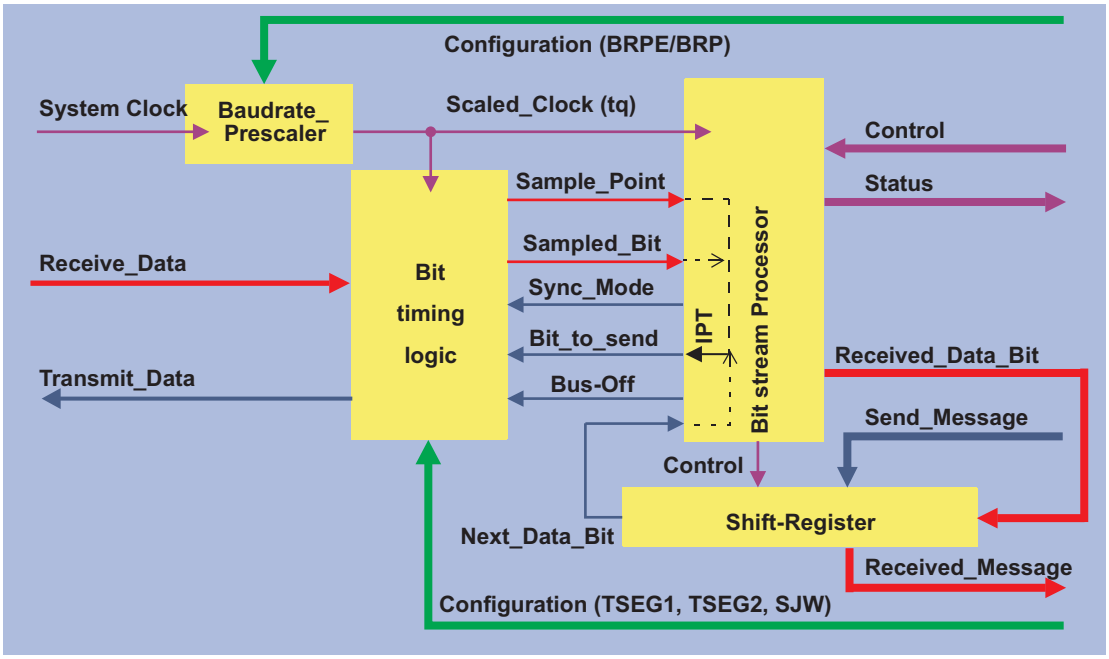
Copyright © 2011–2016, Texas Instruments Incorporated

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

### 5.10.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of four bits ( BRPE) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 5-16).

**Figure 5-16. Structure of the CAN Core's CAN Protocol Controller**



In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, for example, SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] $t_q$ or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] $t_q$.

The data in the bit timing register ( BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Copyright © 2011–2016, Texas Instruments Incorporated

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

#### 5.10.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

**NOTE:** 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum $t_q$ is defined by the baud rate prescaler with $t_q$ = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of $t_q$).

The Sync_Seg is 1 $t_q$ long (fixed), leaving (bit time – Prop_Seg – 1) $t_q$ for the two Phase Buffer Segments. If the number of remaining $t_q$ is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] $t_q$.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 5.10.2.3.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register:

Tseg2 = Phase_Seg2-1

Tseg1 = Phase_Seg1+ Prop_Seg-1

SJW = SynchronizationJumpWidth-1

BRP = Prescaler-1

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.10.2.2 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

| | | | |
|---|---|---|---|
| $t_q$ | 100 ns | = | $t_{CAN_CLK}$ |
| delay of bus driver | 90 ns | = | |
| delay of receiver circuit | 40 ns | = | |
| delay of bus line (40 m) | 220 ns | = | |
| $t_{Prop}$ | 700 ns | = | INT (2*delays + 1) = 7 • $t_q$ |
| $t_{SJW}$ | 100 ns | = | 1 • $t_q$ |
| $t_{TSeg1}$ | 800 ns | = | $t_{Prop}$ + $t_{SJW}$ |
| $t_{TSeg2}$ | 100 ns | = | Information Processing Time + 1 • $t_q$ |
| $t_{Sync\text{-}Seg}$ | 100 ns | = | 1 • $t_q$ |
| bit time | 1000 ns | = | $t_{Sync\text{-}Seg}$ + $t_{TSeg1}$ + $t_{TSeg2}$ |
| tolerance for CAN_CLK | 0.43 % | = | $\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$ |
| | | = | $\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$ |

In this example, the concatenated bit time parameters are $(1\text{-}1)_3\&(8\text{-}1)_4\&(1\text{-}1)_2\&(1\text{-}1)_6$, so the bit timing register is programmed to = 0x00000700.

### 5.10.2.3 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

| | | | |
|---|---|---|---|
| $t_q$ | 1 µs | = | $t_{CAN_CLK}$ |
| Delay of bus driver | 200 ns | = | |
| Delay of receiver circuit | 80 ns | = | |
| Delay of bus line (40 m) | 220 ns | = | |
| $t_{Prop}$ | 1 µs | = | 1 • $t_q$ |
| $t_{SJW}$ | 4 µs | = | 4 • $t_q$ |
| $t_{TSeg1}$ | 5 µs | = | $t_{Prop}$ + $t_{SJW}$ |
| $t_{TSeg2}$ | 3 µs | = | Information Processing Time + 3 • $t_q$ |
| $t_{Sync\text{-}Seg}$ | 1 µs | = | 1 • $t_q$ |
| Bit time | 9 µs | = | $t_{Sync\text{-}Seg}$ + $t_{TSeg1}$ + $t_{TSeg2}$ |
| Tolerance for CAN_CLK | | = | $\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$ |
| | | = | $\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$ |

In this example, the concatenated bit time parameters are $(3\text{-}1)_3\&(5\text{-}1)_4\&(4\text{-}1)_2\&(2\text{-}1)_6$, so the bit timing register is programmed to = 0x000024C1.

## 5.11 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in the command register, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in the command register, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent CPU accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 5.12.1) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 5.14.1.19) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

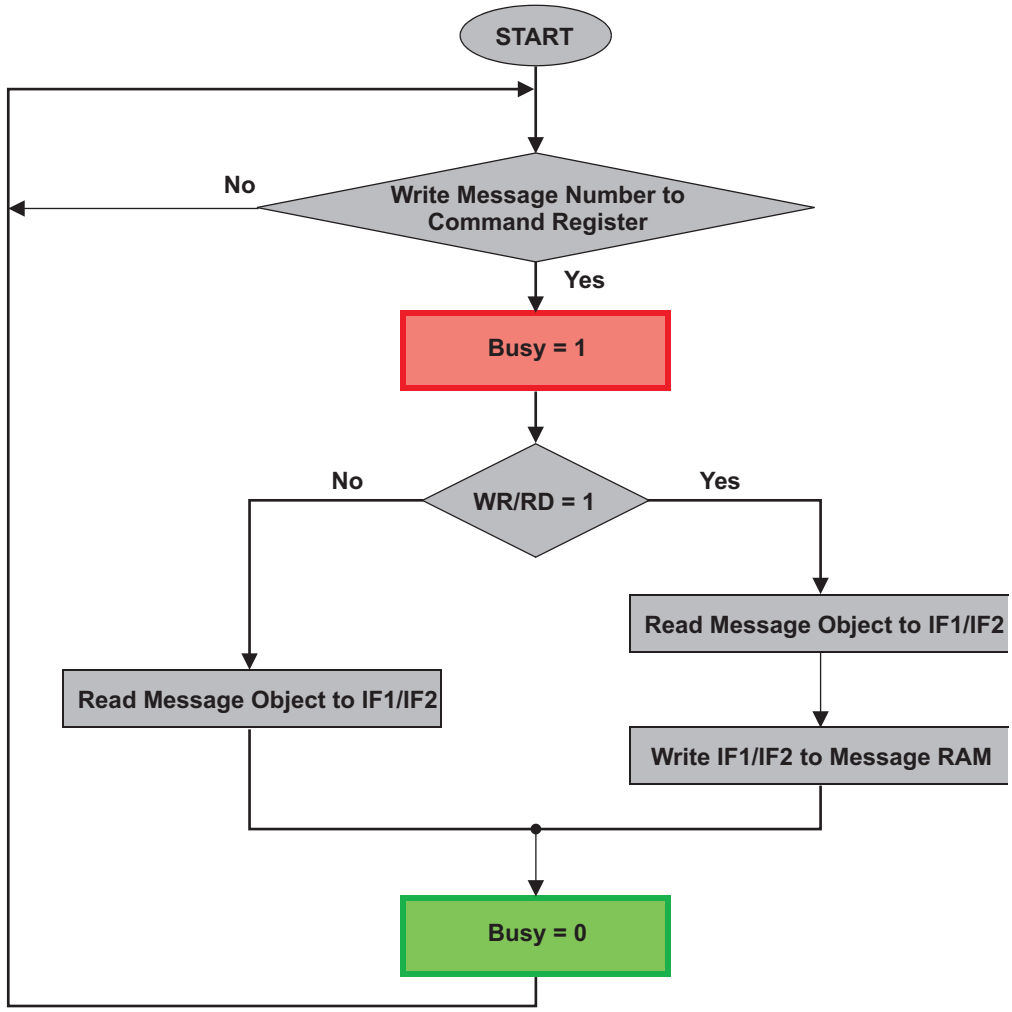
### *5.11.1 Message Interface Register Sets 1 and 2*

The IF1 and IF2 register sets control the data transfer to and from the message object. The command register addresses the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the command register.

When the CPU initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the busy bit in the respective command register to ‘1’. After the transfer has completed, the busy bit is set back to ‘0’ (see Figure 5-17).

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 5-17. Data Transfer Between IF1/IF2 Registers and Message RAM**



### 5.11.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (Section 5.14.1.28).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN control register. Please refer to the device datasheet to find out if this DMA source is available.

**NOTE:** The IF3 register set can not be used for transferring data into message objects.

Copyright © 2011–2016, Texas Instruments Incorporated

## 5.12 Message RAM

**CAUTION**

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the CPU cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the CPU to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the CPU:

- Debug/Suspend mode (see Section 5.12.3)
- RAM Direct Access (RDA) mode (see Section 5.12.4)

For the message RAM base address, see the device-specific data sheet.

### 5.12.1 Structure of Message Objects

Table 5-5 shows the structure of a message object. Table 5-6 provides a description of the fields.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Table 5-5. Structure of a Message Object**

| Message Object | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| UMask | Msk[28:0] | MXtd | MDir | EoB | unused | NewDat | MsgLst | RxIE | TxIE | IntPnd | RmtEn | TxRqst |
| MsgVal | ID[28:0] | Xtd | Dir | DLC[3:0] | Data 0 | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 | Data 7 |

**Table 5-6. Field Descriptions**

| Name | Value | Description |
|---|---|---|
| MsgVal | | Message valid. The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the Init bit in the CAN control register. |
| | 0 | The message object is ignored by the message handler. |
| | 1 | The message object is to be used by the message handler. |
| | | Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. |
| UMask | | Use acceptance mask |
| | 0 | Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering. |
| | 1 | Mask bits are used for acceptance filtering. |
| | | Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. |
| ID[28:0] | | Message identifier |
| | ID[28:0] | 29-bit ("extended") identifier bits |
| | ID[28:18] | 11-bit ("standard") identifier bits |
| Msk[28:0] | | Identifier mask |
| | 0 | The corresponding bit in the message identifier is not used for acceptance filtering (don't care). |
| | 1 | The corresponding bit in the message identifier is used for acceptance filtering. |
| Xtd | | Extended identifier |
| | 0 | The 11-bit ("standard") identifier will be used for this message object. |
| | 1 | The 29-bit ("extended") identifier will be used for this message object. |
| MXtd | | Mask extended identifier |
| | 0 | The extended identifier bit (IDE) has no effect on the acceptance filtering. |
| | 1 | The extended identifier bit (IDE) is used for acceptance filtering. |
| | | Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered. |
| Dir | | Message direction |
| | 0 | Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object. |
| | 1 | Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one). |
| MDir | | Mask message direction |
| | 0 | The message direction bit (Dir) has no effect on the acceptance filtering. |
| | 1 | The message direction bit (Dir) is used for acceptance filtering. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-6. Field Descriptions (continued)**

| Name | Value | Description |
|---|---|---|
| EOB | | End of block |
| | 0 | The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block. |
| | 1 | The message object is a single message object or the last message object in a FIFO Buffer Block. |
| | | Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. |
| NewDat | | New data |
| | 0 | No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU. |
| | 1 | The message handler or the CPU has written new data into the data bytes of this message object. |
| MsgLst | | Message lost (only valid for message objects with direction = receive) |
| | 0 | No message was lost since the last time when this bit was reset by the CPU. |
| | 1 | The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten. |
| RxIE | | Receive interrupt enable |
| | 0 | IntPnd will not be triggered after the successful reception of a frame. |
| | 1 | IntPnd will be triggered after the successful reception of a frame. |
| TxIE | | Transmit interrupt enable |
| | 0 | IntPnd will not be triggered after the successful transmission of a frame. |
| | 1 | IntPnd will be triggered after the successful transmission of a frame. |
| IntPnd | | Interrupt pending |
| | 0 | This message object is not the source of an interrupt. |
| | 1 | This message object is the source of an interrupt. The interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority. |
| RmtEn | | Remote enable |
| | 0 | At the reception of a remote frame, TxRqst is not changed. |
| | 1 | At the reception of a remote frame, TxRqst is set. |
| TxRqst | | Transmit request |
| | 0 | This message object is not waiting for a transmission. |
| | 1 | The transmission of this message object is requested and is not yet done. |
| DLC[3:0] | | Data length code |
| | 0-8 | Data frame has 0-8 data bits. |
| | 9-15 | Data frame has 8 data bytes. |
| | | Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. |
| Data 0 | | 1st data byte of a CAN data frame |
| Data 1 | | 2nd data byte of a CAN data frame |
| Data 2 | | 3rd data byte of a CAN data frame |
| Data 3 | | 4th data byte of a CAN data frame |
| Data 4 | | 5th data byte of a CAN data frame |
| Data 5 | | 6th data byte of a CAN data frame |
| Data 6 | | 7th data byte of a CAN data frame |
| Data 7 | | 8th data byte of a CAN data frame |
| | | Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values. |

### 5.12.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) * 0x20

This means that message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

‘0’ is not a valid message object number.

The base address for DCAN0 RAM is 0x481C_D000 and DCAN1 RAM is 0x481D_1000.

Message object number 1 has the highest priority.

**Table 5-7. Message RAM addressing in Debug/Suspend and RDA Mode**

| Message Object Number | Offset From Base Address | Word Number | Debug/Suspend Mode, see Section 5.12.3 | RDA mode, see Section 5.12.4 |
|---|---|---|---|---|
| 1 | 0x0020 | 1 | Parity | Data Bytes 4-7 |

### 5.12.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

**NOTE:** During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

**Table 5-8. Message RAM Representation in Debug/Suspend Mode**

| Bit # | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |

### 5.12.4 Message RAM Representation in Direct Access Mode

When the RDA bit in the test register is set while the DCAN module is in test mode (test bit in the CAN control register is set), the CPU has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit not set) will be ignored.

**Table 5-9. Message RAM Representation in RAM Direct Access Mode**

| Bit # | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| MsgAddr + 0x00 | Data 4 | | | | | | | | Data 5 | | | | | | | |
| | Data 6 | | | | | | | | Data 7 | | | | | | | |
| MsgAddr + 0x04 | Data 0 | | | | | | | | Data 1 | | | | | | | |
| | Data 2 | | | | | | | | Data 3 | | | | | | | |
| MsgAddr + 0x08 | ID[27:12] | | | | | | | | | | | | | | | |
| | ID[11:0] | | | | | | | | | | | | DLC[3:0] | | | |
| MsgAddr + 0x0C | Msk[28:13] | | | | | | | | | | | | | | | |
| | Msk[12:0] | | | | | | | | | | | | | Xtd | Dir | ID[28] |
| MsgAddr + 0x10 | Reserved | | | | | | | | | | | | | | | Parity [4] |
| | Parity[3:0] | | | | Unused | | | | Msg Lst | UMask | TxIE | RxTE | Rmt En | EOB | MXtd | MDir |

**NOTE:** Writes to unused bits has no effect.

## 5.13 GIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN TIOC) (see Section 5.14.1.29) and the CAN RX IO control register (DCAN RIOC) (see Section 5.14.1.30).

## 5.14 Registers

The base address for the:

- DCAN0 registers is 0x481C_C000
- DCAN1 registers is 0x481D_0000

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1 DCAN Control Registers

After hardware reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The Init bit in the CAN control register is set to enable the software initialization. The DCAN will not influence the CAN bus until the CPU resets Init to '0'.

**Table 5-10. DCAN Control Register Summary Table**

LEGEND: R/W = Read/Write; R = Read only; WP = Write protected by init bit; -*n* = value after reset

**Table 5-11. CAN Control Register (DCAN CTL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-26 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 26 | WUBA | | Automatic wake up on bus activity when in local power-down mode |
| | | 0 | No detection of a dominant CAN bus level while in local power-down mode. |
| | | 1 | Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*). |
| | | | Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. |
| 24 | PDR | | Request for local low power-down mode |
| | | 0 | No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the Init bit has to be cleared. |
| | | 1 | Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the error and status register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*). |
| 23-21 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 20 | DE3 | | Enable DMA request line for IF3 |
| | | 0 | Disabled |
| | | 1 | Enabled |
| | | | Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. |
| 19 | DE2 | | Enable DMA request line for IF2 |
| | | 0 | Disabled |
| | | 1 | Enabled |
| | | | Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. |
| 18 | DE1 | | Enable DMA request line for IF1 |
| | | 0 | Disabled |
| | | 1 | Enabled |
| | | | Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. |
| 17 | IE1 | | Interrupt line 1 enable |
| | | 0 | Disabled - Module interrupt DCAN1INT is always low. |
| | | 1 | Enabled - interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-11. CAN Control Register (DCAN CTL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 16 | InitDbg | | Internal init state while debug access |
| | | 0 | Not in debug mode, or debug mode requested but not entered. |
| | | 1 | Debug mode requested and internally entered; the DCAN is ready for debug accesses. |
| 15 | SWR | | SW reset enable |
| | | 0 | Normal Operation |
| | | 1 | Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one OCP clock cycle.<br>Note: To execute software reset, the following procedure is necessary:<br>1. Set Init bit to shut down CAN communication.<br>2. Set SWR bit additionally to Init bit. |
| 14 | Reserved | 0 | This bit is always read as 0. Writes have no effect. |
| 13-10 | PMD | | Parity on/off |
| | | 0x5 | Parity function disabled |
| | | Others | Parity function enabled |
| 9 | ABO | | Auto-Bus-On enable |
| | | 0 | The Auto-Bus-On feature is disabled |
| | | 1 | The Auto-Bus-On feature is enabled |
| 8 | IDS | | Interruption debug support enable |
| | | 0 | When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode |
| | | 1 | When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately. |
| 7 | Test | | Test mode enable |
| | | 0 | Normal Operation |
| | | 1 | Test Mode |
| 6 | CCE | | Configuration change enable |
| | | 0 | The CPU has no write access to the configuration registers. |
| | | 1 | The CPU has write access to the configuration registers (when Init bit is set). |
| 5 | DAR | | Disable automatic retransmission |
| | | 0 | Automatic retransmission of not successful messages enabled. |
| | | 1 | Automatic retransmission disabled. |
| 4 | Reserved | 0 | This bit is always read as 0. Writes have no effect. |
| 3 | EIE | | Error interrupt enable |
| | | 0 | Disabled - PER, BOff and EWarn bits can not generate an interrupt. |
| | | 1 | Enabled - PER, BOff and EWarn bits can generate an interrupt at DCAN0INT line and affect the interrupt register. |
| 2 | SIE | | Status change interrupt enable |
| | | 0 | Disabled - WakeUpPnd, RxOk, TxOk and LEC bits can not generate an interrupt. |
| | | 1 | Enabled - WakeUpPnd, RxOk, TxOk and LEC can generate an interrupt at DCAN0INT line and affect the interrupt register. |
| 1 | IE0 | | Interrupt line 0 enable |
| | | 0 | Disabled - Module interrupt DCAN0INT is always low. |
| | | 1 | Enabled - interrupts will assert line DCAN0INT to one; line remains active until pending interrupts are processed. |
| 0 | Init | | Initialization |
| | | 0 | Normal operation |
| | | 1 | Initialization mode is entered |

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities.

When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset.

After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the error and status register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

### 5.14.1.2 Error and Status Register (DCAN ES) and DCAN Parity Error EOI Register (PARITYERR_EOI)

The error and status register (DCAN ES) is shown in Figure 5-19 and described in Table 5-12. The DCAN Parity Error EOI register is shown in Figure 5-20 and described in Table 5-13.

**Figure 5-19. Error and Status Register (DCAN ES)**

**Table 5-12. Error and Status Register (DCAN ES) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-11 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 10 | PDA | | Local power-down mode acknowledge |
| | | 0 | DCAN is not in local power-down mode. |
| | | 1 | Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode. |
| 9 | WakeUp Pnd | | Wake up pending. This bit can be used by the CPU to identify the DCAN as the source to wake up the system. |
| | | 0 | No Wake Up is requested by DCAN. |
| | | 1 | DCAN has initiated a wake up of the system due to dominant CAN bus while module power down. |
| | | | This bit will be reset if error and status register is read. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-12. Error and Status Register (DCAN ES) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 8 | PER | | Parity error detected |
| | | 0 | No parity error has been detected since last read access. |
| | | 1 | The parity check mechanism has detected a parity error in the Message RAM. |
| | | | This bit will be reset if error and status register is read. |
| 7 | BOff | | Bus-Off state |
| | | 0 | The CAN module is not bus-off state. |
| | | 1 | The CAN module is in bus-off state. |
| 6 | EWarn | | Warning state |
| | | 0 | Both error counters are below the error warning limit of 96. |
| | | 1 | At least one of the error counters has reached the error warning limit of 96. |
| 5 | EPass | | Error passive state |
| | | 0 | On CAN Bus error, the DCAN could send active error frames. |
| | | 1 | The CAN core is in the error passive state as defined in the CAN Specification. |
| 4 | RxOk | | Received a message successfully |
| | | 0 | No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. |
| | | 1 | A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering). |
| | | | This bit will be reset if error and status register is read. |
| 3 | TxOk | | Transmitted a message successfully |
| | | 0 | No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. |
| | | 1 | A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU. |
| | | | This bit will be reset if error and status register is read. |
| 2-0 | LEC | | Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. |
| | | 0 | No error |
| | | 1 | Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. |
| | | 2 | Form error: A fixed format part of a received frame has the wrong format. |
| | | 3 | Ack error: The message this CAN core transmitted was not acknowledged by another node. |
| | | 4 | Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. |
| | | 5 | Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). |
| | | 6 | CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). |
| | | 7 | No CAN bus event was detected since the last time the CPU read the error and status register. Any read access to the error and status register re-initializes the LEC to value '7.' |

**Table 5-13. Parity Error End of Interrupt Register (PARITYERR_EOI) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 8 | PARITYERR_ EOI | | End of interrupt indication for parity error |
| | | 0 | Has no effect writing |
| | | 1 | Indicated end of interrupt for parity error |
| 7-0 | Reserved | | These bits are always read as 0. Writes have no effect. |

Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN control register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN control register is set).

A change of bit EPass will not generate an interrupt.

PARITYERR_EOI is used to signal an end of interrupt of the parity error interrupt (dcan_parity) to the IP. PARITYERR_EOI register is a *Write only* register.

A read from this offset address will result in a read from the DCAN ES register, where as a write will result in a write to the PARITYERR_EOI register.

**NOTE:** Reading the error and status register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the interrupt register will be replaced by the next lower priority interrupt value. The EOI for all other interrupts (DCANINT0 and DCANINT1) are automatically handled by hardware.

**NOTE:** For debug support, the auto clear functionality of error and status register (clear of status flags by read) is disabled when in debug/suspend mode.

### 5.14.1.3 Error Counter Register (DCAN ERRC)

The error counter register (DCAN ERRC) is shown in Figure 5-21 and described in Table 5-14.

**Figure 5-21. Error Counter Register (DCAN ERRC)**

| 31 | | | | | | | | | | | | | | | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | | | | | | | | | | | | | | | |
| R-0 | | | | | | | | | | | | | | | |
| 15 | 14 | | | | | | 8 | 7 | | | | | | | 0 |
| RP | REC[6:0] | | | | | | | TEC[7:0] | | | | | | | |
| R-0 | R-0 | | | | | | | R-0 | | | | | | | |

LEGEND: R = Read only; -*n* = value after reset

**Table 5-14. Error Counter Register (DCAN ERRC) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 15 | RP | | Receive error passive |
| | | 0 | The receive error counter is below the error passive level. |
| | | 1 | The receive error counter has reached the error passive level as defined in the CAN specification. |
| 14-8 | REC[6:0] | | Receive error counter. Actual state of the receive error counter (values from 0 to 255). |
| 7-0 | TEC[7:0] | | Transmit error counter. Actual state of the transmit error counter (values from 0 to 255). |

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.4 Bit Timing Register (DCAN BTR)

The bit timing register (DCAN BTR) is shown in Figure 5-22 and described in Table 5-15.

**Figure 5-22. Bit Timing Register (DCAN BTR)**

| 31 | 20 | 19 | 16 |
|---|---|---|---|
| Reserved | | BRPE | |
| R-0 | | R-0 | |

| 15 | 14 12 | 11 8 | 7 6 | 5 0 |
|---|---|---|---|---|
| Reserved | TSeg2 | TSeg1 | SJW | BRP |
| R-0 | R/WP-0x2 | R/WP-0x3 | R/WP-0 | R/WP-0x1 |

LEGEND: R = Read only; WP = Write protected by CCE bit; *-n* = value after reset

**Table 5-15. Bit Timing Register (DCAN BTR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-20 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 19-16 | BRPE | 0x00-0x0F | Baud rate prescaler extension.<br>Valid programmed values are 0 to 15.<br>By programming BRPE the baud rate prescaler can be extended to values up to 1024. |
| 15 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 14-12 | TSeg2 | 0x0-0x7 | Time segment after the sample point<br>Valid programmed values are 0 to 7.<br>The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1. |
| 11-8 | TSeg1 | 0x01-0x0F | Time segment before the sample point<br>Valid programmed values are 1 to15.<br>The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1. |
| 7-6 | SJW | 0x0-0x3 | Synchronization Jump Width<br>Valid programmed values are 0 to 3.<br>The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1. |
| 5-0 | BRP | 0x00-0x3F | Baud rate prescaler<br>Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta.<br>Valid programmed values are 0 to 63.<br>The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1. |

**NOTE:** This register is only writable if CCE and Init bits in the CAN control register are set.

**NOTE:** The CAN bit time may be programmed in the range of 8 to 25 time quanta.

**NOTE:** The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

With a CAN_CLK of 8 MHz and BRPE = 0x00, the reset value of 0x00002301 configures the DCAN for a bit rate of 500kBit/s.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.5 Interrupt Register (DCAN INT)

The interrupt register (DCAN INT) is shown in Figure 5-23 and described in Table 5-16.

**Figure 5-23. Interrupt Register (DCAN INT)**

| 31 | 24 | 23 | 16 |
|---|---|---|---|
| Reserved | | Int1ID[7:0] | |
| R-0 | | R-0 | |

| 15 | 0 |
|---|---|
| Int0ID[15:0] | |
| R-0 | |

LEGEND: R = Read only; -*n* = value after reset

**Table 5-16. Interrupt Register (DCAN INT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-24 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 23-16 | Int1ID[23:16] | | Interrupt 1 Identifier (indicates the message object with the highest pending interrupt) |
| | | 0x00 | No interrupt is pending |
| | | 0x01-0x80 | Number of message object which caused the interrupt. |
| | | 0x81-0xFF | Unused |
| | | | If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared. |
| | | | A message interrupt is cleared by clearing the message object's IntPnd bit. |
| | | | Among the message interrupts, the message object's interrupt priority decreases with increasing message number. |
| 15-0 | Int0ID[15:0] | | Interrupt Identifier (the number here indicates the source of the interrupt) |
| | | 0x0000 | No interrupt is pending |
| | | 0x0001-0x0080 | Number of message object which caused the interrupt. |
| | | 0x0081-0x7FFF | Unused |
| | | 0x8000 | Error and status register value is not 0x07. |
| | | 0x8001-0xFFFF | Unused |
| | | | If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. |
| | | | The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. |

### 5.14.1.6 Test Register (DCAN TEST)

The test register (DCAN TEST) is shown in Figure 5-24 and described in Table 5-17.

**Figure 5-24. Test Register (DCAN TEST)**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | | RDA | EXL | Rx | Tx[1:0] | | LBack | Silent | Reserved | | |
| R-0 | | R/WP-0 | R/WP-0 | R-U | R/WP-0 | | R/WP-0 | R/WP-0 | R-0 | | |

LEGEND: R = Read only; WP = Write protected by test bit; *-n* = value after reset; U = Undefined

**Table 5-17. Test Register (DCAN TEST) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 9 | RDA | | RAM direct access enable |
| | | 0 | Normal pperation |
| | | 1 | Direct access to the RAM is enabled while in test mode |
| 8 | EXL | | External loopback mode |
| | | 0 | Disabled |
| | | 1 | Enabled |
| 7 | Rx | | Receive pin. Monitors the actual value of the CAN_RX pin |
| | | 0 | The CAN bus is dominant |
| | | 1 | The CAN bus is recessive |
| 6-5 | Tx[1:0] | | Control of CAN_TX pin |
| | | 00 | Normal operation, CAN_TX is controlled by the CAN core. |
| | | 01 | Sample point can be monitored at CAN_TX pin. |
| | | 10 | CAN_TX pin drives a dominant value. |
| | | 11 | CAN_TX pin drives a recessive value. |
| 4 | LBack | | Loopback mode |
| | | 0 | Disabled |
| | | 1 | Enabled |
| 3 | Silent | | Silent mode |
| | | 0 | Disabled |
| | | 1 | Enabled |
| 2-0 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |

For all test modes, the test bit in CAN control register needs to be set to one. If test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when test bit is cleared.

**NOTE:** The test register is only writable if test bit in CAN control register is set.

**NOTE:** Setting Tx[1:0] other than '00' will disturb message transfer.

**NOTE:** When the internal loop-back mode is active (bit LBack is set), bit EXL will be ignored.

### 5.14.1.7 Parity Error Code Register (DCAN PERR)

The parity error code register (DCAN PERR) is shown in Figure 5-25 and described in Table 5-18.

**Figure 5-25. Parity Error Code Register (DCAN PERR)**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 11 | 10 | 8 | 7 | 0 |
|---|---|---|---|---|---|
| Reserved | | Word Number | | Message Number | |
| R-0 | | R-U | | R-U | |

LEGEND: R = Read only; -*n* = value after reset; U = Undefined

**Table 5-18. Parity Error Code Register (DCAN PERR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-11 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 10-8 | Word Number | 0x01-0x05 | Word number where parity error has been detected<br>RDA word number (1 to 5) of the message object (according to the message RAM representation in RDA mode). |
| 7-0 | Message Number | 0x01-0x80 | Message object number where parity error has been detected |

If a parity error is detected, the PER flag will be set in the error and status register. This bit is not reset by the parity check mechanism; it must be reset by reading the error and status register.

In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number).

If more than one word with a parity error was detected, the highest word number with a parity error will be displayed.

After a parity error has been detected, the register will hold the last error code until power is removed.

### 5.14.1.8 Auto-Bus-On Time Register (DCAN ABOTR)

The Auto-Bus-On time register (DCAN ABOTR) is shown in Figure 5-26 and described in Table 5-19.

**Figure 5-26. Auto-Bus-On Time Register (DCAN ABOTR)**

| 31 | 16 | 15 | 0 |
|---|---|---|---|
| ABO Time[31:16] | | ABO Time[15:0] | |
| R/W-0 | | R/W-0 | |

LEGEND: R = Read only; W = Write only; -*n* = value after reset

**Table 5-19. Auto-Bus-On Time Register (DCAN ABOTR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | ABO Time | | Number of OCP clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit.<br>This function has to be enabled by setting bit ABO in CAN control register.<br>The Auto-Bus-On timer is realized by a 32-bit counter that starts to count down to zero when the module goes Bus-Off.<br>The counter will be reloaded with the preload value of the ABO time register after this phase. |

**NOTE:** On write access to the CAN control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.

**NOTE:** During Debug/Suspend mode, running Auto-Bus-On timer will be paused.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.9 Transmission Request X Register (DCAN TXRQ X)

With the transmission request X register (DCAN TXRQ X), the CPU can detect if one or more bits in the different transmission request registers are set. Each register bit represents a group of eight message objects. If at least one of the TxRqst bits of these message objects are set, the corresponding bit in the transmission request X register will be set. The transmission request X register is shown in Figure 5-27.

**Figure 5-27. Transmission Request X Register (DCAN TXRQ X)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | | | | | | | | | | | | | | | |

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| TxRqstReg8 | | TxRqstReg7 | | TxRqstReg6 | | TxRqstReg5 | | TxRqstReg4 | | TxRqstReg3 | | TxRqstReg2 | | TxRqstReg1 | |
| R-0 | | R-0 | | R-0 | | R-0 | | R-0 | | R-0 | | R-0 | | R-0 | |

LEGEND: R = Read only; -*n* = value after reset

**Example 1.** Bit 0 of the transmission request X register represents byte 0 of the transmission request 1 register. If one or more bits in this byte are set, bit 0 of the transmission request X register will be set.

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.10 Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

These registers hold the TxRqst bits of the implemented message objects. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific message object can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

The transmission request registers are shown in Table 5-20 and described in Table 5-21.

**Table 5-20. Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0x88 CAN TXRQ12 | TxRqst[32:17] | | | | | | | | | | | | | | | |

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | TxRqs[128:1] | | Transmission request bits (for all message objects) |
| | | 0 | No transmission has been requested for this message object. |
| | | 1 | The transmission of this message object is requested and is not yet done. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.11 New Data X Register (DCAN NWDAT X)

With the new data X register, the CPU can detect if one or more bits in the different new data registers are set. Each register bit represents a group of eight message objects. If at least on of the NewDat bits of these message objects are set, the corresponding bit in the new data X register will be set.

The new data X register (DCAN NWDAT X) is shown in Figure 5-28.

**Figure 5-28. Transmission Request X Register (DCAN TXRQ X)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 5.14.1.12 New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

These registers hold the NewDat bits of the implemented message objects. By reading out these bits, the CPU can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

The new data registers (DCAN NWDAT12 to DCAN NWDAT78) are shown in Table 5-22 and described in Table 5-23.

**Table 5-22. New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |

### 5.14.1.13 Interrupt Pending X Register (DCAN INTPND X)

With the interrupt pending X register, the CPU can detect if one or more bits in the different interrupt pending registers are set. Each bit of this register represents a group of eight message objects. If at least one of the IntPnd bits of these message objects are set, the corresponding bit in the interrupt pending X register will be set.

The interrupt pending X register (DCAN INTPND X) is shown in Figure 5-29.

**Figure 5-29. Interrupt Pending X Register (DCAN INTPND X)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 5.14.1.14 Interrupt Pending Registers (DCAN INTPND12 to DCAN INTPND78)

These registers hold the IntPnd bits of the implemented message objects. By reading out these bits, the CPU can check for pending interrupts in the message objects. The IntPnd bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The interrupt pending registers (DCAN INTPND12 to DCAN INTPND78) are shown in Table 5-24 and described in Table 5-25.

**Table 5-24. New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |

### 5.14.1.15 Message Valid X Register (DCAN MSGVAL X)

With the message valid X register, the CPU can detect if one or more bits in the different message valid registers are set. Each bit of this register represents a group of eight message objects. If at least one of the MsgVal bits of these message objects are set, the corresponding bit in the message valid X register will be set.

The message valid X register (DCAN MSGVAL X) is shown in Figure 5-30.

**Figure 5-30. Message Valid X Register (DCAN MSGVAL X)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 5.14.1.16 Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the CPU can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The message valid registers (DCAN MSGVAL12 to MSGVAL78) is shown in Table 5-26 and described in Table 5-27.

**Table 5-26. Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |

### 5.14.1.17 Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register.

The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

The interrupt multiplexer registers are shown in Table 5-28 and described in Table 5-29.

**Table 5-28. Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |

### 5.14.1.18 IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD)

The IF1/IF2 Command Register (DCAN IF1CMD, DCAN IF2CMD) configure and initiate the transfer between the IF1/IF2 register sets and the message RAM. It is configurable which portions of the message object should be transferred.

A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress.

After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

The IF1/IF2 command registers are shown in Figure 5-31 and Figure 5-32 and described in Table 5-30.

**NOTE:** While Busy bit is one, IF1/IF2 register sets are write protected.

**NOTE:** For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode.

**NOTE:** If an invalid Message Number is written to bits [7:0] of the IF1/IF2 command register, the message handler may access an implemented (valid) message object instead.

**Table 5-30. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-24 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 23 | WR/RD | | Write/Read |
| | | 0 | Direction = Read: Transfer direction is from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set. |
| | | 1 | Direction = Write: Transfer direction is from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]). |
| 22 | Mask | | Access mask bits |
| | | 0 | Mask bits will not be changed |
| | | 1 | Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set. |
| | | | Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]). |
| 21 | Arb | | Access arbitration bits |
| | | 0 | Arbitration bits will not be changed |
| | | 1 | Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 register set. |
| | | | Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]). |
| 20 | Control | | Access control bits |
| | | 0 | Control bits will not be changed |
| | | 1 | Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF1/IF2 registerset. |
| | | | Direction = Write: The message control bits will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]). |
| | | | If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF1/IF2 message control register will be ignored. |
| 19 | ClrIntPnd | | Clear interrupt pending bit |
| | | 0 | IntPnd bit will not be changed |
| | | 1 | Direction = Read: Clears IntPnd bit in the message object. |
| | | | Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1/IF2 Registers to message RAM can only be controlled by the control flag (Bit [20]). |
| 18 | TxRqst/NewDat | | Access transmission request bit |
| | | 0 | Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit. |
| | | 1 | Direction = Read: Clears NewDat bit in the message object.<br>Direction = Write: Sets TxRqst/NewDat in message object. |
| | | | Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF1/IF2 message control Register. |
| | | | Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1/IF2 message control registeralways reflect the status before resetting them. |
| 17 | Data A | | Access Data Bytes 0-3 |
| | | 0 | Data Bytes 0-3 will not be changed. |
| | | 1 | Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset. |
| | | | Direction = Write: The data bytes 0-3 will be transferred from the IF1/IF2 registerset to the message object addressed by the Message Number (Bits [7:0]). |
| | | | Note: The duration of the message transfer is independent of the number of bytes to be transferred. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-30. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 16 | Data B | | Access Data Bytes 4-7 |
| | | 0 | Data Bytes 4-7 will not be changed. |
| | | 1 | Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset. |
| | | | Direction = Write: The data bytes 4-7 will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]). |
| | | | Note: The duration of the message transfer is independent of the number of bytes to be transferred. |
| 15 | Busy | | Busy flag |
| | | 0 | No transfer between IF1/IF2 register set and message RAM is in progress. |
| | | 1 | Transfer between IF1/IF2 register set and message RAM is in progress. |
| | | | This bit is set to one after the message number has been written to bits [7:0]. IF1/IF2 register set will be write protected. The bit is cleared after read/write action has been finished. |
| 14 | DMAactive | | Activation of DMA feature for subsequent internal IF1/IF2 update |
| | | 0 | DMA request line is independent of IF1/IF2 activities. |
| | | 1 | DMA is requested after completed transfer between IF1/IF2 register set and message RAM. |
| | | | The DMA request remains active until the first read or write to one of the IF1/IF2 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one. |
| | | | Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately. |
| 13-8 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 7-0 | Message Number | | Number of message object in message RAM which is used for data transfer |
| | | 0x00 | Invalid message number |
| | | 0x01-0x80 | Valid message numbers |
| | | 0x81-0xFF | Invalid message numbers |

### 5.14.1.19 IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK)

The bits of the IF1/IF2 mask registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 mask registers (DCAN IF1MSK, DCAN IF2MSK) are shown in Figure 5-33 and Figure 5-34 and described in Table 5-31.

**NOTE:** While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

**Figure 5-33. IF1 Mask Register (DCAN IF1MSK)**

| 31 | 30 | 29 | 28 | 16 |

**Table 5-31. IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | MXtd | | Mask Extended Identifier |
| | | 0 | The extended identifier bit (IDE) has no effect on the acceptance filtering. |
| | | 1 | The extended identifier bit (IDE) is used for acceptance filtering. |
| | | | When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered. |
| 30 | MDir | | Mask Message Direction |
| | | 0 | The message direction bit (Dir) has no effect on the acceptance filtering. |
| | | 1 | The message direction bit (Dir) is used for acceptance filtering. |
| 29 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 28-0 | Msk[28:0] | | Identifier Mask |
| | | 0 | The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care). |
| | | 1 | The corresponding bit in the identifier of the message object is used for acceptance filtering. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.20 IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB)

The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 arbitration registers (DCAN IF1ARB, DCAN IF2ARB) are shown in Figure 5-35 and Figure 5-36 and described in Table 5-32.

**NOTE:** While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

**Figure 5-35. IF1 Arbitration Register (DCAN IF1ARB)**

| 31 | 30 | 29 | 28 ... 16 |
|---|---|---|---|
| MsgVal | Xtd | Dir | ID[28:16] |
| R/WP-0 | R/WP-0 | R/WP-0 | R/WP-0 |

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

**Figure 5-36. IF2 Arbitration Register (DCAN IF2ARB)**

| 31 | 30 | 29 | 28 ... 16 |
|---|---|---|---|
| MsgVal | Xtd | Dir | ID[28:16] |
| R/WP-0 | R/WP-0 | R/WP-0 | R/WP-0 |

| 15 ... 0 |
|---|
| ID[15:0] |
| R/WP-0 |

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

**Table 5-32. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | MsgVal | | Message valid |
| | | 0 | The message object is ignored by the message handler. |
| | | 1 | The message object is to be used by the message handler. |
| | | | The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN control register. This bit must also be reset before the identifier ID[28:0], the control bits Xtd, Dir or DLC[3:0] are modified, or if the messages object is no longer required. |
| 30 | Xtd | | Extended identifier |
| | | 0 | The 11-bit (“standard”) Identifier is used for this message object. |
| | | 1 | The 29-bit (“extended”) Identifier is used for this message object. |
| 29 | Dir | | Message direction |
| | | 0 | Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object. |
| | | 1 | Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1). |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-32. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 28-0 | ID[28:0] | | Message identifier |
| | | ID[28:0] | 29-bit identifier (extended frame) |
| | | ID[28:18] | 11-bit identifier (standard frame) |

The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

### 5.14.1.21 IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL)

The bits of the IF1/IF2 message control registers mirror the message control bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 message control registers (DCAN IF1MCTL, DCAN IF2MCTL) are shown in Figure 5-37 and Figure 5-38 and described in Table 5-33.

**NOTE:** While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

**Table 5-33. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 15 | NewDat | | New data |
| | | 0 | No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the CPU. |
| | | 1 | The message handler or the CPU has written new data into the data portion of this message object. |
| 14 | MsgLst | | Message lost (only valid for message objects with direction = receive) |
| | | 0 | No message lost since the last time when this bit was reset by the CPU. |
| | | 1 | The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten. |
| 13 | IntPnd | | Interrupt pending |
| | | 0 | This message object is not the source of an interrupt. |
| | | 1 | This message object is the source of an interrupt. The Interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority. |
| 12 | UMask | | Use acceptance mask |
| | | 0 | Mask ignored |
| | | 1 | Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering |
| | | | If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. |

**Table 5-33. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 11 | TxIE | | Transmit interrupt enable |
| | | 0 | IntPnd will not be triggered after the successful transmission of a frame. |
| | | 1 | IntPnd will be triggered after the successful transmission of a frame. |
| 10 | RxIE | | Receive interrupt enable |
| | | 0 | IntPnd will not be triggered after the successful reception of a frame. |
| | | 1 | IntPnd will be triggered after the successful reception of a frame. |
| 9 | RmtEn | | Remote enable |
| | | 0 | At the reception of a remote frame, TxRqst is not changed. |
| | | 1 | At the reception of a remote frame, TxRqst is set. |
| 8 | TxRqst | | Transmit request |
| | | 0 | This message object is not waiting for a transmission. |
| | | 1 | The transmission of this message object is requested and is not yet done. |
| 7 | EoB | | End of Block |
| | | 0 | The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. |
| | | 1 | The message object is a single message object or the last message object in a FIFO Buffer Block. |
| | | | Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. |
| 6-4 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 3-0 | DLC[3:0] | | Data length code |
| | | 0-8 | Data frame has 0-8 data bits. |
| | | 9-15 | Data frame has 8 data bytes. |
| | | | Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. |

### 5.14.1.22 IF1/IF2 Data A and Data B Registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB)

The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order:

1. In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received.
2. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

The IF1/IF2 data A and data B registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB) registers are shown in Figure 5-39, Figure 5-40, Figure 5-41 and Figure 5-42.

### 5.14.1.23 IF3 Observation Register (DCAN IF3OBS)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU (Additional information can be found in *Structure of Message Objects*).

The observation flags (Bits [4:0]) in the IF3 observation register are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

**NOTE:** If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register.

The status of the current read-cycle can be observed via status flags (Bits [12:8]).

If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device-specific data sheet for the availability of this interrupt source.

With this interrupt, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

The IF3 observation register (DCAN IF3OBS) is shown in Figure 5-43 and described in Table 5-34.

**Figure 5-43. IF3 Observation Register (DCAN IF3OBS)**

### 5.14.1.24 IF3 Mask Register (DCAN IF3MSK)

The IF3 mask register (DCAN IF3MSK) is shown in Figure 5-44 and described in Table 5-35.

**Figure 5-44. IF3 Mask Register (DCAN IF3MSK)**

| 31 | 30 | 29 | 28 | 16 |
|---|---|---|---|---|
| MXtd | MDir | Rsvd | Msk[28:16] | |
| R-1 | R-1 | R-1 | R/WP-0x1FFF | |

| 15 | 0 |
|---|---|
| Msk[15:0] | |
| R/WP-0xFFFF | |

LEGEND: R = Read only; -*n* = value after reset

**Table 5-35. IF3 Mask Register (DCAN IF3MSK) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | MXtd | | Mask Extended Identifier |
| | | 0 | The extended identifier bit (IDE) has no effect on the acceptance filtering. |
| | | 1 | The extended identifier bit (IDE) is used for acceptance filtering. |
| | | | When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered. |
| 30 | MDir | | Mask Message Direction |
| | | 0 | The message direction bit (Dir) has no effect on the acceptance filtering. |
| | | 1 | The message direction bit (Dir) is used for acceptance filtering. |
| 29 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 28-0 | Msk[28:0] | | Identifier Mask |
| | | 0 | The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care). |
| | | 1 | The corresponding bit in the identifier of the message object is used for acceptance filtering. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.25 IF3 Arbitration Register (DCAN IF3ARB)

The IF3 arbitration register (DCAN IF3ARB) is shown in Figure 5-45 and described in Table 5-36.

**Figure 5-45. IF3 Arbitration Register (DCAN IF3ARB)**

| 31 | 30 | 29 | 28 | 16 |
|---|---|---|---|---|
| MsgVal | Xtd | Dir | ID[28:16] | |
| R-0 | R-0 | R-0 | R-0 | |

| 15 | 0 |
|---|---|
| ID[15:0] | |
| R-0 | |

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

**Table 5-36. IF3 Arbitration Register (DCAN IF3ARB) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | MsgVal | | Message Valid |
| | | 0 | The message object is ignored by the message handler. |
| | | 1 | The message object is to be used by the message handler. |
| | | | The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN control register. This bit must also be reset before the identifier ID[28:0], the control bits Xtd, Dir or DLC[3:0] are modified, or if the messages object is no longer required. |
| 30 | Xtd | | Extended Identifier |
| | | 0 | The 11-bit (“standard”) Identifier is used for this message object. |
| | | 1 | The 29-bit (“extended”) Identifier is used for this message object. |
| 29 | Dir | | Message Direction |
| | | 0 | Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object. |
| | | 1 | Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1). |
| 28-0 | ID[28:0] | | Message Identifier |
| | | ID[28:0] | 29-bit Identifier (“extended frame”) |
| | | ID[28:18] | 11-bit Identifier (“standard frame”) |

| R-0 | R-0 | R-0 | R-0 | R-0 | R-0 | R-0 | R-0 | R-0 | R-0 | R-0 |

LEGEND: R = Read only; -*n* = value after reset

**Table 5-37. IF3 Message Control Register (DCAN IF3MCTL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |
| 15 | NewDat | | New Data |
| | | 0 | No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the CPU. |
| | | 1 | The message handler or the CPU has written new data into the data portion of this message object. |
| 14 | MsgLst | | Message Lost (only valid for message objects with direction = receive) |
| | | 0 | No message lost since the last time when this bit was reset by the CPU. |
| | | 1 | The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten. |
| 13 | IntPnd | | Interrupt Pending |
| | | 0 | This message object is not the source of an interrupt. |
| | | 1 | This message object is the source of an interrupt. The Interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority. |
| 12 | UMask | | Use Acceptance Mask |
| | | 0 | Mask ignored |
| | | 1 | Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering |
| | | | If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. |
| 11 | TxIE | | Transmit Interrupt enable |
| | | 0 | IntPnd will not be triggered after the successful transmission of a frame. |
| | | 1 | IntPnd will be triggered after the successful transmission of a frame. |
| 10 | RxIE | | Receive Interrupt enable |
| | | 0 | IntPnd will not be triggered after the successful reception of a frame. |
| | | 1 | IntPnd will be triggered after the successful reception of a frame. |
| 9 | RmtEn | | Remote enable |
| | | 0 | At the reception of a remote frame, TxRqst is not changed. |
| | | 1 | At the reception of a remote frame, TxRqst is set. |
| 8 | TxRqst | | Transmit Request |
| | | 0 | This message object is not waiting for a transmission. |
| | | 1 | The transmission of this message object is requested and is not yet done. |
| 7 | EoB | | End of Block |
| | | 0 | The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. |
| | | 1 | The message object is a single message object or the last message object in a FIFO Buffer Block. |
| | | | Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. |
| 6-4 | Reserved | 0 | These bits are always read as 0. Writes have no effect. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 5-37. IF3 Message Control Register (DCAN IF3MCTL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 3-0 | DLC[3:0] | | Data Length Code |
| | | 0-8 | Data frame has 0-8 data bits. |
| | | 9-15 | Data frame has 8 data bytes. |
| | | | Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 5.14.1.27 IF3 Data A and Data B Registers (DCAN IF3DATA/DATB)

The data bytes of CAN messages are stored in the IF3 registers in the following order.

In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

The IF3 data A and data B registers (DCAN IF3DATA/DATB) are shown in Figure 5-47 and Figure 5-48.

**Figure 5-47. IF3 Data A Register (DCAN IF3DATA)**

### 5.14.1.28 Update Enable Registers (DCAN IF3UPD12 to IF3UPD78)

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set.

The update enable registers (DCAN IF3UPD12 to IF3UPD78) are shown in Table 5-38 and described in Table 5-39.

**NOTE:** IF3 Update enable should not be set for transmit objects.

**Table 5-38. Update Enable Registers (DCAN IF3UPD12 to IF3UPD78))**

| Offset/Register | 31/15 | 30/14 | 29/13 | 29/12 | 27/11 | 26/10 | 25/9 | 24/8 | 23/7 | 22/6 | 21/5 | 20/4 | 19/3 | 18/2 | 17/1 | 16/0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

### 5.14.1.29 CAN TX I/O Control Register (DCAN TIOC)

The CAN_TX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN TX I/O control register (DCAN TIOC) is shown in Figure 5-49 and described in Table 5-40.

**NOTE:** The values of the IO control registers are only writable if Init bit of the CAN control register is set.

**NOTE:** The OD, Func, Dir and Out bits of the CAN TX IO control register are forced to certain values when Init bit of CAN control register is reset (see bit descriptions).

**Figure 5-49. CAN TX I/O Control Register (DCAN TIOC)**

### 5.14.1.30 CAN RX IO Control Register (DCAN RIOC)

The CAN_RX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN RX I/O control register (DCAN RIOC) is shown in Figure 5-50 and described in Table 5-41.

**NOTE:** The values of the IO control registers are writable only if Init bit of CAN control register is set.

**NOTE:** The OD, Func and Dir bits of the CAN RX IO control register are forced to certain values when the Init bit of CAN control register is reset (see bit descriptions).

## 6.1 Introduction

### 6.1.1 Overview

This section describes the Dynamic Memory Manager (DMM) and its Tiling and Isometric Lightweight Engine for Rotation (TILER) submodule.

As shown in Figure 6-1, the DMM is located in front to the SDRAM controllers and thus interfaces to the memory accesses generated by all the initiators.

The dynamic memory manager (DMM), is a module aimed at managing – in a broad sense – various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM memory interleaving configuration
- Block object transfer optimization – tiling and sub-tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability – and, hence, the run-time nature – of the four aspects of memory management handled by the DMM.

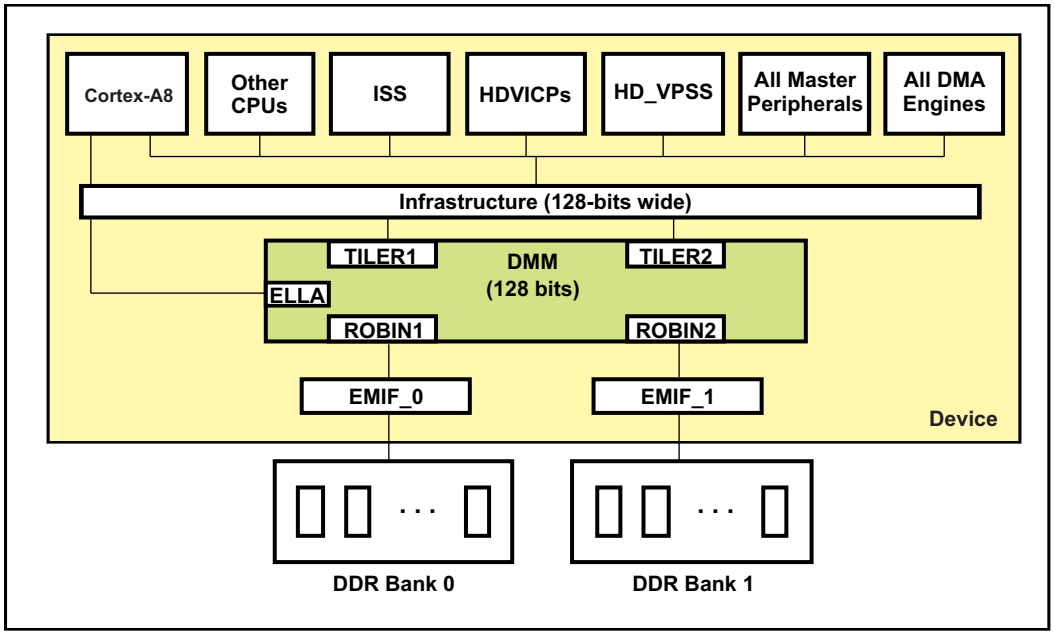
On a functional perspective, the role of the DMM is to:

- add initiator-based priority to any incoming requests
- perform to-and-fro tiling conversions of "tiled" requests
- provide an optional low-latency page-based translation to handle memory fragmentation - MMU
- distribute the traffic on both the attached memory controllers according to the interleaving configuration

The TILER is a submodule within the DMM aimed at efficient handling of two dimensional data, such as video/graphics accesses for HDVICP2, by the use of tiled format.

- optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- making on-the-fly, zero overhead transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection

**Figure 6-1. DMM Integration**



Copyright © 2011–2016, Texas Instruments Incorporated

### 6.1.2 Features

- Special low latency interconnect port. ELLA, only for Cortex-A8 accesses.
- Ability to interleave the DDR data between two EMIF banks, using the programmable multi-zone DRAM memory mapping . This increases the memory throughput by a factor of 2. Up-to four unique memory sections supported.
- Programmable Initiator based request priority extension, for up to 16 Initiator groups.
- Support for address translations of tiled data, on a 4KB page granularity using the PAT. This helps manage memory fragmentation.
- One internal address lookup table (LUT) with 256x128 entries. Four refill engines to program the LUT, with automatic synchronized reload.
- Supports up to 4 unique PAT views.

### 6.1.3 Functional Block Diagram

Figure 6-2 shows the DMM macro architecture. The DMM consists of six blocks:

- A Priority Extension Generator (PEG) to generate priorities required by the SDRAM controller, note that these priorities are not used in the DMM
- One Extra Low Latency Access (ELLA), having its own interconnect slave port, for providing lower latency accesses to the memory
- A Local Interconnect and Synchronization Agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers
- A Physical Address Translator (PAT) for managing the memory fragmentation
- Two Re-Ordering Buffer and Initiator Nodes (ROBIN), having each their own interconnect master port, to initiate requests to the SDRAM controller and allow tiled data, tiled response and split response reconstruction. The ROBIN block is only managing the re-ordering buffer and performing the data re-ordering due to the orientation.
- Two Tiling and Isometric Lightweight Engine for Rotation (TILER), having each their own interconnect slave port, for converting requests to-and-fro between the input virtual addressing mode and the output physical tiled addressing mode. Note that, the tiling conversions of requests, write data and responses is fully performed in the TILER blocks.

### 6.1.4 Terminologies and Acronyms Used in this Document

The following is a brief explanation of some terms used in this document:

**bpp—** Bits per pixel

**DMM—** Dynamic Memory Manager

**ELLA—** Extra Low Latency Access

**GB, GiB—** Both imply Giga Byte

**Initiator—** A node inside the Device and is either a CPU, peripheral or DMA engine, which can be internal bus Master. Each initiator is identified by a ConnID (Connection ID). With a limit of only 16 ConnIDs, some of the Initiators are grouped together with same ConnID.

**Interlaced—** Qualifier for accesses skipping one line every line

**IVA—** Image Video Accelerator. Also called HDVICP2, IVA_HD.

**LISA—** Local Interconnect and Synchronisation Agent

**KB, KiB—** Both imply Kilo Byte

**LUT—** Look Up Table

**MMU—** Memory Management Unit

**MPU—** Main Processing Unit. For this device, it is Cortex-A8

**PAT—** Physical Address Translator

**PEG—** Priority Extension Generator

**Progressive—** Qualifier for line-by-line accesses

**ROBIN—** Re-Ordering Buffer and Initiator Node

**Tiled access—** 1D or 2D Access to the tiled area, where the image data is read and written in two dimensional format, to improve the efficiency of accesses of 2D accesses, example image macro block. TILER Tiling and Isometric Lightweight Engine for Rotation 1D access A simple linear read or write access request. The DMM responds with read/write from/to the contiguous memory starting with address specified in the request.

**2D access—** HDVICP2 and HD_VPSS, can generate a special access to 2D image buffers, with read/write request, with Height and Width information. The DMM-TILER decodes the access type based on the Height, width and address, and responds with read/write from/to data in the physical memory, which has been co-located, with sub-tile granularity.

## 6.2 Architecture

### 6.2.1 DMM Functional Description

#### 6.2.1.1 Priority Extension Generator (PEG)

The priority extension generator (PEG) is a dynamic software-programmable initiator-indexed table of priorities. Its unique role is to generates priorities for each access forwarded by the DMM to the SDRAM controller. For initiators that do not generate their own per-transaction priority, the priority value that is programmed in the table, will be assigned to all SDRAM accesses generated by that initiator. These priorities are not used by the DMM, for internal arbitrations.

The 64 priority entries are software-programmable with DMM_PEG_PRIO0 (for the first eight entries of the ConnID table) through DMM_PEG_PRIO7 (for the last eight entries) registers and set on a 3-bit scale, ranging from values 0-7, with Priority=0, being the highest priority.

When a request is passed to the SDRAM controller, the priority from the corresponding DMM_PEG_PRIOx field for an initiator is passed to SDRAM. For example, an access from the C674x DSP is sent to SDRAM with the priority captured in DMM_PEG_PRIOn. Note that the priority does not impact the behavior in DMM itself. It is passed to the SDRAM controller and the controller may use it in the prioritization of requests. However, for HD_VPSS, the peripheral itself generates a priority. The DMM_PEG_PRIOx field for HD_VPSS is bypassed and the priority indicated by HD_VPSS access is sent to SDRAM controller.

#### 6.2.1.2 ELLA

The Extra Low Latency Access (ELLA) of the DMM is a simple interface port for all accesses made by Cortex-A8. As the name suggests, this interface is simplified to reduce latency to the request from Cortex-A8. In this respect, the ELLA block:

- Is limited to 1D bursts only
- Is not capable of performing tiling conversions
- Does not interact with the PAT block

The ELLA block main role is to split incoming requests at DMM atomic unit boundaries to ensure that requests sent to the SDRAM controller fit in a single SDRAM page. More precisely, the ELLA block is responsible for:

- Allocating an internal response context to timely generate the appropriate responses
- Splitting the incoming requests at DMM atomic section boundaries
- Requesting internal buffer allocation in the appropriate ROBIN
- In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer

**NOTE:** In the device, Cortex-A8 accesses in the system address space of 8000 0000h-FFFF FFFFh, are only routed through ELLA port. Accesses made by Cortex-A8, in the all four tiled modes, including Paged mode, will be routed through the TILER ports, thus not getting benefit of lower latency of the ELLA port.

ELLA sub-module is not software configurable.

#### 6.2.1.3 LISA

The Local Interconnect and Synchronisation Agent (LISA) is a hardware interconnect module, aimed at setting priorities, managing tags and memory mapping. LISA maps the system addresses on the incoming DMM requests to the SDRAM addresses, as per the LISA sections programming.

LISA interconnect routes:

1. ELLA and TILER requests on the ROBIN initiator nodes.
2. ELLA and TILER write data on the ROBIN write buffers.

Copyright © 2011–2016, Texas Instruments Incorporated

3. ROBIN read data to the relevant TILER initiators or to ELLA initiator.

The LISA block registers are DMM_LISA_MAP_i (i = 0 to 3) and DMM_LISA_LOCK.

LISA block manages all the incoming requests to ELLA, TILER and PAT and translates then to requests to Registers and ROBIN ports. Highest priority is given to accesses coming to the low-latency port (ELLA). When both DMM-ROBIN ports are in use, LISA module interleaves the two ports at a programmable boundary from 128 Bytes or more, as programmed in the DMM_LISA_MAPn registers. See sub-section on Section Mapping for details about LISA sections programming.

#### *6.2.1.3.1 LISA LOCK*

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to one, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK itself cannot be written back to 0. A reset is required to re-program the sections.

It is expected that LISA MAP is set up once during system configuration and not changed subsequently. The LOCK feature helps accomplish this and is expected to be set once the configuration is done.

### 6.2.1.4 PAT, Physical Address Translator Engine

The physical address translation engine (PAT) of the DMM is composed of two 32-k entry physical address translation vector table and a set of four refill engines. The refill engine is a specialized DMA aimed at refilling the content of the physical address translation table.

The address translation mechanism is only available when the incoming request is hitting a page mode or tiled mode container, that is, when the incoming address is targeting the TILER or its aliased view in the system addressing space. Otherwise the physical address translation logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT is supporting multiple address translation schemes, called views, which can be bound to one or more initiator through a view mapping mechanism.

The usage of the Refill Engines is described in detail in the later section.

#### *6.2.1.4.1 PAT Views*

A PAT view defines the kind of physical address translation to perform for each tiled mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to either use PAT Direct Access Translation or PAT In-Direct Access Translation.

The PAT supports up to four unique Views, using the DMM_PAT_VIEW_MAP[0..3] Registers.

#### *6.2.1.4.2 PAT View Mappings*

The 16 groups of initiators of the Device, each identified by their ConnID, share a set of 4 PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. The register DMM_PAT_VIEW0 is used for the first eight initiator groups and DMM_PAT_VIEW1 for the second eight. Thus each initiator can choose one of the four configurable PAT views in the system.

#### *6.2.1.4.3 PAT View Map Base Address*

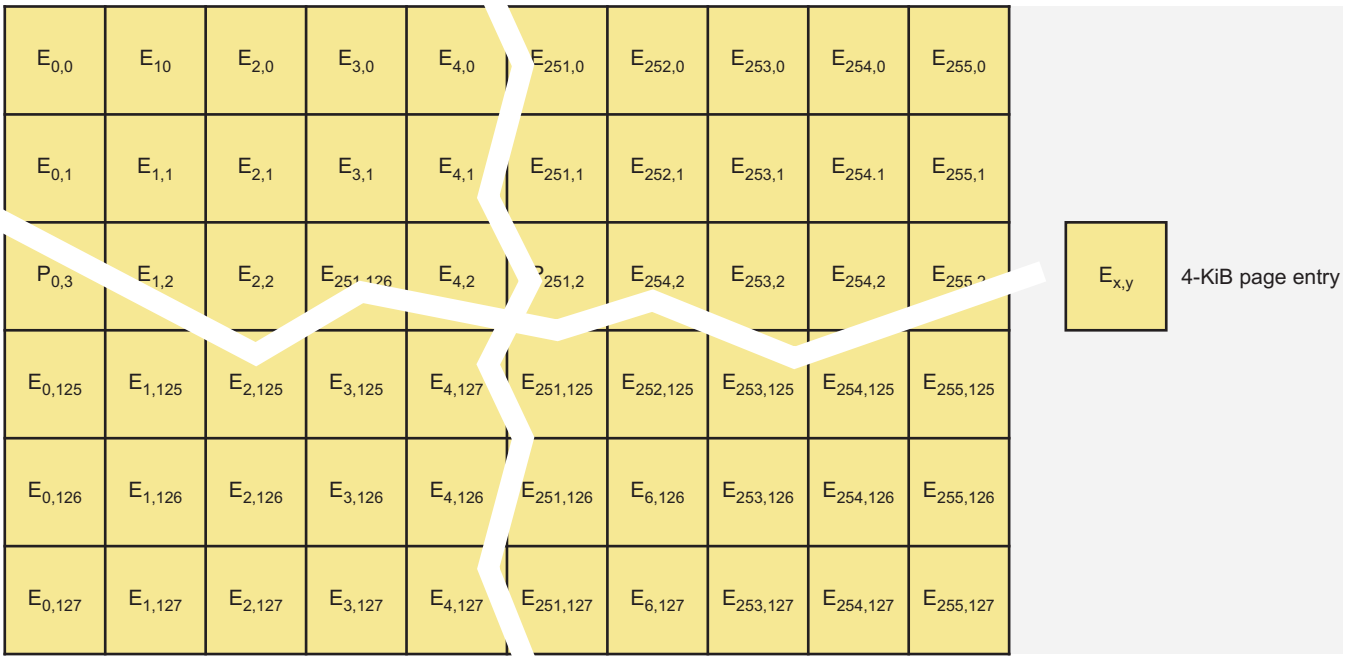
The PAT view map base address is defining the base address of all PAT translated addresses. The bit 31 of all PAT translated address is set to BASE_ADDR. In the Device, the bit 31 should be set to 1, which corresponds top 2GB assigned for external SDRAM in the system memory map. Hence the addresses translated by PAT range in addresses 8000 0000h-FFFF FFFFh.

#### *6.2.1.4.4 PAT - Look Up Tables (LUTs)*

The PAT contains one LUT, having 32K (256 × 128) entries. This geometry corresponds to that of the Virtual TILER container. So incoming address maps the actual entry in the LUT. The PAT shall then translate to a physical memory mapped to any 4K page the DDR. Each entry of the PAT address corresponds to the page in the DMM container that has the same location. For example - The entry (74, 42) in the table corresponds to the page (74, 42) in any DMM container.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 6-3. DMM Look-Up Table**



Each of this entry points to a 4K page in the memory. Hence a total of 128 MB of tiled memory can be mapped using one LUT. With upto 2G of DDR space, supported in the Device, each LUT entry is 19 bits wide.

The PAT uses the LUTs only in case of PAT In-Direct Access Translation.

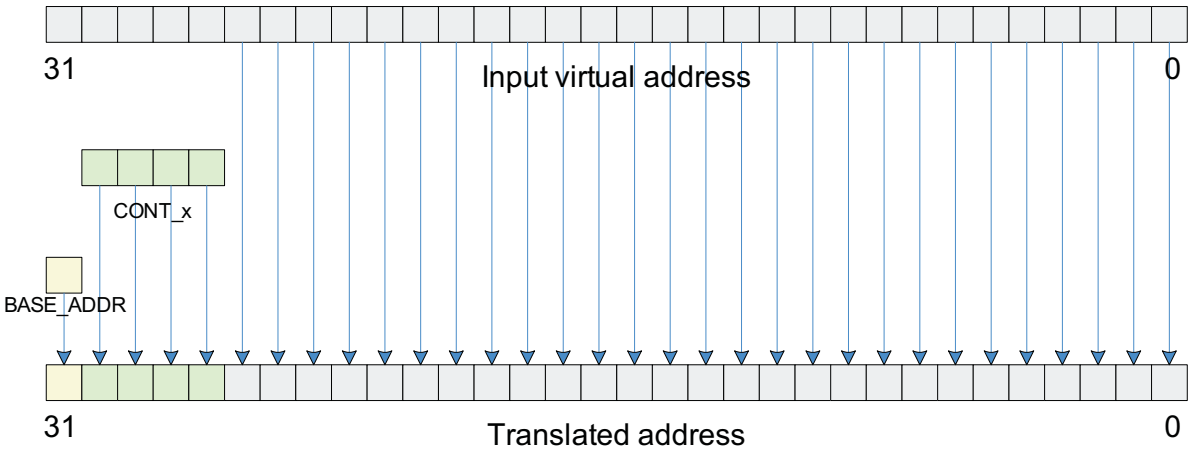
#### *6.2.1.4.5 PAT Direct Access Translation*

The container-grained translation is named the direct access. In this mode, the translation vector is directly given by the CONT_x field, in DMM_PAT_VIEW_MAP register, corresponding to the accessed mode(8-bit/16-bit/32-bit/paged mode).

With PAT Direct Access translation, the 128 MB virtual containers for all the four modes, 8-bit, 16-bit, 32-bit, and paged modes can be mapped to their unique System Address, by defining their base addresses.

Figure 6-4 describes the actual translation that happens.

**Figure 6-4. DMM PAT Direct Access Translation**



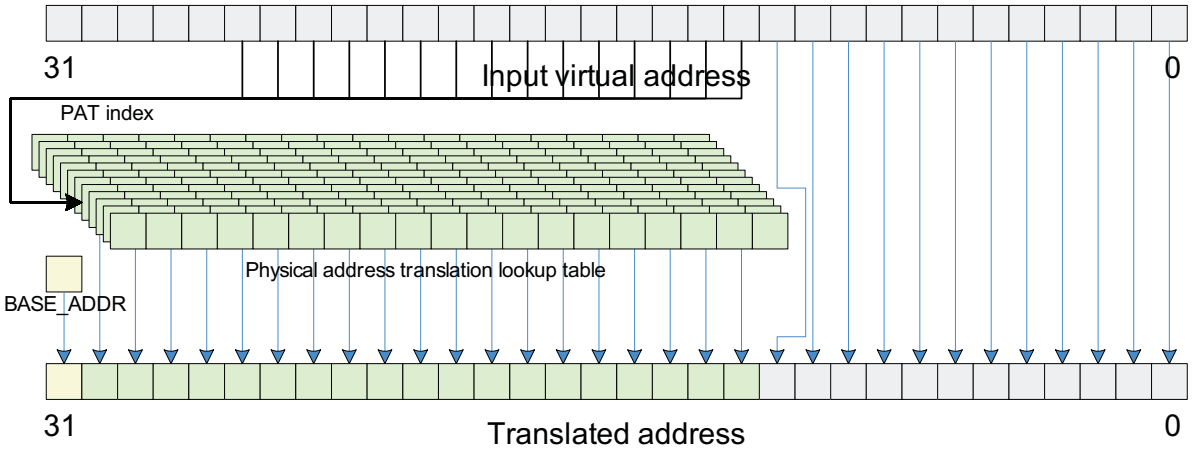
Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.1.4.6 PAT In-Direct Access Translation - Paged Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. In case of In-direct access translation, the single LUT in the system is used for address lookup. Then bits [19:12] of input address specify the X co-ordinate and bits [26:20] of input address specify the Y co-ordinate LUT entry. The PAT replaces bits[30:12] of input address, with 19-bit value specified in LUT entry.

This translation happens on the 4K page boundary and hence the lower 12 bits are not translated. Figure 6-5 describes the actual translation that happens.

**Figure 6-5. DMM PAT In-Direct Access Translation**



#### 6.2.1.4.7 PAT In-Direct Access Translation - 8-bit, 16-bit, 32-bit Mode Access

DMM_PAT_VIEW[0..3] specify, whether to do Direct or In-direct access translation. Per each of the 8-bit,16-bit ,32-bit and paged container mode, user specifies which LUT to use for address lookup, by using CONT_x field, in DMM_PAT_VIEW_MAP registers.

How the 26 LSBs of this incoming virtual address is interpreted by the PAT is different for 8-bit,16-bit ,32-bit mode accesses, as compared to the paged mode access described in the preceding section. Please refer the TILER section describes the rationale behind decoding the address this way.

Virtual address decoding in 8-bit mode access mode is:

- Bits 0:5 - 6 bits offset into the horizontal line of the page
- Bits 6:13 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 14:19 - 6 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 8 bit mode, their value is binary (01100), that is address in range 6000 0000h-67FF FFFFh

Virtual address decoding in 16-bit mode access mode is:

- Bit 0 - is always 0, as accesses are at-least 16-bit aligned
- Bits 1:6 - 6 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 16 bit mode, their value is binary (01101), that is address in range 6800 0000h-

Copyright © 2011–2016, Texas Instruments Incorporated

6FFF FFFFh

Virtual address decoding in 32-bit mode access mode is:

- Bit 0,1 - are always 0, as accesses are at-least 32-bit aligned
- Bits 2:6 - 5 bits offset into the horizontal line of the page
- Bits 7:14 - 8 bits, that select horizontal page in the tiler container as well as the X co-ordinate of the LUT table
- Bits 15:19 - 5 bits offset to select the line inside the page
- Bits 20:26 - 7 bits, that select vertical page in the tiler container and also Y co-ordinate of the LUT table
- Bits 27:31 - In 32 bit mode, their value is binary (01110), that is address in range 7000 0000h-77FF FFFFh

#### 6.2.1.5 ROBIN

The re-ordering buffer and initiator node (ROBIN) is a block aimed at providing some working buffering for converting data and responses to-and-fro between raster and tiled organizations and a master port to connect to the SDRAM controller.

The ROBIN block does:

- Request Forwarding
- Buffering of Write access data and buffering of Read access Response data
- Keeps write data ordering
- Intra-word tiling and orientation transforms
- Tag handling

**NOTE:** Both ROBIN sub-modules are not software configurable.

#### 6.2.1.6 Section Mapping

In the device, DMM supports two unique SDRAM controllers, with a software configurable option to interleave data between both banks, at granularity of 128 Bytes, 256 Bytes and 512 Bytes. When accessing tiled data in 8-bit, 16-bit and 32-bit modes, which in the interleaved section of the memory, the interleaving will happen at the tile boundary of 1KB, over-riding the interleaving definition of the section.

For optimal system performance, it is recommended to enable interleaving between the 2 EMIF banks and thus have same sized memory on both the EMIF banks. Example : 512MB of DDR3 on EMIF bank 0 and 512MB of DDR3 on EMIF bank 1, for a total system DDR3 memory of 1GB.

**NOTE:** This interleaving is supported only if DDRs system connected to both the SDRAM controllers have same electrical characteristics.

If for cost reduction, one chooses to build a system with asymmetrical memory on both EMIF banks, then a few limited configurations can be supported by using the LISA section programming feature of DMM.

The address mapping inside the DMM is configurable through up to four sections. Each section is defined based on:

- Its system address: the base address of the decoding range for the section. This is the address of the incoming access to the DMM, also referred to as System Address.
- Its size: the encoding is the number of bits actually used in the upper 8-bits of the incoming system address. Hence the size of the section can be a value 16MB-2GB and power of 2. With interleaving enabled, the minimum size of the section is 32 MB.
- Its physical address: the base address of the memory range access in the external memory controller. It is also referred to as SDRC address.
- The target memory controller: A section may hit either of EMIF banks or both.

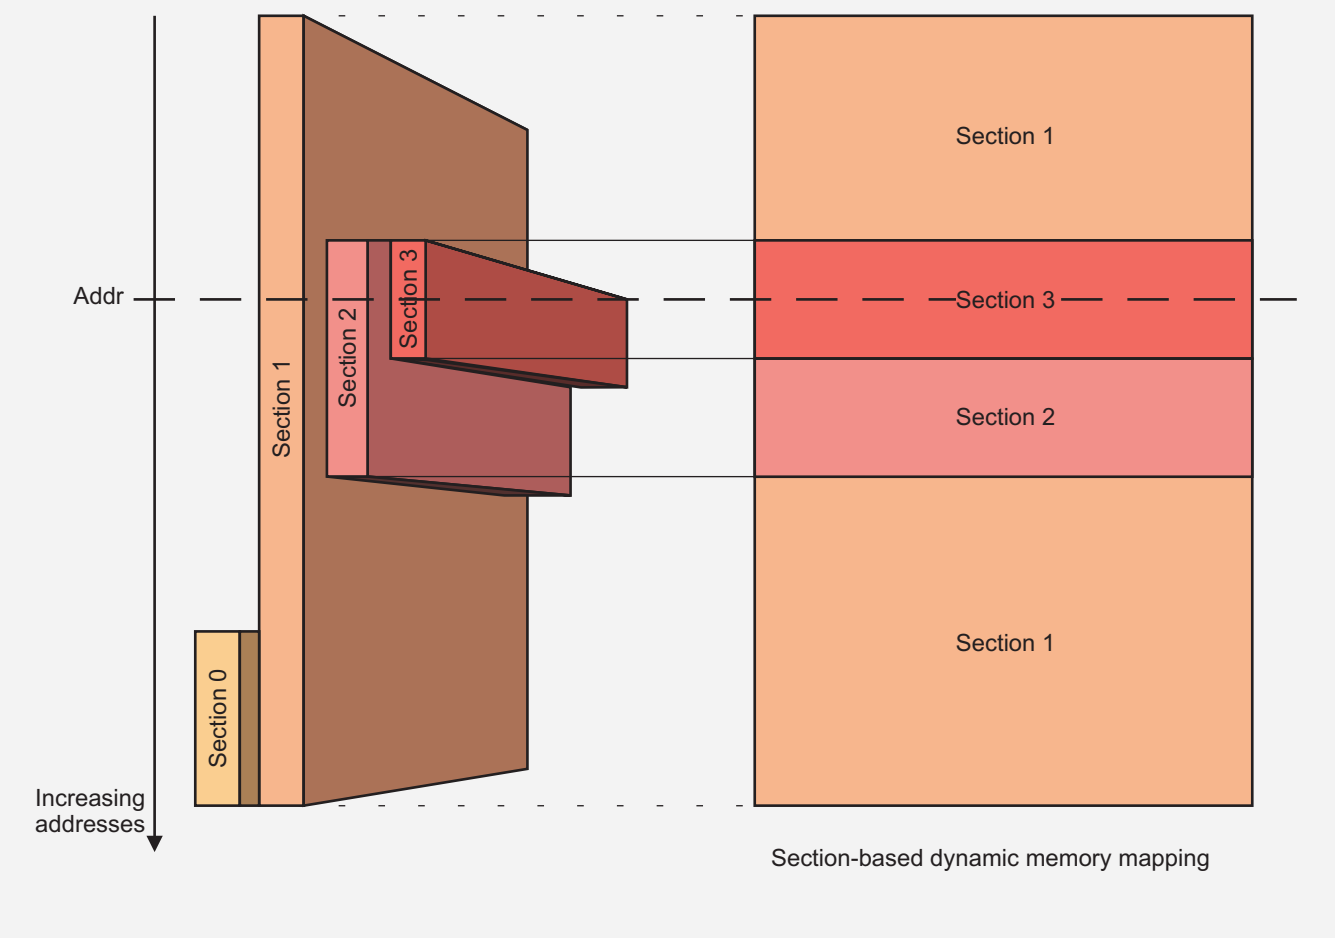
Copyright © 2011–2016, Texas Instruments Incorporated

- Its interleaving definition : Interleave at 128Bytes, 256 Bytes, 512 Bytes or no interleaving.

A LISA section is:

- a memory segment of size 16MB – 2GB, which is a power of two and aligned to that size in the system map. If the section is configured to interleave data between 2 EMIF, then the minimum section size is 32 MB.
- An area with constant interleaving scheme, with fixed interleaving granularity. Interleaving between 2 EMIF banks can be also disabled, for this section.
- If two sections overlap, then the property of higher section number will be applied, as shown in Figure 6-6. There can be a total of 4 unique section definition in DMM.

**Figure 6-6. DMM Section and Memory Mapping**



In Figure 6-6, a request at the system address Addr will follow the interleaving scheme of section 3, although hitting sections 1, 2 and 3. Similarly, this DMM configuration also prevents any request to use the interleaving scheme of section 0, since section 0 is fully masked by section 1 – which has a higher priority.

The DMM section specifies the range of incoming (to DMM) System address (granularity of 16 MB) and how it maps to the physical SDRC address of EMIF0 and/or EMIF 1, with similarly aligned granularity.

The interleaving of data between two EMIF banks is transparent to all the initiators of the system and will not require special address conversions. Figure 6-7 and Figure 6-8 give examples of all the interleaving schemes.

#### 6.2.1.7 TILER

As can be seen in Figure 6-2, the two TILER ports interface to the incoming accesses to DMM. Its primary function is increase efficiency of a 2D Tiled Block access. Mentioned below are the main functions of the TILER module:

1. primary handling efficiently 2 dimensional data mapped in tiles, such as video or graphics macro blocks.
2. optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation, on 4KB page granularity.
3. making isometric – distance preserving – transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection, with no overhead.

Written differently, the functionality of this TILER module is to map a 2D virtually-addressed incoming request into one or more physically-addressed SDRAM requests by:

1. Decoding the incoming access address to qualify whether the request targets the TILER or the memory directly.
2. If the incoming access is a TILER-specific requests, then transforming to the virtual address, data and byte enable to match the requested 0°, 90°, 180°, or 270° orientation in a tiled 2D addressing space.
3. optionally translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing, as shown in Figure 6-9.
4. Splitting tiled requests at tile boundaries and non-tiled requests at DMM atomic section boundaries
5. Requesting the page-based address translation
6. Requesting buffer allocation in the appropriate ROBIN.
7. In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer.

**Figure 6-9. Overview of Request Conversion**

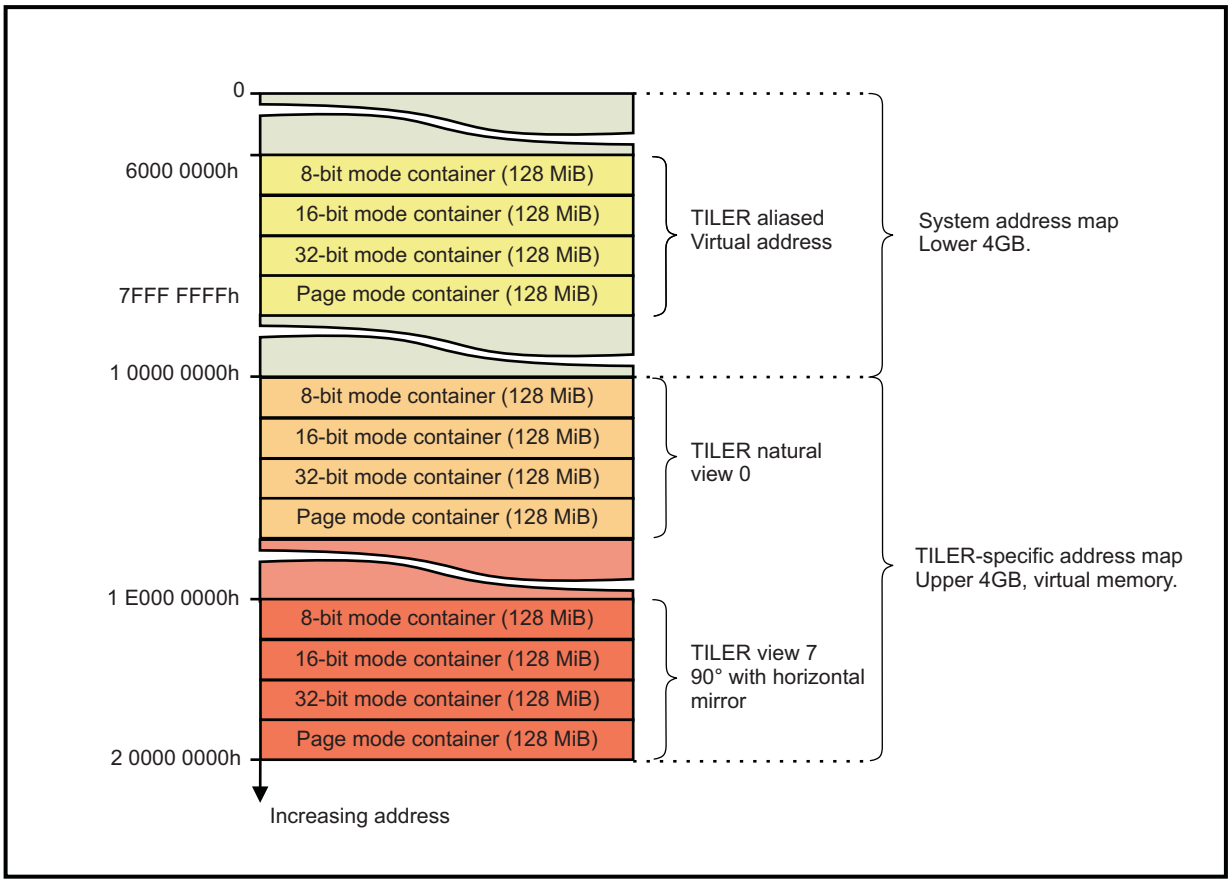
#### 6.2.1.7.1 Device Memory Map - For Tiled Data

In the Device, the initiators read and write tiled data by generating accesses to the tiled space by the one of the two methods:

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh), and allows any of the eight 512-MB oriented sub-spaces – or views – to be remapped in the system virtual addressing space.

**Figure 6-10. Memory Map**



**NOTE:** Despite the larger virtual address windows, 512 MB in the system memory map and 4GB in the TILER memory map, the maximum size of physical tiled data is only 128MB. This 128MB is co-located in a 128MB aligned space, if using PAT direct access translation. In case of using the optional PAT Indirect access translation, then this 128MB is mapped to any location in the SDRAM, using the LUT tables, at the granularity of 4KB page.

#### 6.2.1.8 Clock

The DMM is a synchronous design and operates from the same clock as the internal L3 interconnect. All timings use this clock as a reference.

#### 6.2.1.9 Interrupts

DMM module generates interrupt to Cortex-A8, for status and error conditions related to PAT refills engines. There 8 different conditions which can be individually enabled or disabled. With 4 Refill engines, there are total 32 unique sources of interrupts.

Refer to Section 6.3.3 for detailed description on using the PAT refill engines.

Per Refill engine, status and error conditions are mentioned below:

1. FILL_DSCn: Refill of any descriptor, for engine n, complete.
2. FILL_LSTn: Refill of the last descriptor, for engine n, complete.
3. ERR_INV_DSCn: Invalid descriptor pointer, for engine n.
4. ERR_INV_DATAn: Invalid data table pointer, for engine n.
5. ERR_UPD_AREAn: Error caused by area register update while refilling, for engine n.
6. ERR_UPD_CTRLn: Error caused by control register update while refilling, for engine n.
7. ERR_UPD_DATAn: Error caused by data register update while refilling, for engine n.
8. ERR_LUT_MISSn: Access to a yet-to-be-filled entry, that is part of the area being refilled, for engine n.

The six error conditions mentioned above are also reported in the respective DMM_PAT_STATUSn register.

#### 6.2.1.10 Address Translations Within DMM, For Tiled Accesses

This section describes address translations that happen at various interfaces within DMM, for tiled accesses.

From a user perspective, the PAT can be seen as an additional step in the process applied to the tiled addresses by the TILER:

- the TILER first transforms a tiled address into a 27 bit physical address which fits within a 128MB address range.
- the PAT then processes the high order bits of the physical address output by the TILER, and outputs a 32-bit physical address which covers a 4GB address range. Section 6.2.1.4 describes the exact details for this address translation.

The purpose of the PAT is to map the tiled data anywhere in the 4GB physical address range, with a PAGE granularity (The TILER page is the granularity of physical memory allocation in TILER container. Each page is 4KB). This can be summed-up in Figure 6-11 where the PAT process appears in red.

Only the high order bits of the physical address are modified by the PAT: the 12 low-order bits remain unchanged. This means that the data ordering within each 4kB PAGE remains as calculated by the TILER.

A PAT view is defining the kind of physical address translation to perform for each of the page, 8-bit, 16-bit and 32-bit mode accesses. Each mode in each PAT view can be programmed in 2 different modes (direct translation and indirect translation) which will be described in PAT section. Note that indirect mode is the most commonly used. Direct mode is used only for debug or in case of a DMM without PAT module.

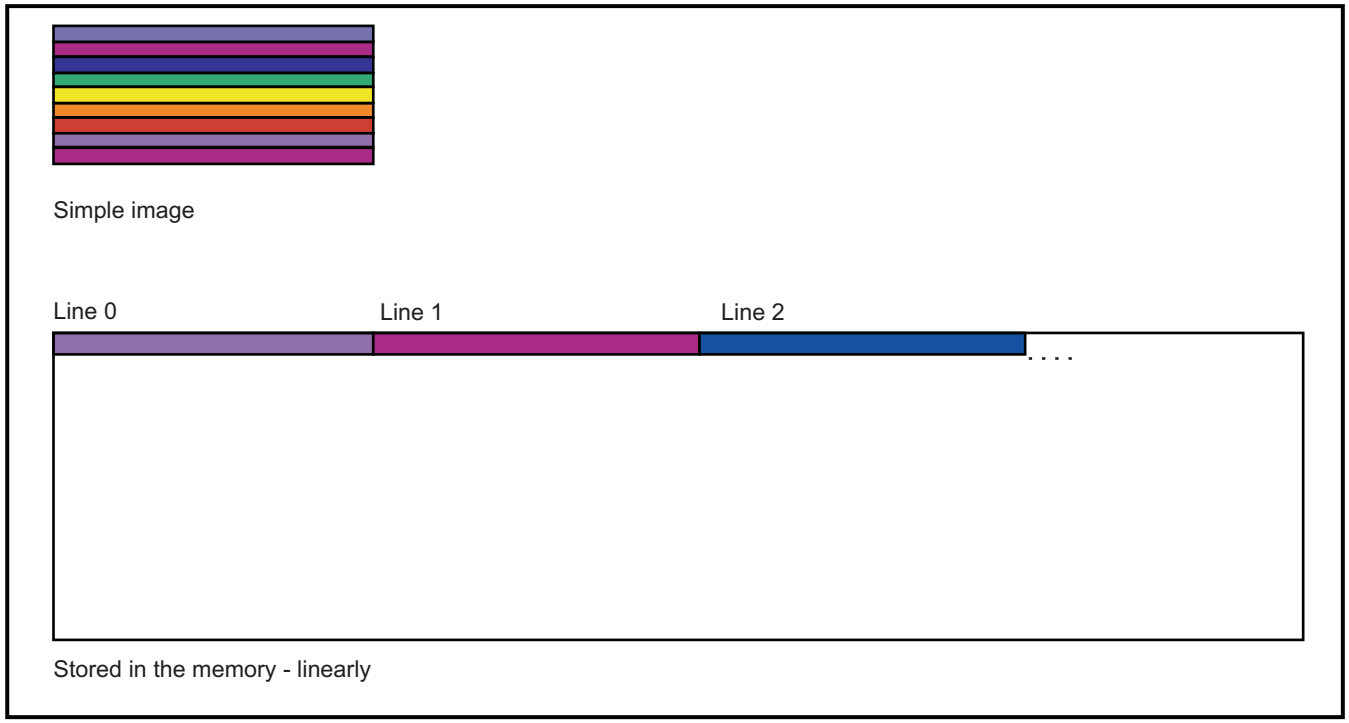
## 6.2.2 TILER Functional Description

### 6.2.2.1 Introduction to TILER

#### 6.2.2.1.1 Need for a TILER

Image processing algorithms like H.264 encode and decode, which works on the principle of spatial locality, access the image data in two-dimensional format, for example, 16 pixels wide by 16 pixels high. If the image is stored in the memory in linear format then it would appear as in Figure 6-12. Thus, to access the macroblock, multiple memory accesses would need to be made. In the device, each memory access can be up to 128 bytes large. However, because macroblock is not stored contiguously in the memory, only partial pixels is useful in each memory access and the rest is discarded and a new access is generated to fetch rest of the data.

**Figure 6-12. Image Stored in the Memory Linearly**



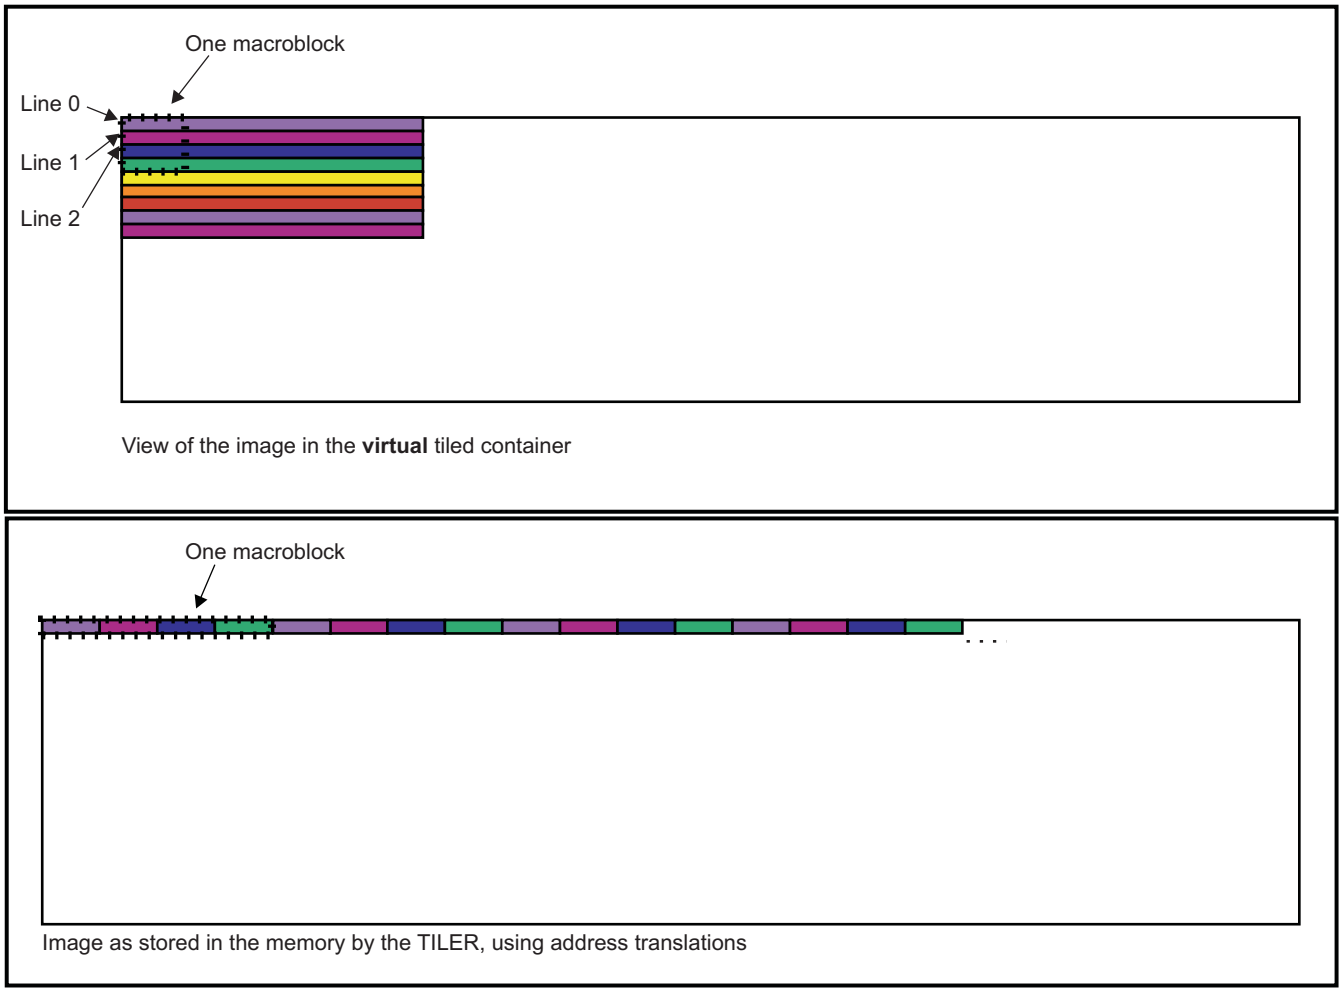
Instead, if the image is stored in bi-dimensional format, much fewer accesses are needed to read the entire macroblock of data, which directly transforms into several advantages:

1. Faster processing of algorithms.
2. Fewer SDRAM page opens.
3. Lesser wastage of memory bandwidth in the system.

This concept is the primary motive for storing the image data in the tiled format.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 6-13. Image Stored in the Memory by TILER**



NOTE : This is only a pictorial representation and actual arrangement of the data in the 128-bit subtile may be different.

#### *6.2.2.1.2 Consuming Tiled Data*

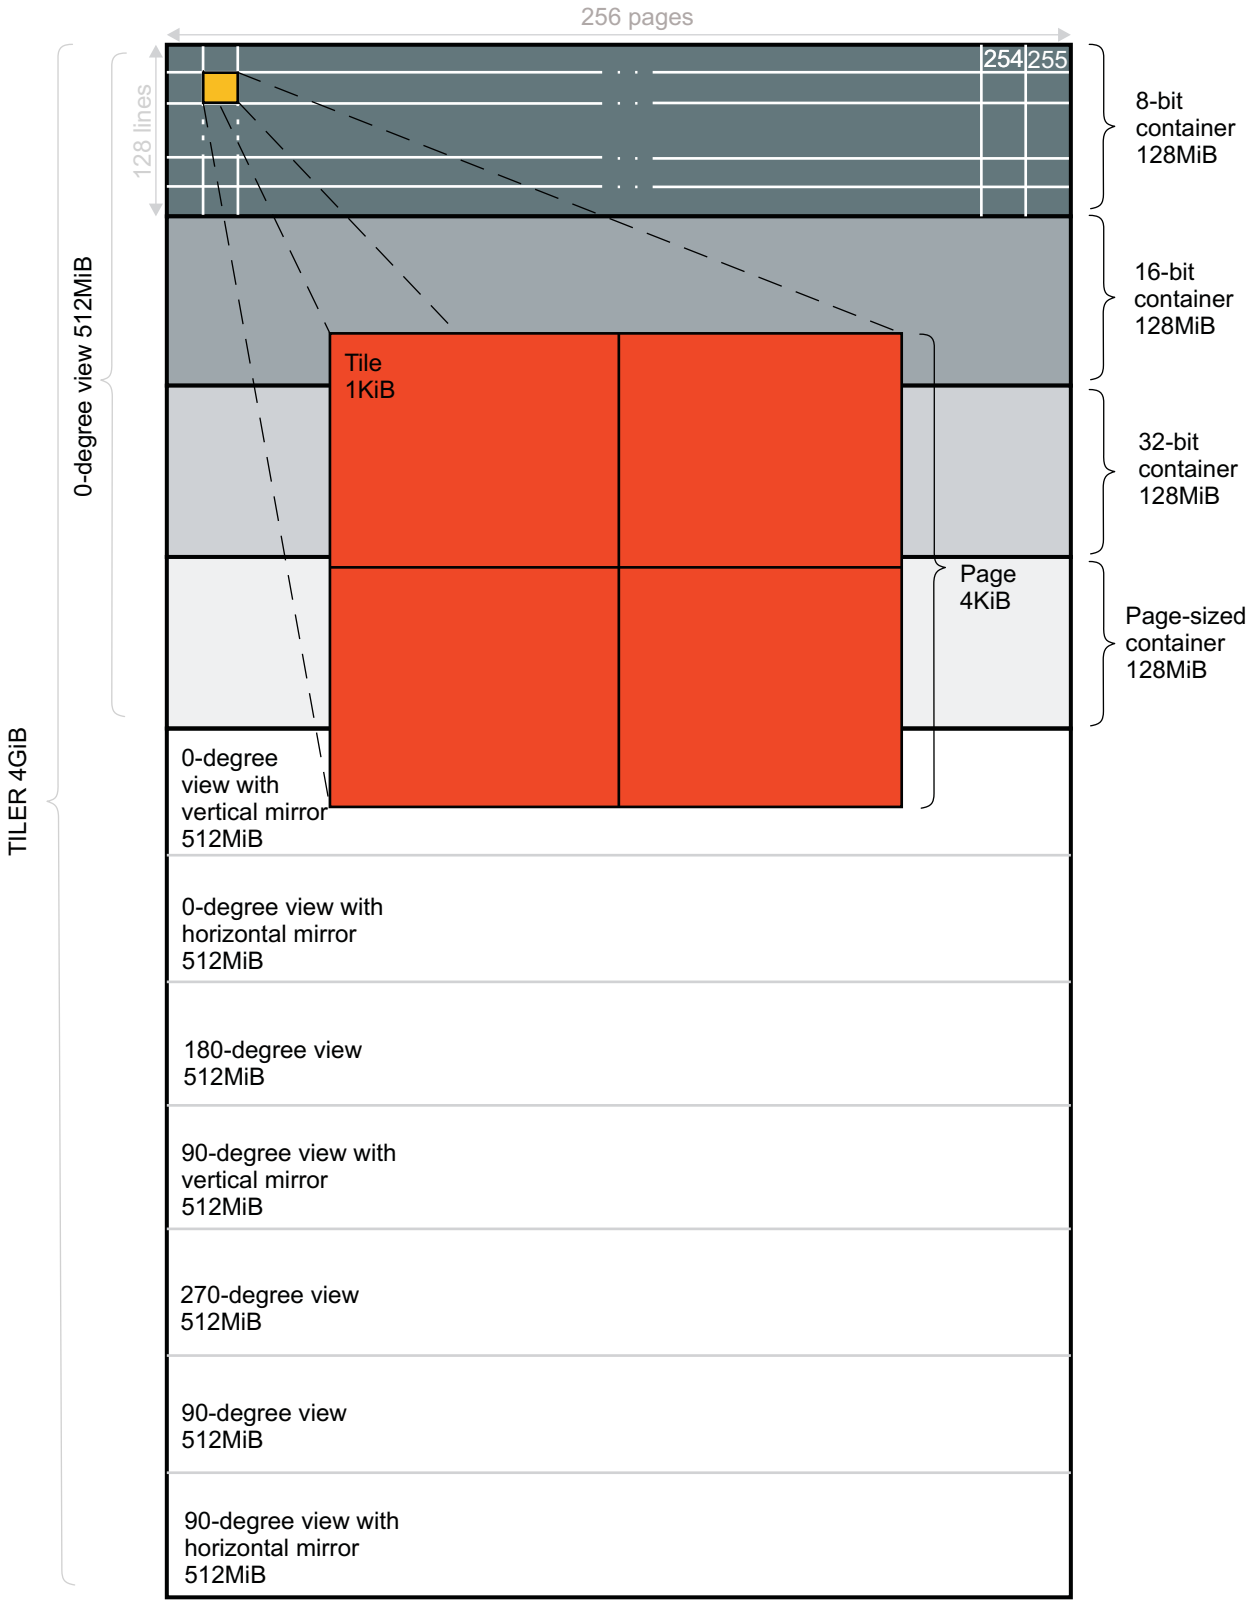
In the device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its capture and display paths (called clients). For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or $2^{2n}$ number of lines.

### 6.2.2.2 TILER Rationale - A Top-down Approach

This section is a synthesis of all TILER concepts, through a top-down approach starting from the main object container, giving one rule per TILER structure level. Figure 6-14 shows the TILER address space structure for tiled modes.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 6-14. Address Space Structure for Tiled Modes**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.2.1 The TILER is a 4-GB Virtual Address Space Composed of Eight Views

A TILER is addressed using a virtual 4 GB address space, containing 8 unique orientation views of 512 MB each. There is one view for each of the eight possible way of scanning a frame-buffer.

1. From left to right then from top to bottom (0 natural orientation)
2. From right to left then from top to bottom
3. From left to right then from bottom to top
4. From right to left then from bottom to top
5. From top to bottom then from left to right
6. From top to bottom then from right to left
7. From bottom to top then from left to right
8. From bottom to top then from right to left

Section 6.2.2.7 summarizes how the view can be visualized on a 128MB TILER container.

#### 6.2.2.2.2 A View is a 512-MB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated. The element is the entity of maximum size - 8 bits, 16 bits, 32 bits or page-sized - which is invariant in any orientation.

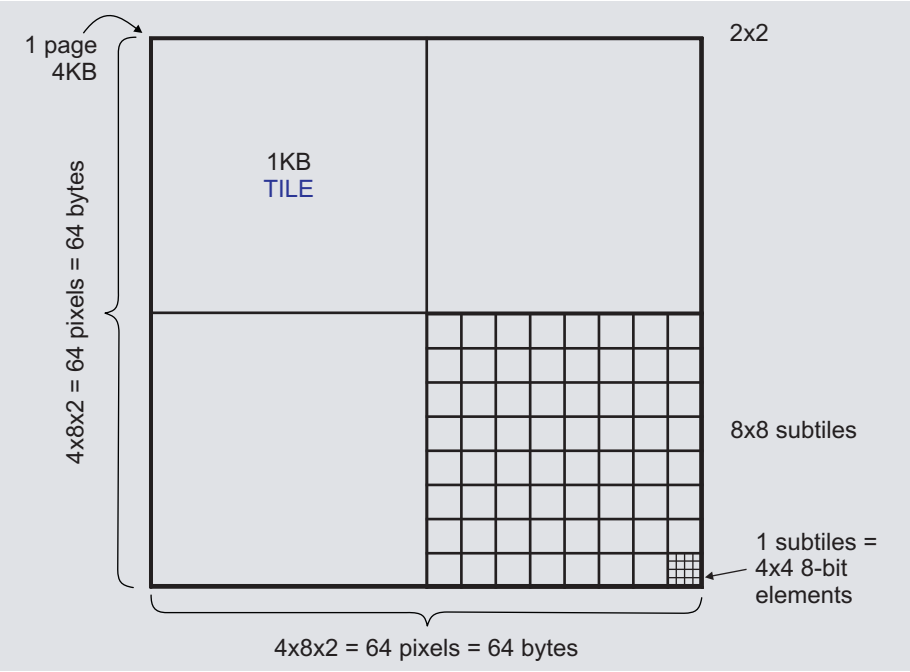
#### 6.2.2.2.3 A Container is a 128-MB Virtual Address Space

A 128 MB container can be visualized as an array of 128 x 256 pages of 4 KB each. The page defines the granularity of physical memory allocation through a physical address translation unit - MMU.

#### 6.2.2.2.4 A Page is a 4-KB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles. Figure 6-15, Figure 6-16, and Figure 6-17 illustrate the Page geometry for 8-,16-, and 32-bit views, respectively.

**Figure 6-15. 4KB Page, 8-bit Mode**



Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 6-16. 4KB Page, 16-bit Mode**

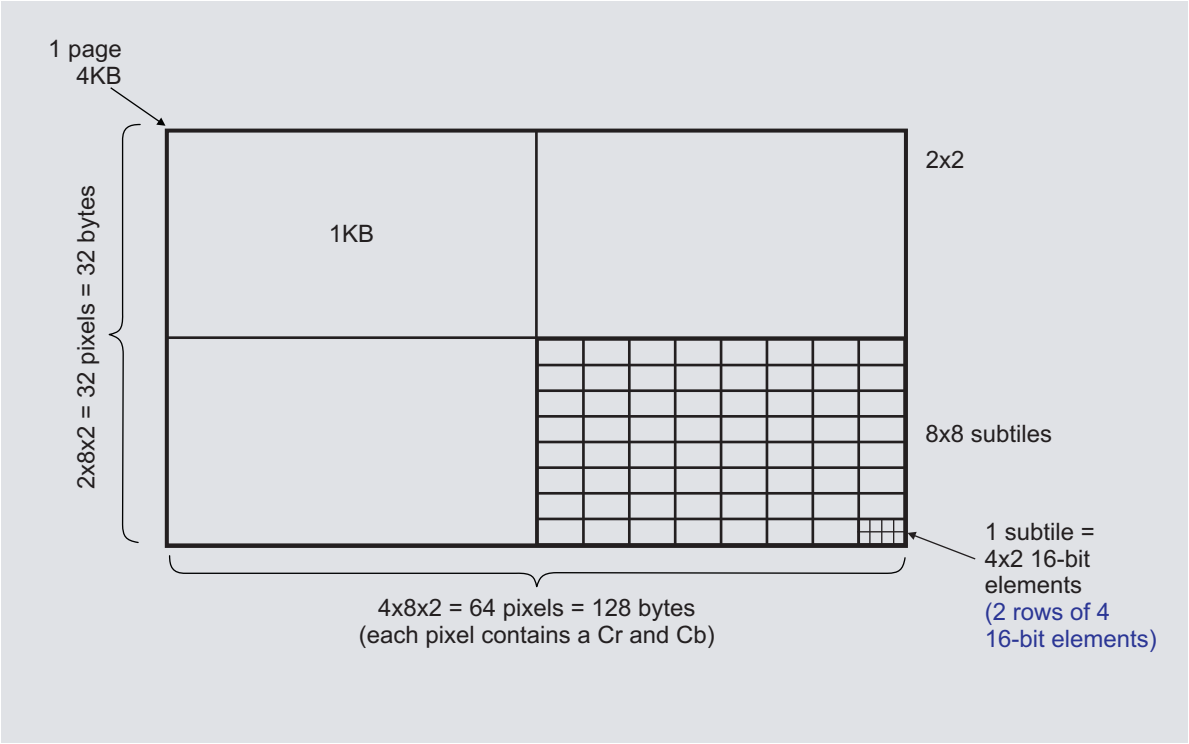


**Figure 6-17. 4KB Page, 32-bit Mode**

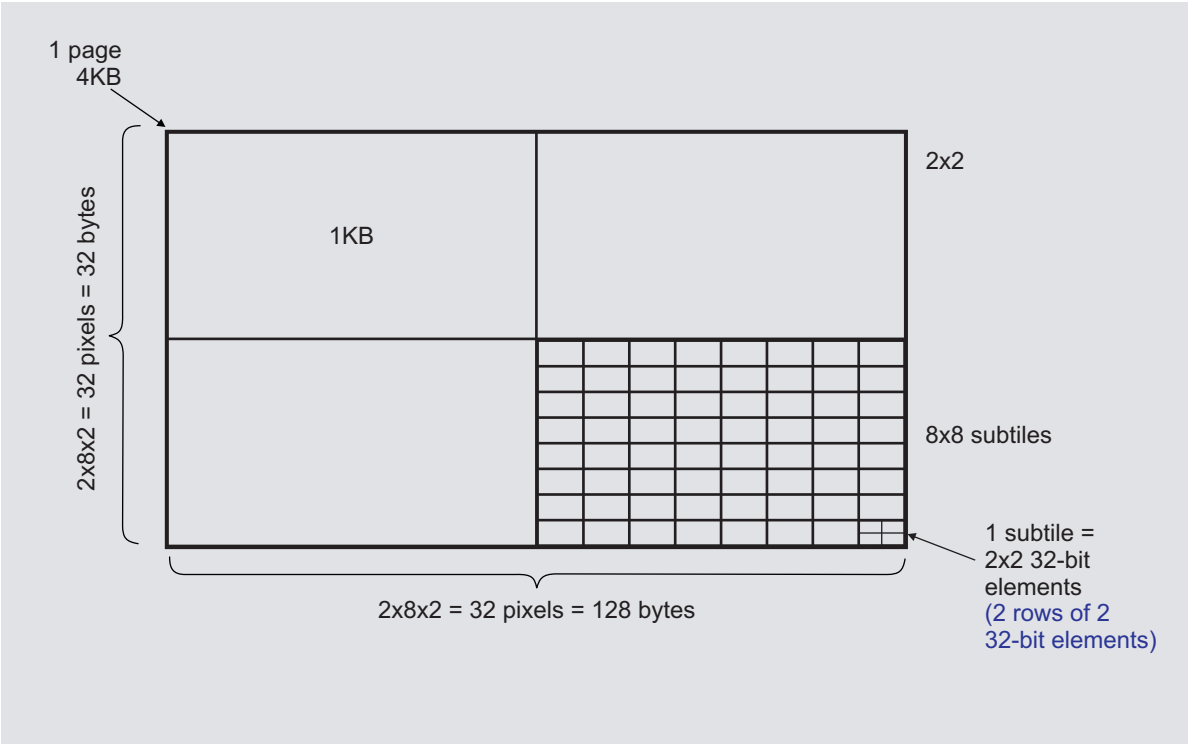


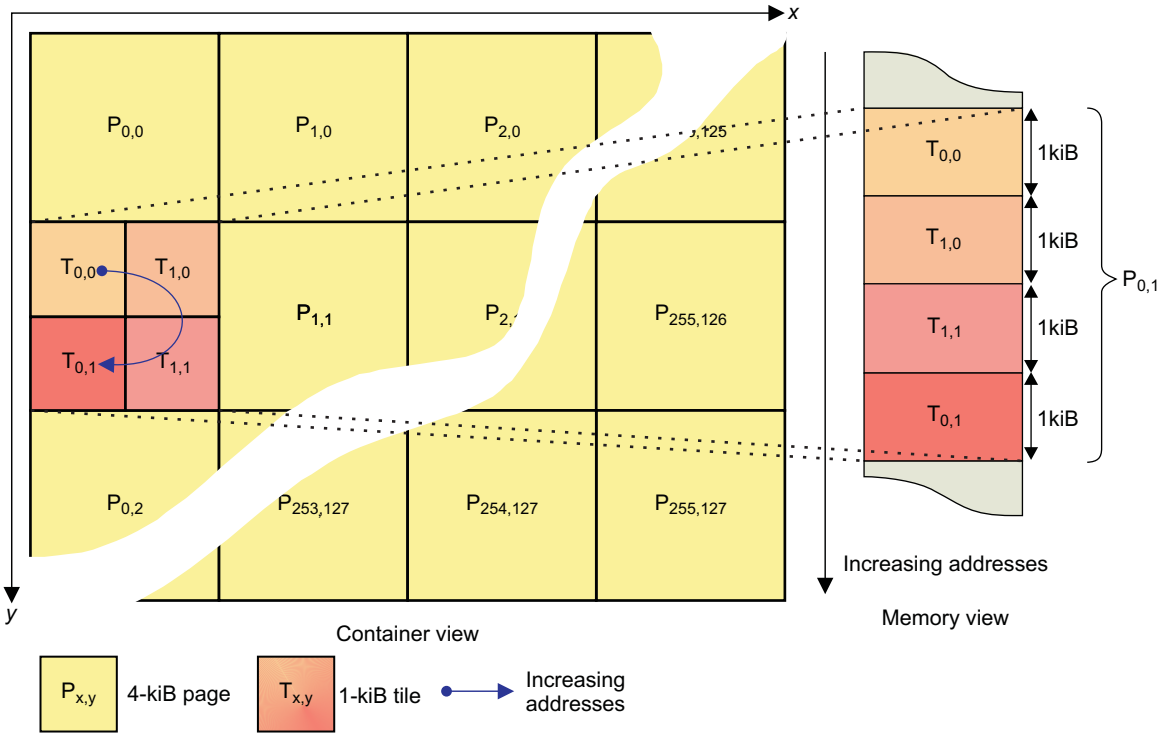
Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.2.5 A Tile is a 1-KB Address Space

The tile is designed to offer bi-dimensional data locality in a single SDRAM page. In this respect, it has been sized to 1 KB (the size of the smallest SDRAM page).

Figure 6-18 shows how 4 tiles are arranged in a page. This arrangement ensures that any two adjacent tiles in a page are not stored on the same EMIF(when interleaving is enabled). Thus a large tiled access will be efficient as it will be evenly spread across both SDRAM controllers.

**Figure 6-18. Four 1KB Tiles in One 4KB Page**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.2.6 A Sub-tile is a 128-bit Address Space

A 1KB tile is further decomposed into 64 sub-tiles, each sized 128 bits. The sub-tile structure is such that it balances accesses in two-dimensional modes, thus improving SDRAM access efficiency.

Furthermore, using Sub-tile pairing, the interlaced accesses to the tiled data can be improved. A Sub-tile is defined as follows:

1. An 8-bit sub-tile (Figure 6-19) is defined as an array of four horizontal lines of four 8-bit data. Thus, in 8-bit tiled mode, the TILER container is a 16384 × 8192 2D array of 8-bit elements.
2. A 16-bit sub-tile (Figure 6-20) is defined as an array of two horizontal lines of four 16-bit data. Thus, in 16-bit tiled mode, the TILER container is a 16384 × 4096 2D array of 16-bit elements.
3. A 32-bit tiled (Figure 6-21) mode as an array of two horizontal lines of two 32-bit data. Thus, in 32-bit tiled mode, the TILER container is an 8192 × 4096 2D array of 32-bit elements.

**Figure 6-19. 8-bit Sub-tile**

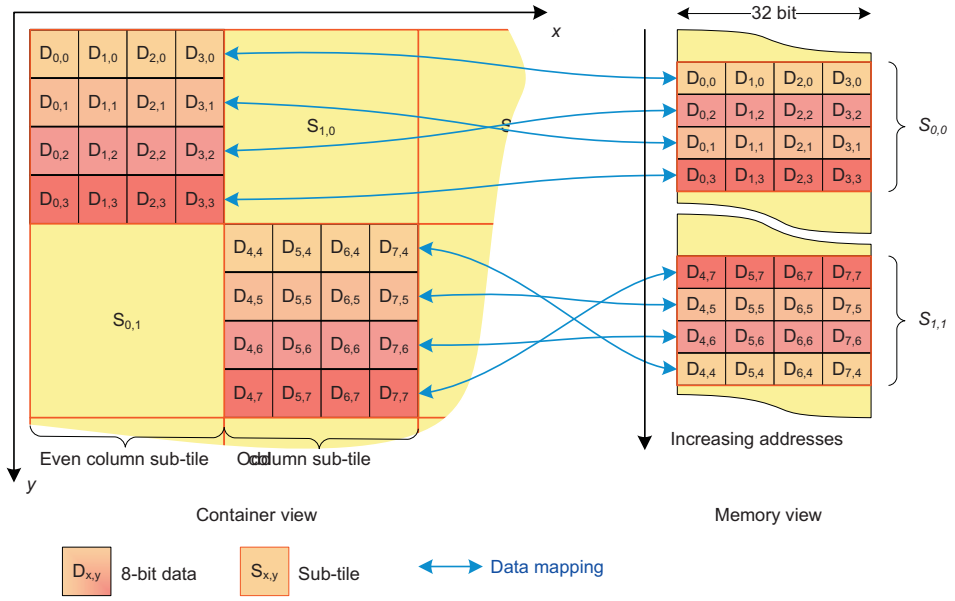


**Figure 6-20. 16-bit Sub-tile**

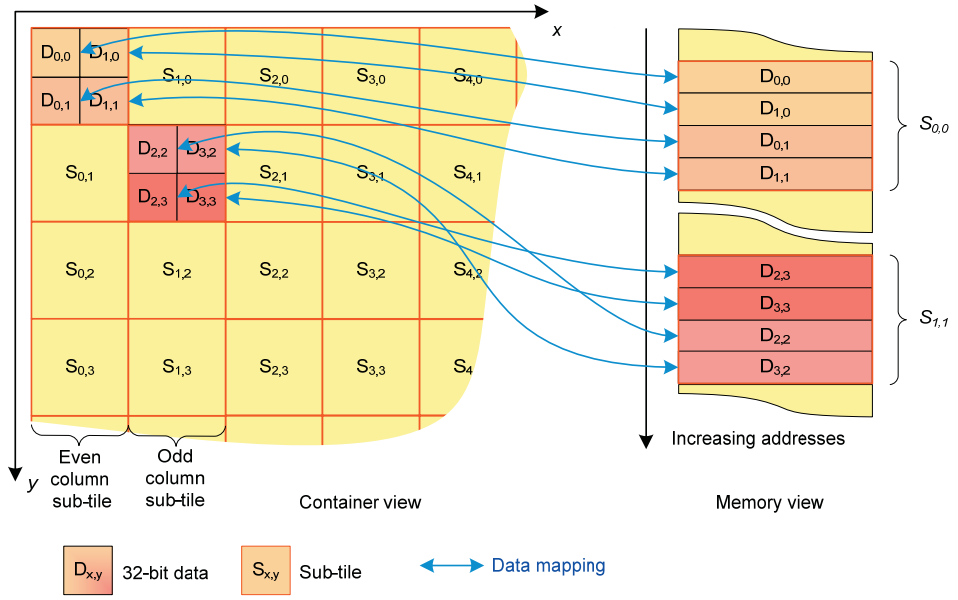
**Figure 6-21. 32-bit Sub-tile**



### 6.2.2.3 TILER Container - Summary

TILER is a 128-MB virtual container arranged in 2 dimensions as 256 × 128 pages, each of 4KB.

Each 4-KB page is has 4 tiles.

Each 1-KB tile has 64 subtiles, each of size 128 bits.

Based on the mode of access, 8/16/32 bit, the data stored can be aligned differently, as explained in the previous section.

#### *6.2.2.3.1 Where Will the Tiled Data Be Stored in Physical Memory?*

Using PAT Direct Access Translation:

By bypassing the LUT, the entire 128MB space has to be contiguous in the physical memory. Then each of the 8-bit 128 MB virtual container, 16-bit 128 MB virtual container, 32-bit 128 MB virtual container and paged container, can be mapped to either the same physical 128 MB space or at different locations. Refer to the PAT_VIEW_MAP register, which defines the base address of this 128 MB space. As can be seen, this base address is 256 MB aligned.

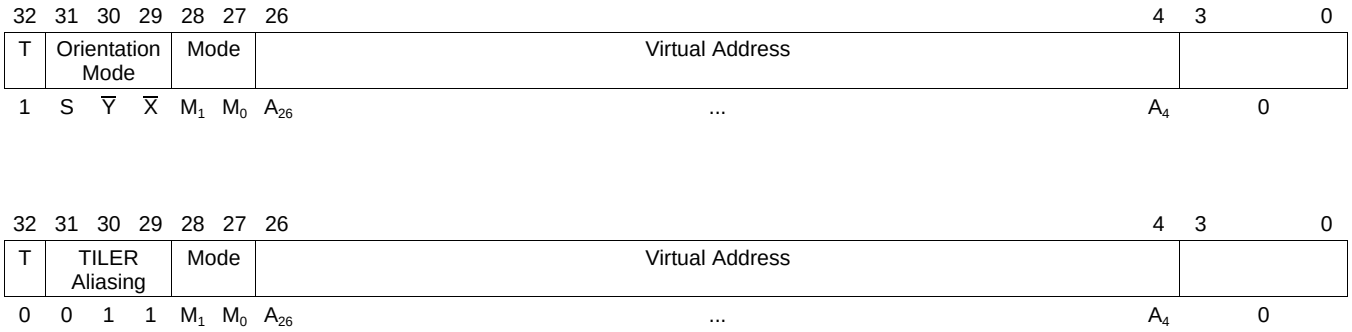
Using PAT In-Direct Access Translation:

A more common use case would be to use the single LUT in the DMM, to map the virtual data to physical address, at 4KB granularity. Then the physical 128MB need not be contiguous. However, with one LUT in the system, only 128 MB of data is possible; therefore the 8, 16, 32-bit and paged containers may need to be aliased to same pages. Thus use the LUT to map 8-bit, 16-bit, 32-bit containers, and paged mode containers, whereby they would all correspond to same physical memory pages, as shown in Figure 6-24.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.3.2 Addressing Formats

**Figure 6-22. Address Format**



1. The 33rd bit, noted T, is aimed at distinguishing the standard 4-GB system address map from the 4-GB TILER-specific address map In the Device, only HD_VPSS can generate accesses in the latter space.
2. The orientation bits, noted S, Y, and X, define the request orientation as specified in Section 6.2.2.7.
3. The mode bits, noted M1 and M0, encoded as in Section 6.2.2.8.1.
4. The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address.

### 6.2.2.4 TILER Modes

The TILER is supporting three major access modes - bypass, page and tiled - each having a specific output request generation.

#### 6.2.2.4.1 Bypass Mode

This mode is transparent at the TILER perspective. Bypass mode is for accesses generated by initiators with System addresses outside the virtual tiled address range, since TILER will bypass PAT. Still, at the DMM perspective:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at the DMM atomic unit of the section hit by the burst at:
  - at the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - at 1-KB boundary in non-interleaved sections

#### 6.2.2.4.2 Paged Mode

The purpose of this mode is to use the DMM PAT address translation mechanism for non-tiled accesses. In this respect it is similar to the bypass mode:

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at:
  - the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
  - 1-KB boundary in non-interleaved sections

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.4.3 Tiled Mode

When the being accessed in tiled mode, it can be either of the following:

- A well formed 2D block requests - conforming to the orientation, mode and stride
- A 1D incremental requests and ill-formed 2D block requests

**Table 6-1. Stride for Well-formed Tiled Mode 2D Block Requests**

| Orientation | | | Mode | | Stride (bytes) | Description |
|---|---|---|---|---|---|---|
| S | Y | X | M1 | M0 | | |
| 0 | x | x | 0 | 0 | 16384 | Plain access to an 8-bit progressive frame in 0° or 180° |
| | | | | | 32768 | Field access to an 8-bit interlaced frame in 0° or 180° |
| | | | 0 | 1 | 32768 | Plain access to a 16-bit progressive frame in 0° or 180° |
| | | | | | 65536 | Field access to a 16-bit interlaced frame in 0° or 180° |
| | | | 1 | 0 | 32768 | Plain access to a 32-bit progressive frame in 0° or 180° |
| | | | | | 65536 | Field access to a 32-bit interlaced frame in 0° or 180° |
| 1 | x | x | 0 | 0 | 8192 | Plain access to an 8-bit progressive frame in 90° or 270° |
| | | | | | 16384 | Field access to an 8-bit interlaced frame in 90° or 270° |
| | | | 0 | 1 | 8192 | Plain access to a 16-bit progressive frame in 90° or 270° |
| | | | | | 16384 | Field access to a 16-bit interlaced frame in 90° or 270° |
| | | | 1 | 0 | 16384 | Plain access to a 32-bit progressive frame in 90° or 270° |
| | | | | | 32768 | Field access to a 32-bit interlaced frame in 90° or 270° |

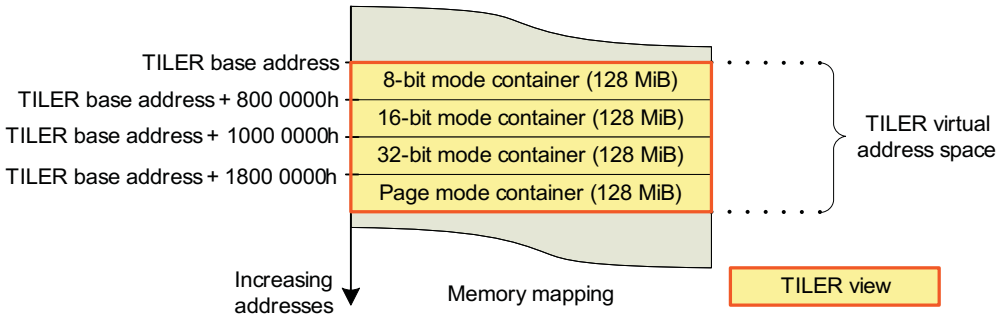
### 6.2.2.5 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MB virtual address space, where all objects of a same kind - and orientation - are allocated. Four main types of containers are present in the TILER, each one being referred by a mode:

- A 8-bit element mode, for efficiently accessing bi-dimensional arrays of 8-bit data, example 8-bits per pixel Luma buffers of image.
- A 16-bit element mode, for efficiently accessing bi-dimensional arrays of 16-bit data, example 16-bits per pixel interleaved-Chroma(CbCr) buffers of image.
- A 32-bit element mode, for efficiently accessing bi-dimensional arrays of 32-bit data, example 32-bits per pixel, ARGB graphics buffers.
- A page mode, for efficient 1D accesses

Figure 6-23 shows the TILER object containers and views.

**Figure 6-23. TILER Object Containers and Views**

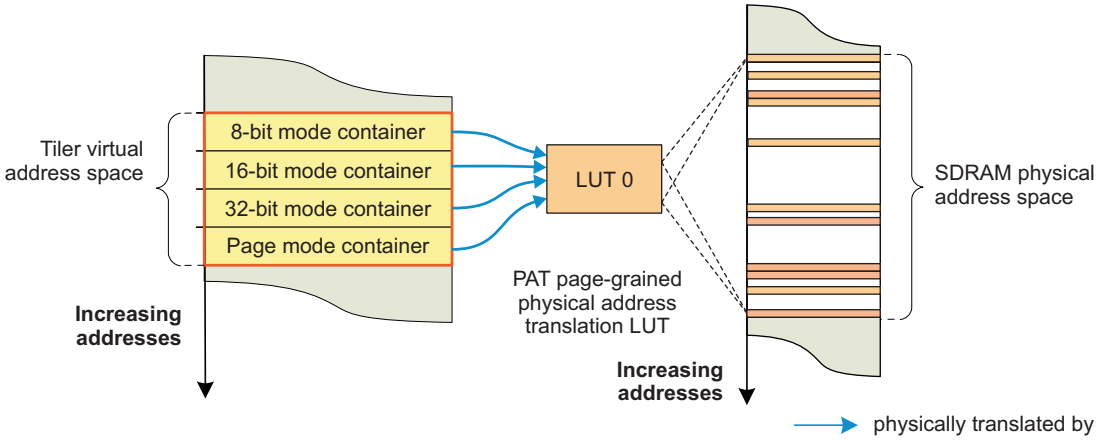


Copyright © 2011–2016, Texas Instruments Incorporated

In the device, there is a single LUT in the PAT. Each LUT can map up to 128MB of objects at a 4KB page granularity. The four modes share the single LUT.

As shown in Figure 6-24, 128MB of objects are available simultaneously in 8, 16, 32-bit modes and paged mode accesses.

**Figure 6-24. Using LUT to Translate Tiled Virtual Address to Physical SDRC Address**



**NOTE:** You need to ensure that an object allocated in a particular container mode does not physically overlap with any other object either in the same mode or other container modes.

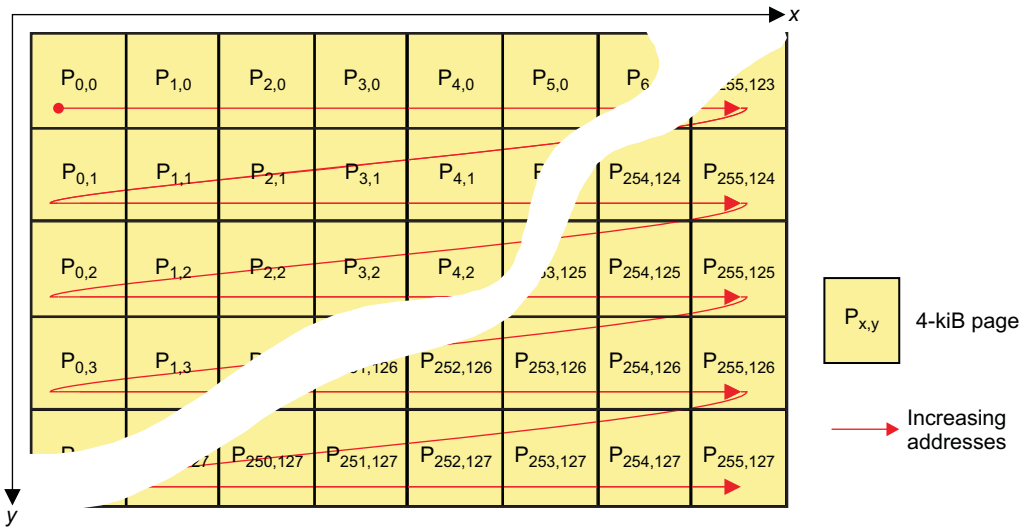
### 6.2.2.6 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers. Given that the sub-page structure is mode specific, the 4KB page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

#### *6.2.2.6.1 Container Geometry with 4-kiB Pages*

As pages size is 4KB, any 128MB object container is a set of 256 × 128 = 32768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 6-25.

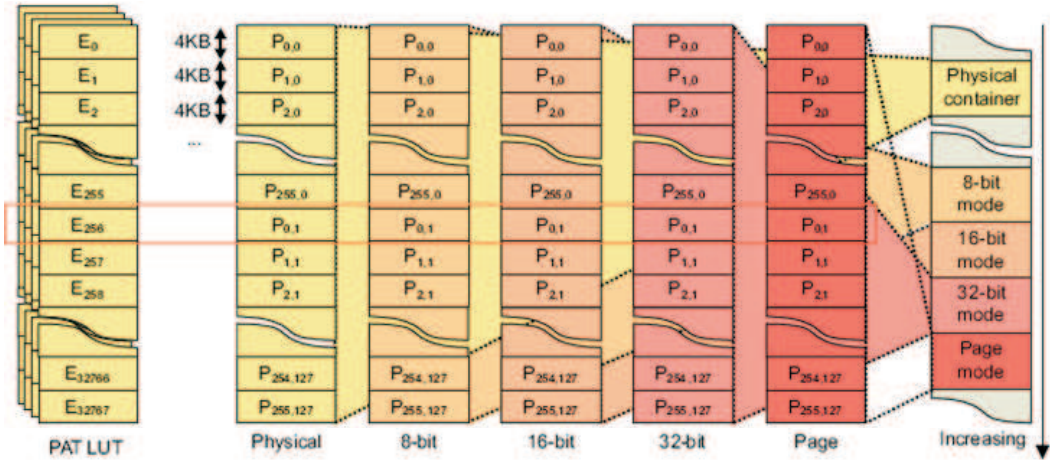
**Figure 6-25. Object Container Geometry with 4KB Pages**



Copyright © 2011–2016, Texas Instruments Incorporated

This array of pages is mapped to the system address space as shown in Figure 6-26.

**Figure 6-26. TILER Page Mapping When Using 4KB Pages**



In any 128-MB object container, the 4KB page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is found at an offset of 4096. (x + 256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (0 ≤ x < 256) and row y (0 ≤ y < 128), is translated by the LUT entry Ex + 256.y found at the index x + 256.y.

#### *6.2.2.6.2 Container Geometry and Page Mapping Summary*

The TILER has a page size of 4096 bytes. The page Px,y:

- has maxx = 256 and maxy = 128
- is found at an offset of: 4096.(x + maxx.y) bytes from the base address of the related object container
- is translated by the entry found at the index (x + maxx.y) of the LUT table

### 6.2.2.7 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, corresponding to all available changes of orthonormal basis in the TILER container bi-dimensional space.

Figure 6-27 shows isometric transforms in the TILER container.

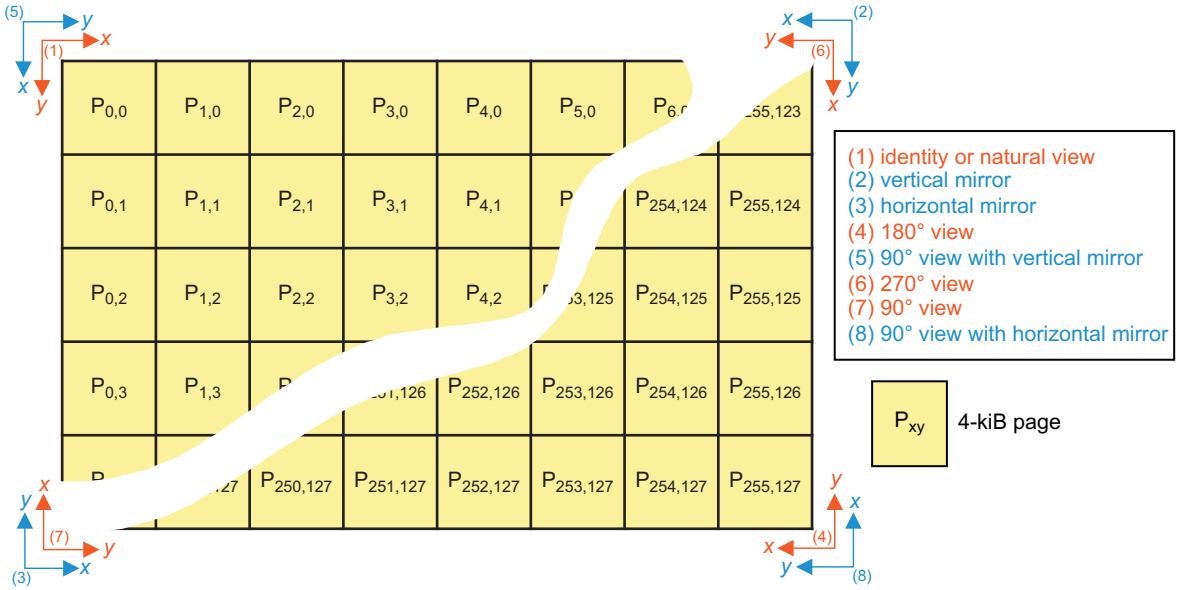
Mathematically speaking, all these transforms correspond to the composition of a 0º, 90º, 180º, or 270º rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- X to change the direction of the x axis of the TILER container
- Y to change the direction of the y axis of the TILER container
- S to swap the modified x and y axis

From now on, and in the rest of this document, the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal - flip-flop - or vertical mirroring.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 6-27. Isometric Transforms in the TILER Container**



**Selection of orientation:**

1. For all initiators except, HD_VPSS, the tiled space is accessed in the 512 MB address range of (6000 0000h to 7FFF FFFFh). These initiators use the access the any of the 8 views by using the respective DMM_TILER_OR0 or DMM_TILER_OR1 registers.
2. For HD_VPSS, the TILER module supports its own 4-GB virtual addressing space, from address (1 0000 0000h to 1 FFFF FFFFh). These eight 512MB spaces correspond to the 8 availables views. With multiple display, capture and transcode path, using the unique 512 MB address space, these ports of HD_VPSS can simultaneously generate access in any of the 8 views.

### 6.2.2.8 Tile Definition

A tile is a subdivision of a page, aimed at:

- Representing a 2D block to better balance the accesses in both directions
- Ensuring that any "tiled" access that fits within a tile is made atomic in the SDRAM controller, and fits in a single SDRAM memory page
- Minimising the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1KB 2D block, and a 4KB page as an array of 2 lines of 2 tiles each, as described in section detailing a 4KB page.

When the considered page is in an interleaved DMM section, it is necessary that:

- the DMM memory interleaving size of tiled accesses is set to 1 KB - a tile size - so that any tiled request that fits within a tile, fits in a single SDRAM memory page
- any request that spans over 2 or 4 tiles, is distributed on a maximum number of SDRAM memory controllers

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.2.2.8.1 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes, namely 8-bit, 16-bit, 32-bit and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 6-2.

**Table 6-2. TILER Modes**

| Mode | Name | Granularity (element size) |
|---|---|---|
| 0 | 8-bit tiled mode | 8 bits |
| 1 | 16-bit tiled mode | 16 bits |
| 2 | 32-bit tiled mode | 32 bits |
| 3 | Page mode | 4096 bytes |

For instance, making a vertical mirroring of a 16-byte horizontal line containing the word 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh, leads to:

- 0F0E 0D0C 0B0A 0908 0706 0504 0302 0100h in 8-bit tiled mode
- 0E0F 0C0D 0A0B 0809 0607 0405 0203 0001h in 16-bit tiled mode
- 0C0D 0E0F 0809 0A0B 0405 0607 0001 0203h in 32-bit tiled mode
- 0001 0203 0405 0607 0809 0A0B 0C0D 0E0Fh in page mode - unchanged as the element granularity is 4KB

Besides, as each of the eight orientations is available for any of the four modes, this gives 32 TILER addressing possibilities.

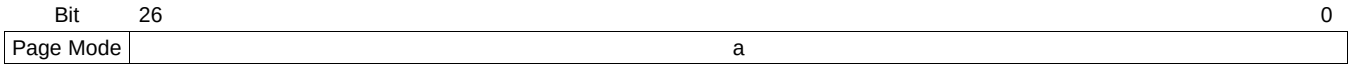
**NOTE:** The format that the TILER manages the tiled data is dictated by which 4 modes (8-,16-, 32-bit or paged) and which orientation (8 views) is used while accessing (read and write) the data.

As long as the data accessed is written and read in the same mode, it is assured that the response to the access will be correct. While accessing in the same mode, if written in one view and read back in the other view, then the read back data will be rotated and/or mirrored as per the view used.

#### 6.2.2.8.2 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32768 pages of 4 kiB each. The access sequence inside a page is left unchanged. Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

**Figure 6-28. Paged Mode Addressing**



#### 6.2.2.8.3 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer - the container. The addressing and characteristics of this giant frame-buffer depends on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis - and hence the container geometry

Table 6-3 summarizes tiled mode container characteristics.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 6-3. Tiled Mode Container Characteristics**

| Orientation | | | Element Size (bits) | Width (elements) | Height (elements) | Stride (bytes) | |
|---|---|---|---|---|---|---|---|
| S | Y | X | | | | Progressive | Interlaced |
| 0 | x | x | 8 | 16384 | 8192 | 16384 | 32768 |
| | | | 16 | 16384 | 4096 | 32768 | 65536 |
| | | | 32 | 8192 | 4096 | 32768 | 65536 |
| 1 | x | x | 8 | 8192 | 16384 | 8192 | 16384 |
| | | | 16 | 4096 | 16384 | 8192 | 16384 |
| | | | 32 | 4096 | 8192 | 16384 | 32768 |

As a result, the coordinate (x0, y0) of a pixel in an oriented view is translated in a virtual address as shown in Figure 6-29 and Figure 6-30, for all the four orientations.

**Figure 6-29. Tiled Mode Addressing in 0° or 180° Orientations, (S = 0)**

| Bit | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 8-bit tiled mode | $y_0$ | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | | |
| 16-bit tiled mode | $y_0$ | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | | |
| 32-bit tiled mode | $y_0$ | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | | |

|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 8-bit tiled mode | $y_0$ | | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | |
| 16-bit tiled mode | $y_0$ $x_0$ | | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | |
| 32-bit tiled mode | $y_0$ | | | | | | | | | | | | | $x_0$ | | | | | | | | | | | | | |

Having understood the characteristic of the tiled container and the how the data is stored in bi-dimensional manner, it is easy to understand how stride is calculated. Stride is calculated as the number bytes between pixel (m,n) and pixel (m,(n+1)), where m = x co-ordinate of the image buffer, n = y co-ordinate of the image buffer.

**For S = 0, that is, all views with 0º and 180º:**

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 1 × 8 × 2 × 256 = 16KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 256 pages = 4 × 2 × 8 × 2 × 256 = 32KB

For S = 1, that is, all views with 90º and 270º:

- 8-bit mode: stride_8bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 8KB
- 16-bit mode: stride_16bitmode = 4 bytes per sub-tile × 1 byte height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 1 × 8 × 2 × 128 = 16KB
- 32-bit mode: stride_32bitmode = 4 bytes per sub-tile × 2 bytes height of a sub-tile line × 8 sub-tiles per tile × 2 tiles per page × 128 pages = 4 × 2 × 8 × 2 × 128 = 16KB

#### 6.2.2.8.4 Element Ordering in the TILER Container

This section highlights how elements - 8-bit data, 16-bit data, 32-bit data or 4-kiB page - are ordered in the container. In other words, this section highlights how the path of incrementing virtual addresses is mapped in the container.

It is interesting to note that whatever the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and only depends on the related orientation. In other words:

- Mode is about element granularity
- Orientation is about change of orthornormal basis for ordering the elements in the mode-specific container

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged whatever the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the next sections, the natural container orthonormal basis is referenced as: (Xn , Yn) and the oriented orthonormal basis as: (Xo , Yo).

#### 6.2.2.8.4.1 Natural View or 0º View (Orientation 0)

This orientation defined by S = 0, Y = 0, and X = 0 and means that the operated change of basis is:

X0 = Xn

Y0 = Yn

In any TILER mode, the elements are then ordered from left-to-right and then from top-to-bottom in their container, as shown in Figure 6-31 and Figure 6-32.

**Figure 6-31. Tiled Mode Ordering of Elements in Natural View**

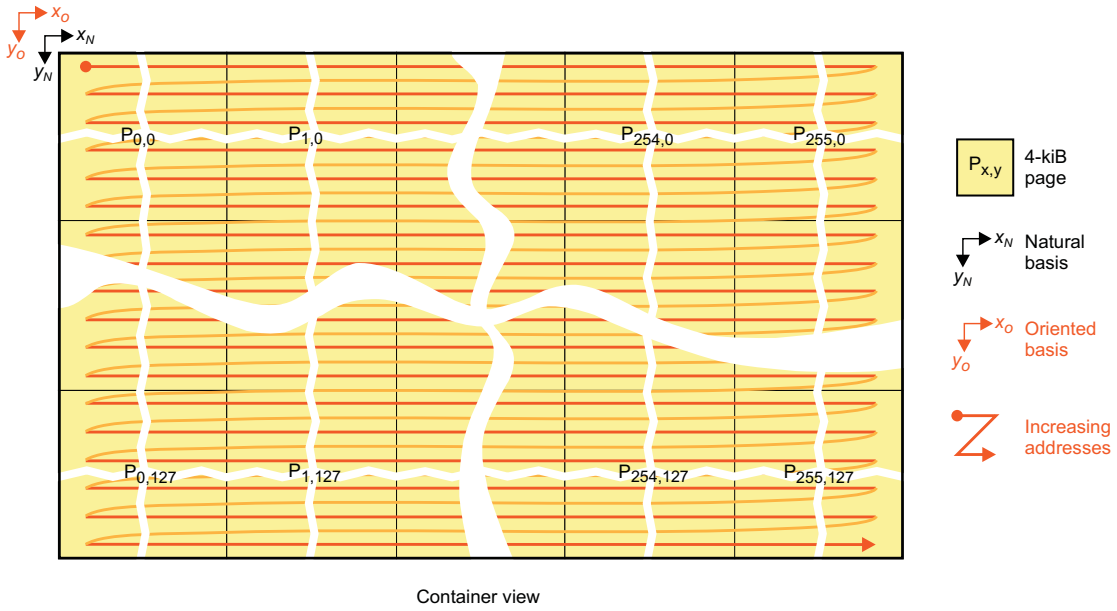

**Figure 6-32. Page Mode Ordering of Elements in Natural View**

#### 6.2.2.8.5 Tiled and Rotational Efficiency

Because of the distribution of the image data in both direction and co-locating them, using sub-tiling, the Image processing algorithms running on the HDVICPs are more efficient by making fewer accesses to the SDRAM, to fetch Macro-blocks of data.

In the Device, the DMA engine of HD_VPSS, also known as VPDMA, has internal line buffers of its clients. For every tiled access, it is ensured that rastering tiled data has zero overhead, when processing an entire frame, or $2^{2n}$ number of lines.

## 6.3 Use Case

### 6.3.1 DMM Basic Register Setup

This section describes basic steps to initialize the DMM, in the device.

1. Set base address, DMM_PAT_VIEW_MAP_BASE to value 8000 0000h, which corresponds to base SDRAM address in the device memory map.
2. Program the four PAT views, by writing DMM_PAT_VIEW_MAP__0..3 registers. By default, all the four PAT views are having value of 0, which implies Direct access translation for all the four tiled modes of (8,16,32-bit and paged mode) and all the four containers will overlap with their base address mapped to 8000 0000h.
3. Program PAT views for all initiators, indexed by ConnID, by programming the DMM_PAT_VIEW__0..1 registers. There are 4 possible views available in device. Default is for all initiators to use PAT view 0.
4. Program PEG priority for all the initiators. By default - all are having priority = 0.
5. Program the TILER orientation for all the initiators, by writing to DMM_TILER_OR__0..1 registers. By default - all will access tiled data in Orientation = 0, which is the normal view.
6. Program Section mapping, based on the SDRAM configuration of the system, which depends on the size of the SDRAM on one or both the banks.
   - Example 1: Symmetrical DDRs on both EMIF banks. Each size = 512MB to add up to 1GB of total SDRAM memory. In all DMM_LISA_MAP__0..3 registers, program value 8064 0300h, which implies 1GB section starting from System address : 8000 0000h, mapped to 0000 0000h of both EMIF0 and EMIF1, with interleaving of 128 bytes enabled. Note that the above example uses only one DMM section and the three other are identical. There are other ways to define up-to 4 sections and configure each differently

#### 6.3.1.1 PAT Direct Access Translation with Distinct 128 MB Containers for Each of the 4 Modes

Following is a simplistic use case, bypassing the LUTs for address translation and setting aside a chunk of 128MB contiguous memory, with base address 128MB aligned, for each of the 4 modes (8, 16,32-bit and paged mode). The same addresses will be used by all initiators in the system.

Configure PAT view 0:

Program DMM_PAT_VIEW_MAP__0 to a value of 0302 0100h. Here : 8-bit mode container will be mapped to 8000 0000h. 16-bit mode container will be mapped to 8800 0000h. 32-bit mode container will be mapped to 9000 0000h. Paged mode container will be mapped to 9800 0000h.

Configure all initiators to use PAT view 0:

Program DMM_PAT_VIEW__0..1 to a value of 0.

### 6.3.2 Simple LUT Bypass Use Case: Arrangement of Video Buffers

This section describes one possible arrangement of H.264 video buffers which are in YUV 420 format. Setup is as follows:

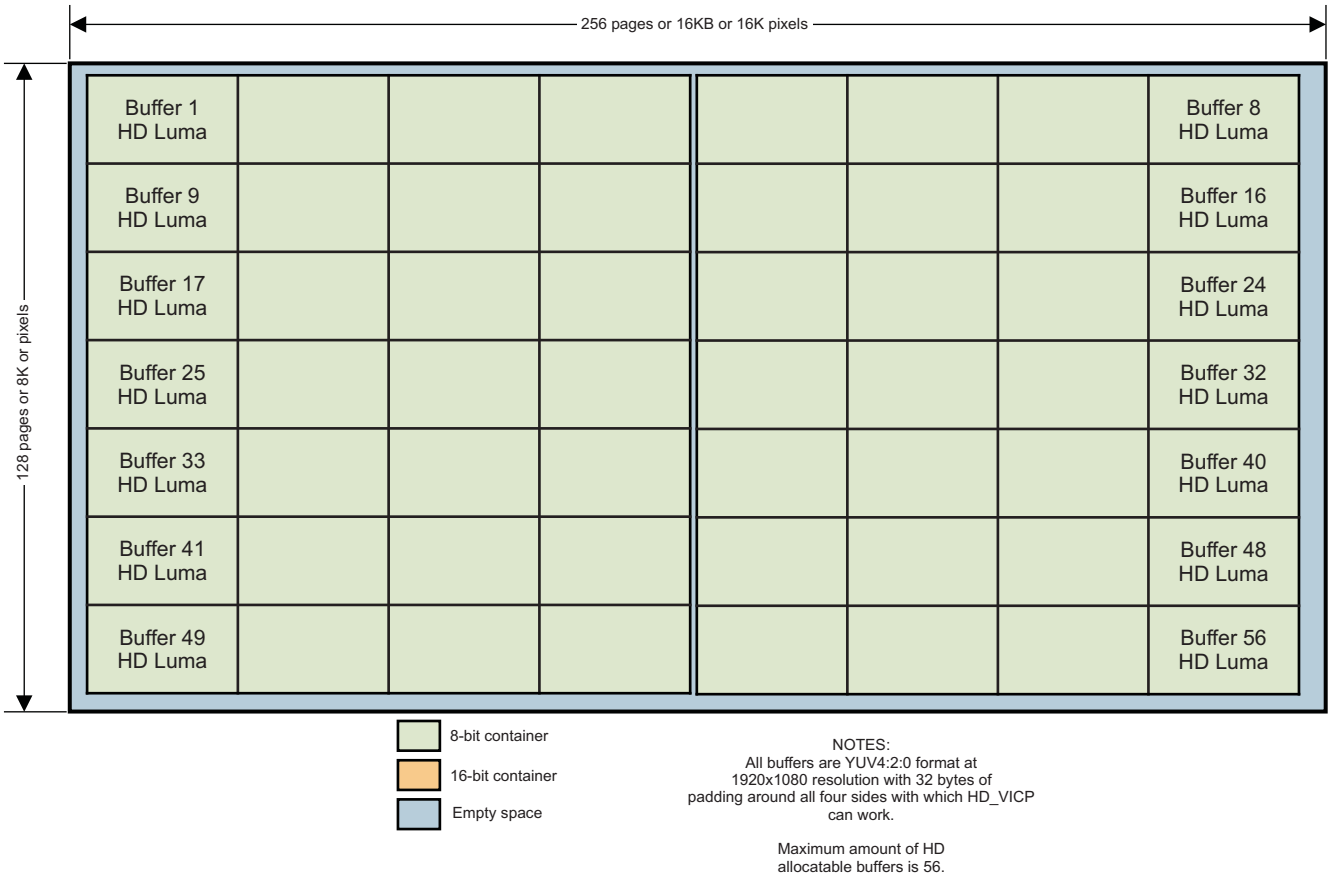
1. The buffers size if 1920 × 1080
2. The Luma buffers are allocated in the 8-bit mode container
3. The Chroma buffers are allocated in the 16-bit mode container
4. The H.264 algorithm needs 32 bytes of padding on each side for Luma buffer and 16 bytes padding in each side for a chroma buffer
5. All buffers are allocated on a 4K aligned address

#### 6.3.2.1 Luma Buffers

In 8-bit tiled mode (Figure 6-47), each 4K page is arranged as 64-pixels wide and 64-pixels high, where each pixel is of size 8-bits. In YUV 420 format, the Luma buffer of the image is 1920 × 1080 and each pixel is 8-bits. Thus, each buffer is 1920 bytes wide. With a pad of 32 bytes on each side, the buffer is (1920 + 64 =) 1984-bytes wide. So one video buffer needs (1984/64 =) 31 pages, along the width of the tiler container. So the tiler container can fit (256/31 ~) 8 buffers, along its width.

Similarly, with a pad of 32 bytes on top and bottom, the buffer is (1080 + 64 =) 1144. Rounding it to (1144 + 8 =) 1152, so that buffer is allocated on page boundary. So one video buffer needs (1152/64 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

**Figure 6-47. Buffer Arrangement for HD Luma Buffers in 128MB 8-bit Mode Container**



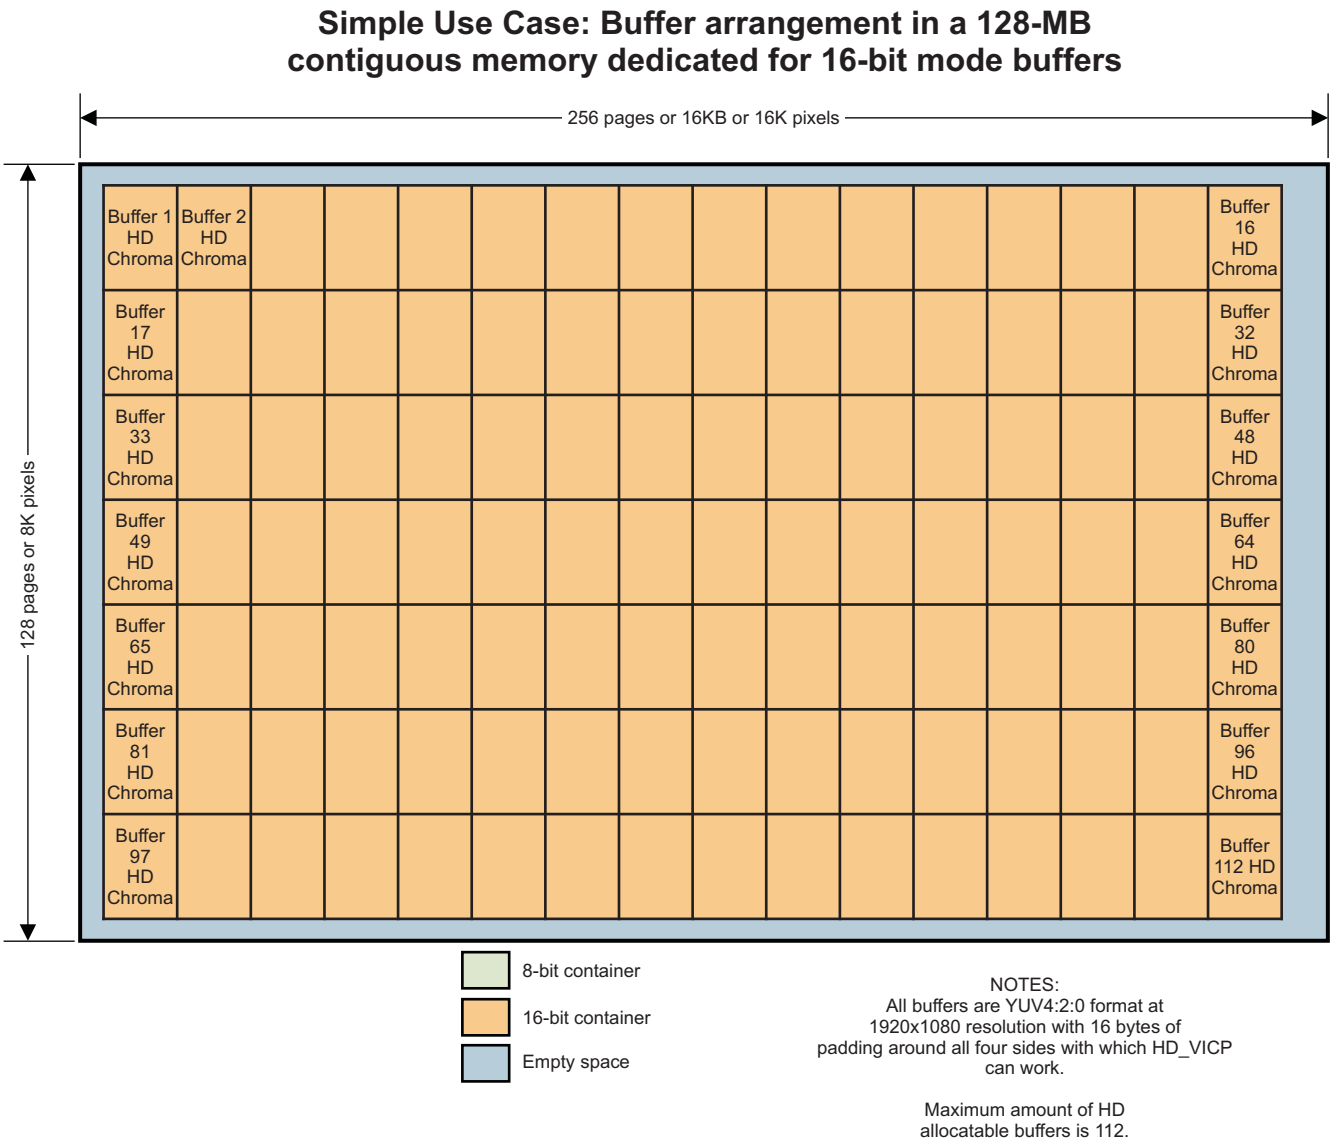
Copyright © 2011–2016, Texas Instruments Incorporated

### 6.3.2.2 Chroma Buffers

In 16-bit tiled mode (Figure 6-48), each 4K page is arranged as 64-pixels wide and only 32-pixels high, where each pixel is of size 16-bits. In YUV 420 format, the Chroma buffer of the image is 960 × 540 and each pixel is 16-bits. Thus, each buffer is 960-bytes wide. With a pad of 16 bytes on each side, the buffer is (960 + 32 =) 992-bytes wide. Rounding it to (992 + 32 =) 1024, so that buffer is allocated on page boundary. So one video buffer needs (1024/64 =) 16 pages, along the width of the tiler container. So the tiler container can fit (256/16 =) 16 buffers, along its width.

Similarly, with a pad of 16 bytes on top and bottom, the buffer is (540 + 32 =) 572. Rounding it to (572 + 4 =) 576, so that buffer is allocated on page boundary. So one video buffer needs (576/32 =) 18 pages, along the height of the tiler container. So the tiler container can fit (128/18 ~) 7 buffers, along its height.

**Figure 6-48. Buffer Arrangement for HD Chroma Buffers in 128MB 16-bit Mode Container**



**NOTE:** The above scheme of Luma and Chroma buffer arrangement can be optimized further, by allocating buffers on sub-tile boundary, instead of page boundary (which is required when using LUT for address translation).

### 6.3.3 LUT Refill Using the PAT Refill Engines

There is a single LUT of size 256 × 128 elements, in the device.

There four refill engines, along with their own set of registers, to program the LUTs.

Also in this section are described in five different ways to program the LUT.

1. Simple manual area refill
2. Single auto-configured area refill
3. Chained auto-configured area refill
4. Synchronised auto-configured area refill
5. Cyclic synchronised auto-configured area refill

Some of the guidelines, in programming the LUTs are mentioned below:

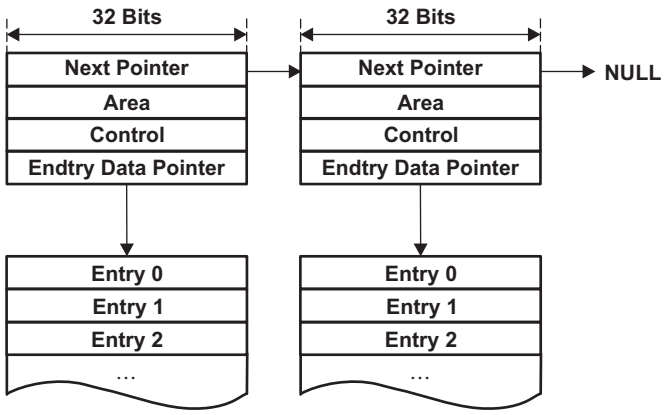
1. Entry table must be in DDR and cannot be split between 2 EMIF banks, when data interleaving enabled.
2. The data table should start from address 16-byte aligned.
3. With one set of descriptor, up to 64 LUT entries can be programmed, in any 2D area dimension.

#### 6.3.3.1 PAT Memory Mapped Refill Descriptors

A PAT descriptor is a singly-linked list node as shown in Figure 6-49, containing:

- a description of the LUT area to reload
- a description of how to reload the defined LUT area
- a pointer to the location where the corresponding LUT entries are stored

**Figure 6-49. PAT Descriptor Node**



The PAT descriptor node and the entry data pointer must both be 16-byte aligned. A typical 'C' language description of this node is as follows:

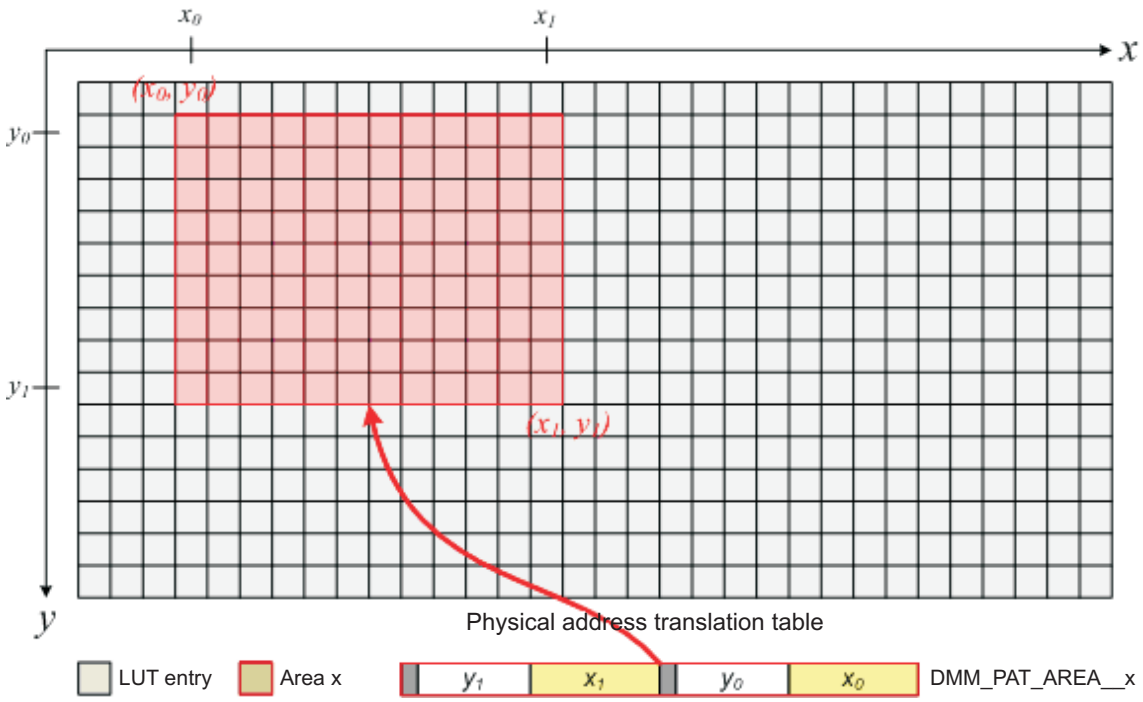
```
struct PAT_desc {
        struct PAT_desc *next;
   u32_t            area;
   u32_t            ctrl;
   PAT_data        *data;
} __attribute__ ((aligned(16)));
```

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.3.3.1.1 PAT Area Refill Description

The area refill description is actually describing the top-left and bottom right corner of the PAT vector table as shown in Figure 6-50.

**Figure 6-50. PAT Area Description**



#### 6.3.3.1.2 PAT Data Description

The pointer to the address in SDRAM, containing the memory based Data table, should be 16 byte aligned. Each field in this table is a 32 bit value, corresponding to the value to be programmed in one LUT entry. Though it is a 32 bit value, only 19 bits [30:12] are relevant. Bit 31 and bits [0:11] are ignored by the PAT refill engine.

#### 6.3.3.1.3 PAT Memory Dump

This section presents how to dump the PAT LUT. This has to be done using the direct access mode of PAT, following the below steps:

1. Set at least one of the refill engine to direct LUT access mode. This has to be done using DMM_PAT_CONFIG register. Only bit 0 to 3 are used for mode of refill engine 0 to 3. (Value 0 is normal mode, value 1 is direct LUT access mode).
2. Set system coordinates we would like to read/write in the LUT. This has to be done using DMM_PAT_AREA__x. x is the refill engine index that has to be coherent with the refill engine used in direct mode (DMM_PAT_CONFIG). Only (x0,y0) is used in direct mode.
3. Select the LUT_ID = 0 using DMM_PAT_CTRL__x register.
4. Read (or write) the data in DMM_PAT_DATA__x register. x is the refill engine index.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.3.3.1.4 PAT Refill Direction

The DMM_PAT_CTRL__x.DIRECTION field gives the “order” of the area refill with the same “SYX” encoding as in the TILER orientations:

- 0: from left to right then from top to bottom
- 1: from right to left then from top to bottom
- 2: from left to right then from bottom to top
- 3: from right to left then from bottom to top
- 4: from top to bottom then from left to right
- 5: from top to bottom then from right to left
- 6: from bottom to top then from left to right
- 7: from bottom to top then from right to left

This feature allows the initiators HD_VPSS and HDVICPs to start an access to an on going refill area. In this case, the direction field is set in accordance with the orientation accesses made by the initiators. The DMM_PAT_STATUS__x.ERROR is asserted to 1 if an access is done to a not yet refilled page.

### 6.3.3.2 Simple Manual Area Refill

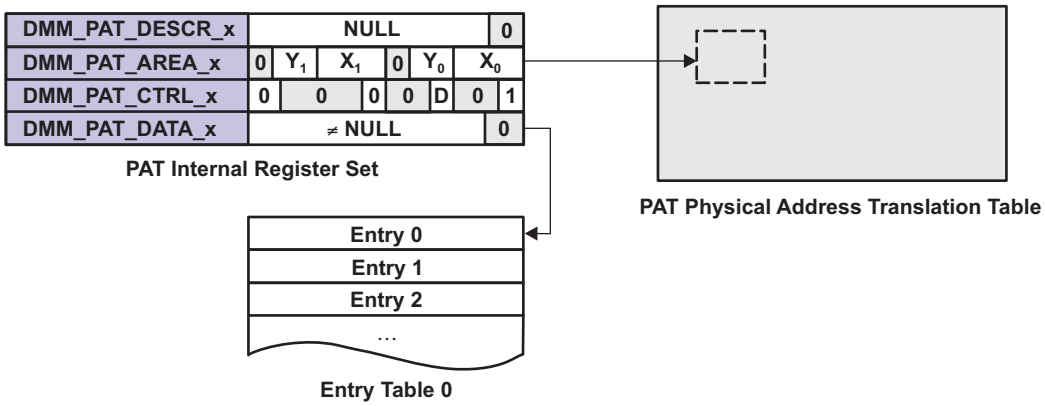
These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 6-51.

- Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition
- Write the DMM_PAT_DATA_i register with the physical address of the created entry table
- Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the

DMM_PAT_CTRL_i[0] START bit:

- The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
- A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

**Figure 6-51. DMM Simple Manual Area Refill**



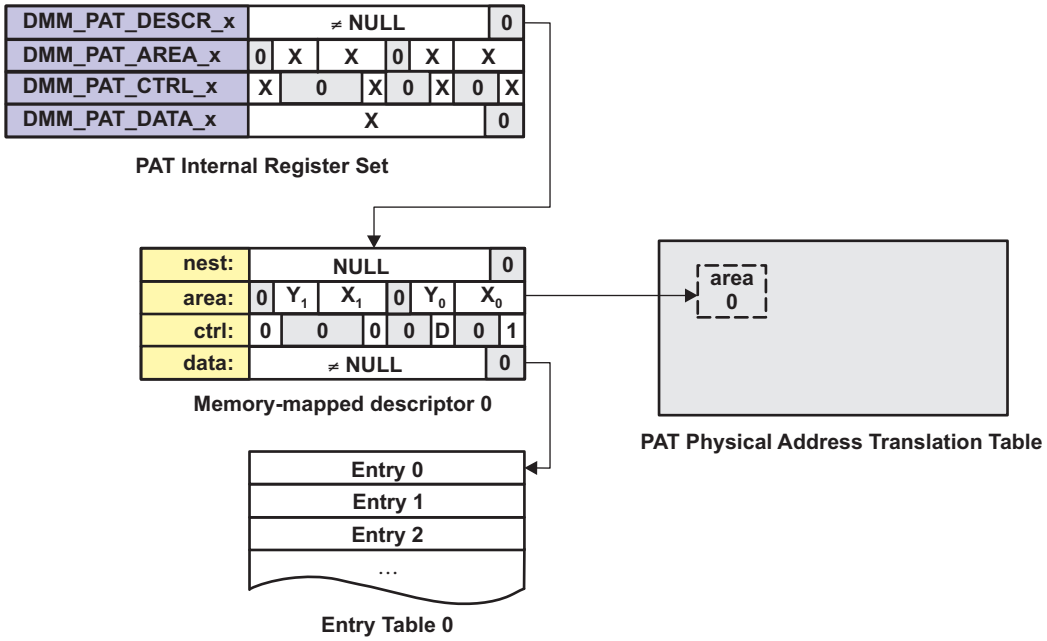
Copyright © 2011–2016, Texas Instruments Incorporated

### 6.3.3.3 Single Auto-Configured Area Refill

These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area, as seen in Figure 6-52.

1. Create a 16-byte aligned memory-mapped descriptor structure where:
   (a) the next field is set to NULL
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the start bit asserted to start refilling as soon as this descriptor enters the PAT refill engine
   (d) the data field is set to the physical address of the created entry table
2. The DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

**Figure 6-52. DMM Single Auto-configured Area Refill**



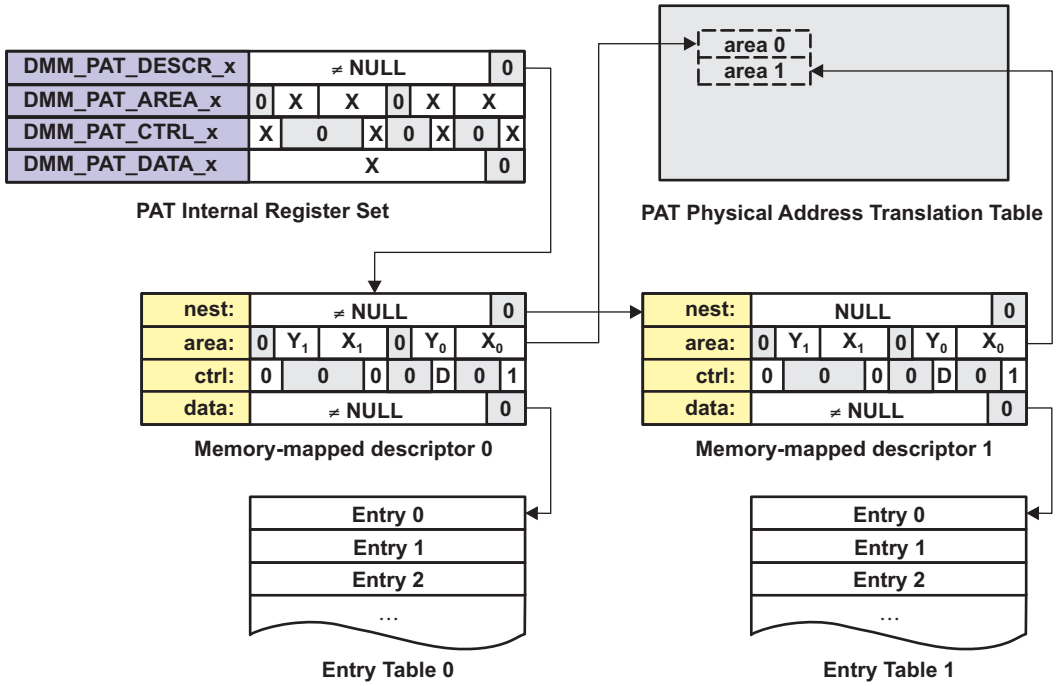
Copyright © 2011–2016, Texas Instruments Incorporated

### 6.3.3.4 Chained Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-53.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the requested direction D and the START bit asserted to start refilling as soon as the previous area refill is done
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

**Figure 6-53. DMM Chained Auto-configured Area Refill**



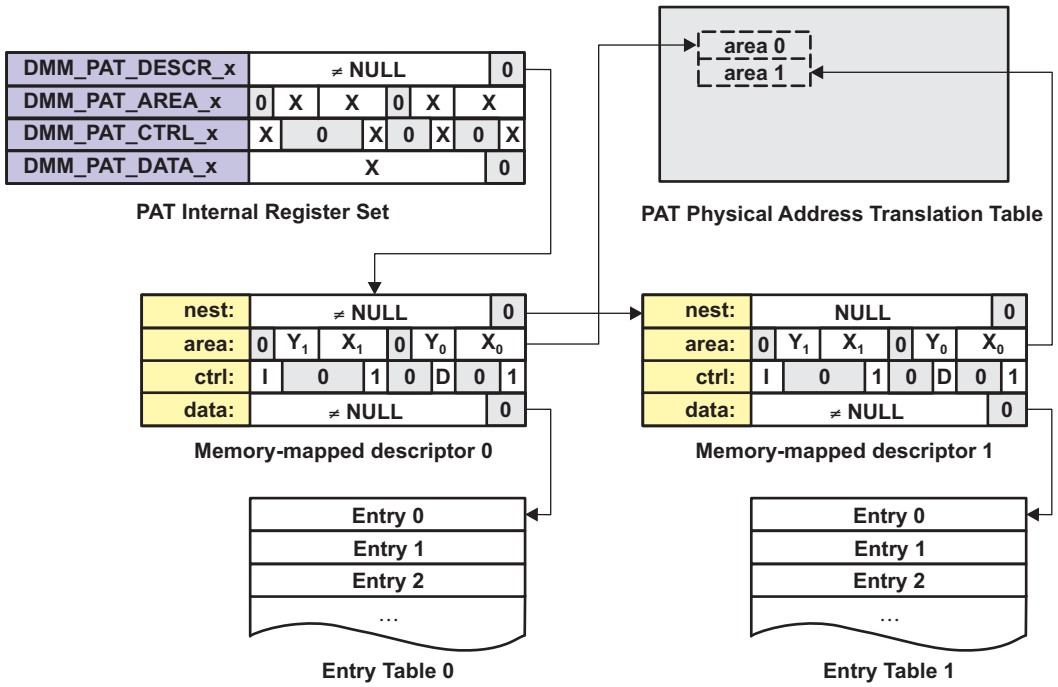
Copyright © 2011–2016, Texas Instruments Incorporated

### 6.3.3.5 Synchronised Auto-configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-54.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor or NULL for the last one
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

**Figure 6-54. DMM Synchronised Auto-configured Area Refill**



Copyright © 2011–2016, Texas Instruments Incorporated

### 6.3.3.6 Cyclic Snchronised Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area, as seen in Figure 6-55.

1. Create one 16-byte aligned memory-mapped descriptor structures per area where:
   (a) the next field is set to the physical address of the next descriptor in the circular list
   (b) the area field is set with the relevant (x0, y0) (x1, y1) area definition
   (c) the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
   (d) the data field is set to the physical address of the corresponding entry table
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i to abort the current one.

**Figure 6-55. DMM Cyclic Synchronised Auto-configured Area Refill**

### 6.3.4 Address Management Using LISA Sections

In the device, there are either one ot two memory controllers (EMIFs).

#### 6.3.4.1 DMM Sections

The DMM section definition is certainly the very first step in the DMM software configuration, as it is about defining the system address map to be used when accessing the SDRAM controllers.

A DMM section description fits in a single 32-bit register (DMM_LISA_MAP_x), where:

- SYS_ADDR defines the base address of the decoding range for the section
- SYS_SIZE defines the size of the section. Note that the encoding of this parameter is the number of bits actually used in the upper 8-bits of the incoming system address.
- SDRC_ADDR defines the physical base address of the section in the external memory controller
- SDRC_ADDRSPC defines the address space used on the SDRAM controller when hitting this section. The address space feature is not supported.
- SDRC_MAP defines the target memory controllers for this section. A section may hit a one or two controllers. The section is not used if this parameter is set to zero.
- SDRC_INTL defines the granularity of the interleaving if the section is mapped on more than one memory controllers

A couple of examples are given in the next subsections.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 6.3.4.1.1 Case 1: Two Memory Controllers, 2GB DDR Symmetrical Distribution

Use Case: In this example we assume 2GB of external memory, spread evenly between 2 SDRAM controllers.

**Table 6-4. Case 1 Memory Controllers**

| System Address Range | Memory Controller | EMIF Address Range |
|---|---|---|
| 8000 0000-FFFF FFFFh | 1 and 2, interleaved at 256 Bytes | 0000 0000h-7FFF FFFFh |

**Configuration:**

**Table 6-5. Controller Configuration**

| Bit | Field | Section 0 |
|---|---|---|
| 31-24 | SYS_ADDR | 80h (incoming System Address MSB) |
| 22-20 | SYS_SIZE | 7h (2 GB) |
| 19-18 | SDRC_INTL | 2h (256 bytes interleaving) |
| 17-16 | SDRC_ADDRSPC | 0 (Unused Reserved field) |
| 8 | SDRC_MAP | 3h (Map to both EMIF0 and EMIF1 |
| 7-0 | SDRC_ADDR | 0 (SDRC address MSB) |

**NOTE:** Section 1, Section 2 and Section 3 - identical to Section 0.

**How DMM decodes and translates:**

1. To check if an address hits a section, use the eight upper address bits of the address and mask them with the hit mask (2 8 - 2SYS_SIZE). If the result is equal to SYS_ADDR, the section is hit.
2. To define the physical address to be issued to the memory controller, use the eight upper address of the system address, mask them with the address mask ($2^{SYS_SIZE} – 1$ ), and then OR them with SDRC_ADDR. This will give the resulting eight upper physical address bits. All lower address bits are forwarded unchanged.
3. If interleaving enabled, the physical address generation is modified. In case of a 256 bytes interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the SDRAM controller ID, 0 for the first controller and 1 for the second one (system address bit 7 would be used for interleaving at 128 bytes boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits 9 to 31 are shifted to bits 8 to 30 when generating the physical address.

**Example with above configuration:**

1. Incoming access's System address 99AE 37F0h:
2. Hit mask: $2^8 - 2^7 = 80h$
3. Masked upper address bits: 80h AND 80h = 80h (the SYS_ADDR) , thus hits section 0
4. Address mask: $2^7 - 1 = 7Fh$
5. Masked upper address bits: 99h AND 7Fh = 19h
6. Full masked address: 19AE 37F0h
7. Bit 8 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 8): 0CD7 1BF0h
9. OR upper physical address bits with SDRC_ADDR: 0CD7 1BF0h
10. Physical address: 0CD7 1BF0h

Copyright © 2011–2016, Texas Instruments Incorporated

This request will be forwarded to address 0CD7 1BF0h, of the second memory controller, that is, EMIF1.

#### 6.3.4.1.2 Case 2: Two Memory Controllers, 1152 MB (1 GB + 128 MB) DDR Symmetrical Distribution

In this example we assume 2GB of external memory, spread evenly between two EMIF controllers.

**Table 6-6. Case 2 Memory Controllers**

| System Address Range | SDRAM Controller | EMIF Address Range |
|---|---|---|
| 8000 0000h-C7FF FFFFh | 1 and 2, interleaved at 256 Bytes | 0000 0000h-47FF FFFFh |

**Configuration:**

**Table 6-7. Controller Configuration**

| Bit | Field | Section 0 | Section 1 |
|---|---|---|---|
| 31-24 | SYS_ADDR | 80h (incoming System Address MSB) | C0h (incoming System Address MSB) |
| 22-20 | SYS_SIZE | 6h (1 GB) | 3h (128 MB) |
| 19-18 | SDRC_INTL | 2h (256 bytes interleaving) | 1 (128 bytes interleaving) |
| 17-16 | SDRC_ADDRSPC | 0 (Unused Reserved field) | 0 (Unused Reserved field) |
| 8 | SDRC_MAP | 3h (Map to both EMIF0 and EMIF1) | 3h (Map to both EMIF0 and EMIF1) |
| 7-0 | SDRC_ADDR | 0 (SDRC address MSB) | 20h (SDRC address MSB) |

**NOTE:** Section 2 and Section 3 are identical to Section 1.

**How DMM decodes and translates:**

Identical to Section 6.3.4.1.1.

See Figure 6-56 for System Address Memory Range and its mapping to EMIFs.

**Example with above configuration:**

Incoming accesses System address C022 34C0h:

1. Upper address bits: C0h
2. Hit mask: $2^8 - 2^3$ = F8h
3. Masked upper address bits: C0h AND F8h = C0h (the SYS_ADDR) , thus hits section 1
4. Address mask: $2^3 - 1$ = 7h
5. Masked upper address bits: C0h AND 7h = 0
6. Full masked address: 0022 34C0h
7. Bit 7 is 1 -> targets the second memory controller
8. Full masked shifted address (suppressing bit 7): 0011 1A60h
9. OR upper physical address bits with SDRC_ADDR: 0011 1A60h
10. Physical address: 0011 1A60h

This request will be forwarded to address 0011 1A60h, of the second memory controller; that is, EMIF1.

#### 6.3.4.1.3 Case 3: Two SDRAM Controllers, 1152 MB (1 GB + 128 MB) DDR Asymmetrical Distribution

**NOTE:** For optimal system performance, symmetric configuration is HIGHLY recommended. Unless dictated by system cost and other constraints, Asymmetrical distribution of memory should not be considered.

There are many ways to configure the section mapping in this use case.

Option 1: Asymmetrical section of EMIF0 is mapped to system address C000 0000h-C7FF FFFFh, higher portion of the SDRAM in system memory map.

**Table 6-8. Section Mapping Option 1**

| Bit | Field | Section 0 | Section 1 |
|---|---|---|---|
| 31-24 | SYS_ADDR | 80h (incoming System Address MSB) | 88h (incoming System Address MSB) |
| 22-20 | SYS_SIZE | 3h (128 MB) | 6h (1 GB) |
| 19-18 | SDRC_INTL | 0 (No interleaving) | 2h (256 bytes interleaving) |
| 17-16 | SDRC_ADDRSPC | 0 (Unused Reserved field) | 0 (Unused Reserved field) |
| 8 | SDRC_MAP | 1 (Map to EMIF0) | 3h (Map to both EMIF0 and EMIF1) |
| 7-0 | SDRC_ADDR | 20h (SDRC address MSB) | 0 (SDRC address MSB) |

Option 2: Asymmetrical section of EMIF0 is mapped to system address 8000 0000h-87FF FFFFh, Lower portion of the SDRAM in system memory map.

**Table 6-9. Section Mapping Option 2**

| Bit | Field | Section 0 | Section 1 |
|---|---|---|---|
| 31-24 | SYS_ADDR | 80h (incoming System Address MSB) | C0h (incoming System Address MSB) |
| 22-20 | SYS_SIZE | 6h (1 GB) | 3h (128 MB) |
| 19-18 | SDRC_INTL | 2h (256 bytes interleaving) | 0 (No interleaving) |
| 17-16 | SDRC_ADDRSPC | 0 (Unused Reserved field) | 0 (Unused Reserved field) |
| 8 | SDRC_MAP | 3h (Map to both EMIF0 and EMIF1) | 1 (Map to EMIF0) |
| 7-0 | SDRC_ADDR | 0 (SDRC address MSB) | 20h (SDRC address MSB) |

## 6.4 DMM/TILER Registers

Table 6-10 lists the DMM/TILER registers.

**Table 6-10. DMM/TILER Registers**

| Address Offset | Register Name | Section |
|---|---|---|
| 0 | DMM_REVISION | Section 6.4.1 |
| 10h | DMM_SYSCONFIG | Section 6.4.2 |
| 1Ch | DMM_LISA_LOCK | Section 6.4.3 |
| 40h-4Ch | DMM_LISA_MAP_0-3 | Section 6.4.4 |
| 220h-224h | DMM_TILER_OR_0-1 | Section 6.4.5 |
| 410h | DMM_PAT_CONFIG | Section 6.4.6 |
| 420h-424h | DMM_PAT_VIEW_0-3 | Section 6.4.7 |
| 440h-44Ch | DMM_PAT_VIEW_MAP_0-3 | Section 6.4.8 |
| 460h | DMM_PAT_VIEW_MAP_BASE | Section 6.4.9 |
| 478h | DMM_PAT_IRQ_EOI | Section 6.4.10 |
| 480h | DMM_PAT_IRQSTATUS_RAW | Section 6.4.11 |
| 490h | DMM_PAT_IRQSTATUS | Section 6.4.12 |
| 4A0h | DMM_PAT_IRQENABLE_SET | Section 6.4.13 |
| 4B0h | DMM_PAT_IRQENABLE_CLR | Section 6.4.14 |
| 4C0h-4CCh | DMM_PAT_STATUS_0-3 | Section 6.4.15 |
| 500h-530h | DMM_PAT_DESCR_0-3 | Section 6.4.16 |
| 504h-534h | DMM_PAT_AREA_0-3 | Section 6.4.17 |
| 508h-538h | DMM_PAT_CTRL_0-3 | Section 6.4.18 |
| 50Ch-53Ch | DMM_PAT_DATA_0-3 | Section 6.4.19 |
| 620h-63Ch | DMM_PEG_PRIO_0-7 | Section 6.4.20 |
| 640h | DMM_PEG_PRIO_PAT | Section 6.4.21 |

### 6.4.1 DMM Revision Register: DMM_REVISION

The DMM Revision register is shown in Figure 6-57 and described in Table 6-11.

**Figure 6-57. DMM_REVISION Register**

| 31 | 30 | 29 | 28 | 27 | 16 |
|---|---|---|---|---|---|
| SCHEME | | Reserved | | FUNC | |
| R-1 | | R-0 | | R-0 | |

| 15 | 11 | 10 | 8 | 7 | 6 | 5 | 0 |
|---|---|---|---|---|---|---|---|
| RRTL | | XMAJOR | | CUSTOM | | YMINOR | |
| R-0 | | R-0 | | R-0 | | R-8h | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-11. DMM_REVISION Register Field Descriptions**

| Bit | Field | Value | Description | Type |
|---|---|---|---|---|
| 31-30 | SCHEME | 1 | Used to distinguish between old scheme and current. | R |
| 29-28 | Reserved | 0 | Reserved | R |
| 27-16 | FUNC | 0 | Software compatability level | R |
| 15-11 | RRTL | 0 | RTL Version (R) | R |
| 10-8 | XMAJOR | 0 | Major Revision (X) | R |
| 7-6 | CUSTOM | 0 | Special DMM version | R |
| 5-0 | YMINOR | 8h | Minor Revision (Y) | R |

### 6.4.2 DMM Clock Management Configuration: DMM_SYSCONFIG

The DMM Clock Management Configuration register is shown in Figure 6-58 and described in Table 6-12.

**Figure 6-58. DMM_SYSCONFIG Register**

| 31 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|
| Reserved | | IDLEMODE | | Rsvd | |
| R-0 | | R/W-2h | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-12. DMM_SYSCONFIG Register Field Descriptions**

| Bit | Field | Value | Description | Type |
|---|---|---|---|---|
| 31-4 | Reserved | 0 | Reserved | R |
| 3-2 | IDLEMODE | | Configuration of the local target state management mode. | R/W |
| | | 0 | Force-idle mode. Backup mode, for debug only. | |
| | | 1h | No idle mode. Backup mode, for debug only. | |
| | | 2h | Smart-idle mode: local target's idle state eventually follows systems IDLE request. | |
| | | 3h | Reserved | |
| 1-0 | Reserved | 0 | Reserved | R |

### 6.4.3 LISA Configuration Locking Register: DMM_LISA_LOCK

The LISA Configuration Locking register is shown in Figure 6-59 and described in Table 6-13.

**Figure 6-59. DMM_LISA_LOCK Register**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | LOCK |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-13. DMM_LISA_LOCK Register Field Descriptions**

| Bit | Field | Value | Description | Type |
|---|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved | R |
| 0 | LOCK | | DMM lock map | R/W |
| | | R0 | DMM_LISA_MAP__x un-locked | |
| | | W0 | No effect (clear on reset only) | |
| | | R1 | DMM_LISA_MAP__xlocked | |
| | | W1 | Locking DMM_LISA_MAP__x registers | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 6-18. DMM_PAT_VIEW_MAP Registers Field Descriptions**

| Bit | Field | Value | Description | Type |
|---|---|---|---|---|
| 31 | ACCESS_PAGE | | Kind of access for this page mode container | R/W |
| | | 0 | Direct access, container base address given in CONT_PAGE | |
| | | 1 | Indirect access translation, through the LUT indexed by CONT_PAGE, which should be 0, pointing to the single LUT in the device | |
| 30-28 | Reserved | 0 | Reserved | R |
| 27-24 | CONT_PAGE | 0 | Base address of Container for page mode -or - LUT index | R/W |
| 23 | ACCESS_32 | | Kind of access for this 32-bit mode container | R/W |
| | | 0 | Direct access, container base address given in CONT_32 | |
| | | 1 | Indirect access translation, through the LUT indexed by CONT_32, which should be 0, pointing to the single LUT in the device | |
| 22-20 | Reserved | 0 | Reserved | R |
| 19-16 | CONT_32 | 0 | Base address of Container for 32-bit mode -or - LUT index | R/W |
| 15 | ACCESS_16 | 0 | Kind of access for this 16-bit mode container | R/W |
| | | 0 | Direct access, container base address given in CONT_16 | |
| | | 1 | Indirect access translation, through the LUT indexed by CONT_16, which should be 0, pointing to the single LUT in the device | |
| 14-12 | Reserved | 0 | Reserved | R |
| 11-8 | CONT_16 | 0 | Base address of Container for 16-bit mode -or - LUT index | R/W |
| 7 | ACCESS_8 | | Kind of access for this 8-bit mode container | R/W |
| | | 0 | Direct access, container base address given in CONT_8 | |
| | | 1h | Indirect access translation, through the LUT indexed by CONT_8, which should be 0, pointing to the single LUT in the device | |
| 6-4 | Reserved | 0 | Reserved | R |
| 3-0 | CONT_8 | 0 | Base address of Container for 8-bit mode -or - LUT index | R/W |

Copyright © 2011–2016, Texas Instruments Incorporated

### 6.4.9 DMM PAT View Mapping Base Address Register: DMM_PAT_VIEW_MAP_BASE

The DMM PAT View Mapping Base Address register is shown in Figure 6-65 and described in Table 6-19.

**Figure 6-65. DMM_PAT_VIEW_MAP_BASE Register**

| 31 | 30 | 0 |
|---|---|---|
| BASEADDR | Reserved | |
| R/W-0 | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 6-19. DMM_PAT_VIEW_MAP_BASE Register Field Descriptions**

| Bit | Field | Value | Description | Type |
|---|---|---|---|---|

### 6.4.10 DMM PAT End of Interrupt Register: DMM_PAT_IRQ_EOI

The DMM PAT End of Interrupt register is shown in Figure 6-66 and described in Table 6-20. This register is per-event raw interrupt status vector. The purpose is mostly for debug. Raw status is set even if the related event is not enabled. Write 1 to set the (raw) status.

### 6.4.16 DMM PAT Descriptor Registers: DMM_PAT_DESCR_0-DMM_PAT_DESCR_3

The DMM PAT Descriptor register is shown in Figure 6-72 and described in Table 6-26.

- Physical address of the next table refill descriptor
- Writing to this register aborts the current ongoing area reload
- Write also resets the corresponding DMM_PAT_AREA_x, DMM_PAT_CTRL_x and DMM_PAT_DATA_x registers
- The descriptor address must be in the DDR and not any other internal memory

**Figure 6-72. DMM_PAT_DESCR Registers**

## 7.1 Introduction

This document describes the DDR2 and DDR3 memory controller specifications and general information.

### 7.1.1 Purpose of the Peripheral

The DDR2 and DDR3 memory controller is used to interface with JESD79-2E and JESD79-3C standard-compliant DDR2 and DDR3 SDRAM devices, respectively. Memory types such as DDR1 SDRAM, SDR SDRAM, SBSRAM, and asynchronous memories are not supported.

### 7.1.2 Features Supported

The DDR2 and DDR3 memory controller supports the following features:

- JESD79-2E standard compliant DDR2 SDRAM
- JESD79-3C standard compliant DDR3 SDRAM
- 1024 Mbyte memory space
- Data bus width of 32 or 16 bits
- CAS latencies(DDR2): 3,4,5,6 and 7
- CAS latencies(DDR3): 5,6,7,8,9,10 and 11
- Internal banks DDR2 and DDR3: 1,2,4,8
- Capable of supporting two chip select signals (refer to the device data manual for the exact number of chip selects supported)
- Burst length:8
- Burst type: Sequential
- Page sizes: 256, 512, 1024 and 2048 word
- SDRAM auto-initialization on configuration change
- Self-refresh and power-down modes for low power
- Periodic ZQ calibration (DDR3 only)
- Self-refresh mode
- Prioritized refresh
- Programmable refresh rate and backlog counter
- Programmable timing parameters
- Little endian
- Software write/read leveling (calibration)
- Support for fly-by topology board routing for DDR3 interfaces via leveling
- ODT on DDR2 and DDR3
- Class of service support

### 7.1.3 Features Not Supported

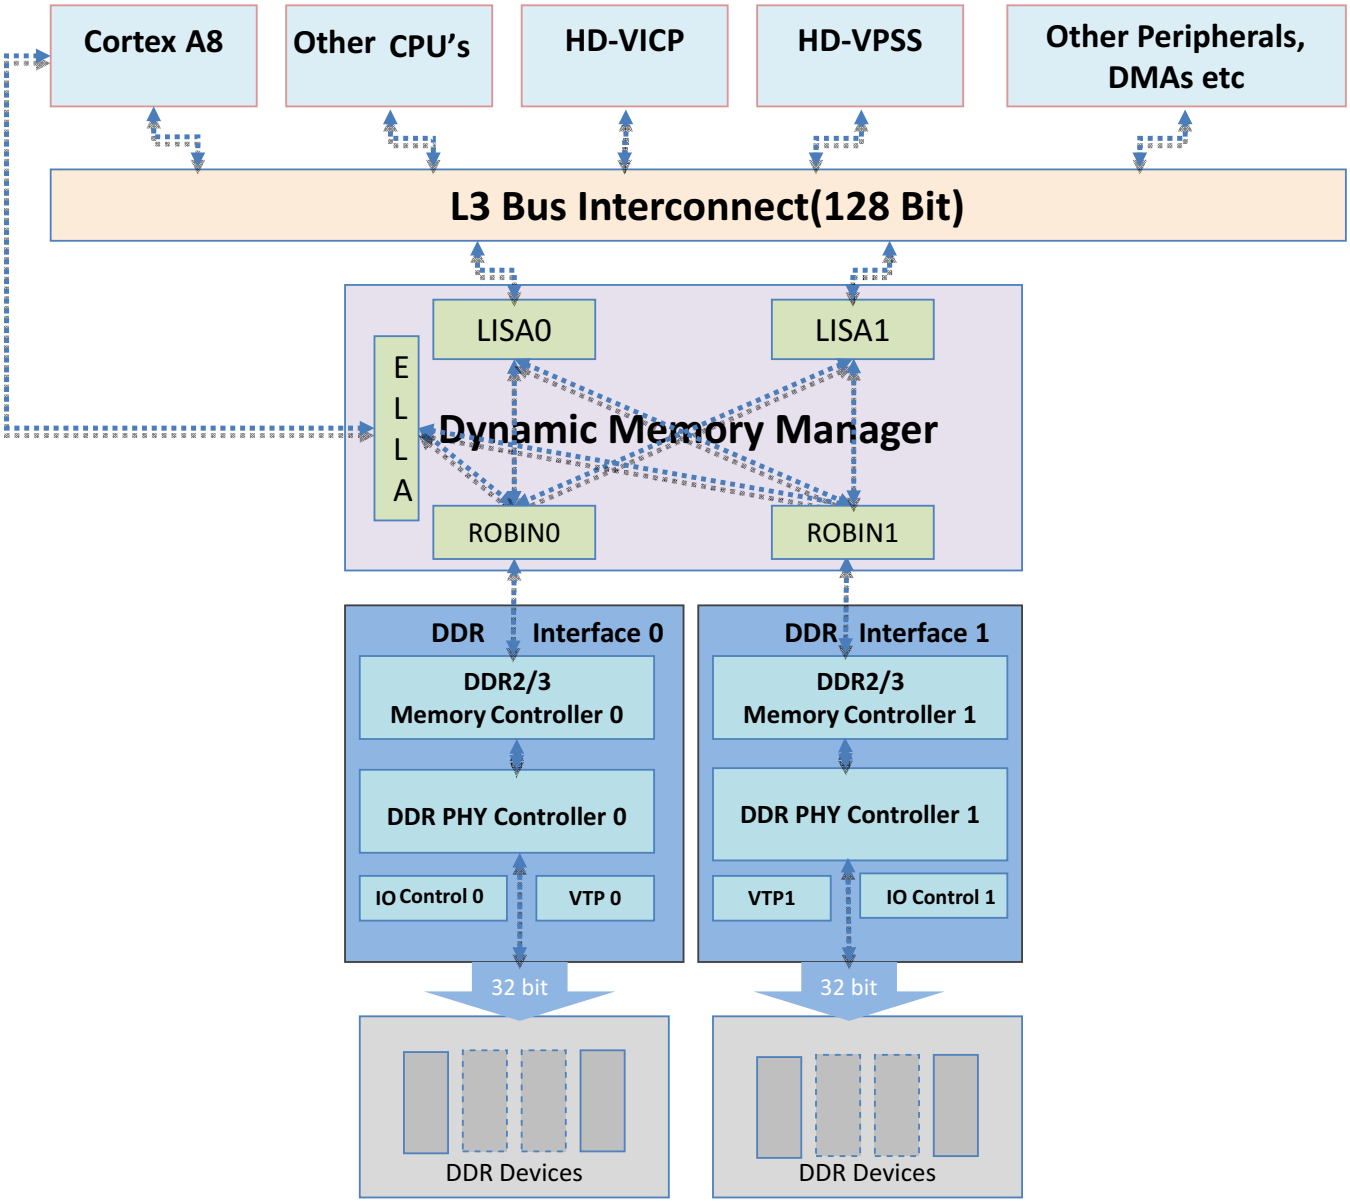
- DDR1, LPDDR1, and LPDDR2 memory types
- Burst Length other than 8
- Interleave burst type
- OCD calibration for DDR2
- DDR3 burst chop support

## 7.2 Architecture

Figure 7-1 shows the DDR subsystem interconnection to the rest of the system and the data paths. Please refer to the *DMM/TILER* chapter in the TRM for a detailed description of the dynamic memory controller. This chapter focuses only on the DDR subsystem and various sub-blocks inside the DDR subsystem.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 7-1. DDR Block Diagram**



The DDR2/DDR3 memory controllers and their associated PHYs provide the physical interface to external DDR2 or DDR3 memory devices. Data, which is read from or written to external memories by internal initiators (for example, Cortex A8, HD-VPSS, etc), is managed internally by the Dynamic Memory Manager (DMM).

In the most common usage case, the DMM acts to transparently interleave memory accesses across the two DDR interfaces on a 128B, 256B or 512B boundary. For example, the EDMA could write an 8KB block of consecutive addresses to external memory space and if 512B interleaving is enabled, the DMM would cause the write to be interleaved across both DDR interfaces on 256B boundaries. Likewise, when the same 8KB block of addresses is read back from external memory, the DMM would interleave the reads from appropriate sub-blocks so that the original data set is read back. This interleaving process substantially improves memory efficiency and is transparent to the memory requestors.

It is also possible to operate with interleaving function deactivated in which case the two external DDR interfaces can be mapped to different address spaces.

### 7.2.1 Signal Descriptions

The DDR2 and DDR3 memory controller signals are shown in Figure 7-2 and described in Table 7-1. The following features are included:

- The maximum width for the data bus (DDR[x]_D[31:0]) is 32-bits
- The address bus (DDR[x]_A[14:0]) is 15-bits wide with an additional 3-bank address pins (DDR[x]_BA[2:0])
- Two differential output clocks (DDR[x]_CLK and $\overline{\text{DDR[x]_CLK}}$ driven by internal clock sources
- Command signals: Row and column address strobe ($\overline{\text{DDR[x]_RAS}}$ and $\overline{\text{DDR[x]_CAS}}$), write enable strobe

($\overline{\text{DDR[x]_WE}}$), data strobe (DDR[x]_DQS[3:0] and $\overline{\text{DDR[x]_DQS[3:0]}}$), and data mask (DDR[x]_DQM[3:0]).

- Two chip-select signals ($\overline{\text{DDR[x]_CS[1:0]}}$) and one clock enable signal (DDR[x]_CKE)
- Two on-die termination output signals (DDR[x]_ODT[1:0])

**Figure 7-2. DDR2 and DDR3 Memory Controller Signals**

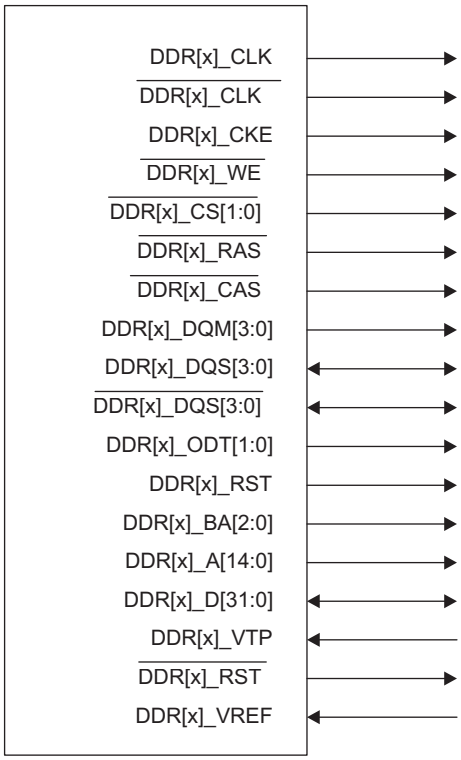

**Table 7-1. DDR2 and DDR3 Memory Controller Signal Descriptions**

| Pin | Description |
|---|---|
| DDR[x]_D[31:0] | Bidirectional data bus. Input for data reads and output for data writes. |
| DDR[x]_A[14:0] | External address output. |
| $\overline{\text{DDR[x]_CS[1:0]}}$ | Chip select output. Allows two banks of DDR2 and DDR3. |
| DDR[x]_DQM[3:0] | Active-low output data mask. |
| DDR[x]_CLK/$\overline{\text{DDR[x]_CLK}}$ | Differential clock outputs. All DDR2 and DDR3 interface signals are synchronous to these clocks. |
| DDR[x]_CKE | Clock enable. Used to select power-down and self-refresh operations. |
| $\overline{\text{DDR[x]_CAS}}$ | Active-low column address strobe. |
| $\overline{\text{DDR[x]_RAS}}$ | Active-low row address strobe. |
| $\overline{\text{DDR[x]_WE}}$ | Active-low write enable. |
| DDR[x]_DQS[3:0]/$\overline{\text{DDR[x]_DQS[3:0]}}$ | Differential data strobe bidirectional signals. Edge-aligned inputs on reads and center-aligned outputs on writes. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-1. DDR2 and DDR3 Memory Controller Signal Descriptions (continued)**

| Pin | Description |
|---|---|
| DDR[x]_ODT[1:0] | ODT[1:0] On-die termination signals to external DDR2 and DDR3 SDRAM per chip select. |
| DDR[x]_BA[2:0] | Bank-address control outputs. |
| DDR[x]_VREF | Memory Controller reference voltage. This voltage must be supplied externally. See the device-specific data manual for more details. |
| DDR[x]_VTP | DDR2 and DDR3 VTP Compensation Resistor Connection. |
| $\overline{\text{DDR[x]_RST}}$ | Reset output. Asynchronous reset for DDR3 devices. |

### 7.2.2 Memory Map

Please see the device-specific data manual for information describing the device memory map.

### 7.2.3 Clock Control

The DDR2/DDR3 clock is derived directly from the DDR PLL's VCO output. The frequency of DDR[x]_CLK can be determined by using the following formula:

DDR[x]_CLK frequency = (DDRPLL input clock frequency x mulitplier)/((pre-divider+1)*post-divider)

The second output clock of the DDR2/DDR3 memory controller $\overline{\text{DDR[x]_CLK}}$, is the inverse of DDR[x]_CLK. You can change the muliplier, pre-divider and post-divider to get the desired DDR[x]_CLK frequency.

Where x=0,1

For detailed information on DDRPLL, see the chip level resources.

### 7.2.4 DDR2/DDR3 Memory Controller Subsytem Overview

The DDR2/DDR3 memory controller can gluelessly interface to most standard DDR2/DDR3 SDRAM devices and supports such features as self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The DDR2/DDR3 subsystem consists of the following:

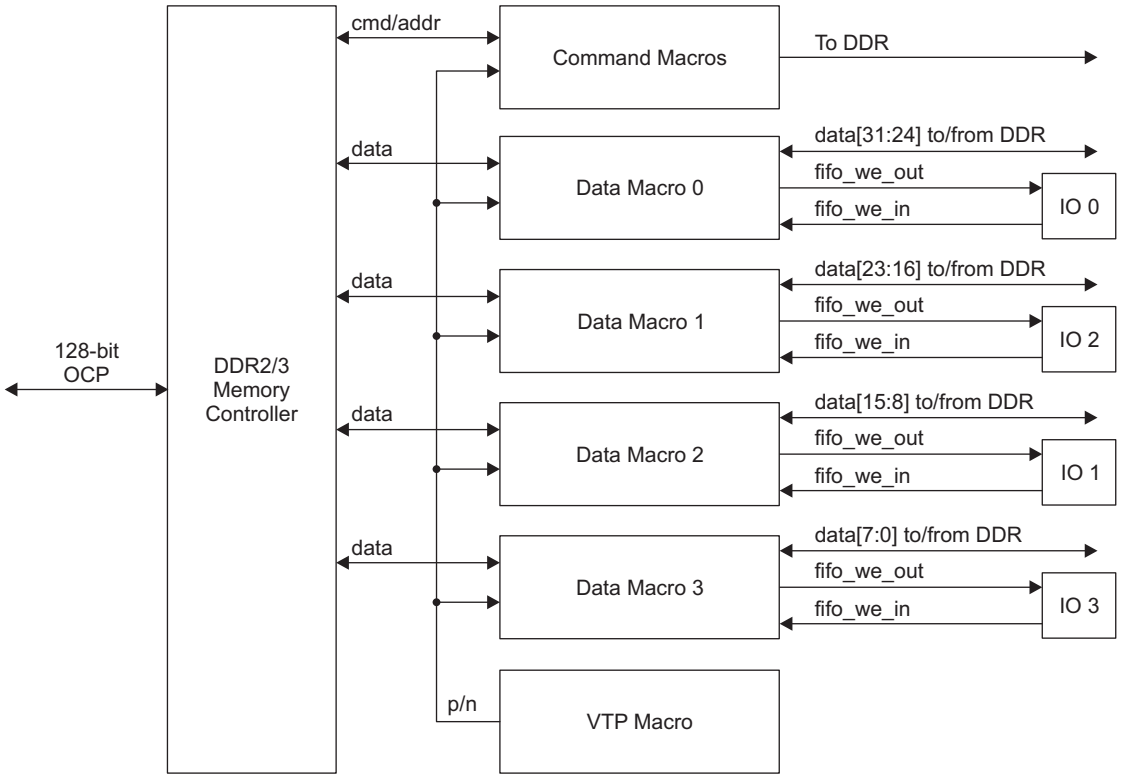
- DDR2/DDR3 memory controller
- Command macro
- Data macro
- VTP controller macro
- IO's for DQS gate

The subsystem supports JEDEC standard-compliant DDR2 and DDR3 devices. It does not support CAS latency of two for DDR2 due to data and command macro limitations. It supports a 128-bit wide OCP interface on the core side for programmability. The subsystem can be used to connect to 16- or 32-bit memory devices.

Figure 7-3 shows the DDR2/DDR3 subsystem block diagram.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 7-3. DDR2/DDR3 Subsystem Block Diagram**



Where
fifo_we_out = DQS enable output for timing match between DQS and system (Memory) clock.
fifo_we_in = DQS enable input for timing match between DQS and system (Memory) clock.

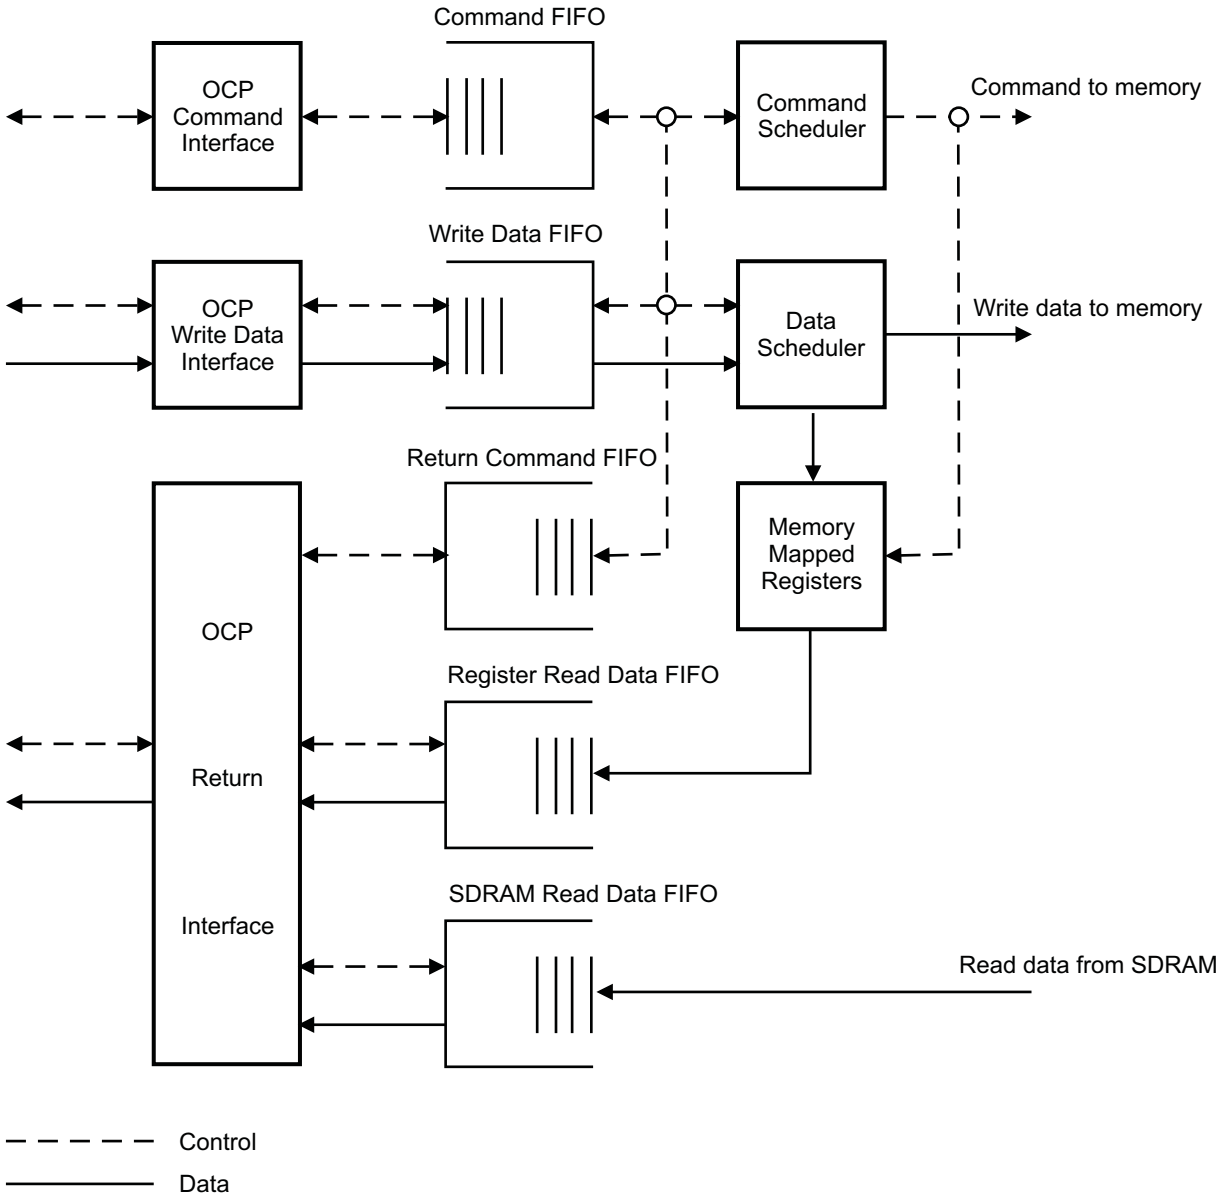
### 7.2.4.1 DDR2/DDR3 Memory Controller Interface

To move data efficiently from on-chip resources to the external DDR2/DDR3 SDRAM device, the DDR2/DDR3 memory controller makes use of a command FIFO, a write data FIFO, a return command FIFO, and two read data FIFOs. The purpose of each FIFO is described below.

Figure 7-4 shows the block diagram of the DDR2/DDR3 memory controller FIFOs. Commands, write data, and read data arrive at the DDR2/DDR3 memory controller parallel to each other. The same peripheral bus is used to write and read data from external memory as well as internal memory-mapped registers.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 7-4. DDR2/DDR3 Memory Controller FIFO Block Diagram**



The command FIFO stores all the commands coming in on the OCP command interface.

The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface.

The Return Command FIFO stores all the return transactions that are to be issued to the OCP return interface. These include the write status return and the read data return commands.

There are two Read Data FIFOs that store the read data to be sent to the OCP return interface. One Read Data FIFO stores read data from the memory mapped registers and other Read Data FIFO stores read data from external memory.

### 7.2.4.2 Data Macro

The data macro consists of eight data channels, one pair of complementary strobes (one pair for 8 bits of data), and one data mask channel (one for eight bits of data).

The data macros consists of PHY data macro, DLLs and IOs integrated into a macro.

Copyright © 2011–2016, Texas Instruments Incorporated

The data macro is a bidirectional interface. It is used to transmit data from the memory controller to the external memory chip during a write operation and receive data from memory and transmit it to the memory controller during a read operation.

During a write operation, the data macro translates 32/16-bit words from memory controller to 8-bit words and transmits them at double the bit rate to the memory along with the strobe. The strobe is center-aligned to the data. Data can be prevented from writing to the memory using data mask signal.

During a read operation, the data macro receives 8-bit DDR data along with the strobe and converts it to 32/16- bit words and transmits them to the memory controller along with the read-valid signals.

#### 7.2.4.3 Command Macro

It consists of the PHY command macro, DLLs and the IOs integrated together. The command macro acts as a unidirectional macro that transmits address and control bits from memory controller to the memory chip. The clocks DDR[x]_CLK and $\overline{\text{DDR[x]_CLK}}$ are used by the memory to register the command and address transmitted on the transmit channels. All address and control signals are transmitted clock-centered with respect to DDR[x]_CLK and $\overline{\text{DDR[x]_CLK}}$. The memory, on the positive edge of DDR[x]_CLK and the negative edge of $\overline{\text{DDR[x]_CLK}}$[x], samples all address and control signals.

#### 7.2.4.4 VTP Controller Macro

The VTP controller macro evaluates silicon performance at current voltage, temperature, and process (VTP) to enable IO drivers to set constant predetermined output driver impedance. The controller operates by comparing driver impedances to the external reference resistor and adjusting driver impedance to obtain an impedance match. The VTP controller supports the following features:

- The VTP controller generates information regarding the voltage, temperature, and process(VTP) on a chip to be shared with the device's IO drivers
- Requires a clock input from the core running at 20 MHz or less
- Requires 56 clock cycles to guarantee the VTP outputs are initially set after reset is removed
- Can be used in static or dynamic update mode of operation
- The VTP controller has internal noise filtering which allows it to control spurious update requests due to noise

Impedance of the drivers and terminations must be updated often even while in operation. In such scenarios where voltage and temperature are variables VTP macro can be configured in dynamic update mode. In contrast, static mode of operation does not allow dynamic calibration of IO impedance, and hence consumes lesser power compared to dynamic update mode.

It is possible that under noisy conditions, dynamic update controller can generate too frequent update requests. Noise can cause the controller to request a change in the impedance that can again be quickly reversed on subsequent clock cycles. To prevent the controller from making excessive numbers of impedance changes, a digital filter is included which can be configured to regulate the update rate. For example, if the user configures the filter value as F2=0,F1=1 and F0=1, then an impedance update will be performed only if four successive update requests are generated from the VTP controller. It is recommended to use a filter value of 011'b.

Table 7-2 shows the configuration details of the digital filter.

**Table 7-2. Digital Filter Configuration**

| F2 | F1 | F0 | Description |
|---|---|---|---|
| 0 | 0 | 0 | Off |
| 0 | 0 | 1 | Update on 2 consecutive update requests |
| 0 | 1 | 0 | Update on 3 consecutive update requests |
| 0 | 1 | 1 | Update on 4 consecutive update requests |
| 1 | 0 | 0 | Update on 5 consecutive update requests |
| 1 | 0 | 1 | Update on 6 consecutive update requests |
| 1 | 1 | 0 | Update on 7 consecutive update requests |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-2. Digital Filter Configuration (continued)**

| F2 | F1 | F0 | Description |
|---|---|---|---|
| 1 | 1 | 1 | Update on 8 consecutive update requests |

#### 7.2.4.5 DQS-Gate IOs

To effectively model the I/O delay on the DQS gating signal during a read request (the DQS receiver and the CLK driver I/Os), the signal is expected to be looped on a single I/O connecting fifo_we_in to fifo_we_out. The board and memory delay, being fairly constant across PTV variations, are calibrated within the IDID using a compensated delay line. The loop-back is done at the die level without bringing the signals out to the package level. Each data macro supports delay compensation independent of each other.

The data and command macros are responsible for system level flight time compensation. The following controls are supported by the DDR2/DDR3 controller subsystem:

- Aligning DDR[x]_DQS w.r.t DDR[x]_CLK during Write Cycle. To produce a given amount of skew to center the DDR[x]_DQS signals vsersus the SDRAM clock (DDR[x]_CLK) the DATA0/1/2/3_REG_PHY_WR_DQS_SLAVE_RATIO_0 registers must be programmed. The value to be loaded in these registers is calculated through the following formula:

  Data Macro 0/1/2/3 Write DQS Slave Ratio Register=256 x ([command delay] – [DDR[x]_DQS delay]) / DDR[x]_CLK clock period.
- Aligning ADDR/CMD w.r.t DDR[x]_CLK
- Aligning DDR[x]_DQ[31:0] w.r.t DDR[x]_DQS during write operation
- Offset DDR[x]_D[31:0] w.r.t DDR[x]_DQS during read operation
- Align FIFO WE window

### *7.2.5 Address Mapping*

Each DDR2/DDR3 memory controller views external DDR2/DDR3 SDRAM as one continuous block of memory. This statement is true regardless of the number of memory devices located on the chip select space. The DDR2/DDR3 memory controller receives DDR2/DDR3 memory access requests along with a 32-bit logical address from the rest of the system. In turn, this memory controller uses the logical address to generate a row/page, column, and bank address for the DDR2/DDR3 SDRAM. The number of column, row, and bank address bits used is determined by the IBANK, RSIZE, and PAGESIZE fields (see Table 7-3). The DDR2/DDR3 memory controller uses up to 15 bits for the row/page address.

**Table 7-3. IBANK, RSIZE and PAGESIZE Fields Information**

| Bit Field | Bit Value | Bit Description |
|---|---|---|
| RSIZE | | Defines the number of address lines to be connected to DDR2/DDR3 memory device |
| | 0 | 9 row bits |
| | 1h | 10 row bits |
| | 2h | 11 row bits |
| | 3h | 12 row bits |
| | 4h | 13 row bits |
| | 5h | 14 row bits |
| | 6h | 15 row bits |
| PAGESIZE | | Defines the page size of each page of the external DDR2/DDR3 memory device |
| | 0 | 256 words (requires 8 column address bits) |
| | 1h | 512 words (requires 9 column address bits) |
| | 2h | 1024 words (requires 10 column address bits) |
| | 3h | 2048 words (requires 11 column address bits) |
| IBANK | | Defines the number of internal banks on the external DDR2/DDR3 memory device |
| | 0 | 1 bank |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-3. IBANK, RSIZE and PAGESIZE Fields Information (continued)**

| Bit Field | Bit Value | Bit Description |
|---|---|---|
| | 1h | 2 banks |
| | 2h | 4 banks |
| | 3h | 8 banks |
| EBANK | | Defines whether DDR2/DDR3 memory controller accesses will use 1 or 2 chip selects |
| | 0 | CS0 only |
| | 1h | CS0, CS1 |

When addressing SDRAM, if the IBANK_POS field in the SDRAM Config register is set to 0, and the EBANK_POS field in the SDRAM Config 2 register is also set to 0, the DDR2/DDR3 memory controller uses the three fields, IBANK, EBANK and PAGESIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select.

If the IBANK_POS field in the SDRAM Config register is set to 1, 2, or 3, or the EBANK_POS field in the SDRAM Config 2 register is set to 1, the DDR2/DDR3 memory controller uses the four fields - IBANK, EBANK, PAGESIZE, and ROWSIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select.

In all cases, the DDR2/DDR3 memory controller considers its SDRAM address space to be a single logical block, regardless of the number of physical devices or whether the devices are mapped across 1 or 2 memory controller chip selects.

### 7.2.5.1 Address Mapping when IBANK_POS=0 and EBANK_POS=0

For IBANK_POS=0 and EBANK_POS=0, the effect of address mapping scheme is that, as the source address increments across DDR2/DDR3 memory device page boundaries, the DDR2/DDR3 controller moves onto the same page in the next bank in the current device $\overline{\text{DDR[x]_CS[0]}}$. This movement along the banks of the current proceeds to the same page in the next device (if EBANK=1, $\overline{\text{DDR[x]_CS[1]}}$) and proceeds through the same page in all its banks before moving over to the next page in the first device ($\overline{\text{DDR[x]_CS[0]}}$). The DDR2/DDR3 controller exploits this traversal across internal banks and chip selects while remaining on the same page, to maximize the number of open DDR2/DDR3 memory device banks within the overall memory device space.

Thus, the DDR2/DDR3 controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, and can interleave among all of them.

**Table 7-4. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=0 and EBANK_POS=0**

| Logical Address | | | |
|---|---|---|---|
| **Row Address** | **Chip Select** | **Bank Address** | **Column Address** |
| | # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| 15 bits | EBANK=0 => 0 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| | EBANK=1 => 1 bit | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| | | IBANK=2 => 2 bits | PAGESIZE=2 => 10 bits |
| | | IBANK=3 => 3 bits | PAGESIZE=3 => 11 bits |

### 7.2.5.2 Address Mapping when IBANK_POS= 1 and EBANK_POS = 0

For IBANK_POS= 1 and EBANK_POS = 0, the interleaving of banks within a device (per chip select) is limited to four banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/DDR3 controller can keep a maximum of 16 banks (8 internal banks across two chip selects) open at a time, but can only interleave among eight of them.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-5. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=1 and EBANK_POS=0**

| Logical Address | | | | |
|---|---|---|---|---|
| **Bank Address[2]** | **Row Address** | **Chip Select** | **Bank Address[1:0]** | **Column Address** |
| # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| IBANK=0 => 0 bits | RSIZE=0 => 9 bits | EBANK=0 => 0 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| IBANK=1 => 0 bits | RSIZE=1 => 10 bits | EBANK=1 => 1 bit | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| IBANK=2 => 0 bits | RSIZE=2 => 11 bits | | IBANK=2 => 2 bits | PAGESIZE=2 => 10 bits |
| IBANK=3 => 1 bit | RSIZE=3 => 12 bits | | IBANK=3 => 3 bits | PAGESIZE=3 => 11 bits |
| | RSIZE=4 => 13 bits | | | |
| | RSIZE=5 => 14 bits | | | |
| | RSIZE=6 => 15 bits | | | |

### 7.2.5.3 Address Mapping when IBANK_POS=2 and EBANK_POS = 0

For IBANK_POS=2 and EBANK_POS = 0, the interleaving of banks within a device (per chip select) is limited to two banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/DDR3 controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but can only interleave among four of them.

**Table 7-6. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=2 and EBANK_POS=0**

| Logical Address | | | | |
|---|---|---|---|---|
| **Bank Address[2:1]** | **Row Address** | **Chip Select** | **Bank Address[0]** | **Column Address** |
| # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| IBANK=0 => 0 bits | RSIZE=0 => 9 bits | EBANK=0 => 0 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| IBANK=1 => 0 bits | RSIZE=1 => 10 bits | EBANK=1 => 1 bit | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| IBANK=2 => 1 bit | RSIZE=2 => 11 bits | | IBANK=2 => 1 bit | PAGESIZE=2 => 10 bits |
| IBANK=3 => 2 bits | RSIZE=3 => 12 bits | | IBANK=3 => 1 bit | PAGESIZE=3 => 11 bits |
| | RSIZE=4 => 13 bits | | | |
| | RSIZE=5 => 14 bits | | | |
| | RSIZE=6 => 15 bits | | | |

### 7.2.5.4 Address Mapping when IBANK_POS= 3 and EBANK_POS = 0

For IBANK_POS= 3 and EBANK_POS = 0, the DDR2/DDR3 controller cannot interleave banks within a device (per chip select). However, it can still interleave banks between the two chip selects. Thus, the DDR2/DDR3 controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but can only interleave among two of them.

**Table 7-7. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=3 and EBANK_POS=0**

| Logical Address | | | |
|---|---|---|---|
| **Bank Address** | **Row Address** | **Chip Select** | **Column Address** |
| # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by EBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| IBANK=0 => 0 bits | RSIZE=0 => 9 bits | EBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| IBANK=1 => 1 bit | RSIZE=1 => 10 bits | EBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| IBANK=2 => 2 bits | RSIZE=2 => 11 bits | | PAGESIZE=2 => 10 bits |
| IBANK=3 => 3 bits | RSIZE=3 => 12 bits | | PAGESIZE=3 => 11 bits |
| | RSIZE=4 => 13 bits | | |
| | RSIZE=5 => 14 bits | | |
| | RSIZE=6 => 15 bits | | |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 7.2.5.5 Address Mapping when IBANK_POS = 0 and EBANK_POS = 1

For IBANK_POS = 0 and EBANK_POS = 1, the DDR2/DDR3 memory controller interleaves among all the banks within a device (per chip select). However, the DDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the DDR2/DDR3 memory controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but can only interleave among 8 of them.

**Table 7-8. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=0 and EBANK_POS=1**

| Logical Address | | | |
|---|---|---|---|
| **Chip Select** | **Row Address** | **Bank Address** | **Column Address** |
| # of bits defined by EBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| EBANK=0 => 0 bits | RSIZE=0 => 9 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| EBANK=1 => 1 bit | RSIZE=1 => 10 bits | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| | RSIZE=2 => 11 bits | IBANK=2 => 2 bits | PAGESIZE=2 => 10 bits |
| | RSIZE=3 => 12 bits | IBANK=3 => 3 bits | PAGESIZE=3 => 11 bits |
| | RSIZE=4 => 13 bits | | |
| | RSIZE=5 => 14 bits | | |
| | RSIZE=6 => 15 bits | | |

#### 7.2.5.6 Address Mapping when IBANK_POS = 1 and EBANK_POS = 1

For IBANK_POS = 1 and EBANK_POS = 1, the interleaving of banks within a device (per chip select) is limited to four banks. Also, the DDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the DDR2/DDR3 memory controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but can only interleave among four of them.

**Table 7-9. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=1 and EBANK_POS = 1**

| Logical Address | | | | |
|---|---|---|---|---|
| **Chip Select** | **Bank Address[2]** | **Row Address** | **Bank Address[1:0]** | **Column Address** |
| # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| EBANK=0 => 0 bits | IBANK=0 => 0 bits | RSIZE=0 => 9 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| EBANK=1 => 1 bit | IBANK=1 => 0 bits | RSIZE=1 => 10 bits | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| | IBANK=2 => 0 bits | RSIZE=2 => 11 bits | IBANK=2 => 2 bits | PAGESIZE=2 => 10 bits |
| | IBANK=3 => 1 bit | RSIZE=3 => 12 bits | IBANK=3 => 2 bits | PAGESIZE=3 => 11 bits |
| | | RSIZE=4 => 13 bits | | |
| | | RSIZE=5 => 14 bits | | |
| | | RSIZE=6 => 15 bits | | |

#### 7.2.5.7 Address Mapping when IBANK_POS = 2 and EBANK_POS = 1

For IBANK_POS = 2 and EBANK_POS = 1, the interleaving of banks within a device (per chip select) is limited to two banks. Also, the DDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the DDR2/DDR3 memory controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but can only interleave among two of them.

**Table 7-10. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=2 and EBANK_POS = 1**

| Logical Address | | | | |
|---|---|---|---|---|
| **Chip Select** | **Bank Address[2:1]** | **Row Address** | **Bank Address[0]** | **Column Address** |
| # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by PAGESIZE of SDRCR |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-10. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=2 and EBANK_POS = 1 (continued)**

| Logical Address | | | | |
|---|---|---|---|---|
| **Chip Select** | **Bank Address[2:1]** | **Row Address** | **Bank Address[0]** | **Column Address** |
| EBANK=0 => 0 bits | IBANK=0 => 0 bits | RSIZE=0 => 9 bits | IBANK=0 => 0 bits | PAGESIZE=0 => 8 bits |
| EBANK=1 => 1 bit | IBANK=1 => 0 bits | RSIZE=1 => 10 bits | IBANK=1 => 1 bit | PAGESIZE=1 => 9 bits |
| | IBANK=2 => 1 bit | RSIZE=2 => 11 bits | IBANK=2 => 1 bit | PAGESIZE=2 => 10 bits |
| | IBANK=3 => 2 bits | RSIZE=3 => 12 bits | IBANK=3 => 1 bit | PAGESIZE=3 => 11 bits |
| | | RSIZE=4 => 13 bits | | |
| | | RSIZE=5 => 14 bits | | |
| | | RSIZE=6 => 15 bits | | |

#### 7.2.5.8 Address Mapping when IBANK_POS = 3 and EBANK_POS = 1

For IBANK_POS = 3 and EBANK_POS = 1, the DDR2/DDR3 memory controller cannot interleave banks within a device (per chip select) or between the two chip selects. Thus, the DDR2/DDR3 memory controller can keep a maximum of 16 banks (eight internal banks across two chip selects) open at a time, but cannot interleave among of them.

**Table 7-11. OCP Address to DDR2/DDR3 Address Mapping for IBANK_POS=3 and EBANK_POS=1**

| Logical Address | | | |
|---|---|---|---|
| **Chip Select** | **Bank Address** | **Row Address** | **Column Address** |
| # of bits defined by EBANK of SDRCR | # of bits defined by IBANK of SDRCR | # of bits defined by RSIZE of SDRCR | # of bits defined by PAGESIZE of SDRCR |
| EBANK=0 => 0 bits | IBANK=0 => 0 bits | RSIZE=0 => 9 bits | PAGESIZE=0 => 8 bits |
| EBANK=1 => 1 bit | IBANK=1 => 1 bit | RSIZE=1 => 10 bits | PAGESIZE=1 => 9 bits |
| | IBANK=2 => 2 bits | RSIZE=2 => 11 bits | PAGESIZE=2 => 10 bits |
| | IBANK=3 => 3 bits | RSIZE=3 => 12 bits | PAGESIZE=3 => 11 bits |
| | | RSIZE=4 => 13 bits | |
| | | RSIZE=5 => 14 bits | |
| | | RSIZE=6 => 15 bits | |

Since the DDR2/DDR3 memory controller interleaves among less number of banks when IBANK_POS!= 0 or EBANK_POS= 1, these cases are lower in performance than the IBANK_POS= 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

### *7.2.6 Performance Management*

#### 7.2.6.1 Command Ordering and Scheduling

The DDR2/DDR3 memory controller performs command re-ordering and scheduling in an attempt to achieve efficient transfers with maximum throughput. The goal is to maximize the utilization of the data, address, and command buses while hiding the overhead of opening and closing DDR2/DDR3 SDRAM rows. Command re-ordering takes place within the command FIFO.

Copyright © 2011–2016, Texas Instruments Incorporated

The DDR2/DDR3 memory controller examines all the commands stored in the command FIFO to schedule commands to the external memory. All commands from same master will complete in order, regardless of the master priority. The memory controller does not guarantee ordering between commands from different masters. However, the memory controller will maintain data coherency. Therefore, the memory controller will block a command, regardless of master priority, if that command is to the same block address (2048 bytes) as an older command. Thus, the memory controller might have one or more pending read or write for each master. Among all pending reads, the memory controller selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the memory controller selects all writes that have their corresponding SDRAM banks already open.

As a result of the above reordering, at any point of time the memory controller might have several pending reads and writes that have their corresponding banks open. The memory controller then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the memory controller selects the oldest command. As a result, the memory controller might now have a final read and a final write command. The memory controller will pick either the read or the write command depending on the value programmed in the Read Write Execution Threshold register. The memory controller will keep executing reads until the read threshold is met and then switch to executing writes. The memory controller will then keep executing writes until the write threshold is met and then switch back to executing reads. The memory controller will satisfy meeting the threshold values only if that type of command is available for execution, otherwise it will switch to the other type. Similarly, the memory controller will satisfy meeting the threshold value only if the FIFOs for that type have space (Read Data FIFO for reads and Write Status FIFO for writes), otherwise it will switch to the other type.

The memory controller completes executing an OCP command before it switches to another command.

All the accesses to an SDRAM are pipe-lined to maximize the external bus utilization. In other words accesses to an SDRAM are issued back to back such that there are minimum idle cycles between any two accesses. This includes the scheduling listed above to minimize the overhead of opening and closing of SDRAM banks. All of these is done while fulfilling the access timing requirements of an SDRAM.

Besides commands received from on-chip resources, the DDR2/DDR3 memory controller also issues refresh commands. The DDR2/DDR3 memory controller attempts to delay refresh commands as long as possible to maximize performance while meeting the SDRAM refresh requirements. As the DDR2/DDR3 memory controller issues read, write, and refresh commands to DDR2/DDR3 SDRAM device, it follows the priority scheme shown in Table 7-12.

**Table 7-12. DDR2/DDR3 Memory Controller Commands Priority**

| Priority Level | Command Description |
|---|---|
| 0 (Highest priority) | SDRAM refresh request due to Refresh Must level of refresh urgency reached (Section 7.2.6.5) |
| 1 | Request for a read or a write. |
| 2 | SDRAM Activate commands. |
| 3 | SDRAM Deactivate commands. |
| 4 | SDRAM Deep Power-Down request. |
| 5 | SDRAM clock stop or Power-Down request. |
| 6 | SDRAM refresh request due to Refresh May or Release level of refresh urgency reached (Section 7.2.6.5) |
| 7 (Lowest priority) | SDRAM self-refresh request. |

### 7.2.6.2 Command Starvation

The reordering and scheduling rules listed above may lead to command starvation, which is the prevention of certain commands from being processed by the DDR2/DDR3 memory controller. Command starvation results from the following conditions:

- A continuous stream of high-priority read commands can block a low-priority write command
- A continuous stream of DDR2/DDR3 SDRAM commands to a row in an open bank can block commands to the closed row in the same bank.

Copyright © 2011–2016, Texas Instruments Incorporated

To avoid these conditions, the DDR2/DDR3 memory controller can momentarily raise the priority of the oldest command in the command FIFO after a set number of transfers have been made. The COS_COUNT_1,COS_COUNT_2 field in the Peripheral Bus Burst Priority Register (PBBPR) sets the number of the transfers that must be made before the DDR2/DDR3 memory controller will raise the priority of the oldest command. See the Section 7.2.6.4 section for more details.

**NOTE:** Leaving the COS bits at their default value (FFh) in the PBBPR register disables this feature of the DDR2/DDR3 memory controller. This means commands can stay in the command FIFO indefinitely. Therefore, these bits should be set to FEh immediately following reset, to enable this feature with the highest level of allowable memory transfers. It is suggested that system-level prioritization be set to avoid placing high-bandwidth masters on the highest priority levels. These bits can be left as FEh unless advanced bandwidth/prioritization control is required.

### 7.2.6.3 Possible Race Condition

A race condition may exist when certain masters write data to the DDR2/DDR3 memory controller. For example, if master A passes a software message via a buffer in DDR2/DDR3 memory and does not wait for indication that the write completes, when master B attempts to read the software message it may read stale data and therefore receive an incorrect message. In order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write completion status from the DDR2/DDR3 memory controller before indicating to master B that the data is ready to be read. If master A does not wait for indication that a write is complete, it must perform the following workaround:

1. Perform the required write.
2. Perform a dummy write to the DDR2/DDR3 memory controller module ID and revision register.
3. Perform a dummy read to the DDR2/DDR3 memory controller module ID and revision register.
4. Indicate to master B that the data is ready to be read after completion of the read in step 3.

The completion of the read in step 3 ensures that the previous write was done.

For a list of the master peripherals that need this workaround, see the device-specific data manual.

### 7.2.6.4 Class of Service (COS)

The commands in the Command FIFO can be mapped to 2 classes of service namely 1 and 2. The mapping of commands to a particular class of service can be done based on the priority or the connection ID. Table 7-83 shows the master connection IDs for the various initiators in the system, as seen by the DDR controllers.

The mapping based on priority can be done by setting the appropriate values in the Priority to Class of Service Mapping register (PRI_COS_MAP). Table 7-12 shows the priority of the commands issued by the DDR2/DDR3 memory controller.

The mapping based on connection ID can be done by setting the appropriate values of connection ID and the masks in the Connection ID to Class of Service Mapping registers (CONNID_COS_1_MAP and CONNID_COS_2_MAP).

There are three connection ID and mask values that can be set for each class of service. In conjunction with the masks, each class of service can have a maximum of 144 connection IDs mapped to it. For example, a connection ID value of 0xFF, along with a mask value of 0x3, will map all connection IDs from 0xF8 to 0xFF to that particular class of service.

Each class of service has an associated latency counter (COS_COUNT). The value of this counter can be set in the Peripheral Bus Burst Priority Register (PBBPR). When the latency counter for a command expires, that is, reaches the value programmed for the class of service to which the command belongs, that command will be the one that is executed next. If there is more than one command that has expired latency counters, the command with the highest priority will be executed first. One exception to this rule is, if the oldest command in the queue has an expired PR_OLD_COUNT, that command will be executed first, irrespective of priority or class of service. This is done to prevent a continuous block effect.

Copyright © 2011–2016, Texas Instruments Incorporated

The connection ID mapping allows the same connection ID to be put in both class of service 1 and 2. Also, a transaction might belong to one class of service if viewed by connection ID and might belong to another class of service if viewed by priority. In these cases, the command will belong to both class of service. The DDR2/DDR3 memory controller will try executing the command as soon as possible, when the smaller of the two counters ( COS_COUNT_1 or COS_COUNT_2) expire.

#### 7.2.6.5 Refresh Scheduling

The DDR2/DDR3 memory controller issues autorefresh (REFR) commands to DDR2/DDR3 SDRAM devices at a rate defined in the refresh rate (REFRESH_RATE) bit field in the SDRAM refresh control register (SDRFC). A refresh interval counter is loaded with the value of the REFRESH_RATE bit field and decrements by 1 each cycle until it reaches zero. Once the interval counter reaches zero, it reloads with the value of the REFRESH_RATE bit. Each time the interval counter expires, a refresh backlog counter increments by 1. Conversely, each time the DDR2/DDR3 memory controller performs a REFR command, the backlog counter decrements by 1. This means the refresh backlog counter records the number of REFR commands the DDR2/DDR3 memory controller currently has outstanding.

The DDR2/DDR3 memory controller issues REFR commands based on the level of urgency. The level of urgency is defined below. Whenever the refresh level of urgency is reached, the DDR2/DDR3 memory controller issues a REFR command before servicing any new memory access requests. Following a REFR command, the DDR2/DDR3 memory controller waits T_RFC cycles, defined in the SDRAM timing 1 register (SDRTIM1), before rechecking the refresh urgency level.

The refresh counters do not operate when the SDRAM memory is in self-refresh mode.

**Table 7-13. Refresh Modes**

| Urgency Level | Description |
|---|---|
| Refresh May | Backlog count is greater than 0. Indicates there is a backlog of REFR commands, when the DDR2/DDR3 memory controller is not busy it will issue the REFR command. |
| Refresh Release | Backlog count is greater than 4. Indicates that the refresh backlog of REFR commands is getting high and when DDR2/DDR3 memory controller is not busy it should issue the REFR command. |
| Refresh Must | Backlog count is greater than 7. Indicates that the refresh backlog of REFR commands is getting excessive and DDR2/DDR3 memory controller should perform an auto refresh cycle before servicing any new memory access requests. |

The DDR2/DDR3 memory controller starts servicing new memory accesses after Refresh Release level is cleared. If any of the commands in the Command FIFO have class of service latency counters that are expired, the DDR2/DDR3 memory controller will not wait for Refresh Release level to be cleared but will only perform one refresh command and exit the refresh state.

### *7.2.7 Performance Counter Usage*

There are two performance counters on each memory controller that can be configured to monitor the DDR bandwidth utilization by various masters in the system. The PERF_CNT_1 and PERF_CNT_2 registers can be used to monitor or calculate the EMIF bandwidth and efficiency. These counters can be configured to count events such as total SDRAM accesses, SDRAM activates, reads, writes, etc. Each counter counts events independent of the other counter. In addition to the ability to count events, the counters can also be configured to filter the events from a particular master based on the Master Connection ID (MConnID). The events to be counted and the filter enabling can be configured using the PERF_CNT_CFG register. The filter value to be used can be configured using the PERF_CNT_SEL register. Each counter can be configured independently.

Table 7-14 shows all the events that can be counted and whether or not a filter can be applied to that particular event.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-14. Performance Counter Filter Configuration**

| CNTRn_CFG | CNTRn_MCONNID_EN | Description |
|---|---|---|
| 0x0 | 0x0 or 0x1 | Count total SDRAM accesses. |
| 0x1 | 0x0 or 0x1 | Count total SDRAM activates. |
| 0x2 | 0x0 or 0x1 | Count total reads. |
| 0x3 | 0x0 or 0x1 | Count total writes. |
| 0x4 - 0xF | 0x0 | Reserved for future use. |

**Note:** The DDR performance counters do NOT count the bytes but the events (commands from various masters). As different commands could be for different byte counts, the performance counter values may not directly correlate with the amount of data that is being transferred. However performance counters can be effectively used to monitor the DDR bus utilization by different masters.

**Example 1**

PERF_CNT_1 register needs to count all write accesses from master 0x7. To enable counting writes, the CNTR1_CFG field in the PERF_CNT_CFG register must be set to 0x3. The MCONNID1 field in the PERF_CNT_SEL must be set to 0x7. Finally, to enable filtering, the CNTR1_MCONNID_EN bit in the PERF_CNT_CFG register must be set to 0x1.

With the above configuration, PERF_CNT_1 will count every write made to the DDR from master 0x7. This will not include accesses from other masters and will not include commands other than writes.

**Example 2**

PERF_CNT_2 register needs to count total accesses to SDRAM irrespective of masters. To enable counting all SDRAM accesses, the CNTR2_CFG field in the PERF_CNT_CFG must be set to 0x0. Finally, to disable filtering, the CNTR1_MCONNID_EN bit in the PERF_CNT_CFG register must be set to 0x0.

With the above configuration, PERF_CNT_2 will count every access made to the DDR. This will include all accesses from all masters.

### 7.2.8 DDR3 Software Write/Read Leveling

The memory controller supports only software leveling. Software leveling is a procedure by which the time delays between DDR3 signals can be compensated by appropriate values programmed in the corresponding slave ratio registers of the DDR PHY. For description of these registers, see Table 7-66. Software leveling can be done independently for each data and command macro. When software leveling is used there is no need to enable the leveling feature of the external DDR3 SDRAM, which is controlled by one of its MR registers. However, during write leveling the ODT function must be on. Proper ODT values must be turned on at the external memory side by setting Rtt_Nom (A9,A6,A2) bits in external DDR3 MR1 register.

For more information about the concept of the software leveling, see http://processors.wiki.ti.com/index.php/TI814x-DDR3-Init-U-Boot.

### 7.2.9 PRCM Sequence for DDR2/DDR3 Memory Controller

The memory controller clock, reset and power are handled by the device PRCM module. Refer to the Power Reset Clock Management (PRCM) chapter for the PRCM register details.

### 7.2.10 Interrupt Support

The controller supports generation of an error interrupt if an unsupported command or a command with unsupported addressing mode is received. The controller supports only Idle, Write, Read, and WriteNonPost commands and only incrementing, wrapping, and 2-dimensional block addressing modes.

### 7.2.11 EDMA Event Support

The DDR2/DDR3 memory controller is a DMA slave peripheral and therefore does not generate EDMA events. Data read and write requests may be made directly by masters including the EDMA controller.

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.2.12 Emulation Considerations

The DDR2/DDR3 memory controller will remain fully functional during emulation halts to allow emulation access to external memory.

### 7.2.13 Power Management

This section defines the power management capabilities and requirements.

#### 7.2.13.1 Self-Refresh Mode

The DDR2/DDR3 memory controller supports self-refresh mode for low power. The memory controller automatically puts the SDRAM into self-refresh after the memory controller is idle for SR_TIM number of DDR clock cycles and the LP_MODE field is set to 2. The LP_MODE and SR_TIM fields can be programmed in the Power Management Control register(PMCR). The memory controller will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR_TIM, the memory controller will start issuing refreshes to complete the refresh backlog, and then issue a SELF-REFRESH command to the SDRAM.

In self-refresh mode, the memory controller automatically stops the clocks DDR[x]_CLK to the SDRAM. The memory controller maintains DDR[x]_CKE low to maintain the self-refresh state. When the SDRAM is in self-refresh, the memory controller services register accesses as normal. If the LP_MODE field is set not equal to 2, or an SDRAM access is requested while it is in self-refresh, and T_CKE + 1 cycles have elapsed since the SELF-REFRESH command was issued, the memory controller will bring the SDRAM out of self-refresh. The value of T_CKE is taken from SDRAM Timing 2 register.

**Exit sequence of self-refresh mode for the DDR2 device:** The memory controller:

- Enables clocks
- Drives DDR[x]_CKE high
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM Timing 2 register
- If the DDR_DISABLE_DLL bit in the SDRAM Config register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the DDR address lines set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Output buffer enabled |
| DDR[x]_A[11] | 0x0 | RDQS disable |
| DDR[x]_A[10] | DDR2_DDQS | Differential DQS enable value from SDRAM Config register |
| DDR[x]_A[9:7] | 0x0 | Exit OCD calibration mode |
| DDR[x]_A[6] | DDR_TERM[1] | DDR2 termination resistor value from SDRAM Config register |
| DDR[x]_A[5:3] | 0x0 | Additive latency = 0 |
| DDR[x]_A[2] | DDR_TERM[0] | DDR2 termination resistor value from SDRAM Config register |
| DDR[x]_A[1] | SDRAM_DRIVE | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[0] | 0x1 | Disable DLL |

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after T_XSRD + 1 clock cycles have elapsed since DDR[x]_CKE is driven high. The value of T_XSRD is taken from SDRAM Timing 2 register.

Exit sequence of self-refresh mode for DDR3 device: The memory controller:

- Enables clocks.
- Drives DDR[x]_CKE high.
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM Timing 2 register.
- If the DDR_DISABLE_DLL bit in the SDRAM Config register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the DDR address lines set as follows:

Copyright © 2011–2016, Texas Instruments Incorporated

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Output buffer enabled |
| DDR[x]_A[11] | 0x0 | TDQS disable |
| DDR[x]_A[10] | 0x0 | Reserved |
| DDR[x]_A[9] | DDR_TERM[2] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[8] | 0x0 | Reserved |
| DDR[x]_A[7] | 0x0 | External DDR3 write leveling feature disabled |
| DDR[x]_A[6] | DDR_TERM[1] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[5] | SDRAM_DRIVE[1] | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[4:3] | 0x0 | Additive latency = 0 |
| DDR[x]_A[2] | DDR_TERM[0] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[1] | SDRAM_DRIVE[0] | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[0] | 0x1 | Disable DLL |

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after T_XSRD + 1 clock cycles have elapsed since DDR[x]_CKE is driven high. The value of T_XSRD is taken from SDRAM Timing 2 register.

#### 7.2.13.2 Power-Down Mode

The memory controller also supports power-down mode for low power. The memory controller automatically puts the SDRAM into power-down mode after the memory controller is idle for PD_TIM number of DDR clock cycles and the LP_MODE field is set to 4. The LP_MODE and PD_TIM fields can be programmed in the Power Management Control register (PMCR). If the Refresh Must level is not reached before the entry into power-down, the memory controller will not precharge all banks before issuing the POWER-DOWN command. This will result in SDRAM entering active power-down mode.

If the Refresh Must level is reached before the entry into power-down, the memory controller will precharge all banks and issue refreshes until the Refresh Release Level is reached before issuing the POWER-DOWN command. This will result in SDRAM entering precharge power-down mode.

In power-down mode, the memory controller does not stop the clocks DDR[x]_CLK to the SDRAM. The memory controller maintains DDR[x]_CKE low to maintain the power-down state.

When the SDRAM is in power-down, the memory controller services register accesses as normal. If the LP_MODE field is set not equal to 4, or an SDRAM access is requested, or the Refresh Must level is reached while the SDRAM is in power-down, the memory controller will bring the SDRAM out of power-down.

Exit sequence of power-down mode for DDR2 and DDR3: The memory controller

- Drives DDR[x]_CKE high after T_CKE + 1 cycles have elapsed since the POWER-DOWN command was issued. The value of T_CKE is taken from SDRAM Timing 2 register.
- Waits for T_XP + 1 cycles. The value of T_XP is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

#### 7.2.13.3 EMIF PHY Clock Gating

The clock to the DDR2/DDR3 PHY can be gated off to achieve power saving. Refer to the EMIF0/1 Clock Gate Control register (EMIF_CLK_GATE).

## 7.3 DDR PHY

### *7.3.1 Functional Overview*

DDR PHY is a fully digital, flexible and advanced solution designed to get ultimate performance form the memory interface. The DDR PHY supports:

Copyright © 2011–2016, Texas Instruments Incorporated

- Bi-directional DQS
- Software write/read leveling

DDR PHY consists of three separate blocks:

- Control Block (Address and Command Block)
- Byte-wide data block
- Master DLL block

The control block handles all the address and command signals. The primary function of the PHY control block is to control the timing of the generation of all the SDRAM address and control signals such as CKE, ODT, CSN, RASN,CASN, WEN, BA (bank address) and ADDR (column/row address). The data slices or macros contain the data signal path and the slave DLLs for write data, write DQS, and read DQS. The master DLL block controls the Ratio logic functions which are used to adjust the signal timing for each signal edge. The operations of these blocks are explained in detail in the following sections.

### 7.3.2 Data Slice Block

The data slice block contains all the logic required to support read and write interface for a single memory data slice of 8 bits. It handles the DQ, DM, DQS, FIFO_WE signals. The block has data macro and multi-rank ratio logic.

### 7.3.3 Master DLL

The master DLL measures the cycle period in terms of a number of taps and passes this number through the ratio logic to the slave delay lines. The DLL is comprised of a delay line, an FSM, a clock divider, a phase detector and output filter. The FSM sends different control values to the delay line until phase detector detects transition from 0 to 1. When cross is detected, control values are provided to output filter which generates dll lock as well as final full cycle delay value. The master DLL manages on-chip variation (OCV) and continuously monitors core clock over PVT.

### 7.3.4 Ratio Logic Block

The ratio logic takes the output from the master DLL, which indicates the number of delay taps required to form a full-cycle shift, and scales it by an input ratio value in the range of 0 to 511 in units of 1/256th of a clock cycle. The result from ratio logic is the number of delay taps for slave delay line.

### 7.3.5 Command Write, Write, and Read Operation

#### 7.3.5.1 Memory Clock inversion Feature

This is a feature for pushing out the DDR[x]_CLK and the corresponding address/command by one half cycle, enabled by asserting CMD0/1/2_PHY_INVERT_CLKOUT_0. There is no need to configure this register if one of the following conditions is met:

- There is no fly-by routing on the board.
- There is no multiple fanout on DDR[x]_CLK (multiple ranks).

#### 7.3.5.2 Write Operation

On a write operation, the DDR PHY accepts signals synchronous to the core or memory clock from controller. DDR[x]_CLK/$\overline{\text{DDR[x]_CLK}}$ are generated inside the DDR PHY and sent out edge-aligned with DDR[x]_CLK/$\overline{\text{DDR[x]_CLK}}$ for DDR2 operation, and delayed from core clock by software write leveling delay for DDR3 operation. DDR[x]_D[31:0] and DDR[x]_DQM[3:0] are phase shifted by approximately 90 degrees with respect to DDR[x]_DQS[3:0].

Copyright © 2011–2016, Texas Instruments Incorporated

#### 7.3.5.3 Read Operation

For a read operation, the DDR[x]_D[31:0] signal sent by memory is edge-aligned with DDR[x]_DQS[3:0], so DDR[x]_DQS[3:0] must be shifted by PHY data slice to center-align DDR[x]_D[31:0] with DDR[x]_DQS[3:0]. This is approximately a 90-degree phase shift, with the exact shift dependent on the result of read DQS eye training in DDR3 applications, or register programming for DDR2 applications. After DDR[x]_D[31:0] is sampled by DDR[x]_DQS[3:0] and converted from DDR to SDR domain, the sampled data is re-synchronized by the core clock through a FIFO. Read data is then sent to the controller along with a data-valid signal.

## 7.4 Electrical Characteristics Control

### *7.4.1 Output Impedance Calibration*

The DDR2/DDR3 controller supports automatic output impedance calibration for DDR3. The ZQ calibration can be enabled per chip select by setting ZQ_CS0EN and ZQ_CS1EN fields in the SDRAM Output Impedance Calibration Config register. The DDR2/DDR3 memory controller supports following three types of ZQ calibration commands:

- ZQINIT – ZQ calibration command during initialization
- ZQCS – ZQ calibration short command
- ZQCL – ZQ calibration long command

For DDR3, the memory controller will automatically issue a ZQINIT command during initialization. The memory controller will wait and block any other command for (ZQ_ZQINIT_MULT+1)*(ZQ_ZQCL_MULT+1)*(T_ZQCS+1) number of clock DDR3 clock cycles every time a ZQINIT command is issued.

The memory controller periodically issues a ZQCS command every time ZQ_REFINTERVAL expires. In other words, the ZQ_REFINTERVAL defines the interval between ZQCS commands. The memory controller will wait and block any other command for (T_ZQCS+1) number of DDR3 clock cycles every time a ZQCS command is issued.

If the ZQ_SFEXITEN field is set to a 1, the memory controller will issue a ZQCL command every time it exits Self-Refresh, Active Power-Down, and Precharge Power-Down. The memory controller will wait and block any other command for (ZQ_ZQCL_MULT+1)*(T_ZQCS+1) number of clock DDR clock cycles every time a ZQCL command is issued.

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both the chip selects. To enable ZQ calibration to be performed simultaneously over both chip selects, the ZQ_DUALCALEN field must be set to a 1. If ZQ_DUALCALEN is set to a 0, the EMIF will perform ZQ calibration per chip select serially.

### *7.4.2 IO Configuration and Slew Rate Control*

On this device, programmability is given to control the output driver strength/impedance and slew rate.

Where Rext is the external resistor between device VTP pin and ground. Recommended value is 50 Ohm with 1% tolerance.

The IO output Impedance for each DDR interface is configurable through the corresponding DDRn_IO_CTRL Control Registers, described in this document.

The supported output impedance settings are shown in Table 7-15. The recommended IO buffer impedance setting is 0b011.

**Table 7-15. Output Impedance Settings**

| I2 | I1 | I0 | Output Impedance (Ron) | Ron for Rext=50 Ohms | Drive Strength (mA) for Rext=50 Ohms |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 1.6*Rext | 80 | 5 |
| 0 | 0 | 1 | 1.33*Rext | 67 | 6 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-15. Output Impedance Settings (continued)**

| I2 | I1 | I0 | Output Impedance (Ron) | Ron for Rext=50 Ohms | Drive Strength (mA) for Rext=50 Ohms |
|---|---|---|---|---|---|
| 0 | 1 | 0 | 1.14*Rext | 57 | 7 |
| 0 | 1 | 1 | Rext | 50 | 8 Recommended Setting |
| 1 | 0 | 0 | 0.88*Rext | 44 | 9 |
| 1 | 0 | 1 | 0.80*Rext | 40 | 10 |
| 1 | 1 | 0 | 0.73*Rext | 36 | 11 |
| 1 | 1 | 1 | 0.67*Rext | 33 | 12 |

To achieve optimal noise/frequency trade off, the slew rate of the output signal can also be programmed using the slew rate control bits of the corresponding DDRn_IO_CTRL Control Registers described in this document. Table 7-16 shows the programmable slew-rate settings. The recommended value is 00'b.

**Table 7-16. Programmable Slew-rate Settings**

| SR1 | SR0 | Description |
|---|---|---|
| 0 | 0 | Fastest Slew Rate<br>Recommended Setting |
| 0 | 1 | Fast Slew Rate |
| 1 | 0 | Slow Slew Rate |
| 1 | 1 | Slowest Slew Rate |

### *7.4.3 ODT Control*

The DDR2/DDR3 controller supports ODT programming. ODT means On-Die-Termination. It involves terminating the data transfer at the receive end using switchable on-chip resistances. ODT may be required for better system level signal integrity and performance. ODT strength level is a function of output driver strength. Table 7-17 shows the ODT settings.

For a data write to the DDR3 memory, the ODT is controlled through appropriate bits in MR1 register of the DDR3 memory. These are the A9, A6 and A2 bits which are configured by DDR_TERM field in the SDRCR register. When ODT is configured, the external device switches on the terminating resistances in response to the ODT output signal of the DDR2/DDR3 memory controller.

For a data read from the DDR3 memory, the ODT function is controlled in the applications processor's PHY. When it performs a memory read, the internal terminating resistances are switched on to terminate the signal at the PHY receiver if the ODT is enabled in the PHY.

The READ ODT for each DDR interface is configurable through the corresponding DDRPHYCR registers described in the register description section of this document.

**Table 7-17. ODT Settings**

| ODT1 | ODT0 | Description |
|---|---|---|
| 0 | 0 | ODT off |
| 0 | 1 | Reserved |
| 1 | 0 | Termination=Ron (eg., Rth = 50 ohms with Ron=50 ohms) |
| 1 | 1 | Termination=2*Ron (eg., Rth = 100 ohms with Ron=50 ohms) |

Refer to DDR PHY Control Register (DDRPHYCR) and DDR PHY Control Shadow register (DDRPHYCSR) for register programming.

Copyright © 2011–2016, Texas Instruments Incorporated

## 7.5 DDR2/DDR3 SDRAM Memory Initialization

### 7.5.1 DDR2 SDRAM Memory Initialization

After cold reset, if the MEMTYPE field in the SDRCR is equal to 2 and the INITREF_DIS bit in the SDRRCR is set to 0, DDR2/DDR3 controller performs DDR2 SDRAM initialization sequence as follows.

1. Drives DDR[x]_CKE low
2. After 16 SDRAM refresh rate intervals, issues a NOP command with DDR[x]_CKE held high. The SDRAM refresh rate is as defined in SDRRCR.
3. Issues PRECHARGE command with DDR[x]_A[10] held high to indicate all banks.
4. Issues a LOAD MODE REGISTER command to the extended mode register 2(DDR[x]_BA[2:0]=2h) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:8] | 0x0 | Reserved |
| DDR[x]_A[7] | SRT | Self-Refresh temperature range from SDRAM Refresh Control register |
| DDR[x]_A[6:4] | 0x0 | Reserved |
| DDR[x]_A[3] | 0x0 | DCC disable |
| DDR[x]_A[2:0] | PASR | Partial array self-refresh from SDRAM Refresh Control register |

5. Issues a LOAD MODE REGISTER command to the extended mode register 3(DDR[x]_BA[2:0]=3h) with DDR[x]_A[x]=0h.
6. Issues a LOAD MODE REGISTER command to the extended mode register 1(DDR[x]_BA[2:0]=0x1) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Output buffer enabled |
| DDR[x]_A[11] | 0x0 | RDQS disable |
| DDR[x]_A[10] | DDR2_DDQS | Differential DQS enable value from SDRAM Config register |
| DDR[x]_A[9:7] | 0x0 | Exit OCD calibration mode |
| DDR[x]_A[6] | DDR_TERM[1] | DDR2 termination resistor value from SDRAM Config register |
| DDR[x]_A[5:3] | 0x0 | Additive latency = 0 |
| DDR[x]_A[2] | DDR_TERM[0] | DDR2 termination resistor value from SDRAM Config register |
| DDR[x]_A[1] | SDRAM_DRIVE | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[0] | 0x0 | Enable DLL |

7. Issues a LOAD MODE REGISTER command to the mode register (DDR[x]_BA[2:0]=0x0) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Fast exit active power-down exit time |
| DDR[x]_A[11:9] | T_WR[2:0] | Write recovery for auto precharge from SDRAM Timing 1 register |
| DDR[x]_A[8] | 0x1 | DLL reset |
| DDR[x]_A[7] | 0x0 | Normal mode |
| DDR[x]_A[6:4] | CL[2:0] | CAS latency from SDRAM Config register |
| DDR[x]_A[3] | 0x0 | Sequential burst type |
| DDR[x]_A[2:0] | 0x3 | Burst length of 8 |

8. After 267 clock cycles, issues a PRECHARGE command with DDR[x]_A[10] held high to indicate all banks.
9. After two AUTO REFRESH commands, issues LOAD MODE REGISTER command to the mode register(DDR[x]_BA[2:0]=0h) with DDR[x]_A bits set as follows:

Copyright © 2011–2016, Texas Instruments Incorporated

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:9] | Equal to step 7 | |
| DDR[x]_A[8] | 0x0 | DLL not reset |
| DDR[x]_A[7:0] | Equal to step 7 | |

10. Issues a LOAD MODE REGISTER command to the exteded mode register 1(DDR[x]_BA[2:0]=1h) with DDR[x]_A bits set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:10] | Equal to step 6 | |
| DDR[x]_A[9:7] | 0x7 | Default OCD calibration |
| DDR[x]_A[6:0] | Equal to step 6 | |

11. Issues a LOAD MODE REGISTER command to the extended mode register 1(DDR[x]_BA[2:0]) with DDR[x]_A bits equal to step 6.
12. If the DDR_DISABLE_DLL bit in the SDRAM Config register is 1, issues a LOAD MODE REGISTER command to extended mode register 1(DDR[x]_BA[2:0]=1h) with DDR[x]_A bits, set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:1] | Equal to step 6 | |
| DDR[x]_A[0] | 0x1 | Disable DLL |

13. The DDR2/DDR3 controller enters its idle state.

The controller also performs the initialization sequence whenever the SDRCR is written, if already INITREF_DIS bit of SDRRCR is set to 1. But in this case, the controller starts at step 3.

### 7.5.2 DDR3 SDRAM Memory Initialization

After cold reset, if the MEMTYPE field in the SDRCR is equal to 3 and the INITREF_DIS bit in the SDRRCR is set to 0, DDR2/DDR3 controller performs DDR3 SDRAM initialization sequence as follows.

1. Drives DDR[x]_CKE low.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with DDR[x]_CKE held high. The SDRAM refresh rate is as defined in SDRRCR.
3. Issues a LOAD MODE REGISTER command to the extended mode register 2(DDR[x]_BA[2:0]=2h) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:11] | 0x0 | Reserved |
| DDR[x]_A[10:9] | DYN_ODT | Dynamic ODT value from SDRAM Config register |
| DDR[x]_A[8] | 0x0 | Reserved |
| DDR[x]_A[7] | SRT | Self-Refresh temperature range from SDRAM Refresh Control register |
| DDR[x]_A[6] | ASR | Auto self-refresh enable from SDRAM Refresh Control register |
| DDR[x]_A[5:3] | CWL | CAS write latency from SDRAM Config register |
| DDR[x]_A[2:0] | PASR | Partial array self-refresh from SDRAM Refresh Control register |

4. Issues a LOAD MODE REGISTER command to the extended mode register 3(DDR[x]_BA[2:0]=3h) with DDR[x]_A[15:0]=0h.
5. Issues a LOAD MODE REGISTER command to the extended mode register 1(DDR[x]_BA[2:0]=0x1) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Output buffer enabled |
| DDR[x]_A[11] | 0x0 | TDQS disable |
| DDR[x]_A[10] | 0x0 | Reserved |

Copyright © 2011–2016, Texas Instruments Incorporated

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[9] | DDR_TERM[2] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[8] | 0x0 | Reserved |
| DDR[x]_A[7] | 0x0 | External DDR3 write leveling feature disabled |
| DDR[x]_A[6] | DDR_TERM[1] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[5] | SDRAM_DRIVE[1] | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[4:3] | 0x0 | Additive latency = 0 |
| DDR[x]_A[2] | DDR_TERM[0] | DDR3 termination resistor value from SDRAM Config register |
| DDR[x]_A[1] | SDRAM_DRIVE[0] | SDRAM drive strength from SDRAM Config register |
| DDR[x]_A[0] | 0x0 | DDR_DISABLE_DLL value from SDRAM Config register |

6. Issues a LOAD MODE REGISTER command to the mode register 0(DDR[x]_BA[2:0]=0x0) with DDR[x]_A[x] set as follows:

| Bits | Value | Description |
|---|---|---|
| DDR[x]_A[15:13] | 0x0 | Reserved |
| DDR[x]_A[12] | 0x0 | Fast exit active power-down exit time |
| DDR[x]_A[11:9] | T_WR[2:0] | Write recovery for auto precharge from SDRAM Timing 1 register |
| DDR[x]_A[8] | 0x1 | DLL reset |
| DDR[x]_A[7] | 0x0 | Normal mode |
| DDR[x]_A[6:4] | CL[3:1] | CAS latency from SDRAM Config register |
| DDR[x]_A[3] | 0x0 | Sequential burst type |
| DDR[x]_A[2] | CLI[0] | CAS latency from SDRAM Config register |
| DDR[x]_A[1:0] | 0x0 | Burst length of 8 |

7. Issues a ZQCL command to start long ZQ calibration.
8. Issues an AUTO REFRESH command.
9. The memory controller enters its idle state.

The controller also performs the initialization sequence, whenever the SDRCR is written, if the INITREF_DIS bit of the SDRRCR register is set to 0x1. But in this case, the controller starts at step 3.

## 7.6 Interfacing the DDR2/DDR3 Memory Controller to DDR Memory Devices

The following sections describe the architecture of the DDR2/DDR3 memory controller and how to configure it to perform read and write operations to DDR2/DDR3 SDRAM devices. Refer the device-specific data manual to get details of supported configurations and topologies.

### *7.6.1 Configuring DDR2/DDR3 Memory Controller Registers to Meet DDR2 SDRAM Specifications*

The DDR2/DDR3 memory controller allows a high degree of programmability for shaping DDR2 accesses. This provides the DDR2/DDR3 memory controller with the flexibility to interface with a variety of DDR2 devices. By programming the SDRAM Configuration Register (SDRCR), SDRAM Refresh Control Register (SDRRCR), SDRAM Timing 1 Register (SDRTIM1), SDRAM Timing 2 Register (SDRTIM2), and SDRAM Timing 3 Register (SDRTIM3), the DDR2/DDR3 memory controller can be configured to meet the data sheet specification for JESD79-2E compliant DDR2 SDRAM devices.

As an example, the following sections describe how to configure each of these registers for access to two 1Gb, 16-bit wide DDR2 SDRAM devices, where each device has the following configuration:

- SDRAM Clock Frequency : 400 MHz
- SDRAM Data Rate : 800 MHz
- Number of banks: 8
- Page size: 1024 words

Copyright © 2011–2016, Texas Instruments Incorporated

- CAS latency: 5

#### 7.6.1.1 Programming the SDRAM Configuration Register (SDRCR)

The SDRAM configuration register (SDRCR) contains register fields that configure the DDR2 memory controller to match the data bus width, CAS latency, number of banks, and page size of the attached DDR2 memory. Table 7-18 shows the resulting SDRCR configuration.

**Table 7-18. SDRCR Configuration**

| Field | Value | Function Selection |
|---|---|---|
| SDRAM_TYPE | 2h | To select DDR2 Memory Type |
| DDR_TERM | 1h | To select 75 ohm termination register |
| DDR2_DDQS | 1h | To select Differential Ended DQS |
| DDR_DISABLE_DLL | 0h | Enable DLL for Normal Operation |
| SDRAM_DRIVE | 0h | To select a drive strength |
| NARROW_MODE | 0h | To configure the DDR2 memory controller for a 32-bit data bus width |
| CL | 5h | To select CAS latency of 5 |
| IBANK | 3h | To select 8 internal DDR2 banks |
| EBANK | 0h | To select single chip select, CS0 |
| PAGESIZE | 2h | To select 1024-word page size |

#### 7.6.1.2 Programming the SDRAM Refresh Control Register (SDRRCR)

The SDRAM refresh control register (SDRRCR) configures the DDR2 memory controller to meet the refresh requirements of the attached DDR2 device. SDRRCR also allows the DDR2 memory controller to enter and exit self refresh. In this example, we assume that the DDR2 memory controller is in self-refresh mode.

The RR field in SDRRCR is defined as the rate at which the attached DDR2 device is refreshed in DDR2 cycles. The value of this field may be calculated using the following equation:

*Refresh_Rate = DDR2 clock frequency (in MHz) x DDR2 memory fresh rate (in $\mu$s)*

Table 7-19 displays the DDR2-800 refresh rate specification.

**Table 7-19. DDR2-800 Refresh Rate Specification**

| Symbol | Value | Description |
|---|---|---|
| tREF | 7.8µs | Average Periodic Refresh Interval |

Therefore, the value for the Refresh Rate (RR) can be calculated as follows:

*RR = 400MHz x 7.8µs = 3120=C30h*

Table 7-20 shows the RR calculated value.

**Table 7-20. Refresh Rate Calculated Value**

| Filed | Value | Function Selection |
|---|---|---|
| INITREF_DIS | 0h | To enable DDR3 Initialization and Refreshes |
| RR | C30h | Set to C30h DDR2 clock cycles to meet the DDR2 memory refresh rate requirement |

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.6.1.3 Configuring SDRAM Timing Registers (SDRTIM1, SDRTIM2 and SDTIM3)

The SDRAM timing 1 register (SDRTIM1), SDRAM timing 2 register (SDRTIM2), and SDRAM timing 3 register (SDRTIM3) configure the DDR2 memory controller to meet the data sheet timing parameters of the attached DDR2 device. Each field in SDRTIM1, SDRTIM2 and SDTIM3 register corresponds to a timing parameter in the DDR2 data sheet specification. Table 7-21, Table 7-22, and Table 7-23 display the register field name and corresponding DDR2 data sheet parameter name, along with the data sheet value. These tables also provide a formula to calculate the register field value and displays the resulting calculation. Each of the equations include a minus 1 because the register fields are defined in terms of DDR2|| clock cycles minus 1.

**Table 7-21. SDRTIM1 Configuration**

| Register Field Name | DDR3 SDRAM Data Sheet Parameter Name | Description | Example Data Sheet Value | Unit | Formula (Register Field Must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_RP | tRP | Precharge command to refresh or activate command | 15 | ns | (tRP x fDDR[x]_CLK)-1 | 5 |
| T_RCD | tRCD | Activate command to read/write command | 15 | ns | (tRCD x fDDR[x]_CLK)-1 | 5 |
| T_WR | tWR | Write recovery time | 15 | ns | (tWR x fDDR[x]_CLK)-1 | 5 |
| T_RAS | tRAS | Active to precharge command | 40 | ns | (tRAS x fDDR[x]_CLK)-1 | 15 |
| T_RC | tRC | Activate to Activate command in the same bank | 55 | ns | (tRC x fDDR[x]_CLK)-1 | 21 |
| T_RRD | tRRD/tFAW | Activate to Activate command in a different bank | 50 (For x16 mode) | ns | (tFAW x fDDR[x]_CLK/4)-1 for 8 bank DDR3 memory | 4 |
| T_WTR | tWTR | Write to read command delay | 7.5 | ns | (tWTR x fDDR[x]_CLK)-1 | 2 |

**Table 7-22. SDRTIM2 Configuration**

| Register Field Name | DDR3 SDRAM Data Sheet Parameter Name | Description | Example Data Sheet Value | Unit | Formula(Register Field Must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_XP | tXP | Exit precharge power-down to any non-read command | 2 | ns | (tXP x fDDR[x]_CLK)-1 | 1 |
| T_XSNR | tXSNR | Exit self-refresh to a non-read command | 137.5 | ns | (tXSNR x fDDR[x]_CLK)-1 | 54 |
| T_XSRD | tXSRD | Exit self-refresh to a read command | 200 | tCK | (tXSRD -1) | 199 |
| T_RTP | tRTP | Read to precharge command delay | 7.5 | ns | (tRTP x fDDR[x]_CLK)-1 | 2 |
| T_CKE | tCKE | CKE minimum pulse width (high and low pulse width) | 3 | tCK | (tCKE-1) | 2 |

**Table 7-23. SDRTIM3 Configuration**

| Register Field Name | DDR3 SDRAM Data Sheet Parameter Name | Description | Example Data Sheet Value | Unit | Formula(Register Field Must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_RFC | tRFC | Auto-refresh to active/auto-refresh command time | 127.5 | ns | (tRFC x fDDR[x]_CLK)-1 | 50 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-23. SDRTIM3 Configuration (continued)**

| Register Field Name | DDR3 SDRAM Data Sheet Parameter Name | Description | Example Data Sheet Value | Unit | Formula(Register Field Must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_RASMAX | | Maximum number of refresh rate intervals from Active to Precharge command | | | This field must be programmed to 0xF for DDR2/DDR3 | 15 |

#### 7.6.1.4 Configuring the DDR PHY Control Register

The DDR2/DDR3 PHY control register (DDRPHYCR) contains a read latency (RL) and ODT fields that need to be configured properly for the DDR2 memory controller to register data properly.

**Table 7-24. DDR2/DDR3 Memory Controller Control Register (DDRPHYCR)**

| Field | Value | Description |
|---|---|---|
| DYN_PWRDN_EN | 1 | When set to 1, dynamic power down is enabled. IO receiver is powered down when not doing any reads |
| IDLE_LOCAL_ODT | 0x0 | ODT off (recommended value) |
| RD_LOCAL_ODT | 0x2 | Read ODT (recommended value) |
| READ_LATENCY | 8 | CL + 4 cycles selected. Should be CL + 1 <= RL <= CL + 7 cycles. |

The value to write to register DDRPHYCR is 0x00170208.

#### 7.6.1.5 Configuring the DDR IO Control Register(DDRn_IO_CTRL)

The DDR2/DDR3 IO_CTRL register has to be configured with appropriate values to select the IO output impedance and Slew rates. A high precision 50 Ohm resistor should be connected between VTP pin and ground in order to achieve the output impedance as mentioned below.

**Table 7-25. Configuring DDRn_IO_CTRL**

| Field | Value | Function Selection |
|---|---|---|
| CS_SLEW | 0h | Fastest slew rate for chip select |
| CS_Impedance | 3h | Chip select signal impedance = 50 Ohms (=8mA Drive Strength) |
| CMD_SLEW | 0h | Fastest slew rate for command lines |
| CMD_Impedance | 3h | Command lines impedance = 50 Ohms (=8mA drive strength) |
| DATA_SLEW | 0h | Fastest slew rate for data pins |
| DATA_Impedance | 3h | Data impedance = 50 Ohms (=8mA Drive Strength) |

The value to write to DDRn_IO_CTRL register is 0x00030303.

### *7.6.2 Configuring DDR2/DDR3 Memory Controller Registers to Meet DDR3 SDRAM Specifications*

This section describes the memory controller setup for DDR3. The following sections describe how to configure each of the registers for access to four 1Gb, 8-bit wide DDR3 SDRAM devices, where each device has the following configuration:

- SDRAM Clock Frequency : 400 MHz
- SDRAM Data Rate : 800 MHz
- Number of banks: 8
- Page size: 1024 words
- CAS latency: CL = 6

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.6.2.1 Programming the SDRAM Configuration Register (SDRCR)

The SDRAM configuration register (SDRCR) contains register fields that configure the DDR3 memory controller to match the data bus width, CAS latency, number of banks, and page size of the attached DDR3 memory. Table 7-26 shows the resulting SDRCR configuration.

**Table 7-26. SDRCR Configuration**

| Field | Value | Function Selection |
|---|---|---|
| SDRAM_TYPE | 3h | To select DDR3 Memory Type |
| DDR_TERM | 1h | To select RZQ/4 |
| DDR2_DDQS | 1h | To select Differential Ended DQS (DDR3 only supports differential ended) |
| DYN_ODT | 2h | DDR3 Dynamic ODT (RZQ/2) |
| DDR_DISABLE_DLL | 0h | 0h Enable DLL for Normal Operation |
| SDRAM_DRIVE | 0h | To select a drive strength of RZQ/6 |
| CWL | 0h | DDR3 CAS Write Latency of 5 |
| NARROW_MODE | 0h | To configure the DDR3 memory controller for a 32-bit data bus width |
| CL | 4h | To select CAS latency of 6 |
| IBANK | 3h | To select 8 internal DDR3 banks |
| EBANK | 0h | To select single chip select, CS0 |
| PAGESIZE | 2h | To select 1024-word page size |

The value to write to register SDRCR is 0x61C01032.

### 7.6.2.2 Programming the SDRAM Refresh Control Register (SDRRCR)

The SDRAM refresh control register (SDRRCR) configures the DDR3 memory controller to meet the refresh requirements of the attached DDR3 device. SDRRCR also allows the DDR3 memory controller to enter and exit self refresh. In this example, we assume that the DDR3 memory controller is in self-refresh mode.

The RR field in SDRRCR is defined as the rate at which the attached DDR3 device is refreshed in DDR3 cycles. The value of this field may be calculated using the following equation:

*Refresh_Rate = DDR2/DDR3 clock frequency (in MHz) x DDR2/DDR3 fresh rate (in μs)*

Table 7-27 displays the DDR3-800 refresh rate specification.

**Table 7-27. Periodic Refresh Interval Specification**

| Symbol | Value | Description |
|---|---|---|
| tREF | 7.8μs | Average Periodic Refresh Interval |

RR = 400MHz x 7.8μs = 3120 = C30h

Table 7-28 shows the SDRRCR configuration.

**Table 7-28. SDRRCR Configuration**

| Field | Value | Function Selection |
|---|---|---|
| INITREF_DIS | 0h | Enable SDRAM initialization and Refreshes |
| SRT | 0h | Normal Operating Temperature range |
| ASR | 1h | Auto Self Refresh Enable |
| PASR | 0h | Full Array Refresh |
| REFRESH_RATE | C30h | Refresh Rate |

Copyright © 2011–2016, Texas Instruments Incorporated

The value to write to register SDRRCR register is 0x10000C30.

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.6.2.3 Configuring SDRAM Timing Registers (SDRTIM1, SDRTIM2, SDTRIM3)

The SDRAM timing 1 register (SDRTIM1), SDRAM timing 2 register (SDRTIM2), and SDRAM timing 3 register (SDRTIM3) configure the DDR3 memory controller to meet the data sheet timing parameters of the attached DDR3 device. Each field in SDRTIM1, SDRTIM2 and SDTIM3 corresponds to a timing parameter in the DDR3 data sheet specification. Table 7-29, Table 7-30, and Table 7-31 display the register field name and corresponding DDR3 data sheet parameter name along with the data sheet value. These tables also provide a formula to calculate the register field value and displays the resulting calculation. Each of the equations include a minus 1 because the register fields are defined in terms of DDR3 clock cycles minus 1.

**Table 7-29. SDRTIM1 Configuration**

| Register Field Name | DDR3 SDRAM Datasheet Parameter Name | Description | Example Datasheet Value | Unit | Formula (Register Field must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_RP | tRP | Precharge command to refresh or activate command | 13.75 | ns | (tRP/DDR[X]_CLK period)-1 | 5 |
| T_RCD | tRCD | Activate command to read/write command | 13.75 | ns | (tRCD/DDR[X]_CLK period)-1 | 5 |
| T_WR | tWR | Write recovery time | 15 | ns | (tWR/DDR[X]_CLK period)-1 | 5 |
| T_RAS | tRAS | Active to precharge command | 35 | ns | (tRAS/DDR[X]_CLK period)-1 | 13 |
| T_RC | tRC | Activate to Activate command in the same bank | 48.75 | ns | (tRC/DDR[X]_CLK period)-1 | 19 |
| T_RRD | tRRD or tFAW | Activate to Activate command in a different bank | 35 | ns | (tFAW/(4*DDR[X]_CLK period))-1 | 3 |
| T_WTR | tWTR | Write to read command delay | 10 | ns | (tWTR/DDR[X]_CLK period)-1 | 3 |

The value to write to register SDRTIM1 is 0x0AAAD4DB.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-30. SDRTIM2 Configuration**

| Register Field Name | DDR3 SDRAM Datasheet Parameter Name | Description | Example Datasheet Value | Unit | Formula (Register Field must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_XP | tXP | Exit precharge power-down to any non-read command | 3 | tCK | tXP - 1 | 2 |
| T_XSNR | tXSNR | Exit self-refresh to a non-read command | 120 | ns | (tXSNR/DDR[X]_CLK period)-1 | 47 |
| T_XSRD | tXSRD | Exit self-refresh to a read command | 512 | tCK | tXSRD - 1 | 511 |
| T_RTP | tRTP | Read to precharge command delay | 10 | ns | (tRTP/DDR[X]_CLK period)-1 | 3 |
| T_CKE | tCKE | CKE minimum pulse width (high and low pulse width) | 3 | tCK | tCKE - 1 | 2 |

The value to write to register SDRTIM2 is 0x202F7FDA.

**Table 7-31. SDRTIM3 Configuration**

| Register Field Name | DDR3 SDRAM Datasheet Parameter Name | Description | Example Datasheet Value | Unit | Formula (Register Field must be ≥) | Field Value |
|---|---|---|---|---|---|---|
| T_PDLL_UL | | Number of cycles for DLL to unlock | | tCK | This field must be written with 5 | 5 |
| T_CSTA | tCSTA | Write-to-write or read-to-read data phase | 1 | tCK | tCSTA - 1 | 0 |
| T_ZQCS | tZQCS | Number of cycles for ZQCS command | 64 | tCK | tZQCS - 1 | 63 |
| T_RFC | tRFC | Auto-refresh to active/auto-refresh command time | 110 | ns | (tRFC/DDR[X]_CLK period)-1 | 43 |
| T_RAS_MAX | | Maximum number of refresh rate intervals from Active to Precharge command | | | | 15 |

The value to write to register SDRTIM3 is 0x501F82BF.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 7.6.2.4 Configuring the DDR PHY Control Register

The DDR2/DDR3 PHY control register (DDRPHYCR) contains a read latency (RL) and ODT fields that needs to be configured properly for the DDR3 memory controller to register data properly.

**Table 7-32. PHY Control Register (DDRPHYCR)**

| Field | Value | Function Selection |
|---|---|---|
| DYN_PWRDN_EN | 1h | Power down IO receiver when not performing a read |
| RDEYE_LVL_DIS | 1h | Disable read eye auto-leveling |
| GATE_LVL_DIS | 1h | Disable read gate auto-leveling |
| WR_LVL_DIS | 1h | Disable write auto-leveling |
| PHY_RST | 0h | PHY in functional mode |
| IDLE_LOCAL_ODT | 0h | ODT off |
| RD_LOCAL_ODT | 2h | 50 Ohms Read ODT termination |
| READ_LATENCY | 9h | CL + 4 cycles selected. Should be CL + 1 <= RL <= CL + 7 cycles. |

The value to write to register DDRPHYCR is 0x00170209.

#### 7.6.2.5 Configuring the ZQCR Control Register

The DDR3 ZQCR register has to be configured with appropriate values to enable periodic ZQ calibration.

The ZQ Refresh interval can be calculated with the following equation:

*ZQ Refresh Interval = 0.5%/( (Tsens × Tdriftrate) + (Vsens × Vdriftrate)).*

As per the DDR3 specification, the maximum values for Tsens and Vsens are as follows:

Tsens = 1.5%/°C
Vsens = 0.15%/mV

The temperature and voltage drift rates depend on the system environment. For illustrative purpose the following values are assumed.

Tdriftrate = 1.2°C/s
Vdriftrate = 10 mV/s

ZQ calibration Interval = 0.5%/((1.5%/°C
x1.2°C/s)+(0.15%/mV x10 mV/s) = 151.515ms approx.

Number of Refresh periods to make up for the ZQ calibration Interval = 151.515ms/7.8µs = 19425= 0x4BE1.

**Table 7-33. ZQCR Configuration**

| Field | Value | Function Selection |
|---|---|---|
| ZQ_CS1EN | 0h | Disable ZQ calibration for CS1 |
| ZQ_CS0EN | 1h | Enable ZQ calibration for CS0 |
| ZQ_DUALCALEN | 0h | Disable dual calibration |
| ZQ_SEFXITEN | 1h | ZQCL enabled after a Self Refresh Exit |
| ZQ_ZQINIT_MULT | 1h | number of ZQCL intervals that make up a ZQINIT interval - 1 |
| ZQ_ZQCL_MULT | 3h | Number of ZQCS intervals that make up a ZQCL interval - 1 |
| ZQ_REFINTERVAL | 4BE1h | Number of refresh intervals to make up the delay between ZQ commands |

The value to write to ZQCR register is 0x50074BE1.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 7.6.2.6 Configuring the DR IO Control Register (DDR n_IO_CTRL)

The DDR2/DDR3 IO_CTRL register has to be configured with appropriate values to select the IO output impedance and Slew rates. A high precision 50 Ohm resistor should be connected between VTP pin and ground in order to achieve the output impedance as mentioned below.

**Table 7-34. DDR2/DDR3 IO_CTRL Configuration**

| Field | Value | Function Selection |
|---|---|---|
| CS_SLEW | 0h | Fastest Slew Rate for Chip Select |
| CS_IMPEDENCE | 3h | Chip Select signal impedance = 50 Ohms (=8mA Drive Strength) |
| CMD_SLEW | 0h | Fastest Slew Rate for Command lines |
| CMD_IMPEDENCE | 3h | Command lines impedance = 50 Ohms (=8mA Drive Strength) |
| DATA_SLEW | 0h | Fastest Slew Rate for Data pins |
| DATA_IMPEDENCE | 3h | Data impedance = 50 Ohms (=8mA Drive Strength) |

The value to write to DDRn_IO_CTRL register is 0x00030303.

Copyright © 2011–2016, Texas Instruments Incorporated

## 7.7 DDR2/DDR3 SDRAM Device Configuration Steps

The following are recommended steps to initialize connected SDRAM devices:

1. Configure the DDR ADPLL to generate the desired frequency of operation.(Refer to the device's Technical Reference Manual for ADPLL configuration details).
2. Perform the PRCM sequences for DDR controllers and DMM (refer to the device's Technical Reference Manual for DMM details)
3. Configure the DDR related Control module registers (IO impedance, Slew Rate, and more).
4. Perform VTP0/1 calibration.
5. Configure DDR0/1 PHY registers with calculated ratio values based on the board routing delays (see DDR2/DDR3 PHY register for details). Note that in case of a DDR2-based system, the default PHY register configurations need not be changed if the DDR PCB layout guidelines in the device-specific data manual are followed strictly.
6. Program LISA/PAT mapping registers of DMM for the desired address mapping, interleaving/non-interleaving configurations, etc.
7. Program DDR memory controller MMRs (For configuring PHY read latency, device type, various timing parameters, addressing modes etc. Please note that all MMRs are initialized with proper configurations before clearing the INITREF_DIS bit, as the same triggers the SDRAM device initialization procedure. Refer to DDR2/DDR3 SDRAM Memory initialization section for more detailed register configuration procedure.

Copyright © 2011–2016, Texas Instruments Incorporated

## 7.8 DDR2/DDR3 Configuration Registers

### 7.8.1 DDR2/DDR3 Memory Controller Registers

Table 7-35 lists the memory-mapped registers for the DDR2/DDR3 memory controller.

**Table 7-35. DDR2/DDR3 Memory Controller Registers**

| Address Offset | Acronym | Register Description | Section |
|---|---|---|---|
| 4h | SDRSTAT | SDRAM Status Register | Section 7.8.1.1 |
| 8h | SDRCR | SDRAM Configuration Register | Section 7.8.1.2 |
| Ch | SDRCR2 | SDRAM Configuration Register 2 | Section 7.8.1.3 |
| 10h | SDRRCR | SDRAM Refresh Control Register | Section 7.8.1.4 |
| 14h | SDRRCSR | SDRAM Refresh Control Shadow Register | Section 7.8.1.5 |
| 18h | SDRTIM1 | SDRAM Timing 1 Register | Section 7.8.1.6 |
| 1Ch | SDRTIM1SR | SDRAM Timing 1 Shadow Register | Section 7.8.1.7 |
| 20h | SDRTIM2 | SDRAM Timing 2 Register | Section 7.8.1.8 |

### 7.8.1.1 SDRAM Status Register (SDRSTAT)

The SDRAM status register (SDRSTAT) is shown and described in the figure and table below.

**Figure 7-5. SDRAM Status Register (SDRSTAT)**

| 31 | 30 | 29 | 28 24 |
|---|---|---|---|
| BE | DUAL_CLK_MODE | FAST_INIT | Reserved |
| R-0 | R-0 | R-0 | R-0 |

| 23 16 |
|---|
| Reserved |
| R-0 |

| 15 8 |
|---|
| Reserved |
| R-0 |

| 7 3 | 2 | 1 0 |
|---|---|---|
| Reserved | PHY_DLL_READY | Reserved |
| R--0 | R-0 | R-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-36. SDRAM Status Register (SDRSTAT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | BE | | Defines whether the memory controller is in big or little endian mode. |
| | | 0 | Little Endian |
| | | 1 | |
| 30 | DUAL_CLK_MODE | | Dual Clock mode. Defines whether the ocp_clk and m_clk are asynchronous. |
| | | 0 | Not sync |
| | | 1 | Sync |
| 29 | FAST_INIT | | Fast Init. Defines whether the memory controller fast initialization mode has been enabled. |
| | | 0 | Disabled |
| | | 1 | Enabled |
| 28-3 | Reserved | | Reserved |
| 2 | PHY_DLL_READY | | DDR PHY Ready. Reflects the value active high that defines whether the DDR PHY is ready for normal operation. |
| | | 0 | |
| | | 1 | |
| 1-0 | Reserved | | Reserved |

### 7.8.1.2 SDRAM Configuration Register(SDRCR)

The SDRAM configuration register (SDRCR) is described in the figure and table below.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 7-6. SDRAM Configuration Register (SDRCR)**

| 31–29 | 28–27 | 26–24 | 23 | 22–21 | 20 | 19–18 | 17–16 |
|---|---|---|---|---|---|---|---|
| SDRAM_TYPE | IBANK_POS | DDR_TERM | DDR2_DDQS | DYN_ODT | DDR_DISABLE_DLL | SDRAM_DRIVE | CWL |
| R/W-2 | R/W-0 | R/W-0 | R/W-1 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

| 15 | 14–13 | 10–9 | 8 |
|---|---|---|---|
| NARROW_MODE | CL | ROWSIZE | |
| R/W-0 | R/W-5 | R/W-0 | |

| 7 | 6–4 | 3 | 2–0 |

| R/W-0 | R/W-2 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-37. SDRAM Configuration Register (SDRCR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-29 | SDRAM_TYPE | | SDRAM Type Selection |
| | | 0 | Reserved |
| | | 1h | Reserved |
| | | 2h | DDR2 |
| | | 3h | DDR3 |
| | | | All other values are reserved |
| 28-27 | IBANK_POS | | Internal Bank position selection |
| | | 0 | Set 0,1,2,3. Refer to Table 7-4 to Table 7-11 for more details |
| | | 1 | |
| 26-24 | DDR_TERM | | DDR2 & DDR3 termination resistor value |
| | | 0 | Disable |
| | | | **For DDR2 Only :** |
| | | 1h | 75 Ohm (Recommended) |
| | | 2h | 150 Ohm |
| | | 3h | 50 Ohm |
| | | | **For DDR3 Only** |
| | | 1h | RZQ/4 (Recommended value of external resistor RZQ is 240 ohm) |
| | | 2h | Reserved |
| | | 3h | Reserved |
| | | 4h | Reserved |
| | | 5h | Reserved |
| 23 | DDR2_DDQS | | DDR2 Differential DQS Enable |
| | | 0 | Single Ended DQS |
| | | 1 | Differential Ended DQS<br>**Note: DDR3 supports only Differential DQS** |
| 22-21 | DYN_ODT | | Controls the Dynamic ODT on the DDR3 device side. Refer to DDRPHYCR for configuring the ODT on the DDR PHY side. |
| | | 0 | OFF |
| | | 1h | RZQ/4 |
| | | 2h | RZQ/2 (Recommended value of external resistor RZQ is 240 ohm) |
| 20 | DDR_DISABLE_DLL | | Disable DLL Select |
| | | 0 | Enable DLL for Normal Operation. This bit must be set to low for normal operation. |
| | | 1 | Disable DLL |
| 19-18 | SDRAM_DRIVE | | SDRAM Drive strength. Configures output drive impedance control value of the DDR2/DDR3 SDRAM memory |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 7-37. SDRAM Configuration Register (SDRCR) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| | | | **For DDR2** |
| | | 0 | Full drive strength |
| | | 1h | Reduced drive strength |
| | | | **For DDR3** |
| | | 0 | RZQ/6 drive strength |
| | | 1h | RZQ/7 drive strength |
| 17-16 | CWL | | DDR3 CAS Write Latency |
| | | 0 | CWL of 5 |
| | | 1h | CWL of 6 |
| | | 2h | CWL of 7 |
| | | 3h | CWL of 8 |
| | | | **For DDR2: NA** |
| 15-14 | NARROW_MODE | | Data Bus Width |
| | | 0 | 32 bits |
| | | 1 | 16 bits |
| 13-10 | CL | | CAS Latency |
| | | | **For DDR2 CAS Latency** |
| | | 2 | CAS latency of 2 |
| | | 3 | CAS latency of 3 |
| | | 4 | CAS latency of 4 |
| | | 5 | CAS latency of 5 |
| | | 6 | CAS latency of 6 |
| | | 7 | CAS latency of 7 |
| | | | **For DDR3 CAS Latency** (1) |
| | | 2 | CAS latency of 5 |
| | | 4 | CAS latency of 6 |
| | | 6 | CAS latency of 7 |
| | | 8 | CAS latency of 8 |
| | | 10 | CAS latency of 9 |
| | | 12 | CAS latency of 10 |
| | | 14 | CAS latency of 11 |
| 9-7 | ROWSIZE | | Row Size Selection. Don't care if both EBANK_POS and IBANK_POS are 0. |
| | | 0 | 9 Rows bits |
| | | 1h | 10 Rows bits |
| | | 2h | 11 Rows bits |
| | | 3h | 12 Rows bits |
| | | 4h | 13 Rows bits |
| | | 5h | 14 Rows bits |
| | | 6h | 15 Rows bits |
| | | 7h | Reserved |
| 6-4 | IBANK | | Bank Selection. Defines number of internal banks on the external DDR2/DDR3 memory. |
| | | 0 | 1 Bank |
| | | 1h | 2 Banks |
| | | 2h | 4 Banks |
| | | 3h | 8 Banks |
| | | 6-7h | Reserved |

(1) DDR3 devices typically specify Max and Min allowable CAS latency. EMIF must be set to an acceptable value within that range.

### 7.8.1.4 SDRAM Refresh Control Register (SDRRCR)

The SDRAM Refresh Control Register (SDRRCR) is described in the figure and table below.

**Figure 7-8. SDRAM Refresh Control Register (SDRRCR)**

| 31 | 30 | 29 | 28 | 27 | 26 24 | 23 16 |
|---|---|---|---|---|---|---|
| INITREF_DIS | Rsvd | SRT | ASR | Rsvd | PASR | Reserved |
| R/W-1 | R/W-0 | R/W-0 | R/W-0 | R-0 | R/W-0 | R-0 |

| 15 0 |
|---|
| Refresh_Rate |
| R/W-1388h |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-39. SDRAM Refresh Control Register (SDRRCR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | INITREF_DIS | | Initialization and Refresh Disable |
| | | 0 | Enable SDRAM Initialization and Refreshes |
| | | 1 | Disable SDRAM Initialization and Refreshes but carries out SDRAM Write/Read transactions. |
| 30 | Reserved | 0h | Reserved |
| 29 | SRT | | DDR2 and DDR3 Self Refresh Temperature Range |
| | | 0 | Normal Operating Temperature range |
| | | 1 | Extended Operating Temperature range |
| | | | For DDR3, this bit must be set to '0' if ASR is set to 1. A write to this field will cause the DDR2/DDR3 to start the initialization sequence |
| 28 | ASR | | DDR3 Auto Self Refresh Enable |
| | | 0 | Manual Self Refresh reference indicated by SRT field |
| | | 1 | Auto Self Refresh Enable |
| | | | A write to this field causes the DDR3 to start the SDRAM initialization sequence. |
| 27 | Reserved | | Reserved |
| 26-24 | PASR | | Partial Array Self Refresh. These bits determine what portion of the array will be refreshed with the external memory is in partial array self refresh mode. These bits gets loaded into the EMR of the external DDR2/DDR3 memory during initialization. If the external memory does not support Partial Array Self Refresh, this field should be set to 0h. A write to this field will cause the EMIF to start the SDRAM initialization sequence. |
| | | | **For DDR2/DDR3 set** |
| | | 0h | Full Array |
| | | 1h or 5h | 1/2 Array |
| | | 2h or 6h | 1/4 Array |
| | | 3h or 7h | 1/8 Array |
| | | 4h | 3/4 Array |
| | | | to be refreshed. A write to this field will cause the memory controller to start the SDRAM initialization sequence. |
| 23-16 | Reserved | | Reserved |
| 15-0 | REFRESH_RATE | 1388h | Refresh rate. Defines the rate at which the attached DDR2/DDR3 devices are refreshed. The value of this field is calculated with the following equation: |
| | | | *Refresh_Rate = DDR2/DDR3 clock frequency (in MHz) x DDR2/DDR3 fresh rate (in µs)* |
| | | | Where DDR2/DDR3 refresh rate is derived from DDR2/DDR3 data sheet |

### 7.8.1.5 SDRAM Refresh Control Shadow Register (SDRRCSR)

The SDRAM Refresh Control Shadow Register (SDRRCSR) is shown in the figure and table below.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 7-9. SDRAM Refresh Control Shadow Register (SDRRCSR)**

| 31 | 16 | 15 | 0 |
|---|---|---|---|
| Reserved | | REFRESH_RATE_SHDW | |
| R-0 | | R/W-1388h | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-40. SDRAM Refresh Control Shadow Register (SDRRCSR) Field Descriptions**

| Bits | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | | Reserved |
| 15-0 | REFRESH_RATE_SHDW | 1388h | Shadow field for refresh rate in SDRRCR. This field is loaded into the REFRESH_RATE_SHDW field in SDRRCR when Slave Idle Acknowledge(SIdleAck) is asserted. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.8.1.6 SDRAM Timing 1 Register (SDRTIM1)

The SDRAM Timing 1 Register (SDRTIM1) is described in the figure and table below.

**Figure 7-10. SDRAM Timing 1 Register (SDRTIM1)**

| 31 29 | 28 25 | 24 21 | 20 17 |
|---|---|---|---|
| Reserved | T_RP | T_RCD | T_WR |
| R-0 | R/W-4h | R/W-4h | R/W-4h |

| 16 12 | 11 6 | 5 3 | 2 0 |
|---|---|---|---|
| T_RAS | T_RC | T_RRD | T_WTR |
| R/W-11h | R/W-16h | R/W-3h | R/W-1h |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-41. SDRAM Timing 1 Register (SDRTIM1) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-29 | Reserved | | Reserved |
| 28-25 | T_RP | 4h | Specifies the mimimum number of DDR[X]_CLK cycles from a precharge command to a refresh or activate command, minus 1. Corresponds to tRP AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RP=(tRP/DDR[X]_CLK period)-1 |
| 24-21 | T_RCD | 4h | Specifies the mimimum number of DDR[X]_CLK cycles from an activate command to read or write command, minus 1. Corresponds to tRCD AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RP=(tRCD/DDR[X]_CLK period)-1 |
| 20-17 | T_WR | 4h | Specifies the minimum number of DDR[X]_CLK cycles from the last write transfer to a pre-charge command, minus 1. Corresponds to tWR AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RP=(tWR/DDR[X]_CLK period)-1 |
| 16-12 | T_RAS | 11h | Specifies the mimimum number of DDR[X]_CLK cycles from an active command to a pre-charge command, minus 1. Corresponds to tRAS AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RP=(tRAS/DDR[X]_CLK period)-1 |
| 11-6 | T_RC | 16h | Specifies the mimimum number of DDR[X]_CLK cycles from an active command to an active command, minus 1. Corresponds to tRC AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RP=(tRC/DDR[X]_CLK period)-1 |
| 5-3 | T_RRD | 3h | Specifies the mimimum number of DDR[X]_CLK cycles from an activate command to an activate command in a different bank, minus 1. Corresponds to tRRD AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_RRD=(tRRD/DDR[X]_CLK period)-1<br>For an 8-bank DDR2 or DDR3 this field must be equal to ((tFAW/(4*DDR[X]_CLK))-1) |
| 2-0 | T_WTR | 1h | Specifies the minimum number of DDR[X]_CLK cycles from the last write to a read command, minus 1. Corresponds to the tWTR AC timing parameter in the DDR2/DDR3 data sheet.<br>Calculated by T_WTR=(tWTR/DDR[X]_CLK period)-1 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.8.1.7 SDRAM Timing 1 Shadow Register (SDRTIM1SR)

The SDRAM Timing 1 Shadow Register (SDRTIM1SR) is described in the figure and table below.

**Figure 7-11. SDRAM Timing 1 Shadow Register (SDRTIM1SR)**

| 31 29 | 28 25 | 24 21 | 20 17 |
|---|---|---|---|
| Reserved | T_RP_SHDW | T_RCD_SHDW | T_WR_SHDW |

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-28 | T_PDLL_UL | 5h | Specifies number of DDR[X]_CLK cycles for PHY DLL to unlock. A value of N will be equal to N x 128 clocks. This field must be written with a value of 5. |
| 27-24 | T_CSTA | 0h | Specifies the mimimum number of DDR[X]_CLK cycles between write-to-write or read-to-read data phases to different chip selects, minus one. This is a don't care when only only one chip select is being used. Refer the device data manual for the number of supported chip selects. |
| 23-21 | T_CKESR | 7h | Specifies the minimum number of DDR[x]_CLK cycles for which the memory must remain in self refresh, minus one. |
| 20-15 | T_ZQCS | 0-3Fh | Specifies the mimimum number of DDR[X]_CLK cycles for a ZQCS command, minus one. This is applicable only for DDR3. Corresponds to TZQCS=(tZQCS-1) Where tZQCS in DDR clock cycles. |
| 14-13 | Reserved | 3h | Reserved |
| 12-4 | T_RFC | 0-82h | Specifies the mimimum number of DDR[X]_CLK cycles from Refresh or Load Mode to Refresh or Activate, minus one.<br>Calculated by T_RFC=(tRFC/DDR[x]_CLK period)-1 |
| 3-0 | T_RAS_MAX | 0-Fh | Specifies the maximum number of refresh rate intervals from Active to Precharge command. This field must be programmed to Fh for DDR2/DDR3 SDRAM types. |

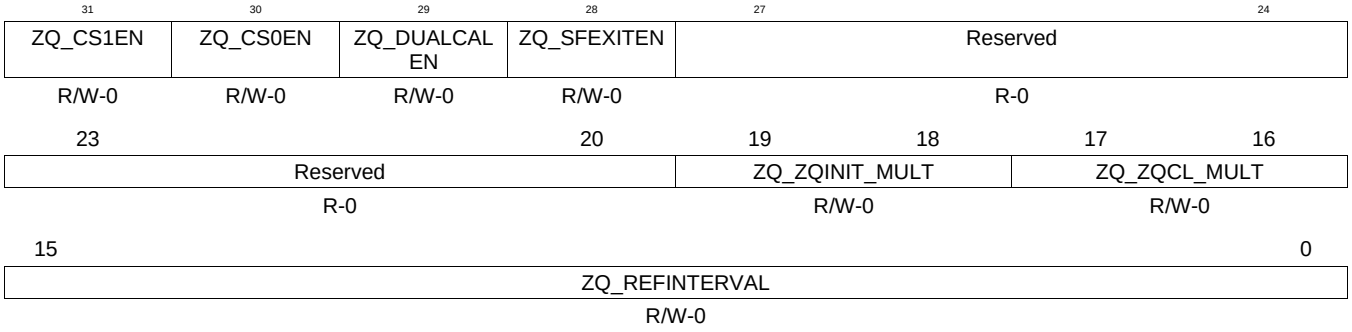
### 7.8.1.24 SDRAM Output Impedance Calibration Configuration Register (ZQCR)

The SDRAM Output Impedance Calibration Configuration Register (ZQCR) is shown in the figure and table below.

**Figure 7-28. SDRAM Output Impedance Calibration Configuration Register (ZQCR)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-59. SDRAM Output Impedance Calibration Configuration Register (ZQCR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | ZQ_CS1EN | | Writing a 1 enables ZQ calibration for CS1 |
| 30 | ZQ_CS0EN | | Writing a 1 enables ZQ calibration for CS0 |
| 29 | ZQ_DUALCALEN | | ZQ Dual Calibration Enable.<br>Allows both ranks (chip selects) to be ZQ calibrated simultaneously.<br>Setting this bit requires both chip selects to have a separate calibration resistor per device. |
| 28 | ZQ_SFEXITEN | 0<br>1 | ZQCL on Self-Refresh, Active Power-Down and Precharge Power-Down exit enable.<br>Writing a 1 enables the issuing of ZQCL on Self-Refresh, Active Power-Down and Precharge Power Down exit. |
| 27-20 | Reserved | | Reserved |
| 19-18 | ZQ_ZQINIT_MULT | | Indicates number of ZQCL intervals that make up a ZQINIT interval, minus 1 |
| 17-16 | ZQ_ZQCL_MULT | | Indicates number of ZQCS intervals that make up a ZQCL interval, minus 1 |
| 15-0 | ZQ_REFINTERVAL | | Number of refresh periods between ZQCS commands. Supports between one refresh period to 256 ms between ZQCS calibration commands.<br>Refresh period is defined by REFRESH_RATE field in SDRAM Refresh Control Register. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 7.8.1.25 DDR PHY Control Register (DDRPHYCR)

The DDR PHY Control Register (DDRPHYCR) is shown in the figure and table below.

**Figure 7-29. DDR PHY Control Register (DDRPHYCR)**

| 31 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|
| Reserved | | DYN_PWRDN_EN | Rsvd | RDEYE_LVL_DIS | GATE_LVL_DIS | WR_LVL_DIS |

| R/W-0 | R/W-0 | R/W-0 | | R-0 | | R/W-0 | | R-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-60. DDR PHY Control Register (DDRPHYCR) Field Descriptions**

| Bit | Field | Value | Description | |
|---|---|---|---|---|
| 31-21 | Reserved | 0 | Reserved | |
| 20 | DYN_PWRDN_EN | 0 | Enables dynamically powering down the IO Receiver when not performing a read. This will help in reducing DDR IO power. It is recommended to set this bit to '1' always. | |
| 19 | Reserved | 0 | Reserved | |
| 18 | RDEYE_LVL_DIS | 0 | When set to 1, read eye auto-leveling is disabled. This is applicable only for DDR3 | For proper work, it is reccomended that each of these three bits must be set to 0b1. |
| 17 | GATE_LVL_DIS | 0 | When set to 1, read gate auto-leveling is disabled. This is applicable only for DDR3 | |
| 16 | WR_LVL_DIS | 0 | When set to 1, write auto-leveling is disabled. This is applicable only for DDR3 | |
| 15 | PHY_RST | 0 | When set to 1, DDR PHY is reset .Both data and command macros will be reset | |
| 14 | Reserved | 0 | Reserved | |
| 13-12 | IDLE_LOCAL_ODT | 0 | This bit fields specify the ODT selection on the DDR Controller side when the breceiver is powered down. IDLE_LOCAL_ODT is applicable only when DYN_PWRDN_EN is set to '1'. Please refer to Table1-16 for the supported ODT termination values.<br>Recommended value is 0x0 [ODT OFF] | |
| 11-10 | Reserved | 0 | Reserved | |
| 9-8 | RD_LOCAL_ODT | 0 | This bit fields specifies the ODT selection on the DDR PHY side during READ. To control the ODT on the DDR device side, refer to the SDRCR register details. Please refer to Table1-16 for the supported ODT termination values.<br>Recommended value is 0x2 [50 Ohms termination] | |
| 7-5 | Reserved | 0 | Reserved | |
| 4-0 | READ_LATENCY | 0 | Defines the latency for read data from DDR SDRAM in number of 1x cycles. The value applied should be equal to the required value minus one. The maximum read latency supported by the DDR PHY is equal to CAS latency plus 7 clock cycles. The minimum read latency must be equal to CAS latency plus 1 clock cycles. | |

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-21 | Reserved | | Reserved |
| 20 | DYN_PWRDN_EN | | Shadow field for DYN_PWRDN_EN in DDRPHYCR. This field is loaded into DYN_PWRDN_EN field in DDR PHY Control Register when SIdleAck is asserted |
| 19 | Reserved | | Reserved |
| 18 | RDEYE_LVL_DIS | | Shadow field for RDEYE_LVL_DIS in DDRPHYCR. This field is loaded into RDEYE_LVL_DIS field in DDR PHY Control Register when SIdleAck is asserted. |
| 17 | GATE_LVL_DIS | | Shadow field for GATE_LVL_DIS in DDRPHYCR. This field is loaded into GATE_LVL_DIS field in DDR PHY Control Register when SIdleAck is asserted. |
| 16 | WR_LVL_DIS | | Shadow field for WR_LVL_DIS in DDRPHYCR. This field is loaded into WR_LVL_DIS field in DDR PHY Control Register when SIdleAck is asserted |
| 15 | PHY_RST | | Shadow field for PHY_RST in DDRPHYCR. This field is loaded into PHY_RST field in DDR PHY Control Register when SIdleAck is asserted. |
| 14 | Reserved | | Reserved |
| 13-12 | IDLE_LOCAL_ODT | | This bit fields specify the ODT selection on the DDR Controller side when the breceiver is powered down. IDLE_LOCAL_ODT is applicable only when DYN_PWRDN_EN is set to '1'.<br>Please refer to Table1-16 for the supported ODT termination values. |
| 11-10 | Reserved | | Recommended value is 0x0 [ODT OFF] |
| 9-8 | RD_LOCAL_ODT | | This bit fields specifies the ODT selection on the DDR PHY side during READ. To control the ODT on the DDR device side, refer to the SDRCR register details.<br>Please refer to Table1-16 for the supported ODT termination values. |
| 7-5 | Reserved | | Recommended value is 0x2 [50 Ohms termination] |
| 4-0 | READ_LATENCY | | Shadow field for READ_LATENCY in DDRPHYCR. This field is loaded into READ_LATENCY field in DDR PHY Control Register when SIdleAck is asserted. |

### 7.8.1.27 Priority to Class of Service Mapping Register (PRI_COS_MAP)

The Priority to Class of Service Mapping Register(PRI_COS_MAP) is shown in the figure and table below.

**Figure 7-31. Priority to Class of Service Mapping Register (PRI_COS_MAP)**

| 31 | 30 | 16 |
|---|---|---|
| PRI_COS_MAP_EN | Reserved | |
| R/W-0 | R-0 | |

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| PRI_7_COS | | PRI_6_COS | | PRI_5_COS | | PRI_4_COS | | PRI_3_COS | | PRI_2_COS | | PRI_1_COS | | PRI_0_COS | |
| R/W-0 | | R/W-0 | | R/W-0 | | R/W-0 | | R/W-0 | | R/W-0 | | R/W-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-62. Priority to Class of Service Mapping Register (PRI_COS_MAP) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | PRI_COS_MAP_EN | 0 | Disable mapping |
| | | 1 | Enable priority to class of service mapping |
| 30-16 | Reserved | | Reserved |
| 15-14 | PRI_7_COS | | Class of service for commands with priority of 7. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 7 is mapped to class of service 1 or 2 |
| 13-12 | PRI_6_COS | | Class of service for commands with priority of 6. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 6 is mapped to class of service 1 or 2 |
| 11-10 | PRI_5_COS | | Class of service for commands with priority of 5. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 5 is mapped to class of service 1 or 2 |
| 9-8 | PRI_4_COS | | Class of service for commands with priority of 4. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 4 is mapped to class of service 1 or 2 |
| 7-6 | PRI_3_COS | | Class of service for commands with priority of 3. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 3 is mapped to class of service 1 or 2 |
| 5-4 | PRI_2_COS | | Class of service for commands with priority of 2. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 2 is mapped to class of service 1 or 2 |
| 3-2 | PRI_1_COS | | Class of service for commands with priority of 1. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 1 is mapped to class of service 1 or 2 |
| 1-0 | PRI_0_COS | | Class of service for commands with priority of 0. |
| | | 0 or 3 | Setting a value of 0 or 3 will not assign any class of service. |
| | | 1 or 2 | Commands with priority 0 is mapped to class of service 1 or 2 |

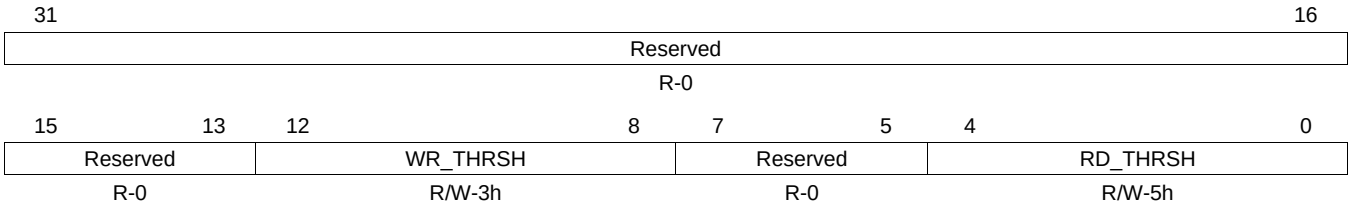
### 7.8.1.30 Read Write Execution Threshold Register (RD_WR_EXEC_THRSH)

The Read Write Execution Threshold Register (RD_WR_EXEC_THRSH) is shown in the figure and table below.

**Figure 7-34. Read Write Execution Threshold Register (RD_WR_EXEC_THRSH)**



LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 7-65. Read Write Execution Threshold Register (RD_WR_EXEC_THRSH) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-13 | Reserved | | Reserved |
| 12-8 | WR_THRSH | 3h | Write Threshold. Number of SDRAM write bursts after which the DDR2/DDR3 memory controller arbitration will switch to executing read commands. The value programmed is always minus one the required number. |
| 7-5 | Reserved | | Reserved |
| 4-0 | RD_THRSH | 5h | Read Threshold. Number of SDRAM read bursts after which the DDR2/DDR3 memory controller arbitration will switch to executing write commands. The value programmed is always minus one the required number. |

### 7.8.2 DDR2/DDR3 PHY Registers

Table 7-66 lists the memory-mapped registers for the DDR2/DDR3 PHY. Configure the DDR PHY Control Register for calibration of board delay and other parameters to get the SDRAM device working at a different speed. See the device-specific data manual for the base memory address of these registers.

**Table 7-66. Memory-Mapped Registers for DDR2 and DDR3 PHY**

| Register Name | Type | Description | Reset | Offset |
|---|---|---|---|---|
| CMD0_REG_PHY_CTRL_SLAVE_RATIO_0 | RW | DDR PHY Command 0 Address/Command Slave Ratio Register | 0x80 | 0x01C |
| CMD0_REG_PHY_DLL_LOCK_DIFF_0 | RW | DDR PHY Command 0 Address/Command DLL Lock Difference Register | 0x4 | 0x028 |
| CMD0_REG_PHY_INVERT_CLKOUT_0 | RW | DDR PHY Command 0 Invert Clockout Selection Register | 0x0 | 0x02C |
| CMD1_REG_PHY_CTRL_SLAVE_RATIO_0 | RW | DDR PHY Command 1 Address/Command Slave Ratio Register | 0x80 | 0x050 |

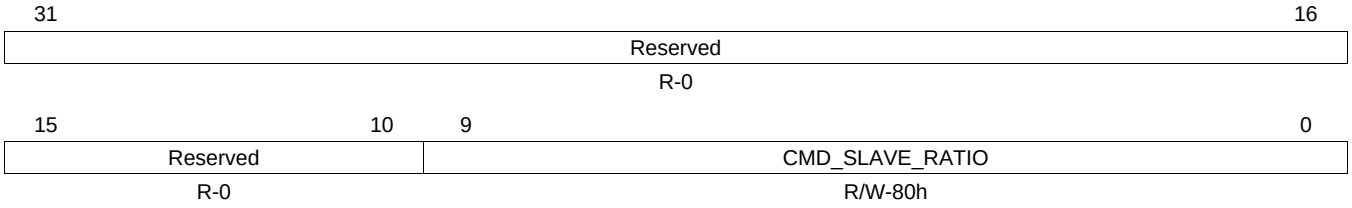
### 7.8.2.1 DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0)

The DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0) is shown in the figure and table below.

**Figure 7-35. DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 7-67. DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | | Reserved |
| 9-0 | CMD_SLAVE_RATIO | 0-80h | Ratio value for address/command launch timing in DDR PHY macro. This is the fraction of a clock cycle represented by the shift to be applied to the read DQS in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line. |

### 7.8.2.2 DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register ( MD0/1/2_REG_PHY_DLL_LOCK_DIFF_0)

The DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register (CMD0/1/2_REG_PHY_DLL_LOCK_DIFF_0) is shown in the figure and table below.

Copyright © 2011–2016, Texas Instruments Incorporated

| 5 | READY | | IO training sequence completion status |
| | | 0 | IO training is not completed |
| | | 1 | IO training is completed |
| 4 | LOCK | | Dynamic Update Locking |
| | | 0 | Dynamic update enabled based on VTP variations. |
| | | 1 | Dynamic impedance update is disabled and VTP macro powered down. |
| 3-1 | FILTER | 0 | Digital filter bits to control the update rate. |
| | | 1h | Update on 2 consecutive update requests |
| | | 2h | Update on 3 consecutive update requests |
| | | 3h | Update on 4 consecutive update requests |
| | | 4h | Update on 5 consecutive update requests |
| | | 5h | Update on 6 consecutive update requests |
| | | 6h | Update on 7 consecutive update requests |
| | | 7h | Update on 8 consecutive update requests |
| 0 | CLRz | | Clears the flops, start count again, after low going pulse |

### 7.8.3.6 VTP Initialization

VTP-controller can be used in static or dynamic update modes. For both the modes VTP- controller is required to be initialized after every power-up cycle or for recalibration. The ‘READY’ bit reflects the status of initialization sequence completion.

To initialize the VTP-controller a negative going CLRz pulse should be asserted for at least 4ns. Once CLRz is removed, user needs to poll for READY bit to go high to know when the impedance gets fully trained. The READY bit stays high until CLRz is asserted again to re-initialize the training sequence.

When the LOCK bit is set Dynamic update ceases and VTP controller enters static mode. In order to save power, in static mode, VTP-controller goes into power-down mode. It is to be noted that in the LOCK mode, VTP-controller cannot be cleared (CLRz is disabled).

Table 7-83 shows the master connection IDs for the various initiators in the system, as seen by the DDR controllers.

# Enhanced Direct Memory Access Controller

This document describes the features and operations of the enhanced direct memory access (EDMA3) controller.

The EDMA3 is a high-performance, multichannel, multithreaded DMA controller that allows you to program a wide variety of transfer geometries and transfer sequences.

Section 8.1 provides an overview of features and terminology. Section 8.2 provides the details of the architecture and the common operations of the EDMA3 channel controller (EDMA3CC) and the EDMA3 transfer controller (EDMA3TC). Section 8.3 contains examples and common usage scenarios. describes the memory-mapped registers that are associated with the EDMA3 controller.

## 8.1 Overview

The enhanced direct memory access (EDMA3) controller's primary purpose is to service user-programmed data transfers between two memory-mapped slave endpoints on the device.

Typical usage includes, but is not limited to the following:

- Servicing software-driven paging transfers (for example, transfers from external memory, such as DDR2 to internal device memory, such as DSP L2 SRAM).
- Servicing event-driven peripherals, such as a serial port.
- Performing sorting or sub-frame extraction of various data structures.
- Offloading data transfers from the main device CPU(s) or DSP(s) (see the device-specific data manual for specific peripherals that are accessible via the EDMA3 controller.).

The EDMA3 controller has a different architecture from the previous EDMA2 controller on the TMS320C621x/C671x DSPs and TMS320C64x DSPs. (See the *EDMA v3.0 (EDMA3) Migration Guide for TMS320C645x DSP* (SPRAAB9) for more information on new/advanced features.)

The EDMA3 controller consists of two principal blocks:

- EDMA3 channel controller (EDMA3CC).
- EDMA3 transfer controller(s) (EDMA3TC).

The EDMA3 channel controller serves as the user interface for the EDMA3 controller. The EDMA3CC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA3CC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The EDMA3 transfer controllers are slaves to the EDMA3 channel controller that is responsible for data movement. The transfer controller issues read/write commands to the source and destination addresses that are programmed for a given transfer. The operation is transparent to user.

## 8.2 Features

The EDMA3 channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.
  - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
  - Transfer completion.
  - Error conditions.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.
- 64 DMA channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set register).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:

Copyright © 2011–2016, Texas Instruments Incorporated

  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Four transfer controllers/event queues. You program the system-level priority of these queues. (See the device data manual for the possible system priorities.)
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The EDMA3 transfer controller has the following features:

- Four transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA3CC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

## 8.3 Terminology Used in This Document

The following is a brief explanation of some terms that are used in this document:

| Term | Meaning |
|---|---|
| A-synchronized transfer | A transfer type where one dimension is serviced per synchronization event. |
| AB-synchronized transfer | A transfer type where two dimensions are serviced per synchronization event. |
| Chaining | A trigger mechanism in which a transfer can be initiated at the completion of another transfer or sub-transfer. |
| CPU(s) | The main processing engine or engines on a device. The CPU is typically a DSP or general-purpose processor (see the device-specific data manual to learn more about the CPU on your system.) |
| DMA channel | One of the 64 channels that external, manual, or chained events can trigger. All direct memory access (DMA) channels exist in the EDMA3CC. |
| Dummy set or dummy PaRAM set | A PaRAM set for which at least one of the count fields is equal to 0 and at least one of the count fields is nonzero. All of the count fields are cleared in a null PaRAM set. |
| Dummy transfer | A dummy set results in the EDMA3CC performing a dummy transfer. This is not an error condition. A null set results in an error condition. |
| EDMA3 channel controller (EDMA3CC) | The EDMA3CC is the portion of the EDMA3 that you program. The EDMA3CC contains the parameter RAM (PaRAM), event processing logic, DMA/QDMA channels, and event queues. The EDMA3CC service events (external, manual, chained, and QDMA) and is responsible for submitting transfer requests to the transfer controllers (EDMA3TC) that perform the actual transfer. |
| EDMA3 programmer | Any entity on the chip that has read/write access to the EDMA3 registers and can program an EDMA3 transfer. |
| EDMA3 transfer controller(s) (EDMA3TC) | Transfer controllers are the transfer engines for the EDMA3 controller. They perform the read/writes, as dictated by the EDMA3CC's transfer requests. |
| Enhanced direct memory access (EDMA3) controller | EDMA3 consists of the EDMA3 channel controller (EDMA3CC) and the EDMA3 transfer controller(s) (EDMA3TC), referred to as EDMA3 in this document. |
| L3 | System bus infrastructure that arbitrates and decodes bus transactions from multiple masters to multiple slaves. |
| Link parameter set | A PaRAM set that is used for linking. |

Copyright © 2011–2016, Texas Instruments Incorporated

| Term | Meaning |
|---|---|
| Linking | The mechanism of reloading a PaRAM set with new transfer characteristics on completion of the current transfer. |
| Memory-mapped slave | All on-chip memories, off-chip memories, and slave peripherals. These typically rely on the EDMA3 (or other master peripheral) to perform transfers to and from them. |
| Master peripherals | All peripherals that are capable of initiating read and write transfers to the system that may not solely rely on the EDMA3 for their data transfers. |
| Null set or null PaRAM set | A PaRAM set that has all count fields cleared (except for the link field). A dummy PaRAM set has at least one of the count fields nonzero. |
| Null transfer | A trigger event for a null PaRAM set results in the EDMA3CC performing a null transfer. This is an error condition. A dummy transfer is not an error condition. |
| Parameter RAM (PaRAM) | Programmable RAM that stores PaRAM sets that DMA channels, QDMA channels, and linking uses. |
| Parameter RAM (PaRAM) set | The PaRAM set is a 32-byte EDMA3 channel transfer definition. Each parameter set consists of eight words (that are four bytes each) that store the context for a DMA/QDMA/link transfer. A PaRAM set includes source address, destination address, counts, indexes, and options. |
| Parameter RAM (PaRAM) set entry | A PaRAM set entry is one of the eight four-byte components of the parameter set. |
| QDMA channel | A QDMA channel is one of the channels that you can trigger when writing to the trigger word (TRWORD) of a PaRAM set. All QDMA channels exist in the EDMA3CC. |
| Slave end points | Slave end points are all on-chip memories, off-chip memories, and slave peripherals. Slave end points may rely on the EDMA3 to perform transfers to and from them. |
| Transfer request (TR) | A command for data movement that is issued from the EDMA3CC to the EDMA3TC. A TR includes source and destination addresses, counts, indexes, and options. |
| Trigger event | A trigger event is an action that causes the EDMA3CC to service the channel and to submit a transfer request to the EDMA3TC. Trigger events for the DMA channels include events that are triggered manually, externally, and by chain. Trigger events for QDMA channels include events that are triggered automatically and by link. |
| Trigger word | For QDMA channels, the trigger word specifies the PaRAM set entry that results in a QDMA trigger event when it is written. The trigger word is programmed via the QDMA channel map register (QCHMAP) and can point to any of the PaRAM set entries. |
| TR synchronization (sync) event | See Trigger event. |

# EDMA3 Architecture

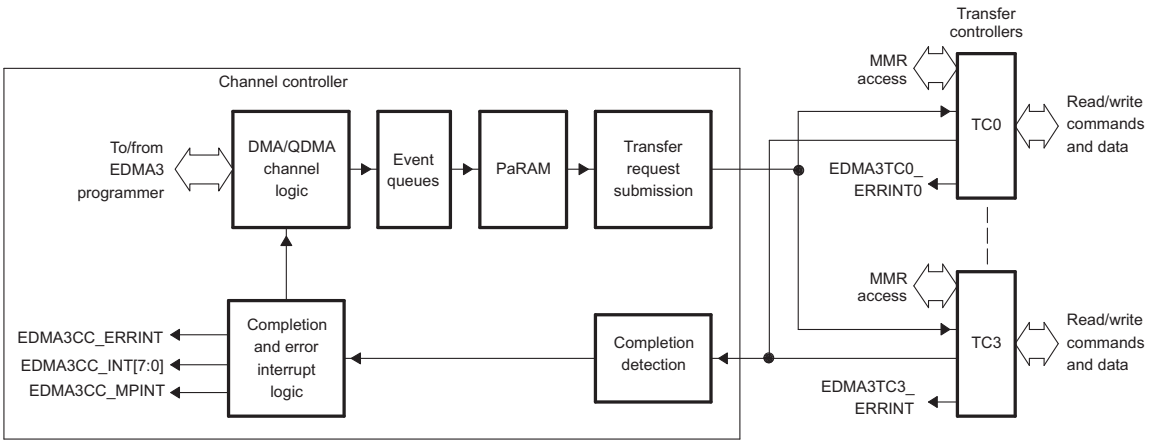
This chapter discusses the architecture of the EDMA3 controller.

## 8.3.1 Functional Overview

### 8.3.1.1 EDMA3 Controller Block Diagram

Figure 8-1 shows a block diagram for the EDMA3 controller.

**Figure 8-1. EDMA3 Controller Block Diagram**



### 8.3.1.2 EDMA3 Channel Controller (EDMA3CC)

Figure 8-2 shows a functional block diagram of the EDMA3 channel controller (EDMA3CC).

The main blocks of the EDMA3CC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. You must write the PaRAM with the transfer context for the desired channels and link parameter sets. EDMA3CC processes sets based on a trigger event and submits a transfer request (TR) to the transfer controller.
- EDMA3 event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA3TC and/or slave peripherals. You can optionally use completion of transfers to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

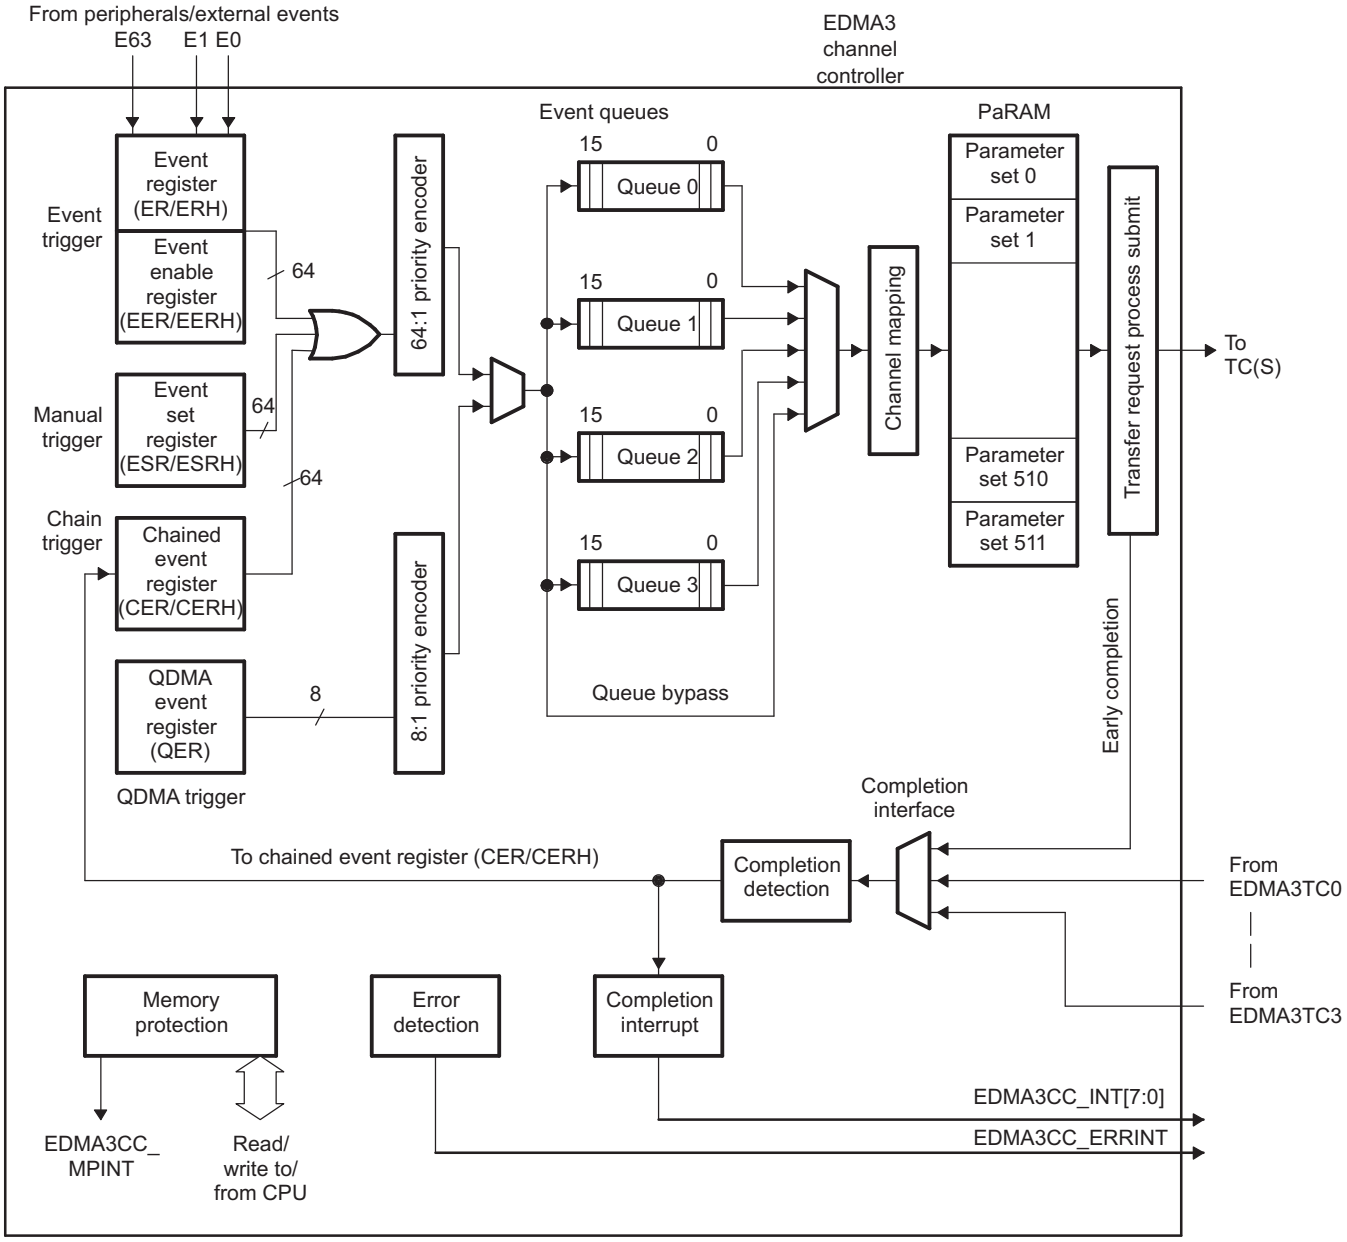
- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA3 programmers own (for example, ARM or DSP).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA3CC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main thing that differentiates a DMA channel from a QDMA channel is the method that the system uses to trigger transfers. See Section 8.3.4.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 8-2. EDMA3 Channel Controller (EDMA3CC) Block Diagram**



A trigger event is needed to initiate a transfer. A trigger event may be due to an external event, manual write to the event set register, or chained event for DMA channels. QDMA channels auto-trigger when a write to the trigger word that you program occurs on the associated PaRAM set. All such trigger events are logged into appropriate registers upon recognition.

Once a trigger event is recognized, the appropriate event gets queued in the EDMA3CC event queue. The assignment of each DMA/QDMA channel to an event queue is programmable. Each queue is 16 events deep; therefore, you can queue up to 16 events (on a single queue) in the EDMA3CC at a time. Additional pending events that are mapped to a full queue are queued when the event queue space becomes available. See Section 8.3.11.

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Copyright © 2011–2016, Texas Instruments Incorporated

Each event in the event queue is processed in FIFO order. When the head of the queue is reached, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to the EDMA3TC association, Q0 goes to TC0 , Q1 goes to TC1, Q2 goes to TC2, and Q3 goes to TC3). For more information, refer to Section 8.3.3.

The EDMA3TC receives the request and is responsible for data movement, as specified in the transfer request packet (TRP), other necessary tasks like buffering, and ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMA3TC, refer to Section 8.3.1.3.

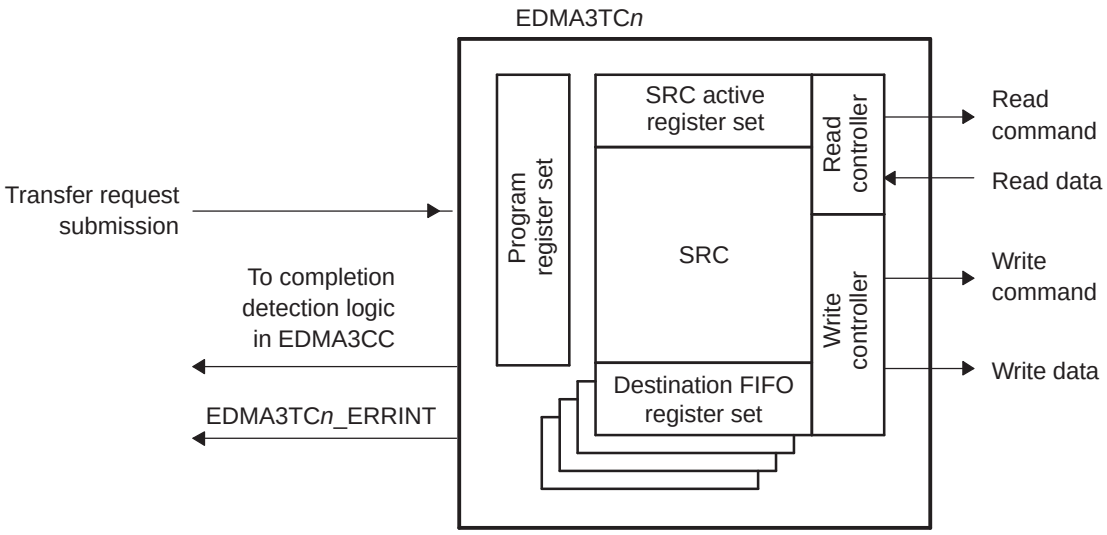
If you have decided to receive an interrupt or to chain to another channel on completion of the current transfer, the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is complete. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more information, refer to Section 8.3.5.

Additionally, the EDMA3CC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, refer to Section 8.3.9.4.

### 8.3.1.3 EDMA3 Transfer Controller (EDMA3TC)

Section 8.3.9.4 shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

**Figure 8-3. EDMA3 Transfer Controller (EDMA3TC) Block Diagram**



The main blocks of the EDMA3TC are:

- DMA program register set: The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- DMA source active register set: The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- Read controller: The read controller issues read commands to the source address.
- Destination FIFO register set: The destination (DST) FIFO register set stores the context for the DMA transfer request(s) currently in progress in the write controller.
- Write controller: The write controller issues write commands/write data to the destination slave.
- Data FIFO: The data FIFO exists for holding temporary in-flight data.
- Completion interface: The completion interface sends completion codes to the EDMA3CC when a transfer completes, and generates interrupts and chained events (also, see Section 8.3.1.2 for more information on transfer completion reporting).

Copyright © 2011–2016, Texas Instruments Incorporated

When the EDMA3TC is idle and receives its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization. For more information on command fragmentation and optimization, refer to Section 8.3.12.1.1.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

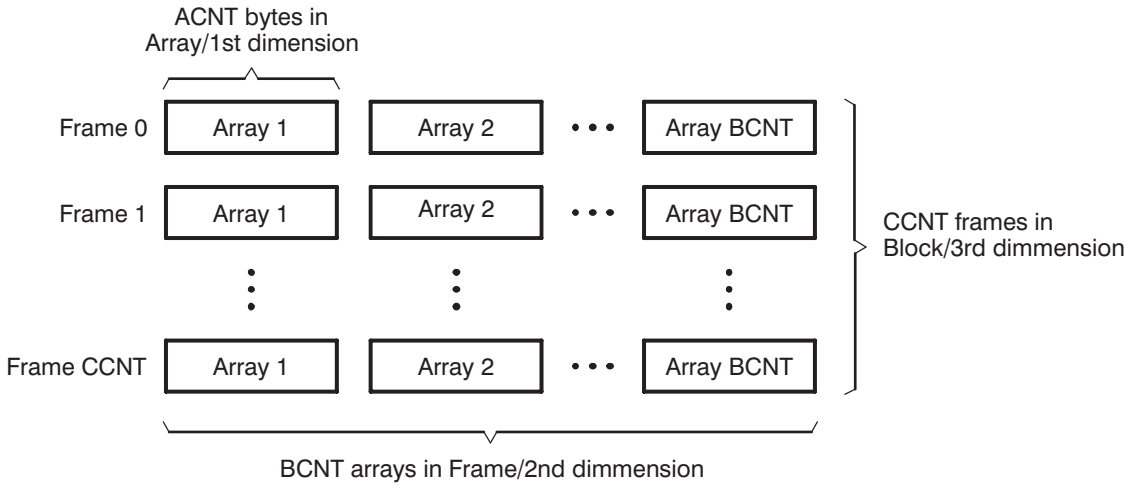
### 8.3.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. Figure 8-4 shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

**Figure 8-4. Definition of ACNT, BCNT, and CCNT**



Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.2.1 A-Synchronized Transfers

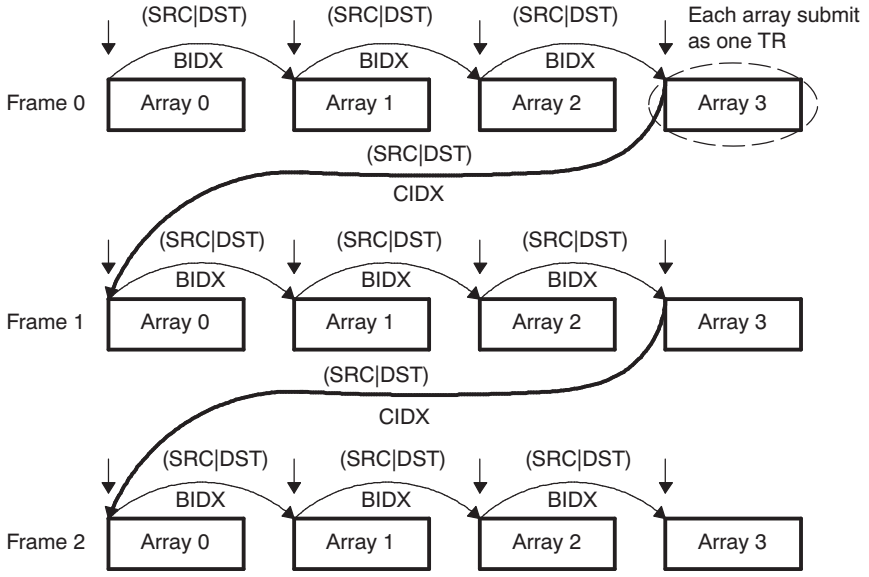
In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in Figure 8-5, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 8-5, SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 8-5 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Section 8.3.3.6 for details on parameter set updates.

**Figure 8-5. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.2.2 AB-Synchronized Transfers

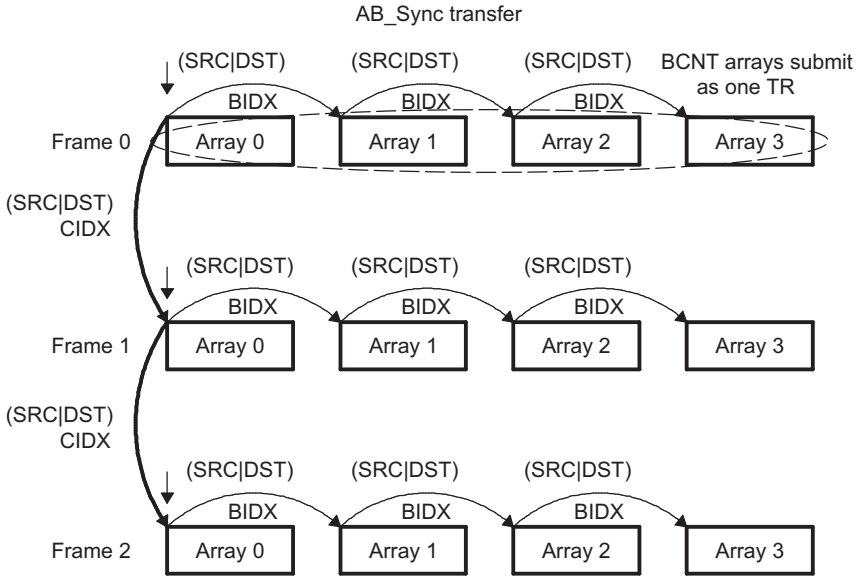
In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 8-6. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 8.3.3.6 for details on parameter set updates.

Figure 8-6 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

**Figure 8-6. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)**



**NOTE:** ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

### *8.3.3 Parameter RAM (PaRAM)*

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

Copyright © 2011–2016, Texas Instruments Incorporated

By default, all channels map to PaRAM set to 0. These should be remapped before use. For more information, see Section 8.5.1.1.3 (DCHMAP registers) and Section 8.5.1.1.4 (QCHMAP registers).

**Table 8-1. EDMA3 Parameter RAM Contents**

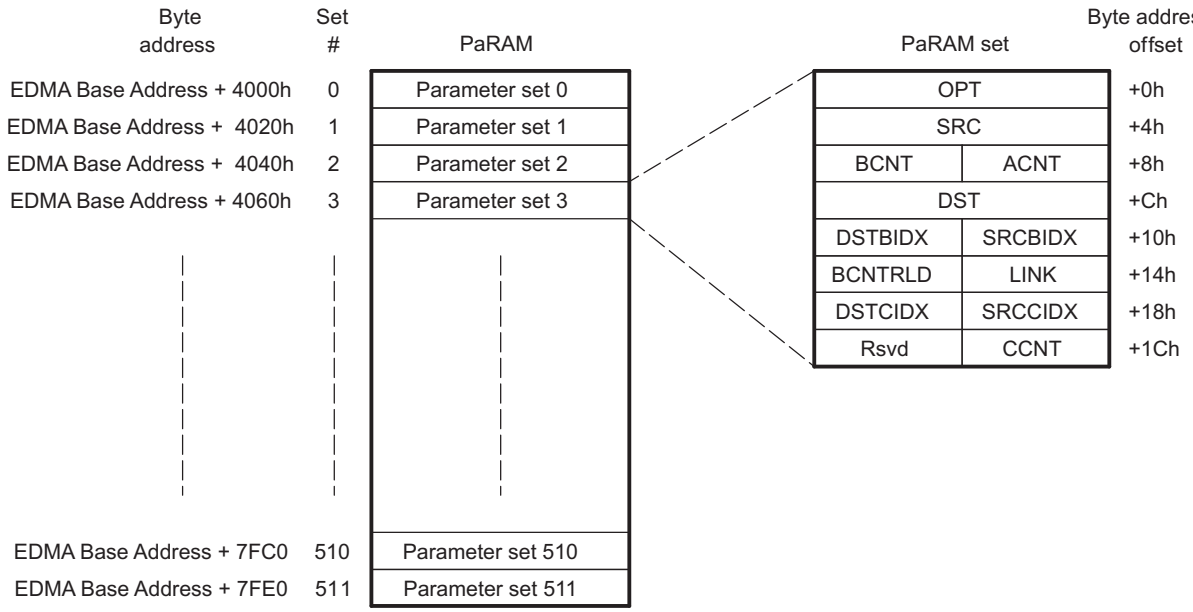
| PaRAM Set Number | Address[1] | Parameters[2] |
|---|---|---|
| 0 | EDMA Base Address + 4000h to EDMA Base Address + 401Fh | PaRAM set 0 |
| 1 | EDMA Base Address + 4020h to EDMA Base Address + 403Fh | PaRAM set 1 |
| 2 | EDMA Base Address + 4040h to EDMA Base Address + 405Fh | PaRAM set 2 |
| 3 | EDMA Base Address + 4060h to EDMA Base Address + 407Fh | PaRAM set 3 |
| 4 | EDMA Base Address + 4080h to EDMA Base Address + 409Fh | PaRAM set 4 |
| 5 | EDMA Base Address + 40A0h to EDMA Base Address + 40BFh | PaRAM set 5 |
| 6 | EDMA Base Address + 40C0h to EDMA Base Address + 40DFh | PaRAM set 6 |
| 7 | EDMA Base Address + 40E0h to EDMA Base Address + 40FFh | PaRAM set 7 |
| 8 | EDMA Base Address + 4100h to EDMA Base Address + 411Fh | PaRAM set 8 |
| 9 | EDMA Base Address + 4120h to EDMA Base Address + 413Fh | PaRAM set 9 |
| : | : | : |
| 63 | EDMA Base Address + 47E0h to EDMA Base Address + 47FFh | PaRAM set 63 |
| 64 | EDMA Base Address + 4800h to EDMA Base Address + 481Fh | PaRAM set 64 |
| 65 | EDMA Base Address + 4820h to EDMA Base Address + 483Fh | PaRAM set 65 |
| : | : | : |
| 510 | EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh | PaRAM set 510 |
| 511 | EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh | PaRAM set 511 |

(1) The EDMA base address can be obtained from the device-specific data manual. See EDMA TPCC Registers.
(2) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

### 8.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 8-7 and described in Table 8-2. Each PaRAM set consists of 16-bit and 32-bit parameters.

**Figure 8-7. PaRAM Set**



Copyright © 2011–2016, Texas Instruments Incorporated

**Table 8-2. EDMA3 Channel Parameter Description**

| Offset Address (bytes) | Acronym | Parameter | Description |
|---|---|---|---|
| 0h | OPT | Channel Options | Transfer configuration options |
| 4h | SRC | Channel Source Address | The byte address from which data is transferred |
| 8h(1) | ACNT | Count for 1st Dimension | Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535. |
| | BCNT | Count for 2nd Dimension | Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535. |
| Ch | DST | Channel Destination Address | The byte address to which data is transferred |
| 10h(1) | SRCBIDX | Source BCNT Index | Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767. |
| | DSTBIDX | Destination BCNT Index | Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767. |
| 14h(1) | LINK | Link Address | The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link. |
| | BCNTRLD | BCNT Reload | The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers. |
| 18h(1) | SRCCIDX | Source CCNT Index | Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.<br>A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame.<br>AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame. |
| | DSTCIDX | Destination CCNT index | Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.<br>A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame.<br>AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame. |
| 1Ch | CCNT | Count for 3rd Dimension | Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535. |
| | RSVD | Reserved | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.3.2 EDMA3 Channel PaRAM Set Entry Fields

#### *8.3.3.2.1 Channel Options Parameter (OPT)*

The channel options parameter (OPT) is shown in Figure 8-8 and described in Table 8-3.

**Figure 8-8. Channel Options Parameter (OPT)**

| 31 | 30 28 | 27 24 | 23 | 22 | 21 | 20 | 19 18 | 17 16 |
|---|---|---|---|---|---|---|---|---|
| PRIV | Reserved | PRIVID | ITCCHEN | TCCHEN | ITCINTEN | TCINTEN | Reserved | TCC |
| R-0 | R-0 | R-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

| 15 12 | 11 | 10 8 | 7 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| TCC | TCCMODE | FWID | Reserved | STATIC | SYNCDIM | DAM | SAM |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

**Table 8-3. Channel Options Parameters (OPT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | PRIV | | Privilege level (supervisor versus user) for the host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege value when any part of the PaRAM set is written. |
| | | 0 | User level privilege. |
| | | 1 | Supervisor level privilege. |
| 30-28 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 27-24 | PRIVID | 0-Fh | Privilege identification for the external host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege identification value when any part of the PaRAM set is written. |
| 23 | ITCCHEN | | Intermediate transfer completion chaining enable. |
| | | 0 | Intermediate transfer complete chaining is disabled. |
| | | 1 | Intermediate transfer complete chaining is enabled. |
| | | | When enabled, the chained event register (CER/CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified. |
| 22 | TCCHEN | | Transfer complete chaining enable. |
| | | 0 | Transfer complete chaining is disabled. |
| | | 1 | Transfer complete chaining is enabled. |
| | | | When enabled, the chained event register (CER/CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified. |
| 21 | ITCINTEN | | Intermediate transfer completion interrupt enable. |
| | | 0 | Intermediate transfer complete interrupt is disabled. |
| | | 1 | Intermediate transfer complete interrupt is enabled. |
| | | | When enabled, the interrupt pending register (IPR / IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set. |
| 20 | TCINTEN | | Transfer complete interrupt enable. |
| | | 0 | Transfer complete interrupt is disabled. |
| | | 1 | Transfer complete interrupt is enabled. |
| | | | When enabled, the interrupt pending register (IPR / IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER[TCC] / IERH [TCC] bit must be set. |
| 19-18 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 8-3. Channel Options Parameters (OPT) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 17-12 | TCC | 0-3Fh | Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] /CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts. |
| 11 | TCCMODE | | Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation. |
| | | 0 | Normal completion: A transfer is considered completed after the data has been transferred. |
| | | 1 | Early completion: A transfer is considered completed after the EDMA3CC submits a TR to the EDMA3TC. TC may still be transferring data when the interrupt/chain is triggered. |
| 10-8 | FWID | 0-7h | FIFO Width. Applies if either SAM or DAM is set to constant addressing mode. |
| | | 0 | FIFO width is 8-bit. |
| | | 1h | FIFO width is 16-bit. |
| | | 2h | FIFO width is 32-bit. |
| | | 3h | FIFO width is 64-bit. |
| | | 4h | FIFO width is 128-bit. |
| | | 5h | FIFO width is 256-bit. |
| | | 6h-7h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | STATIC | | Static set. |
| | | 0 | Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers. |
| | | 1 | Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers. |
| 2 | SYNCDIM | | Transfer synchronization dimension. |
| | | 0 | A-synchronized. Each event triggers the transfer of a single array of ACNT bytes. |
| | | 1 | AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes. |
| 1 | DAM | | Destination address mode. |
| | | 0 | Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO. |
| | | 1 | Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width. |
| 0 | SAM | | Source address mode. |
| | | 0 | Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO. |
| | | 1 | Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width. |

#### *8.3.3.2.2 Channel Source Address (SRC)*

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 8.3.12.3 for additional details.

#### *8.3.3.2.3 Channel Destination Address (DST)*

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 8.3.12.3 for additional details.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 8.3.3.5 and Section 8.3.5.3 for details on dummy/null completion conditions.

#### 8.3.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 8.3.3.5 and Section 8.3.5.3 for details on dummy/null completion conditions.

#### 8.3.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

A CCNT value of 0 is considered either a null or dummy transfer. See Section 8.3.3.5 and Section 8.3.5.3 for details on dummy/null completion conditions.

#### 8.3.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

#### 8.3.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

#### 8.3.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX for examples.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 8-5), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 8-6).

#### 8.3.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 8-5), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 8-6).

#### 8.3.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 8.3.5 for details on terminating a transfer.

### 8.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR, EMRH, or QEMR). This bit remains set in the associated secondary event register (SER, SERH, or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER, SERH, or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. See Section 8.5.1.6.8 and Section 8.5.1.2.1 for more information on the SER and EMR registers, respectively.

### 8.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR, EMRH, or QEMR) and the secondary event register (SER, SERH, or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. See Section 8.5.1.6.8 and Section 8.5.1.2.1 for more information on the SER and EMR registers, respectively.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EMR to get set and the E*n* bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 8-4 summarizes the conditions and effects of null and dummy transfer requests.

**Table 8-4. Dummy and Null Transfer Request**

| Feature | Null TR | Dummy TR |
|---|---|---|
| EMR/EMRH/QEMR is set | Yes | No |
| SER/SERH/QSER remains set | Yes | No |
| Link update (STATIC = 0 in OPT) | Yes | Yes |
| QER is set | Yes | Yes |
| IPR/IPRH CER/CERH is set using early completion | Yes | Yes |

#### 8.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See Table 8-5 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 8.3.3.7.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.

Copyright © 2011–2016, Texas Instruments Incorporated

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 8.3.12. For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

Table 8-5 shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

**Table 8-5. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)**

| | A-Synchronized Transfer | | | AB-Synchronized Transfer | | |
|---|---|---|---|---|---|---|
| | **B-Update** | **C-Update** | **Link Update** | **B-Update** | **C-Update** | **Link Update** |
| **Condition:** | **BCNT > 1** | **BCNT == 1 && CCNT > 1** | **BCNT == 1 && CCNT == 1** | **N/A** | **CCNT > 1** | **CCNT == 1** |
| SRC | += SRCBIDX | += SRCCIDX | = Link.SRC | in EDMA3TC | += SRCCIDX | = Link.SRC |
| DST | += DSTBIDX | += DSTCIDX | = Link.DST | in EDMA3TC | += DSTCIDX | = Link.DST |
| ACNT | None | None | = Link.ACNT | None | None | = Link.ACNT |
| BCNT | –= 1 | = BCNTRLD | = Link.BCNT | in EDMA3TC | N/A | = Link.BCNT |
| CCNT | None | –= 1 | = Link.CCNT | in EDMA3TC | –=1 | = Link.CCNT |
| SRCBIDX | None | None | = Link.SRCBIDX | in EDMA3TC | None | = Link.SRCBIDX |
| DSTBIDX | None | None | = Link.DSTBIDX | None | None | = Link.DSTBIDX |
| SRCCIDX | None | None | = Link.SRCBIDX | in EDMA3TC | None | = Link.SRCBIDX |
| DSTCIDX | None | None | = Link.DSTBIDX | None | None | = Link.DSTBIDX |
| LINK | None | None | = Link.LINK | None | None | = Link.LINK |
| BCNTRLD | None | None | = Link.BCNTRLD | None | None | = Link.BCNTRLD |
| OPT[1] | None | None | = LINK.OPT | None | None | = LINK.OPT |

(1) In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

**NOTE:** The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the STATIC bit in OPT is cleared.

**NOTE:** You should always link a transfer (EDMA3 or QDMA) to another useful transfer. If you must terminate a transfer, then you should link the transfer to a NULL parameter set. See Section 8.3.3.3.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location that LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA3CC reads the entire set (eight words) from the PaRAM set specified by LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 8-9 shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (see Section 8.3.6) should only be used for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by QCHMAP*n*), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in QER because a write to the trigger word was performed. You can use this feature to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See Section 8.3.4.2.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 8-10 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

**NOTE:** If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed.

### 8.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bits). The EDMA3CC does not recognize errors here, but the EDMA3TC asserts an error if this is not true. See Section 8.3.12.3.

**NOTE:** The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. See the device-specific data manual and/or peripheral user`s guide to verify if the constant addressing mode is supported. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM =0) by appropriately programming the count and indices values.

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.3.9 Element Size

The EDMA3 controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that must be transferred to a serial port, you can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

**Figure 8-9. Linked Transfer**

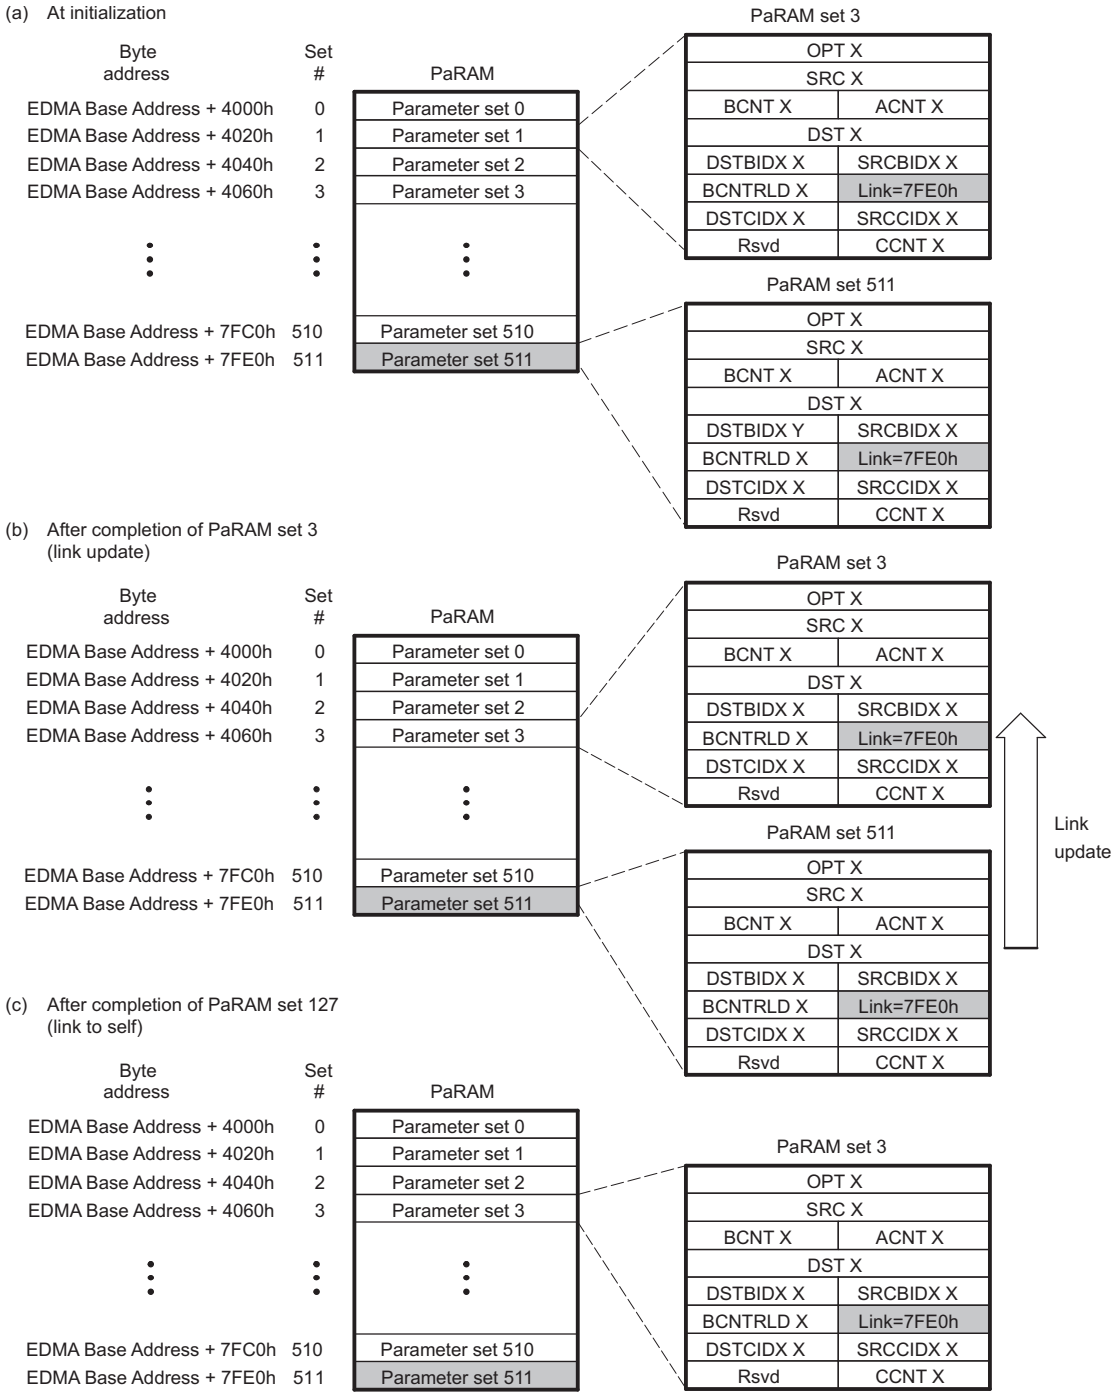
**Figure 8-10. Link-to-Self Transfer**



### 8.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the

Copyright © 2011–2016, Texas Instruments Incorporated

corresponding bit in the event set register (ESR/ESRH).

- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

#### 8.3.4.1 DMA Channel

##### *8.3.4.1.1 Event-Triggered Transfer Request*

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (ER.E*n* = 1). For peripheral event to DMA event mapping, see the device-specific data manual. If the corresponding event in the event enable register (EER) is enabled (EER.E*n* = 1), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the E*n* bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaRAM set associated with the channel is a NULL set (see Section 8.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (ER.E*n* = 1), regardless of the state of EER.E*n*. If the event is disabled when an external event is received (ER.E*n* = 1 and EER.E*n* = 0), the ER.E*n* bit remains set. If the event is subsequently enabled (EER.E*n* = 1), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the ER.E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (ER.E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

The EDMA section in the device-specific data manual gives the table of the synchronization events associated with each of the programmable DMA channels in the device. It also provides the mapping of events to the EDMA event crossbar. See the device-specific data manual to determine the event to channel mapping.

##### *8.3.4.1.2 Manually-Triggered Transfer Request*

The CPU or any EDMA programmer initiates a DMA transfer by writing to the event set register (ESR). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EER.E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 8.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register (ESR.E*n* = 1) prior to the original being cleared (ESR.E*n* = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 8.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER.E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR.E*n* = 1).

**NOTE:** Chained event registers, event registers, and event set registers operate independently. An event (E*n*) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

### 8.3.4.2 QDMA Channels

#### 8.3.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER.E*n* = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP*n*)) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER.E*n* = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP*n* settings) and the corresponding channel is enabled via the QDMA event enable register (QEER.E*n* = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER.E*n* = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR.E*n* = 1).

### 8.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

Copyright © 2011–2016, Texas Instruments Incorporated

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

### 8.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 8-6 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

**Table 8-6. Expected Number of Transfers for Non-Null Transfer**

| Sync Mode | Counts at time 0 | Total # Transfers | Counts prior to final TR |
|---|---|---|---|
| A-synchronized | ACNT<br>BCNT<br>CCNT | (BCNT × CCNT ) TRs of ACNT bytes each | BCNT == 1 && CCNT == 1 |
| AB-synchronized | ACNT<br>BCNT<br>CCNT | CCNT TRs for ACNT × BCNT bytes each | CCNT == 1 |

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See Section 8.3.8 for details on chaining (intermediate/final chaining) and Section 8.3.9 for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See Section 8.3.3.7 for more details.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See Section 8.3.3.5.

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

#### 8.3.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

#### 8.3.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

#### 8.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set (Section 8.3.3.4) or null set (Section 8.3.3.3). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (IPR/IPRH) or chained event register (CER/CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

### *8.3.6 Event, Channel, and PaRAM Mapping*

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the EDMA_EVT[3:0] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. At the SoC level, the EDMA event crossbar can be used to select which SoC level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in section *EDMA Channel Synchronization Events* of the *Chip Level Resources* chapter. The event crossbar mapping is controlled by the EDMA3CC_EVTMUX_m_n registers (refer to Control Module chapter for their description).

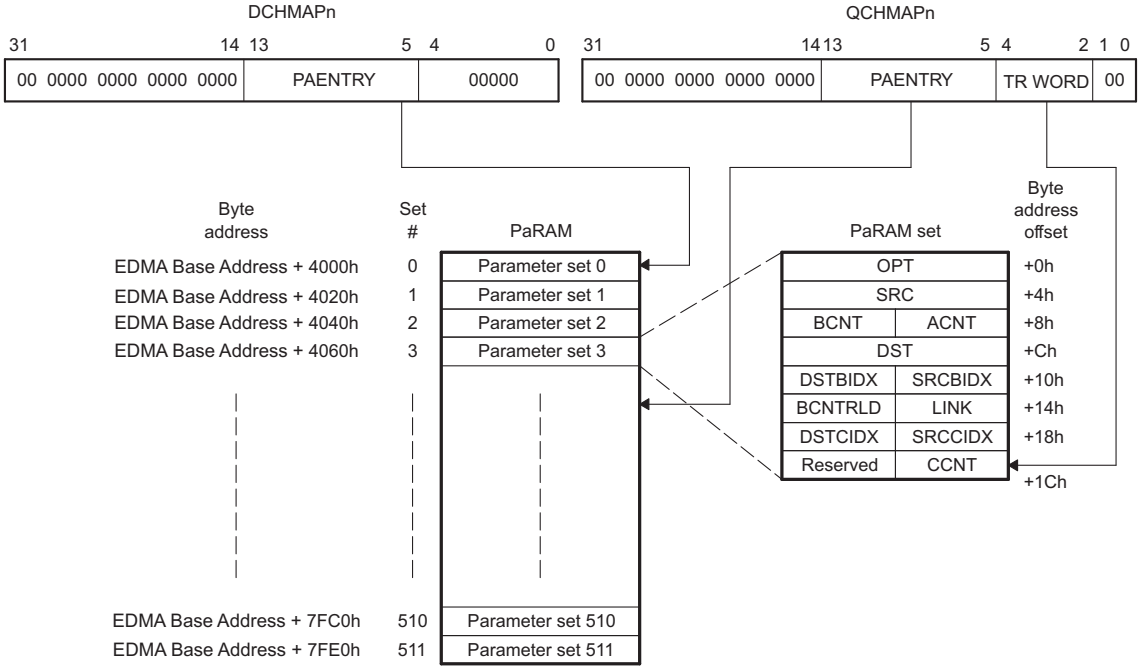
In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 8-1). The DMA channel mapping registers (DCHMAPn) in the EDMA3CC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 8-11 illustrates the use of DCHMAP. There is one DCHMAP register per channel.

**Figure 8-11. DMA Channel and QDMA Channel to PaRAM Mapping**



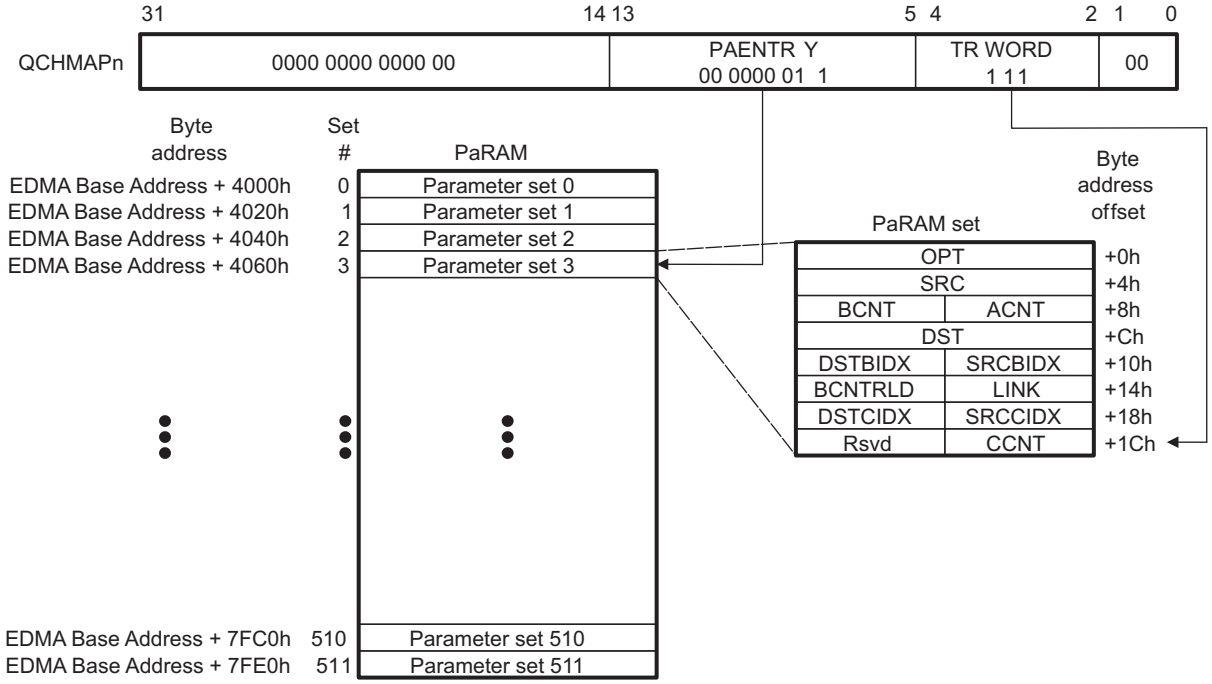
### 8.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register (QCHMAP) in the EDMA3CC allows you to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 8-12 illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0. You must appropriately re-map PaRAM set 0 before you use it.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 8-12. QDMA Channel to PaRAM Mapping**



## 8.3.7 EDMA3 Channel Controller Regions

The EDMA3 channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

You can design the application software to use regions or to ignore them altogether. You can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in Section 8.3.10.

### 8.3.7.1 Region Overview

The EDMA3 channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information. See the device-specific data manual for the EDMA3CC memory map.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register (EER) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers (DRAE*m*) and the QDMA region access enable registers (QRAE*n*) control the underlying control register bits that are accessible via the shadow region address space (except for IEVAL*n*). Table 8-7 lists the registers in the shadow region memory map. See the EDMA3CC memory map (Table 8-19) for the complete global and shadow region memory maps. Figure 8-13 illustrates the conceptual view of the regions.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 8-7. Shadow Region Registers**

| DRAE*m* | DRAEH*m* | QRAE*n* |
|---|---|---|
| ER | ERH | QER |
| ECR | ECRH | QEER |

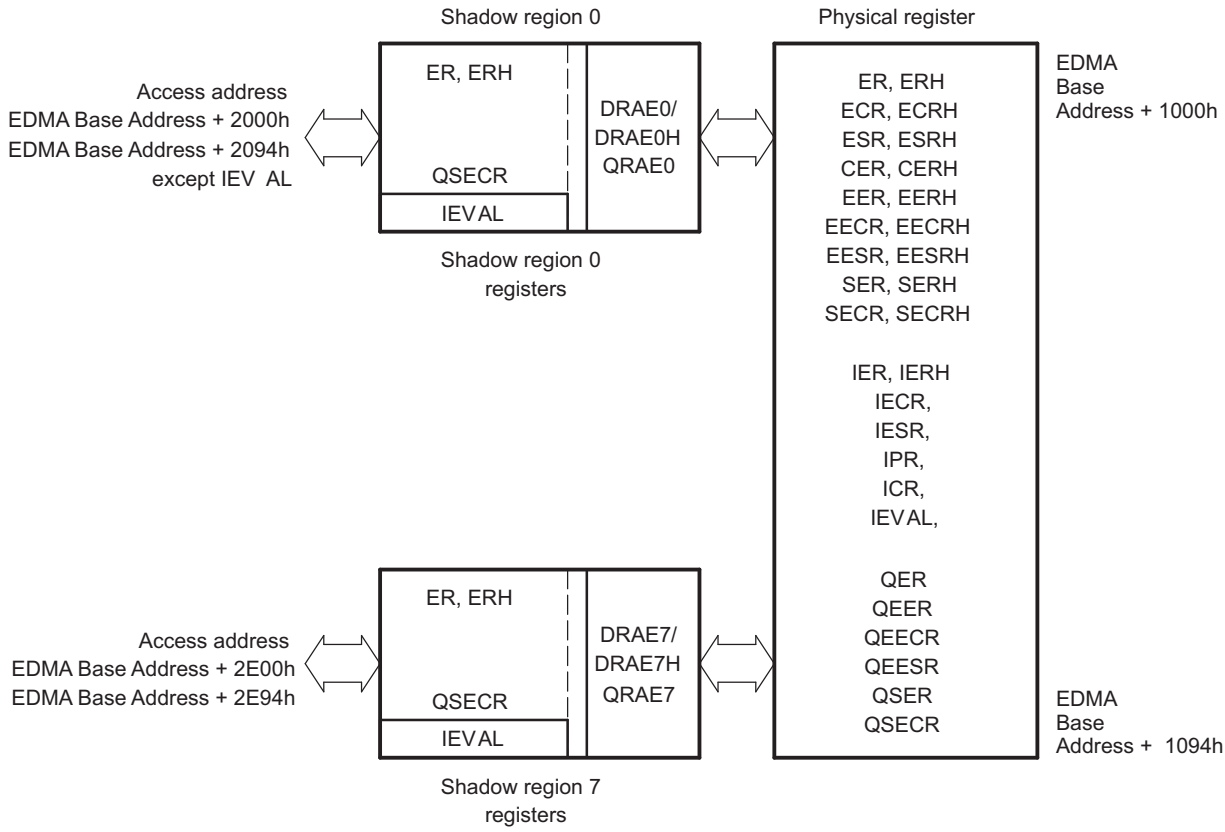
| ICR | ICRH | |
| **Register not affected by DRAE\DRAEH** | | |
| IEVAL | | |

**Figure 8-13. Shadow Region Registers**



### 8.3.7.2 Channel Controller Regions

There are eight EDMA3 shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

Copyright © 2011–2016, Texas Instruments Incorporated

- DRAE*m* and DRAEH*m*: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- QRAE*n*: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.
- MPPA*n* and MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/ORAE registers. If exclusive access to any given channel / TCC code is required for a region, then only that region's DRAE/ORAE should have the associated bit set.

***Example 8-1. Resource Pool Division Across Two Regions***

This example illustrates a judicious resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEH, DRAE = 0xFFFF0000, 0x0000FFFF QRAE = 0x0000001
Region 1: DRAEH, DRAE = 0x0000FFFF, 0xFFFF0000 QRAE = 0x00000FE
```

#### 8.3.7.3 Region Interrupts

In addition to the EDMA3CC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register (IER), DRAE acts as a secondary interrupt enable for the respective shadow region interrupts. See Section 8.3.9 for more information.

### *8.3.8 Chaining EDMA3 Channels*

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 8.3.3.7). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see Section 8.3.4.1.3 for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the TCC bit of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

Copyright © 2011–2016, Texas Instruments Incorporated

- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 8-8 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 8-8. Chain Event Triggers**

| | (Number of chained event triggers on channel 30) | |
|---|---|---|
| **Options** | **A-Synchronized** | **AB-Synchronized** |
| TCCHEN = 1, ITCCHEN = 0 | 1 (Owing to the last TR) | 1 (Owing to the last TR) |
| TCCHEN = 0, ITCCHEN = 1 | 19 (Owing to all but the last TR) | 4 (Owing to all but the last TR) |
| TCCHEN = 1, ITCCHEN = 1 | 20 (Owing to a total of 20 TRs) | 5 (Owing to a total of 5 TRs) |

### 8.3.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 8-9. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the DSP and ARM interrupt controllers.

**Table 8-9. EDMA3 Transfer Completion Interrupts**

| Name | Description |
|---|---|
| EDMA3CC_INT0 | EDMA3CC Transfer Completion Interrupt Shadow Region 0 |
| EDMA3CC_INT1 | EDMA3CC Transfer Completion Interrupt Shadow Region 1 |
| EDMA3CC_INT2 | EDMA3CC Transfer Completion Interrupt Shadow Region 2 |
| EDMA3CC_INT3 | EDMA3CC Transfer Completion Interrupt Shadow Region 3 |
| EDMA3CC_INT4 | EDMA3CC Transfer Completion Interrupt Shadow Region 4 |
| EDMA3CC_INT5 | EDMA3CC Transfer Completion Interrupt Shadow Region 5 |
| EDMA3CC_INT6 | EDMA3CC Transfer Completion Interrupt Shadow Region 6 |
| EDMA3CC_INT7 | EDMA3CC Transfer Completion Interrupt Shadow Region 7 |

**Table 8-10. EDMA3 Error Interrupts**

| Name | Description |
|---|---|
| EDMA3CC_ERRINT | EDMA3CC Error Interrupt |
| EDMA3CC_MPINT | EDMA3CC Memory Protection Interrupt |
| EDMA3TC0_ERRINT | TC0 Error Interrupt |
| EDMA3TC1_ERRINT | TC1 Error Interrupt |
| EDMA3TC2_ERRINT | TC2 Error Interrupt |
| EDMA3TC3_ERRINT | TC3 Error Interrupt |

#### 8.3.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA3 masters). The EDMA3 generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA3 interrupt generation.

Copyright © 2011–2016, Texas Instruments Incorporated

The software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR/IPRH). For example, if TCC = 10 0001b, IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 8.3.9.1.1 for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in IPR/IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

**Table 8-11. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping**

| TCC Bits in OPT (TCINTEN/ITCINTEN = 1) | IPR Bit Set | TCC Bits in OPT (TCINTEN/ITCINTEN = 1) | IPRH Bit Set(1) |
|---|---|---|---|
| 0 | IPR0 | 20h | IPR32/IPRH0 |
| 1 | IPR1 | 21h | IPR33/IPRH1 |
| 2h | IPR2 | 22h | IPR34/IPRH2 |
| 3h | IPR3 | 23h | IPR35/IPRH3 |
| 4h | IPR4 | 24h | IPR36/IPRH4 |
| ... | ... | ... | ... |
| 1Eh | IPR30 | 3Eh | IPR62/IPRH30 |
| 1Fh | IPR31 | 3Fh | IPR63/IPRH31 |

(1) Bit fields IPR[32-63] correspond to bits 0 to 31 in IPRH, respectively.

You can program the transfer completion code (TCC) to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and you intend for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in IER/IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

You can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCCINT = 1 in OPT) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCCINT = 1 in OPT) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCCINT = 1, and ITCCINT = 1 in OPT) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 8-12 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 8-12. Number of Interrupts**

| Options | A-Synchronized | AB-Synchronized |
|---|---|---|
| TCINTEN = 1, ITCINTEN = 0 | 1 (Last TR) | 1 (Last TR) |
| TCINTEN = 0, ITCINTEN = 1 | 19 (All but the last TR) | 4 (All but the last TR) |
| TCINTEN = 1, ITCINTEN = 1 | 20 (All TRs) | 5 (All TRs) |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

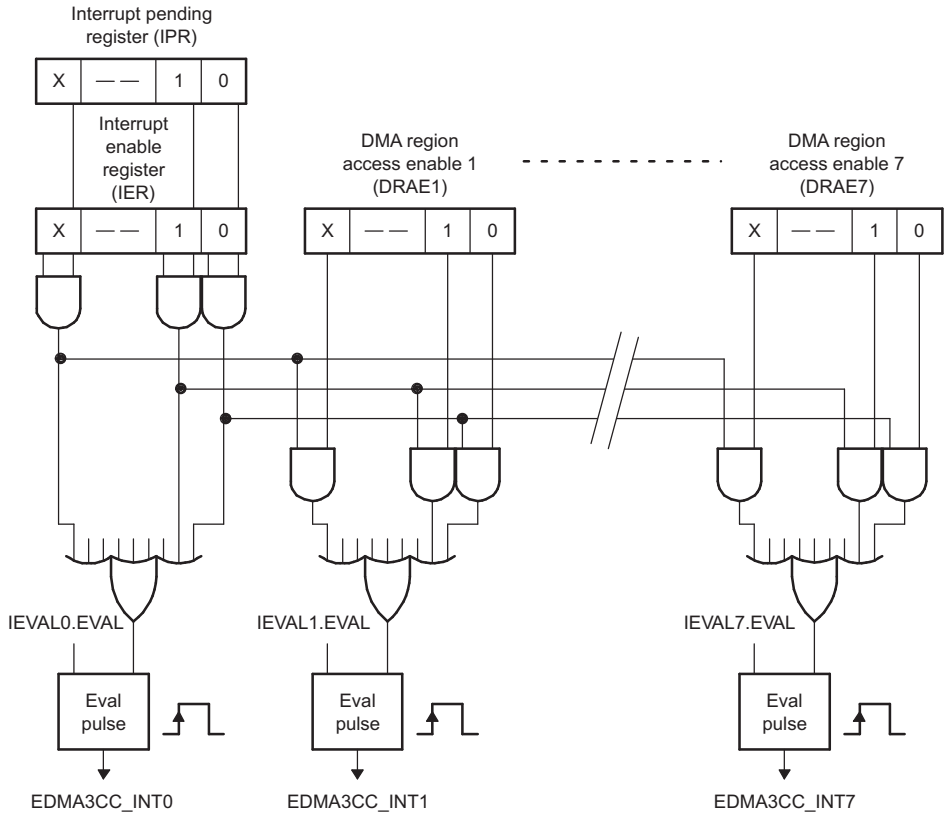
The EDMA3 channel controller has interrupt enable registers (IER/IERH) and each bit location in IER/IERH serves as a primary enable for the corresponding interrupt pending registers (IPR/IPRH).

All of the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (IPR/IPRH) and single set of interrupt enable registers (IER/IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by IER/IERH. see Figure 8-14

The region interrupt outputs are gated by IER and the specific DRAE/DRAEH associated with the region. See Figure 8-14.

**Figure 8-14. Interrupt Diagram**



For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE0.E63)
- EDMA3CC_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | …| (IPRH.E63 & IERH.E63 & DRAHE1.E63)
- EDMA3CC_INT2 : (IPR.E0 & IER.E0 & DRAE2.E0) | (IPR.E1 & IER.E1 & DRAE2.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE2.E63)....

Copyright © 2011–2016, Texas Instruments Incorporated

- Up to EDMA3CC_INT7 : (IPR.E0 & IER.E0 & DRAE7.E0) | (IPR.E1 & IER.E1 & DRAE7.E1) | …|(IPRH.E63 & IERH.E63 & DRAEH7.E63)

**NOTE:** The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to IPRH bit that is set upon completion).

#### *8.3.9.1.2 Clearing Transfer Completion Interrupts*

Transfer completion interrupts that are latched to the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR/ICRH). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR/IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

### 8.3.9.2 EDMA3 Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending registers (IPR/IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR/IPRH, thereby enabling recognition of future interrupts. The EDMA3CC will only assert additional completion interrupts when all IPR/IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in IPR/IPRH, thereby resulting in additional interrupts. Each of the bits in IPR/IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA3CC completion interrupt are shown in Example 8-2 and Example 8-3.

The ISR routine in Example 8-2 is more exhaustive and incurs a higher latency.

***Example 8-2. Interrupt Servicing***

The pseudo code:

1. Reads the interrupt pending register (IPR/IPRH).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register (ICR/ICRH) to clear the corresponding IPR/IPRH bit(s).
4. Reads IPR/IPRH again:
   (a) If IPR/IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
   (b) If IPR/IPRH is equal to 0, this should assure you that all of the enabled interrupts are inactive.

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 8-2. Interrupt Servicing (continued)***

**NOTE:** An event may occur during step 4 while the IPR/IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

Example 8-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

***Example 8-3. Interrupt Servicing***

If you want to leave any enabled and pending (possibly lower priority) interrupts; you must force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code is as follows:

1. Enters ISR.
2. Reads IPR/IPRH.
3. For the condition that is set in IPR/IPRH that you want to service, do the following:
   (a) Service interrupt as the application requires.
   (b) Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Reads IPR/IPRH prior to exiting the ISR:
   (a) If IPR/IPRH is equal to 0, then exit the ISR.
   (b) If IPR/IPRH is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

#### 8.3.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing a 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via IER/IERH) is still pending (IPR/IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See Example 8-3 for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly an error evaluation register (EEVAL) exists in the global region. Writing a 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR/EMRH, QEMR, or CCERR. See Section 8.3.9.4 for additional information regarding error interrupts.

**NOTE:** While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA3CC error interrupt. If the EDMA3CC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3CC_ERRINT) that is asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to pulse:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers (EMR/EMRH).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These are latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 63. This is also latched in the EDMA3CC error register (CCERR).

Figure 8-15 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA3CC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA3CC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, there is an error evaluate register (EEVAL) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register (IEVAL). You can use this so that the CPU(s) does not miss any error events.

**NOTE:** It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status); additionally, it provides a good debug mechanism for unexpected error conditions.

**Figure 8-15. Error Interrupt Operation**

### 8.3.10 Memory Protection

The EDMA3 channel controller supports two kinds of memory protection: active and proxy.

#### 8.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA3 programmer) to the EDMA3CC registers (based on permission characteristics that you program). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMA3CC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to section Table 8-7.

Each of the eight shadow regions has an associated MPPA register (MPPA*n*) that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (MPPAG). The MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, refer to the register memory-map in section Table 8-14.

See Section 8.5.1.5.4 for the bit field descriptions of MPPA*n*. The MPPA*n* have a certain set of access rules.

Table 8-13 shows the accesses that are allowed or not allowed to the MPPAG and MPPA*n*. The active memory protection uses the PRIV and PRIVID attributes of the EDMA programmer. The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer. See the device-specific data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

**Table 8-13. Allowed Accesses**

| Access | Supervisor | User |
|---|---|---|
| Read | Yes | Yes |
| Write | Yes | No |

Table 8-14 describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

**Table 8-14. MPPA Registers to Region Assignment**

| Register | Registers Protect | Address Range | PaRAM Protect[1] | Address Range |
|---|---|---|---|---|
| MPPAG | Global Range | 0000h-1FFCh | N/A | N/A |
| MPPA0 | DMA Shadow 0 | 2000h-21FCh | 1st octant | 4000h-47FCh |
| MPPA1 | DMA Shadow 1 | 2200h-23FCh | 2nd octant | 4800h-4FFCh |
| MPPA2 | DMA Shadow 2 | 2400h-25FCh | 3rd octant | 5000h-57FCh |
| MPPA3 | DMA Shadow 3 | 2600h-27FCh | 4th octant | 5800h-5FFCh |
| MPPA4 | DMA Shadow 4 | 2800h-29FCh | 5th octant | 6000h-67FCh |
| MPPA5 | DMA Shadow 5 | 2A00h-2BFCh | 6th octant | 6800h-6FFCh |

Example Access denied.

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EER is not written to.

**Table 8-15. Example Access Denied**

| Register | Value | Description |
|---|---|---|
| EER<br>(offset 0x1020) | 0x0000 0000 | Value in EER to begin with. |
| EESR<br>(offset 0x2E30) | 0xFF00 FF00<br>↓ | Value attempted to be written to shadow region 7's EESR.<br>This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0. |
| MPPA[7]<br>(offset 0x082C) | 0x0000 04B0 | Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1. |
| | X | Access Denied |
| EER<br>(offset 0x1020) | 0x0000 0000 | Final value of EER |

Example Access Allowed

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.
5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 0x9FF00FC2.
6. The value finally written to EER is 0x8BC00102.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 8-16. Example Access Allowed**

| Register | Value | Description |
|---|---|---|
| EER (offset 0x1020) | 0x0000 0000 | Value in EER to begin with. |
| EESR (offset 0x2E30) | 0xFF00 FF00 | Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0. |
| MPPA[7] (offset 0x082C) | 0x0000 04B3 | Memory Protection Filter AID = 1, UW = 1, UR = 1, SW = 1, SR = 1. |
| | √ ↓ | Access allowed. |
| DRAE[7] (offset 0x0378) | 0x9FF0 0FC2 ↓ | DMA Region Access Enable Filter |
| EESR (offset 0x2E30) | 0x8BC0 0102 ↓ | Value written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and a Privilege ID of 0. |
| EER (offset 0x1020) | ↓ 0xBC0 0102 | Final value of EER. |

### 8.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA3 transfer programmed by a given EDMA3 programmer to have its permissions travel with the transfer through the EDMA3TC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA3 programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer.

See the data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The PRIV is 0 for user-level and the CPU has a PRIVID of 0.

The PaRAM set is shown in Figure 8-16.

Copyright © 2011–2016, Texas Instruments Incorporated

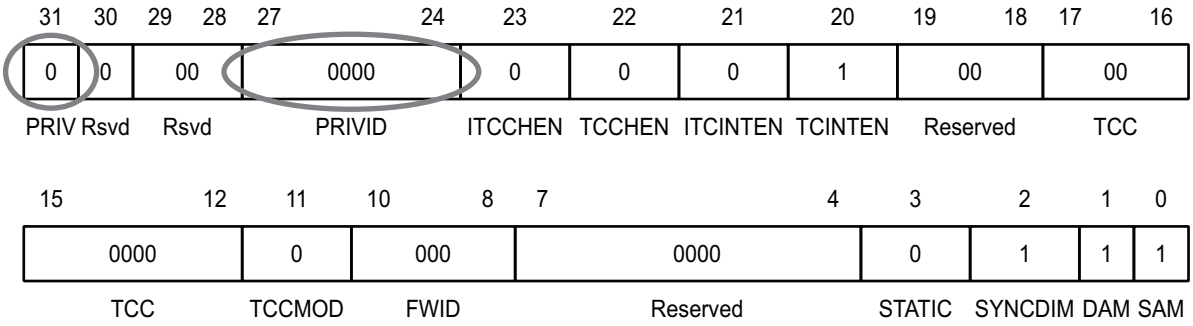
**Figure 8-16. PaRAM Set Content for Proxy Memory Protection Example**

*(a) EDMA3 Parameters*

| Parameter Contents | | Parameter | |
|---|---|---|---|
| 0010 0007h | | Channel Options Parameter (OPT) | |
| 009F 0000h | | Channel Source Address (SRC) | |
| 0001h | 0004h | Count for 2nd Dimension (BCNT) | Count for 1st Dimension (ACNT) |
| 00F0 7800h | | Channel Destination Address (DST) | |
| 0001h | 0001h | Destination BCNT Index (DSTBIDX) | Source BCNT Index (SRCBIDX) |
| 0000h | FFFFh | BCNT Reload (BCNTRLD) | Link Address (LINK) |
| 0001h | 1000h | Destination CCNT Index (DSTCIDX) | Source CCNT Index (SRCCIDX) |
| 0000h | 0001h | Reserved | Count for 3rd Dimension (CCNT) |

**Figure 8-17. Channel Options Parameter (OPT) Example**

(b) Channel Options Parameter (OPT) Content



The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR,SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID 0. For more information regarding how to set memory protection attributes for pages of memory in L2/L1D, please refer to the *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (SPRU732).

Because the programmers privilege level and privilege identification travel with the read and write requests, EDMA3 acts as a proxy.

Figure 8-18 illustrates the propagation of PRIV and PRIVID at the boundaries of all the interacting entities (CPU, EDMA3CC, EDMA3TC, and slave memories).

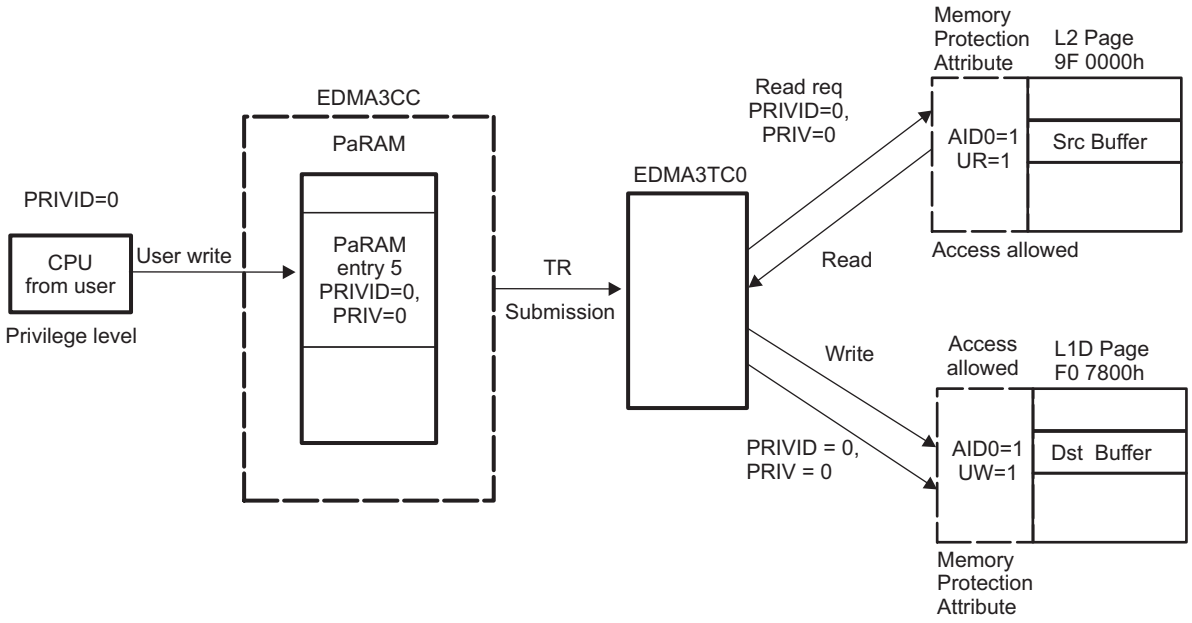
**Figure 8-18. Proxy Memory Protection Example**



## 8.3.11 Event Queue(s)

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are four event queues for the device: Queue0, Queue1, Queue2, and Queue3. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. Similarly, transfer requests that are associated with events in Queue3 are submitted to TC3.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

Queue0 has highest priority and Queue3 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See Section 8.3.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers (Q0E0, Q0E1,…Q1E15, etc.). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. See Section 8.5.1.4.1 for a description of the bit fields in the queue event entry registers.

### 8.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register (DMAQNUM) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. See Section 8.3.11.4.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** If an event is ready to be queued and both the event queue and the EDMA3 transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

#### 8.3.11.2 Queue RAM Debug Visibility

There are four event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO manner. There is a queue status register (QSTAT) associated with each queue. These along with all of the 16 entries per queue can be read via registers QSTAT*n* and QxEy, respectively.

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (Q*x*E*y*) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA3CC memory-mapped register. By reading the event queue, you see the history of the last 16 TRs that have been processed by the EDMA3 on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n*) includes fields for the start pointer (STRTPTR) which provides the offset to the head entry of an event. It also includes a field called NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR may be used to index appropriately into the 16 event entries. NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry may be read to determine what's already de-queued and submitted to the associated transfer controller.

#### 8.3.11.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT*n*) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT*n* and the maximum number of entries (WM bit in QSTAT*n*).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCD*n* bit in the channel controller error register (CCERR) and the THRXCD bit in QSTAT*n*, where *n* stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

#### 8.3.11.4 Performance Considerations

The main system bus infrastructure (L3) (see the device-specific data manual) arbitrates bus requests from all of the masters (TCs, CPU(S), PCIe and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to other masters within the system crossbar are programmed using the Control Module INIT_PRIORITY_n and INITIATOR_PRIO_m registers. The QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA3TC (dictated by the priority set using the Control Module INIT_PRIORITY_n and INITIATOR_PRIO_m registers).

### 8.3.12 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR; thus, the EDMA3TC is a slave to the EDMA3CC.

#### 8.3.12.1 Architecture Details

##### 8.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 8.3.12.5.

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 8-17 lists the TR segmentation rules that are followed by the EDMA3TC. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA3TC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2.

Table 8-17 lists conditions in which the optimizations are performed.

**Table 8-17. Read/Write Command Optimization Rules**

| ACNT ≤ DBS | ACNT is power of 2 | BIDX = ACNT | BCNT ≤ 1023 | SAM/DAM = Increment | Description |
|---|---|---|---|---|---|
| Yes | Yes | Yes | Yes | Yes | Optimized |
| No | x | x | x | x | Not Optimized |
| x | No | x | x | x | Not Optimized |
| x | x | No | x | x | Not Optimized |
| x | x | x | No | x | Not Optimized |
| x | x | x | x | No | Not Optimized |

##### 8.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries, which is 4.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 8-4. Command Fragmentation (DBS = 64)***

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DSTBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT=128, BCNT = 1,SRCADDR = 63, DSTADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

#### *8.3.12.1.3 Performance Tuning*

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the RDRATE register. The RDRATE register defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

### 8.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA3TC and used by the EDMA3TC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA3 transfer in the channel controller.

### 8.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA3TC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Copyright © 2011–2016, Texas Instruments Incorporated

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is pulsed.

#### 8.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

##### *8.3.12.4.1 Destination FIFO Register Pointer*

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

#### 8.3.12.5 EDMA3TC Configuration

Table 8-18 provides the configuration of the individual EDMA3 transfer controllers present on the device. The DBS for each transfer controller is configurable using the TPTC_CFG register in the chip configuration module.

**Table 8-18. EDMA3 Transfer Controller Configurations**

| Name | TC0 | TC1 | TC2 | TC3 |
|---|---|---|---|---|
| FIFOSIZE | 1024 bytes | 1024 bytes | 1024 bytes | 1024 bytes |
| BUSWIDTH | 16 bytes | 16 bytes | 16 bytes | 16 bytes |
| DSTREGDEPTH | 4 entries | 4 entries | 4 entries | 4 entries |
| DBS | Configurable | Configurable | Configurable | Configurable |

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n* /ESRH.E*n*, QER.E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the SER.E*n*\SERH.E*n* (or QSER.E*n*) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n*/ESRH.E*n*, QER.E*n*) bit and the SER.E*n*/SERH.E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the SER.E*n*/SERH.E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]-32).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TC*n*'s Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA3TC*n* then signals completion status to the EDMA3CC.

### 8.3.14 EDMA3 Prioritization

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 8-19 shows the different places EDMA3 priorities come into play.

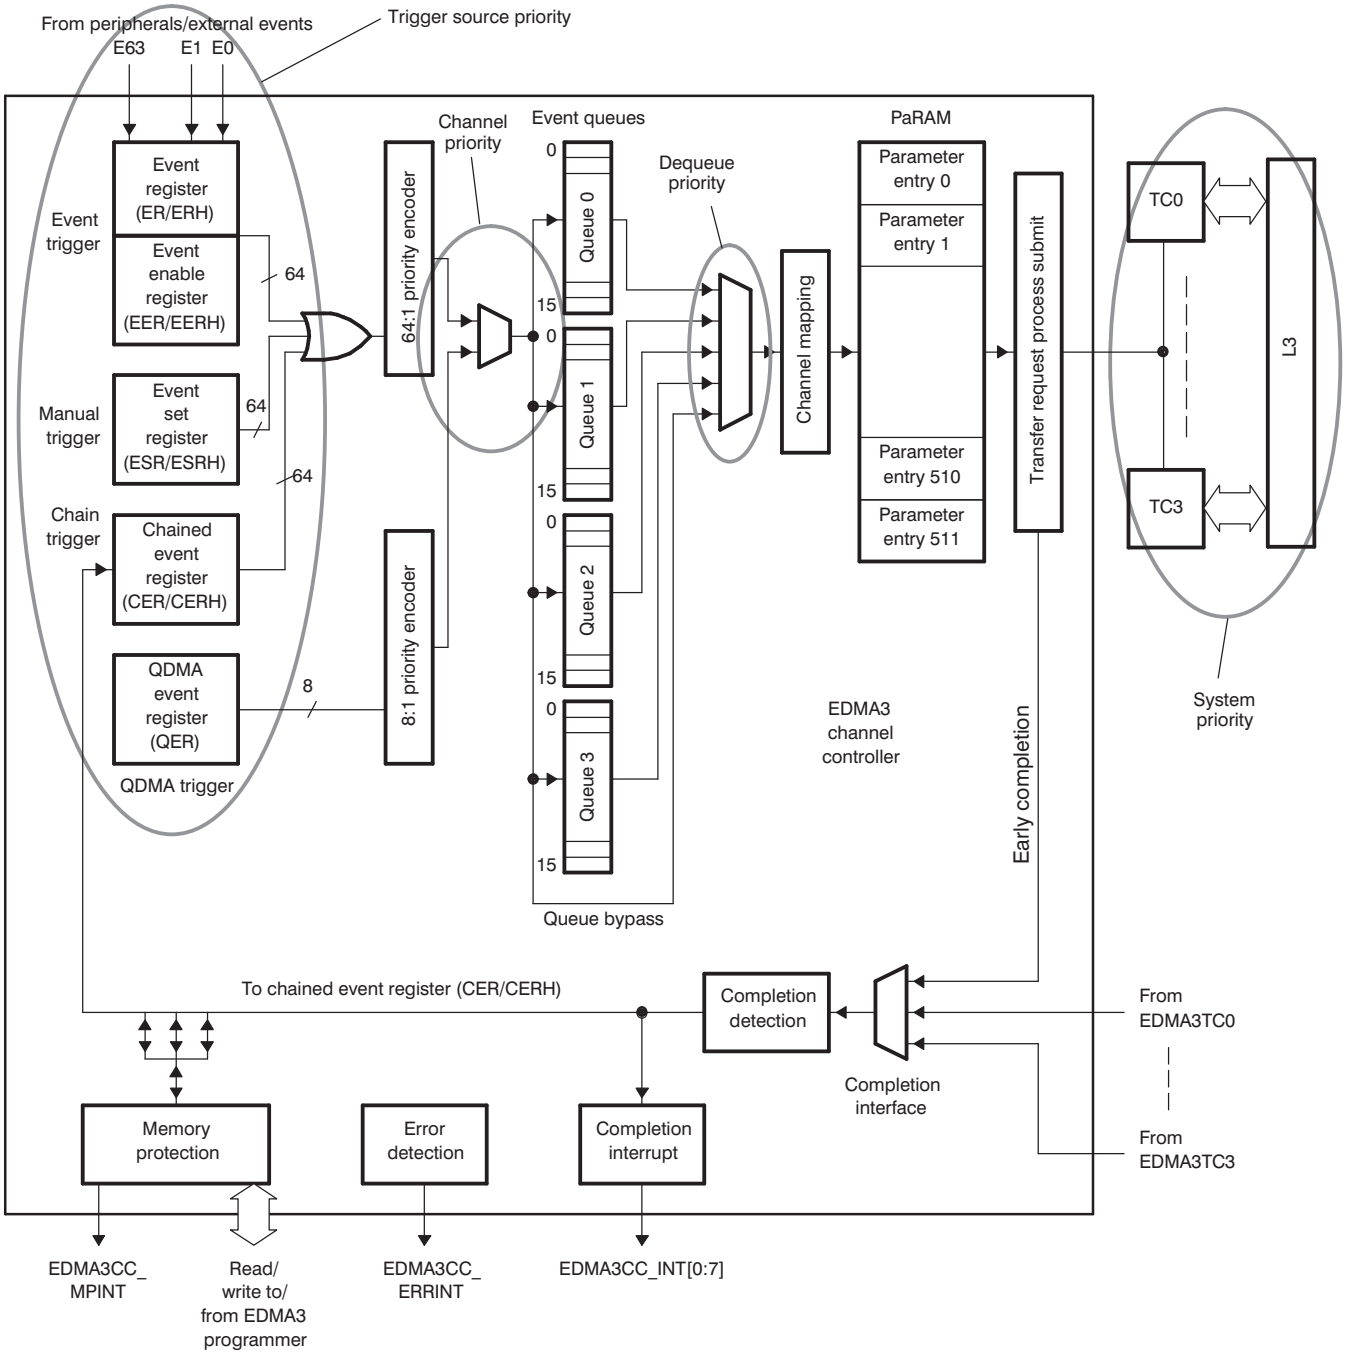
#### 8.3.14.1 Channel Priority

The DMA event registers (ER and ERH) capture up to 64 events; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 8-19. EDMA3 Prioritization**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.3.14.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (ER.E*n* = 1, ESR.E*n* = 1 , CER.E*n* = 1) , then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both ER.E0 = 1 and CER.E0 = 1 at the same time, then the ER.E0 event is always queued before the CER.E0 event.

#### 8.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM and QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 3 the lowest.

### *8.3.15 EDMA3 Operating Frequency (Clock Control)*

The EDMA3 channel controller and transfer controller are clocked from SYSCLK4. The EDMA3 system runs at the L3 clock frequency.

### *8.3.16 Reset Considerations*

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used.

### *8.3.17 Power Management*

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the power reset clock management (PRCM). The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA3 controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA3CC and EDMA3TC are separate. In general, it should be verified that there are no pending activities in the EDMA3 controller

### *8.3.18 Emulation Considerations*

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA3 channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA3 is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA3 for emulation halts. EDMA3 functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a McASP is halted during an emulation access (FREE = 0 and SOFT = 0 or 1 in McASP registers), the McASP stops generating the McASP receive or transmit events (REVT or XEVT) to the EDMA. From the point of view of the McASP, the EDMA3 is suspended, but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

## 8.4 EDMA Transfer Examples

The EDMA3 channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

### *8.4.1 Block Move Example*

The most basic transfer performed by the EDMA3 is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 8-20. Figure 8-21 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 8-21 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. You may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

### 8.4.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 8-22 shows the transfer of a subframe from external memory to L2. Figure 8-23 shows the parameters for this transfer.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

### 8.4.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. Figure 8-24 shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SRCBIDX - Program this to be the size of the element or ACNT.
- DSTBIDX - CCNT × ACNT
- SRCCDX - ACNT × BCNT
- DSTCIDX - ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA3 channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 8-25 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

### 8.4.4 Peripheral Servicing Example

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA3 channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming an EDMA3 channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

#### 8.4.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA3 channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. Figure 8-26 shows servicing incoming McASP data.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA3 channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. Figure 8-27 shows the parameters for this transfer. The source address of the EDMA3 channel is set to the data port address(DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA3 channel should be programmed to be on queue 0.

### 8.4.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. Figure 8-28 shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 8-29 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to 640 × 2.

### 8.4.4.3 Continuous Operation

Configuring an EDMA3 channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA3 channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown Figure 8-30.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, them DMA channels associated with the McASP (channels 12 and 15) must be setup for 1D-to-1D transfers with A-synchronization.

Figure 8-31 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA3 channels reload and continue. Figure 8-32 shows the reload parameters for the channel.

#### *8.4.4.3.1 Receive Channel*

EDMA3 channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

#### *8.4.4.3.2 Transmit Channel*

EDMA3 channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA3 channel, with duplicate PaRAM set entries at PaRAM set 65.

#### 8.4.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. Figure 8-33 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA3 channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 8-34 shows the EDMA3 channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA3 channel is initially loaded with the ping parameters (Figure 8-34). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 8-35). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 8-36). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

##### *8.4.4.4.1 Synchronization with the CPU*

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register (IPR) is set; when channel 12 empties an output buffer, the E12 bit in IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

### 8.4.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

#### *8.4.4.5.1 Servicing Input/Output FIFOs with a Single Event*

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 8-37 shows the EDMA3 setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register (IER) is set.

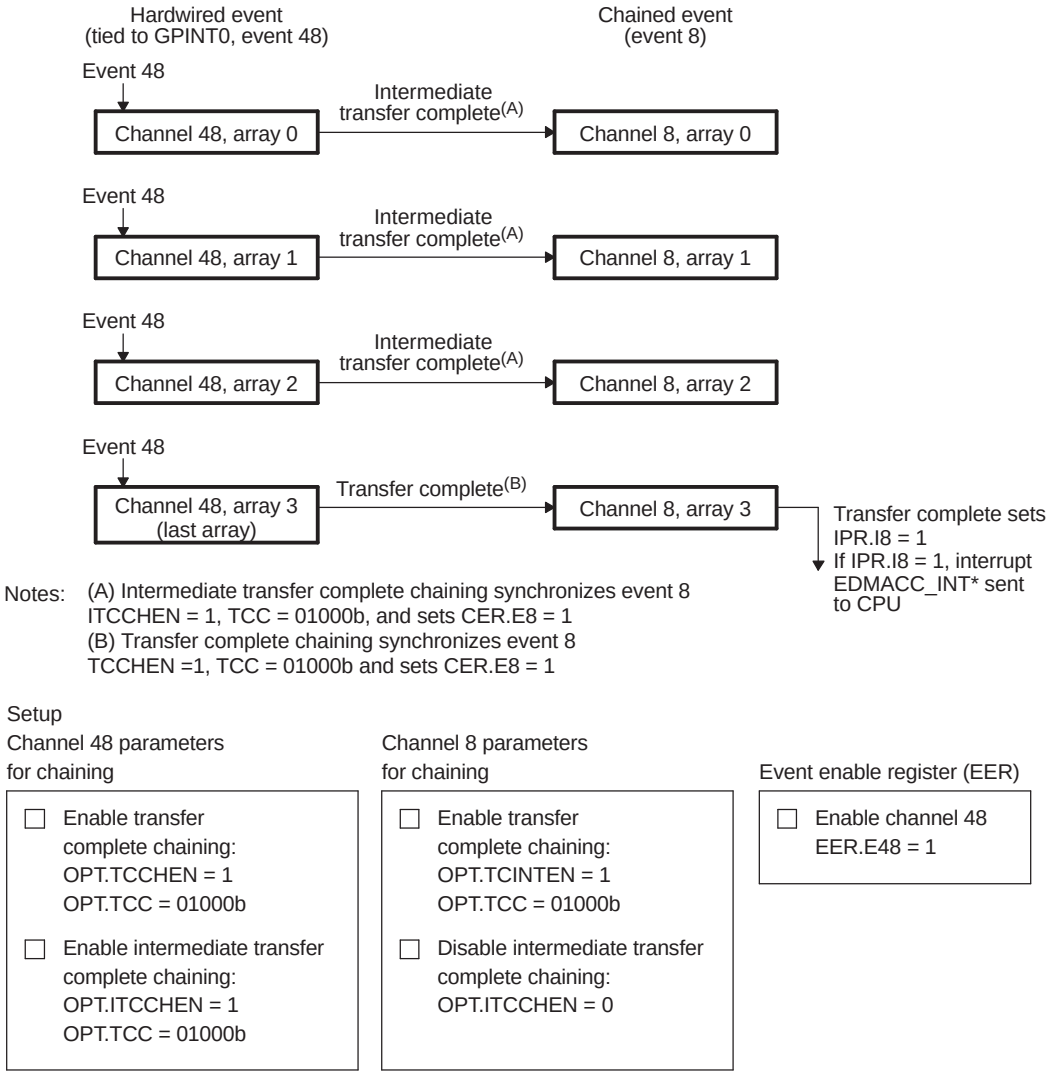
**Figure 8-37. Intermediate Transfer Completion Chaining Example**

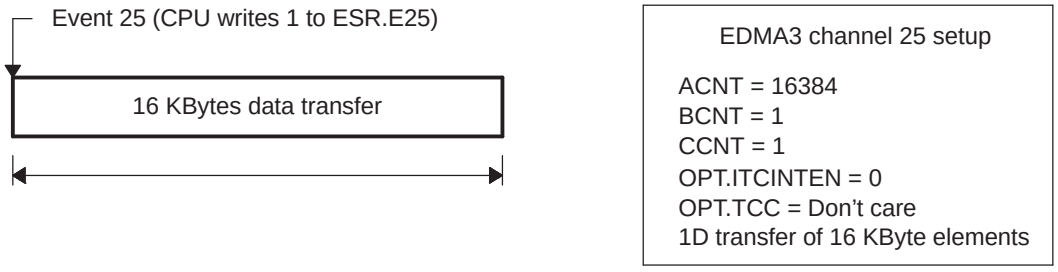


#### 8.4.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 8-38 shows the EDMA3 setup and illustration of an example single large block transfer.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 8-38. Single Large Block Transfer Example**



The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA3 channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA3 channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 8-39 shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

## 8.5 EDMA3 Registers

### 8.5.1 EDMA3 Channel Controller Registers

Table 8-19 lists the memory-mapped registers for the EDMA3 channel controller (EDMACC). All other register offset addresses not listed in Table 8-19 should be considered as reserved locations and the register contents should not be modified. See your device-specific data manual for the register memory maps.

### 8.5.1.1 Global Registers

#### *8.5.1.1.1 Peripheral Identification Register (PID)*

The peripheral identification register (PID) uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

The PID is shown in Figure 8-40 and described in Table 8-20.

**Figure 8-40. Peripheral ID Register (PID)**

| 31 | 16 | 15 | 0 |
|---|---|---|---|

#### 8.5.1.1.2 EDMA3CC Configuration Register (CCCFG)

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device.

The CCCFG is shown in Figure 8-41 and described in Table 8-21.

**Figure 8-41. EDMA3CC Configuration Register (CCCFG)**

| 4-0 | Reserved | 0 | Reserved |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.1.4 QDMA Channel Map *n* Registers (QCHMAP*n*)

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map *n* register (QCHMAP*n*).

The QCHMAP*n* is shown in Figure 8-43 and described in Table 8-23.

**NOTE:** At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP*n* is programmed appropriately to point to a different PaRAM entry.

**Figure 8-43. QDMA Channel Map *n* Registers (QCHMAP*n*)**

#### 8.5.1.1.5 DMA Channel Queue *n* Number Registers (DMAQNUM*n*)

The DMA channel queue number register (DMAQNUM*n*) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0.

The DMAQNUM*n* is shown in Figure 8-44 and described in Table 8-24. Table 8-25 shows the channels and their corresponding bits in DMAQNUM*n*.

**NOTE:** Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM*n* for a particular DMA channel *n* also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

**Figure 8-44. DMA Channel Queue *n* Number Registers (DMAQNUM*n*)**

| 31 | 30 28 | 27 | 26 24 | 23 | 22 20 | 19 | 18 16 |

#### 8.5.1.1.6 QDMA Channel Queue Number Register (QDMAQNUM)

The QDMA channel queue number register (QDMAQNUM) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC.

The QDMAQNUM is shown in Figure 8-45 and described in Table 8-26.

**Figure 8-45. QDMA Channel Queue Number Register (QDMAQNUM)**

### 8.5.1.2 Error Registers

The EDMA3CC contains a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

#### *8.5.1.2.1 Event Missed Registers (EMR/EMRH)*

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The EMR is shown in Figure 8-46 and described in Table 8-27. The EMRH is shown in Figure 8-47 and described in Table 8-28.

**Figure 8-46. Event Missed Register (EMR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 8.5.1.2.2 Event Missed Clear Registers (EMCR/EMCRH)

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect.

The EMCR is shown in Figure 8-48 and described in Table 8-29. The EMCRH is shown in Figure 8-49 and described in Table 8-30.

**Figure 8-48. Event Missed Clear Register (EMCR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | | 0 | No effect. |
| | | 1 | Corresponding missed event bit in the event missed register high (EMRH) is cleared (E*n* = 0). |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.2.3 QDMA Event Missed Register (QEMR)

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The QEMR is shown in Figure 8-50 and described in Table 8-31.

**Figure 8-50. QDMA Event Missed Register (QEMR)**

#### 8.5.1.2.4 QDMA Event Missed Clear Register (QEMCR)

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect.

The QEMCR is shown in Figure 8-51 and described in Table 8-32.

#### 8.5.1.2.5 EDMA3CC Error Register (CCERR)

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR).

The CCERR is shown in Figure 8-52 and described in Table 8-33.

**Figure 8-52. EDMA3CC Error Register (CCERR)**

| 31 | 17 | 16 |

**Table 8-33. EDMA3CC Error Register (CCERR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-17 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 16 | TCCERR | | Transfer completion code error. TCCERR is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Total number of allowed TCCs outstanding has not been reached. |
| | | 1 | Total number of allowed TCCs has been reached. |
| 15-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | QTHRXCD3 | | Queue threshold error for queue 3. QTHRXCD3 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Watermark/threshold has not been exceeded. |
| | | 1 | Watermark/threshold has been exceeded. |
| 2 | QTHRXCD2 | | Queue threshold error for queue 2. QTHRXCD2 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Watermark/threshold has not been exceeded. |
| | | 1 | Watermark/threshold has been exceeded. |
| 1 | QTHRXCD1 | | Queue threshold error for queue 1 . QTHRXCD1 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Watermark/threshold has not been exceeded. |
| | | 1 | Watermark/threshold has been exceeded. |
| 0 | QTHRXCD0 | | Queue threshold error for queue 0. QTHRXCD0 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Watermark/threshold has not been exceeded. |
| | | 1 | Watermark/threshold has been exceeded. |

#### 8.5.1.2.6 EDMA3CC Error Clear Register (CCERRCLR)

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTAT*n*) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect.

The CCERRCLR is shown in Figure 8-53 and described in Table 8-34.

**Figure 8-53. EDMA3CC Error Clear Register (CCERRCLR)**

| 31 | 17 | 16 |
|---|---|---|
| Reserved | | TCCERR |

**Table 8-34. EDMA3CC Error Clear Register (CCERRCLR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-17 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 16 | TCCERR | | Transfer completion code error clear. |
| | | 0 | No effect. |
| | | 1 | Clears the TCCERR bit in the EDMA3CC error register (CCERR). |
| 15-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | QTHRXCD3 | | Queue threshold error clear for queue 3. |
| | | 0 | No effect. |
| | | 1 | Clears the QTHRXCD3 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 3 (QSTAT3). |
| 2 | QTHRXCD2 | | Queue threshold error clear for queue 2. |
| | | 0 | No effect. |
| | | 1 | Clears the QTHRXCD2 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 2 (QSTAT2). |
| 1 | QTHRXCD1 | | Queue threshold error clear for queue 1. |
| | | 0 | No effect. |
| | | 1 | Clears the QTHRXCD1 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 1 (QSTAT1). |
| 0 | QTHRXCD0 | | Queue threshold error clear for queue 0. |
| | | 0 | No effect. |
| | | 1 | Clears the QTHRXCD0 bit in the EDMA3CC error register (CCERR) and the WM and THRXCD bits in the queue status register 0 (QSTAT0). |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.2.7 Error Evaluation Register (EEVAL)

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an “all the error bits cleared” to “at least one error bit is set”. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EEVAL is shown in Figure 8-54 and described in Table 8-35.

**Figure 8-54. Error Evaluation Register (EEVAL)**

### 8.5.1.3 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAE*m* and DRAEH*m*) and the QDMA access enable registers (QRAE*m*). Where *m* is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

#### *8.5.1.3.1 DMA Region Access Enable for Region m (DRAEm)*

The DMA region access enable register for shadow region *m* (DRAE*m*/DRAEH*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region *m* view of the DMA channel registers. See the EDMA3CC register memory map (Table 8-19) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the DRAE*m*/DRAEH*m* configuration determines completion of which DMA channels will result in assertion of the shadow region *m* DMA completion interrupt (see *EDMA3 Interrupts*).

The DRAE*m* is shown in Figure 8-55 and described in Table 8-36. The DRAEH*m* is shown in Figure 8-56 and described in Table 8-36.

**Figure 8-55. DMA Region Access Enable Register for Region *m* (DRAE*m*)**

#### 8.5.1.3.2 QDMA Region Access Enable Registers (QRAE*m*)

The QDMA region access enable register for shadow region *m* (QRAE*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region *m* view of the QDMA registers. This includes all 4-bit QDMA registers.

The QRAE*m* is shown in Figure 8-57 and described in Table 8-37.

### 8.5.1.4 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

#### *8.5.1.4.1 Event Queue Entry Registers (QxEy)*

The event queue entry registers (Q*x*E*y*) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC.

There are Q0E0 to Q0E15, Q1E0 to Q1E15, Q2E0 to Q2E15, and Q3E0 to Q3E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The Q*x*E*y* is shown in Figure 8-58 and described in Table 8-38.

**Figure 8-58. Event Queue Entry Registers (Q*x*E*y*)**

#### 8.5.1.4.2 Queue Status Registers (QSTAT*n*)

The queue status registers (QSTAT*n*) is shown in Figure 8-59 and described in Table 8-39.

**Figure 8-59. Queue Status Register *n* (QSTAT*n*)**

| 31 | 25 | 24 | 23 | 21 | 20 | 16 |
|---|---|---|---|---|---|---|
| Reserved | | THRXCD | Reserved | | WM | |
| R-0 | | R-0 | R-0 | | R-0 | |

| 15 | 13 | 12 | 8 | 7 | 4 | 3 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | | NUMVAL | | Reserved | | STRTPTR | |
| R-0 | | R-0 | | R-0 | | R-0 | |

LEGEND: R = Read only; -*n* = value after reset

**Table 8-39. Queue Status Register *n* (QSTAT*n*) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-25 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 24 | THRXCD | | Threshold exceeded. THRXCD is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0 | Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has not been exceeded. |
| | | 1 | Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has been exceeded. |
| 23-21 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 20-16 | WM | 0-10h | Watermark for maximum queue usage. Watermark tracks the most entries that have been in queue *n* since reset or since the last time that the watermark (WM) bit was cleared. WM is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR). |
| | | 0-10h | Legal values are 0 (empty) to 10h (full). |
| | | 11h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 15-13 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 12-8 | NUMVAL | 0-10h | Number of valid entries in queue *n*. The total number of entries residing in the queue manager FIFO at a given instant. Always enabled. |
| | | 0-10h | Legal values are 0 (empty) to 10h (full). |
| | | 11h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3-0 | STRTPTR | 0-Fh | Start pointer. The offset to the head entry of queue *n*, in units of entries. Always enabled. Legal values are 0 (0th entry) to Fh (15th entry). |

**Table 8-40. Queue Watermark Threshold A Register (QWMTHRA) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-29 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 28-24 | Q3 | 0-1Fh | Queue threshold for queue 3 value. The QTHRXCD3 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 3 (QSTAT3) are set when the number of events in queue 3 at an instant in time (visible via the NUMVAL bit in QSTAT3) equals or exceeds the value specified by Q3. |
| | | 0-10h | The default is 16 (maximum allowed). |
| | | 11h | Disables the threshold errors. |
| | | 12h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 23-21 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 20-16 | Q2 | 0-1Fh | Queue threshold for queue 2 value. The QTHRXCD2 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 2 (QSTAT2) are set when the number of events in queue 2 at an instant in time (visible via the NUMVAL bit in QSTAT2) equals or exceeds the value specified by Q2. |
| | | 0-10h | The default is 16 (maximum allowed). |
| | | 11h | Disables the threshold errors. |
| | | 12h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 15-13 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 12-8 | Q1 | | Queue threshold for queue 1 value. The QTHRXCD1 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 1 (QSTAT1) are set when the number of events in queue 1 at an instant in time (visible via the NUMVAL bit in QSTAT1) equals or exceeds the value specified by Q1. |
| | | 0-10h | The default is 16 (maximum allowed). |
| | | 11h | Disables the threshold errors. |
| | | 12h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-5 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 4-0 | Q0 | | Queue threshold for queue 0 value. The QTHRXCD0 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 0 (QSTAT0) are set when the number of events in queue 0 at an instant in time (visible via the NUMVAL bit in QSTAT0) equals or exceeds the value specified by Q0. |
| | | 0-10h | The default is 16 (maximum allowed). |
| | | 11h | Disables the threshold errors. |
| | | 12h-1Fh | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

#### 8.5.1.4.4 EDMA3CC Status Register (CCSTAT)

The EDMA3CC status register (CCSTAT) has a number of status bits that reflect which parts of the EDMA3CC logic is active at any given instant of time. The CCSTAT is shown in Figure 8-61 and described in Table 8-41.

**Figure 8-61. EDMA3CC Status Register (CCSTAT)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-20 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 19 | QUEACTV3 | | Queue 3 active. |
| | | 0 | No events are queued in queue 3. |
| | | 1 | At least one TR is queued in queue 3. |
| 18 | QUEACTV2 | | Queue 2 active. |
| | | 0 | No events are queued in queue 2. |
| | | 1 | At least one TR is queued in queue 2. |
| 17 | QUEACTV1 | | Queue 1 active. |
| | | 0 | No events are queued in queue 1. |
| | | 1 | At least one TR is queued in queue 1. |
| 16 | QUEACTV0 | | Queue 0 active. |
| | | 0 | No events are queued in queue 0. |
| | | 1 | At least one TR is queued in queue 0. |
| 15-14 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 13-8 | COMPACTV | 0-3Fh | Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less then 63 (or return a transfer completion code from a transfer controller, which would decrement the count). |
| | | 0 | No completion requests outstanding. |
| | | 1h-3Fh | Total of 1 completion request to 63 completion requests are outstanding. |
| 7-5 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

**Table 8-41. EDMA3CC Status Register (CCSTAT) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 4 | ACTV | | Channel controller active. Channel controller active is a logical-OR of each of the *ACTV bits. The ACTV bit remains high through the life of a TR. |
| | | 0 | Channel is idle.. |
| | | 1 | Channel is busy. |
| 3 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 2 | TRACTV | | Transfer request active. |
| | | 0 | Transfer request processing/submission logic is inactive. |
| | | 1 | Transfer request processing/submission logic is active. |
| 1 | QEVTACTV | | QDMA event active. |
| | | 0 | No enabled QDMA events are active within the EDMA3CC. |
| | | 1 | At least one enabled QDMA event (QER) is active within the EDMA3CC. |
| 0 | EVTACTV | | DMA event active. |
| | | 0 | No enabled DMA events are active within the EDMA3CC. |
| | | 1 | At least one enabled DMA event (ER and EER, ESR, CER) is active within the EDMA3CC. |

### 8.5.1.5 Memory Protection Address Space

#### *8.5.1.5.1 Memory Protection Fault Address Register (MPFAR)*

The memory protection fault address register (MPFAR) is shown in Figure 8-62 and described in Table 8-42. A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFAR to be cleared.

**Figure 8-62. Memory Protection Fault Address Register (MPFAR)**

**Table 8-42. Memory Protection Fault Address Register (MPFAR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | FADDR | 0-FFFF FFFFh | Fault address. This 32-bit read-only status register contains the fault address when a memory protection violation is detected. This register can only be cleared via the memory protection fault command register (MPFCR). |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.5.2 Memory Protection Fault Status Register (MPFSR)

The memory protection fault status register (MPFSR) is shown in Figure 8-63 and described in Table 8-43. A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFSR to be cleared.

### 8.5.1.6 DMA Channel Registers

The following sets of registers pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUM*n*) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format *reg_name* that corresponds to DMA channels 0 through 31 and *reg_name_High* that corresponds to DMA channels 32 through 64.

For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register.

The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAE*m*/DRAEH*m*). The registers are described in Section 8.5.1.3.1 and the details for shadow region/global region usage is explained in *EDMA3 Channel Controller Regions*.

#### *8.5.1.6.1 Event Registers (ER, ERH)*

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.E*n*/EERH.E*n* = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.E*n*/ERH.E*n* = 0) once the corresponding events are prioritized and serviced. If ER.E*n*/ERH.E*n* are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.E*n*/EMRH.E*n*), provided that the event was enabled (EER.E*n*/EERH.E*n* = 1).

Event *n* can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The *Debug List* table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events.

#### 8.5.1.6.2 Event Clear Registers (ECR, ECRH)

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH.

The ECR is shown in Figure 8-68 and described in Table 8-48. The ECRH is shown in Figure 8-69 and described in Table 8-49.

**Figure 8-68. Event Clear Register (ECR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 8.5.1.6.3 Event Set Registers (ESR, ESRH)

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (E*n*) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.E*n*/EERH.E*n*).

Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.E*n*/ESRH.E*n* bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1).

The ESR is shown in Figure 8-70 and described in Table 8-50. The ESRH is shown in Figure 8-71 and described in Table 8-51.

#### 8.5.1.6.4 Chained Event Registers (CER, CERH)

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The E*n* bit is set (regardless of the state of EER.E*n*/EERH.E*n*) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the E*n* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The CER is shown in Figure 8-72 and described in Table 8-52. The CERH is shown in Figure 8-73 and described in Table 8-53.

#### 8.5.1.6.5 Event Enable Registers (EER, EERH)

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event.

The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.E*n*/CERH.E*n* = 1) and manually set events (ESR.E*n*/ESRH.E*n* = 1).

The EER is shown in Figure 8-74 and described in Table 8-54. Th EERH is shown in Figure 8-75 and described in Table 8-55.

**Figure 8-74. Event Enable Register (EER)**

#### 8.5.1.6.6 Event Enable Clear Register (EECR, EECRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EECR is shown in Figure 8-76 and described in Table 8-56. The EECRH is shown in Figure 8-77 and described in Table 8-57.

**Figure 8-76. Event Enable Clear Register (EECR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 8.5.1.6.7 Event Enable Set Registers (EESR, EESRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable set registers (EESR/EESRH) are used to enable events. Writes of 1 to the bits in EESR/EESRH set the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EESR is shown in Figure 8-78 and described in Table 8-58. The EESRH is shown in Figure 8-79 and described in Table 8-59.

**Figure 8-78. Event Enable Set Register (EESR)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### 8.5.1.6.8 Secondary Event Registers (SER, SERH)

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.E*n*/ESRH.E*n* = 1, ER.E*n*/ERH.E*n* = 1, or CER.E*n*/CERH.E*n* = 1), which results in the setting of a corresponding event bit in SER/SERH (SER.E*n*/SERH.E*n* = 1), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see *EDMA Overview*.

The SER is shown in Figure 8-80 and described in Table 8-60. The SERH is shown in Figure 8-81 and described in Table 8-61.

**Figure 8-80. Secondary Event Register (SER)**

#### 8.5.1.6.9 Secondary Event Clear Registers (SECR, SECRH)

The secondary event clear registers (SECR/SECRH) clear the status of the secondary event registers (SER/SERH). CPU writes of 1 clear the corresponding set bits in SER/SERH. Writes of 0 have no effect.

The SECR is shown in Figure 8-82 and described in Table 8-62. The SECRH is shown in Figure 8-83 and described in Table 8-63.

**Figure 8-82. Secondary Event Clear Register (SECR)**

### 8.5.1.7 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following set of registers is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see *EDMA3 Interrupts*.

#### *8.5.1.7.1 Interrupt Enable Registers (IER, IERH)*

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH).

The IER is shown in Figure 8-84 and described in Table 8-64. The IERH is shown in Figure 8-85 and described in Table 8-65.

#### 8.5.1.7.2 Interrupt Enable Clear Register (IECR, IECRH)

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IECR is shown in Figure 8-86 and described in Table 8-66. The IECRH is shown in Figure 8-87 and described in Table 8-67.

**Figure 8-86. Interrupt Enable Clear Register (IECR)**

#### 8.5.1.7.3 Interrupt Enable Set Registers (IESR, IESRH)

The interrupt enable set registers (IESR/IESRH) are used to enable interrupts. Writes of 1 to the bits in IESR/IESRH set the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IESR is shown in Figure 8-88 and described in Table 8-68. The IESRH is shown in Figure 8-89 and described in Table 8-69.

#### 8.5.1.7.4 Interrupt Pending Register (IPR, IPRH)

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with TCC = *n* is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.I*n*, if *n* = 0 to 31; IPRH.I*n,* if *n* = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH).

The IPR is shown in Figure 8-90 and described in Table 8-70. The IPRH is shown in Figure 8-91 and described in Table 8-71.

#### 8.5.1.7.5 Interrupt Clear Registers (ICR, ICRH)

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts.

The ICR is shown in Figure 8-92 and described in Table 8-72. The ICRH is shown in Figure 8-93 and described in Table 8-73.

**Figure 8-92. Interrupt Clear Register (ICR)**

### 8.5.1.7.6 Interrupt Evaluate Register (IEVAL)

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAE*m*/DRAEH*m*, QRAE*n*/QRAEH*n*). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU.

The IEVAL is shown in Figure 8-94 and described in Table 8-74.

**Table 8-74. Interrupt Evaluate Register (IEVAL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-2 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 1 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 0 | EVAL | | Interrupt evaluate. |
| | | 0 | No effect. |
| | | 1 | Causes EDMA3CC completion interrupt to be pulsed, if any enabled (IER*n*/IERH*n* = 1) interrupts are still pending (IPR*n*/IPRH*n* = 1).<br>The EDMA3CC completion interrupt that is pulsed depends on which IEVAL is being exercised. For example, writing to the EVAL bit in IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt. |

### 8.5.1.8 QDMA Registers

The following sets of registers control the QDMA channels in the EDMA3CC. The QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAE*n*/QRAEH*n*). *EDMA3 Channel Controller Regions* details shadow region/global region usage.

#### *8.5.1.8.1 QDMA Event Register (QER)*

The QDMA event register (QER) channel *n* bit is set (E*n* = 1) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAP*n*)) in the PaRAM entry associated with QDMA channel *n* (which is also programmed using QCHMAP*n*). The E*n* bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAP*n* settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel *n* bit is also enabled (QEER.E*n* = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. For additional conditions that can lead to the setting of QER bits, see *EDMA Overview*.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the E*n* bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR (E*n* = 1).

The QER is shown in Figure 8-95 and described in Table 8-75.

#### 8.5.1.8.2 QDMA Event Enable Register (QEER)

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER.

The QEER is shown in Figure 8-96 and described in Table 8-76.

**Figure 8-96. QDMA Event Enable Register (QEER)**

| 31 | 16 |

| 31-8 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-0 | E*n* | | QDMA event enable for channels 0-7. |
| | | 0 | QDMA channel *n* is not enabled. QDMA event will not be recognized and will not latch in the QDMA event register (QER). |
| | | 1 | QDMA channel *n* is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER). |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.8.3 QDMA Event Enable Clear Register (QEECR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEECR is shown in Figure 8-97 and described in Table 8-77.

**Figure 8-97. QDMA Event Enable Clear Register (QEECR)**

### 8.5.1.8.4 QDMA Event Enable Set Register (QEESR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable set register (QEESR) is used to enable events. Writes of 1 to the bits in QEESR set the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEESR is shown in Figure 8-98 and described in Table 8-78.

**Figure 8-98. QDMA Event Enable Set Register (QEESR)**

#### 8.5.1.8.5 QDMA Secondary Event Register (QSER)

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. For additional conditions that can cause the secondary event registers (QSER\SER) to be set, see *EDMA Overview*.

The QSER is shown in Figure 8-99 and described in Table 8-79.

**Figure 8-99. QDMA Secondary Event Register (QSER)**

| 31 | 16 |

|---|---|---|---|
| 31-8 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-0 | E*n* | | QDMA secondary event register for channels 0-7. |
| | | 0 | QDMA event is not currently stored in the event queue. |
| | | 1 | QDMA event is currently stored in the event queue. EDMA3CC will not prioritize additional events. |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.1.8.6 QDMA Secondary Event Clear Register (QSECR)

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers.

The QSECR is shown in Figure 8-100 and described in Table 8-80.

**Figure 8-100. QDMA Secondary Event Clear Register (QSECR)**

| R-0 | | R-x | | R-0 | | R-n | | R-0 | R-x | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset; -x = value is indeterminate after reset

**Table 8-83. EDMA3TC Configuration Register (TCCFG) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 9-8 | DREGDEPTH | 0-3h | Destination register FIFO depth parameterization. |
| | | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 1h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 2h | 4 entry (for TC0, TC1, TC2, and TC3) |
| | | 3h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7-6 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 5-4 | BUSWIDTH | 0-3h | Bus width parameterization. |
| | | 0-1h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 2h | 128-bit |
| | | 3h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 2-0 | FIFOSIZE | 0-7h | FIFO size |
| | | 0-1h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 2h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 3h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 4h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| | | 5h | 1024 byte FIFO (for TC0, TC1, TC2 and TC3) |
| | | 6h-7h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

### 8.5.2.3 EDMA3TC Channel Status Register (TCSTAT)

The EDMA3TC channel status register (TCSTAT) is shown in Figure 8-103 and described in Table 8-84.

**Figure 8-103. EDMA3TC Channel Status Register (TCSTAT)**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 14 | 13 | 12 | 11 | 9 | 8 |
|---|---|---|---|---|---|---|
| Reserved | | DFSTRTPTR | | Reserved | | Reserved |
| R-0 | | R-0 | | R-0 | | R-1 |

| 7 | 6 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|
| Reserved | DSTACTV | | Reserved | WSACTV | SRCACTV | PROGBUSY |
| R-0 | R-0 | | R-0 | R-0 | R-0 | R-0 |

LEGEND: R = Read only; -*n* = value after reset

**Table 8-84. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-14 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 13-12 | DFSTRTPTR | 0-3h | Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries. |
| 11-9 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 8 | Reserved | 1 | Reserved. Always read as 1. |
| 7 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 6-4 | DSTACTV | 0-7h | Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter. |
| | | 0 | Destination FIFO is empty. |
| | | 1h | Destination FIFO contains 1 TR. |
| | | 2h | Destination FIFO contains 2 TRs. |
| | | 3h | Destination FIFO contains 3 TRs. |
| | | 4h | Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4). |
| | | | If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle. |
| | | | If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed. |
| | | 5h-7h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 2 | WSACTV | | Write status active |
| | | 0 | Write status is not pending. Write status has been received for all previously issued write commands. |
| | | 1 | Write status is pending. Write status has not been received for all previously issued write commands. |
| 1 | SRCACTV | | Source active state |
| | | 0 | Source controller is idle. Source active register set contains a previously processed transfer request. |
| | | 1 | Source controller is busy servicing a transfer request. |

### 8.5.2.4 Error Registers

#### *8.5.2.4.1 Error Register (ERRSTAT)*

The error status register (ERRSTAT) is shown in Figure 8-104 and described in Table 8-85.

**Figure 8-104. Error Register (ERRSTAT)**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|
| Reserved | | MMRAERR | TRERR | Reserved | BUSERR |
| R-0 | | R-0 | R-0 | R-0 | R-0 |

LEGEND: R = Read only; -*n* = value after reset

**Table 8-85. Error Register (ERRSTAT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | MMRAERR | | MMR address error. |
| | | 0 | Condition is not detected. |
| | | 1 | User attempted to read or write to an invalid address in configuration memory map. |
| 2 | TRERR | | Transfer request (TR) error event. |
| | | 0 | Condition is not detected. |
| | | 1 | TR detected that violates constant addressing mode transfer (SAM or DAM is set) alignment rules or has ACNT or BCNT == 0. |
| 1 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 0 | BUSERR | | Bus error event. |
| | | 0 | Condition is not detected. |
| | | 1 | EDMA3TC has detected an error at source or destination address. Error information can be read from the error details register (ERRDET). |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.2.4.2 Error Enable Register (ERREN)

The error enable register (ERREN) is shown in Figure 8-105 and described in Table 8-86.

When any of the enable bits are set, a bit set in the corresponding ERRSTAT causes an assertion of the EDMA3TC interrupt.

**Figure 8-105. Error Enable Register (ERREN)**

| 31 | 16 |
|---|---|
| Reserved | |

**Table 8-87. Error Clear Register (ERRCLR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3 | MMRAERR | | Interrupt enable clear for the MMRAERR bit in the error status register (ERRSTAT). |
| | | 0 | No effect. |
| | | 1 | Clears the MMRAERR bit in ERRSTAT but does not clear the error details register (ERRDET). |
| 2 | TRERR | | Interrupt enable clear for the TRERR bit in the error status register (ERRSTAT). |
| | | 0 | No effect. |
| | | 1 | Clears the TRERR bit in ERRSTAT but does not clear the error details register (ERRDET). |
| 1 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 0 | BUSERR | | Interrupt clear for the BUSERR bit in the error status register (ERRSTAT). |
| | | 0 | No effect. |
| | | 1 | Clears the BUSERR bit in ERRSTAT and clears the error details register (ERRDET). |

#### 8.5.2.4.4 Error Details Register (ERRDET)

The error details register (ERRDET) is shown in Figure 8-107 and described in Table 8-88.

**Figure 8-107. Error Details Register (ERRDET)**

| 31 | 18 | 17 | 16 |
|---|---|---|---|
| Reserved | | TCCHEN | TCINTEN |
| R-0 | | R-0 | R-0 |

| 15 | 14 | 13 | 8 | 7 | 4 | 3 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | | TCC | | Reserved | | STAT | |
| R-0 | | R-0 | | R-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 8-88. Error Details Register (ERRDET) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-8 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 17 | TCCHEN | 0-1 | Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error. |
| 16 | TCINTEN | 0-1 | Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error. |
| 15-14 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 13 - 8 | TCC | 0-3Fh | Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error. |
| 7-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3-0 | STAT | 0-Fh | Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMA3TC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority. |
| | | 0 | No error. |
| | | 1h-7h | Read error. |
| | | 8h-Fh | Write error. |

### 8.5.2.5 Read Rate Register (RDRATE)

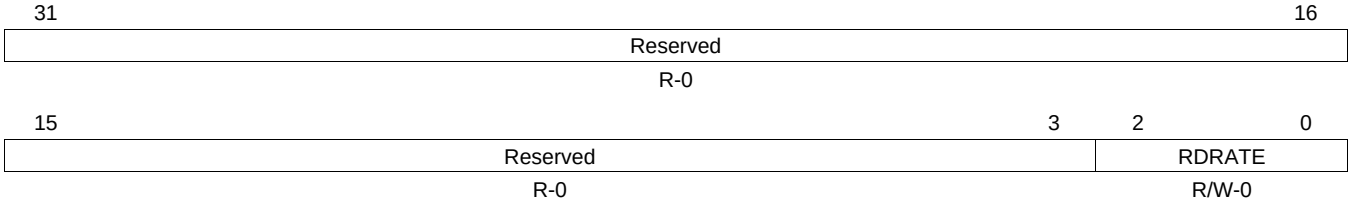
The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads.

RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles.

The RDRATE is shown in Figure 8-109 and described in Table 8-90.

**NOTE:** It is expected that the RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the fly.

**Figure 8-109. Read Rate Register (RDRATE)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 8-90. Read Rate Register (RDRATE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-3 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 2-0 | RDRATE | 0-7h | Read rate. Controls the number of cycles between read commands. This is a global setting that applies to all TRs for this EDMA3TC. |
| | | 0 | Reads issued as fast as possible. |
| | | 1h | 4 cycles between reads. |
| | | 2h | 8 cycles between reads. |
| | | 3h | 16 cycles between reads. |
| | | 4h | 32 cycles between reads. |
| | | 5h-7h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

### 8.5.2.6 EDMA3TC Channel Registers

The EDMA3TC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO register. This section describes the registers and their functions. The program register set is programmed by the channel controller, and is for internal use. The other two sets are read-only and provided to facilitate advanced debug capabilities. The number of destination FIFO register sets depends on the destination FIFO depth.

TC0 has a FIFO depth of 2, so there are two sets of destination FIFO registers associated with TC0. TC1, TC2, and TC3 have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

#### *8.5.2.6.1 Source Active Options Register (SAOPT)*

The source active options register (SAOPT) is shown in Figure 8-110 and described in Table 8-91.

**Figure 8-110. Source Active Options Register (SAOPT)**

| 31 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 8-91. Source Active Options Register (SAOPT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-23 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 22 | TCCHEN | | Transfer complete chaining enable |
| | | 0 | Transfer complete chaining is disabled. |
| | | 1 | Transfer complete chaining is enabled. |
| 21 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 20 | TCINTEN | | Transfer complete interrupt enable. |
| | | 0 | Transfer complete interrupt is disabled. |
| | | 1 | Transfer complete interrupt is enabled. |
| 19-18 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 17-12 | TCC | 0-3Fh | Transfer complete code. This 6-bit code is used to set the relevant bit in CER or IPR of the EDMA3PCC module. |
| 11 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 10-8 | FWID | 0-7h | FIFO width. Applies if either SAM or DAM is set to constant addressing mode. |
| | | 0 | FIFO width is 8-bit. |
| | | 1h | FIFO width is 16-bit. |
| | | 2h | FIFO width is 32-bit. |
| | | 3h | FIFO width is 64-bit. |
| | | 4h | FIFO width is 128-bit. |
| | | 5h | FIFO width is 256-bit. |
| | | 6h-7h | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 7 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |

**Table 8-91. Source Active Options Register (SAOPT) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 6-4 | PRI | 0-7h | Transfer priority. Reflects the values programmed in the QUEPRI register in the EDMACC. |
| | | 0 | Priority 0 - Highest priority |
| | | 1h-6h | Priority 1 to priority 6 |
| | | 7h | Priority 7 - Lowest priority |
| 3-2 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 1 | DAM | | Destination address mode within an array |
| | | 0 | Increment (INCR) mode. Destination addressing within an array increments. |
| | | 1 | Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width. |
| 0 | SAM | | Source address mode within an array |
| | | 0 | Increment (INCR) mode. Source addressing within an array increments. |
| | | 1 | Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width. |

#### 8.5.2.6.2 Source Active Source Address Register (SASRC)

The source active source address register (SASRC) is shown in Figure 8-111 and described in Table 8-92.

**Figure 8-111. Source Active Source Address Register (SASRC)**

| 31 | 0 |
|---|---|
| SADDR | |
| R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 8-92. Source Active Source Address Register (SASRC) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SADDR | 0-FFFF FFFFh | Source address for program register set. EDMA3TC updates value according to source addressing mode (SAM bit in the source active options register, SAOPT) . |

#### 8.5.2.6.3 Source Active Count Register (SACNT)

The source active count register (SACNT) is shown in Figure 8-112 and described in Table 8-93.

**Figure 8-112. Source Active Count Register (SACNT)**

| 31 | 16 |
|---|---|
| BCNT | |
| R-0 | |
| 15 | 0 |
| ACNT | |
| R-0 | |

LEGEND: R = Read only; -*n* = value after reset

**Table 8-93. Source Active Count Register (SACNT) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | BCNT | 0-FFFFh | B dimension count. Number of arrays to be transferred, where each array is ACNT in length. It is decremented after each read command appropriately. Represents the amount of data remaining to be read. It should be 0 when transfer request (TR) is complete. |
| 15-0 | ACNT | 0-FFFFh | A dimension count. Number of bytes to be transferred in first dimension. It is decremented after each read command appropriately. Represents the amount of data remaining to be read. It should be 0 when transfer request (TR) is complete. |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.2.6.4 Source Active Destination Address Register (SADST)

The source active destination address register (SADST) is shown in Figure 8-113 and described in Table 8-94.

**Figure 8-113. Source Active Destination Address Register (SADST)**

| R-0 | | R-0 | R-0 | | R-0 | |

LEGEND: R = Read only; -*n* = value after reset

**Table 8-96. Source Active Memory Protection Proxy Register (SAMPPRXY) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 8 | PRIV | | Privilege level. The privilege level used by the host to set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC.<br>The privilege ID is used while issuing read and write command to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIV of the host that set up the DMA transaction. |
| | | 0 | User-level privilege. |
| | | 1 | Supervisor-level privilege. |
| 7-4 | Reserved | 0 | Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior. |
| 3-0 | PRIVID | 0-Fh | Privilege ID. This contains the privilege ID of the host that set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC.<br>This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction. |

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | BCNT | 0-FFFFh | B-dimension count. Number of arrays to be transferred, where each array is ACNT in length. Count/count remaining for destination register set. Represents the amount of data remaining to be written. |
| 15-0 | ACNT | 0-FFFFh | A-dimension count. Number of bytes to be transferred in first dimension count/count remaining for destination register set. Represents the amount of data remaining to be written. |

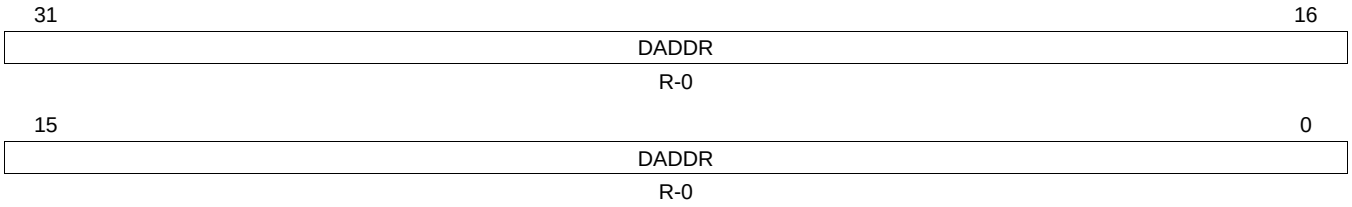
Copyright © 2011–2016, Texas Instruments Incorporated

#### 8.5.2.6.13 Destination FIFO Destination Address Register (DFDSTn)

The destination FIFO destination address register (DFDSTn) is shown in Figure 8-122 and described in Table 8-103.

**NOTE:** The value for *n* varies from 0 to DSTREGDEPTH for the given EDMA3TC.

**Figure 8-122. Destination FIFO Destination Address Register (DFDSTn)**



LEGEND: R = Read only; -*n* = value after reset

**Table 8-103. Destination FIFO Destination Address Register (DFDSTn) Field Descriptions**

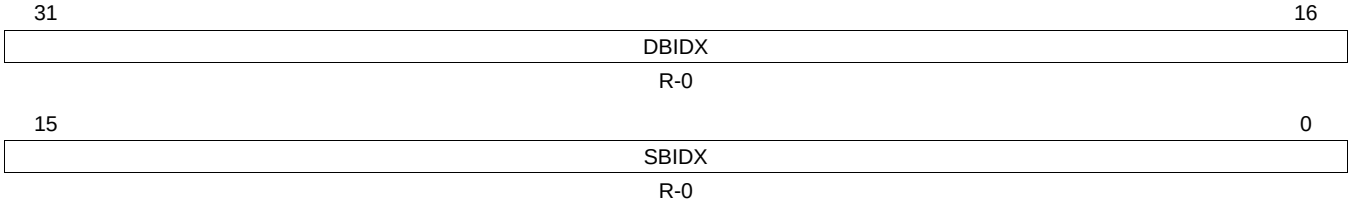
| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | DADDR | 0 | Destination address for the destination FIFO register set. When a transfer request (TR) is complete, the final value should be the address of the last write command issued. |

#### 8.5.2.6.14 Destination FIFO B-Index Register (DFBIDXn)

The destination FIFO B-index register (DFBIDXn) is shown in Figure 8-123 and described in Table 8-104.

**NOTE:** The value for *n* varies from 0 to DSTREGDEPTH for the given EDMA3TC.

**Figure 8-123. Destination FIFO B-Index Register (DFBIDXn)**



LEGEND: R = Read only; -*n* = value after reset

**Table 8-104. Destination FIFO B-Index Register (DFBIDXn) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | DBIDX | 0-FFFFh | B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination. |
| 15-0 | SBIDX | 0 | Always read as 0. |

## 8.6 Appendix A

### 8.6.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3.

The following table provides some common issues and their probable causes and resolutions.

**Table 8-109. Debug List**

| Issue | Description/Solution |
|---|---|
| The transfer associated with the channel does not happen. The channel does not get serviced. | The EDMA3CC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:<br>1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers (ER/ERH), make sure that the event is enabled in the Event Enable Registers (EER/EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (QEER).<br>2) Verify that the DMA or QDMA Secondary Event Register (SER/SERH/QSERH) bits corresponding to the particular event or channel are not set. |
| The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel. | It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:<br>1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., OPT.STATIC = 0, LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the QEMR and QSER. This will disable further prioritization of the channel.<br>2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the SER.Ex and EMR.Ex set, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (SER/SERH/QSER) and Event Missed Registers (EMR/EMRH/QEMR) before trying to perform subsequent transfers for the event/channel. |
| Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt. | You must ensure the following:<br>1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1).<br>2) The interrupts are enabled in the EDMA3 Channel Controller, via the Interrupt Enable Registers (IER/IERH).<br>3) The corresponding interrupts are enabled in the device interrupt controller.<br>4) The set interrupts are cleared in the interrupt pending registers (IPR/IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 8.3.9.1.2 for details on writing EDMA3 ISRs.<br>5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the IER/IERH registers.<br>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC=63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPRH.I63 (not IPR.I0). |

Copyright © 2011–2016, Texas Instruments Incorporated

### 8.6.2 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (ER/ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (ECR/ECRH). Similarly, the Event Enable Register (EER/EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EESR/EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EECR/EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC=0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

Copyright © 2011–2016, Texas Instruments Incorporated

## 8.7 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

(a) Determine the type of channel (QDMA or DMA) to be used.

(b) Channel mapping

(i) If using a QDMA channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.

(ii) If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.

(c) If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 8.3.7.1.)

(d) Determine the type of triggering used.

(i) If external events are used for triggering (DMA channels), enable the respective event in EER/EERH by writing into EESR/EESRH.

(ii) If QDMA Channel is used, enable the channel in QEER by writing into QEESR.

(e) Queue setup

(i) If a QDMA channel is used, set up the QDMAQNUM to map the channel to the respective event queue.

(ii) If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.

Step 2. Parameter set setup

(a) Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.
See Section 8.4 for parameter set field setups for different types of transfers. See the sections on chaining (Section 8.3.8) and interrupt completion (Section 8.3.9) on how to set up final/intermediate completion chaining and/or interrupts.

Step 3. Interrupt setup

(a) Enable the interrupt in the IER/IERH by writing into IESR/IESRH.

(b) Ensure that the EDMA3CC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.

(c) Ensure the EDMA3CC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.

(d) Set up the interrupt controller properly to receive the expected EDMA3 interrupt.

Copyright © 2011–2016, Texas Instruments Incorporated

Step 4. Initiate transfer

(a) This step is highly dependent on the event trigger source:

(i) If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.

(ii) For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.

(iii) Manually triggered transfers will be initiated by writes to the Event Set Registers (ESR/ESRH).

(iv) Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

(a) If the interrupts are enabled as mentioned in step 3 above, then the EDMA3CC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR/IPRH). The set bits must be cleared in the IPR\IPRH by writing to corresponding bit in ICR\ICRH.

(b) If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the IPR\IPRH. Again, the set bits in the IPR\IPRH must be manually cleared via ICR\ICRH before the next set of transfers is performed for the same transfer completion code values.

## 9.1 Introduction

The three port switch gigabit ethernet subsystem provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII), reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), the management data input output (MDIO) for physical layer device (PHY) management.

### *9.1.1 Features*

The 3PSW Ethernet Subsystem provides these functions:

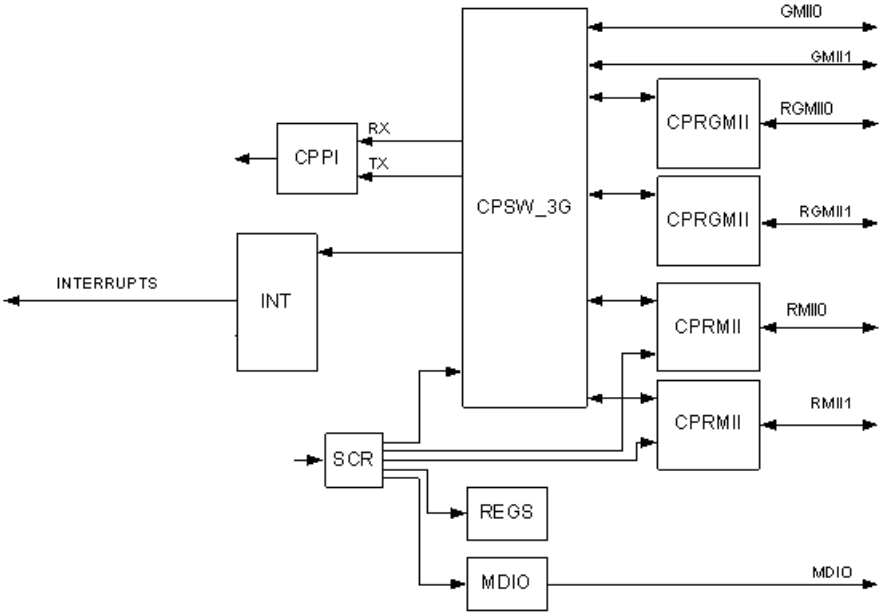
- Two Ethernet ports with Selectable G/MII, RMII, and RGMII interfaces
- Synchronous 10/100/1000 Mbit operation.
- Wire rate switching (802.1d)
- Non Blocking switch fabric
- Flexible logical FIFO based packet buffer structure
- Four priority level QOS support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization
- Reset isolation
- Communications port programming interface (CPPI) 3.1 compliant DMA controllers
- Maximum frame size 2016 bytes (2020 with VLAN)
- Programmable priority escalation on transmit
- Flow Control Support (802.3x)
- MDIO module for PHY Management
- Address Lookup
  - 1024 total address lookup engine (ALE) entries of VLANs and/or MAC addresses
  - L2 address lock and L2 filtering support
  - Multicast/broadcast filtering and forwarding state control
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Host controlled time-based aging
  - MAC authentication (802.1x)
  - Remapping of priority level of VLAN or ports
  - Multiple spanning tree support (spanning tree per VLAN)
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3 Stats RMON statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- CPGMAC_SL transmit to CPGMAC_SL receive Loopback mode (digital loopback) supported
- CPGMAC_SL receive to CPGMAC_SL transmit Loopback mode (FIFO loopback) supported
- Programmable interrupt control with selected interrupt pacing
- Programmable Transmit Inter Packet Gap (IPG)
- Half duplex mode supported only in 10/100 Mbps mode.

Copyright © 2011–2016, Texas Instruments Incorporated

- Full duplex mode supported in 10/100/1000 Mbps mode
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Emulation support
- IEEE 802.3 gigabit Ethernet conformant

### 9.1.2 Functional Block Diagram

**Figure 9-1. 3PSW Ethernet Subsystem Top Level Block Diagram**



### 9.1.3 Interface Mode Selection

The 3 port switch (3PSW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable G/MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register (GMII_SEL) in the *Control Module* chapter.

### 9.1.4 Subsystem Signal Summary

The tables below provide the signals names for different Interfaces (RGMII, G/MII, RMII). These signals are pin muxed. For more details on the signal descriptions/connections please refer to section of Ethernet Mac Sliver in this document.

See the pin mux selection details in the device data manual for configuring the PINMUX as per the Interface (RGMII, G/MII, RMII) selected.

**Table 9-1. G/MII Signal Description**

| Signal name | Width | Input/Output | Description |
|---|---|---|---|
| EMAC[0]_MtCLK | 1 | I | GMII0 transmit clock |
| EMAC[0]_Mtxd[0-7] | 8 | O | GMII0 transmit data |
| EMAC[0]_Mtxen | 1 | O | GMII0 transmit data enable |
| EMAC[0]_gMTclk | 1 | O | GMII0 source synchronous transmit clock |
| EMAC[0]_Mcol | 1 | I | GMII0 collision (asynchronous) |
| EMAC[0]_Mcrs | 1 | I | GMII0 carrier sense (asynchronous) |

## 9.1.5 Clocking

### 9.1.5.1 Subsystem Clocking

The 3 port switch (3PSW) Ethernet Subsystem clocks are derived from SATA SERDES PLL.

The SATA SERDES provides reference clocks to the modules G/MII (125 MHz), RMII (50 MHz), RGMII (50 MHz) and RGMII (5 MHz) as shown in Figure 9-2.

The SATA SerDes PLL configuration registers are available in the device control module register space. The *Control Module* chapter has more details on SATA PLL Register configuration.

The 3PSW Ethernet clocking provides option to receive or output the RMII reference clock (EMAC_RMREFCLK) from the pin as shown in Figure 9-2. See the RMII _REFCLK_SRC register in the device Control Module to configure the clocking option of RMII.

1588 reference clock, CPTS_RFT_CLK (250 MHz) and RGMII (250 MHz) reference clocks are provided by any of the Video-0/Video-1/Video_clk2/Audio/L3 PLLs as shown in Figure 9-2. The PLL is used for generating the clocks for CPTS_RFT_CLK, RGMII shall be selected by configuring the RMII_REFCLK_SRC register in the device Control Module.

### 9.1.5.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

#### *9.1.5.2.1 G/MII Interface Clocking*

EMAC [0/1] _MtCLK and EMAC [0/1] _MRCLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps (This is valid only for the EMAC[0/1]_MRCLK, the EMAC[0/1]_MTCLK is not used in gigabit/1000Mbps mode.)

EMAC [0/1] _gMTclk runs at 125 MHz in all the modes of operation.

#### *9.1.5.2.2 RGMII Interface Clocking*

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

See the MII mode selection register (GMII_SEL) in the device Control Module to configure the CPRGMII Internal Delay/No Delay in Transmit Mode of Operation. See Section 9.2.1.8.3 for more details.

#### *9.1.5.2.3 RMII Interface Clocking*

RMII interface clock EMAC_RMREFCLK frequencies are:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

See the RMII _REFCLK_SRC register in the device Control Module to configure the Clocking Option of RMII.

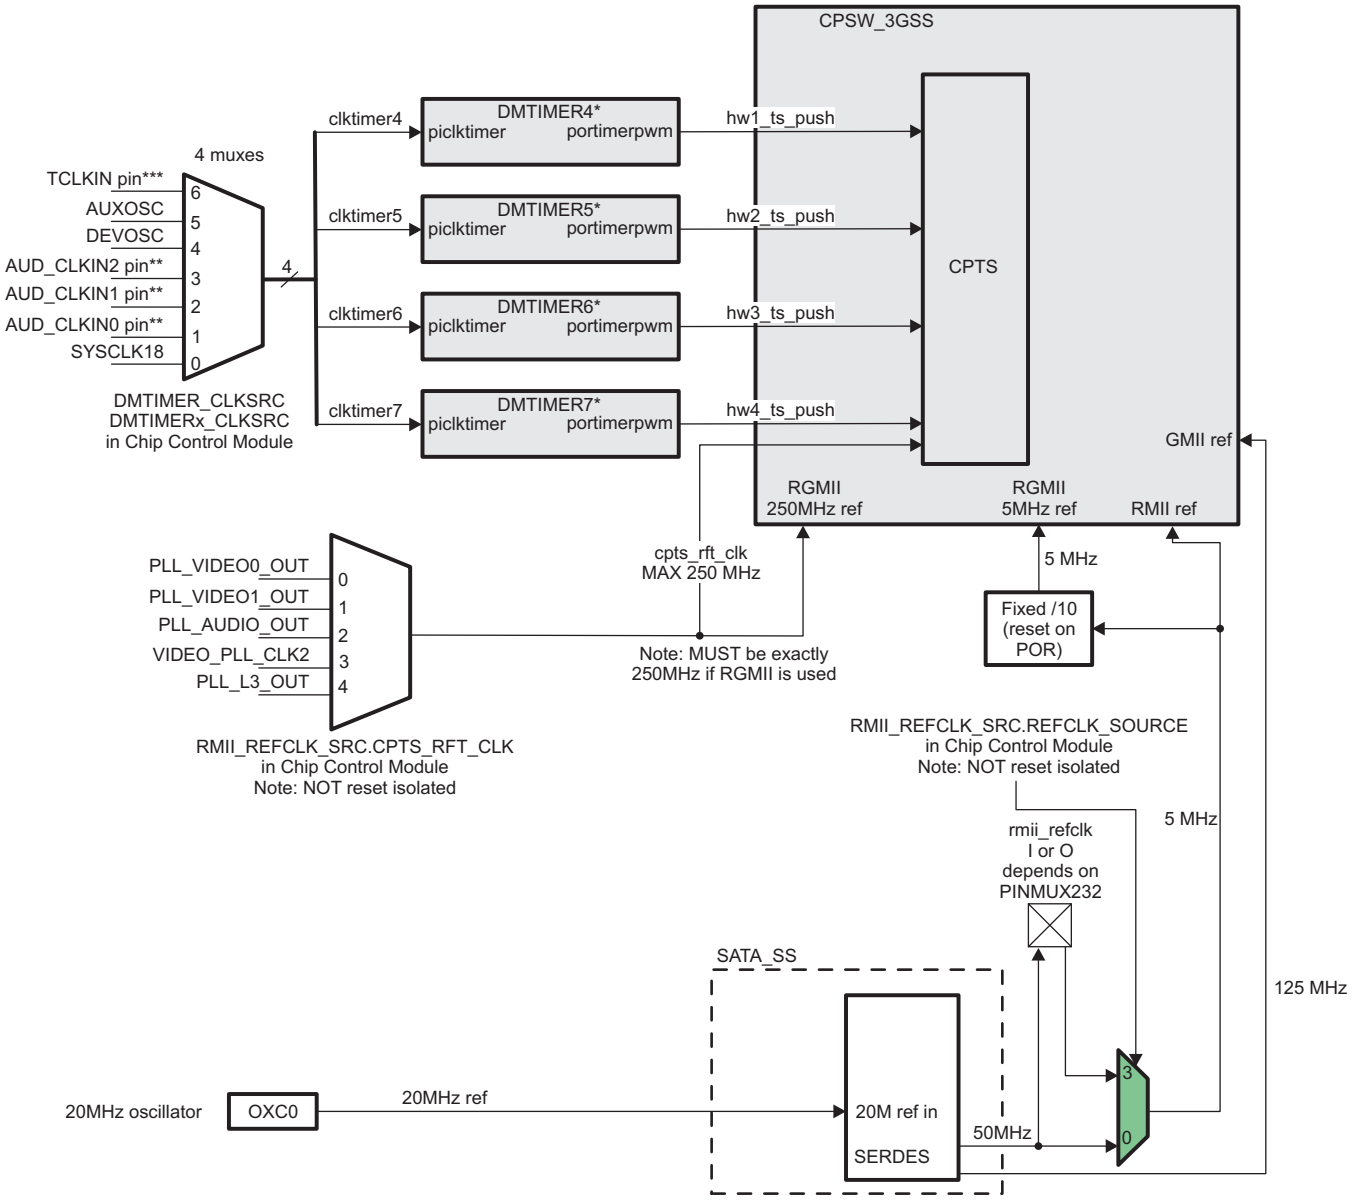
#### *9.1.5.2.4 MDIO Clocking*

The MDIO clock is based on a divide-down of the peripheral clock, running at 125 MHz.The application software or driver must control the divide-down value.

See the MDIO Control Register for configuring the Clock Divider (CLKDIV) value.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-2. 3PSW Subsystem Clocking Block Diagram**



### 9.1.6 Interrupt Support

3PSW Ethernet Subsystem has 4 Interrupts:

- RX_thresh_pulse - Receive Threshold Interrupt
- RX_pulse - Receive Interrupt
- TX_pulse - Transmit Interrupt
- Misc_pulse - Miscellaneous Interrupt.

See Section 9.2.5 for more details. See the device data manual for more details on the mapping of these interrupts at the device level.

### 9.1.7 Memory Map

The Addresses for the Modules in the 3 port switch (3PSW) Ethernet Subsystem are:

Copyright © 2011–2016, Texas Instruments Incorporated

- CPSW_3G Module: The start address of the CPSW_3G module is 4A10 0000h. See Section 9.4.1.
- MDIO Module: The start address of the MDIO module is 4A10 0800h. See Section 9.4.2.
- CPSW Subsystem Module: The start address of the CPSW subsystem is 4A10 0900h. See Section 9.4.3.
- CPPI Descriptors: The start address of the CPPI descriptors is 4A10 2000h.

  The 8K bytes of CPPI memory begin at address 4A10 2000h from the EMAC perspective. The buffer descriptors programmed to access the CPPI RAM memory from the CPU perspective should use the address range from 4A10 2000h to 4A10 4000h.

### 9.1.8 3PSW Ports

Ethernet Subsystem has 3 Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

Copyright © 2011–2016, Texas Instruments Incorporated

## 9.2 CPSW Architecture

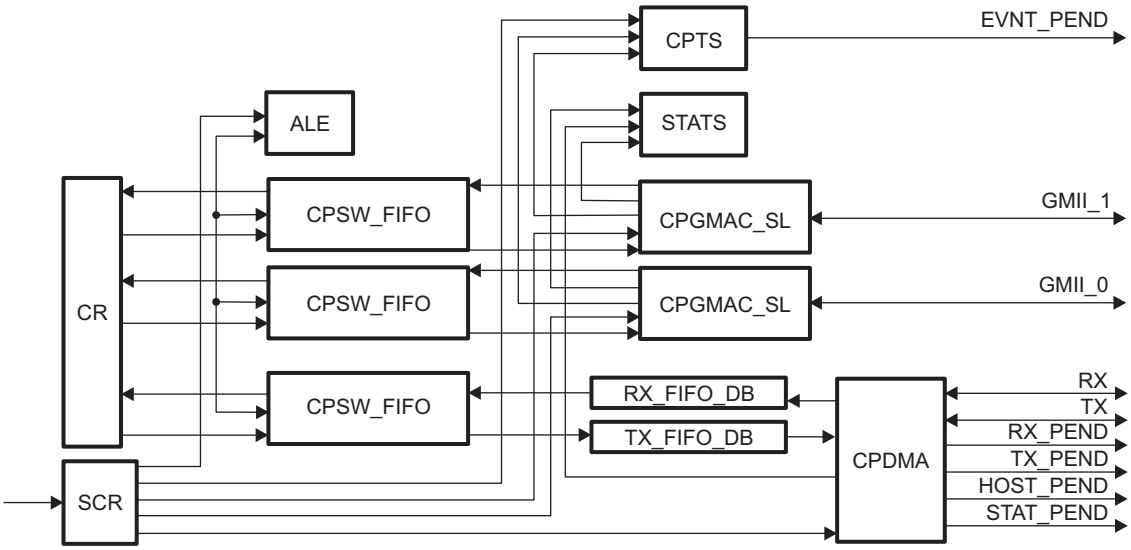
The 3 port switch (3PSW) Ethernet Subsystem peripheral are compliant to the IEEE Std 802.3 Specification. The 3PSW Ethernet Subsystem contains two RGMII/RMII interfaces, one CPPI 3.0 interface, Interrupt Controller, MDI0 and CPSW_3G which contains two G/MII interfaces as shown in Figure 9-3.

### *9.2.1 CPSW_3G*

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI 3.0 interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 9-3.

**Figure 9-3. CPSW_3G Block Diagram**



#### 9.2.1.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI 3.0 compliant packet DMA transfer controller. The CPPI 3.0 interface is port 0.

##### *9.2.1.1.1 Functional Operation*

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI 3.0 protocol. See the CPPI Buffer Descriptors section for detailed description of Buffer Descriptors.

##### *9.2.1.1.2 Receive DMA Interface*

The receive DMA is an eight channel CPPI 3.0 compliant interface. Each channel has a single queue for frame reception.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.
3. Enable the desired receive interrupts in the INTMASK register.
4. Write the RX_BUFFER_OFFSET register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0.
6. Enable the RX DMA controller by setting the RX_EN bit in the RX_CONTROL register.

#### 9.2.1.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the RX_TEARDOWN register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

### 9.2.1.1.3 Transmit DMA Interface

The tranmsit DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX_PTYPE bit in the DMACONTROL register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

#### 9.2.1.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX_HDP registers to 0.
2. Enable the desired transmit interrupts in the INTMASK register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
4. Configure and enable the transmit operation as desired in the TX_CONTROL register.
5. Write the appropriate TX_HDP registers with the appropriate values to start transmit operations.

#### 9.2.1.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the TX_TEARDOWN register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Copyright © 2011–2016, Texas Instruments Incorporated

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

#### *9.2.1.1.4 Transmit Rate Limiting*

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

*Priority Transfer rate in Mbit/s = ((PRI_IDLE_CNT/(PRI_IDLE_CNT + PRI_SEND_CNT)) × frequency × 32*

Where the frequency is the CLK frequency.

#### *9.2.1.1.5 Command IDLE*

The CMD_IDLE bit in the DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

### 9.2.1.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPGMAC_SL configuration bit(s) cef, csf, or cmf are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

Copyright © 2011–2016, Texas Instruments Incorporated

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

#### *9.2.1.2.1 Address Table Entry*

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 9-4. Learned Address Control Bits**

| | |
|---|---|
| unicast_type | 11 |
| Block | 0 |
| Secure | 0 |

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

**Table Entry Type**

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40 .**

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**

##### *9.2.1.2.1.1 Free Table Entry*

**Table 9-5. Free (Unused) Address Table Entry Bit Values**

| 71-62 | 61-60 | 59-0 |
|---|---|---|
| Reserved | ENTRY_TYPE(00) | Reserved |

##### *9.2.1.2.1.2 Multicast Address Table Entry*

**Table 9-6. Multicast Address Table Entry Bit Values**

| 71-69 | 68-66 | 65 | 64 | 63-62 | 61-60 | 59-48 | 47-0 |
|---|---|---|---|---|---|---|---|

Copyright © 2011–2016, Texas Instruments Incorporated

**Supervisory Packet (SUPER)**

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

**Port Mask(2:0) (PORT_MASK)**

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

**Multicast Forward State (MCAST_FWD_STATE)**

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

**Table Entry Type (ENTRY_TYPE)**

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

**Packet Address (MULTICAST_ADDRESS)**

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### *9.2.1.2.1.3 VLAN/Multicast Address Table Entry*

**Table 9-7. VLAN/Multicast Address Table Entry Bit Values**

| 71-69 | 68-66 | 65 | 64 | 63-62 | 61-60 | 59-48 | 47-0 |
|---|---|---|---|---|---|---|---|
| Reseved | PORT_MASK | SUPER | Reserved | MCAST_FWD_STATE | ENTRY_TYPE (11) | VLAN_ID | MULTICAST_ADDRESS |

**Supervisory Packet (SUPER)**

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

**Port Mask(2:0) (PORT_MASK)**

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

**Multicast Forward State (MCAST_FWD_STATE)**

Copyright © 2011–2016, Texas Instruments Incorporated

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASk has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

**Table Entry Type (ENTRY_TYPE)**

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

**VLAN ID (VLAN_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Packet Address (MULTICAST_ADDRESS)**

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### *9.2.1.2.1.4 Unicast Address Table Entry*

**Table 9-8. Unicast Address Table Entry Bit Values**

| 71-68 | 67-66 | 65 | 64 | 63-62 | 61-60 | 59-48 | 47-0 |
|---|---|---|---|---|---|---|---|
| Reseved | PORT_ NUMBER | BLOCK | SECURE | UNICAST_ TYPE (00) or (X1) | ENTRY_TYPE (01) | Reserved | UNICAST_ ADDRESS |

**Port Number (PORT_NUMBER)**

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

**Block (BLOCK)**

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

**Secure (SECURE)**

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

Copyright © 2011–2016, Texas Instruments Incorporated

address and do not update the address (block must be zero)

**Unicast Type (UNICAST_TYPE)**

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

**Table Entry Type (ENTRY_TYPE)**

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

**Packet Address (UNICAST_ADDRESS)**

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### *9.2.1.2.1.5 OUI Unicast Address Table Entry*

**Table 9-9. OUI Unicast Address Table Entry Bit Values**

| 71-64 | 63-62 | 61-60 | 59-48 | 47-24 | 23-0 |
|---|---|---|---|---|---|
| Reserved | UNICAST_TYPE(10) | ENTRY_TYPE(01) | Reserved | UNICAST_OUI | Reserved |

**Unicast Type (UNICAST_TYPE)**

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

**Table Entry Type (ENTRY_TYPE)**

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

**Packet Address (UNICAST_OUI)**

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

#### *9.2.1.2.1.6 VLAN/Unicast Address Table Entry*

**Table 9-10. Unicast Address Table Entry Bit Values**

| 71:68 | 67:66 | 65 | 64 | 63:62 | 61:60 | 59:48 | 47:0 |
|---|---|---|---|---|---|---|---|
| Reseved | PORT_ NUMBER | BLOCK | SECURE | UNICAST_ TYPE (00) or (X1) | ENTRY_TYPE (11) | VLAN_ID | UNICAST_ ADDRESS |

Copyright © 2011–2016, Texas Instruments Incorporated

**Port Number (PORT_NUMBER)**

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

**Block (BLOCK)**

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

**Secure (SECURE)**

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

**Unicast Type (UNICAST_TYPE)**

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

**Table Entry Type (ENTRY_TYPE)**

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

**VLAN ID (VLAN_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Packet Address (UNICAST_ADDRESS)**

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### *9.2.1.2.1.7 VLAN Table Entry*

**Table 9-11. VLAN Table Entry**

| 71-62 | 61-60 | 59-48 | 47-27 | 26-24 | 23-19 | 18-16 | 15-11 | 10-8 | 7-3 | 2-0 |
|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | ENTRY_ TYPE(10) | VLAN_ID | Reserved | FORCE_ UNTAGGED_ EGRESS | Reserved | REG_ MCAST_ FLOOD_MASK | Reserved | UNREG_MCAST_ FLOOD_MASK | Reserved | VLAN_ MEMBER_ LIST |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table Entry Type (ENTRY_TYPE)**

10: VLAN entry

**VLAN ID (VLAN_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)**

This field causes the packet VLAN tag to be removed on egress (except on port 0).

**Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)**

Mask used for multicast when the multicast address is found.

**Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)**

Mask used for multicast when the multicast address is not found.

**VLAN Member List (VLAN_MEMBER_LIST)**

This 3-bit field indicates which port(s) are members of the associated VLAN.

#### *9.2.1.2.2 Packet Forwarding Processes*

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port. The receive packet processes

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set. Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the SL1/2_MACCONTROL register.

**RX_CEF_EN -**This CPGMAC_SL control bit enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded.

**RX_CSF_EN -**This CPGMAC_SL bit enables short frames to be forwarded.

**RX_CMF_EN -**This CPGMAC_SL control bit enables mac control frames to be forwarded.

#### *9.2.1.2.3 Learning Process*

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.2.4 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register. In VLAN aware mode, ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set RX_VLAN_ENCAP bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information.

#### 9.2.1.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the CPSW_CONTROL register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 transmit packets are never VLAN encapsulated.

### 9.2.1.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

### 9.2.1.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKS field in the FIFOs associated MAX_BLKS register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKS field in the FIFO's associated MAX_BLKS register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKS value plus the RX_MAX_BLKS value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

### 9.2.1.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to Section 9.2.1.3.

#### 9.2.1.5.2 Dual Mac Mode

When operating in dual mac mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual mac mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the ALE_CONTROL register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in CPSW_CONTROL) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in P0_TX_IN_CTL. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

### 9.2.1.6 Audio Video Bridging

IEEE802.1BA is the standard for networked Audio Video Bridging (AVB) Systems. It defines the concept of an AVB domain as the intersection of a time domain and a stream reservation domain. The time domain is established based on the IEEE 802.1AS standard, wherein each node must support the generalized Precision Time Protocol (gPTP). Typically this takes the form of a state machine running on the host processor (such as the MPU) which, among other duties, processes the associated ethernet packets carrying timing information. A necessary input is the accurate time stamping of ethernet packets. This process is facilitated on SoC by the Common Platform Time Sync (CPTS), which is able to time stamp ingress and egress packets at the MAC layer with sufficient precision and accuracy to meet the AVB standard (refer to *Common Platform Time Sync (CPTS)*). A stream reservation domain is established

Copyright © 2011–2016, Texas Instruments Incorporated

between nodes, primarily through the use of two mechanisms: the Stream Reservation Protocol (SRP) and Forwarding and Queuing of Time Sensitive Streams (FQTSS). Both mechanisms are specified in the IEEE802.1Q standard (clauses 35 and 34, respectively). SRP is a software component which normally runs on the host processor and requires no hardware assistance. On the other hand, FQTSS has significant performance demands, as it requires the shaping of egress packets at small time scales. The SoC CPSW facilitates this process through the conjunction of rate-limited CPDMA channels and egress traffic shaping (refer to *CPSW 3G* for more details).

#### 9.2.1.7 Hardware Example Usage

##### *9.2.1.7.1 Rate Limit Mode*

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the CPSW_3G PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
4. P0_TX_IN_CTL[17:16] TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the CPDMA DMACONTROL register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

##### *9.2.1.7.2 Configuring the device for 802.1Qav operation:*

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-12. Example of TX Configuration**

| TX DMA CHANNEL | Packet Priority | Switch Queue Priority |
|---|---|---|
| 7 | 7 | 3 |
| 6 | 5 | 2 |
| 5 | 3 | 1 |
| 4 | 1 | 0 |

**Table 9-13. Example of RX Configuration**

| RX DMA CHANNEL | Packet Priority | Switch Queue Priority |
|---|---|---|
| 0 | 7 | 0 |
| 0 | 5 | 0 |
| 0 | 3 | 0 |
| 0 | 1 | 0 |

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

**Table 9-14. Example of Rate-limit Configurations**

| Register | Value | DESCRIPTION |
|---|---|---|
| CPSW_PTYPE | 0006 0000h | For Port1 -- 2 highest priority channels. |
| P1_TX_IN_CTL:<br>TX_RATE_EN<br>TX_IN_SEL | <br>1100<br>10 | <br>2 highest priority channels are rate limited<br>Rate limit mode |
| P1_SEND_PERCENT | 14 3E00h | 20% PRI7, 62% PRI5 |
| DMACONTROL | C001h | Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel. |
| TX_PRI7_RATE | 10013h | 200 Mbps |
| TX_PRI6_RATE | 10005h | ~600 Mbps |

### 9.2.1.8 Ethernet Mac Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation.
- G/MII Interface.
- Hardware Error handling including CRC.
- Full Duplex Gigabit operation (half duplex gigabit is not supported).
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module.
- Transmit CRC generation selectable on a per channel basis.
- Emulation Support.
- VLAN Aware Mode Support.
- Hardware flow control.
- Programmable Inter Packet Gap (IPG)

#### *9.2.1.8.1 G/MII Media Independent Interface*

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.8.1.1 Data Reception

##### 9.2.1.8.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

##### 9.2.1.8.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

#### 9.2.1.8.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

##### 9.2.1.8.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

##### 9.2.1.8.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

##### 9.2.1.8.1.2.3 MTXER

The GMII_MTXER signal is not used. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

##### 9.2.1.8.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the MACCONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

Copyright © 2011–2016, Texas Instruments Incorporated

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

#### 9.2.1.8.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the MACCONTROL register enables the TX_SHORT_GAP input to determine whether the transmit IPG is shorted by eight bit times.

#### 9.2.1.8.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

#### 9.2.1.8.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### 9.2.1.8.1.2.8 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

### 9.2.1.8.1.3 G/MII Interface Signal Connections and Descriptions

G/MII Interface can operate in GIG/MII Modes.

- In GIG (1000 Mbps) Mode: 3PSW operates only in full duplex mode.
- In MII Mode (100/10 Mbps): 3PSW operates in full duplex and half duplex.

The pin connections of the G/MII Interface is shown in Figure 9-4. The detailed description of the signals in GIG/MII Mode are listed in the following tables.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-4. G/MII Interface Connections**

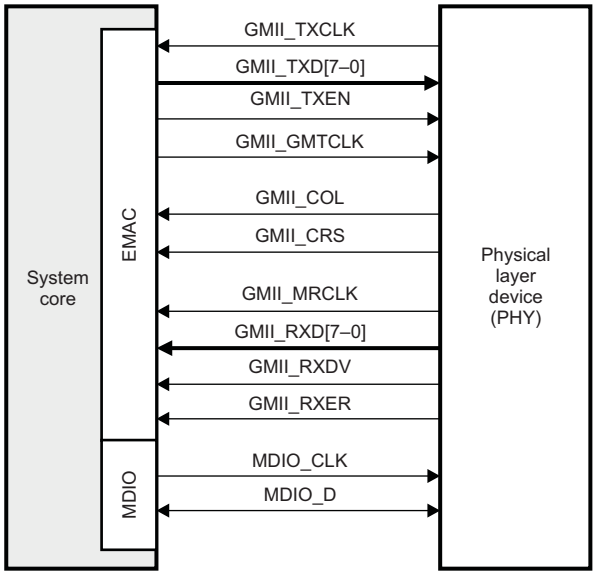

**Table 9-15. G/MII Interface Signal Descriptions in GIG (1000 Mbps) Mode**

| Signal | Type | Description |
|---|---|---|
| GMTCLK | O | The transmit clock is a continuous clock that provides the timing reference for transmit operations. The clock is generated by the CPSW and is 125 MHz at 1000 Mbps operation. It requires a free running clock on MTCLK pin.<br>If the MTCLK is not generated by the PHY, then configure the CPGMAC_SL Mac Control Register Force Gig bit to 1, to generate the required o/p GMTCLK of 125 MHz. |
| MTCLK | I | The transmit clock is a continuous free running clock and is generated by the PHY. |
| MTXD | O | The transmit data pins are a collection of 8 data signals comprising 8 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by GMTCLK and valid only when MTXEN is asserted. |
| MTXEN | O | The transmit enable signal indicates that the MTXD pins are generating 8bit data for use by the PHY. It is driven synchronously by GMTCLK. |
| MCOL | I | In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used. |
| MCRS | I | In full-duplex operation, the MCRS pin should be held low. |
| MRCLK | I | The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 125 MHz at 1000Mbps of operation. |
| MRXD | I | The receive data pins are a collection of 8 data signals comprising 8 bits of data.MRXD0 is the least-significant bit (LSB). The signals are synchronized by MRCLK and valid only when MRXDV is asserted. |
| MRXDV | I | The receive data valid signal indicates that the MRXD pins are generating byte data for use by the 3PSW. It is driven synchronously to MRCL. |
| MDCLK | O | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. |
| MDIO | I/O | MDIO DATA (MDI0_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-16. G/MII Interface Signal Descriptions in MII (100/10 Mbps) Mode**

| Signal | Type | Description |
|---|---|---|
| GMTCLK | O | The clock is generated by the CPSW and is running at 125 MHz. |
| MTCLK | I | The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation. |
| MTXD | O | MTXD[7-4] pins of MTXD data are not used. The transmit data pins are a collection of 4 data signals MTXD[3-0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MTCLK and valid only when MTXEN is asserted. |
| MTXEN | O | The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MTCLK. |
| MCOL | I | In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MTCLK nor MRCLK.<br>In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used. |
| MCRS | I | In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MTCLK nor MRCLK.<br>In full-duplex operation, the MCRS pin should be held low. |
| MRCLK | I | The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation. |
| MRXD | I | MRXD[7-4] bits are unused in the MII mode. The receive data pins are a collection of 4 data signals comprising 4 bits of data.MRXD0 is the least-significant bit (LSB).The signals are synchronized by MRCLK and valid only when MRXDV is asserted. |
| MRXDV | I | The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the 3PSW. It is driven synchronously to MRCLK. |
| MDCLK | O | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. |
| MDIO | I/O | MDIO DATA (MDI0_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

#### *9.2.1.8.2 RMII Interface*

The CPRMII peripheral shall be compliant to the RMII specification document.

##### *9.2.1.8.2.1 Features*

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

##### *9.2.1.8.2.2 RMII Receive (RX)*

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Copyright © 2011–2016, Texas Instruments Incorporated

Any received packet that ends with an improper nibble boundary aligned RMCRSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCRSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

#### 9.2.1.8.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the 3PSW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The 3PSW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

#### 9.2.1.8.2.4 RMII Signal Connections and Descriptions

Figure 9-5 shows a device with integrated 3PSW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 9-17.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 9-5. RMII Interface Connections**

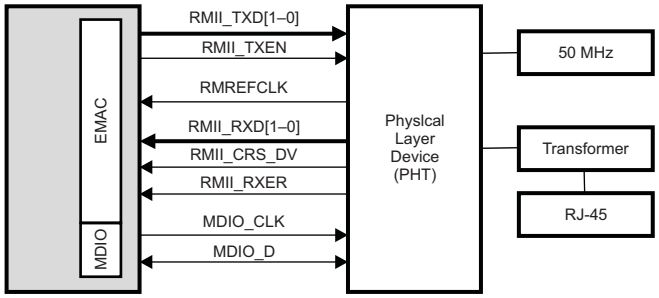

**Table 9-17. RMII Signal Descriptions**

| Signal | Type | Description |
|---|---|---|
| RMTXD (1-0) | O | Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMREFCLK and valid only when RMTXEN is asserted. |
| RMXEN | O | Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMREFCLK. |
| RMREFCLK | I/O | RMII reference clock. (RMREFCLK).<br>The reference clock is used to synchronize all RMII signals. RMREFCLK must be continuous and fixed at 50 MHz. |
| RMRXD (1-0) | I | Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMREFCLK and valid only when RMCRSDV is asserted and RMRXER is de-asserted. |
| RMCRSDV | I | Carrier sense/receive data valid (RMCRSDV). Multiplexed signal between carrier sense and receive data valid. |
| R,RXER | I | Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame. |
| MDCLK | O | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-17. RMII Signal Descriptions (continued)**

| Signal | Type | Description |
|---|---|---|
| MDIO | I/O | MDIO DATA(MDI0_D). MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

#### 9.2.1.8.3 RGMII Interface

The CPRGMII peripheral shall be compliant to the RGMII specification document.

##### 9.2.1.8.3.1 Features

- Supports 1000/100/10 Mbps Speed
- MII mode is not supported
- Selectable internal delay on transmit

##### 9.2.1.8.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

##### 9.2.1.8.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII_RX_INBAND input is asserted. RGMII_RX_INPUT is asserted by configuring the EXT_EN bit to 1 of the SLn_MACCONTROL register. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification. The link speed is indicated as shown in Table 9-18.

**Table 9-18. Link Speed**

| RGMII_SPEED (1:0) | Link Speed |
|---|---|
| 00 | 10 Mbs mode |
| 01 | 100 Mbs mode |
| 10 | 1000 Mbs mode |
| 11 | reserved |

##### 9.2.1.8.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII_RX_INBAND input is de-asserted. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the RGMII_FULLDUPLEX_IN and RGMII_GIG_IN inputs. If the RGMII_GIG_IN input is asserted, then operation is gigabit mode (RGMII_SPEED (1:0) = 10). If the RGMII_GIG_IN input is de-asserted, the operation is 100 Mbps mode (RGMII_SPEED (1:0) = 01).

##### 9.2.1.8.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (MTXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

Copyright © 2011–2016, Texas Instruments Incorporated

In 10/100 mode, the MTXD (7:0) data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first GMII_MTXEN rising edge after the 4096 transmit clock count has expired.

The RGMII0/1_ID_MODE bit value in the GMII_SEL register determines whether or not the transmit delay is included in the CPRGMII or not. When RGMII0/1_ID_MODE bit is cleared to 0, the transmit delay is included. The RGMII0/1_ID_MODE input is a configuration input only and is not intended to be changed during packet operations.

See the *Control Module* chapter, MII mode selection register (GMII_SEL) to configure the CPRGMII Internal Delay/No Delay in Transmit Mode of Operation.

#### 9.2.1.8.3.6 RGMII Signal Connections and Descriptions

Figure 9-6 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 9-19.

**Figure 9-6. RGMII Interface Connections**

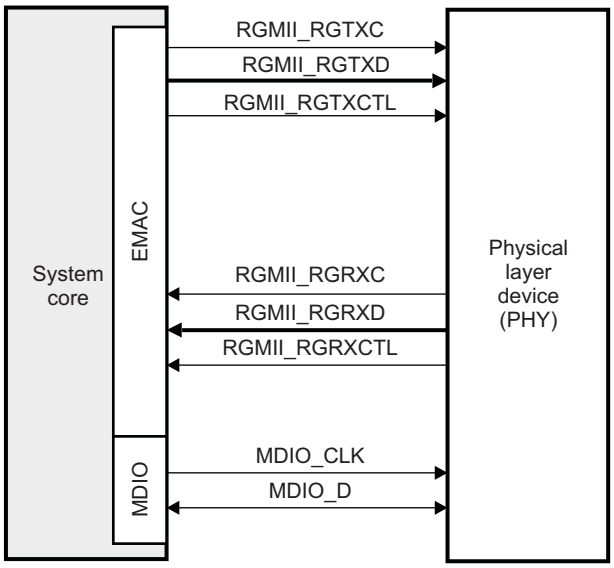

**Table 9-19. RGMII Signal Descriptions**

| Signal | Type | Description |
|---|---|---|
| RGTXD[3-0] | O | The transmit data pins are a collection of 4 bits of data.RGTDX0 is the least-significant bit (LSB). The signals are valid only when RGTXCTL is asserted. |
| RGTXCTL | O | Transmit Control/enable. The transmit enable signal indicates that the RGTXD pins are generating data for use by the PHY. |
| RGTXC | O | The transmit reference clock will be 125 MHz, 25 MHz, or 2.5 MHz depending on speed of operation. |
| RGRXD[3-0] | I | The receive data pins are a collection of 4 bits of data. RGRDX0 is the least-significant bit (LSB).<br>The signals are valid only when RGRXCTL is asserted |
| RGRXCTL | I | The receive data valid/control signal indicates that the RGRXD pins are nibble data for use by the 3PSW. |
| RGRXC | I | The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation. |
| MDCLK | O | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-19. RGMII Signal Descriptions (continued)**

| Signal | Type | Description |
|---|---|---|
| MDIO | I/O | MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

#### *9.2.1.8.4 Frame Classification*

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the RX_MAXLEN register. The RX_MAXLEN register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

### 9.2.1.9 Embedded Memories

**Table 9-20. Embedded Memories**

| Memory Type Description | Number of Instances | |
|---|---|---|
| Single port 2560 by 64 RAM | 3 | (Packet FIFO's) |
| Single port 64-word by 1152-bit RAM | 1 | (ALE) |
| Single port 2048-word by 32-bit RAM | 1 | (CPPI) |

### 9.2.1.10 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

#### *9.2.1.10.1 CPPI Port Flow Control*

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the CPSW_FLOW_CONTROL register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.10.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

##### 9.2.1.10.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the MACCONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the fullduplex bit in the MACCONTROL register.

###### 9.2.1.10.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in MACCONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

###### 9.2.1.10.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in MACCONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Copyright © 2011–2016, Texas Instruments Incorporated

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - SL_SA(47:0).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

#### *9.2.1.10.2.2 Transmit Flow Control*

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the MACCONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in MACCONTROL register, and
- the frame's length is 64 to RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

Copyright © 2011–2016, Texas Instruments Incorporated

- A 48-bit destination address equal to:
- The reserved multicast destination address 01.80.C2.00.00.01, or the SL_SA (47:0) input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

#### 9.2.1.11 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL1_MACCONTROL (SL2_MACCONTROL) register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The CPSW_GAP_THRESH register value determines the port 1 short gap threshold, and the CPSW_GAP_THRESH register value determines the port 2 short gap threshold.

#### 9.2.1.12 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

**Table 9-21. Switch Latency**

| Mode | Latency |
|---|---|
| Gig (1000) | 880 ns |
| 100 | 1.3 µs |
| 10 | 6.5 µs |

#### 9.2.1.13 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

**CPGMAC_SL Emulation Control**

Copyright © 2011–2016, Texas Instruments Incorporated

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

**CPDMA Emulation Control**

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the EMCONTROL register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 9-22 shows the operations of the emulation control input and register bits.

**Table 9-22. Emulation Control Input**

| EMUSUSP | SOFT | FREE | Description |
|---|---|---|---|
| 0 | X | X | Normal Operation |
| 1 | 0 | 0 | Normal Operation |
| 1 | 1 | 0 | Emulation Suspend |
| 1 | X | 1 | Normal Operation |

#### 9.2.1.14 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The CPSW_SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW_SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

#### 9.2.1.15 Software Reset

The CPSW_3G software reset register, CPSW_3GSS software reset register and the three submodule software reset registers enable the CPSW_3GSS to be reset by software. There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.1.16 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the CPSW_CONTROL register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in fullduplex mode only.

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.2.2 Common Platform Time Sync (CPTS)

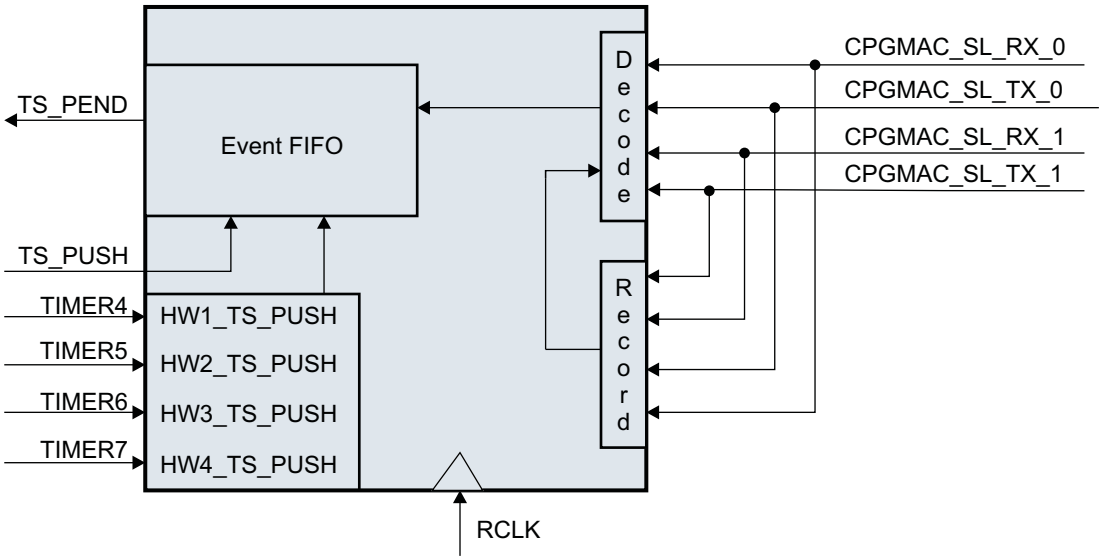
The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

#### 9.2.2.1 Architecture

Figure 9-7 shows the architecture of the CPTS module inside the 3PSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the 3PSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

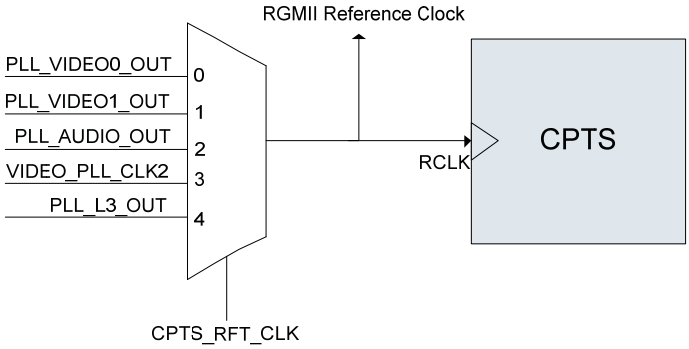
In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO

**Figure 9-7. CPTS Block Diagram**



The reference clock used for the time stamp (RCLK) is sourced from one of the five sources, as shown in Figure 9-8. The PLL used for sourcing RCLK can be selected by configuring the RMII _REFCLK_SRC register in the *Control Module* chapter. Note that if RGMII mode is used, RCLK must be exactly 250 MHz.

**Figure 9-8. CPTS RCLK Source**



#### 9.2.2.2 Common Platform Time Sync Initialization

The CPTS module should be configured as:

Copyright © 2011–2016, Texas Instruments Incorporated

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the CPTS_RFT_CLK value in the RMII_RFTCLK_SEL register in the Control Module with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

#### 9.2.2.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL and CPTS_TS_LOAD_EN registers).

#### 9.2.2.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 9.2.2.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. The two 32-bit registers, CPTS_EVENT_HIGH and CPTS_EVENT_LOW, are described in Section 9.4. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

##### *9.2.2.5.1 Time Stamp Push Event*

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

##### *9.2.2.5.2 Time Stamp Counter Rollover Event*

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

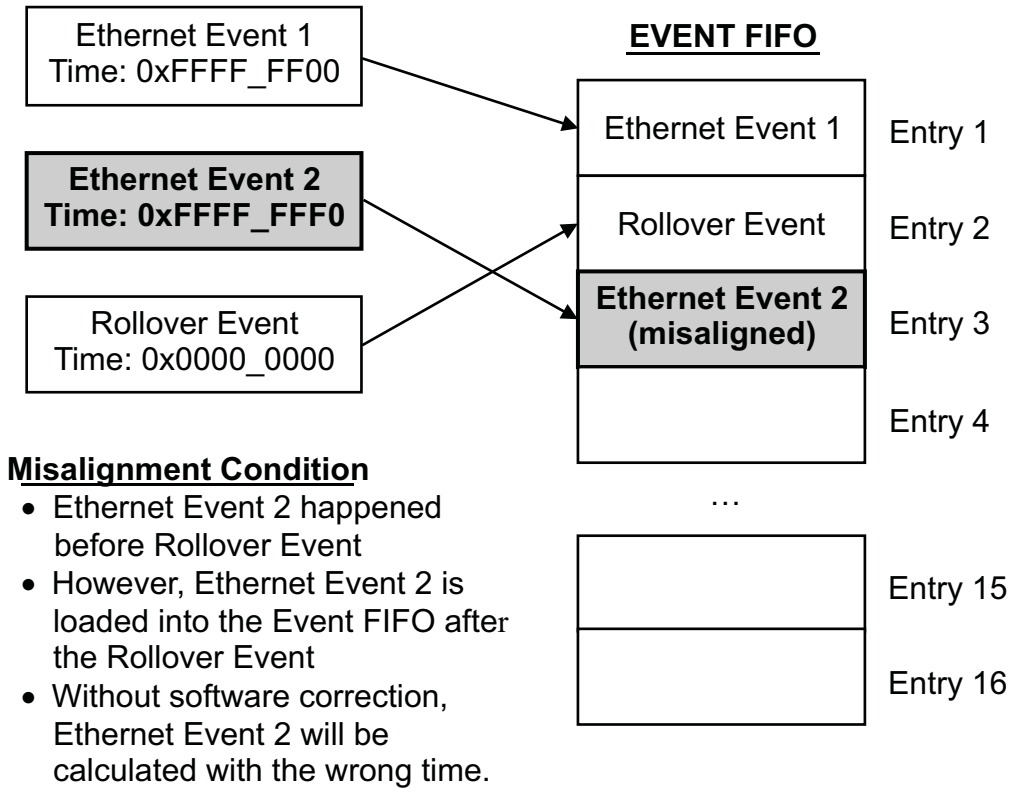
Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.2.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 9-9 shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

**Figure 9-9. Event FIFO Misalignment Condition**

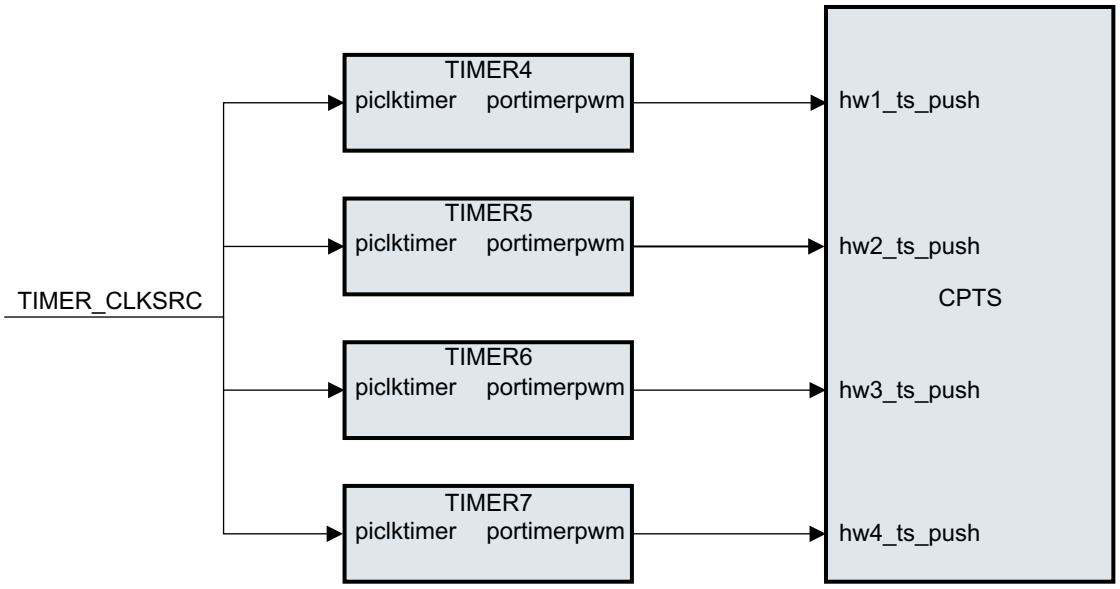


#### 9.2.2.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 9-10.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-10. HW1/4_TSP_PUSH Connection**



The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the EVENT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### *9.2.2.5.5 Ethernet Port Events*

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

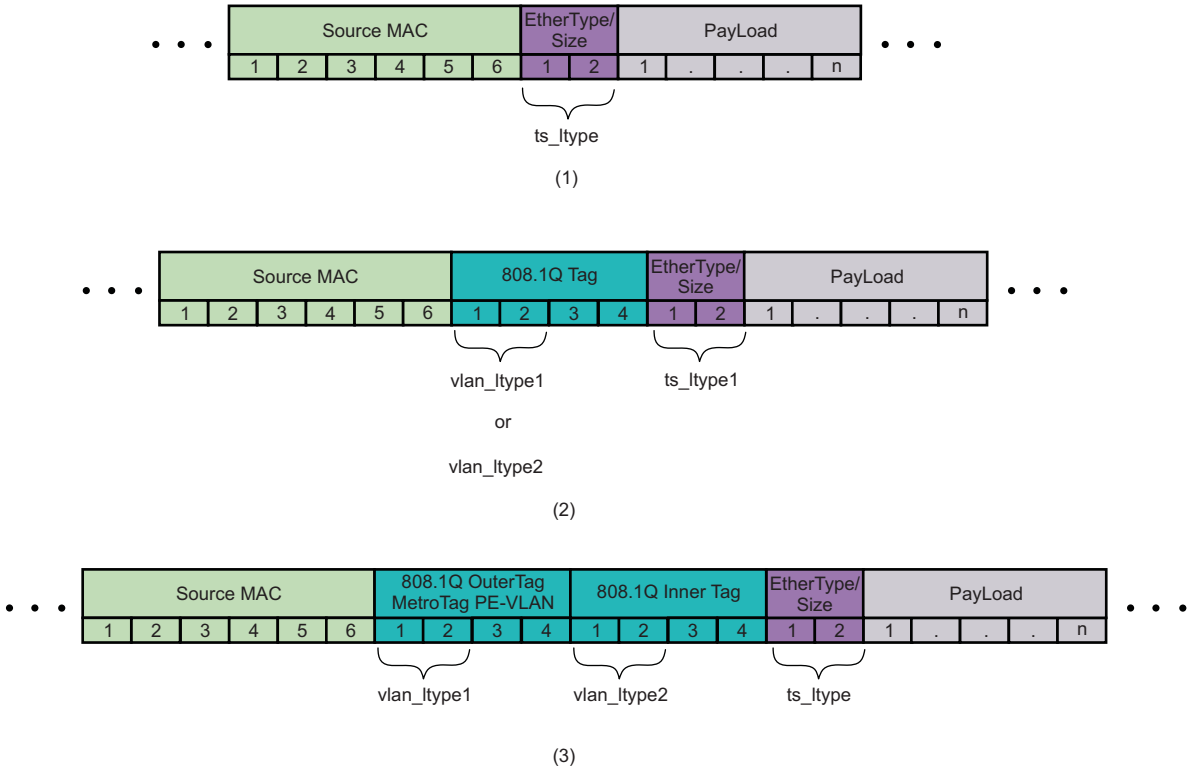
According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 9-11. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the Pn_TS_LTYPE field in the Pn_TS_SEQ_LTYPE register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-11. To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN (or Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN) enable bit must be set in the Pn_TS_CTL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CTPS hardware will compare this value to the Pn_TS_VLAN_LTYPE1 (or Pn_TS_VLAN_LTYPE2 depending on which enable bit was set) field in the Pn_TS_VLAN register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-11. In this case, both Pn_TS_VLAN_LTYPE1 and Pn_TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the Pn_TS_VLAN_LTYPE1 field, and the inner tag must match the value of the Pn_TS_VLAN_LTYPE2 field.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-11. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)**



To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where n is the port number:

1. Set the Pn_TS_TX_EN/Pn_TS_RX_EN bit in the Pn_TS_CTL register to enable transmit/receive event packets
2. Configure the Pn_TS_SEQ_LTYPE register:
   (a) Set the Pn_TS_LTYPE field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
   (b) Set the Pn_TS_SEQ_ID_OFFSET field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
   (a) Set the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN or Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN bit in the Pn_TS_CTL register.
   (b) Set the Pn_TS_VLAN_LTYPE1 or Pn_TS_VLAN_LTYPE2 field (matching what was used in step 3a) in the Pn_TS_VLAN register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
   (a) Set the Pn_TS_TX_VLAN_LTYPE1_EN/Pn_TS_RX_VLAN_LTYPE1_EN and Pn_TS_TX_VLAN_LTYPE2_EN/Pn_TS_RX_VLAN_LTYPE2_EN bit in the Pn_TS_CTL register.
   (b) Set the Pn_TS_VLAN_LTYPE1 field in the Pn_TS_VLAN register to match the EtherType of the outer tag.
   (c) Set the Pn_TS_VLAN_LTYPE2 field in the Pn_TS_VLAN register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the Pn_TS_MSG_TYPE_EN field in the Pn_TS_CTL register to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-23 lists the message types defined in the IEEE 1588-2008 specification.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-23. Values of Message Type Field**

| Message Type | Value (hex) |
|---|---|
| Sync | 0 |
| Delay_Req | 1 |
| Pdelay_Req | 2 |
| Pdelay_Resp | 3 |
| Reserved | 4-7 |
| Follow_Up | 8 |

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The CPTS_EVENT_HIGH register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_LOW register contains the time stamp value when the packet arrived at the corresponding port.

#### 9.2.2.6 Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_TS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP field (bit 0) of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_TS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP bit of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four VBUSP_CLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

### *9.2.3 CPPI Buffer Descriptors*

The buffer descriptor is a central part of the 3PSW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Copyright © 2011–2016, Texas Instruments Incorporated

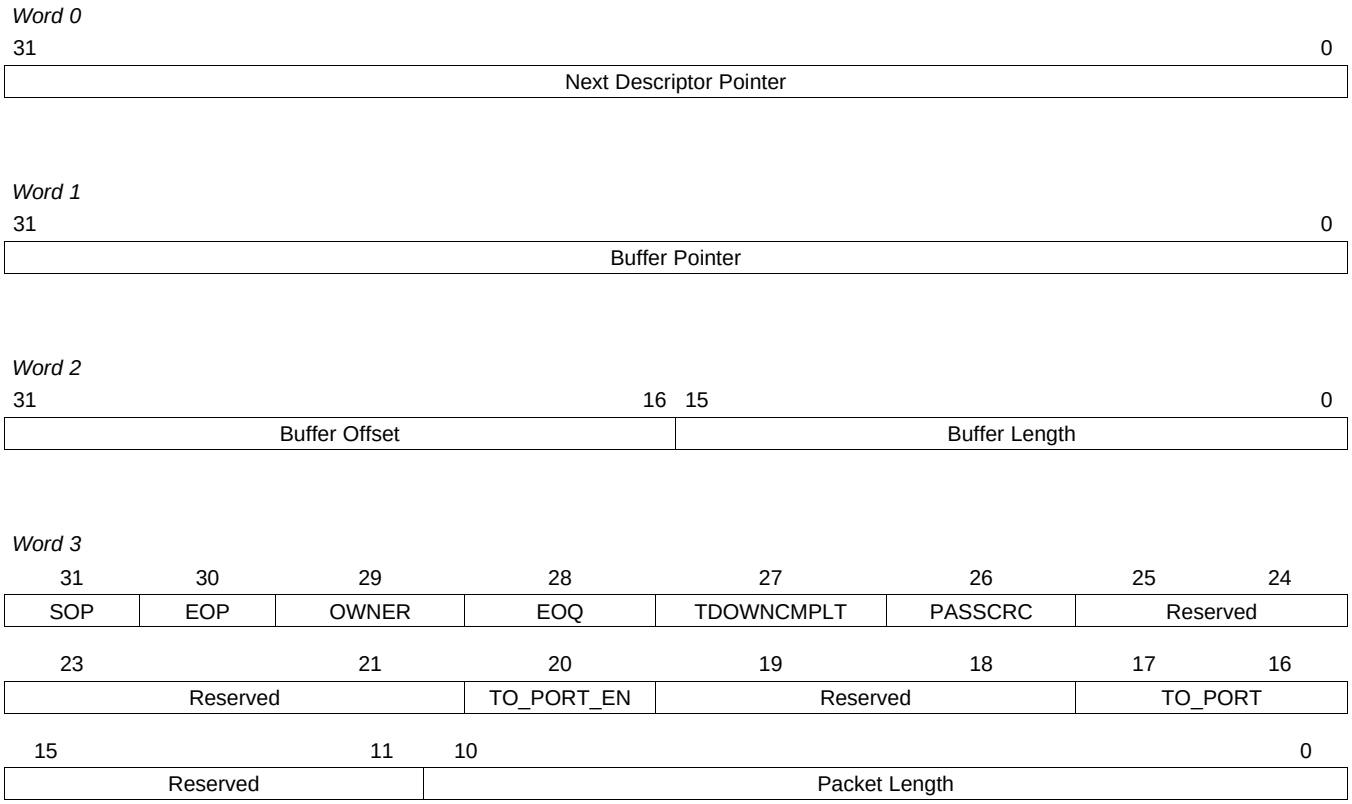
Host Software sends and receives network frames via the CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

**NOTE:** The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 4A10 2000h and end at 4A10 3FFFh from the 3PSW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use the address range from 4A10 2000h.

#### 9.2.3.1 TX Buffer Descriptors

A TX buffer descriptor (Figure 9-12) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 9-12. TX Buffer Descriptor Format**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.3.1.1 CPPI TX Data Word 0

**Next Descriptor Pointer**

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

#### 9.2.3.1.2 CPPI TX Data Word 1

**Buffer Pointer**

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### 9.2.3.1.3 CPPI TX Data Word 2

**Buffer Offset**

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the Buffer_Offset value (which may be zero to the buffer length minus 1). Valid only on SOP.

**Buffer Length**

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer_Length. The Buffer_Length must be greater than zero.

#### 9.2.3.1.4 CPPI TX Data Word 3

**Packet Length**

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

**Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise,,the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

**End of Packet (EOP) Flag**

Copyright © 2011–2016, Texas Instruments Incorporated

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

**Ownership (OWNER) Flag**

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

**End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

**Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

**Pass CRC (PASSCRC) Flag**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

**TO_PORT**

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

Copyright © 2011–2016, Texas Instruments Incorporated

1 - Send the packet to port 1 if TO_PORT_EN is asserted.

2 - Send the packet to port 2 if TO_PORT_EN is asserted.

**TO_PORT_ENABLE**

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

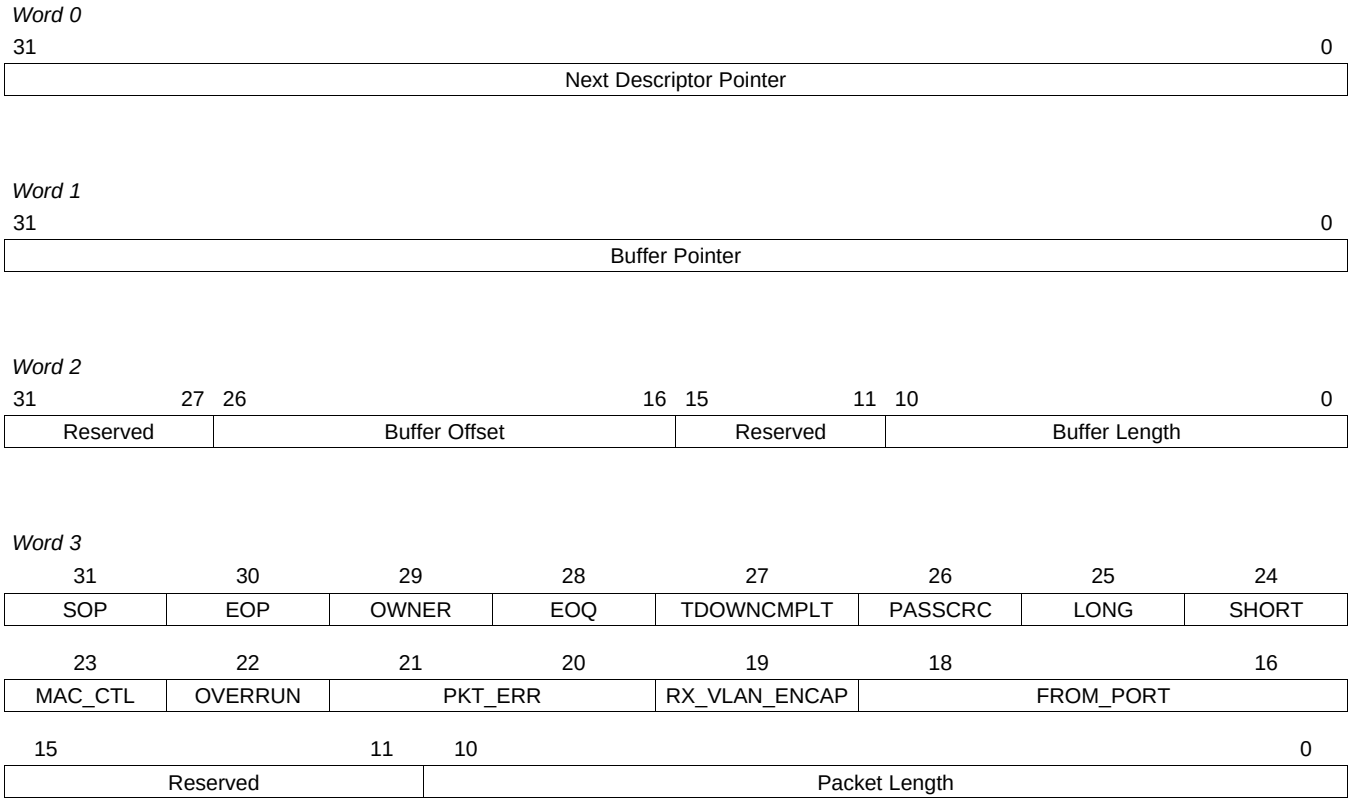
0 - not a directed packet

1 - directed packet

#### 9.2.3.2 RX Buffer Descriptors

A RX buffer descriptor (Figure 9-13) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 9-13. Receive Buffer Descriptor Format**



##### *9.2.3.2.1 CPPI RX Data Word 0*

**Next Descriptor Pointer**

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

##### *9.2.3.2.2 CPPI RX Data Word 1*

**Buffer Pointer**

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.3.2.3 CPPI RX Data Word 2

**Buffer Offset**

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the RX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

**Buffer Length**

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

#### 9.2.3.2.4 CPPI RX Data Word 3

**Packet Length**

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

**Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

**End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

**Ownership (OWNER) Flag**

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

**End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

**Teardown Complete (TDOWNCMPLT) Flag**

Copyright © 2011–2016, Texas Instruments Incorporated

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**Long (Jabber) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the MACCONTROL register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**Short (Fragment) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the MACCONTROL register.

**Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the MACCONTROL register.

**Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

**Packet Error (PKT_ERR) Flag**

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

**VLAN Encapsulated Packet (RX_VLAN_ENCAP)**

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW control register RX_VLAN_ENCAP bit.

**FROM_PORT**

Indicates the port number that the packet was received on (ingress to the switch).

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.2.4 MDIO

The MII Management I/F module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers control and monitor up to two PHYs simultaneously.

#### 9.2.4.1 MII Management Interface Frame Formats

Table 9-24 shows the read format and Table 9-25 shows the write format of the 32-bit MII Management interface frames.

**Table 9-24. MDIO Read Frame Format**

| Pre-amble | Start Delimiter | Operation Code | PHY Address | Register Address | Turnaround | Data |
|---|---|---|---|---|---|---|
| FFFF FFFFh | 01 | 10 | AAAAA | RRRRR | Z0 | DDDD.DDDD.DDDD.DDDD |

**Table 9-25. MDIO Write Frame Format**

| Pre-amble | Start Delimiter | Operation Code | PHY Address | Register Address | Turnaround | Data |
|---|---|---|---|---|---|---|
| FFFF FFFFh | 01 | 01 | AAAAA | RRRRR | 10 | DDDD.DDDD.DDDD.DDDD |

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

**Preamble**

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

**Start Delimiter**

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

**Operation Code**

The operation code for a read is 10, while the operation code for a write is a 01.

**PHY Address**

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

**Register Address**

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

**Turnaround**

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

**Data**

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.4.2 Functional Description

The MII Management I/F will remain idle until enabled by setting the enable bit in the MDIO CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO LINK register. The LINKSEL bit in the MDIO USERPHYSEL register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO LINKINTRAW register and the MDIO LINKINTMASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO USERPHYSEL register.

The MDIO ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO USERACCESS register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO USERINTRAW register corresponding to the MDIO USERACCESS register being used. The corresponding bit in the MDIO USERINTMASKED register may also be set depending on the mask setting in the MDIO USERINTMASKSET and MDIO USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO USERACCESS registers. The host should check the status of the GO bit in the MDIO USERACCESS register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO USERACCESS register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the MACCONTROL register in the corresponding MAC.

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.2.5 Interrupts

The 3Port Switch Ethernet Subsystem generates four interrupt events.

#### 9.2.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the 3PSW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register (RX_EN) . The masked interrupt status can be read in the address location of RX_STAT bit in the receive status register.

When the 3PSW completes a packet reception, the subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX *n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the 3PSW completion pointer(s) (RX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the 3PSW has received more packets than the CPU has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the 3PSW is expecting is found by reading the receive channel *n* completion pointer register (RX *n*_CP).
4. Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the RX_EN register.

The software could still poll for the RX_INTSTAT_RAW and RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

#### 9.2.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the 3PSW TX_PEND [7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the TX_INTMASK_SET register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register TX_EN .The masked interrupt status can be read in the address location of TX_STAT bit in the transmit status register.

Copyright © 2011–2016, Texas Instruments Incorporated

When the 3PSW completes the transmission of a packet, the 3PSW subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the 3PSW completion pointer(s) (TX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the 3PSW (address of last buffer descriptor used by the 3PSW). If the two values are not equal (which means that the 3PSW has transmitted more packets than the CPU has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the 3PSW is expecting is found by reading the transmit channel *n*completion pointer register (TX *n*_CP).
4. Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the TX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the TX_EN register. The software could still poll for the TX_INTSTAT_RAW and TX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

#### 9.2.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
2. he receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register RX_THRESH_EN. The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the receive threshold status register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*_FREEBUFFER is less than or equal to the corresponding RX *n*_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLEAR register.
2. The receive threshold pulse interrupt could be disabled by clearing to Zero the corresponding bits in the RX_THRESH_EN register. The software could still poll for the RX_INTSTAT_RAW and INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.2.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT). The miscellaneous interrupt(s) is selected by setting one or more bits in the MISC_EN register. The masked interrupt status can be read in the MISC_STAT address location. Upon reception of an interrupt, software should perform the following:

1. Read the MISC_STAT address location to determine which caused the interrupt.
2. Process the interrupt.
3. Write the appropriate value (3h) to the CPDMA_EOI_VECTOR register.

**NOTE:** The MISC_STAT register's MDIO_LINKINT and MDIO_USERINT bitfields represent the Port0/Phy0 status. MDIO_LINKINT[1] and MDIO_USERINT[1] are not provided in MISC_STAT register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the LINKINTMASKED or USERINTMASKED registers.

##### *9.2.5.4.1 EVNT_PEND( CPTS_PEND) Interrupt*

See Section 9.2.2 for more details on this interrupt.

##### *9.2.5.4.2 Statistics Interrupt*

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the TX_INTSTAT_RAW and TX_INTSTAT_MASKED registers, respectively.

##### *9.2.5.4.3 Host Error interrupt*

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked statistics interrupt status can be read by reading the TX_INTSTAT_RAW and TXINTSTAT_MASKED registers, respectively.

The transmit host error conditions are:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0
- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The host error interrupt is disabled by clearing to 0 the appropriate bit in the CPDMA_INTMASK_CLEAR register.

#### 9.2.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the USERPHYSEL*n* register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the LINKINTMASKED register. When the GO bit in the USERACCESS*n* register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the USERINTMASKSET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the USERINTMASKED register.

To enable the miscellaneous pulse interrupt:

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (MISC_EN).

- The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the DMA_INTMASK_SET register.
- The HOST_PEND is enabled by setting to 1 the HOST_ERR_INTMASK in the DMA_INTMASK_SET register.

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.2.6 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache. Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 µs pulse that is created from a prescale counter whose value is set in the INT_PRESCALE field in the INT_CONTROL register. The INT_PRESCALE value should be written with the number of VBUSP_CLK periods in 4 µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 µs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
  else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
  else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
  else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
  else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

### 9.2.7 Reset Isolation

Reset isolation for the Ethernet switch on Device is that the switch function of the ethernet IP remains active even in case of all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the 3PSW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related IO and reference clocks needed by the Ethernet switch IP to be active is controlled by a protected control module bit. If reset isolation is enabled, then only a POR pin or ICEPICK COLD reset event should fully reset the Ethernet switch IP including the actual switch and also the reference clocks and pin mux control specifically associated with the Ethernet IP.

#### 9.2.7.1 Modes of Operation

The device has two modes of operation concerning the reset of the 3PSW Ethernet switch. The mode is controlled by the ISO_CONTROL bit in the RESET_ISO register of the device Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the ISO_CONTROL bit and to the lock register must all be supervisor mode writes.

**Mode1: ISO_CONTROL = 0 (reset isolation disabled)**

1. This mode is selected when the ISO_CONTROL bit = 0. This should be the default state of the bit after control module reset.
2. Upon any device level resets, the entire CPSW_3GSS_R IP, SATA_SS, SATA SERDES PLL, L3/L4, control module (including all pin mux control and the ISO_CONTROL bit) is immediately reset.

**Mode2: ISO_CONTROL = 1 (reset isolation enabled)**

1. This mode is selected when the ISO_CONTROL bit = 1.
2. Upon any device reset source other than POR pin or ICEPICK cold (so this includes SW global cold, any watchdog reset, warm RESETn pin, ICEPICK warm, SW global warm or security violation), the following should be true:
   (a) The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the IP are reset.
   (b) The 50 MHz and 125 MHz reference clocks to the 3PSW Ethernet Subsystem remains active throughout the entire reset condition.
   (c) The control for pin multiplexing for all of the signals should maintain their current configuration throughout the entire reset condition.
   (d) The reset isolated logic inside 3PSW Ethernet Subsystem IP which maintains the switch functionality
3. Upon any cold reset sources, the entire 3PSW Ethernet Subsystem, SATA SERDES PLL, control module (including all pin mux control and the ISO_CONTROL bit itself) is reset.

For more details on the register configuration, see the Control Module RESET_ISO register.

### 9.2.8 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP_RST_N. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing FFFF FFFFh clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

See Section 9.4 for more details on the registers.

## 9.3 Software Operation

### 9.3.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (ram). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

Copyright © 2011–2016, Texas Instruments Incorporated

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

### 9.3.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.
5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start

Copyright © 2011–2016, Texas Instruments Incorporated

of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

### 9.3.3 MDIO Software Interface

#### 9.3.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL*n*), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS*n*). Since only one PHY is used in this device, the application software can use one USERACCESS*n* to trigger a completion interrupt; the other USERACCESS*n* is not setup.

#### 9.3.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS*n* corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS *n* for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS *n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

#### 9.3.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS *n*) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS*n* corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS*n* after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS*n*. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

### 9.3.4 Initialization and Configuration of CPSW

To configure the 3PSW Ethernet Subsystem for operation the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the 3PSW Ethernet Subsystem Clocks
4. Configure the PRCM registers CM_ETHERNET_CLKSTCTRL, CM_ALWON_ETHERNET_0_CLKCTRL to enable power and clocks to 3PSW Ethernet Subsystem.
5. Apply Soft Reset to 3PSW Subsystem, CPSW_3G, CPGMAC_SL1/2, and CPDMA
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the CPSW_3G CONTROL register
9. Configure the Statistics Port Enable register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure CPGMAC_SL1 and CPGMAC_SL2, as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

## 9.4 Registers

### 9.4.1 CPSW_3G Module

This section describes the memory-mapped registers for the CPSW_3G module. The base address of the CPSW_3G registers is 4A10 0000h. Table 9-26 lists the memory-mapped registers for the CPSW_3G module.

**Table 9-26. CPSW_3G Module Registers**

| Offset | Acronym | Register Name |
|---|---|---|
| 000h | CPSW_ID_VER | CPSW ID Version Register |
| 004h | CPSW_CONTROL | CPSW Switch Control Register |
| 008h | CPSW_SOFT_RESET | CPSW Soft Reset Register |
| 00Ch | CPSW_STAT_PORT_EN | CPSW Statistics Port Enable Register |
| 010h | CPSW_PTYPE | CPSW Transmit Priority Type Register |
| 014h | CPSW_SOFT_IDLE | CPSW Software Idle Register |
| 018h | CPSW_THRU_RATE | CPSW Throughput Rate Register |
| 01Ch | CPSW_GAP_THRESH | CPSW CPGMAC_SL Short Gap Threshold Register |
| 020h | CPSW_TX_START_WDS | CPSW Transmit Start Words Register |
| 024h | CPSW_FLOW_CONTROL | CPSW Flow Control Register |
| 028h | P0_MAX_BLKS | CPSW Port 0 Maximum FIFO Blocks Register |
| 02Ch | P0_BLK_CNT | CPSW Port 0 FIFO Block Usage Count Register (read only) |
| 030h | P0_TX_IN_CTL | CPSW Port 0 Transmit FIFO Control Register |
| 034h | P0_PORT_VLAN | CPSW Port 0 VLAN Register |
| 038h | P0_TX_PRI_MAP | CPSW Port 0 TX Header Priority to Switch Priority Mapping Register |
| 03Ch | CPDMA_TX_PRI_MAP | CPSW CPDMA TX (Port 0 RX) Packet Priority to Header Priority Mapping Register |
| 040h | CPDMA_RX_CH_MAP | CPSW CPDMA RX (Port 0 TX) Switch Priority to DMA channel Mapping Register |
| 050h | P1_MAX_BLKS | CPSW Port 1 Maximum FIFO Blocks Register |
| 054h | P1_BLK_CNT | CPSW Port 1 FIFO Block Usage Count Register (read only) |
| 058h | P1_TX_IN_CTL | CPSW Port 1 Transmit FIFO Control Register |
| 05Ch | P1_PORT_VLAN | CPSW Port 1 VLAN Register |
| 060h | P1_TX_PRI_MAP | CPSW Port 1 TX Header Priority to Switch Priority Mapping Register |
| 064h | P1_TS_CTL | CPSW_3G Port 1 Time Sync Control Register |
| 068h | P1_TS_SEQ_LTYPE | CPSW_3G Port 1 Time Sync LTYPE Register (and SEQ_ID_OFFSET) |
| 06Ch | P1_TS_VLAN | CPSW_3G Port 1 Time Sync VLAN2 and VLAN2 Register |
| 070h | SL1_SA_LO | CPSW CPGMAC_SL1 Source Address Low Register |
| 074h | SL1_SA_HI | CPSW CPGMAC_SL1 Source Address High Register |
| 078h | P1_SEND_PERCENT | CPSW Port 1 Transmit Queue Send Percentages Register |
| 090h | P2_MAX_BLKS | CPSW Port 2 Maximum FIFO Blocks Register |
| 094h | P2_BLK_CNT | CPSW Port 2 FIFO Block Usage Count Register (read only) |
| 098h | P2_TX_IN_CTL | CPSW Port 2 Transmit FIFO Control Register |
| 09Ch | P2_PORT_VLAN | CPSW Port 2 VLAN Register |
| 0A0h | P2_TX_PRI_MAP | CPSW Port 2 TX Header Priority to Switch Priority Mapping Register |
| 0A4h | P2_TS_CTL | CPSW_3GF Port 2 Time Sync Control Register |
| 0A8h | P2_TS_SEQ_LTYPE | CPSW_3GF Port 2 Time Sync LTYPE Register (and SEQ_ID_OFFSET) |
| 0ACh | P2_TS_VLAN | CPSW_3GF Port 2 Time Sync VLAN2 and VLAN2 Register |
| 0B0h | SL2_SA_LO | CPSW CPGMAC_SL2 Source Address Low Register |
| 0B4h | SL2_SA_HI | CPSW CPGMAC_SL2 Source Address High Register |
| 0B8h | P2_SEND_PERCENT | CPSW Port 2 Transmit Queue Send Percentages |
| 100h | TX_IDVER | CPDMA_REGS TX Identification and Version Register |

**Table 9-27. Register Bit Definitions**

| Term | Definition |
|---|---|
| w | A writeable bit or field |
| wc | A Write-to-clear bit. Writing a bit of this type with a one will clear the bit to zero. Writing a zero to a bit of this type has no effect. |
| ws | A Write-to-set bit. Writing a bit of this type with a one will set the bit to one. Writing a zero to a bit of this type has no effect. |
| wi | A Write-to-increment field. Writing a value to this field increments the field value by the value written. Reads are permitted and do not alter the field value. |
| wd | A Write-to-decrement field. Writing a value to this field decrements the field by the value written. Reads are permitted and do not alter the field value. |
| r | A readable bit or field |

### 9.4.1.2 CPSW Control Register (CPSW_CONTROL) (0x004)

**Figure 9-17. CPSW Control Register (CPSW_CONTROL)**

| 31 | 8 |
|---|---|
| Reserved | |
| R-0 | |

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | | P2_PASS_PRI_TAGGED | P1_PASS_PRI_TAGGED | P0_PASS_PRI_TAGGED | RX_VLAN_ENCAP | VLAN_AWARE | FIFO_LOOPBACK |
| R-0 | | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-29. CPSW Control Register (CPSW_CONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-6 | Reserved | 0 | Read as zero. |
| 5 | P2_PASS_PRI_TAGGED | | Port 2 Pass Priority Tagged |
| | | 0 | Priority tagged packets have the zero VID replaced with the input port P2_PORT_VLAN[11:0] |
| | | 1 | Priority tagged packets are processed unchanged. |
| 4 | P1_PASS_PRI_TAGGED | | Port 1 Pass Priority Tagged |
| | | 0 | Priority tagged packets have the zero VID replaced with the inputport P1_PORT_VLAN[11:0] |
| | | 1 | Priority tagged packets are processed unchanged. |
| 3 | P0_PASS_PRI_TAGGED | | Port 0 Pass Priority Tagged |
| | | 0 | Priority tagged packets have the zero VID replaced with the inputport P0_PORT_VLAN[11:0] |
| | | 1 | Priority tagged packets are processed unchanged. |
| 2 | RX_VLAN_ENCAP | | Port 0 VLAN Encapsulation (egress) |
| | | 0 | Port 0 receive packets (from CPSW_3G) are not VLAN encapsulated. |
| | | 1 | Port 0 receive packets (from CPSW_3G) are VLAN encapsulated. |
| 1 | VLAN_AWARE | | VLAN Aware Mode |
| | | 0 | CPSW_3G is in the VLAN unaware mode. |
| | | 1 | CPSW_3G is in the VLAN aware mode. |
| 0 | FIFO_LOOPBACK | | FIFO Loopback Mode |
| | | 0 | Loopback is disabled |
| | | 1 | FIFO Loopback mode enabled. Each packet received is turned around and sent out on the same port's transmit path. Port 2 receive is fixed on channel zero. The RXSOFOVERRUN statistic will increment for every packet sent in FIFO loopback mode. |

### 9.4.1.3 CPSW Software Reset Register (CPSW_SOFT_RESET) (0x008)

**Figure 9-18. CPSW Software Reset Register (CPSW_SOFT_RESET)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | SOFT_RESET |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-30. CPSW Software Reset Register (CPSW_SOFT_RESET) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Read as zero. |
| 0 | SOFT_RESET | | Software reset |
| | | 0 | If a zero is read then reset has occurred. |
| | | 1 | Writing a one to this bit causes the CPSW_3G logic to be reset. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. |

### 9.4.1.4 CPSW Statistics Port Enable Register (CPSW_STAT_PORT_EN) (0x00C)

**Figure 9-19. CPSW Statistics Port Enable Register (CPSW_STAT_PORT_EN)**

| 31 | 16 |
|---|---|

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 9-32. CPSW Transmit Priority Type Register (CPSW_PTYPE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-22 | Reserved | 0 | Read as zero. |
| 21 | P2_PRI3_SHAPE_EN | 0-1 | Port 2 Queue Priority 3 Transmit Shape Enable<br>If there is only one shaping queue then it must be priority 3. |
| 20 | P2_PRI2_SHAPE_EN | 0-1 | Port 2 Queue Priority 2 Transmit Shape Enable<br>If there are two shaping queues then they must be priorities 3 and 2. |
| 19 | P2_PRI1_SHAPE_EN | 0-1 | Port 2 Queue Priority 1 Transmit Shape Enable<br>If there are three shaping queues all three bits should be set. |
| 18 | P1_PRI3_SHAPE_EN | 0-1 | Port 1 Queue Priority 3 Transmit Shape Enable<br>If there is only one shaping queue then it must be priority 3. |
| 17 | P1_PRI2_SHAPE_EN | 0-1 | Port 1 Queue Priority 2 Transmit Shape Enable<br>If there are two shaping queues then they must be priorities 3 and 2. |
| 16 | P1_PRI1_SHAPE_EN | 0-1 | Port 1 Queue Priority 1 Transmit Shape Enable<br>If there are three shaping queues all three bits should be set. |
| 15-11 | Reserved | 0 | Read as zero. |
| 10 | P2_PTYPE_ESC | | Port 2 Priority Type Escalate |
| | | 0 | Port 2 priority type fixed |
| | | 1 | Port 2 priority type escalate. Escalate should not be used with queue shaping. |
| 9 | P1_PTYPE_ESC | | Port 1 Priority Type Escalate |
| | | 0 | Port 1 priority type fixed |
| | | 1 | Port 1 priority type escalate. Escalate should not be used with queue shaping. |
| 8 | P0_PTYPE_ESC | | Port 0 Priority Type Escalate |
| | | 0 | Port 0 priority type fixed |
| | | 1 | Port 0 priority type escalate. Escalate should not be used with queue shaping. |
| 7-5 | Reserved | 0 | Read as zero. |
| 4-0 | ESC_PRI_LD_VAL | 0-1Fh | Escalate Priority Load Value When a port is in escalate priority, this is the number of higher priority packets sent before the next lower priority is allowed to send a packet. Escalate priority allows lower priority packets to be sent at a fixed rate relative to the next higher priority. |

### 9.4.1.29 CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKS) (0x090)

**Figure 9-44. CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKS)**

| 31 9 | 8 4 | 3 0 |
|---|---|---|
| Reserved | P2_TX_MAX_BLKS | P2_RX_MAX_BLKS |
| R-0 | R/W-11h | R/W-3h |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-56. CPSW Port 2 Maximum FIFO Blocks Register (P2_MAX_BLKS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | Read as zero. |
| 8-4 | P2_TX_MAX_BLKS | 0-1Fh | Transmit FIFO Maximum Blocks<br>This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 11h is the recommended value of P2_TX_MAX_BLKS unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKS will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKS. Eh is the minimum value TX_MAX_BLKS. |
| 3-0 | P2_RX_MAX_BLKS | 0-Fh | Receive FIFO Maximum Blocks<br>This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 3h. It should be increased In fullduplex flow control mode to 5h or 6h, depending on the required runout space. The P2_TX_MAX_BLKS value must be decreased by the amount of increase in P2_RX_MAX_BLKS. 3h is the minimum value RX_MAX_BLKS and 6h is the maximum value. |

### 9.4.1.45 CPDMA_REGS RX Teardown Register (RX_TEARDOWN) (0x118)

**Figure 9-60. CPDMA_REGS RX Teardown Register (RX_TEARDOWN)**

| 31 | 30 3 | 2 0 |
|---|---|---|
| RX_TDN_RDY | Reserved | RX_TDN_CH |
| R-0 | R-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-72. CPDMA_REGS RX Teardown Register (RX_TEARDOWN) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | RX_TDN_RDY | | Teardown Ready. Read as zero, but is always assumed to be one (unused). |
| 30-3 | Reserved | 0 | Read as zero |
| 2-0 | RX_TDN_CH | | RX Teardown Channel. Transmit channel teardown is commanded by writing the encoded value of the transmit channel to be torn down. The teardown register is read as zero. |
| | | 0-7h | Teardown transmit channel 0 to teardown transmit channel 7 |

### 9.4.1.46 CPDMA_REGS Software Reset Register (SOFT_RESET) (0x11C)

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-61. CPDMA_REGS Software Reset Register (SOFT_RESET)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | SOFT_RESET |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-73. CPDMA_REGS Software Reset Register (SOFT_RESET) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Read as zero |
| 0 | SOFT_RESET | | Software reset. Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred. |

### 9.4.1.47 CPDMA_REGS Control Register (DMACONTROL) (0x120)

**Figure 9-62. CPDMA_REGS Control Register (DMACONTROL)**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 8 |
|---|---|
| TX_RLIM | |
| R/W-0 | |

| 7 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|
| Reserved | | RX_CEF | CMD_IDLE | RX_OFFLEN_BLOCK | RX_OWNERSHIP | TX_PTYPE |
| R-0 | | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-74. CPDMA_REGS Control Register (DMACONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Read as zero |
| 15-8 | TX_RLIM | | Transmit Rate Limit Channel Bus |
| | | 0 | No rate-limited channels |
| | | 80h | Channel 7 is rate-limited |
| | | C0h | Channels 7 to 6 are rate-limited |
| | | E0h | Channels 7 to 5 are rate-limited |
| | | F0h | Channels 7 to 4 are rate-limited |
| | | F8h | Channels 7 to 3 are rate-limited |
| | | FCh | Channels 7 to 2 are rate-limited |
| | | FEh | Channels 7 to 1 are rate-limited |
| | | FFh | Channels 7 to 0 are rate-limited |
| | | | All others invalid – this bus must be set MSB towards LSB. TX_PTYPE must be set, if any TX_RLIM bit is set for fixed priority. |
| 7-5 | Reserved | 0 | Read as zero |
| 4 | RX_CEF | | RX Copy Error Frames Enable. Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. |
| | | 0 | Frames containing overrun errors are filtered. |
| | | 1 | Frames containing overrun errors are transferred to memory. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-74. CPDMA_REGS Control Register (DMACONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 3 | CMD_IDLE | | Command Idle |
| | | 0 | Idle not commanded |
| | | 1 | Idle Commanded (read idle in DMAStatus) |
| 2 | RX_OFFLEN_BLOCK | | Receive Offset/Length word write block |
| | | 0 | Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. |
| | | 1 | Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor. |
| 1 | RX_OWNERSHIP | | Receive Ownership Write Bit Value |
| | | 0 | The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. |
| | | 1 | The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used. |
| 0 | TX_PTYPE | | Transmit Queue Priority Type |
| | | 0 | The queue uses a round robin scheme to select the next channel for transmission. |
| | | 1 | The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission. |

### 9.4.1.48 CPDMA_REGS Status Register (DMASTATUS) (0x124)

**Figure 9-63. CPDMA_REGS Status Register (DMASTATUS)**

| 31 | 30 | 24 | 23 | 20 | 19 | 18 | 16 |
|---|---|---|---|---|---|---|---|
| IDLE | Reserved | | TX_HOST_ERR_CODE | | Rsvd | TX_ERR_CH | |
| R-0 | R-0 | | R-0 | | R-0 | R-0 | |

| 15 | 12 | 11 | 10 | 8 | 7 | 0 |
|---|---|---|---|---|---|---|
| RX_HOST_ERR_CODE | | Rsvd | RX_ERR_CH | | Reserved | |
| R-0 | | R-0 | R-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-75. CPDMA_REGS Status Register (DMASTATUS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | IDLE | | Idle Status Bit – Indicates when set that the CPDMA is not transferring a packet on transmit or receive. |
| 30-24 | Reserved | 0 | Read as zero |
| 23-20 | TX_HOST_ERR_CODE | | TX Host Error Code – This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. |
| | | 0 | No error |
| | | 1h | SOP error |
| | | 2h | Ownership bit not set in SOP buffer |
| | | 3h | Zero Next Buffer Descriptor Pointer Without EOP |
| | | 4h | Zero Buffer Pointer |
| | | 5h | Zero Buffer Length |
| | | 6h | Packet Length Error (sum of buffers < packet length) |
| | | 7h-Fh | Reserved |
| 19 | Reserved | 0 | Read as zero |
| 18-16 | TX_ERR_CH | | TX Host Error Channel – This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read. |
| | | 0-7h | The host error occurred on TX channel 0 to TX channel 7 |
| 15-12 | RX_HOST_ERR_CODE | | RX Host Error Code – This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. |
| | | 0 | No error |
| | | 1h | Reserved |
| | | 2h | Ownership bit not set in input buffer |
| | | 3h | Reserved |
| | | 4h | Zero Buffer Pointer |
| | | 5h | Zero buffer length on non-SOP descriptor |
| | | 6h | SOP buffer length not greater than offset |
| | | 7h-Fh | Reserved |
| 11 | Reserved | 0 | Read as zero |
| 10-8 | RX_ERR_CH | | RX Host Error Channel – This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read. |
| | | 0-7h | The host error occurred on RX channel 0 to RX channel 7 |
| 7-0 | Reserved | 0 | Read as zero |

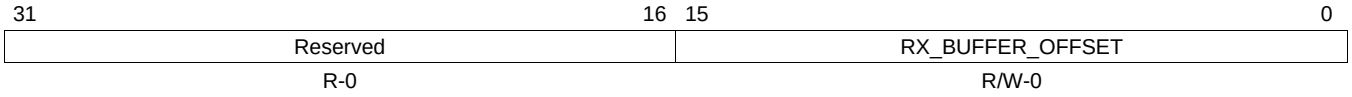
### 9.4.1.49 CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET) (0x128)

**Figure 9-64. CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET)**



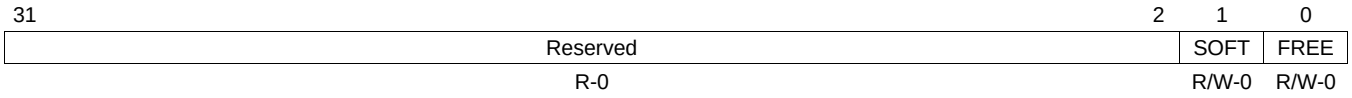
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-76. CPDMA_REGS Receive Buffer Offset Register (RX_BUFFER_OFFSET) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Read as zero |
| 15-0 | RX_BUFFER_OFFSET | | Receive Buffer Offset Value. The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor BUFFER_OFFSET field. The frame data will begin after the RX_BUFFER_OFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

### 9.4.1.50 CPDMA_REGS Emulation Control Register (EMCONTROL) (0x12C)

**Figure 9-65. CPDMA_REGS Emulation Control Register (EMCONTROL)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-77. CPDMA_REGS Emulation Control Register (EMCONTROL) Field Descriptions**

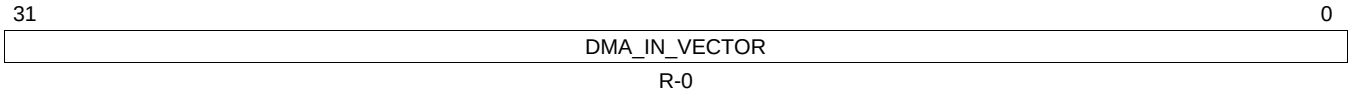
### 9.4.1.56 CPDMA_INT Input Vector (CPDMA_IN_VECTOR) (0x190)

**Figure 9-71. CPDMA_INT Input Vector (CPDMA_IN_VECTOR)**



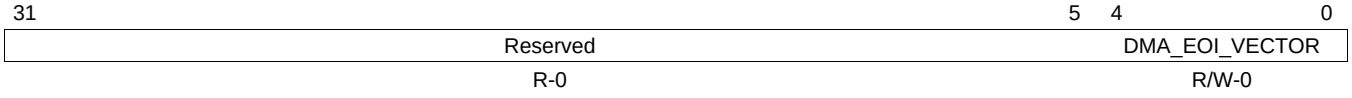
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-83. CPDMA_INT Input Vector (CPDMA_IN_VECTOR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | DMA_IN_VECTOR | 0-FFFF FFFFh | DMA Input Vector. The value of DMA_IN_VECTOR is reset to zero, but will change to the **IN_VECTOR** bus value one clock after reset is deasserted. Thereafter, this value will change to a new **IN_VECTOR** value one clock after the **IN_VECTOR** value changes. |

### 9.4.1.57 CPDMA_INT End Of Interrupt Vector (CPDMA_EOI_VECTOR) (0x194)

**Figure 9-72. CPDMA_INT End Of Interrupt Vector (CPDMA_EOI_VECTOR)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-84. CPDMA_INT End Of Interrupt Vector (CPDMA_EOI_VECTOR) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-5 | Reserved | 0 | Read as zero. |
| 4-0 | DMA_EOI_VECTOR | 0-1Fh | DMA End of Interrupt Vector. The **EOI_VECTOR(4:0)** pins reflect the value written to this location one **CLK** cycle after a write to this location. The **EOI_WR** signal is asserted for a single clock cycle after a latency of two **CLK** cycles when a write is performed to this location. |

| Reserved | | RX(0..7)_FREEBUF | |
| R-0 | | WI-0 | |

LEGEND: R/W = Read/Write; WI = Write to increment field; R = Read only; -*n* = value after reset

**Table 9-94. CPDMA_INT RX Channel Free Buffer Count Registers Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Read as zero. |
| 15-0 | RX(0..7)_FREEBUF | 0-FFFFh | RX Free Buffer Count. This field contains the count of free buffers available. The RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing. |

### 9.4.1.68 CPDMA_STATERAM TX Channel Head Descriptor Pointers (TX0_HDP-TX7_HDP) (0x200-0x21C)

**Figure 9-83. CPDMA_STATERAM TX Channel Head Descriptor Pointers**

| 31 | 0 |
|---|---|
| TX(0..7)_HDP | |
| R/W-X | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; X = Unknown

**Table 9-95. CPDMA_STATERAM TX Channel Head Descriptor Pointers Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | TX(0..7)_HDP | 0-FFFF FFFFh | TX Channel (0..7) DMA Head Descriptor Pointer. Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.4.1.69 CPDMA_STATERAM RX Channel Head Descriptor Pointers (RX0_HDP-RX7_HDP) (0x220-0x23C)

**Figure 9-84. CPDMA_STATERAM RX Channel Head Descriptor Pointers**

| 31 | 0 |
|---|---|
| RX(0..7)_HDP | |
| R/W-X | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; X = Unknown

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | TX(0..7)_CP | 0-FFFF FFFFh | TX Completion Pointer Register. This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted. |

### 9.4.1.71 CPDMA_STATERAM RX Channel Completion Pointer Registers (RX0_CP-RX7_CP) (0x260-0x27C)

The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.

**Figure 9-86. CPDMA_STATERAM RX Channel Completion Pointer Registers**

| 31 | 0 |
|---|---|
| RX(0..7)_CP | |
| R/W-X | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; X = Unknown

### 9.4.1.72 RX (only) Statistics Descriptions (0x400-0x430)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see Figure 9-87) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

**Figure 9-87. Statistics Register**

| 31 | 0 |
|---|---|
| COUNT | |
| R/WD-0 | |

LEGEND: R/W = Read/Write; WD = Write to decrement; -*n* = value after reset

#### *9.4.1.72.1 Good RX Frames (0x400)*

The total number of good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### *9.4.1.72.2 Broadcast RX Frames (0x404)*

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- any data or MAC control frame which was destined for address FFFF FFFF FFFFh only, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### *9.4.1.72.3 Multicast RX Frames (0x408)*

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- any data or MAC control frame which was destined for any multicast address other than FFFF FFFF FFFFh, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.72.4 Pause RX Frames (0x40C)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0001h, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error, and
- pause-frames had been enabled on the port (tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic

#### 9.4.1.72.5 RX CRC Errors (0x410)

The total number of frames received on the port that experienced a CRC error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no code/align error, and
- had a CRC error.

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- a frame containing an even number of nibbles, and
- fails the Frame Check Sequence test.

#### 9.4.1.72.6 RX Align/Code Errors (0x414)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had either an alignment error or a code error.

Over-runs have no effect upon this statistic.

An alignment error is defined to be:

- a frame containing an odd number of nibbles, and
- also fails the Frame Check Sequence test if the final nibble is ignored.

A code error is defined to be:

- a frame which has been discarded because the ports **MRXER** pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing **RX Align/Code Errors** and **RX CRC errors**.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.72.7 Oversize RX Frames (0x418)

The total number of oversized frames received on the port. An oversized frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than RX_MAXLEN in bytes, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 9.4.1.72.8 RX Jabbers (0x41C)

The total number of jabber frames received on the port. A jabber frame is:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than RX_MAXLEN bytes long, and
- had a CRC error, an alignment error, or a code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 9.4.1.72.9 Undersize (Short) RX Frames (0x420)

The total number of undersized frames received on the port. An undersized frame is defined to be:

- any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was less than 64 bytes long, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 9.4.1.72.10 RX Fragments (0x424)

The total number of frame fragments received on the port. A frame fragment is defined to be:

- any data frame (address matching does not matter), and
- was less than 64 bytes long, and
- had a CRC error, an alignment error, or a code error, and
- was not the result of a collision caused by half duplex, collision based flow control.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 9.4.1.72.11 RX Octets (0x430)

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to RX_MAXLEN bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **RX Align/Code Errors** and **RX CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.72.12 RX Start of Frame Overruns (0x484)

The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations. SOF overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations.

#### 9.4.1.72.13 RX Middle of Frame Overruns (0x488)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- the CPDMA had a middle of frame overrun.

#### 9.4.1.72.14 RX DMA Overruns (0x48C)

The total number of frames received on the port that had either a DMA start of frame (SOF) overrun or a DMA MOF overrun. An RX DMA overrun frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > RX_MAXLEN bytes), and
- the CPGMAC_SL was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors and code errors have no effect upon this statistic.

### 9.4.1.73 TX (only) Statistics Descriptions (0x434 -0x464)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see Figure 9-88) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

The maximum and minimum transmit frame size is software controllable.

**Figure 9-88. Statistics Register**

| R/WD-0 | |

LEGEND: R/W = Read/Write; WD = Write to decrement; -*n* = value after reset

#### *9.4.1.73.1 Good TX Frames (0x434)*

The total number of good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

#### *9.4.1.73.2 Broadcast TX Frames (0x438)*

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- any data or MAC control frame destined for address FFFF FFFF FFFFh only, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun

#### *9.4.1.73.3 Multicast TX Frames (0x43C)*

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- any data or MAC control frame destined for any multicast address other than FFFF FFFF FFFFh, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.73.4 Pause TX Frames (0x440)

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the **TX Multicast Frames** and **64octect Frames** statistics.

#### 9.4.1.73.5 Deferred TX Frames (0x444)

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced no collisions before being successfully transmitted, and
- found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic

See RFC1623 Ref. 2.6 dot3StatsDefferredTransmissions.

#### 9.4.1.73.6 Collisions (0x448)

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

- When a transmit data or MAC control frame...
- was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions).

CRC errors have no effect upon this statistic.

- When the port is in half-duplex mode, flow control is active, and a frame reception begins.

#### 9.4.1.73.7 Single Collision TX Frames (0x44C)

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.73.8 Multiple Collision TX Frames (0x450)

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### 9.4.1.73.9 Excessive Collisions (0x454)

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### 9.4.1.73.10 Late Collisions (0x458)

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The **Late Collisions** statistic dominates over the **single, multiple,** and **excessive Collisions** statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect upon this statistic.

#### 9.4.1.73.11 TX Underrun (0x45C)

There should be no transmitted frames that experience underrun.

#### 9.4.1.73.12 Carrier Sense Errors (0x460)

The total number of frames on the port that experienced carrier loss. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- the carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.
- CRC errors and underrun have no effect upon this statistic.

#### 9.4.1.73.13 TX Octets (0x464)

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no late or excessive collisions, no carrier loss and no underrun.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.74 RX and TX (shared) Statistics Descriptions (0x468-0x480)

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero, 38 clocks after the rising edge of reset. When the GMII_EN bit in the MAC control register is set, all statistics registers (see Figure 9-89) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMII_EN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

LEGEND: R/W = Read/Write; WD = Write to decrement; -*n* = value after reset

##### *9.4.1.74.1 RX + TX 64 Octet Frames (0x468)*

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

##### *9.4.1.74.2 RX + TX 65-127 Octet Frames (0x46C)*

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 65 to 127 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

##### *9.4.1.74.3 RX + TX 128-255 Octet Frames (0x470)*

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 128 to 255 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

For RX reference only, see RFC1757 Ref. 1.13 etherStatsPkts128to255Octets.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 9.4.1.74.4 RX + TX 256-511 Octet Frames (0x474)

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 256 to 511 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 9.4.1.74.5 RX + TX 512-1023 Octet Frames (0x478)

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 512 to 1023 bytes long.

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### 9.4.1.74.6 RX + TX 1024_Up Octet Frames (0x47C)

The total number of frames of size 1024 to RX_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 1024 to RX_MAXLEN bytes long on receive, or any size on transmit.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 9.4.1.74.7 Network Octet Frames (0x480)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RX_MAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

**Table 9-101. Reference Clock Select Register (CPTS_RFTCLK_SEL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-5 | Reserved | 0 | Reserved |
| 4-0 | RFTCLK_SEL | 0-1Fh | Reference Clock Select. This signal is used to control an external multiplexer that selects one of up to 32 clocks for time sync reference (RFTCLK). This RFTCLK_SEL value can be written only when the CPTS_EN bit is cleared to 0 in the TS_Control register. |

### 9.4.1.78 Time Stamp Event Push Register (CPTS_TS_PUSH) (0x50C)

**Figure 9-93. Time Stamp Event Push Register (CPTS_TS_PUSH)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | TS_PUSH |
| R-0 | | W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-102. Time Stamp Event Push Register (CPTS_TS_PUSH) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved |
| 0 | TS_PUSH | 0-1 | Time stamp event push. When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero. |

### 9.4.1.79 Time Stamp Load Value Register (CPTS_TS_LOAD_VAL) (0x510)

**Figure 9-94. Time Stamp Load Value Register (CPTS_TS_LOAD_VAL)**

| 31 | 0 |
|---|---|
| TS_LOAD_VAL | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-103. Time Stamp Load Value Register (CPTS_TS_LOAD_VAL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | TS_LOAD_VAL | 0-FFFF FFFFh | Time Stamp Load Value. Writing the TS_LOAD_EN bit in the CPTS_TS_LOAD_EN register causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register. |

### 9.4.1.80 Time Stamp Load Enable Register (CPTS_TS_LOAD_EN) (0x514)

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 9-95. Time Stamp Load Enable Register (CPTS_TS_LOAD_EN)**

| 31 | 1 | 0 |
|---|---|---|

| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-112. ALE Control Register (ALE_CONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | ENABLE_ALE | 0-1 | Enable ALE |
| 30 | CLEAR_TABLE | 0-1 | Clear ALE address table. Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero. |
| 29 | AGE_OUT_NOW | 0-1 | Age Out Address Table Now. Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case. |
| 28-8 | Reserved | 0 | Reserved |
| 7 | LEARN_NO_VID | | Learn No VID |
| | | 0 | VID is learned with the source address |
| | | 1 | VID is not learned with the source address (source address is not tied to VID). |
| 6 | EN_VID0_MODE | | Enable VLAN ID = 0 Mode |
| | | 0 | Process the packet with VID = PORT_VLAN[11:0]. |
| | | 1 | Process the packet with VID = 0. |
| 5 | ENABLE_OUI_DENY | 0-1 | Enable OUI Deny Mode. When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set. |
| 4 | ALE_BYPASS | 0-1 | ALE Bypass. When set, all packets received on ports 1 and 2 are sent to the host (only to the host). |
| 3 | RATE_LIMIT_TX | | Rate Limit Transmit mode |
| | | 0 | Broadcast and multicast rate limit counters are received port based |
| | | 1 | Broadcast and multicast rate limit counters are transmit port based. |
| 2 | ALE_VLAN_AWARE | | ALE VLAN Aware. Determines what is done if VLAN not found. |
| | | 0 | Flood if VLAN not found |
| | | 1 | Drop packet if VLAN not found |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-112. ALE Control Register (ALE_CONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 1 | ENABLE_AUTH_MODE | | Enable MAC Authorization Mode. Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). |
| | | 0 | The ALE is not in MAC authorization mode |
| | | 1 | The ALE is in MAC authorization mode |
| 0 | ENABLE_RATE_LIMIT | | Enable Broadcast and Multicast Rate Limit |
| | | 0 | Broadcast/Multicast rates not limited |
| | | 1 | Broadcast/Multicast packet reception limited to the port control register rate limit fields. |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 9-119. ALE Port Control Registers Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-24 | BCAST_LIMIT | 0-FFh | Broadcast packet rate limit. Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field. |
| 23-16 | MCAST_LIMIT | 0-FFh | Multicast Packet Rate Limit. Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field. |
| 15-5 | Reserved | 0 | Reserved |
| 4 | MCAST_LIMIT | 0-1 | No Learn Mode. When set the port is disabled from learning or updating source addresses. |
| 3 | VID_INGRESS_CHECK | 0-1 | VLAN ID Ingress Check. If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped. |
| 2 | DROP_UNTAGGED | 0-1 | Drop Untagged Packets. Drop non-VLAN tagged ingress packets. |
| 1-0 | PORT_STATE | | Port State |
| | | 0 | Disabled |
| | | 1h | Blocked |
| | | 2h | Learn |
| | | 3h | Forward |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-25 | Reserved | 0 | Reserved |
| 24 | RX_CMF_EN | | RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the **control** bit set in their EOP buffer descriptor. |
| | | 0 | MAC control frames are filtered (but acted upon if enabled). |
| | | 1 | MAC control frames are transferred to memory. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 23 | RX_CSF_EN | | RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the **fragment** or **undersized** bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. |
| | | 0 | Short frames are filtered. |
| | | 1 | Short frames are transferred to memory. |
| 22 | RX_CEF_EN | | RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF _EN is not set. |
| | | 0 | Frames containing errors are filtered. |
| | | 1 | Frames containing errors are transferred to memory. |
| 21 | TX_SHORT_GAP_LIM_EN | 0-1 | Transmit Short Gap Limit Enable. When set, this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed. |
| 20-19 | Reserved | 0 | Reserved |
| 18 | EXT_EN | | Control Enable |
| | | 0 | Use this setting for RMII/GMII mode |
| | | 1 | Use this setting for RGMII mode |
| 17 | GIG_FORCE | 0-1 | Gigabit Mode Force. This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY. |
| 16 | Reserved | 0 | Reserved |
| 15 | IFCTL_A | | Interface Control A |
| | | 0 | 10 Mbps mode |
| | | 1 | 100 Mbps mode |
| 14-12 | Reserved | 0 | Reserved |
| 11 | CMD_IDLE | | Command Idle. |
| | | 0 | Idle not commanded |
| | | 1 | Idle commanded (read IDLE in MACSTATUS register) |
| 10 | TX_SHORT_GAP_EN | | Transmit Short Gap Enable. |
| | | 0 | Transmit with a short IPG is disabled. |
| | | 1 | Transmit with a short IPG (when **TX_SHORT_GAP** input is asserted) is enabled. |
| 9-8 | Reserved | 0 | Reserved. Read as zero |
| 7 | GIG | | Gigabit Mode |
| | | 0 | 10/100 mode |
| | | 1 | Gigabit mode (full duplex only). The **GIG_OUT** output is the value of this bit. |
| 6 | TX_PACE | | Transmit Pacing Enable |
| | | 0 | Transmit pacing is disabled. |
| | | 1 | Transmit pacing is enabled. |
| 5 | GMII_EN | | G/MII Enable. |
| | | 0 | G/MII RX and TX held in reset. |
| | | 1 | G/MII RX and TX are released from reset. |
| 4 | TX_FLOW_EN | | Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_CMF_EN bits determine whether or not received pause frames are transferred to memory. |
| | | 0 | Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon. |
| | | 1 | Transmit flow control is enabled . Full-duplex mode: incoming pause frames are acted upon. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-121. CPGMAC_SL1 MAC Control Register (SL1_MACCONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 3 | RX_FLOW_EN | | Receive Flow Control Enable. |
| | | 0 | Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent. |
| | | 1 | Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered. |
| 2 | MTEST | 0-1 | Manufacturing Test mode. This bit must be set to allow writes to the BOFFTEST and PAUSE registers. |
| 1 | LOOPBACK | | Loop Back Mode. Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. |
| | | 0 | Loop back mode is disabled. |
| | | 1 | Loop back mode is enabled. |
| 0 | FULLDUPLEX | | Full Duplex mode. Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The **FULLDUPLEX_OUT** output is the value of this register bit. |
| | | 0 | Half-duplex mode is enabled. |
| | | 1 | Full-duplex mode is enabled. |

### 9.4.1.98 CPGMAC_SL1 MAC Status Register (SL1_MACSTATUS) (0x708)

**Figure 9-113. CPGMAC_SL1 MAC Status Register (SL1_MACSTATUS)**

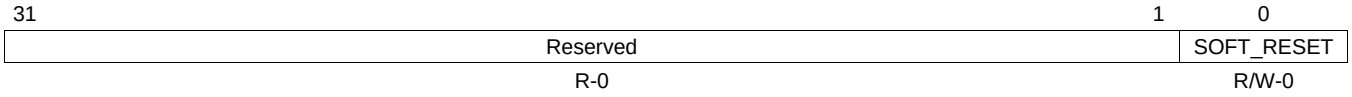
### 9.4.1.99 CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET) (0x70C)

**Figure 9-114. CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET)**



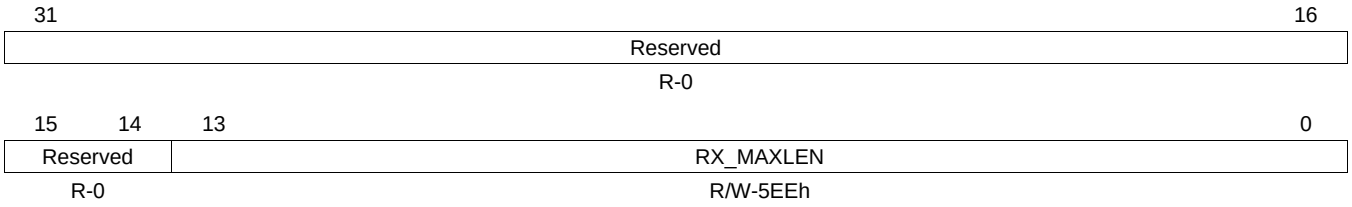
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-123. CPGMAC_SL1 Software Reset Register (SL1_SOFT_RESET) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved |
| 0 | SOFT_RESET | 0-1 | Software reset. Writing a 1 to this bit causes the CPGMAC_SL1 logic to be reset. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then reset has occurred. |

### 9.4.1.100 CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN) (0x710)

**Figure 9-115. CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-124. CPGMAC_SL1 RX Maximum Length Register (SL1_RX_MAXLEN) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-14 | Reserved | 0 | Reserved. Read as zero |
| 13-0 | RX_MAXLEN | 0-3FFFh | RX Maximum Frame Length. This field determines the maximum length of a received frame. The reset value is 5EEh (1518 decimal). Frames with byte counts greater than the RX_MAXLEN value are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383. |

|---|---|---|---|---|---|
| COLL_COUNT | | Reserved | | TX_BACKOFF | |
| R-0 | | R-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-125. CPGMAC_SL1 Backoff Random Number Generator Test Register (SL1_BOFFTEST) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | Reserved | 0 | Reserved |
| 30-26 | PACEVAL | 0-1Fh | Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce capture effects improving overall network bandwidth. |
| 25-16 | RNDNUM | 0-3FFh | Backoff Random Number Generator. This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when MTEST in MACCONTROL register has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLL_COUNT | 0-Fh | Collision Count. The number of collisions the current frame has experienced. |
| 11-10 | Reserved | 0 | Reserved |
| 9-0 | TX_BACKOFF | 0-3FFh | Backoff Count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision. |

### 9.4.1.102 CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE) (0x718)

**Figure 9-117. CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE)**

| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-126. CPGMAC_SL1 RX Pause Timer Register (SL1_RX_PAUSE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Reserved. Read as zero |
| 15-0 | RX_PAUSETIMER | 0-FFFFh | RX Pause Timer Value. This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with FF00h when the CPGMAC_SL sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated. |

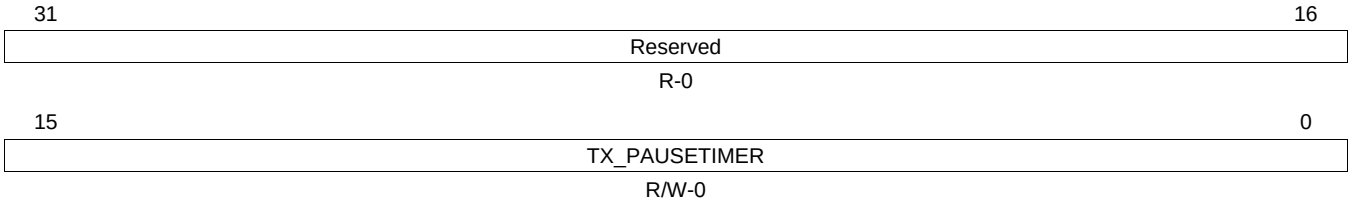
### 9.4.1.103 CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE) (0x71C)

**Figure 9-118. CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE)**



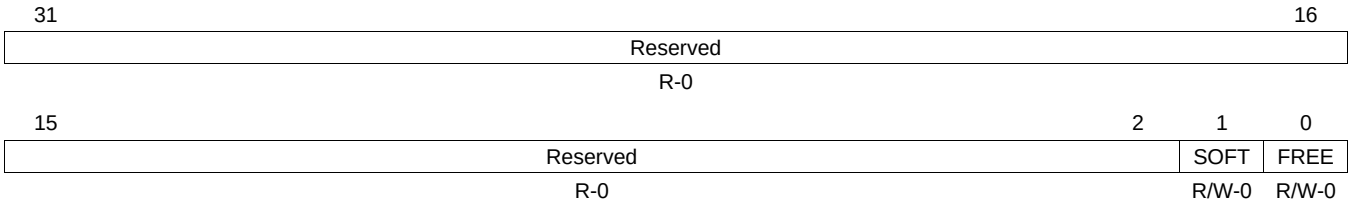
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-127. CPGMAC_SL1 TX Pause Timer Register (SL1_TX_PAUSE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Reserved. Read as zero |
| 15-0 | TX_PAUSETIMER | 0-FFFFh | TX Pause Timer Value. This field allows the contents of the transmit pause timer to be observed (and written in test mode). The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented, at slottime intervals, down to zero at which time CPGMAC_SL transmit frames are again enabled. |

### 9.4.1.104 CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL) (0x720)

**Figure 9-119. CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-128. CPGMAC_SL1 Emulation Control Register (SL1_EMCONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-2 | Reserved | 0 | Reserved. Read as zero |
| 1 | SOFT | | Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1. |
| | | 0 | Soft mode is disabled. EMAC stops immediately during emulation halt. |
| | | 1 | Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation. |
| 0 | FREE | | Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode. |
| | | 0 | Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC. |
| | | 1 | Free-running mode is enabled. During emulation halt, EMAC continues to operate. |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-25 | Reserved | 0 | Reserved |
| 24 | RX_CMF_EN | | RX Copy MAC Control Frames Enable. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the **control** bit set in their EOP buffer descriptor. |
| | | 0 | MAC control frames are filtered (but acted upon if enabled). |
| | | 1 | MAC control frames are transferred to memory. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 23 | RX_CSF_EN | | RX Copy Short Frames Enable. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the **fragment** or **undersized** bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. |
| | | 0 | Short frames are filtered. |
| | | 1 | Short frames are transferred to memory. |
| 22 | RX_CEF_EN | | RX Copy Error Frames Enable. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF _EN is not set. |
| | | 0 | Frames containing errors are filtered. |
| | | 1 | Frames containing errors are transferred to memory. |
| 21 | TX_SHORT_GAP_LIM_EN | 0-1 | Transmit Short Gap Limit Enable. When set, this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed. |
| 20-19 | Reserved | 0 | Reserved |
| 18 | EXT_EN | | Control Enable |
| | | 0 | Use this setting for RMII/GMII mode |
| | | 1 | Use this setting for RGMII mode |
| 17 | GIG_FORCE | 0-1 | Gigabit Mode Force. This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY. |
| 16 | Reserved | 0 | Reserved |
| 15 | IFCTL_A | | Interface Control A |
| | | 0 | 10 Mbps mode |
| | | 1 | 100 Mbps mode |
| 14-12 | Reserved | 0 | Reserved |
| 11 | CMD_IDLE | | Command Idle. |
| | | 0 | Idle not commanded |
| | | 1 | Idle commanded (read IDLE in MACSTATUS register) |
| 10 | TX_SHORT_GAP_EN | | Transmit Short Gap Enable. |
| | | 0 | Transmit with a short IPG is disabled. |
| | | 1 | Transmit with a short IPG (when **TX_SHORT_GAP** input is asserted) is enabled. |
| 9-8 | Reserved | 0 | Reserved. Read as zero |
| 7 | GIG | | Gigabit Mode |
| | | 0 | 10/100 mode |
| | | 1 | Gigabit mode (full duplex only). The **GIG_OUT** output is the value of this bit. |
| 6 | TX_PACE | | Transmit Pacing Enable |
| | | 0 | Transmit pacing is disabled. |
| | | 1 | Transmit pacing is enabled. |
| 5 | GMII_EN | | G/MII Enable. |
| | | 0 | G/MII RX and TX held in reset. |
| | | 1 | G/MII RX and TX are released from reset. |
| 4 | TX_FLOW_EN | | Transmit Flow Control Enable. Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_CMF_EN bits determine whether or not received pause frames are transferred to memory. |
| | | 0 | Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon. |
| | | 1 | Transmit flow control is enabled . Full-duplex mode: incoming pause frames are acted upon. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 9-131. CPGMAC_SL2 MAC Control Register (SL2_MACCONTROL) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 3 | RX_FLOW_EN | | Receive Flow Control Enable. |
| | | 0 | Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent. |
| | | 1 | Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered. |
| 2 | MTEST | 0-1 | Manufacturing Test mode. This bit must be set to allow writes to the BOFFTEST and PAUSE registers. |
| 1 | LOOPBACK | | Loop Back Mode. Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. |
| | | 0 | Loop back mode is disabled. |
| | | 1 | Loop back mode is enabled. |
| 0 | FULLDUPLEX | | Full Duplex mode. Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The **FULLDUPLEX_OUT** output is the value of this register bit. |
| | | 0 | Half-duplex mode is enabled. |
| | | 1 | Full-duplex mode is enabled. |

| R-0 | | R-0 | R-0 | R-0 | R-0 | R-0 |

LEGEND: R = Read only; -*n* = value after reset

**Table 9-132. CPGMAC_SL2 MAC Status Register (SL2_MACSTATUS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | IDLE | | CPGMAC_SL2 IDLE. The CPGMAC_SL2 is in the idle state (valid after an idle command). |
| | | 0 | The CPGMAC_SL2 is not in the idle state. |
| | | 1 | The CPGMAC_SL 2 is in the idle state. |
| 30-5 | Reserved | 0 | Reserved. Read as zero |
| 4 | EXT_GIG | 0-1 | External GIG. This is the value of the EXT_GIG input bit. |
| 3 | EXT_FULLDUPLEX | 0-1 | External Fullduplex. This is the value of the EXT_FULLDUPLEX input bit. |
| 2 | Reserved | 0 | Reserved Read as zero |
| 1 | RX_FLOW_ACT | | Receive Flow Control Active. When asserted, indicates that receive flow control is enabled and triggered. |
| | | 0 | Receive flow control is inactive. |
| | | 1 | Receive flow control is active. |
| 0 | TX_FLOW_ACT | | Transmit Flow Control Active. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. |
| | | 0 | Transmit flow control is inactive. |
| | | 1 | Transmit flow control is active. |

### 9.4.1.109 CPGMAC_SL2 Software Reset Register (SL2_SOFT_RESET) (0x74C)

**Figure 9-124. CPGMAC_SL2 Software Reset Register (SL2_SOFT_RESET)**

| 31 | 1 | 0 |

**Table 9-134. CPGMAC_SL2 RX Maximum Length Register (SL2_RX_MAXLEN) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-14 | Reserved | 0 | Reserved. Read as zero |
| 13-0 | RX_MAXLEN | 0-3FFFh | RX Maximum Frame Length. This field determines the maximum length of a received frame. The reset value is 5EEh (1518 decimal). Frames with byte counts greater than the RX_MAXLEN value are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383. |

### 9.4.1.111 CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST) (0x754)

**Figure 9-126. CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST)**

| 31 | 30 | 26 | 25 | 16 |

| COLL_COUNT | | Reserved | | TX_BACKOFF | |
| R-0 | | R-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-135. CPGMAC_SL2 Backoff Random Number Generator Test Register (SL2_BOFFTEST) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | Reserved | 0 | Reserved. Read as zero |
| 30-26 | PACEVAL | 0-1Fh | Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce capture effects improving overall network bandwidth. |
| 25-16 | RNDNUM | 0-3FFh | Backoff Random Number Generator. This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when MTEST in MACCONTROL register has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLL_COUNT | 0-Fh | Collision Count. The number of collisions the current frame has experienced. |
| 11-10 | Reserved | 0 | Reserved. Read as zero |
| 9-0 | TX_BACKOFF | 0-3FFh | Backoff Count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 9.4.1.112 CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE) (0x758)

**Figure 9-127. CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE)**

| 31 | 16 |

| RX_PAUSETIMER | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-136. CPGMAC_SL2 RX Pause Timer Register (SL2_RX_PAUSE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-16 | Reserved | 0 | Reserved. Read as zero |
| 15-0 | RX_PAUSETIMER | 0-FFFFh | RX Pause Timer Value. This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with FF00h when the CPGMAC_SL sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated. |

### 9.4.1.113 CPGMAC_SL2 TX Pause Timer Register (SL2_TX_PAUSE) (0x75C)

**Figure 9-128. CPGMAC_SL2 TX Pause Timer Register (SL2_TX_PAUSE)**

| 31 | 16 |

### 9.4.2 MDIO Module

This section describes the memory-mapped registers for the MDIO module. The base address of the MDIO module registers is 4A10 0800h. Table 9-140 lists the memory-mapped registers for the MDIO module.

**Table 9-140. MDIO Module Registers**

| Offset | Acronym | Register Name |
|---|---|---|
| 800h | VERSION | MDIO version register |
| 804h | CONTROL | MDIO control register |
| 808h | ALIVE | PHY alive status register |
| 80Ch | LINK | PHY link status register |
| 810h | LINKINTRAW | MDIO link status change interrupt register (raw value) |
| 814h | LINKINTMASKED | MDIO link status change interrupt register (masked value) |
| 820h | USERINTRAW | MDIO user command complete interrupt register (raw value) |
| 824h | USERINTMASKED | MDIO user command complete interrupt register (masked value) |
| 828h | USERINTMASKSET | MDIO user interrupt mask set register |
| 82Ch | USERINTMASKCLEAR | MDIO user interrupt mask clear register |
| 880h | USERACCESS0 | MDIO user access register 0 |
| 884h | USERPHYSEL0 | MDIO user PHY select register 0 |
| 888h | USERACCESS1 | MDIO user access register 1 |
| 88Ch | USERPHYSEL1 | MDIO user PHY select register 1 |

#### 9.4.2.1 MDIO Version Register (VERSION) (800h)

### 9.4.2.2 MDIO Control Register (CONTROL) (804h)

**Figure 9-132. MDIO Control (CONTROL) Register**

| 31 | 30 | 29 | 28 24 | 23 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|
| IDLE | ENABLE | Rsvd | HIGHEST_USER_CHANNEL | Reserved | PREAMBLE | FAULT | FAULT DETECT ENABLE | INT TEST ENABLE | Rsvd |
| R-1 | R/W-0 | R-0 | R-1 | R-0 | R/W-0 | R/WC-0 | R/W-0 | R/W-0 | R-0 |

| 15 0 |
|---|
| CLKDIV |
| R/W |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-142. MDIO Control Register (CONTROL) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | IDLE | | MDIO state machine IDLE. |
| | | 0 | State machine is not in idle state. |
| | | 1 | State machine is in idle state. |
| 30 | ENABLE | | Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register. |
| | | 0 | Disables the MDIO state machine. |
| | | 1 | Enable the MDIO state machine. |
| 29 | Reserved | 0 | Reserved |
| 28-24 | HIGHEST_USER_ CHANNEL | 0-1Fh | Highest user channel. This field specifies the highest useraccess channel that is available in the module and is currently set to 1. This implies that USERACCESS1 is the highest available user access channel. |
| 23-21 | Reserved | 0 | Reserved |
| 20 | PREAMBLE | | Preamble disable. |
| | | 0 | Standard MDIO preamble is used. |
| | | 1 | Disables this device from sending MDIO frame preambles. |
| 19 | FAULT | | Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. |
| | | 0 | No failure |
| | | 1 | Physical layer fault; the MDIO state machine is reset. |
| 18 | FAULT_DETECT_ ENABLE | | Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. |
| | | 0 | Disables the physical layer fault detection. |
| | | 1 | Enables the physical layer fault detection. |
| 17 | INT_TEST_ENABLE | | Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. |
| 16 | Reserved | 0 | Reserved |
| 15-0 | CLKDIV | 0-FFFFh | Clock Divider. This field specifies the division ratio between CLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is cleared to 0. MDCLK frequency = clk frequency/(CLKDIV+1). |

### 9.4.2.3 PHY Alive Status Register (ALIVE) (0x808)

**Figure 9-133. PHY Alive Status Register (ALIVE)**

| 31 | 0 |
|---|---|
| ALIVE | |
| R/WC-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-143. PHY Alive Status Register (ALIVE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | ALIVE | | MDIO Alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. |
| | | 0 | No effect |
| | | 1 | Clears the bit |

### 9.4.2.4 PHY Link Status Register (LINK) (0x80C)

**Figure 9-134. PHY Link Status Register (LINK)**

| 31 | 0 |
|---|---|
| LINK | |
| R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-144. PHY Link Status Register (LINK) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | LINK | 0-FFFF FFFFh | MDIO Link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the USERPHYSEL registers can be determined using the MLINK input pins. This is determined by the LINKSEL bit in the USERPHYSEL register. |

### 9.4.2.5 MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW) (0x810)

**Figure 9-135. MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW)**

| 31 | 2 | 1 | 0 |
|---|---|---|---|
| Reserved | | LINKINTRAW | |
| R-0 | | R/WC-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-145. MDIO Link Status Change Interrupt (raw value) Register (LINKINTRAW) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-2 | Reserved | 0 | Reserved |
| 1-0 | LINKINTRAW | | MDIO link change event, raw value. When asserted '1', a bit indicates that there was an MDIO link change event (that is, change in the MDIO link register) corresponding to the PHY address in the USERPHYSEL register. LINKINTRAW[0] and LINKINTRAW[1] correspond to USERPHYSEL0 and USERPHYSEL1, respectively. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the LINKINTRAW bits to a '1'. This mode may be used for test purposes. |
| | | 0 | No effect |
| | | 1 | Clears the event |

### 9.4.2.6 MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED) (0x814)

**Figure 9-136. MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED)**

| 31 | 2 | 1 | 0 |
|---|---|---|---|
| Reserved | | LINKINTMASKED | |
| R-0 | | R/WC-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-146. MDIO Link Status Change Interrupt (masked value) Register (LINKINTMASKED) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-2 | Reserved | | Reserved |
| 1-0 | LINKINTMASKED | | MDIO link change interrupt, masked value. When asserted '1', a bit indicates that there was an MDIO link change event (that is, change in the MDIO link register) corresponding to the PHY address in the USERPHYSEL register and the corresponding LINKINT_ENABLE bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to USERPHYSEL0 and USERPHYSEL1, respectively. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the LINKINT bits to a '1'. This mode may be used for test purposes. |
| | | 0 | No effect |
| | | 1 | Clears the interrupt |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-147. MDIO User Command Complete Interrupt (raw value) Register (USERINTRAW) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-2 | Reserved | 0 | Reserved |
| 1-0 | USERINTRAW | | Raw value of MDIO user command complete event for USERACCESS1 and MDIOUSERACCESS0, respectively. When asserted '1', a bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS register has completed. Writing a '1' will clear the event and writing '0' has no effect. If the INT_TEST_ENABLE bit in the MDIO control register is set, the host may set the USERINTRAW bits to a '1'. This mode may be used for test purposes. |

### 9.4.2.8 MDIO User Command Complete Interrupt (masked value) Register (USERINTMASKED) (0x824)

**Figure 9-138. MDIO User Command Complete Interrupt (masked value) Register (USERINTMASKED)**

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 9-151. MDIO User Access Register 0 (USERACCESS0) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | GO | 0-1 | Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUserAccess0 register are blocked when the go bit is '1'. If byte access is being used, the go bit should be written last. |
| 30 | WRITE | | Write enable. |
| | | 0 | The MDIO transaction is to be a register read. |
| | | 1 | The MDIO transaction is to be a register write. |
| 29 | ACK | 0-1 | Acknowledge. This bit is set if the PHY acknowledged the read transaction. |
| 28-26 | Reserved | 0 | Reserved. Writes to these bits have no effect. They always read as 0. |
| 25-21 | REGADR | 0-1Fh | Register address. This field specifies the PHY register to be accessed for this transaction. |
| 20-16 | PHYADR | 0-1Fh | PHY address. This field specifies the PHY to be accessed for this transaction. |
| 15-0 | DATA | 0-FFFFh | User data. The data value read from or to be written to the specified PHY register. |

### 9.4.3 CPSW Subsytem Module

This section describes the memory-mapped registers for the CPSW subsytem module (CPSW_3GSS). The base address of the CPSW subsytem module registers is 4A10 0900h. Table 9-155 lists the memory-mapped registers for the CPSW subsytem module.

**Table 9-155. CPSW Subsytem Module Registers**

| Offset | Acronym | Register Name |
|---|---|---|
| 900h | IDVER | Subsystem ID Version Register |
| 904h | SOFT_RESET | Subsystem Software Reset Register |
| 908h | CONTROL | Subsystem Control Register |
| 90Ch | INT_CONTROL | Subsystem Interrupt Control |
| 910h | RX_THRESH_EN | Subsystem Receive Threshold Interrupt Enable Register |
| 914h | RX_EN | Subsystem Receive Interrupt Enable Register |
| 918h | TX_EN | Subsystem Transmit Interrupt Enable Register |
| 91Ch | MISC_EN | Subsystem Miscellaneous Interrupt Enable Register |
| 940h | RX_THRESH_STAT | Subsystem RX Threshold Masked Interrupt Status Register |
| 944h | RX_STAT | Subsystem RX Masked Interrupt Status Register |
| 948h | TX_STAT | Subsystem TX Masked Interrupt Status Register |
| 94Ch | MISC_STAT | Subsystem Miscellaneous Masked Interrupt Status Register |
| 970h | RX_IMAX | Subsystem Receive Interrupts Per Millisecond |
| 974h | TX_IMAX | Subsystem Transmit Interrupts Per Millisecond |
| 988h | RGMII_CTL | RGMII Control Signal Register |

#### 9.4.3.1 Subsystem ID Version Register (IDVER) (0x900)

**Figure 9-145. Subsystem ID Version Register (IDVER)**

| 31–30 | 29–28 | 27–16 |
|---|---|---|

## 10.1 Introduction

### 10.1.1 Purpose of the Peripheral

The general-purpose interface combines two general-purpose input/output (GPIO) banks. Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 64 (2 × 32) pins. These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.

### 10.1.2 Features

Each channel in the GPIO module has the following features:

- The output enable register (GPIO_OE) controls the output capability for each pin.
- The output line level reflects the value written in the data output register (GPIO_DATAOUT) through the peripheral bus.
- The input line can be fed in to the GPIO module through an optional and configurable debouncing cell.
- The input line value is sampled into the data input register (GPIO_DATAIN) and can be read from the peripheral bus.
- In Active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) to be used can be configured.

The global features of the GPIO module are:

- Two identical interrupt generation sub-modules process synchronous interrupt requests from each channel in order to be used independently in a bi-processor environment. Each sub-module controls its own synchronous interrupt request line and has its own interrupt enable and interrupt status registers. The interrupt enable register (GPIO_IRQENABLE_SET_x) selects the channel(s) considered for the interrupt request generation, and the interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel(s) has/have activated the interrupt request. Event detection on GPIO channels is reflected into the interrupt status registers independently from the interrupt enable registers content.

The module provides an alternative to the atomic ‘Test and Set’ operations for the data output and interrupt enable registers. For these registers, the module implements the “Set and Clear protocol register update”.

### 10.1.3 Block Diagram

Figure 10-1 details the GPIO block diagram with its configuration registers and its main functional paths:

- The synchronous path (for Active mode operations), Figure 10-2, used to generate a synchronous interrupt request upon expected event detection on any input GPIO; the synchronous interrupt request lines 0 and 1 are active according to their respective interrupt enable 0 and 1 registers.
- The blocks handling the internal clock (clock gating) and managing the Sleep mode request/acknowledge protocol (enabling the Synchronous path in Active mode).

**Figure 10-1. GPIO Block Diagram**

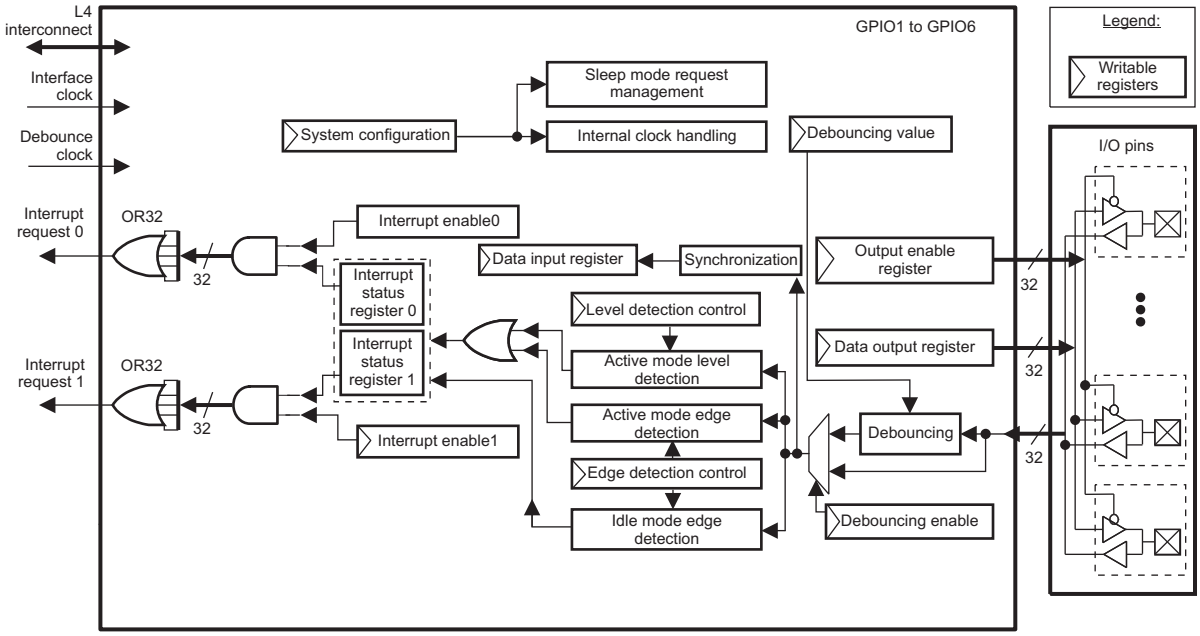

**Figure 10-2. Synchronous Path Block Diagram**

## 10.2 Architecture

This section discusses the operational details and basic functions of the GPIO peripheral.

### *10.2.1 Operating Modes*

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupt can be generated according to the configuration and the external signals.
- **Idle mode:** the module is in a waiting state, interface clock can be stopped , no interrupt can be generated. Check the chip top-level functional specification for the availability of the debouncing clock while in Idle mode.
- **Inactive mode:** the module has no activity, interface clock can be stopped, no interrupt can be generated.
- **Disabled mode:** the module is not used, internal clock paths are gated, no interrupt request can be generated.

The Idle and Inactive modes are configured within the module and activated on request by the host processor through system interface sideband signals. The Disabled mode is set by software through a dedicated configuration bit. It unconditionally gates the internal clock paths not use for the system interface. All module registers are 8, 16 or 32-bit accessible through the OCP compatible interface (little endian encoding). In active mode, the event detection (level or transition) is performed in the GPIO module using the interface clock. The detection's precision is set by the frequency of this clock and the selected internal gating scheme.

### *10.2.2 Clocking and Reset Strategy*

#### 10.2.2.1 Clocks

GPIO module runs using two clocks:

- The debouncing clock is used for the debouncing sub-module logic (without the corresponding configuration registers). This module can sample the input line and filters the input level using a programmed delay.
- The interface clock provided by the peripheral bus (OCP compatible system interface). It is used through the entire GPIO module (except within the debouncing sub-module logic). It clocks the OCP interface and the internal logic. Clock gating features allow adapting the module power consumption to the activity.

#### 10.2.2.2 Clocks, Gating and Active Edge Definitions

The interface clock provided by the peripheral bus (OCP compatible system interface) is used through the entire GPIO module. Two clock domains are defined: the OCP interface and the internal logic. Each clock domain can be controlled independently. Sampling operations for the data capture and for the events detection are done using the rising edge. The data loaded in the data output register (GPIO_DATAOUT) is set at the output GPIO pins synchronously with the rising edge of the interface clock.

Five clock gating features are available:

- Clock for the system interface logic can be gated when the module is not accessed, if the AUTOIDLE configuration bit in the system configuration register (GPIO_SYSCONFIG) is set. Otherwise, this logic is free running on the interface clock.
- Clock for the input data sample logic can be gated when the data in register is not accessed.
- Four clock groups are used for the logic in the synchronous events detection. Each 8 input GPIO_V2 pins group will have a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock will be gated. All channels are also gated using a 'one out of N' scheme. N can take the values 1, 2, 4 or 8. The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free running on the interface clock. When N is between 2 to 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

Copyright © 2011–2016, Texas Instruments Incorporated

- In Inactive mode, all internal clock paths are gated.
- In Disabled mode, all internal clock paths not used for the system interface are gated. All GPIO registers are accessible synchronously with the interface clock.

#### 10.2.2.3 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode according to the IDLEMODE field in the system configuration register (GPIO_SYSCONFIG).

- IDLEMODE = 0 (Force-Idle mode): the GPIO goes in Inactive mode independently of the internal module state and the Idle acknowledge is unconditionally sent. In Force-Idle mode, the module is in Inactive mode.
- IDLEMODE = 1h (No-Idle mode): the GPIO does not go to the Idle mode and the Idle acknowledge is never sent.
- IDLEMODE = 2h (Smart-Idle mode) or IDLEMODE = 3h (Smart-Idle mode): the GPIO module evaluates its internal capability to have the interface clock switched off. Once there is no more internal activity (the data input register completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters Idle mode. When the system is awake, the Idle Request goes inactive, the Idle acknowledge signals are immediately de-asserted.

**NOTE:** Idle mode request and Idle acknowledge are system interface sideband signals. Once the GPIO acknowledges the Sleep mode request (Idle acknowledge has been sent), the interface clock can be stopped anytime.

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode only if there is no active bit in GPIO_IRQSTATUS_RAW_n registers.

#### 10.2.2.4 Reset

The OCP hardware Reset signal has a global reset action on the GPIO. All configuration registers, all DFFs clocked with the Interface clock or Debouncing clock and all internal state machines are reset when the OCP hardware Reset is active (low level). The RESETDONE bit in the system status register (GPIO_SYSSTATUS) monitors the internal reset status: it is set when the Reset is completed on both OCP and Debouncing clock domains. The software Reset (SOFTRESET bit in the system configuration register) has the same effect as the OCP hardware Reset signal, and the RESETDONE bit in GPIO_SYSSTATUS is updated in the same condition.

### *10.2.3 Interrupt Features*

#### 10.2.3.1 Functional Description

In order to generate an interrupt request to a host processor upon a defined event (level or logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- Interrupts for the GPIO channel must be enabled in the GPIO_IRQENABLE_SET_0 and/or GPIO_IRQENABLE_SET_1 registers.
- The expected event(s) on input GPIO to trigger the interrupt request has to be selected in the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers.

For instance, interrupt generation on both edges on input k is configured by setting to 1 the *k*th bit in registers GPIO_RISINGDETECT and GPIO_FALLINGDETECT along with the interrupt enabling for one or both interrupt lines (GPIO_IRQENABLE_SET_n).

**NOTE:** All interrupt sources (the 32 input GPIO channels) are merged together to issue two synchronous interrupt requests 0 and 1.

Copyright © 2011–2016, Texas Instruments Incorporated

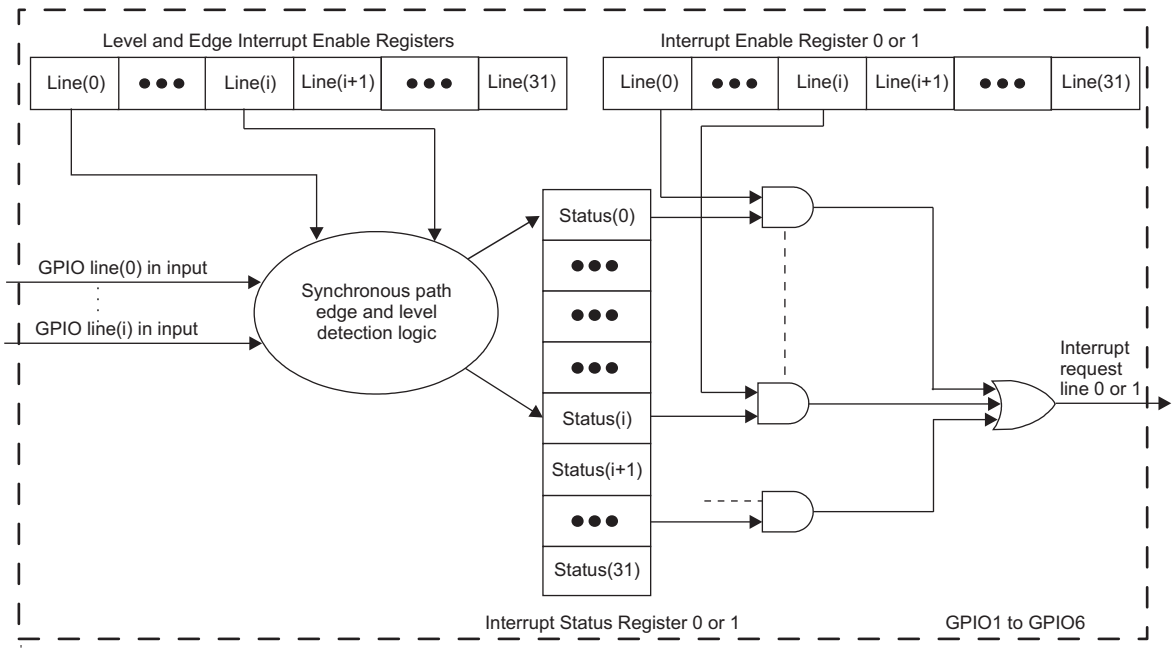
### 10.2.3.2 Synchronous Path: Interrupt Request Generation

In Active mode, once the GPIO configuration registers have been set to enable the interrupt generation, a synchronous path (Figure 10-3) samples the transitions and levels on the input GPIO with the internally gated interface clock. When an event matches the programmed settings, the corresponding bit in the GPIO_IRQSTATUS_RAW_n registers is set to 1 and, on the following interface clock cycle, the interrupt lines 0 and/or 1 are activated (depending on the GPIO_IRQENABLE_SET_n registers).

Due to the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period is equal to N times the interface clock period). This minimum pulse width has to be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

As the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This should not exceed 3 internally gated interface clock cycles + 2 interface clock cycles when the debouncing feature is not used. When the debouncing feature is active, the latency depends on the GPIO_DEBOUNCINGTIME register value and should be less than 3 internally gated interface clock cycles + 2 interface clock cycles + GPIO_DEBOUNCINGTIME value debouncing clock cycles + 3 debouncing clock cycles.

**Figure 10-3. Interrupt Request Generation**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 10.2.3.3 Interrupt Line Release

When the host processor receives an interrupt request issued by the GPIO module, it can read the corresponding GPIO_IRQSTATUS_n register to find out which input GPIO has triggered the interrupt. After servicing the interrupt, the processor resets the status bit and releases the interrupt line by writing a 1 in the corresponding bit of the GPIO_IRQSTATUS_n register. If there is still a pending interrupt request to serve (all bits in the GPIO_IRQSTATUS_RAW_n register not masked by the GPIO_IRQENABLE_SET_n, which are not cleared by setting the GPIO_IRQENABLE_CLR_n), the interrupt line will be re-asserted.

### *10.2.4 General-Purpose Interface Basic Programming Model*

#### 10.2.4.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

- GPIO_LEVELDETECT0
- GPIO_LEVELDETECT1
- GPIO_RISINGDETECT
- GPIO_FALLINGDETECT

are set to 0101 0101h, then all clocks are active (power consumption is high);

are set to 0000 00FFh, then a single clock is active.

**NOTE:** When the clocks are enabled by writing to the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers, the detection starts after 5 clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before a new setting is performed, the following is recommended: first, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

#### 10.2.4.2 Set and Clear Instructions

The GPIO module implements the set-and-clear protocol register update for the data output and interrupt enable registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s).

Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 10.2.4.2.1 Clear Instruction

##### 10.2.4.2.1.1 Clear Interrupt Enable Registers (GPIO_IRQENABLE_CLR_0 and GPIO_IRQENABLE_CLR_1):

- A write operation in the clear interrupt enable0 (or enable1) register clears the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear interrupt enable0 (or enable1) register returns the value of the interrupt enable0 (or enable1) register.

##### 10.2.4.2.1.2 Clear Data Output Register (GPIO_CLEARDATAOUT):

- A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear data output register returns the value of the data output register.

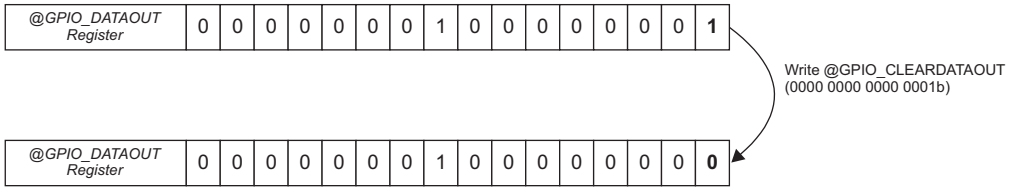
##### 10.2.4.2.1.3 Clear Instruction Example

Assume the data output register (or one of the interrupt enable registers) contains the binary value, 0000 0001 0000 0001h, and you want to clear bit 0.

With the clear instruction feature, write 0000 0000 0000 0001h at the address of the clear data output register (or at the address of the clear interrupt enable register). After this write operation, a reading of the data output register (or the interrupt enable register) returns 0000 0001 0000 0000h; bit 0 is cleared.

**NOTE:** Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

**Figure 10-4. Write @ GPIO_CLEARDATAOUT Register Example**



#### 10.2.4.2.2 Set Instruction

##### 10.2.4.2.2.1 Set Interrupt Enable Registers (GPIO_IRQENABLE_SET_0 and GPIO_IRQENABLE_SET_1):

- A write operation in the set interrupt enable0 (or enable1) register sets the corresponding bit in the interrupt enable0 (or enable1) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set interrupt enable0(or enable1) register returns the value of the interrupt enable0 (or enable1) register.

##### 10.2.4.2.2.2 Set Data Output Register (GPIO_SETDATAOUT):

- A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set data output register returns the value of the data output register.

Copyright © 2011–2016, Texas Instruments Incorporated

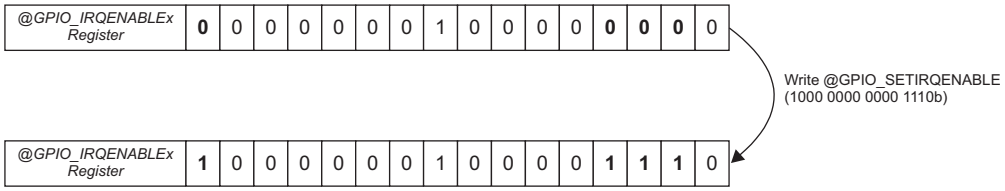
#### *10.2.4.2.2.3 Set Instruction Example*

Assume the interrupt enable0 (or enable1) register (or the data output register) contains the binary value, 0000 0001 0000 0000h, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 1000 0000 0000 1110h at the address of the set interrupt enable0 (or enable1) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable0 (or enable1) register (or the data output register) returns 1000 0001 0000 1110h; bits 15, 3, 2, and 1 are set.

**NOTE:** Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

**Figure 10-5. Write @ GPIO_SETIRQENABLEx Register Example**



### 10.2.4.3 Data Input (Capture)/Output (Drive)

The output enable register (GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module; its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in GPIO_OE), the value of the corresponding bit in the GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address. If the application uses a pin as an output and does not want interrupt generation from this pin, the application must properly configure the interrupt enable registers.

When configured as an input (the desired bit set to 1 in GPIO_OE), the state of the input can be read from the corresponding bit in the GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the interrupt enable registers to the interrupt as needed.

### 10.2.4.4 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

- The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIO_OE register).
- The debouncing time must be set in the debouncing value register (GPIO_DEBOUNCINGTIME). The GPIO_DEBOUNCINGTIME register is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

Copyright © 2011–2016, Texas Instruments Incorporated

The following formula describes the required input stable time to be propagated to the debounced output:

*Debouncing time = (DEBOUNCETIME + 1) × 31 µs*

Where the DEBOUNCETIME field value in the GPIO_DEBOUNCINGTIME register is from 0 to 255.

- The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding DEBOUNCEENABLE bit in the GPIO_DEBOUNCENABLE register).

#### 10.2.4.5 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface (Figure 10-6). You can dedicate channels based on the keyboard matrix size. Figure 10-6 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pull-up. Column channels are configured as outputs and drive a low level.

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 10.2.3).

When the keyboard interrupt is received, the processor can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

**Figure 10-6. General-Purpose Interface Used as a Keyboard Interface**

## 10.3 GPIO Registers

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding). Access to registers is direct; no shadow registers are implemented.

**Table 10-1. GPIO Registers**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|

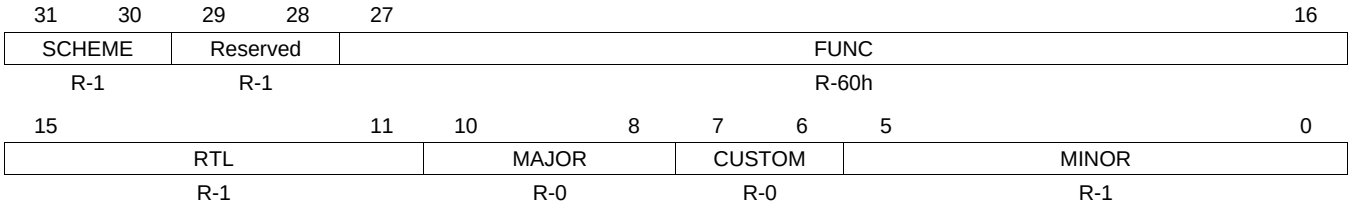
### 10.3.1 GPIO_REVISION Register

The GPIO revision register is a read only register containing the revision number of the GPIO module. A write to this register has no effect, the same as the reset.

**Figure 10-7. GPIO_REVISION Register**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 10-2. GPIO_REVISION Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-30 | SCHEME | R | 1h | Used to distinguish between old Scheme and current. |
| 29-28 | Reserved | R | 1h | Reserved |
| 27-16 | FUNC | R | 60h | Indicates a software compatible module family. |

### 10.3.2 GPIO_SYSCONFIG Register

The GPIO_SYSCONFIG register controls the various parameters of the L4 interconnect.

**NOTE:** When the AUTOIDLE bit is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

**Figure 10-8. GPIO_SYSCONFIG Register**

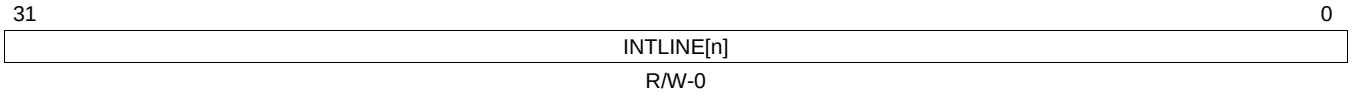
### 10.3.4 GPIO_IRQSTATUS_RAW_0 Register

The GPIO_IRQSTATUS_RAW_0 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

**Figure 10-10. GPIO_IRQSTATUS_RAW_0 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

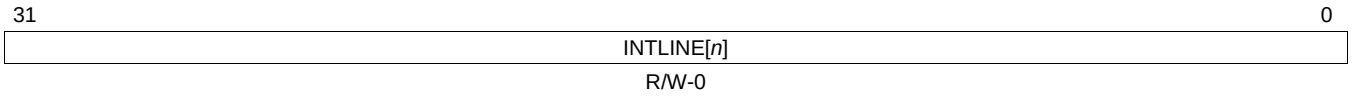
**Table 10-5. GPIO_IRQSTATUS_RAW_0 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n status.<br>0 = No effect<br>1 = IRQ is triggered. |

### 10.3.5 GPIO_IRQSTATUS_RAW_1 Register

The GPIO_IRQSTATUS_RAW_1 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

**Figure 10-11. GPIO_IRQSTATUS_RAW_1 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-6. GPIO_IRQSTATUS_RAW_1 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

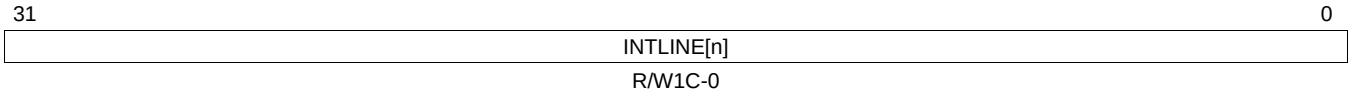
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n status.<br>0 = No effect<br>1 = IRQ is triggered. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.6 GPIO_IRQSTATUS_0 Register

The GPIO_IRQSTATUS_0 register provides core status information for the interrupt handling, showing all enabled events (enabled interrupts only). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

**Figure 10-12. GPIO_IRQSTATUS_0 Register**



LEGEND: R/W = Read/Write; W1C = Write a 1 to clear to 0, a write of 0 has no effect; -*n* = value after reset

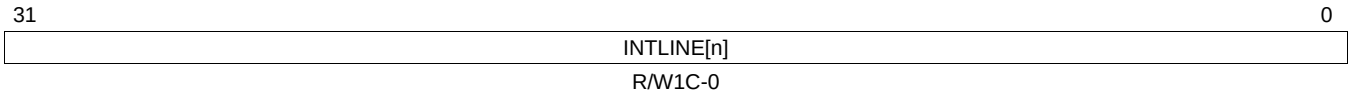
**Table 10-7. GPIO_IRQSTATUS_0 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W1C | 0h | Interrupt n status.<br>0 = No effect<br>1 = IRQ is triggered. |

### 10.3.7 GPIO_IRQSTATUS_1 Register

The GPIO_IRQSTATUS_1 register provides core status information for the interrupt handling, showing all enabled events (enabled interrupts only). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

**Figure 10-13. GPIO_IRQSTATUS_1 Register**



LEGEND: R/W = Read/Write; W1C = Write a 1 to clear to 0, a write of 0 has no effect; -*n* = value after reset

**Table 10-8. GPIO_IRQSTATUS_1 Register Field Descriptions**

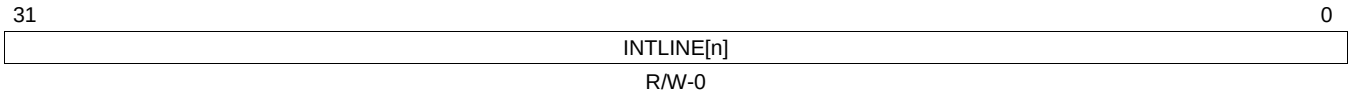
| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W1C | 0h | Interrupt n status.<br>0 = No effect<br>1 = IRQ is triggered. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.8 GPIO_IRQENABLE_SET_0 Register

All 1-bit fields in the GPIO_IRQENABLE_SET_0 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

**Figure 10-14. GPIO_IRQENABLE_SET_0 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

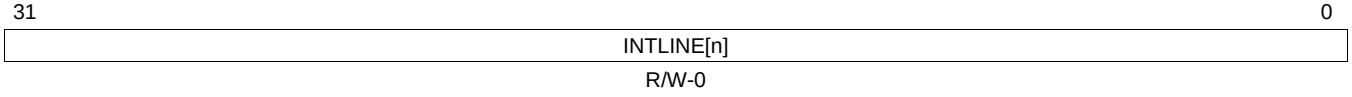
**Table 10-9. GPIO_IRQENABLE_SET_0 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n enable<br>0 = No effect<br>1 = Enable IRQ generation. |

### 10.3.9 GPIO_IRQENABLE_SET_1 Register

All 1-bit fields in the GPIO_IRQENABLE_SET_1 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

**Figure 10-15. GPIO_IRQENABLE_SET_1 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-10. GPIO_IRQENABLE_SET_1 Register Field Descriptions**

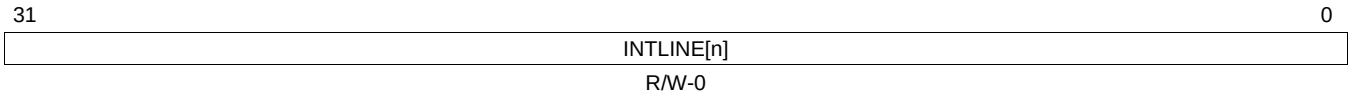
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n enable<br>0 = No effect<br>1 = Enable IRQ generation. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.10 GPIO_IRQENABLE_CLR_0 Register

All 1-bit fields in the GPIO_IRQENABLE_CLR_0 register clear a specific interrupt event. Writing a 1 to a bit disables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

**Figure 10-16. GPIO_IRQENABLE_CLR_0 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

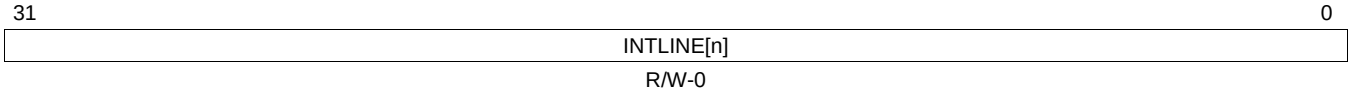
**Table 10-11. GPIO_IRQENABLE_CLR_0 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n enable<br>0 = No effect<br>1 = Disable IRQ generation. |

### 10.3.11 GPIO_IRQENABLE_CLR_1 Register

All 1-bit fields in the GPIO_IRQENABLE_CLR_1 register clear a specific interrupt event. Writing a 1 to a bit disables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

**Figure 10-17. GPIO_IRQENABLE_CLR_1 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-12. GPIO_IRQENABLE_CLR_1 Register Field Descriptions**

|---|---|---|---|---|
| 31-0 | INTLINE[*n*] | R/W | 0h | Interrupt n enable<br>0 = No effect<br>1 = Disable IRQ generation. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.12 GPIO_SYSSTATUS Register

The GPIO_SYSSTATUS register provides the reset status information about the GPIO module. It is a read-only register; a write to this register has no effect.

**Figure 10-18. GPIO_SYSSTATUS Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 10.3.13 GPIO_CTRL Register

The GPIO_CTRL register controls the clock gating functionality. The DISABLEMODULE bit controls a clock gating feature at the module level. When set, this bit forces the clock gating for all internal clock paths. Module internal activity is suspended. System interface is not affected by this bit. System interface clock gating is controlled with the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG). This bit is to be used for power saving when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

**Figure 10-19. GPIO_CTRL Register**

Controls the clock gating for the event detection logic.<br>0 = Functional clock is interface clock.<br>1 = Functional clock is interface clock divided by 2.<br>2 = Functional clock is interface clock divided by 4.<br>3 = Functional clock is interface clock divided by 8. |
| 0 | DISABLEMODULE | R/W | 0h | Module Disable<br>0 = Module is enabled, clocks are not gated.<br>1 = Module is disabled, clocks are gated. |

### 10.3.14 GPIO_OE Register

The GPIO_OE register is used to enable the pins output capabilities. At reset, all the GPIO related pins are configured as input and output capabilities are disabled. This register is not used within the module, its only function is to carry the pads configuration. When the application is using a pin as an output and does not want interrupt generation from this pin, the application can/has to configure properly the Interrupt Enable registers.

**Figure 10-20. GPIO_OE Register**

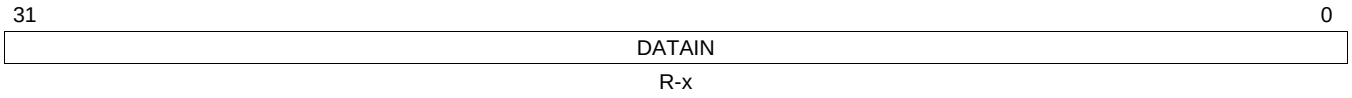
### 10.3.15 GPIO_DATAIN Register

The GPIO_DATAIN register is used to register the data that is read from the GPIO pins. The GPIO_DATAIN register is a read-only register. The input data is sampled synchronously with the interface clock and then captured in the GPIO_DATAIN register synchronously with the interface clock. So, after changing, GPIO pin levels are captured into this register after two interface clock cycles (the required cycles to synchronize and to write the data).

**NOTE:** When the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG) is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

**Figure 10-21. GPIO_DATAIN Register**



LEGEND: R = Read only; -*n* = value after reset

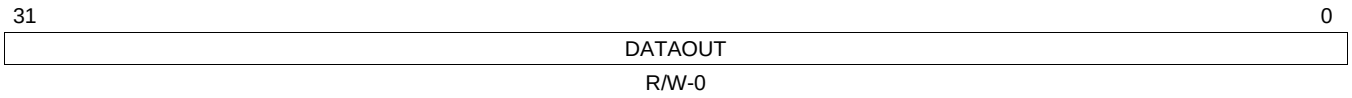
**Table 10-16. GPIO_DATAIN Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | DATAIN | R | x | Sampled Input Data |

### 10.3.16 GPIO_DATAOUT Register

The GPIO_DATAOUT register is used for setting the value of the GPIO output pins. Data is written to the GPIO_DATAOUT register synchronously with the interface clock. This register can be accessed with direct read/write operations or using the alternate 'Set/Clear' feature. This feature enables to set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address.

**Figure 10-22. GPIO_DATAOUT Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-17. GPIO_DATAOUT Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | DATAOUT | R/W | 0 | Data to set on output pins |

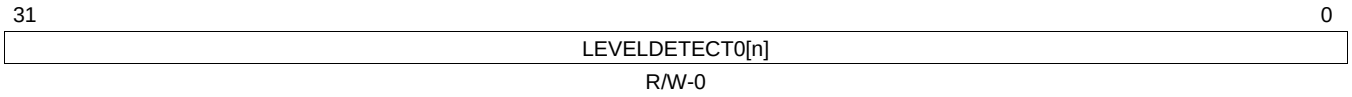
Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.17 GPIO_LEVELDETECT0 Register

The GPIO_LEVELDETECT0 register is used to enable/disable for each input lines the low-level (0) detection to be used for the interrupt request generation.

**NOTE:** Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

**Figure 10-23. GPIO_LEVELDETECT0 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-18. GPIO_LEVELDETECT0 Register Field Descriptions**

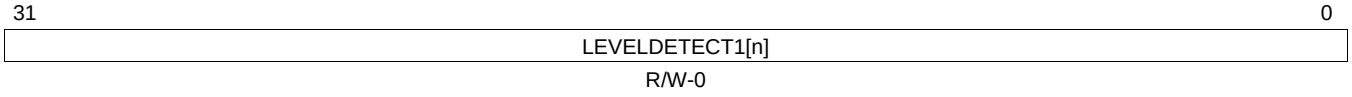
| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | LEVELDETECT0[*n*] | R/W | 0h | Low Level Interrupt Enable<br>0 = Disable the IRQ assertion on low-level detect.<br>1 = Enable the IRQ assertion on low-level detect. |

### 10.3.18 GPIO_LEVELDETECT1 Register

The GPIO_LEVELDETECT1 register is used to enable/disable for each input lines the high-level (1) detection to be used for the interrupt request generation.

**NOTE:** Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

**Figure 10-24. GPIO_LEVELDETECT1 Register**



LEGEND: R/W = Read/Write; -*n* = value after reset

**Table 10-19. GPIO_LEVELDETECT1 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | LEVELDETECT1[*n*] | R/W | 0h | High Level Interrupt Enable<br>0 = Disable the IRQ assertion on high-level detect.<br>1 = Enable the IRQ assertion on high-level detect. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.19 GPIO_RISINGDETECT Register

The GPIO_RISINGDETECT register is used to enable/disable for each input lines the rising-edge (transition 0 to 1) detection to be used for the interrupt request generation.

**Figure 10-25. GPIO_RISINGDETECT Register**

| 31 | 0 |
|---|---|
| RISINGDETECT[n] | |
| R/W-0 | |

LEGEND: R/W = Read/Write; -*n* = value after reset

|---|---|---|---|---|
| 31-0 | RISINGDETECT[*n*] | R/W | 0h | Rising Edge Interrupt Enable<br>0 = Disable IRQ on rising-edge detect.<br>1 = Enable IRQ on rising-edge detect. |

### 10.3.20 GPIO_FALLINGDETECT Register

The GPIO_FALLINGDETECT register is used to enable/disable for each input lines the falling-edge (transition 1 to 0) detection to be used for the interrupt request generation.

**Figure 10-26. GPIO_FALLINGDETECT Register**

| 31 | 0 |
|---|---|
| FALLINGDETECT[n] | |

Copyright © 2011–2016, Texas Instruments Incorporated

### 10.3.21 GPIO_DEBOUNCENABLE Register

The GPIO_DEBOUNCENABLE register is used to enable/disable the debouncing feature for each input line.

**Figure 10-27. GPIO_DEBOUNCENABLE Register**

| 31 | 0 |
|---|---|
| DEBOUNCEENABLE[n] | |
| R/W-0 | |

LEGEND: R/W = Read/Write; -*n* = value after reset

|---|---|---|---|---|
| 31-0 | DEBOUNCEENABLE[*n*] | R/W | 0h | Input Debounce Enable<br>0 = Disable debouncing feature on the corresponding input port.<br>1 = Enable debouncing feature on the corresponding input port. |

### 10.3.22 GPIO_DEBOUNCINGTIME Register

The GPIO_DEBOUNCINGTIME register controls debouncing time (the value is global for all ports). The debouncing cell is running with the debouncing clock (32 kHz), this register represents the number of the clock cycle(s) (31µs long) to be used.

**Figure 10-28. GPIO_DEBOUNCINGTIME Register**

### 10.3.23 GPIO_CLEARDATAOUT Register

Writing a 1 to a bit in the GPIO_CLEARDATAOUT register clears to 0 the corresponding bit in the GPIO_DATAOUT register; writing a 0 has no effect. A read of the GPIO_CLEARDATAOUT register returns the value of the data output register (GPIO_DATAOUT).

**Figure 10-29. GPIO_CLEARDATAOUT Register**

| 31 | 0 |
|---|---|
| INTLINE [n] | |

## 11.1 Introduction

### 11.1.1 Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

### 11.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

Figure 11-1 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

## 11.2 Architecture

### 11.2.1 GPMC Signals

Table 11-1 lists the GPMC subsystem I/O pins.

**NOTE:** In this chapter, the i in GPMC_CONFIGx_i represents GPMC chip-select i, where i = 0 to 5.

**Table 11-1. GPMC I/O Description**

| Pin Name | I/O | Description |
|---|---|---|
| GPMC_A[27:0] | O | Address |
| GPMC_D[15:0] | I/O | Data |
| GPMC_CS[5:0] | O | Chip-selects (active low) |
| GPMC_CLK | O | Clock generated for the external memory or device |
| GPMC_ADV_ALE | O | Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories. |
| GPMC_OE_RE | O | Output enable (active low). Also used as read enable (active low) for NAND protocol memories. |
| GPMC_WE | O | Write enable (active low) |
| GPMC_BE0_CLE | O | Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories. |
| GPMC_BE1 | O | Upper-byte enable (active low) |
| GPMC_WAIT | I | External wait signal for NOR and NAND protocol memories. The wait signal can be mapped on any of the chip-selects. |

Table 11-2 shows the use of address and data GPMC controller pins based on the type of external device.

**Table 11-2. GPMC Pin Multiplexing Options**

| GPMC_D[4] | D4 | D4 | A5/D4 | D4 | D4 |
| GPMC_D[3] | D3 | D3 | A4/D3 | D3 | D3 |
| GPMC_D[2] | D2 | D2 | A3/D2 | D2 | D2 |
| GPMC_D[1] | D1 | D1 | A2/D1 | D1 | D1 |
| GPMC_D[0] | D0 | D0 | A1/D0 | D0 | D0 |

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (i = 0 to 5).
- Asynchronous page mode is not supported for multiplexed address and data devices.

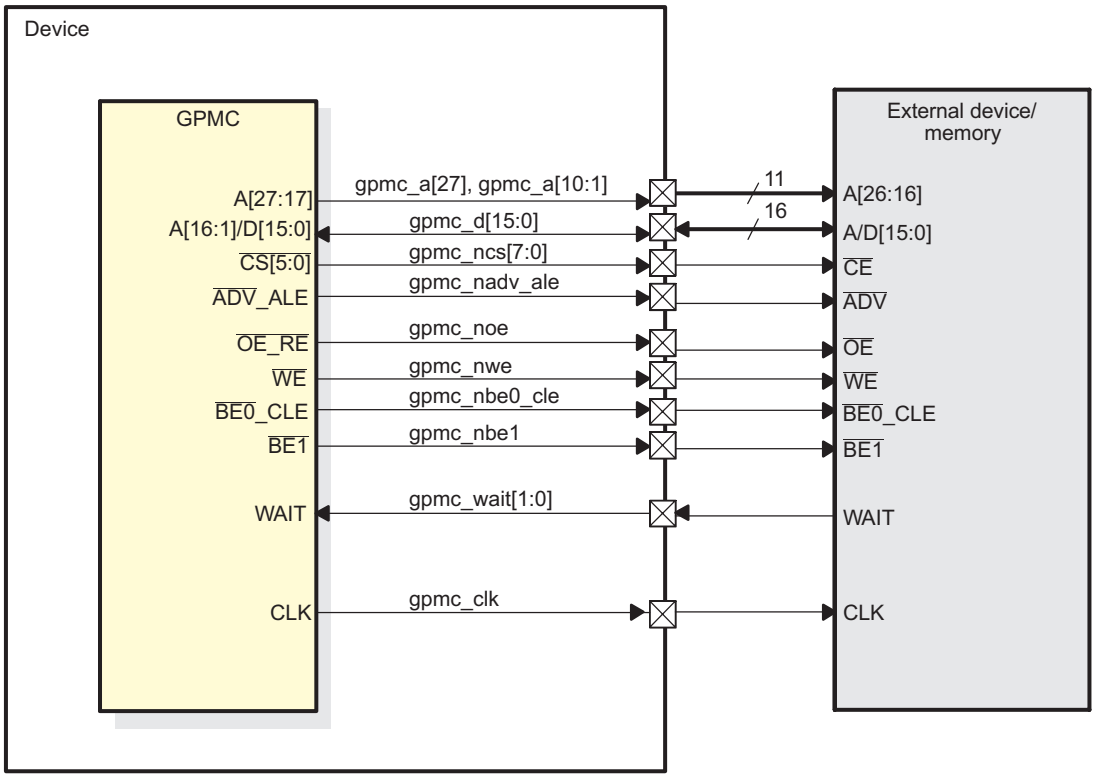
### 11.2.2 GPMC Modes

This section shows three GPMC external connections options:

- Figure 11-2 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- Figure 11-3 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 11-4 shows a connection between the GPMC and a 8-bit NAND device

**Figure 11-2. GPMC to 16-Bit Address/Data-Multiplexed Memory**



A If ROM boot from the NOR device is required, some high-order address lines must be driven or pulled low by external hardware during ROM operation. See the *ROM Code Memory and Peripheral Booting* chapter, XIP Memory section, and the device data manual for details.

### 11.2.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (eDMA) request
- One interrupt request to the Cortex-A8 MPU Interrupt Controller (MA_IRQ)
- One clock for functional and interface domains

Figure 11-5 shows GPMC integration. Table 11-3 through Table 11-5 summarize the integration of the module in the device.

**Figure 11-5. GPMC Integration**

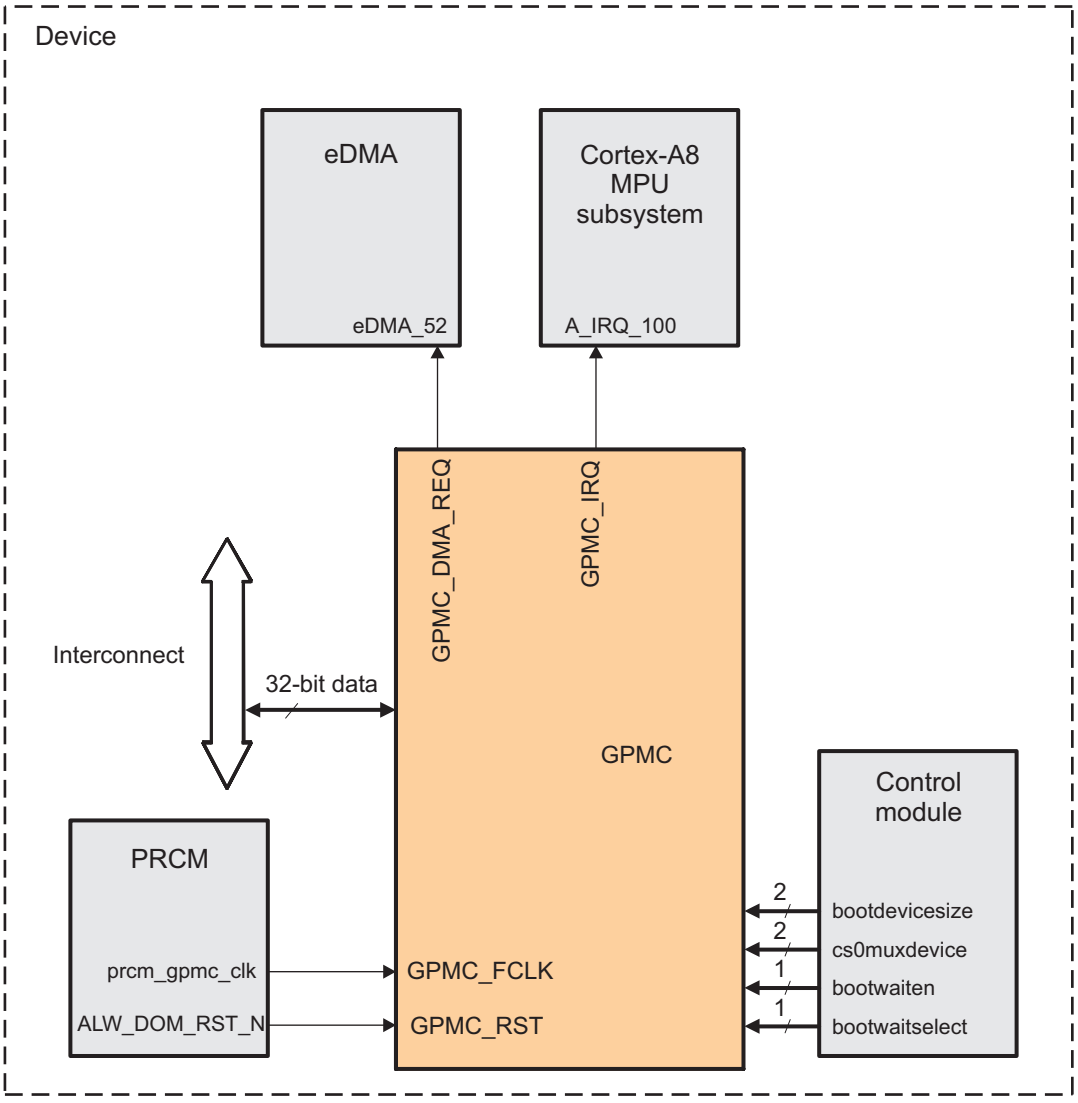

**Table 11-3. GPMC Integration Attributes**

| Module Instance | Attributes | | |
|---|---|---|---|
| | Power Domain | Wake-up Capability | Interconnect |

### *11.2.4 GPMC Functional Description*

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the six configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

#### 11.2.4.1 GPMC Clock Configuration

Table 11-6 describes the GPMC clocks.

**Table 11-6. GPMC Clocks**

| Signal | I/O | Description |
|---|---|---|
| GPMC_FCLK | I | Functional and interface clock |
| GPMC_CLK | O | External clock provided to synchronous external memory devices. |

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 11-4. The GPMC_CLK is configured via the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 11-7.

**Table 11-7. GPMC_CONFIG1_i Configuration**

| Source Clock | GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER | GPMC_CLK Generated Clock Provided to External Memory Device |
|---|---|---|
| GPMC_FCLK | 00 | GPMC_FCLK |
| | 01 | GPMC_FCLK/2 |
| | 10 | GPMC_FCLK/4 |
| | 11 | GPMC_FCLK/8 |

#### 11.2.4.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

#### 11.2.4.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 11-8 describes power-management features available for the GPMC module.

**Table 11-8. GPMC Local Power Management Features**

| Feature | Registers | Description |
|---|---|---|
| Clock Auto Gating | GPMC_SYSCONFIG[0] AUTOIDLE] bit | This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity. |
| Slave Idle Modes | GPMC_SYSCONFIG[4-3] SIDLEMODE bit field | Force-idle, No-idle and Smart-idle wakeup modes are available |
| Clock Activity | N/A | Feature not available |
| Master Standby Modes | N/A | Feature not available |
| Global Wake-up Enable | N/A | Feature not available |
| Wake-up Sources Enable | N/A | Feature not available |

Copyright © 2011–2016, Texas Instruments Incorporated

### 11.2.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in Figure 11-5.

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A8 MPU subsystem: A_IRQ_100

Table 11-9 lists the event flags, and their mask, that can cause module interrupts.

**Table 11-9. GPMC Interrupt Events**

| Event Flag | Event Mask | Sensitivity | Map to | Description |
|---|---|---|---|---|
| GPMC_IRQSTATUS[9] WAIT1EDGEDETECTIONSTATUS | GPMC_IRQENABLE[9] WAIT1EDGEDETECTIONENABLE | Edge | A_IRQ_100 | Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY bit. |
| GPMC_IRQSTATUS[8] WAIT0EDGEDETECTIONSTATUS | GPMC_IRQENABLE[8] WAIT0EDGEDETECTIONENABLE | Edge | A_IRQ_100 | Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY bit. |
| GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS | GPMC_IRQENABLE[1] TERMINALCOUNTENABLE | Level | A_IRQ_100 | Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0. |
| GPMC_IRQSTATUS[0] FIFOEVENTSTATUS | GPMC_IRQENABLE[0] FIFOEVENTENABLE | Level | A_IRQ_100 | FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG[2] DMAMODE bit shall be cleared to 0. |

### 11.2.4.5 GPMC DMA Requests

The GPMC generates one DMA event as shown in Figure 11-5.

- From GPMC (GPMC_DMA_REQ) to the eDMA: e_DMA_53

### 11.2.4.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field ([24-23]) according to the effective attached device page length and to enable the GPMC_CONFIG1_i WRAPBURST bit ([31]) if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

Copyright © 2011–2016, Texas Instruments Incorporated

### 11.2.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC_D[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0] and GPMC I/O: GPMC_D[15-8].

#### *11.2.4.7.1 GPMC I/O Configuration Setting*

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 10
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 01

To select an address/data-nonmultiplexed device , program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

### 11.2.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 11.5 provides the GPMC register locations. For the map of GPMC memory locations, see Table 11-54.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.8.1 Chip-Select Base Address and Region Size

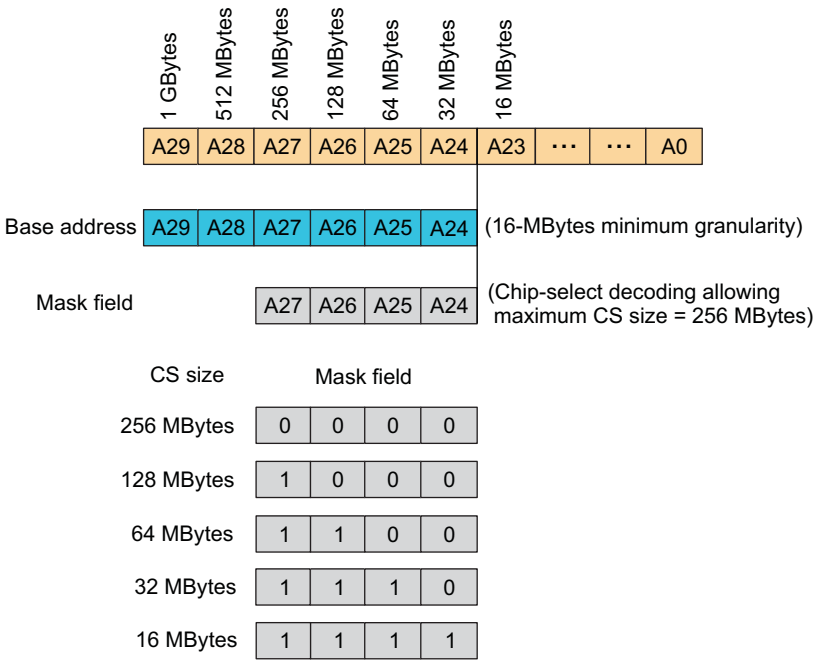
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see Table 11-54.

The GPMC 512 Mbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 Mbytes to 256 Mbytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 11-6 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

**Figure 11-6. Chip-Select Address Mapping and Decoding Mask**



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (i = 0 to 5). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Copyright © 2011–2016, Texas Instruments Incorporated

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to six chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

#### 11.2.4.8.2 Access Protocol

##### 11.2.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 5) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 11.2.4.12 and Section 11.2.4.12.1.

##### 11.2.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE field (i = 0 to 5) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

##### 11.2.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[[9-8] MUXADDDATA bit (i = 0 to 5). The $\overline{\text{ADV}}$ signal must be used as the external device address latch control signal. For the associated chip-select configuration, $\overline{\text{ADV}}$ assertion and deassertion time and $\overline{\text{OE}}$ assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see Section 11.2.3).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see Section 11.2.4.12).

#### 11.2.4.8.3 External Signals

##### 11.2.4.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin:gpmc_wait1, and gpmc_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit (where i = 0 to 5) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

Copyright © 2011–2016, Texas Instruments Incorporated

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

#### *11.2.4.8.3.2 Wait Monitoring During an Asynchronous Read Access*

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

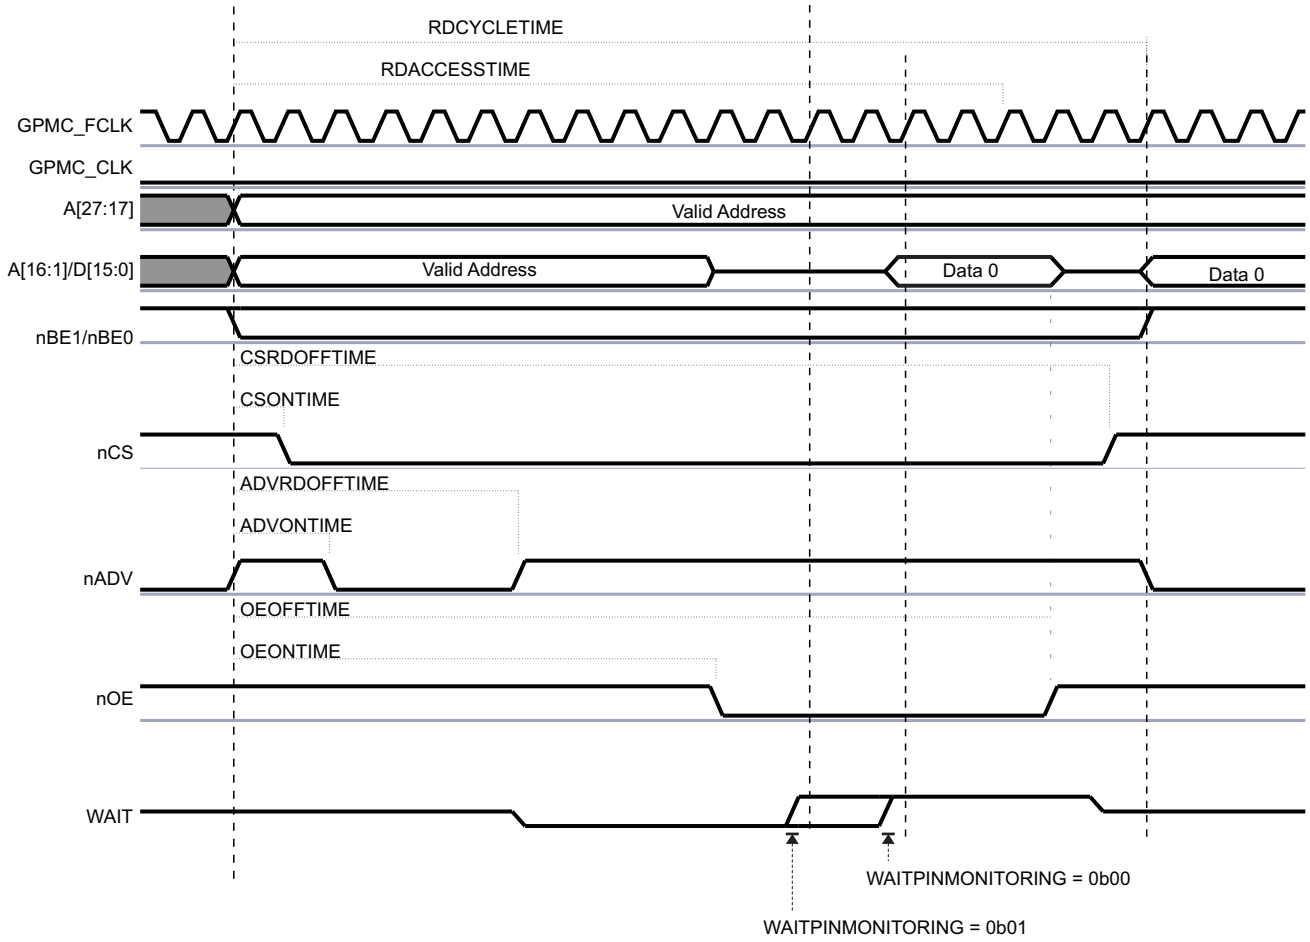
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 11-7 shows wait behavior during an asynchronous single read access.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 11-7. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**



The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 00b or 01b.

#### *11.2.4.8.3.3 Wait Monitoring During an Asynchronous Write Access*

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

Copyright © 2011–2016, Texas Instruments Incorporated

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit (i = 0 to 5).

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

#### *11.2.4.8.3.4 Wait Monitoring During a Synchronous Read Access*

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit (i = 0 to 5), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 ( at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 11-8 shows wait behavior during a synchronous read burst access.

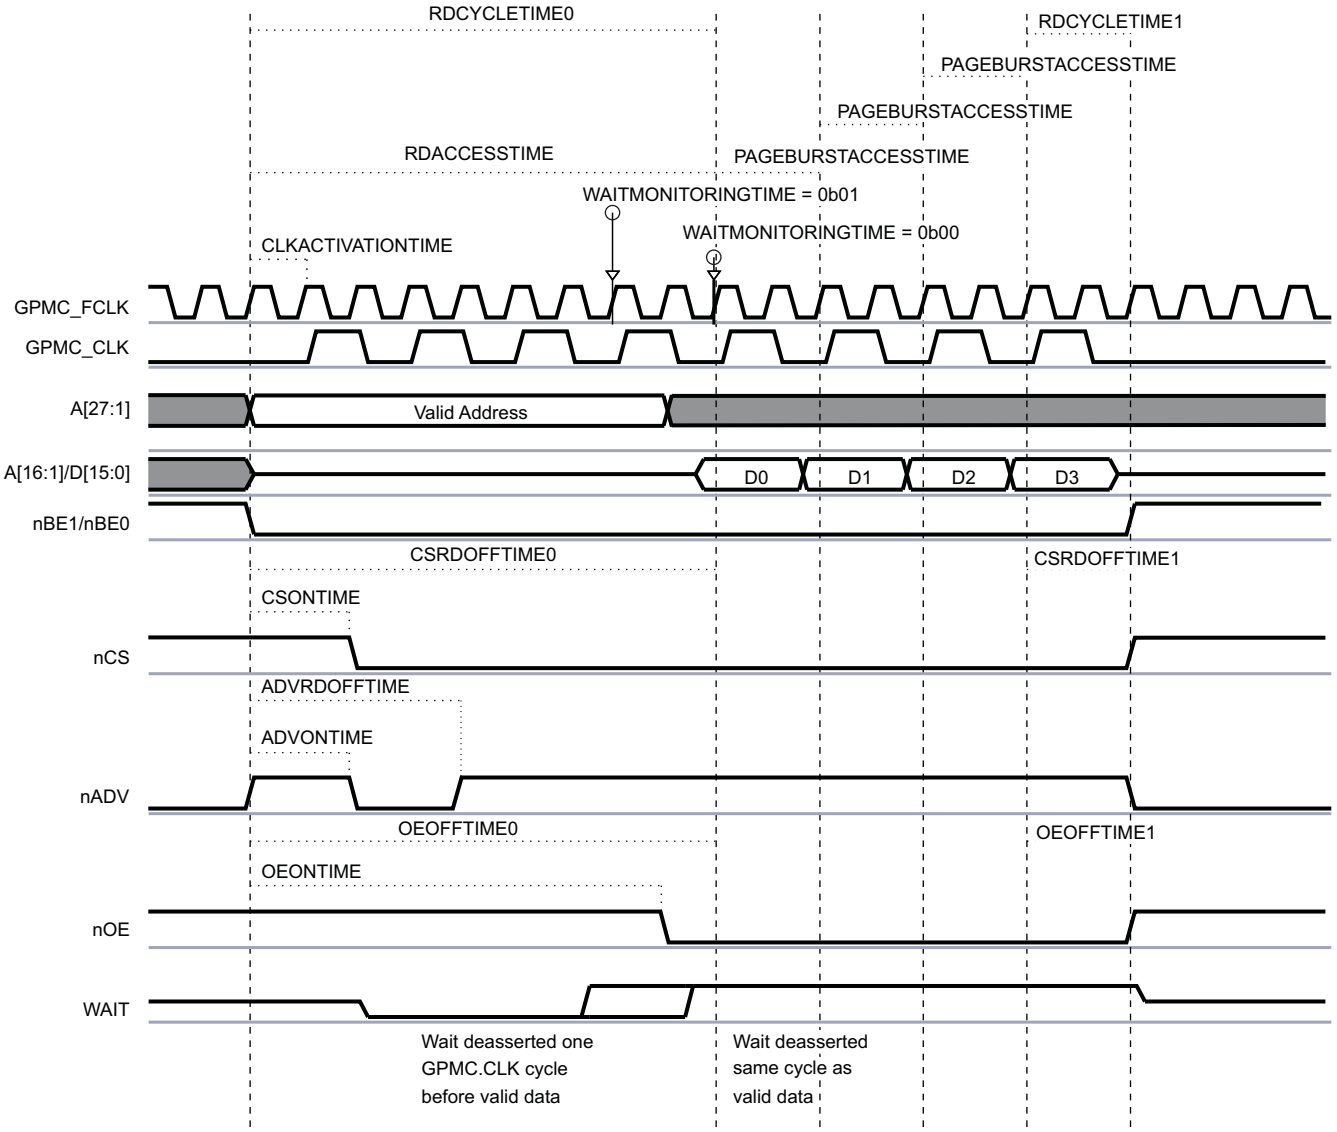
**Figure 11-8. Wait Behavior During a Synchronous Read Burst Access**



The WAIT signal is active low. WAITMONITORINGTIME = 00b or 01b.

#### *11.2.4.8.3.5 Wait Monitoring During a Synchronous Write Access*

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Copyright © 2011–2016, Texas Instruments Incorporated

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field equal to 0 or 1, respectively).

#### 11.2.4.8.3.6 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 11.2.4.12.2.

#### 11.2.4.8.3.7 Idle Cycle Control Between Successive Accesses

##### 11.2.4.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the $\overline{CS}$/$\overline{OE}$ de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after $\overline{CS}$ or $\overline{OE}$ de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit (i = 0 to 5).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See Figure 11-9 to Figure 11-11.

Another way to prevent bus contention is to define an earlier $\overline{CS}$ or $\overline{OE}$ deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

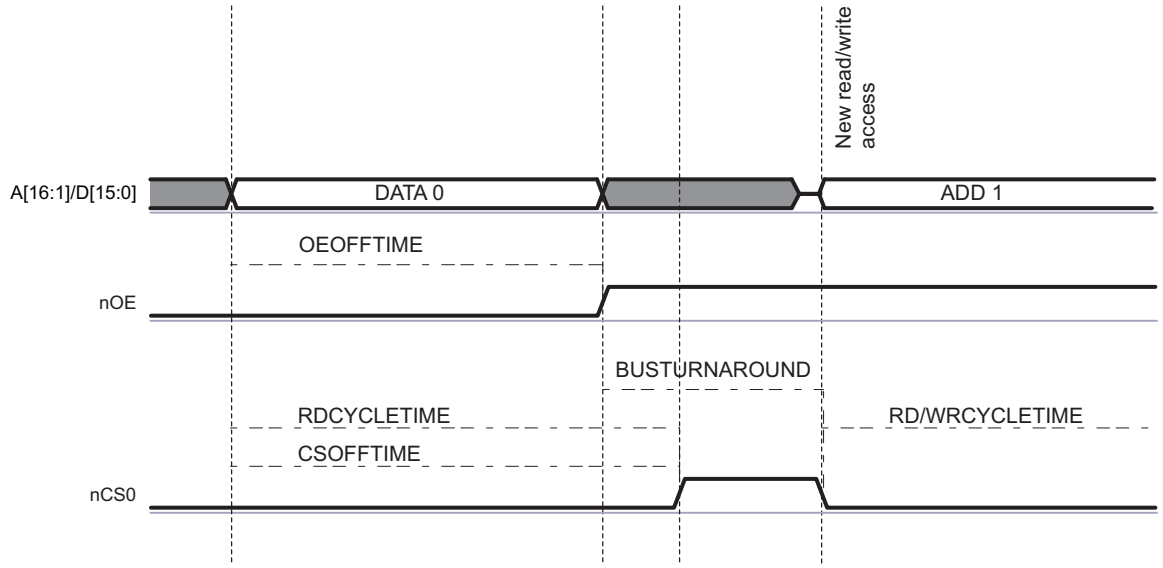
**Figure 11-11. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround**



#### *11.2.4.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)*

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (i = 0 to 5) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### *11.2.4.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)*

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{OE_RE}$, $\overline{WE}$) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals ($\overline{WE}$, $\overline{OE_RE}$) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

Copyright © 2011–2016, Texas Instruments Incorporated

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 11.2.4.8.3.7.1 for more details on bus turnaround.

Table 11-10 describes the configuration required for idle cycle insertion.

**Table 11-10. Idle Cycle Insertion Configuration**

| First Access Type | BUSTURNAROUND Timing Parameter | Second Access Type | Chip-Select | Addr/Data Multiplexed | CYCLE2CYCLE SAMECSEN Parameter | CYCLE2CYCLE DIFFCSEN Parameter | Idle Cycle Insertion Between the Two Accesses |
|---|---|---|---|---|---|---|---|
| R/W | 0 | R/W | Any | Any | 0 | x | No idle cycles are inserted if the two accesses are well pipelined. |
| R | >0 | R | Same | Nonmuxed | x | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R | >0 | R | Different | Nonmuxed | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| R | >0 | R/W | Any | Muxed | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| R | >0 | W | Any | Any | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| W | >0 | R/W | Any | Any | 0 | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R/W | 0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | 0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | >0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY). |
| R/W | >0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY). |

#### *11.2.4.8.3.8 Slow Device Support (TIMEPARAGRANULARITY Parameter)*

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i = 0 to 5). Increasing all access timing parameters allows support of slow devices.

#### *11.2.4.8.3.9 Reset*

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Power, Reset, and Clock Management.

Copyright © 2011–2016, Texas Instruments Incorporated

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

#### *11.2.4.8.3.10 Byte Enable ($\overline{BE1}$/$\overline{BE0}$)*

Byte enable signals ($\overline{BE1}$/$\overline{BE0}$) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

#### *11.2.4.8.4 Error Handling*

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0]ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the

9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

### 11.2.4.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see Section 11.2.4.9.6.

In the following sections, the start access time refer to the time at which the access begins.

#### *11.2.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)*

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME bit (i = 0 to 5) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{OE}$_$\overline{RE}$, $\overline{WE}$, and $\overline{BE0}$_CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

Copyright © 2011–2016, Texas Instruments Incorporated

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{WE}$, and $\overline{OE_RE}$) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

#### 11.2.4.9.2 $\overline{CS}$: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME field (where i = 0 to 5) defines the $\overline{CS}$ signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the $\overline{CS}$ signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

$\overline{CS}$ signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the $\overline{CS}$ assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling $\overline{CS}$ transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the $\overline{CS}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

#### 11.2.4.9.3 $\overline{ADV}$_ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY / ADVAADMUXONTIME / ADVAADMUXRDOFFTIME / ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 5) defines the $\overline{ADV}$_ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the $\overline{ADV}$_ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before $\overline{ADV}$_ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after $\overline{ADV}$_ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

Copyright © 2011–2016, Texas Instruments Incorporated

$\overline{\text{ADV}}$_ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{\text{ADV}}$_ALE assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling $\overline{\text{ADV}}$_ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than $\overline{\text{ADV}}$_ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

The GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high $\overline{\text{ADV}}$ pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, $\overline{\text{ADV}}$ is kept low until it reaches the correct ADVxxOFFTIME.

See Section 11.2.4.12 for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.9.4 $\overline{OE_RE}$: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME bit (where i = 0 to 5) defines the $\overline{OE_RE}$ signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME field defines the $\overline{OE_RE}$ signal deassertion time relative to start access time. It is applicable only to read accesses. $\overline{OE_RE}$ is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before $\overline{OE_RE}$ assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{OE_RE}$ assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the $\overline{OE}$ signal de-asserted before $\overline{OE}$ can be asserted again to define a read command.

The $\overline{OE_RE}$ signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{OE_RE}$ assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling $\overline{OE_RE}$ transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than $\overline{OE_RE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time.

#### 11.2.4.9.5 $\overline{WE}$: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME field (where i = 0 to 3) defines the $\overline{WE}$ signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME field defines the $\overline{WE}$ signal-deassertion time relative to start access time. These bit fields only apply to write accesses. $\overline{WE}$ is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before $\overline{WE}$ assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{WE}$ assertion.

$\overline{WE}$ signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{WE}$ assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling $\overline{WE}$ transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the $\overline{WE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 4, or 8, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit (where i = 0 to 3), with an assured 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME - CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

#### 11.2.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit (i = 0 to 5) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

#### 11.2.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME bit (i = 0 to 5). This allows $\overline{OE}$ and GPMC data capture timing parameters to be independent of $\overline{WE}$ and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

##### 11.2.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i[[20-16] RDACCESSTIME bit (i = 0 to 5) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

Copyright © 2011–2016, Texas Instruments Incorporated

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4-0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 11.2.4.8.1.

#### 11.2.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 11.2.4.8.1.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 11.2.4.8.1.

### 11.2.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit (i = 0 to 5) can be set with a granularity of 1 or 2 throught the GPMC_CONFIG1_i[[4] TIMEPARAGRANULARITY.

#### 11.2.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 11.2.4.8.1.

#### 11.2.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 11.2.4.8.1.

### 11.2.4.9.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

Copyright © 2011–2016, Texas Instruments Incorporated

### 11.2.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (i = 0 to 5). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit (i = 0 to 5).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and $\overline{\text{BE}}$[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

#### *11.2.4.10.1 Asynchronous Access Description*

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

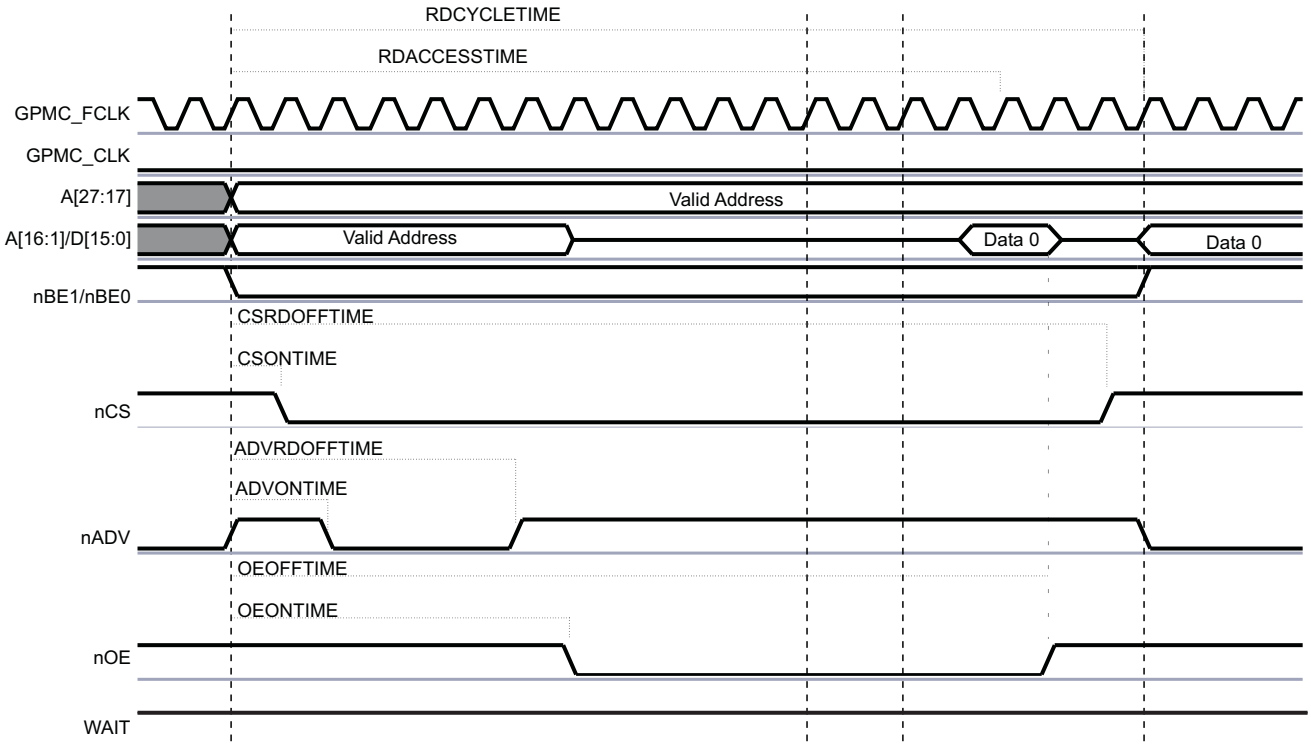
Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.1.1 Access on Address/Data Multiplexed Devices

##### 11.2.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 11-12 shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 11-12. Asynchronous Single Read Operation on an Address/Data Multiplexed Device**



##### 11.2.4.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 11.2.4.8.2.3.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[25:16] are placed on the address bus.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field. It controls the address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field. It controls the address hold time from $\overline{CS}$ deassertion
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.

Copyright © 2011–2016, Texas Instruments Incorporated

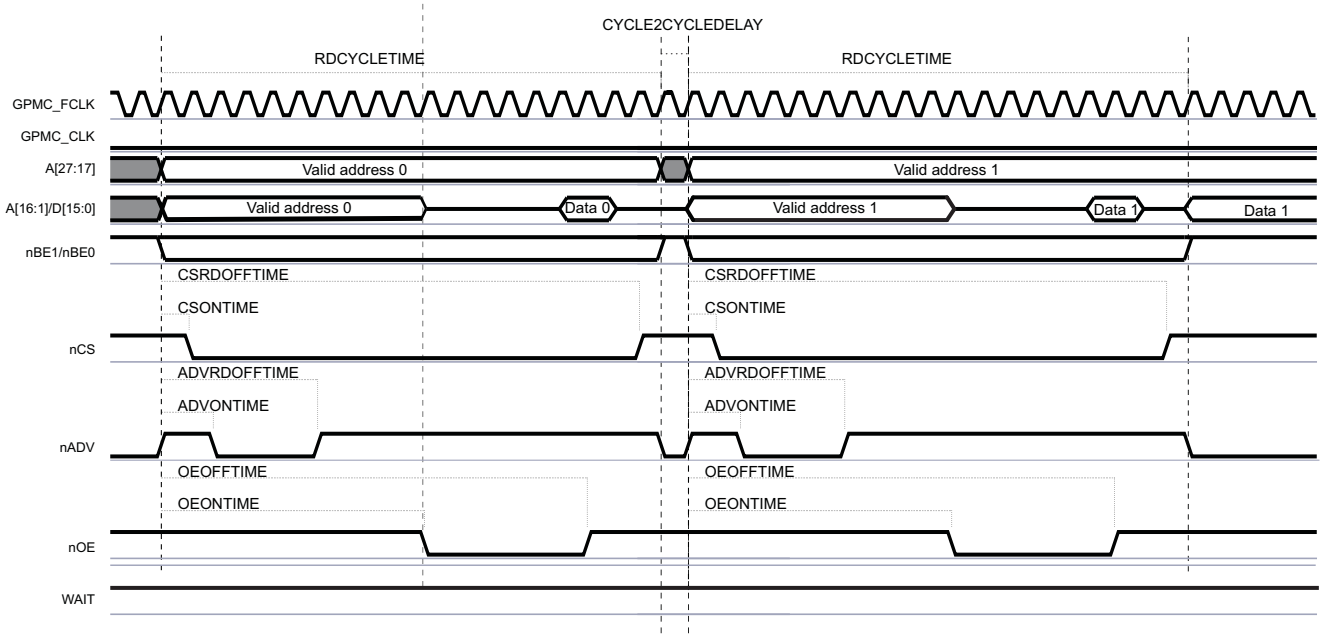
- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[[3-0] OEONTIME field.
  - OE deassertion time is controlled by the GPMC_CONFIG4_i[[12-8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME field.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 11.2.4.10.5. Between two successive accesses, if an $\overline{CS}$ pulse is needed:

- The GPMC_CONFIG6_i[[11-8] CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i[[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 11-13 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

**Figure 11-13. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 × 16-Bit Read)**

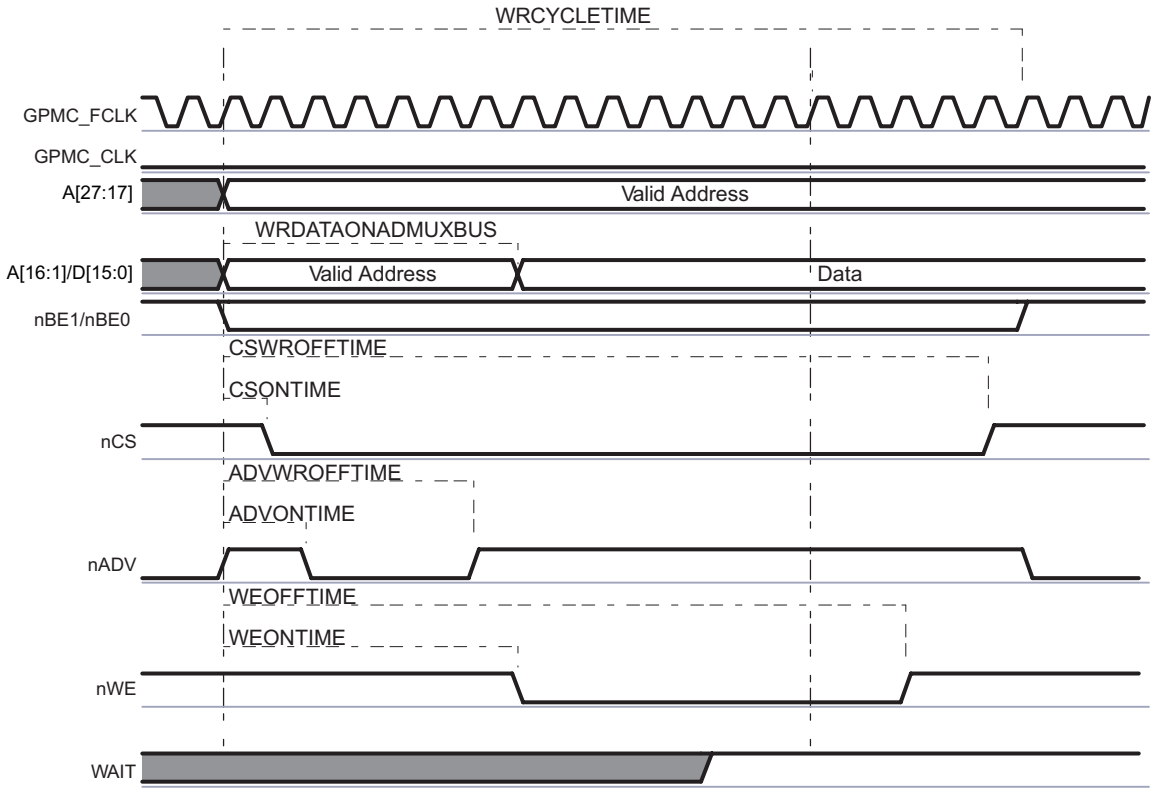


Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 11-14 shows an asynchronous single write operation on an address/data-multiplexed device.

**Figure 11-14. Asynchronous Single Write on an Address/Data-Multiplexed Device**



#### 11.2.4.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until $\overline{WE}$ assertion time. For more information, see Section 11.2.4.8.2.3.

The $\overline{CS}$ and $\overline{ADV}$ signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a write cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 11.2.4.9.10.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

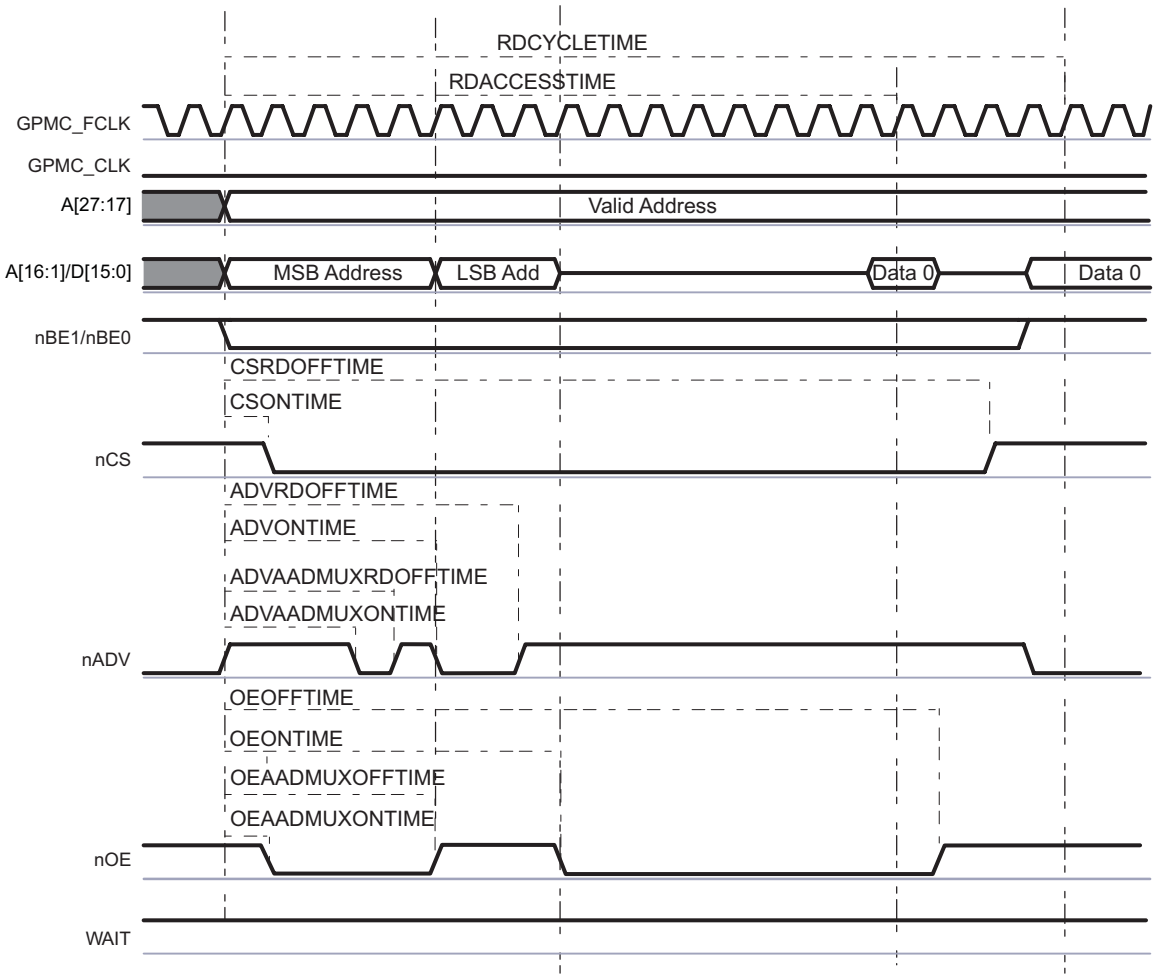
For accesses on non-multiplexed devices, see Section 11.2.4.10.3.

### 11.2.4.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

#### 11.2.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 11-15 shows an asynchronous single read operation on an AAD-multiplexed device.

**Figure 11-15. Asynchronous Single-Read on an AAD-Multiplexed Device**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The first address phase ends at the first $\overline{OE}$ deassertion time. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The second address phase ends at the second $\overline{OE}$ assertion time.

The $\overline{CS}$ signal is controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

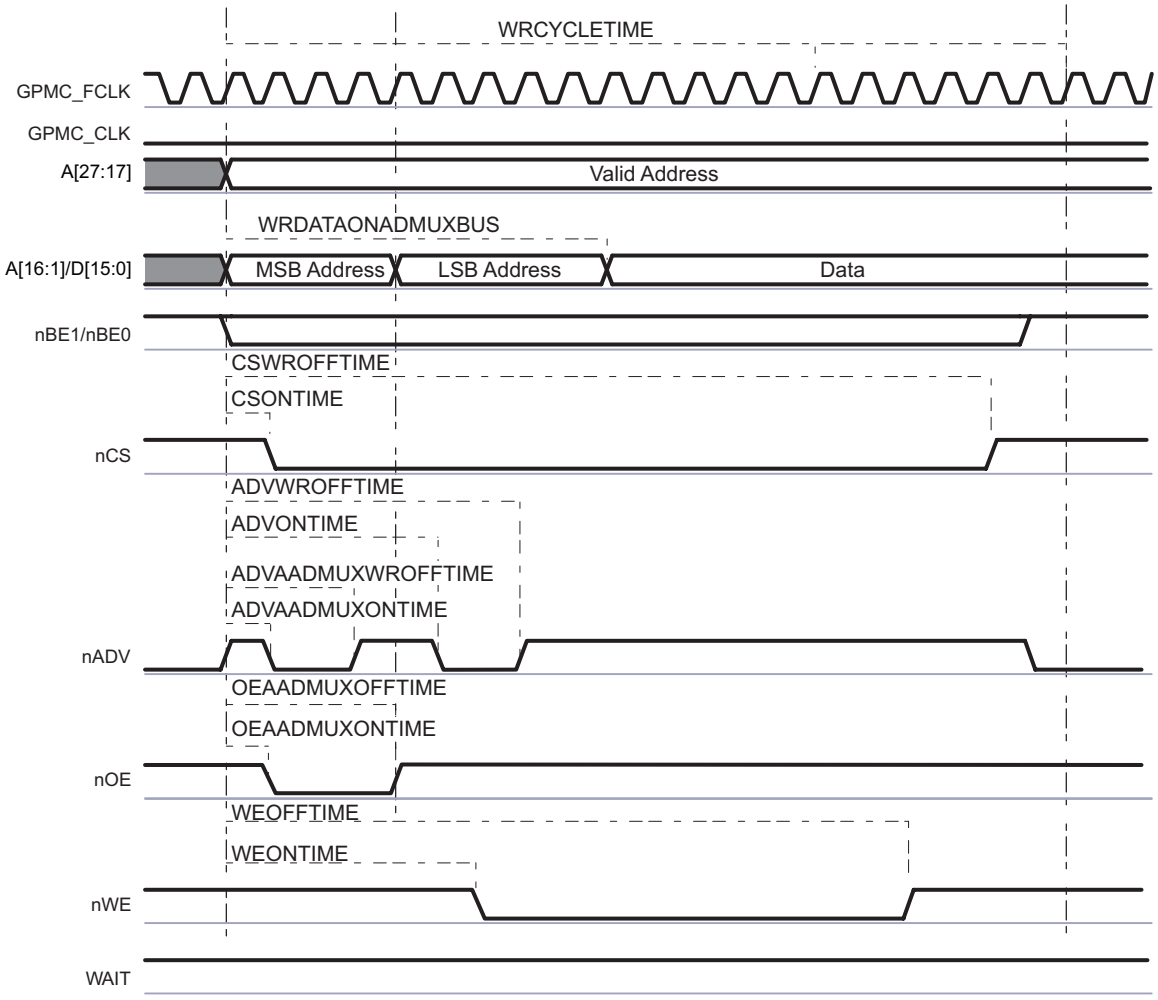
- Address valid signal $\overline{ADV}$. $\overline{ADV}$ is asserted and deasserted twice during a read transaction:
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$. $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle):
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 11-16 shows an asynchronous single write operation on an AAD-multiplexed device.

**Figure 11-16. Asynchronous Single Write on an AAD-Multiplexed Device**



Copyright © 2011–2016, Texas Instruments Incorporated

See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ and $\overline{WE}$ signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a write transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted during the address phase of a write transaction
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until $\overline{OE}$ deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

#### *11.2.4.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device*

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 11.2.4.10.3.

### *11.2.4.10.2 Synchronous Access Description*

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see Section 11.2.4.10.3.

In synchronous operations:

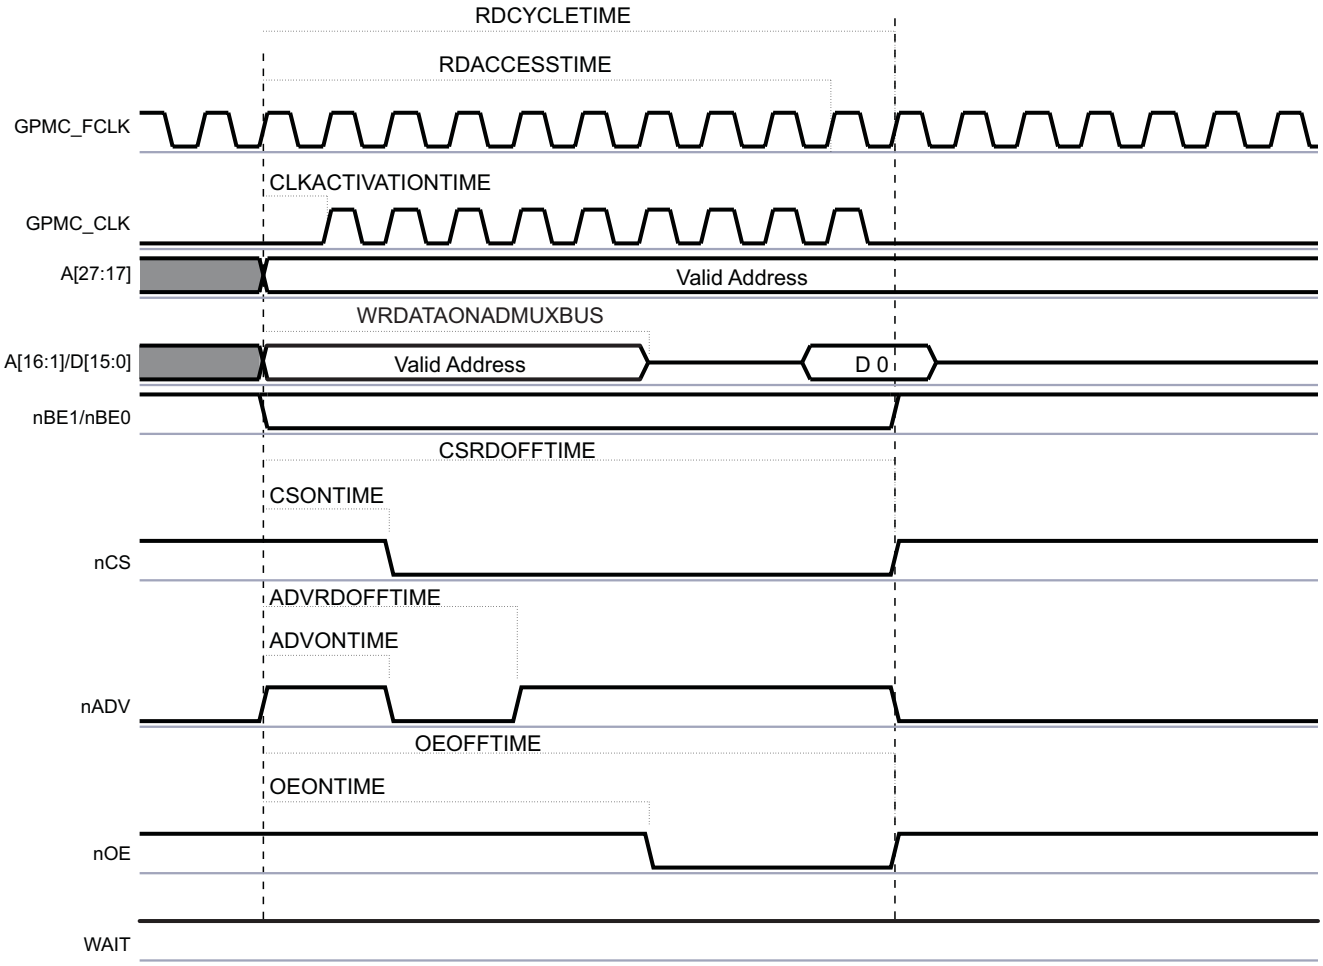
- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field. In the following section, i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.2.1 Synchronous Single Read

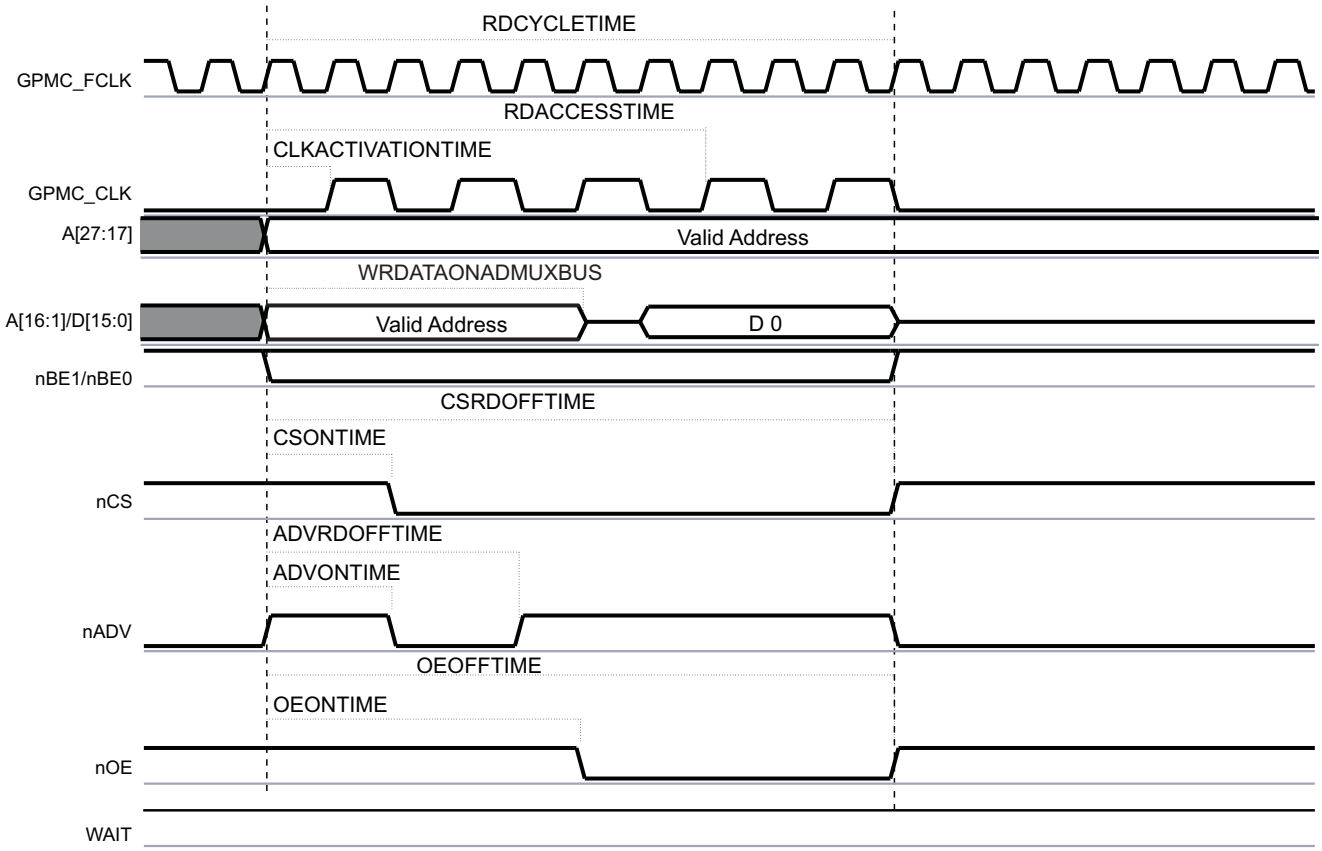
Figure 11-17 and Figure 11-18 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

**Figure 11-17. Synchronous Single Read (GPMCFCLKDIVIDER = 0)**



Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 11-18. Synchronous Single Read (GPMCFCLKDIVIDER = 1)**



See Section 11.3.6.1 for formulas to calculate timing parameters.

Table 11-40 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 11.2.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i[4-0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

Copyright © 2011–2016, Texas Instruments Incorporated

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ signal is controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

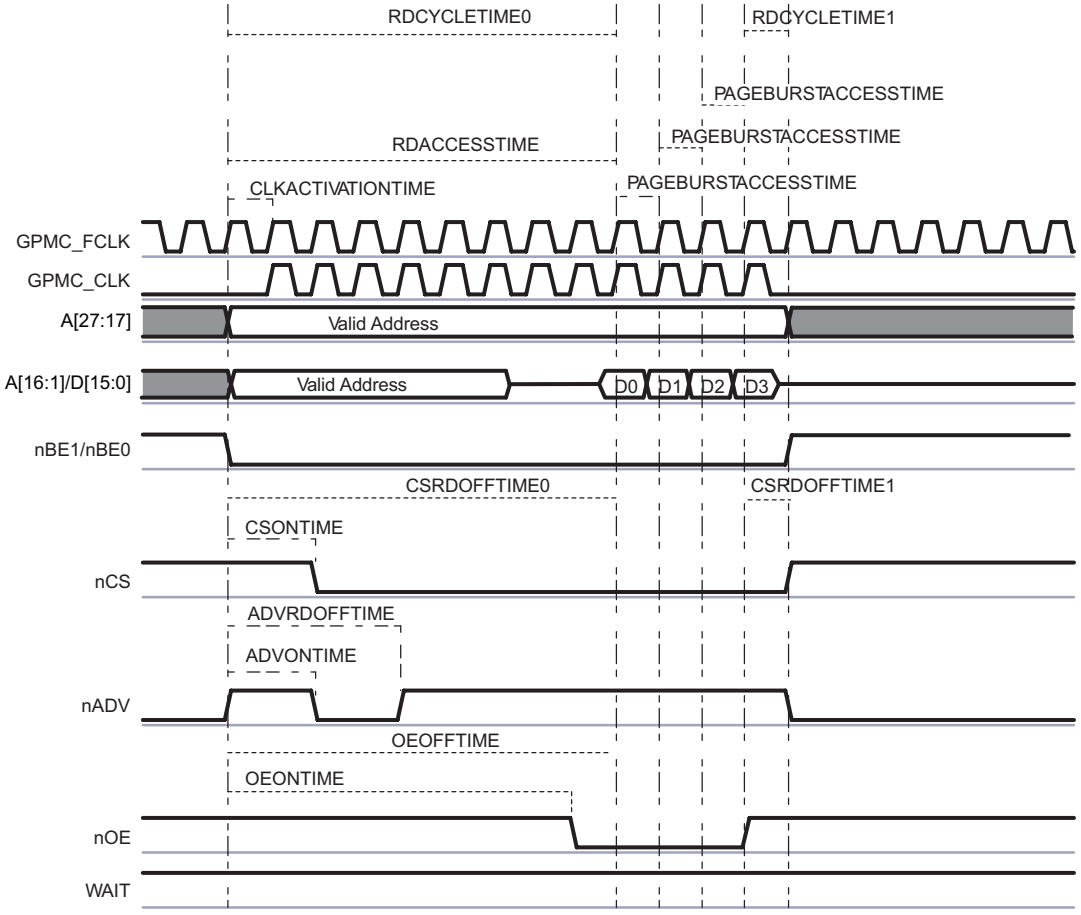
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 11.2.4.9.10.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

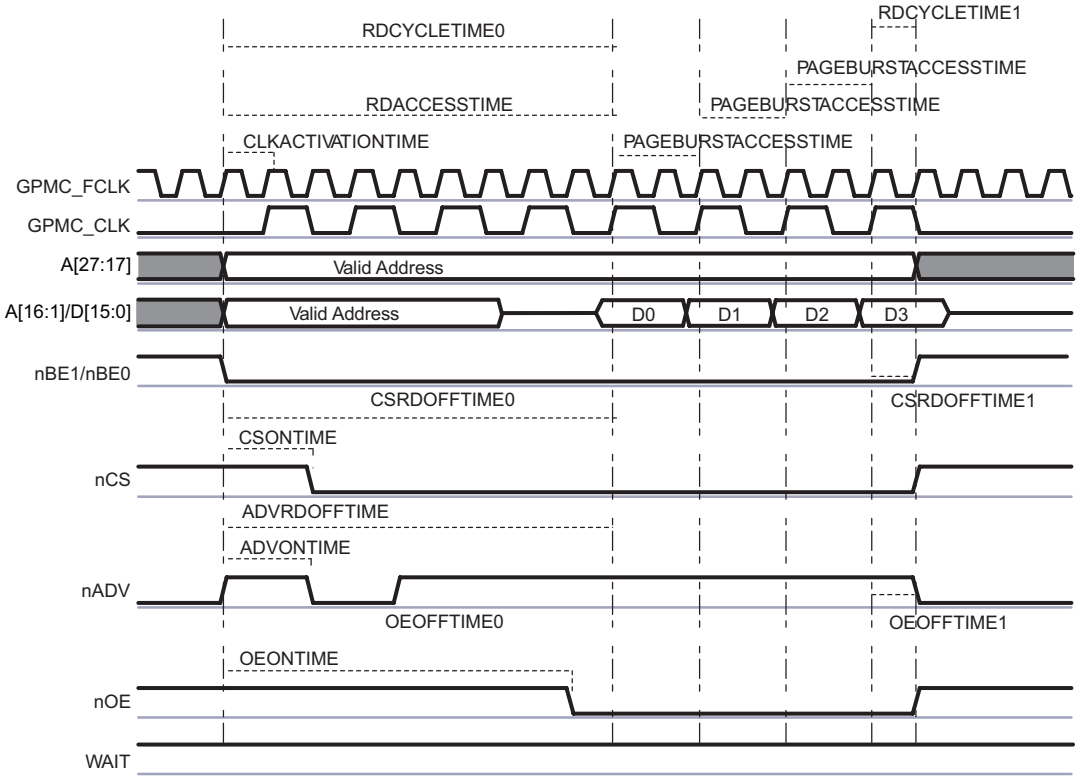
Figure 11-19 and Figure 11-20 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

**Figure 11-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)**



Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 11-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**



When GPMC_CONFIG5_i[20-16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The $\overline{CS}$, $\overline{ADV}$, and $\overline{OE}$ signals are controlled in the same way as for synchronous single read operation. See Section 11.2.4.10.2.1.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 11-19, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 11.2.4.9.10.

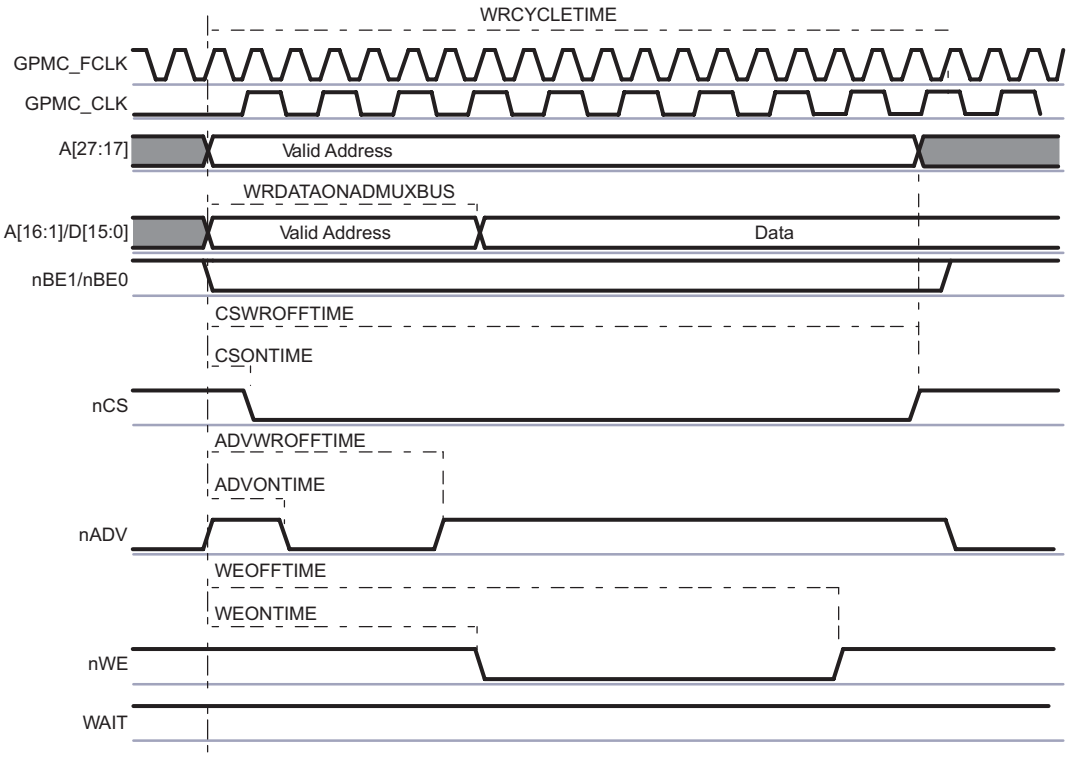
Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see Figure 11-21).

**Figure 11-21. Synchronous Single Write on an Address/Data-Multiplexed Device**



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until [19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses. Figure 11-22 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 11-22. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

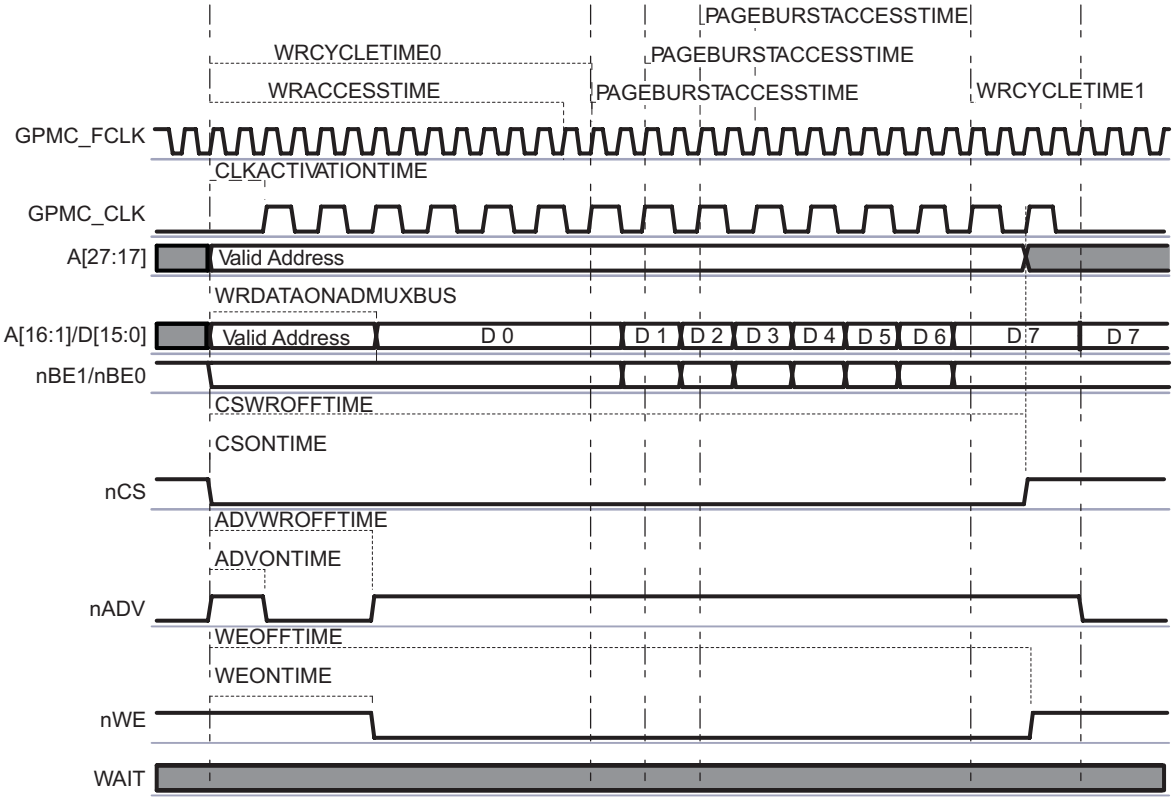


Figure 11-23 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

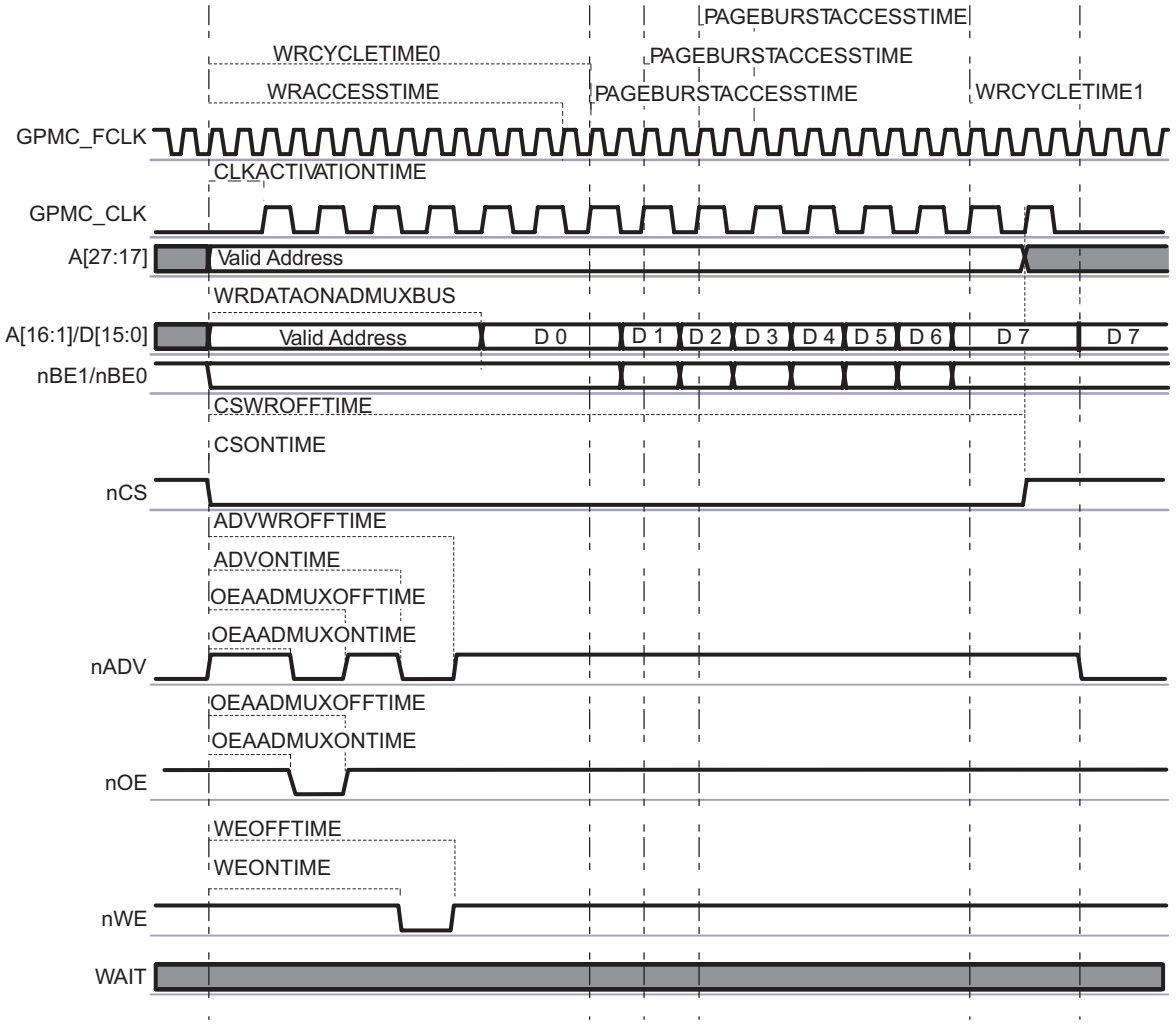
Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 11-23. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode**



The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 11.2.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit (i = 0 to 5) and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.

Copyright © 2011–2016, Texas Instruments Incorporated

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a read cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.

  The $\overline{WE}$ falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the $\overline{WE}$ signal at low during the address phase.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ signal is controlled as detailled above.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 11-23 the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 11.2.4.9.10.

#### *11.2.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*

Page mode is only available in non-multiplexed mode.

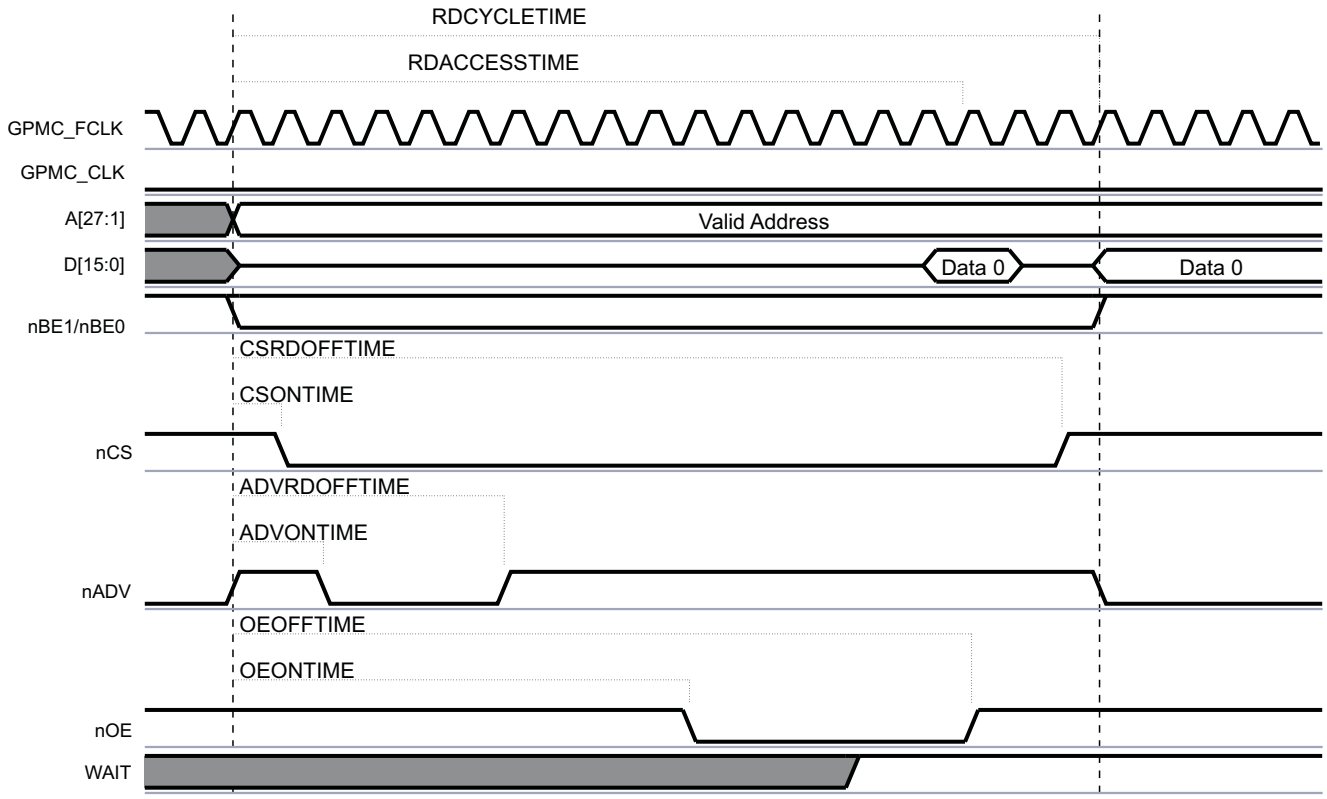
- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 11-24 shows an asynchronous single read operation on a nonmultiplexed device.

**Figure 11-24. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device**



The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

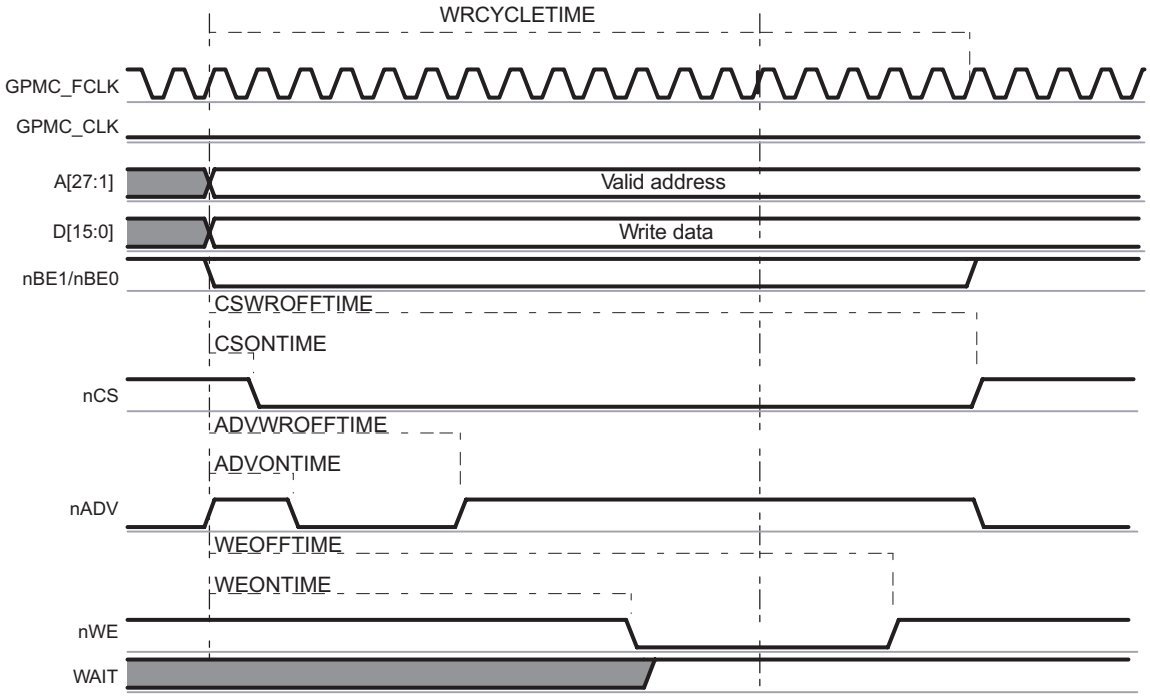
$\overline{CS}$, $\overline{ADV}$, and $\overline{OE}$ signals are controlled in the same way as address/data multiplexed accesses, see Section 11.2.4.10.1.1.2.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 11-25 shows an asynchronous single write operation on a nonmultiplexed device.

**Figure 11-25. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device**



The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

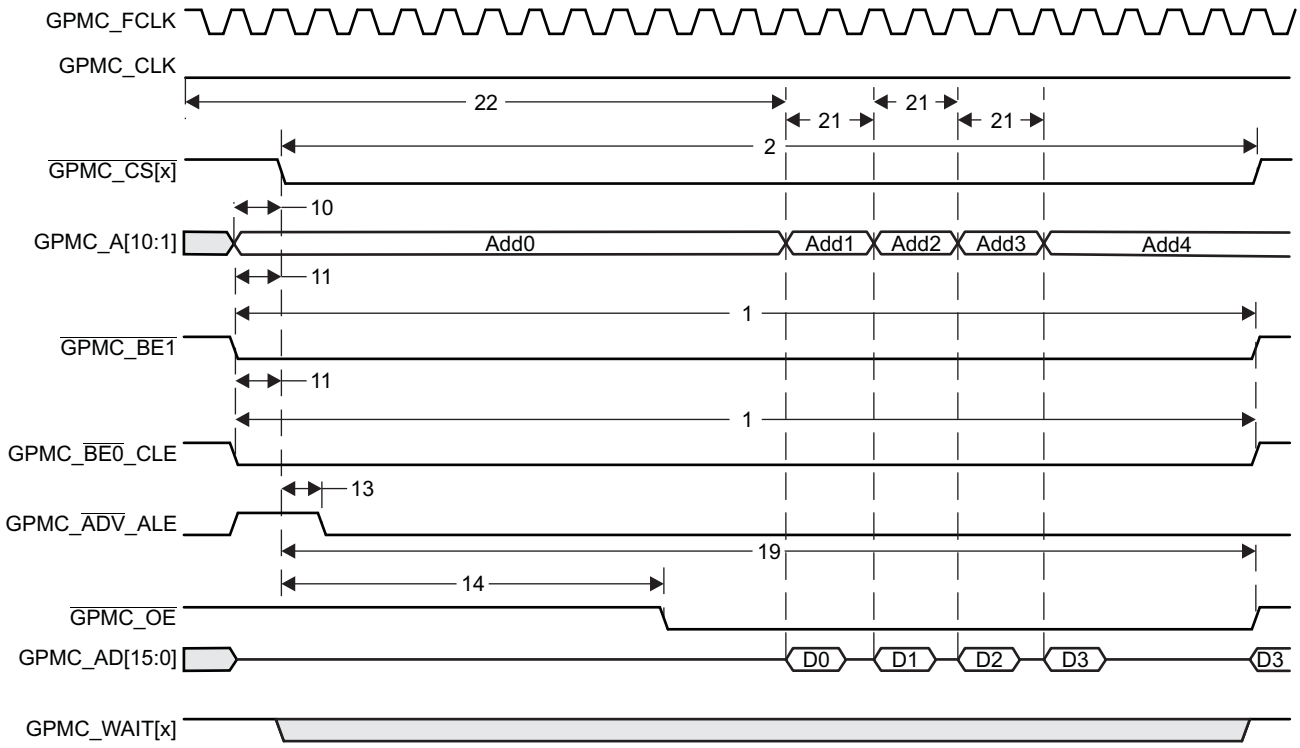
$\overline{CS}$, $\overline{ADV}$, and $\overline{WE}$ signals are controlled in the same way as address/data multiplexed accesses, see Section 11.2.4.10.1.1.3.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 11-26 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word 16) read access to the attached device.

**Figure 11-26. Asynchronous Multiple (Page Mode) Read**



The WAIT signal is active low.

$\overline{CS}$, $\overline{ADV}$, and $\overline{OE}$ signals are controlled in the same way as address/data multiplexed accesses, see Section 11.2.4.10.1.1.2.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (i = 0 to 5). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the $\overline{CS}$ deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME field.
- In Figure 11-26, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 11.2.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 11.3.3.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (i = 0 to 5) are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

#### 11.2.4.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit (i = 0 to 5). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (i = 0 to 5) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

Copyright © 2011–2016, Texas Instruments Incorporated

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

#### 11.2.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[[11-10] DEVICETYPE field (i = 0 to 3) shall be cleared to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum $\overline{CS}$ high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 11.2.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

##### *11.2.4.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode*

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Copyright © 2011–2016, Texas Instruments Incorporated

Any chip-select region can be qualified as a NAND region to constrain the $\overline{\text{ADV}}$_ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the $\overline{\text{BE0}}$_CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 11.2.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 5) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 11-11. Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register (where i = 0 to 5) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

**Table 11-11. Chip-Select Configuration for NAND Interfacing**

| Bit Field | Register | Value | Comments |
|---|---|---|---|
| WRAPBURST | GPMC_CONFIG1_i | 0 | No wrap |
| READMULTIPLE | GPMC_CONFIG1_i | 0 | Single access |
| READTYPE | GPMC_CONFIG1_i | 0 | Asynchronous mode |
| WRITEMULTIPLE | GPMC_CONFIG1_i | 0 | Single access |
| WRITETYPE | GPMC_CONFIG1_i | 0 | Asynchronous mode |
| CLKACTIVATIONTIME | GPMC_CONFIG1_i | 0b00 | |
| ATTACHEDDEVICEPAGELENGTH | GPMC_CONFIG1_i | Don't care | Single-access mode |
| WAITREADMONITORING | GPMC_CONFIG1_i | 0 | Wait not monitored by GPMC access engine |
| WAITWRITEMONITORING | GPMC_CONFIG1_i | 0 | Wait not monitored by GPMC access engine |
| WAITMONITORINGTIME | GPMC_CONFIG1_i | Don't care | Wait not monitored by GPMC access engine |
| WAITPINSELECT | GPMC_CONFIG1_i | | Select which wait is monitored by edge detectors |
| DEVICESIZE | GPMC_CONFIG1_i | 0b00 or 0b01 | 8- or 16-bit interface |
| DEVICETYPE | GPMC_CONFIG1_i | 0b10 | NAND device in stream mode |
| MUXADDDATA | GPMC_CONFIG1_i | 0b00 | Nonmultiplexed mode |
| TIMEPARAGRANULARITY | GPMC_CONFIG1_i | 0 | Timing achieved with best GPMC clock granularity |
| GPMCFCLKDIVIDER | GPMC_CONFIG1_i | Don't care | Asynchronous mode |

#### 11.2.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with $\overline{OE}$ and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) register locations must be posted for faster operations. The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) registers are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (where i = 0 to 5) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

#### 11.2.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i (where i = 0 to 5) register location places the data as the NAND command value on the bus, using a regular asynchronous write access.

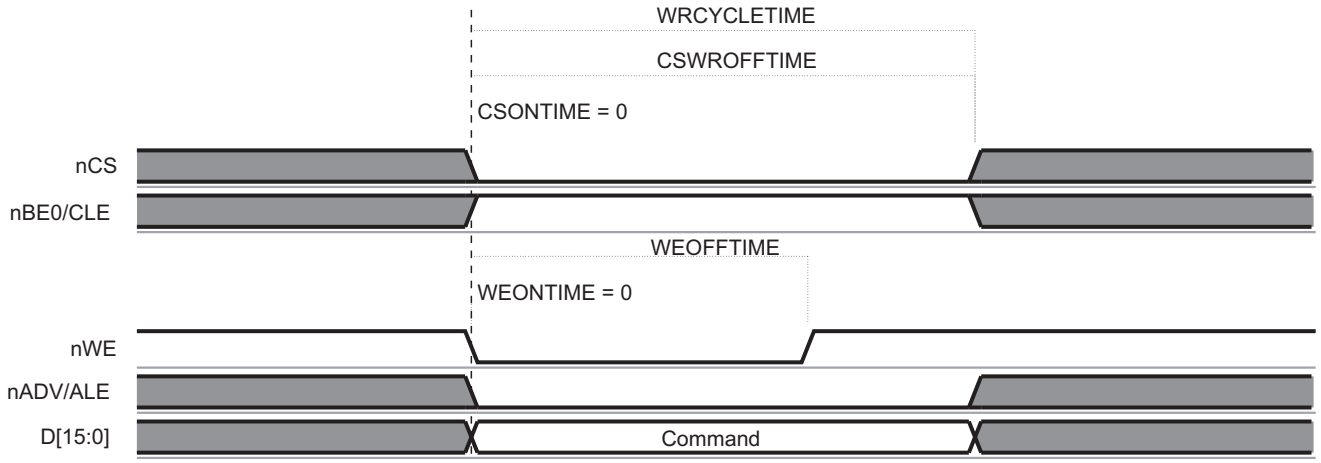
- $\overline{CE}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 11-27 shows the NAND command latch cycle.

CLE is shared with the $\overline{BE0}$ output signal and has an inverted polarity from $\overline{BE0}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, $\overline{BE0}$ (also $\overline{BE1}$) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

**Figure 11-27. NAND Command Latch Cycle**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.1.4 Address Latch Cycle

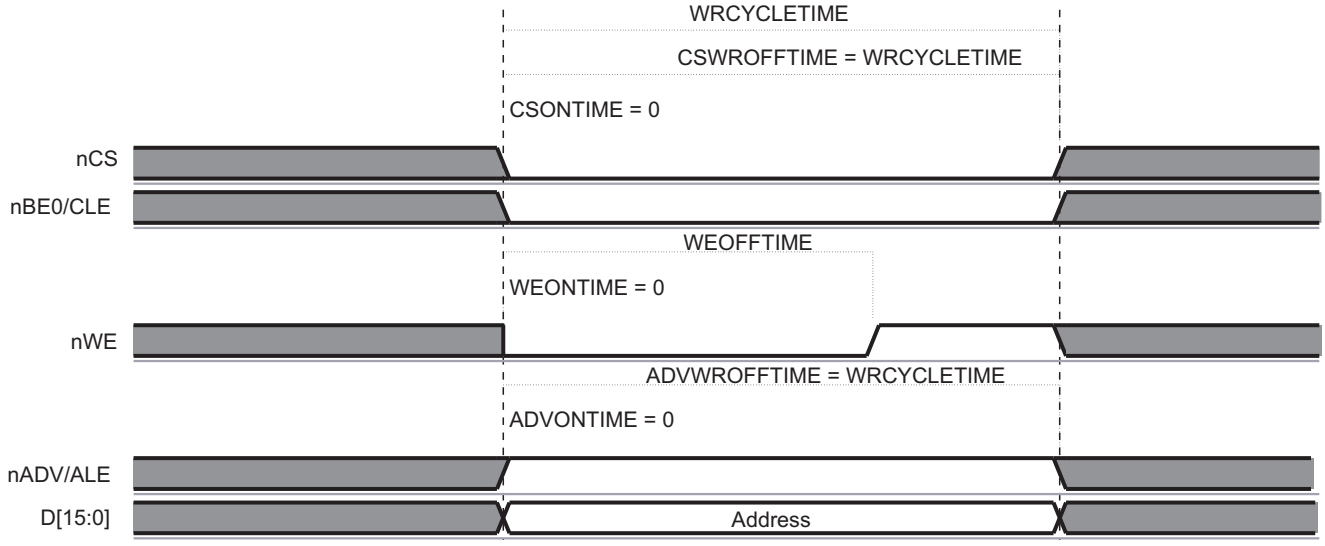
Writing data at the GPMC_NAND_ADDRESS_i (where i = 0 to 5) register location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 11-28 shows the NAND address latch cycle.

ALE is shared with the $\overline{ADV}$ output signal and has an inverted polarity from $\overline{ADV}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

**Figure 11-28. NAND Address Latch Cycle**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i (where i = 0 to 5) register location mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable $\overline{RE}$ or $\overline{WE}$ signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

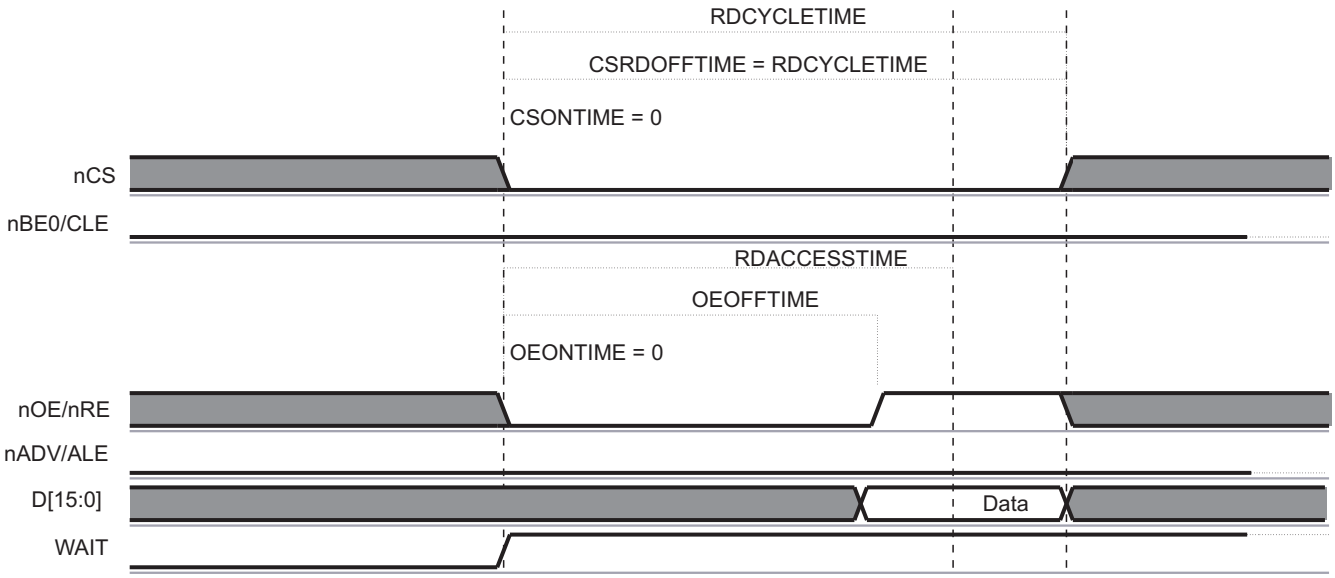
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- $\overline{CS}$ is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- $\overline{RE}$ is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of $\overline{RE}$ high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after $\overline{RE}$ deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and $\overline{WE}$ are maintained inactive.

Figure 11-29 shows the NAND data read cycle.

**Figure 11-29. NAND Data Read Cycle**



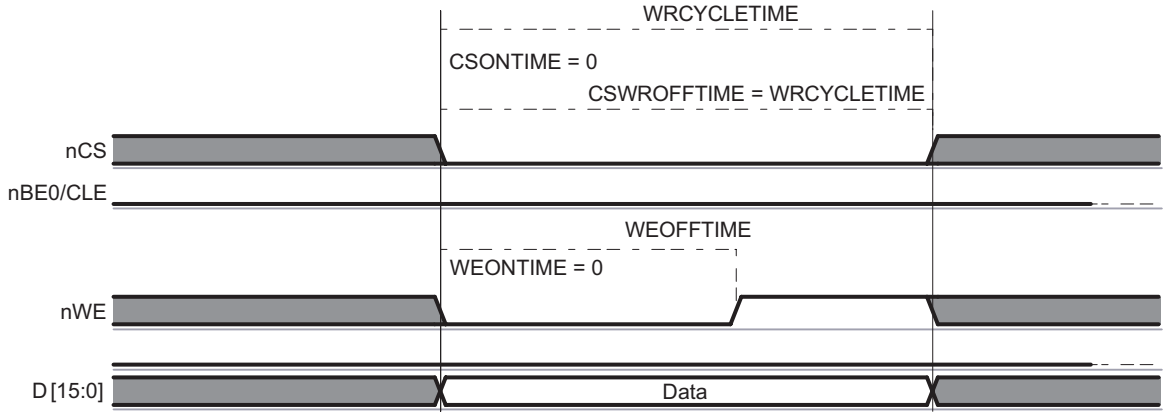
Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 11-30 shows the NAND data write cycle.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 11-30. NAND Data Write Cycle**



#### 11.2.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by $\overline{CS}$-to-data-valid timing and has faster $\overline{RE}$-to-data-valid timing. Successive accesses with $\overline{CS}$ deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that $\overline{CS}$ always stays low between two accesses to the same chip-select. Moreover, an $\overline{CS}$ deassertion time between the same chip-select NAND accesses is likely to be required as follows: the $\overline{CS}$ deassertion requires programming CYCLETIME and RDACCESSTIME according to the $\overline{CS}$-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum $\overline{CS}$ high pulse width between accesses. For more information about optimal prefetch engine access, see Section 11.2.4.12.4.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum $\overline{CS}$ high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important $\overline{RE}$ high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

#### 11.2.4.12.1.7 Read and Write Access Size Adaptation

##### 11.2.4.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

##### 11.2.4.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Copyright © 2011–2016, Texas Instruments Incorporated

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### *11.2.4.12.2 NAND Device-Ready Pin*

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 µs) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[[22] WAITREADMONITORING bits to 0, where i = 0 to 5), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 1) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE [11-8] bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

##### *11.2.4.12.2.1 Ready Pin Monitored by Software Polling*

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (x = 0 or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### *11.2.4.12.2.2 Ready Pin Monitored by Hardware Interrupt*

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

Copyright © 2011–2016, Texas Instruments Incorporated

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (x = 0 or 1) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

#### 11.2.4.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhurl-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

##### 11.2.4.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

Copyright © 2011–2016, Texas Instruments Incorporated

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

#### 11.2.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT register ).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZE bits are cleared to 0, and the ECC9RESULTSIZE bit is set to 1.

#### 11.2.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 11-12 describes the ECC enable settings.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-12. ECC Enable Settings**

| Bit Field | Register | Value | Comments |
|---|---|---|---|
| ECCCS | GPMC_ECC_CONFIG | 0-3h | Selects the chip-select where ECC is computed |
| ECC16B | GPMC_ECC_CONFIG | 0-1 | Selects column number for ECC calculation |
| ECCCLEAR | GPMC_ECC_CONTROL | 0-7h | Clears all ECC result registers |
| ECCPOINTER | GPMC_ECC_CONTROL | 0-7h | A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default. |
| ECCSIZE1 | GPMC_ECC_SIZE_CONFIG | 0-FFh | Defines ECCSIZE1 |
| ECCSIZE0 | GPMC_ECC_SIZE_CONFIG | 0-FFh | Defines ECCSIZE0 |
| ECCjRESULTSIZE | GPMC_ECC_SIZE_CONFIG | 0-1 | Selects the size of ECCn result register |
| ECCENABLE | GPMC_ECC_CONFIG | 1 | Enables the ECC computation |

#### *11.2.4.12.3.1.3 ECC Computation*

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 11-31 and Figure 11-32. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

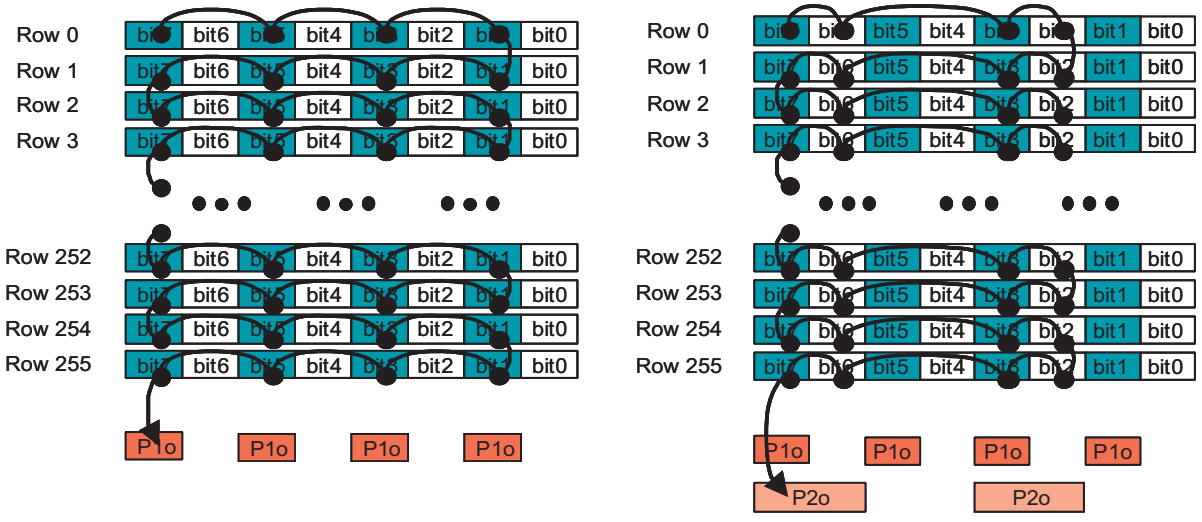
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

**Figure 11-31. Hamming Code Accumulation Algorithm (1 of 2)**



Copyright © 2011–2016, Texas Instruments Incorporated

For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Unused parity bits in the result registers are cleared to 0.

**Figure 11-32. Hamming Code Accumulation Algorithm (2 of 2)**

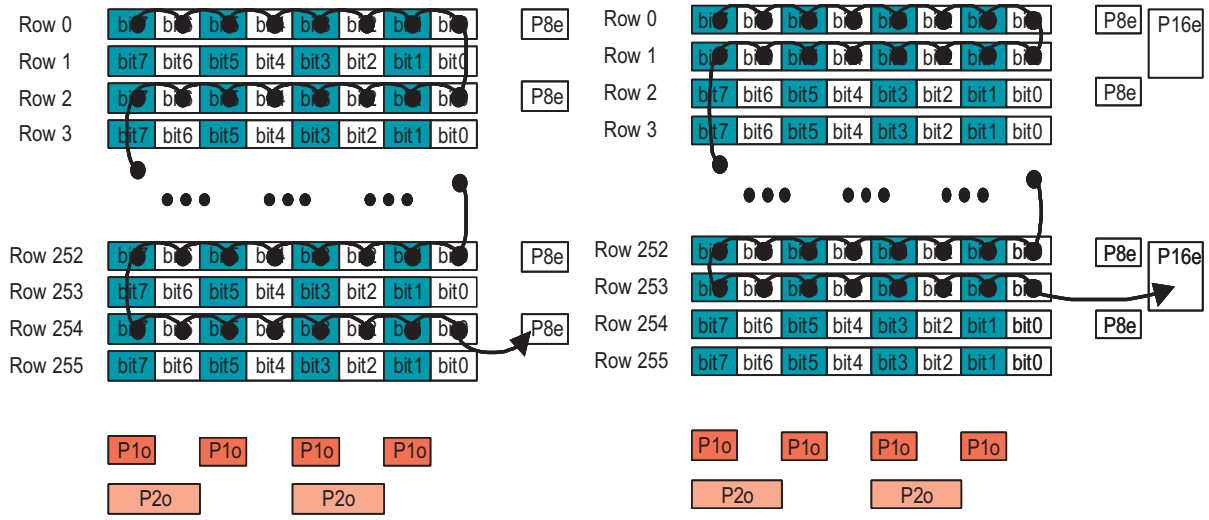


Figure 11-33 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

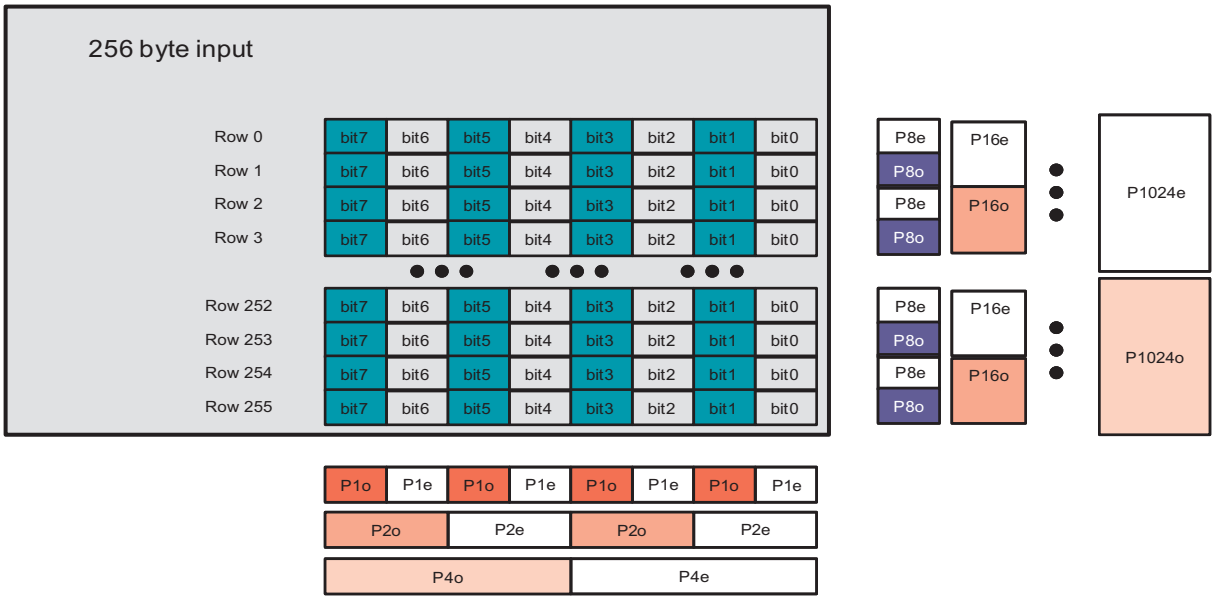
**Figure 11-33. ECC Computation for a 256-Byte Data Stream (Read or Write)**

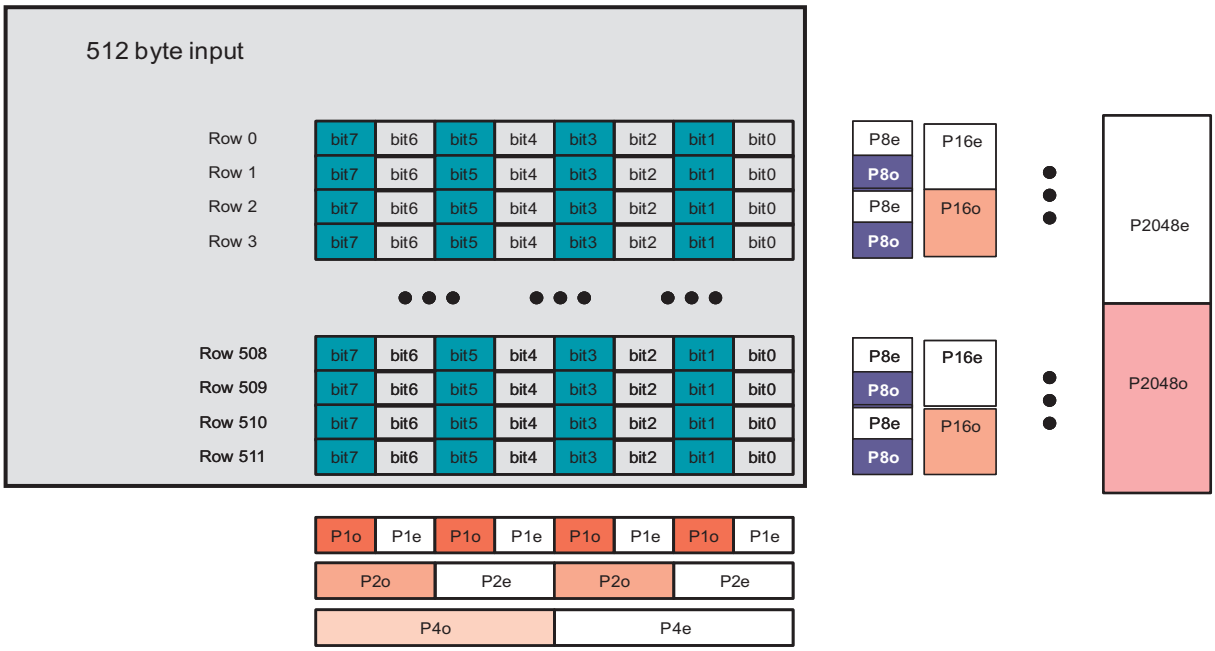


Copyright © 2011–2016, Texas Instruments Incorporated

Figure 11-34 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

**Figure 11-34. ECC Computation for a 512-Byte Data Stream (Read or Write)**



### 11.2.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

### 11.2.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 11-35 and Figure 11-36.

#### 11.2.4.12.3.2 BCH Code (Bose-Chaudhurl-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

##### 11.2.4.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree 2 - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 11-13.

**Table 11-13. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

| | Message M(x) | ECC R(x) | | | | |
|---|---|---|---|---|---|---|
| **Bit number** | M4095 | ... | M0 | R103 | ... | R0 |

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) - 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in , , , and (where i = 0 to 5).

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

#### 11.2.4.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 × x + b6 × x + ... + b0 × x
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

Table 11-14 and Table 11-15 show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^12-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

**Table 11-14. Aligned Message Byte Mapping in 8-bit NAND**

| Byte Offset | 8-Bit Word |
|---|---|
| 0 | (msb) Byte 511 (1FFh) |
| 1h | Byte 510 (1FEh) |
| ⋮ | ⋮ |
| 1FFh | Byte 0 (0) (LSB) |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-15. Aligned Message Byte Mapping in 16-bit NAND**

| Byte Offset | 16-Bit Words MSB | 16-Bit Words LSB |
|---|---|---|
| 0 | Byte 510 (1FEh) | (msb) Byte 511 (1FFh) |
| 2h | Byte 508 (1FCh) | Byte 509 (1FDh) |
| ⋮ | ⋮ | ⋮ |
| 1FEh | Byte 0 (0) | (lsb) Byte 1 (1) |

Table 11-16 and Table 11-17 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

**Table 11-16. Aligned Nibble Mapping of Message in 8-bit NAND**

| Byte Offset | 8-Bit Word | |
|---|---|---|
| | 4-Bit Most Significant Nibble | 4-Bit Less Significant Nibble |
| 1 | (MSB) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-3 | Nibble S-4 |
| ⋮ | ⋮ | ⋮ |
| S/2 - 2 | Nibble 3 | Nibble 2 |

| 0 | Nibble S-3 | Nibble S-4 | (MSB) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ⋮ | ⋮ | ⋮ | ⋮ | ⋮ |
| (S+2)/2 - 4 | Nibble 3 | Nibble 2 | Nibble 5 | Nibble 4 |
| (S+2)/2 - 2 | | | Nibble 1 | Nibble 0 (LSB) |

**Table 11-21. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibble)**

| Byte Offset | 16-Bit Word | | | |
|---|---|---|---|---|
| | 4-Bit Most Significant Nibble | | 4-Bit Less Significant Nibble | |
| 0 | Nibble S-3 | Nibble S-4 | (MSB) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ⋮ | ⋮ | ⋮ | ⋮ | ⋮ |
| (S+3)/2 - 4 | Nibble 2 | Nibble 1 | Nibble 4 | Nibble 3 |
| (S+3)/2 - 2 | | | Nibble 0 (LSB) | |

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

#### *11.2.4.12.3.2.4 Memory Mapping of the ECC*

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

Copyright © 2011–2016, Texas Instruments Incorporated

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 11.2.4.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 11.2.4.12.3.3.

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

#### 11.2.4.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

Figure 11-37 shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

**Figure 11-37. Manual Mode Sequence and Mapping**

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

#### 11.2.4.12.3.2.7 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.2.4.12.3.2.8 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 11.2.4.12.3.2.9 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.2.4.12.3.2.10 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.3.2.11 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 11.2.4.12.3.2.12 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

#### 11.2.4.12.3.2.13 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 11.2.4.12.3.2.14 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1 + size1))

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.3.2.15 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.2.4.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 11.2.4.12.3.2.3.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 11-38 to Figure 11-40, tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of n = 2 - 1 = 8191 bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (Figure 11-38: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (Figure 11-38: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (Figure 11-38: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

#### 11.2.4.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 11-38), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

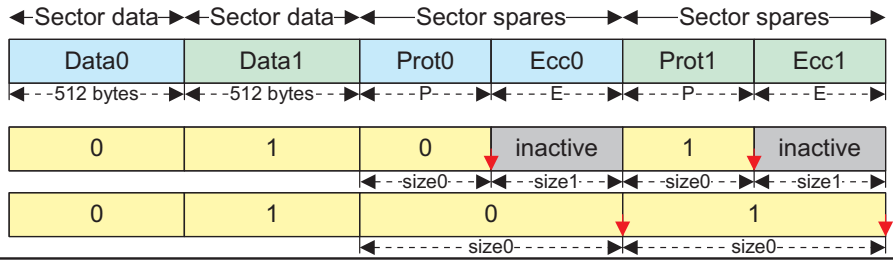
- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

**Figure 11-38. NAND Page Mapping and ECC: Per-Sector Schemes**

M1

Per-sector spares
Spares covered by sector ECC per sector ECC mapping.

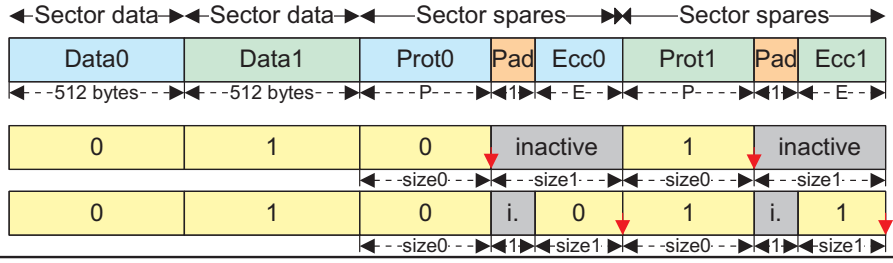
| | Mode | Size0 | Size1 |
|---|---|---|---|
| Write | 1 | P | E |
| Read | 1 | P+E | 0 |



M2

Per-sector spares
Spares covered by sector ECC per sector, left-padded ECC.

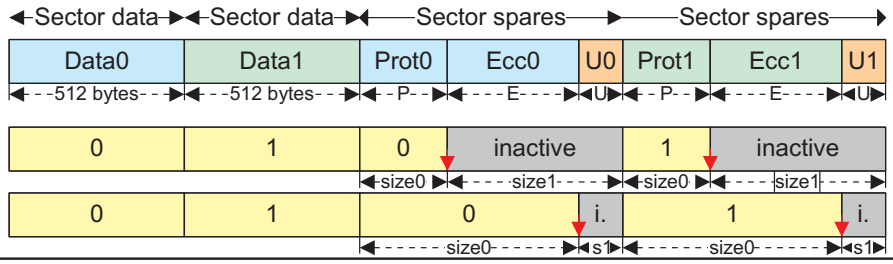
| | Mode | Size0 | Size1 |
|---|---|---|---|
| Write | 1 | P | 1+E |
| Read | 10 | P | E |



M3

Per-sector spares
Spares covered by sector ECC, ECC not right-aligned.

| | Mode | Size0 | Size1 |
|---|---|---|---|
| Write | 1 | P | E+U |
| Read | 1 | P+E | U |



M4

Per-sector spares
Spares not covered by ECC, ECC right-aligned per sector.

| | Mode | Size0 | Size1 |
|---|---|---|---|
| Write | 2 | U+E | 0 |
| Read | 2 | U | E |

#### 11.2.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

#### 11.2.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectivelly uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers (where i = 0 to 5):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (i.e., reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 11.2.4.12.2.2. The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT field.

Table 11-22 describes the prefetch mode configuration.

**Table 11-22. Prefetch Mode Configuration**

| Bit Field | Register | Value | Comments |
|---|---|---|---|
| STARTENGINE | GPMC_PREFETCH_CONTROL | 0 | Prefetch engine can be configured only if STARTENGINE is cleared to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1 | 0 to 3h | Selects the chip-select associated with a NAND device where the prefetch engine is active. |
| ACCESSMODE | GPMC_PREFETCH_CONFIG1 | 0 | Selects prefetch mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1 | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG1 | | Selects the number of bytes to be read or written by the engine to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1 | 0/1 | Selects when the engine starts the access to the chip-select |
| WAITPINSELECT | GPMC_PREFETCH_CONFIG1 | 0 to 1 | Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1) |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1 | 0/1 | See Section 11.2.4.12.4.6 |
| CYCLEOPTIMIZATION | GPMC_PREFETCH_CONFIG1 | | Number of clock cycle removed to timing parameters |
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1 | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONFIG1 | 1 | Starts the prefetch engine |

#### 11.2.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

**NOTE:** The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is trigerred. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

**Write-Posting Mode Configuration**

| Bit Field | Register | Value | Comments |
|---|---|---|---|
| STARTENGINE | GPMC_PREFETCH_CONTROL | 0 | Write-posting engine can be configured only if STARTENGINE is cleared to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1 | 0 to 3h | Selects the chip-select associated with a NAND device where the prefetch engine is active |
| ACCESSMODE | GPMC_PREFETCH_CONFIG1 | 1 | Selects write-posting mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1 | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG2 | | Selects the number of bytes to be read or written by the engine from/to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1 | 0 | Engine starts the access to chip-select as soon as STARTENGINE is set. |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1 | 0/1 | See Section 11.2.4.12.4.6 |
| CYCLEOPTIMIZATION | GPMC_PREFETCH_CONFIG | | |
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1 | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONTROL | 1 | Starts the prefetch engine |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

**NOTE:** The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.2.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated $\overline{CS}$ signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i(where , i = 0 to 5) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 11-41, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field.

**Figure 11-41. NAND Read Cycle Optimization Timing Description**

#### 11.2.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finnaly back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

## 11.3 Basic Programming Model

### 11.3.1 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. Figure 11-42 shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. Table 11-23 and Table 11-24 list each step in the model.

**Table 11-23. GPMC Configuration in NOR Mode**

| Step | Description |
|---|---|
| NOR Memory Type | See Table 11-26 |
| NOR Chip-Select Configuration | See Table 11-27 |
| NOR Timings Configuration | See Table 11-28 |
| Wait Pin Configuration | See Table 11-29 |
| Enable Chip-Select | See Table 11-30 |

**Table 11-24. GPMC Configuration in NAND Mode**

| Step | Description |
|---|---|
| NAND Memory Type | See Table 11-31 |
| NAND Chip-Select Configuration | See Table 11-32 |
| Write Operations (Asynchronous) | See Table 11-33 |
| Read Operations (Asynchronous) | See Table 11-33 |
| ECC Engine | See Table 11-34 |
| Prefetch and Write-Posting Engine | See Table 11-35 |
| Wait Pin Configuration | See Table 11-36 |
| Enable Chip-Select | See Table 11-37 |

### 11.3.2 GPMC Initialization

Table 11-25 describes the settings required to reset the GPMC.

**Table 11-25. Reset GPMC**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Start a software reset | GPMC_SYSCONFIG[1] SOFTRESET | 1 |
| Wait until | GPMC_SYSSTATUS[0] RESETDONE | 1 |

### 11.3.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC. Table 11-26 through Table 11-30 list the steps to configure the GPMC in NOR mode.

**NOTE:** In the tables of this section, 'x' in Value column stands for 'depends on configuration'.

**Table 11-26. NOR Memory Type**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Set the NOR protocol | GPMC_CONFIG1_i[11-10] DEVICETYPE | 0 |
| Set a device size | GPMC_CONFIG1_i[13-12] DEVICESIZE | x |
| Select an address and data multiplexing protocol | GPMC_CONFIG1_i[9] MUXADDDATA | x |
| Set the attached device page length | GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH | x |
| Set the wrapping burst capabilities | GPMC_CONFIG1_i[31] WRAPBURST | x |
| Select a timing signals latencies factor | GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY | x |
| Select an output clock frequency | GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER | x |
| Choose an output clock activation time | GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME | x |
| Set a single or multiple access for read operations | GPMC_CONFIG1_i[30] READMULTIPLE | x |
| Set a synchronous or asynchronous mode for read operations | GPMC_CONFIG1_i[29] READTYPE | x |
| Set a single or multiple access for write operations | GPMC_CONFIG1_i[28] WRITEMULTIPLE | x |
| Set a synchronous or asynchronous mode for write operations | GPMC_CONFIG1_i[27] WRITETYPE | x |

**Table 11-27. NOR Chip-Select Configuration**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Select the chip-select base address | GPMC_CONFIG7_i[5-0] BASEADDRESS | x |
| Select the chip-select mask address | GPMC_CONFIG7_i[11-8] MASKADDRESS | x |

**Table 11-28. NOR Timings Configuration**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Configure adequate timing parameters in various memory modes | See Section 11.3.6 | |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-29. WAIT Pin Configuration**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Enable or disable wait pin monitoring for read operations | GPMC_CONFIG1_i[22] WAITREADMONITORING | x |
| Enable or disable wait pin monitoring for write operations | GPMC_CONFIG1_i[21] WAITWRITEMONITORING | x |
| Select a wait pin monitoring time | GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME | x |
| Choose the input wait pin for the chip-select | GPMC_CONFIG1_i[17-16] WAITPINSELECT | x |

**Table 11-30. Enable Chip-Select**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| When all parameters are configured, enable the chip-select | GPMC_CONFIG7_i[6] CSVALID | x |

### *11.3.4 GPMC Configuration in NAND Mode*

This section gives a generic configuration for parameters related to NAND memory connected to the GPMC.

**Table 11-31. NAND Memory Type**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Set the NAND protocol | GPMC_CONFIG1_i[11-10] DEVICETYPE | 2h |
| Set a device size | GPMC_CONFIG1_i[13-12] DEVICESIZE | x |
| Set the address and data multiplexing protocol to non-multiplexed attached device | GPMC_CONFIG1_i[9] MUXADDDATA | 0 |
| Select a timing signals latencies factor | GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY | x |
| Set a synchronous or asynchronous mode and a single or multiple access for read and write operations | See Section 11.3.5 | x |

**Table 11-32. NAND Chip-Select Configuration**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Select the chip-select base address | GPMC_CONFIG7_i[5-0] BASEADDRESS | x |
| Select the chip-select minimum granularity (16M bytes) | GPMC_CONFIG7_i[11-8] MASKADDRESS | x |

**Table 11-33. Asynchronous Read and Write Operations**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Configure adequate timing parameters in asynchronous modes | See Section 11.3.6 | |

**Table 11-34. ECC Engine**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Select the ECC result register where the first ECC computation is stored (Only applies to Hamming) | GPMC_ECC_CONTROL[3-0] ECCPOINTER | x |
| Clear all ECC result registers | GPMC_ECC_CONTROL[8] ECCCLEAR | Write 1 to clear |
| Define ECCSIZE0 and ECCSIZE1 | GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 and GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1 | x |
| Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1) | GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9 | x |
| Select the chip-select where ECC is computed | GPMC_ECC_SIZE_CONFIG[3-1] ECCCS | x |
| Select the Hamming code or BCH code ECC algorithm in use | GPMC_ECC_SIZE_CONFIG[16] ECCALGORITHM | x |
| Select word size for ECC calculation | GPMC_ECC_SIZE_CONFIG[7] ECC16B | x |
| If the BCH code is used,<br>Set an error correction capability and<br>Select a number of sectors to process | GPMC_ECC_SIZE_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_SIZE_CONFIG[6-4] ECCTOPSECTOR | x |
| Enable the ECC computation | GPMC_ECC_SIZE_CONFIG[0] ECCENABLE | 1 |

**Table 11-35. Prefetch and Write-Posting Engine**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Disable the engine before configuration | GPMC_PREFETCH_CONTROL[0] STARTENGINE | 0 |
| Select the chip-select associated with a NAND device where the prefetch engine is active | GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR | x |
| Select access direction through prefetch engine, read or write. | GPMC_PREFETCH_CONFIG1[0] ACCESSMODE | x |
| Select the threshold used to issue a DMA request | GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD | x |
| Select either DMA synchronized mode or SW manual mode. | GPMC_PREFETCH_CONFIG1[2] DMAMODE | x |
| Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used. | GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE | x |
| Select which wait pin edge detector should start the engine in synchronized mode | GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR | x |
| Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one) | GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION | x |
| Enable the prefetch postwite engine | GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE | 1 |
| Select the number of bytes to be read or written by the engine to the selected chip-select | GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT | x |
| Start the prefetch engine | GPMC_PREFETCH_CONTROL[0] STARTENGINE | 1 |

**Table 11-36. WAIT Pin Configuration**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| Selects when the engine starts the access to CS | GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE | x |
| Select which wait pin edge detector should start the engine in synchronized mode | GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR | x |

**Table 11-37. Enable Chip-Select**

| Sub-process Name | Register / Bitfield | Value |
|---|---|---|
| When all parameters are configured, enable the chip-select | GPMC_CONFIG7_i[6] CSVALID | x |

### 11.3.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

**Table 11-38. Mode Parameters Check List Table**

| Register | Bit | Bit Field Name | Asynchronous | | | | Synchronous | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | Single Read Access | Single Write Access | Multiple Read (Page) Access | Multiple Write (Page) Access | Single Read Access | Single Write Access | Multiple Read (Burst) Access | Multiple Write (Burst) Access |
| GPMC_CONFIG1_i | 30 | READMULTIPLE | 0 | - | 1 | N/S | 0 | - | 1 | - |
| GPMC_CONFIG1_i | 29 | READTYPE | 0 | - | 0 | N/S | 1 | - | 1 | - |
| GPMC_CONFIG1_i | 28 | WRITEMULTIPLE | - | 0 | | N/S | - | 0 | - | 1 |
| GPMC_CONFIG1_i | 27 | WRITETYPE | - | 0 | | N/S | - | 1 | - | 1 |

**Table 11-39. Access Type Parameters Check List Table**

| Register | Bit | Bit Field Name | Access Type | | |
|---|---|---|---|---|---|
| | | | Non-Mux | Address/Data Mux | AAD Mux |
| GPMC_CONFIG1_i | 9-8 | MUXADDDATA | 0 | 2h | 1 |

### 11.3.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

#### *11.3.6.1.1 NAND Flash Interface Timing Parameters Formulas*

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 2h. Table 11-41 details NAND timing parameters.

**Table 11-41. NAND Formulas Description Table**

| Configuration Parameter | Unit | Description |
|---|---|---|
| A | ns | Pulse duration - $\overline{\text{GPMC_WE}}$ valid time |
| B | ns | Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ valid |
| C | ns | Delay time - GPMC_$\overline{\text{BE0}}$_CLE/GPMC_$\overline{\text{ADV}}$_ALE high to $\overline{\text{GPMC_WE}}$ valid |
| D | ns | Delay time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_WE}}$ valid |
| E | ns | Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_AD[15:0] invalid |
| F | ns | Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_$\overline{\text{BE0}}$_CLE/GPMC_$\overline{\text{ADV}}$_ALE invalid |
| G | ns | Delay time - $\overline{\text{GPMC_WE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid |
| H | ns | Cycle time - Write cycle time |
| I | ns | Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ valid |
| J | ns | Setup time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_OE}}$ invalid |
| K | ns | Pulse duration - $\overline{\text{GPMC_OE}}$ valid time |
| L | ns | Cycle time - Read cycle time |
| M | ns | Delay time - $\overline{\text{GPMC_OE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid |

The configuration parameters are calculated through the following formulas.

A = (WEOffTime - WEOnTime) × (TimeParaGranularity + 1) × GPMC_FCLK period

B = ((WEOnTime - CSOnTime) × (TimeParaGranularity + 1) + 0.5 × (WEExtraDelay - CSExtraDelay)) × GPMC_FCLK period

C = ((WEOnTime - ADVOnTime) × (TimeParaGranularity + 1) + 0.5 × (WEExtraDelay - ADVExtraDelay)) × GPMC_FCLK period

D = (WEOnTime × (TimeParaGranularity + 1) + 0.5 × WEExtraDelay ) × GPMC_FCLK period

E = (WrCycleTime - WEOffTime × (TimeParaGranularity + 1) - 0.5 × WEExtraDelay ) × GPMC_FCLK period

F = (ADVWrOffTime - WEOffTime × (TimeParaGranularity + 1) + 0.5 × (ADVExtraDelay - WEExtraDelay ) × GPMC_FCLK period

G = (CSWrOffTime - WEOffTime × (TimeParaGranularity + 1) + 0.5 × (CSExtraDelay - WEExtraDelay ) × GPMC_FCLK period

H = WrCycleTime × (1 + TimeParaGranularity) × GPMC_FCLK period

I = ((OEOnTime - CSOnTime) × (TimeParaGranularity + 1) + 0.5 × (OEExtraDelay - CSExtraDelay)) × GPMC_FCLK period

J = ((RdAccessTime - OEOffTime) × (TimeParaGranularity + 1) - 0.5 × OEExtraDelay)) × GPMC_FCLK period

Copyright © 2011–2016, Texas Instruments Incorporated

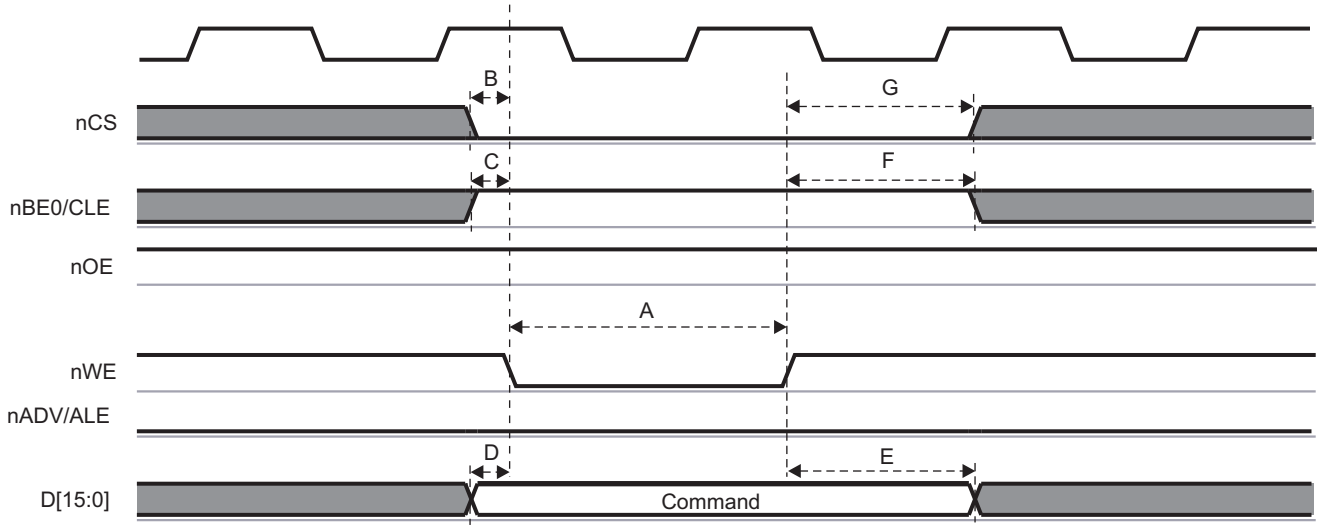
K = (OEOffTime - OEOnTime) × (1 + TimeParaGranularity) × GPMC_FCLK period

L = RdCycleTime × (1 + TimeParaGranularity) × GPMC_FCLK period

M = (CSRdOffTime - OEOffTime × (TimeParaGranularity + 1) + 0.5 × (CSExtraDelay - OEExtraDelay ) × GPMC_FCLK period

Figure 11-44 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

**Figure 11-44. NAND Command Latch Cycle Timing Simplified Example**



### 11.3.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0 and when READTYPE or WRITETYPE are set to synchronous mode.

**Table 11-42. Synchronous NOR Formulas Description Table**

| Configuration Parameter | Unit | Description |
|---|---|---|
| A | ns | Pulse duration - $\overline{\text{GPMC_CS}}$ low |
| B | ns | Delay time - address bus valid to GPMC_CLK first edge |
| | | Delay time - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ valid to GPMC_CLK first edge |
| C | ns | Pulse duration - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ low |
| D | ns | Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ invalid |
| | | Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{ADV}}$_ALE invalid |
| E | ns | Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_CS}}$ invalid |
| | | Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_OE}}$ invalid |
| F | ns | Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_CS}}$ transition |
| G | ns | Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{ADV}}$_ALE transition |
| H | ns | Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_OE}}$ transition |
| I | ns | Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_WE}}$ transition |
| J | ns | Delay time - GPMC_CLK rising edge to GPMC_AD data bus transition |
| | | Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ transition |
| K | ns | Pulse duration - GPMC_$\overline{\text{ADV}}$_ALE low |
| L | ns | Delay time - GPMC_WAIT invalid to first data latching GPMC_CLK edge |

Copyright © 2011–2016, Texas Instruments Incorporated

The configuration parameters are calculated through the following formulas.

For single read accesses:

A = (CSRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = RDCYCLETIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (RDCYCLETIME - RDACCESSTIME) × GPMC_FCLK period

E = (CSRDOFFTIME - RDACCESSTIME) × GPMC_FCLK period

For burst read accesses (where n is the page burst access number):

A = (CSRDOFFTIME - CSONTIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = (RDCYCLETIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (RDCYCLETIME - (RDACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

E = (CSRDOFFTIME - (RDACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

For burst write accesses (where n is the page burst access number):

A = (CSWROFFTIME - CSONTIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

C = (WRCYCLETIME + (n - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

D = (WRCYCLETIME - (WRACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

E = (CSWROFFTIME - (WRACCESSTIME + (n - 1) × PAGEBURSTACCESSTIME)) × GPMC_FCLK period

For all accesses:

For $\overline{CS}$ falling edge ($\overline{CS}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and

Copyright © 2011–2016, Texas Instruments Incorporated

CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise

Copyright © 2011–2016, Texas Instruments Incorporated

- Case where GPMCFCLKDIVIDER = 2

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  F = 0.5 × CSEXTRADELAY × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 × CSEXTRADELAY) × GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ falling edge ($\overline{ADV}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ rising edge ($\overline{ADV}$ de-activated) in reading mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise

Copyright © 2011–2016, Texas Instruments Incorporated

- Case where GPMCFCLKDIVIDER = 2

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{\text{ADV}}$ rising edge ($\overline{\text{ADV}}$ de-activated) in writing mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  G = 0.5 × ADVEXTRADELAY × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 × ADVEXTRADELAY) × GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{\text{OE}}$ falling edge ($\overline{\text{OE}}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{\text{OE}}$ rising edge ($\overline{\text{OE}}$ de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, otherwise

Copyright © 2011–2016, Texas Instruments Incorporated

- Case where GPMCFCLKDIVIDER = 2

  H = 0.5 × OEEXTRADELAY × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 × OEEXTRADELAY) × GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{WE}$ falling edge ($\overline{WE}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, otherwise
- Case where GPMCFCLKDIVIDER = 2

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{WE}$ rising edge ($\overline{WE}$ de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 1

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 2

  I = 0.5 × WEEXTRADELAY × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 × WEEXTRADELAY) × GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For GPMC_$\overline{ADV}$ low pulse duration:

- Read operation

  K = (ADVRDOFFTIME - ADVONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period
- Write operation

  K = (ADVWROFFTIME - ADVONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

L = WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) × GPMC_FCLK period + GPMC_CLK period

#### 11.3.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when [11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

**Table 11-43. Asynchronous NOR Formulas Description Table**

| Configuration Parameter | Unit | Description |
|---|---|---|
| A | ns | Pulse duration - GPMC_CS low |
| B | ns | Delay time - GPMC_CS valid to GPMC_ADV_ALE invalid |
| C | ns | Delay time - GPMC_CS valid to GPMC_OE invalid (single read) |
| D | ns | Pulse duration - address bus valid - 2nd, 3rd and 4th accesses |
| E | ns | Delay time - GPMC_CS valid to GPMC_WE valid |
| F | ns | Delay time - GPMC_CS valid to GPMC_WE invalid |
| G | ns | Address invalid duration between 2 successive R/W accesses |
| H | ns | Setup time - read data valid before GPMC_OE high |
| I | ns | Delay time - GPMC_CS valid to GPMC_OE invalid (burst read) |
| J | ns | Delay time - address bus valid to GPMC_CS valid |
| | | Delay time - data bus valid to GPMC_CS valid |
| | | Delay time - GPMC_BE0_CLE/GPMC_BE1 valid to GPMC_CS valid |
| K | ns | Delay time - GPMC_CS valid to GPMC_ADV_ALE valid |
| L | ns | Delay time - GPMC_CS valid to GPMC_OE valid |
| M | ns | Delay time - GPMC_CS valid to first data latching edge |
| N | ns | Pulse duration - GPMC_BE0_CLE/GPMC_BE1 valid time |
| O | ns | Delay time - GPMC_CS valid to GPMC_ADV_ALE valid |

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

GPMC_CS low pulse:

For single read: A = (CSRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For burst read: A = (CSRDOFFTIME - CSONTIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

For single write: A = (CSWROFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

For burst write: A = (CSWROFFTIME - CSONTIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

GPMC_CS valid to GPMC_ADV_ALE invalid delay:

For reading: B = ((ADVRDOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

For writing: B = ((ADVWROFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

C = ((OEOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

D = PAGEBURSTACCESSTIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

E = ((WEONTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (WEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

F = ((WEOFFTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (WEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

G = CYCLE2CYCLEDELAY × GPMC_FCLK period

Copyright © 2011–2016, Texas Instruments Incorporated

H = ((OEOFFTIME - RDACCESSTIME) × (TIMEPARAGRANULARITY + 11) + 0.5 × OEEXTRADELAY) × GPMC_FCLK period

I = ((OEOFFTIME + (N - 1) × PAGEBURSTACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period, where N = page burst access number

J = (CSONTIME × (TIMEPARAGRANULARITY + 1) + 0.5 × CSEXTRADELAY) × GPMC_FCLK period

K = ((ADVONTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

L = ((OEONTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (OEEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

M = ((RDACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) - 0.5 × CSEXTRADELAY) × GPMC_FCLK period

GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ pulse:

For single read: N = RDCYCLETIME × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period

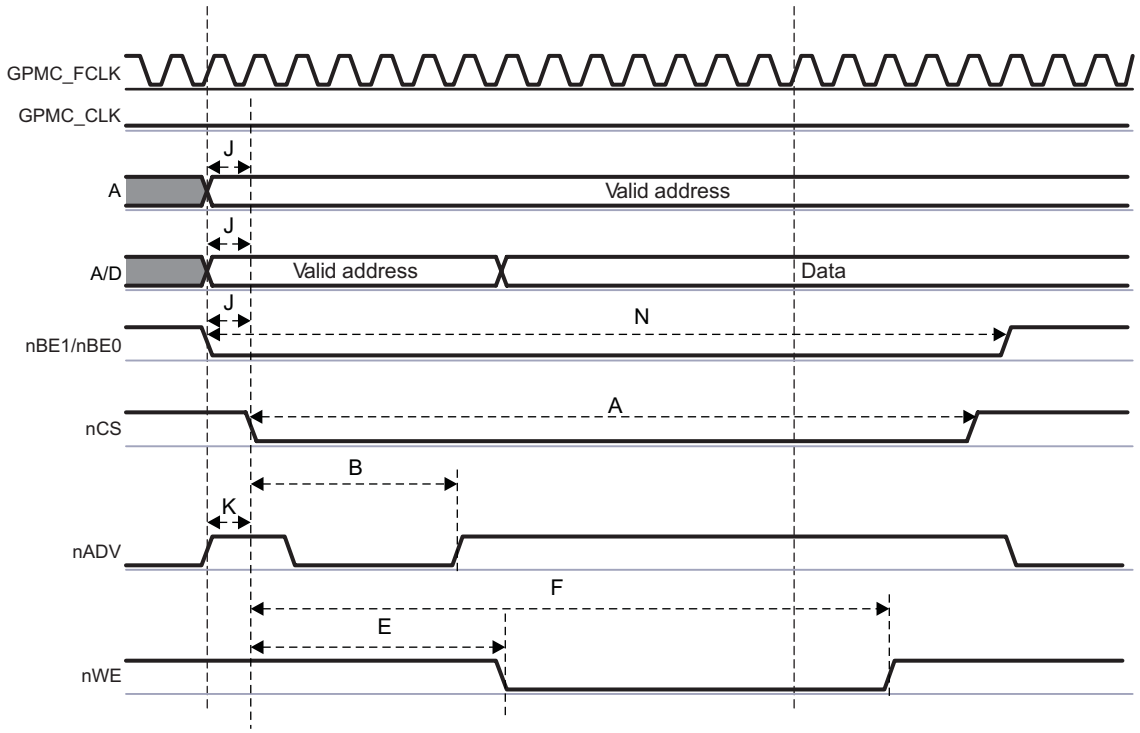
For burst read: N = (RDCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

For burst write: N = (WRCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME) × (TIMEPARAGRANULARITY + 1) × GPMC_FCLK period, where N = page burst access number

O = ((WRCYCLETIME + (N - 1) × PAGEBURSTACCESSTIME - CSONTIME) × (TIMEPARAGRANULARITY + 1) + 0.5 × (ADVEXTRADELAY - CSEXTRADELAY)) × GPMC_FCLK period

Figure 11-46 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

**Figure 11-46. Asynchronous NOR Single Write Simplified Example**



Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

## 11.4 Use Cases And Tips

### 11.4.1 How to Set GPMC Timing Parameters for Typical Accesses

#### 11.4.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 100 MHz clock frequency
- Read access time: 80 ns

#### 11.4.1.2 Typical GPMC Setup

Table 11-44 lists some of the I/Os of the GPMC module.

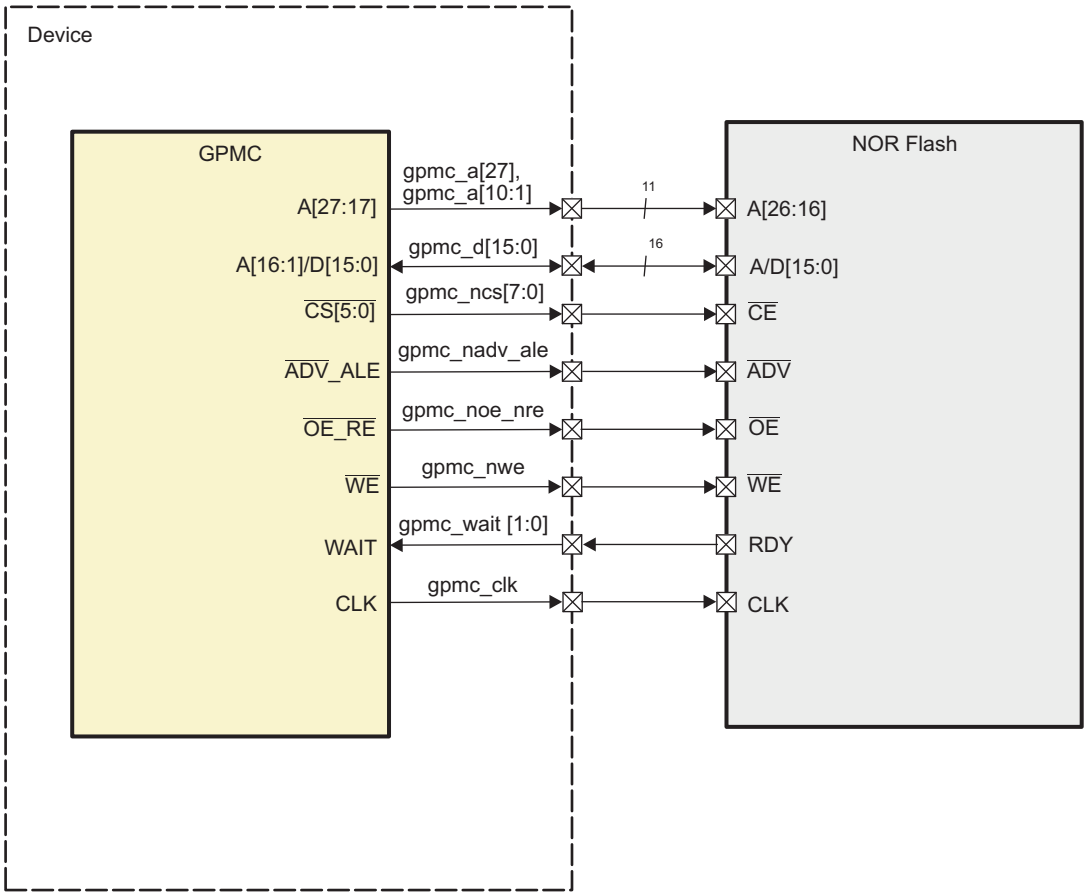
**Table 11-44. GPMC Signals**

| Signal Name | I/O | Description |
|---|---|---|
| GPMC_FCLK | Internal | Functional and interface clock. Acts as the time reference. |
| GPMC_CLK | O | External clock provided to the external device for synchronous operations |
| GPMC_A[27:17] | O | Address |
| GPMC_D[15: 0] | I/O | Data-multiplexed with addresses A[16:1] on memory side |
| $\overline{\text{GPMC_CSx}}$ | O | Chip-select (where x = 0, or 1) |
| GPMC_$\overline{\text{ADV}}$_ALE | O | Address valid enable |
| $\overline{\text{GPMC_OE_RE}}$ | O | Output enable (read access only) |
| $\overline{\text{GPMC_WE}}$ | O | Write enable (write access only) |
| GPMC_WAIT | I | Ready signal from memory device. Indicates when valid burst data is ready to be read |

Copyright © 2011–2016, Texas Instruments Incorporated

Figure 11-47 shows the typical connection between the GPMC module and an attached NOR Flash memory.

**Figure 11-47. GPMC Connection to an External NOR Flash Memory**



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.4.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 100 MHz (f = 100 MHz; T = 10 ns).

Table 11-45 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-46 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-48 shows the synchronous burst read access.

**Table 11-45. Useful Timing Parameters on the Memory Side**

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|---|---|---|
| tCES | $\overline{CS}$ setup time to clock | 0 |
| tACS | Address setup time to clock | 3 |
| tIACC | Synchronous access time | 80 |
| tBACC | Burst access time valid clock to output delay | 5,2 |
| tCEZ | Chip-select to High-Impedance | 7 |
| tOEZ | Output enable to High-Impedance | 7 |
| tAVC | $\overline{ADV}$ setup time | 6 |
| tAVD | $\overline{AVD}$ pulse | 6 |
| tACH | Address hold time from clock | 3 |

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

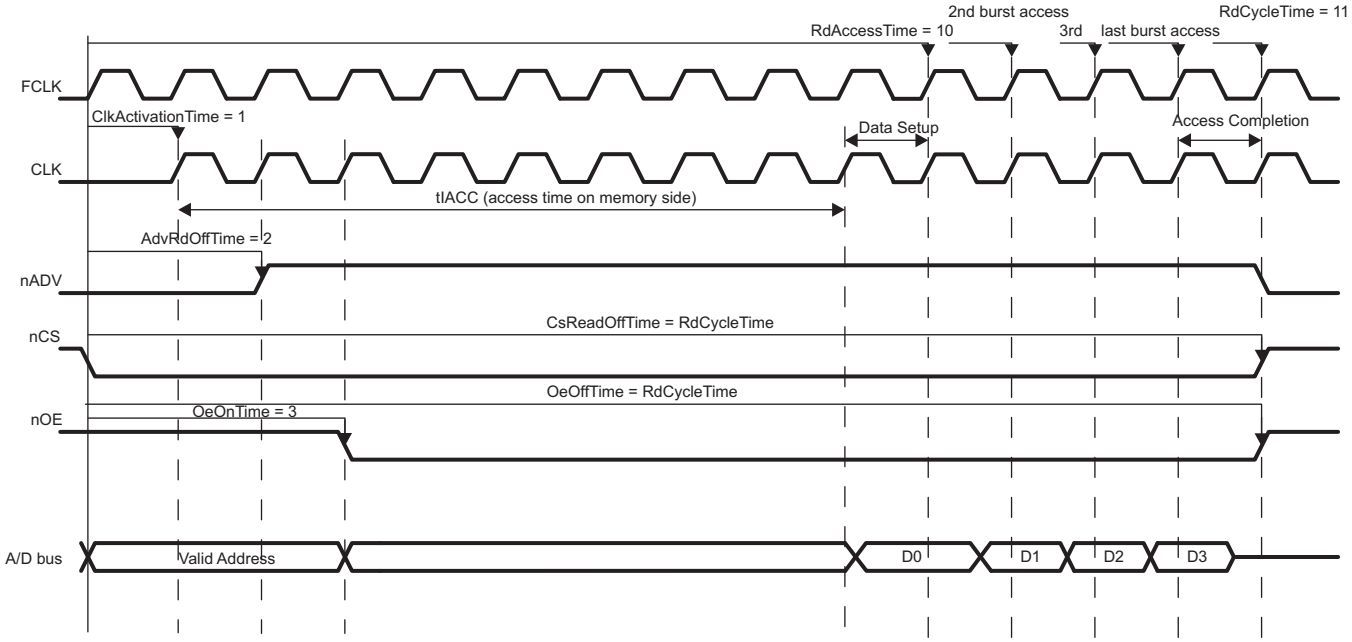
- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 10 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,8 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: $\overline{CS}$/$\overline{OE}$ hold time ($\overline{CS}$ and $\overline{OE}$ must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-46. Calculating GPMC Timing Parameters**

| Parameter Name on GPMC Side | Formula | Duration (ns) | Number of Clock Cycles (F = 100 MHz) | GPMC Register Configurations |
|---|---|---|---|---|
| GPMC FCLK Divider | - | - | - | GPMCFCLKDIVIDER = 0 |
| ClkActivationTime | min ( tCES, tACS) | 3 | 1 | CLKACTIVATIONTIME = 1 |
| RdAccessTime | roundmax (ClkActivationTime + tIACC + DataSetupTime) | 94,8: (10 + 80 + 4,8) | 10 : roundmax (94,8 / 10) | RDACCESSTIME = Ah |
| PageBurstAccessTime | roundmax (tBACC) | roundmax (5,2) | 1 | PAGEBURSTACCESSTIME = 1 |
| RdCycleTime | RdAccessTime + max ( tCEZ, tOEZ) | 101,8: (94,8 + 7) | 11 | RDCYCLETIME = Bh |
| CsOnTime | tCES | 0 | 0 | CSONTIME = 0 |
| CsReadOffTime | RdCycleTime | - | 11 | CSRDOFFTIME = Bh |
| AdvOnTime | tAVC | 0 | 0 | ADVONTIME = 0 |
| AdvRdOffTime | tAVD + tAVC | 12 | 2 | ADVRDOFFTIME = 2h |
| OeOnTime | (ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC) | - | 3, for instance | OEONTIME = 3h |
| OeOffTime | RdCycleTime | - | 11 | OEOFFTIME = Bh |

**Figure 11-48. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.4.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 100 MHz ( f = 100 MHz; T = 10 ns).

Table 11-47 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-48 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-49 shows the asynchronous read access.

**Table 11-47. AC Characteristics for Asynchronous Read Access**

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|---|---|---|
| tCE | Read Access time from $\overline{CS}$ low | 80 |
| tAAVDS | Address setup time to rising edge of $\overline{ADV}$ | 3 |
| tAVDP | $\overline{ADV}$ low time | 6 |
| tCAS | $\overline{CS}$ setup time to $\overline{ADV}$ | 0 |
| tOE | Output enable to output valid | 6 |
| tOEZ | Output enable to High-Impedance | 7 |

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 11-48: the number of clock cycles between the address capture ($\overline{ADV}$ rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

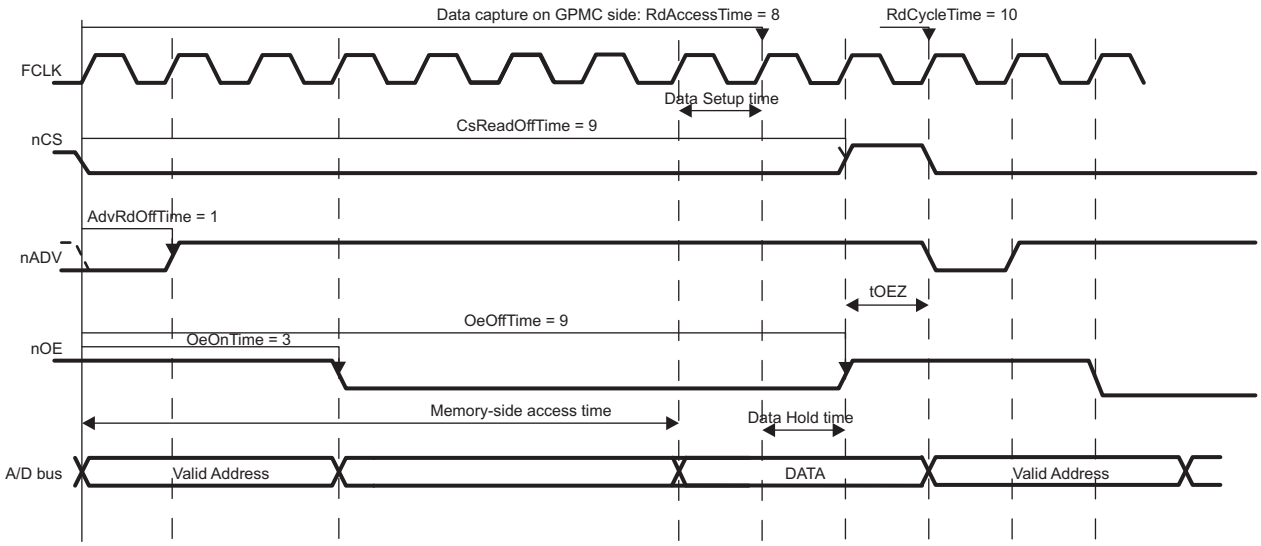
- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no $\overline{OE}$/$\overline{CS}$ deassertion while reading the data). This data hold time is 1 clock cycle (that is, RdAccessTime + 1).
- To complete the access, $\overline{OE}$/$\overline{CS}$ signals are driven to high-impedance. RdAccessTime + 1 cycle + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begins.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-48. GPMC Timing Parameters for Asynchronous Read Access**

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 100 MHz) | GPMC Register Configurations |
|---|---|---|---|---|
| ClkActivationTime | n/a (asynchronous mode) | | | |
| RdAccessTime | round max (tCE) | 80 | 8 | RDACCESSTIME = 8h |
| PageBurstAccessTime | n/a (single access) | | | |
| RdCycleTime | RdAccessTime + 1cycle + tOEZ | 97 | 10 | RDCYCLETIME = Ah |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0 |
| CsReadOffTime | RdAccessTime + 1 cycle | 90 | 9 | CSRDOFFTIME = 9h |
| AdvOnTime | tAAVDS | 3 | 1 | ADVONTIME = 1 |
| AdvRdOffTime | tAAVDS + tAVDP | 9 | 1 | ADVRDOFFTIME = 1 |
| OeOnTime | OeOnTime ≥ AdvRdOffTime (multiplexed mode) | - | 3, for instance | OEONTIME = 3h |
| OeOffTime | RdAccessTime + 1cycle | 90 | 9 | OEOFFTIME = 9h |

**Figure 11-49. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 11.4.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 100 MHz: (f = 100 MHz; T = 10 ns).

Table 11-49 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-50 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-50 shows the synchronous burst write access.

**Table 11-49. AC Characteristics for Asynchronous Single Write (Memory Side)**

| AC Characteristics on the Memory Side | Description | Duration (ns) |
|---|---|---|
| tWC | Write cycle time | 60 |
| tAVDP | $\overline{ADV}$ low time | 6 |
| tWPH | Write pulse width high | 20 |
| tCS | $\overline{CS}$ setup time to $\overline{WE}$ | 3 |
| tCAS | $\overline{CS}$ setup time to $\overline{ADV}$ | 0 |
| tAVSC | $\overline{ADV}$ setup time | 3 |

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires 1 cycle of data hold time ($\overline{CS}$ de-assertion).

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 11-50. GPMC Timing Parameters for Asynchronous Single Write**

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 100 MHz) | GPMC Register Configurations |
|---|---|---|---|---|
| ClkActivationTime | n/a (asynchronous mode) | | | |
| WrAccessTime | Applicable only to WAITMONITORING (the value is the same as for read access) | | | |
| PageBurstAccessTime | n/a (single access) | | | |
| WrCycleTime | WeOffTime + AccessCompletion | 58 | 6 | WRCYCLETIME = 6h |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0 |
| CsWrOffTime | WeOffTime + 1 cycle | 58 | 6 | CSWROFFTIME = 6h |
| AdvOnTime | tAVSC | 3 | 1 | ADVONTIME = 1 |
| AdvWrOffTime | tAVSC + tAVDP | 9 | 1 | ADVWROFFTIME = 1 |
| WeOnTime | tCS | 3 | 1 | WEONTIME = 1 |
| WeOffTime | tCS + tWP + tWPH | 48 | 5 | WEOFFTIME = 5h |

**Figure 11-50. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

### 11.4.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

#### 11.4.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, , ...)
- 8- and 16-bit NAND flash device

#### 11.4.2.2 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories (see Table 11-51).

**Table 11-51. Supported Memory Interfaces**

| Function | 16-bit Address/Data Non-Muxed Flash | 16-bit Address/Data Muxed pSRAM or NOR Flash | OneNAND | 16-bit NAND | 8-bit NAND |

### 11.4.2.3 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 11-52 summarizes the NAND interface signals level applied to external device or memories.

**Table 11-52. NAND Interface Bus Operations Summary**

| Bus Operation | CLE | ALE | $\overline{CE}$ | $\overline{WE}$ | $\overline{RE}$ |
|---|---|---|---|---|---|
| Read (cmd input) | H | L | L | RE | H |
| Read (add input) | L | H | L | RE | H |
| Write (cmd input) | H | L | L | RE | H |
| Write (add input) | L | H | L | RE | H |
| Data input | L | L | L | RE | H |
| Data output | L | L | L | H | FE |
| Busy (during read) | x | x | H | H | H |
| Busy (during program) | x | x | x | x | x |
| Busy (during erase) | x | x | x | x | x |
| Write protect | x | x | x | x | x |
| Stand-by | x | x | H | x | x |

### 11.4.2.4 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; i.e., it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 11-53 summarizes the NOR interface signals level applied to external device or memories.

**Table 11-53. NOR Interface Bus Operations Summary**

| Bus Operation | CLK | $\overline{ADV}$ | $\overline{CS}$ | $\overline{OE}$ | $\overline{WE}$ | WAIT | DQ[15:0] |
|---|---|---|---|---|---|---|---|
| Read (asynchronous) | x | L | L | L | H | Asserted | Output |
| Read (synchronous) | Running | L | L | L | H | Driven | Output |
| Read (burst suspend) | Halted | x | L | H | H | Active | Output |
| Write | x | L | L | H | L | Asserted | Input |
| Output disable | x | x | L | H | H | Asserted | High-Z |
| Standby | x | x | H | x | x | High-Z | High-Z |

#### 11.4.2.5 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventionnal NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

#### 11.4.2.6 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

#### 11.4.2.7 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 256 MBytes divided into six chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

## 11.5 Registers

Table 11-54 provides a summary of the GPMC registers. All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except the GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register is accessed, the endianness is access-dependent.

In this section, i corresponds to the chip-select number, i = 0 to 5.

**Table 11-54. GPMC Registers**

| Address Offset | Register Name | Section |
|---|---|---|
| 0h | GPMC_REVISION | Section 11.5.1 |

### 11.5.1 GPMC_REVISION

This register contains the IP revision code.

**Figure 11-51. GPMC_REVISION**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 8 | 7 | 0 |
|---|---|---|---|
| Reserved | | REV | |
| R-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-55. GPMC_REVISION Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-8 | Reserved | 0 | Reserved |
| 7-0 | REV | 0-FFh | IP revision. Major revision is [7-4]. Minor revision is [3-0].<br>Examples: 10h for revision 1.0, 21h for revision 2.1. |

### 11.5.2 GPMC_SYSCONFIG

This register controls the various parameters of the OCP interface.

**Figure 11-52. GPMC_SYSCONFIG**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 5 | 4 | 3 | 2 | 1 | 0 |

| R-0 | | R/W | | R-0 | R/W | R/W |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-56. GPMC_SYSCONFIG Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-5 | Reserved | 0 | Reserved |
| 4-3 | SIDLEMODE | | Idle mode |
| | | 0 | Force-idle. An idle request is acknowledged unconditionally |
| | | 1h | No-idle. An idle request is never acknowledged |
| | | 2h | Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module |
| | | 3h | Reserved |
| 2 | Reserved | 0 | Reserved |
| 1 | SOFTRESET | | Software reset (Set 1 to this bit triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0) |
| | | 0 | Normal mode |
| | | 1 | The module is reset |
| 0 | AUTOIDLE | | Internal OCP clock gating strategy |
| | | 0 | Interface clock is free-running |
| | | 1 | Automatic Interface clock gating strategy is applied, based on the Interconnect activity |

| 7 | 2 | 1 | 0 |
|---|---|---|---|
| Reserved | | TERMINAL COUNTSTATUS | FIFOEVENT STATUS |
| R-0 | | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-58. GPMC_IRQSTATUS Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | Reserved |
| 9 | WAIT1EDGEDETECTIONSTATUS | | Status of the Wait1 Edge Detection interrupt |
| | | R0 | A transition on WAIT1 input pin has not been detected |
| | | W0 | WAIT1EDGEDETECTIONSTATUS bit unchanged |
| | | R1 | A transition on WAIT1 input pin has been detected |
| | | W1 | WAIT1EDGEDETECTIONSTATUS bit is reset |
| 8 | WAIT0EDGEDETECTIONSTATUS | | Status of the Wait0 Edge Detection interrupt |
| | | R0 | A transition on WAIT0 input pin has not been detected |
| | | W0 | WAIT0EDGEDETECTIONSTATUS bit unchanged |
| | | R1 | A transition on WAIT0 input pin has been detected |
| | | W1 | WAIT0EDGEDETECTIONSTATUS bit is reset |
| 7-2 | Reserved | 0 | Reserved |
| 1 | TERMINALCOUNTSTATUS | | Status of the TerminalCountEvent interrupt |
| | | R0 | Indicates that CountValue is greater than 0 |
| | | W0 | TERMINALCOUNTSTATUS bit unchanged |
| | | R1 | Indicates that CountValue is equal to 0 |
| | | W1 | TERMINALCOUNTSTATUS bit is reset |
| 0 | FIFOEVENTSTATUS | | Status of the FIFOEvent interrupt |
| | | R0 | Indicates than less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode. |
| | | W0 | FIFOEVENTSTATUS bit unchanged |
| | | R1 | Indicates than at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode. |
| | | W1 | FIFOEVENTSTATUS bit is reset |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-60. GPMC_TIMEOUT_CONTROL Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-13 | Reserved | 0 | Reserved |
| 12-4 | TIMEOUTSTARTVALUE | 0-1FFh | Start value of the time-out counter (000 corresponds to 0 GPMC.FCLK cycle, 1h corresponds to 1 GPMC.FCLK cycle, and 1FFh corresponds to 511 GPMC.FCLK cycles) |
| 3-1 | Reserved | 0 | Reserved |
| 0 | TIMEOUTENABLE | | Enable bit of the TimeOut feature |
| | | 0 | TimeOut feature is disabled |
| | | 1 | TimeOut feature is enabled |

### 11.5.7 GPMC_ERR_ADDRESS

The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.

**Figure 11-57. GPMC_ERR_ADDRESS**

| 31 | 30 | 0 |
|---|---|---|
| Rsvd | ILLEGALADD | |
| R-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 11-61. GPMC_ERR_ADDRESS Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | Reserved | 0 | Reserved |
| 30-0 | ILLEGALADD | 0-7FFF FFFFh | Address of illegal access: A30 (0 for memory region, 1 for GPMC register region) and A29-A0 (1GByte maximum) |

Copyright © 2011–2016, Texas Instruments Incorporated

### 11.5.8 GPMC_ERR_TYPE

The GPMC_ERR_TYPE register stores the type of error when an error occurs.

**Figure 11-58. GPMC_ERR_TYPE**

| 31 | | | | | | 16 |
|---|---|---|---|---|---|---|

**Table 11-62. GPMC_ERR_TYPE Field Descriptions**

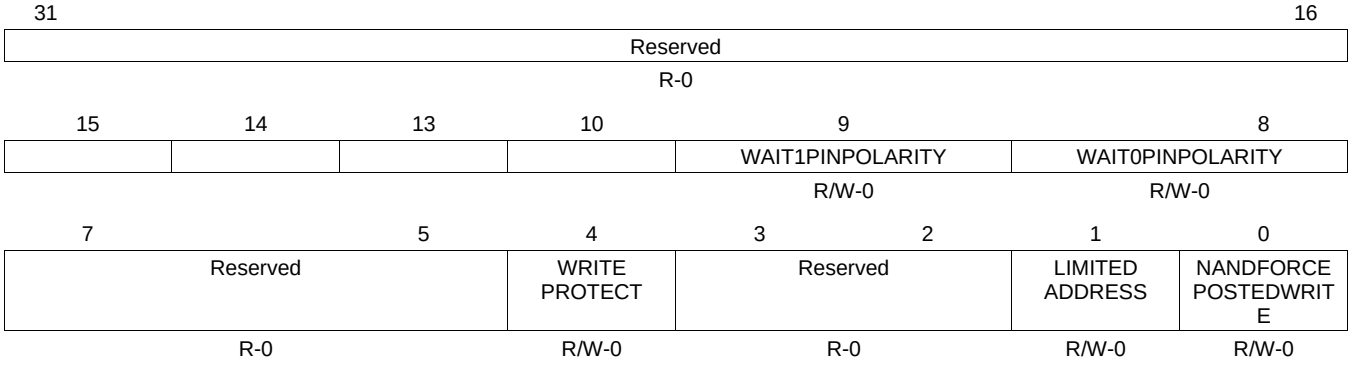
| Bit | Field | Value | Description |
|---|---|---|---|
| 31-11 | Reserved | 0 | Reserved |
| 10-8 | ILLEGALMCMD | 0-7h | System Command of the transaction that caused the error |
| 7-5 | Reserved | 0 | Reserved |
| 4 | ERRORNOTSUPPADD | | Not supported Address error |
| | | 0 | No error occurs |
| | | 1 | The error is due to a non supported Address |
| 3 | ERRORNOTSUPPMCMD | | Not supported Command error |
| | | 0 | No error occurs |
| | | 1 | The error is due to a non supported Command |
| 2 | ERRORTIMEOUT | | Time-out error |
| | | 0 | No error occurs |
| | | 1 | The error is due to a time out |
| 1 | Reserved | 0 | Reserved |
| 0 | ERRORVALID | | Error validity status - Must be explicitly cleared with a write 1 transaction |
| | | 0 | All error fields no longer valid |
| | | 1 | Error detected and logged in the other error fields |

Copyright © 2011–2016, Texas Instruments Incorporated

### 11.5.9 GPMC_CONFIG

The configuration register allows global configuration of the GPMC.

**Figure 11-59. GPMC_CONFIG**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 11-63. GPMC_CONFIG Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | | Reserved |
| 9 | WAIT1PINPOLARITY | | Selects the polarity of input pin WAIT1 |
| | | 0 | WAIT1 active low |
| | | 1 | WAIT1 active high |
| 8 | WAIT0PINPOLARITY | | Selects the polarity of input pin WAIT0 |
| | | 0 | WAIT0 active low |
| | | 1 | WAIT0 active high |
| 7-5 | Reserved | | Reserved |
| 4 | WRITEPROTECT | | Controls the $\overline{WP}$ output pin level |
| | | 0 | $\overline{WP}$ output pin is low |
| | | 1 | $\overline{WP}$ output pin is high |
| 1 | LIMITEDADDRESS | | Limited Address device support. Enabling this function forces A[27:11] high on the GPMC I/O. Thus only devices with 2 kbytes of addressing space can be used. |
| | | 0 | No effect (normal addressing) |
| | | 1 | GPMC_A[27:11] are driven high and not modified during memory accesses |
| 0 | NANDFORCEPOSTEDWRITE | | Enables the Force Posted Write feature to NAND Cmd/Add/Data location |
| | | 0 | Disables Force Posted Write |
| | | 1 | Enables Force Posted Write |

### 11.5.10 GPMC_STATUS

The status register provides global status bits of the GPMC.

**Figure 11-60. GPMC_STATUS**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 10 | 9 | 8 |
|---|---|---|---|
| Reserved | | WAIT1STATUS | WAIT0STATUS |
| R-0 | | R/W-0 | R/W-0 |

| 7 | 1 | 0 |
|---|---|---|
| Reserved | | EMPTYWRITEBUFFERSTATUS |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-64. GPMC_STATUS Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | Reserved |
| 9 | WAIT1STATUS | | Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at IC reset) |
| | | 0 | WAIT1 asserted (inactive state) |
| | | 1 | WAIT1 de-asserted |
| 8 | WAIT0STATUS | | Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at IC reset) |
| | | 0 | WAIT0 asserted (inactive state) |
| | | 1 | WAIT0 de-asserted |
| 7-1 | Reserved | 0 | Reserved |
| 0 | EMPTYWRITEBUFFERSTATUS | | Stores the empty status of the write buffer |
| | | 0 | Write Buffer is not empty |
| | | 1 | Write Buffer is empty |

## 12.1 Description of the Subsystem

### 12.1.1 Overview

The HDVPSS module includes video display and capture processing modules using the latest TI-developed algorithms, flexible compositing and blending engine, and a full range of external video interfaces in order to deliver high-quality video content to end devices.

### 12.1.2 Acronyms and Definitions

**Table 12-1. HDVPSS Acronyms**

| Acronym | Definition |
|---|---|
| HDVPSS | High Definition Video Processing Subsystem |
| DEI | De-Interlacer |
| DVO | Digital Video Output |
| GRPX | Graphics Pipeline |
| HDMI | High Definition Multimedia Interface |
| NF | Noise Filter |
| NTSC | National Television System Committee |
| PAL | Phase Alternating Line |
| SC | Scaler |
| SD | Standard Definition |
| SDK | Software Development Kit |
| COMP | Compositor |
| VENC | Video Encoder |
| VIP | Video Input Port |
| VPDMA | Video Port Direct Memory Access |
| FID | Field ID (Modules inside HDVPSS interpret FID = 0 as a TOP-field and FID = 1 as a BOTTOM field) |

**Table 12-2. HDVPSS Data Format**

| Name | DataFormat A | Arrangement | Tiler Support |
|---|---|---|---|
| 422I/422P | YUV422I_YUYV | Single Buffer: Y U Y V Y U Y V | No |
| 420T | YUV420SP_UV | Y Buffer: Y Y Y Y<br>UV buffer: U V U V | Y: 8-bit container<br>UV: 16-bit container |
| 422S | YUV422SP_UV | Y Buffer: Y Y Y Y<br>UV Buffer: U V U V | Y: 8-bit container<br>UV: 16-bit container |
| 422T | YUV422I_YUYV | Single Buffer: Y U Y V Y U Y V | Yes : 16-bit container |
| 444 | YUV444 | Single Buffer: Y U V | No |
| RGB565 | RGB565 | Single Buffer RGB, 16 bit/pixel | No |
| RGB24 | RGB | Single Buffer RGB, 24 bit/pixel | No |
| ARGB1555 | ARGB1555 | Single Buffer: ARGB, 16 bit/pixel | No |
| ARGB4444 | ARGB4444 | Single Buffer: ARGB, 16 bit/pixel | No |
| ARGB24 | ARGB24 | Single Buffer: ARGB, 24 bit/pixel | No |
| ARGB32 | ARGB32 | Single Buffer: ARGB, 32 bit/pixel | No |
| Bitmap | Bitmap | Single Buffer: Color Lookup Table (RGB input only) | No |

**NOTE:** For the 422T input port, the maximum input width is 960 pixels if the data format is YUV422I_YUYV.

Copyright © 2011–2016, Texas Instruments Incorporated

## 12.1.3 Features

### 12.1.3.1 Overall Features

Features of the HDVPSS module include:

- Supports HD (up to 1080p) and SD (NTSC/PAL) outputs simultaneously.
- Accepts the IVA HD Video Decoder output formats and adjust to several video formats. This includes (but not limited to) scan format conversion, scan rate conversion, aspect-ratio conversion, and frame size conversion.
- Handles both video and graphics efficiently to create high-quality user interfaces. This includes (but not limited to) deinterlacing, scaling, noise reduction, alpha blending, chroma keying, flicker filtering, and pixel format conversion.
- Generates secure video signal with proper content protection mechanisms, that is, HDCP and Macrovision/CGMS-a for digital and analog outputs, respectively.
- Supports VC-1 Range Mapping and Range Reduction on Primary, Auxiliary, and both Independent Transcode 420 Inputs.

### 12.1.3.2 Video Processing Features

- Two parallel video processing pipelines (main and aux) for concurrent HD and SD display are supported.
- The main video pipeline is used for processing video for the full size HD display. The main video pipeline employs motion-adaptive deinterlacer.
- Supported video input formats are 4:2:0 (aligned-chroma, planar, frame/field), 4:2:2 (planar, frame/field), and 444. The output formats of the HDVICP and video formats of captured external digital video data are supported. *Note:* HDVICP is not available on all devices. Refer to the device data manual for details.
- Scan format conversions (that is, interlaced to progressive and vice versa) is supported. Especially the interlaced to progressive conversion will employ a high quality motion-adaptive 3D deinterlacer to properly render both static and dynamic objects in scenes. In addition, sophisticated film-mode detection based on decoded frames (as well as the input bit-stream) is used for best rendering of film-based video.
- Scan rate conversion (up to 1080p 60Hz) is supported to handle video contents with various scan rates. It can be done via frame/field repeating/skipping. . 1080i inputs must result in 1080 lines of vertical resolution when displayed as a 1080i or P output.
- The output of the video processing will be sent to either compositor or external memory. When the output is sent to external memory, context switching between multiple inputs will be handled efficiently.
- Both the main and auxiliary video pipelines will include a write-back path to the external memory to support memory to memory scaling of video frames independently from the display output frame timing. Performance equivalent to scaling up to 16 QVGA (320x240) video windows per 1/60 sec are supported. (ADD video mosaic support).
- Color keying (transparency) is supported.

### 12.1.3.3 Graphics Features

- Three independently generated region-based graphics layers are supported.
- Each graphic layer supports full-screen resolution graphics.
- Each graphics layer can be displayed in either HD or SD output or both.
- Each of the graphics pipelines includes an up/down scaler optimized for graphics application. The scaler supports scaling ratios from 0.25x to 4x with 0.01 scaling step size.
- Scaling of individual regions within a graphics layer will be supported. A scaled region will not overlap with another region
- Supported graphics formats are:
  - 32-bit: ARGB8888
  - 24-bit: RGB888

Copyright © 2011–2016, Texas Instruments Incorporated

- 16-bit: ARGB1555, RGB565, ARGB4444
- Bitmap: 1, 2, 4, 8-bit CLUT table
- Global and pixel-level alpha blending value is supported (256 levels). For pixel-level blending, the alpha value can come from either source or CLUT table.
- Color keying (transparency)

#### 12.1.3.4 Cursor Features

- A dedicated hardware cursor is not supported. If a cursor function is required, it must be implemented in software.

#### 12.1.3.5 HD/SD Compositor Features

- Supports independently controlled compositors (HDMI/DVO1, DVO2, SD) .
- The HD compositors will support composition of video and graphics layers to provide full size video display, graphics overlay, video-in-graphics and picture-in-picture modes for HD video outputs.
- The SD compositor supports video display, graphics overlay, and video-in-graphics for SD video outputs..
- Each input layer will be given a display order priority which determines the display and blending orders.
- Each output supports independent layer visibility control.
- The compositor supports 256-level alpha blending of two overlapping layers.
- The compositor supports display outputs to HDMI/DVO1 and DVO2 at different scan rates or different pixel resolutions in addition to the separate SD output.

#### 12.1.3.6 Video Output and Encoding Features

- A single HDMI 1.3 compliant interface with HDCP to support 1080p (1080p 24, 30, and 60 are mandatory), 1080i, 720p, 480p, 480i. 640x480, 800x600, 1024x768, 1280x768, and 1920x1200.
- Two DVO interfaces that support up to 1080p at 60 MHz 8/16/24 YCbCr/RGB formats are included. Each DVO port supports both embedded and separated sync outputs. VBI data insertion on DVO outputs are not required.
- SD Composite/S-video (NTSC/PAL): meet all requirements defined in ITU-R BT.476-6.
- SD SCART analog outputs.
- All video outputs (SD Composite/S-Video, HDMI/DVO1, and DVO2) may be active simultaneously .
- Supported resolutions are 480i, 480p, 720p, 1080i, 1080p.

#### 12.1.3.7 VBI Features

- VBI Closed Captioning and other data pass-through.
- EIA/CEA-608-B Line 21 Data services – supports both SCTE 20 and SCTE 21 standards.
- EIA-708-B Digital Television (DTV) Closed Captioning – support SCTE21/ATSC A/53e standards.
- Reconstruction of lines 10 through 21 of the VBI from a data source available to the host CPU (video user data DVS706r8 – DVB/SCTE specifications based on PES encoding of VBI data Raw VBI data, Closed Caption (CC), Teletext (NABTS, WSS), CGMS, VPS, VITC, Gemstar 1x and 2x, Extended Data Service(XDS), Moji, V-Chip).

#### 12.1.3.8 Copy Protection

- NTSC Analog outputs (only for SD modes) – Macrovision version 7.1
- HDMI - HDCP
- All analog outputs – CGMS-A on all analog outputs
- Uses 59.94Hz output frame rate for both 59.94 and 60Hz source materials to maintain the same output frame rate on both NTSC and HD outputs

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.1.3.9 Video Capture Features

- HDVPSS supports two independently configurable external video input capture ports.
- Each video input capture port can be operated as one 16/24-bit input channel (with separate Y and Cb/Cr inputs) or two clock independent 8-bit input channels (with interleaved Y/C data input). Embedded sync and external sync modes are supported for all input configurations.

#### 12.1.3.10 Input Data Features

**NOTE:** Due to pinout restrictions, not all combinations are supported on all devices. Refer to the device data manual for details.

- 8-bit input ports:
  - A single non-multiplexed CIF/480i/480p/720p/1080i Y/C data
  - Up to 2-stream multiplexed ED (480p) Y/C data
  - Up to 4-stream multiplexed SD (480i) Y/C data
  - Up to 16-stream multiplexed CIF Y/C data (TBD – 16)
- 16/24-bit input ports:
  - A single non-multiplexed CIF/480i/480p/720p/1080i/1080p Y/C data
  - A single 24-bit YCbCr component or raw RGB data
  - Up to 2-stream multiplexed HD (720p/1080i) Y/C data
  - Up to 4-stream multiplexed ED (480p) Y/C data
  - Up to 8-stream multiplexed SD (480i) Y/C data
  - Up to 8-stream multiplexed CIF Y/C data
- The video capture port channel supports de-multiplexing of both pixel-to-pixel and line-to-line multiplexed streams.
- Up to 1920x1200@60Hz (160MHz) input data rate is supported for 16-bit mode input port.
- Each video capture port supports one scaler capable of both up and down scaling of one non-multiplexed input stream (one of two 8-bit channel inputs or 16-bit input channel input data).
- Each video capture port supports one programmable color space conversion to convert 24-bit RGB data to YCbCr data.
- HDVPSS supports data storage in 444, 422, and 420 formats.
- Each video capture port channel supports chroma down sampling (422 to 420) for any non-multiplexed input data. The chroma down-sampling for multiplexed streams is done as memory-to-memory operations outside of HDVPSS on an individual frame data.
- Deinterlacing is not supported.
- Ancillary data capture is supported for VANC/VBI data (ancillary data within the interval between SAV-EAV sequences during vertical blanking period) on all input channels. HANC data capture is not supported. Decoding of the Ancillary data will be handled by the software.
- Graphics overlay over incoming bitstream is NOT supported.
- Noise Reduction on the incoming video is supported as a separate memory-to-memory operation within the HDVPSS.
- One of the 8-bit channels in each video port may be used as a video write back path for transcoding applications. This channel may also use the color space conversion and/or the scaler. It is up to the application to avoid resource contention.

#### 12.1.3.11 Other Features

- The HDVPSS supports two additional video input source in 420 or 422 tiled format (same as input for main and auxiliary video paths). This path can be used for both video transcode operations (utilizing a scaler and chroma downsampler within one of the VIP ports in a memory to memory configuration) and/or driving video to the SD output display.

Copyright © 2011–2016, Texas Instruments Incorporated

  - Only 1 of the 2 additional video input sources can directly drive the SD display. For display output, there is no processing performed, that is, no scaler or deinterlacing
- The HDVPSS supports video data write back paths for following:
  - Scaled video from aux video channel (for delayed PIP display) saved as 422 video.
  - Scaled video from main video channel saved as 422 video.
  - SD scaled video from the main video compositor (delayed SD output display when CIT is off) saved as 422 video
  - Independently scaled video from main deinterlacer output (transcoding application) – saved as a 420 video using the scaler and chroma_downsampler resources in one of the VIP ports.
  - Independently scaled video from aux output (transcoding application) – saved as a 420 video using the scaler and chroma_downsampler resources in the other VIP port. This path is shared with the independent transcode video input source.
  - Independently scaled video from the 3rd or 4th video input source saved as a 420 video using a scaler and chroma downsampler resource in one of the VIP ports. The 3rd or 4th video input source can be 422 or 420 tiled input data (same as input for main and auxiliary inputs). The 3rd and 4th video input source share the VIP write back paths of the primary and auxiliary deinterlacers.
  - Write back of the scaled video from main, aux or additional video input source video channels supports both tightly (1 frame per 1 display frame period) and loosely (many frames per 1 display frame period) coupled to the display frame period. All other write backs are tightly coupled
  - The HDVPSS includes a highly programmable and bandwidth-efficient DMA controller to support the worst-case bandwidth application.

#### 12.1.3.12 Feature Limitations

The features of the HDVPSS module highlighted above are characteristics of the HDVPSS module and are not supported on all SoCs that use the HDVPSS. Common limitations exist, such as:

- **Device and system bandwidth.** The bandwidth available to the HDVPSS varies based on the frequency and width of the DDR interface provided on the device, the frequency and width of the DDR interface populated on the user's particular board, and the bandwidth demands of the remaining IP in the system. These constraints may limit the data rates that can be concurrently supported on the various input and output interfaces to the HDVPSS.
- **Device and system pinout.** Specific devices within the device family may not provide full availability of all of the Video Input and Video Output ports. In addition, pin multiplexing constraints for a particular end system may further limit the availability of specific HDVPSS signals. Refer to device data manual for details on the device availability and pin muxing with other internal signals.

**NOTE:** The following list is the convention for pin naming:

- Pins with VIN0 are connected to VIP0
- Pins with VIN1 are connected to VIP1
- Pins with VOUT0 are connected to DVO2
- Pins with VOUT1 are connected to DVO1

There is no need for any pinmux configuration for analog outputs.

**NOTE:** The block diagram and text sections of this chapter consistently use the instance numbering for the VIP and GRPX submodules as VIP0/VIP1 and GRPX0/GRPX1/GRPX2. However, the register sections use the numbering VIP1/VIP2 and GRPX1/GRPX2/GRPX3. The following list is the convention for submodule naming to register control:

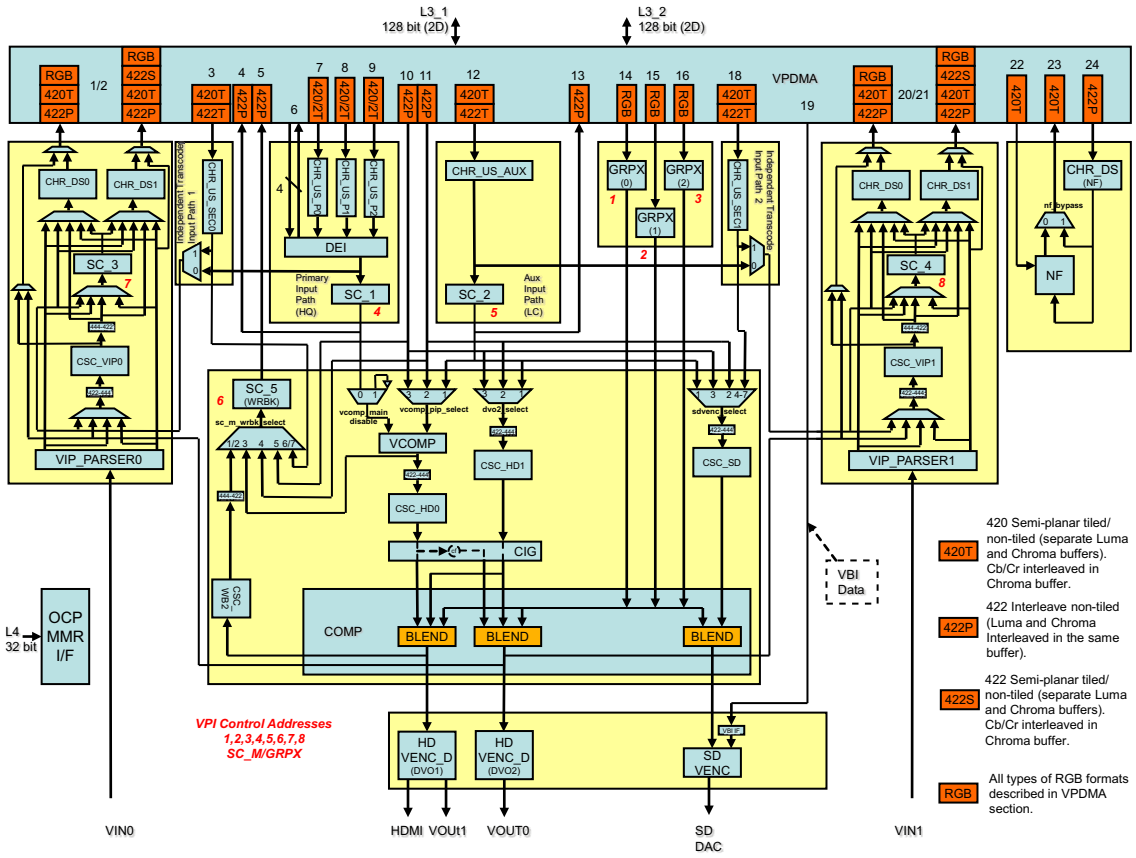
- Submodule VIP0 is controlled by registers VIP1
- Submodule VIP1 is controlled by registers VIP2
- Submodule GRPX0 is controlled by registers GRPX1
- Submodule GRPX1 is controlled by registers GRPX2
- Submodule GRPX2 is controlled by registers GRPX3

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.1.4 Functional Operation

Figure 12-1 shows a block diagram of the HDVPSS.

**Figure 12-1. HDVPSS Detailed Block Diagram**



In Figure 12-1, the primary input path contains a deinterlacer and scaler (down-scale only when the source is VIP_PARSER or the destination is VENC). The auxiliary input path contains a scaler. The main path is capable of deinterlacing up to 1080i sources. The CHR_US modules in both paths are identical.

The 4:2:2–4:4:4 and 4:4:4–4:2:2 modules are used to convert data from YUV422 space to YUV444 space, or from YUV444 space to YUV422 space. These blocks do not have any MMR for configuration and are enabled whenever required by the following modules.

Figure 12-1 also shows the VPDMA VPI Control Addresses for modules within the HDVPSS that use this interface (numbers shown in red). Modules that use the VPDMA VPI Control Address mechanism are any SC (SC_1, SC_2, SC_3, SC_4, SC_5), or GRPX module.

Note that VPDMA only supports 422 paths for display only. In addition, the numbers shown on the VPDMA ports correspond to those listed in Table 12-3.

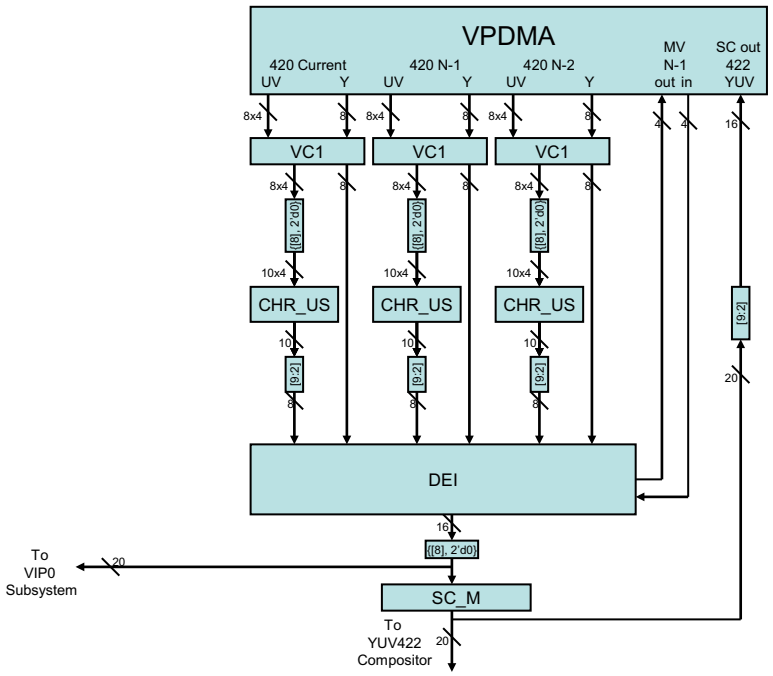
Copyright © 2011–2016, Texas Instruments Incorporated

**Table 12-3. VPDMA Client Number**

| VPDMA Client Number | HDVPSS Port |
|---|---|
| 1 / 2 | VIP0 YUV/RGB/Ancillary Data (To VPDMA) |
| 3 | Secondary-0 Input Path (From VPDMA) |
| 4 | Scaler (SC_1) Output Path (To VPDMA) |
| 5 | Scaler (SC_5) Output Path (To VPDMA) |
| 6 | DEI Motion Data (To/From VPDMA) |
| 7 | Primary Video (Fn) Input Path (From VPDMA) |
| 8 | Primary Video (Fn-1) Input Path (From VPDMA) |
| 9 | Primary Video (Fn-2) Input Path (From VPDMA) |
| 10 | Bypass Path-0 Input (BP0) (From VPDMA) |
| 11 | Bypass Path-1 Input (BP1) (From VPDMA) |
| 12 | Auxiliary Video Input Path (AUX) (From VPDMA) |
| 13 | Scaler (SC_2) Output Path (To VPDMA) |
| 14 | GRPX0 RGB/Stencil/CLUT Input Path (From VPDMA) |
| 15 | GRPX1 RGB/Stencil/CLUT Input Path (From VPDMA) |
| 16 | GRPX2 RGB/Stencil/CLUT Input Path (From VPDMA) |
| 18 | Secondary Input Path-1 Input (From VPDMA) |
| 19 | SDVENC VBI Data (From VPDMA) |
| 20 / 21 | VIP1 YUV/RGB/Ancillary Data (To VPDMA) |
| 22 | 420 Noise Filter Data (From VPDMA) |
| 23 | Noise Filter/Chroma Downsampler Output Data (To VPDMA) |
| 24 | 422 Noise Filter/Chroma Downsampler Input Data (From VPDMA) |

Figure 12-2 provides a more detailed view of the Primary Input Path (PRI), showing the interconnection between various modules and bit widths.

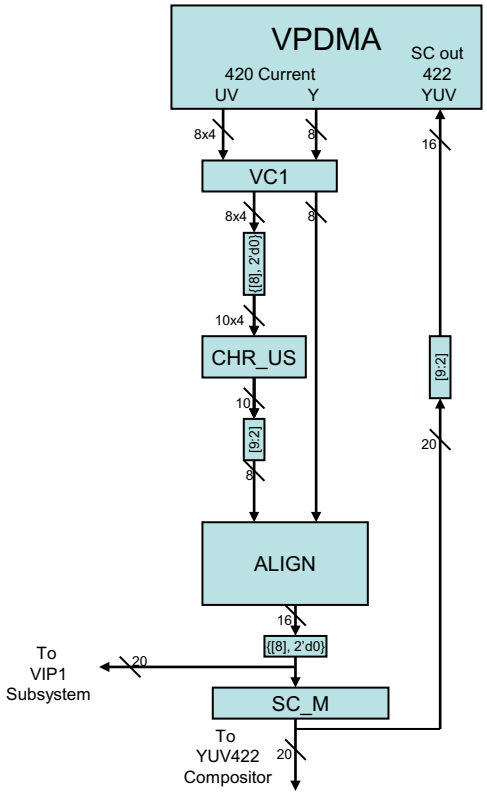
**Figure 12-2. Primary Input Path (PRI) Detailed Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

Figure 12-3 provides a more detailed view of the Auxiliary Input Path (AUX), showing the interconnection between various modules and bit widths.

**Figure 12-3. Auxiliary Input Path Detailed Block Diagram**



The previous diagrams show the details of the interconnect and selections possible within the Video Input Ports. In Figure 12-4, the signals shown on the Video Input Port Parser (VIP_PARSER) module are the outputs generated by this module. External video input drives the input side of this module. A_Y can be in either YUV422 format (A_Y[7:0] in the diagram) or RGB/YUV444 format (A_Y[23:0] in the diagram) depending on the external video input source and configuration options within the VIP_PARSER. If the VIP_PARSER is configured to capture 24bit RGB/444 data, A_Y[23:0] is used and the data path inside the Video Input Port must be configured correctly for it. Multiplexor selections and controls are shown above, and described in CLKC VIN0/2 Data Path Register. The output of the Video Input Port drives the VPDMA module, which sends the resulting video to SDRAM.

### 12.1.4.1 Functional Module Descriptions

The HDVPSS module is composed of many processing blocks. There are multiple instances of most of these processing blocks. The following module descriptions provide a high-level description of each processing module.

#### *12.1.4.1.1 VPDMA*

The VPDMA module is capable of transporting data to and from an external memory location, most often external DDR memory, buffering this data and then delivering the data as demanded to HDVPSS modules as programmed. Additionally in a third-party configuration the VPDMA is capable of performing DMA transfers as requested by the pulsing of an event strobe.

The VPDMA module is also capable of generating an address which may reach any location in the range for which it is configured. It is capable of moving this data either to or from a Shared Buffer and ultimately to or from a Client Buffer. For the two type of Client Buffers that are used to drive data into a subsystem (Streaming Buffer and Random Access Buffer) data is either pushed into the buffer or pulled out of the buffer dependent upon the direction of the data transfer.

For third-party DMA operations the data is transferred into a Client buffer, and then transferred out of the Client Buffer to the transfer destination. These transfers are triggered by an Event pulse to each of the Client Buffers which are Routing Buffer types.

##### *12.1.4.1.1.1 VPDMA Details*

The modules that source or sink data are referred to as clients. That is, the physical interface between the processing module and external memory is called a client. A channel is the mechanism inside the VPDMA that connects a specific memory buffer or transfer to a specific client.

Each of the channels has a type of data that it can support based upon the client that it services. Based on this, four kinds of channel has been defined:

- YUV Channel—Clients taking data in YUV format like DEI, NF, and so on.
- RGB Channel—Clients taking RGB data like GRPX
- Miscellaneous Channel—The Miscellaneous channel type is for any data type that is not a normal video type. The Miscellaneous channel type makes no assumptions on data type and just passes the data to the client and supports a single buffer for the client.
- Free Channel—Used in video compositions. The Free channel data type is always ignored as it uses the same data type of the descriptor that first calls the free channel.

The clients of the VPDMA are the physical connection to the processing modules that source or sinks of the data and control when the channel can be updated. Each client can be configured to have specific start event which allows for the channel data to start flowing to or from the external client. The start event can be selected from one of the signals in the FRAME START Interface or it can be selected by a channel attribute or to be controlled by an internal Frame signal controlled by the List Manager.

The VPDMA controller works on lists of descriptors. Descriptors define how data will be transferred through different channel. In other words, channel is described through a Data Transfer descriptor. The client that the channel is mapped to interprets the information in the descriptor to perform the requested data transfer. List is a group of descriptors that makes up a set of DMA transfers that need to be completed. List can contain any kind of descriptor without limitation and be of any size.

The CPU creates a list of descriptors in DDR in the order it wants them executed. The CPU then writes the location of the list to the LIST_ADDR register, followed by writing the size, type of list and list number of the LIST_ATTR register and posts the list. The List Manager module, which manages different lists, will then schedule a DMA transfer to pull in the portion of the list that it can store in the internal VPDMA memory. The List Manager will sequentially process descriptor in the list and performs the data transfers.

### 12.1.5 HDVPSS Data Flow

#### 12.1.5.1 Data Flow Control

The VPDMA routes input and output video sources to the starting or ending point of each processing pipeline.

Signal routing within the HDVPSS is controlled by an internal protocol referred to as Video Peripheral Protocol (VPI Protocol). This protocol consists of a NewFrame (NF) signal at the start of each frame which indicates to downstream modules that a frame of data is about to start. On the last signal of a frame, an EndofFrame signal is sent to indicate the last pixel of a frame. In addition to preparing downstream modules for frames of data, the NewFrame signal is used in many modules to stage the memory mapped registers. Each processing module will receive a NewFrame signal, and will generate a NewFrame signal to send to its downstream module. Sections in the register section which refer to New Frame, or NF handling, refer to this signal.

Internal Control is accomplished by configuring the selection of data paths available at the input of each of the multiplexers (see Figure 12-1). This configuration can be done in the CLKC Data Path Select Register. This register controls where internal processing pipes are connected.

#### 12.1.5.2 VCOMP Mux

The video compositor (VCOMP) module takes two inputs: MAIN and PIP. The MAIN input comes from Primary Input Path, and PIP input can be selected from one of three sources: Auxiliary Input Path (AUX), Bypass Path0 (BP0), or Bypass Path1 (BP1). The default for the PIP path is disabled, so there is no PIP input unless it is configured.

#### 12.1.5.3 HD Display Mux

The HD display mux selects a data path for HD displays, which include HDMI/DVO1, and DVO2 outputs. The input data path can be selected from three sources: Auxiliary Input Path (AUX), Bypass Path0 (BP0), or Bypass Path1 (BP1). The default for the input data path is disabled, so no input path is selected unless it is configured.

#### 12.1.5.4 SD Display Mux

The SD display mux selects a data path for SD display that includes SDVENC output. The input data path can be selected from one of four sources: Auxiliary Input Path (AUX), Bypass Path0 (BP0), Bypass Path1 (BP1), or Secondary-1 Input Path (SEC1). The default for the input data path is disabled, so no SDVENC input path is selected unless it is configured.

#### 12.1.5.5 SC_5 Mux

The SC_5 mux selects a data path for writing a processed image back to memory. The input data path for this MUX can be selected from one of six sources:

- HDMI Composited Path Output (from COMP)
- VCOMP Block Output
- Bypass Path0 (BP0)
- Bypass Path1 (BP1)
- Secondary-0 Input Path (SEC0)

The default for the input data path is disabled, so there is no scaler input or output.

#### 12.1.5.6 CSC_VIP Mux

The color space converters (CSC_VIP0 and CSC_VIP1) within the VIP subsystem receive data from one of five sources:

- VIP_PARSER PortA Output (422)
- VIP_PARSER PortB Output (422)

Copyright © 2011–2016, Texas Instruments Incorporated

- Secondary Path Output (422): SEC0 for CSC_VIP0 and SEC1 for CSC_VIP1
- VIP_PARSER PortA Output (RGB)
- Compositer Output (RGB) from COMP.

The default for this mux is disabled, so there is no CSC_VIP input.

#### 12.1.5.7 SC_VIP Mux

The scaler modules (SC_VIP0 and SC_VIP1) within the VIP subsystem receive data from one of three sources:

- Color Space Converter Output (from CSC_VIP)
- VIP_PARSER PortA Output
- VIP_PARSER PortB Output
- Secondary Path Output: SEC0 for SC_VIP0 and SEC1 for SC_VIP1

The default for this mux is disabled, so there is no SC_VIP input.

#### 12.1.5.8 VIP RGB Mux

The RGB output of the VIP subsystem can come from one of two sources:

- Compositer Output (from COMP)
- Color Space Converter Output (from CSC_VIP)

#### 12.1.5.9 Video Compositor PIP Input

The Video Compositor PIP input path can come from 1 of 3 sources: The Auxiliary Input Pipe, or from either of the Bypass-422 pipes (non-tiled format). These sources will usually be either the Primary Composited Writeback Path or the memory stored version of the Auxiliary Input Path. However, the only requirement on these two VPDMA input paths is that they have been stored in 422 “private data” format, which is an untiled raster format.

The default for this path is disabled, meaning no PIP input.

#### 12.1.5.10 PIP Display Input

The HD Composite VENC path can come from 1 of 3 sources: The Auxiliary Input Pipe, or from either of the Bypass-422 pipes (non-tiled format). These sources will usually be either the Primary Composited Writeback Path or the memory stored version of the Auxiliary Input Path. However, the only requirement on these two VPDMA input paths is that they have been stored in 422 “private data” format, which is an untiled raster format.

The default for this path is disabled, meaning no input.

#### 12.1.5.11 Standard Definition Video Encoder Input

The standard definition vdeo encoder (SD VENC) input path can come from 1 of 4 sources: The auxiliary input pipe, the secondary-2 input pipe or one of the two bypass-422 input pipes. These sources will usually be either the primary composited writeback path or the memory stored version of the Auxiliary Input Path. However, the only requirement on these two VPDMA input paths is that they have been stored in 422 “private data” format, which is an untiled raster format.

The default for this path is disabled, meaning no SD VENC input.

#### 12.1.5.12 Primary Composited Writeback Scaler Input

The primary composited writeback scaler Input is used to scale the primary input path (normally HD) and send to memory so that this data can be fed back into the HDVPSS for display on either the high-definition VENC or standard-definition VENC. The input to this scaler can come from 1 of 6 sources: the output of the video compositor, the composited HDMI output, one of the two bypass-422 paths, or the secondary-1 input.

Copyright © 2011–2016, Texas Instruments Incorporated

The default for this path is disabled, meaning no scaler input (or output).

#### 12.1.5.13 Video Input Port Color Space Converter Input (2)

The color space converters within the video inputs ports can come from 1 of 3 sources: The Video Input Port Parser (VIP_PARSER), the composited HD DAC output or from either the Primary Input DEI (Video Input Port 0) or the Auxiliary Input DEI (Video Input Port 1). The feeds from the primary and auxiliary DEIs are for dual stream transcode (Secondary Input Paths) with write back to memory as RGB data.

The default for this path is disabled, meaning no CSC input (or output).

#### 12.1.5.14 Video Input Port Scaler Input (2)

The scalers within each of the video input ports can come from 1 of 3 sources: The Video Input Port Parser (A or B channel), the Video Input Port Color Space Converter or either the Primary Input DEI (Video Input Port 0) or either the Auxiliary Input DEI or Secondary Video Path Input (Video Input Port 1). The feeds from the Primary and Auxiliary input DEIs are for dual stream transcoding purposes.

The default for this path is disabled, meaning no scaler input.

#### 12.1.5.15 Video Input Port RGB Output (2)

The RGB output of the Video Input Port can come from 1 of 2 sources: The Video Input Port Parser or the Video Input Port Color Space Converter. The feed from the Video Input Port Color Space Converter are for dual stream transcode (via Secondary Input Path) with write back to memory as RGB data. The source of this data is either the Primary Input DEI (Video Input Port 0) or the Auxiliary Input DEI (Video Input Port 1). When the source of the Video Input Port Color Space Converter is set to one of the DEI inputs, this mux will pass the output of the Color Space Converter out instead of the output of the Video Input Port Parser.

The default for this path is from the Video Input Port Parser (VIP_PARSER).

#### 12.1.5.16 Noise Filter Output

The Noise Filter Output can come from 1 of 2 inputs: The Noise Filter or from the Noise Filter Chroma Downsampler (allowing this chroma downsampler to be used standalone).

The default for this path is connected to the Noise Filter output.

##### *12.1.5.16.1 Data Formats*

The following section describes the data formats for the HDVPSS. Each of the channels has a type of data that it can support based upon the client that it services. Also, for each channel the data type will assume that data is packed in memory a certain way and will be presented to the client in the same manner no matter what the format of the data in memory.

The YUV formatted channels expect video data that is in YUV color space. The YUV data type is for YUV data and it can support both interleaved data where Luma and Chroma are in the same data buffer or it can support co-planar data where the Luma and Chroma are in separate data buffers. The YUV channel also can be configured to give a different start position for the client instead of the default upper left hand corner of the frame. The storage format for YUV data depends on the data type field. The data type must be set to a data type that the channel can support. All the clients that data are provided to will either accept Luma Only, Chroma Only or Luma and Chroma in a parallel data bus.

The data formats in Figure 12-5 map as follows:

422P data:

- 422 interleave non-tiled (luma and chroma interleaved in the same buffer)

422S data:

- 422 semi-planar tiled/non-tiled (separate luma and chroma buffers). Cb/Cr interleaved in chroma buffer.

420T data:

Copyright © 2011–2016, Texas Instruments Incorporated

- 420 semi-planar tiled/non-tiled (separate luma and chroma buffers). Cb/Cr interleaved in Chroma buffer.

RGB data:

- All types of RGB formats described in VPDMA section.

Each of these data formats are discussed in the VPDMA data formats section.

### 12.1.6 Example Data Flows

Several concurrent data flows within the HDVPSS are possible. The following sections outline several of the possible data flow scenarios capable within the HDVPSS, including the HDVPSS level mux register selections required for the flow. The flows shown are not all encompassing, and there are variations within each. For example, the first data flow shown is Dual Display. Single Display is also possible. Dual Transcode (Secondary Input Path 1 and 2) is possible, or Single Transcode (Secondary Input Path 1). Transcode is possible without display, etc.

#### 12.1.6.1 Dual Display

A standard dual display data flow is shown in Figure 12-5.

In this case, the primary display (HDMI) contains two video sources in a Picture-in-Picture format. On the secondary HD display, the auxiliary display is being shown.

**Figure 12-5. HDVPSS Dual Display (PIP) Data Flow**

#### 12.1.6.2 Tri Display

There are several display configurations for the Tri-Display format.

The first configuration, Figure 12-6, shows the auxiliary video path on the SD display. In this case, graphics overlays are also being applied to each video encoder output. Because HD DV02 and SD DAC paths are sharing the same input (meaning same size and interlaced format), they share a graphics input. In this case, because the SD path must be interlaced, all video paths must be interlaced.

The second configuration, Figure 12-7, shows the HDMI composited Picture-in-Picture display content on the SD display. In this case, the three output displays are independent. The SC WRBK scaler will be used to scale the primary blended display and convert to interlaced format for the SD output.

### 12.1.6.3 Tri Display and Dual Transcode

In addition to display, each video source can be transcoded while being displayed through the use of the Secondary Input Paths.

Either or both video sources can be transcoded while simultaneously being displayed.

**Figure 12-8. HDVPSS Tri Display Dual Transcode**

### 12.1.6.4 Tri Display, Dual Transcode, and Video Capture

The Video Input Port has the capability to capture either one or two video sources. In the previous case, only one video source can be captured per Video Input Port, since the other path is dedicated to transcode. Also in this case, video captured cannot be resized.

**Figure 12-9. HDVPSS Tri Display Dual Transcode with Video Capture**

### 12.1.6.5 Tri Display and Video Capture

As can be seen in Figure 12-10, as long as there is no transcode operations, video display and video capture are independent. In this usage, up to four video sources can be captured (two per video input port) while display is active.

To improve the quality of captured video sources, the Noise Filter (NF) can be used on captured video (see Figure 12-11). This Noise Filter is a memory to memory operation, meaning that captured video goes to memory, and then is read back into to the Noise Filter, operated on, and written back to memory. The below diagram shows this flow (with display active).

**Figure 12-10. HDVPSS Tri Display with Video Capture**

### 12.1.7 Interrupt Mapping

HDVPSS generates four interrupts which can be mapped different processors as listed in Table 12-11.

**Table 12-11. HDVPSS Interrupts**

| Interrupt No. | Interrupt Name (INTRx) | Mapped Processor | MMR Address Offset Range |
|---|---|---|---|
| 0 | INTR0 | Cortex-A8 | 0x20 - 0x3F |
| 1 | INTR1 | GEM | 0x40 - 0x5F |
| 2 | INTR2 | Media controller processors | 0x60 - 0x7F |
| 3 | INTR3 | Media controller processors | 0x80 - 0x9F |

Interrupts INTR2 and INTR3 are mapped to both media controller processors (Video Media Controller and HDVPSS Media Controller).

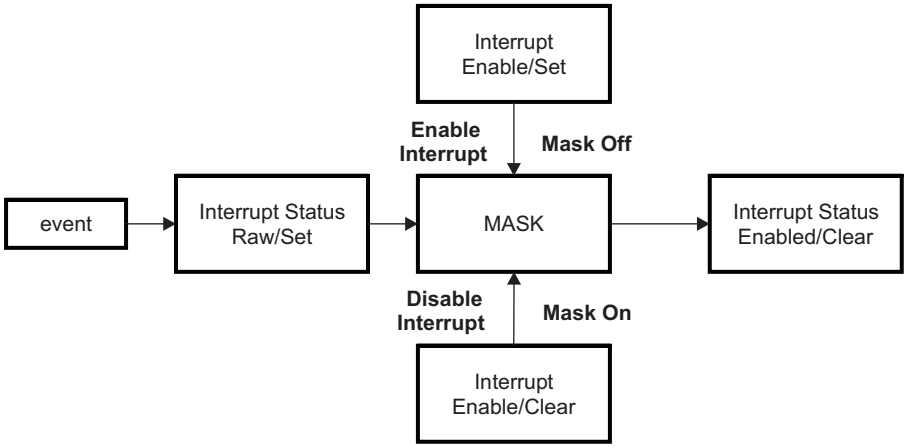
The configuration of each of the above interrupts (INTRx) is controlled by the MMR present in the offset address range mentioned above in INTC (offset: 0x0100) module.

The following group of MMR constitutes the configuration of interrupts.

- Interrupt Status Raw/Set
- Interrupt Status Enabled/Clear
- Interrupt Enable/Set
- Interrupt Enable/Clear

Figure 12-12 shows the functionality of these MMR.

**Figure 12-12. MMR Functionality**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.1.7.1 Status Before Mask

Interrupt Status Raw/Set register bit-fields show the status of interrupts before the MASK. A bit-field is set to ‘1’ when either an event happened on the signal mentioned in the corresponding bit-field or manual write of ‘1’ to the corresponding bit-field. Writing ‘0’ has no effect.

#### 12.1.7.2 Status After Mask

Interrupt Status Enabled/Clear register bit-fields show the status of interrupts after the MASK. The value of Interrupt Status Raw/Set register is transferred to Interrupt Status Enabled/Clear register for the bit-fields with MASK off. Writing ‘1’ to a bit-field clears its value to ‘0’ and also clears the corresponding bit-field in Interrupt Status Raw/Set register.

#### 12.1.7.3 Mask OFF (Enable Interrupt)

Interrupt Enable/Set register is used to disable the MASK for selected signals in Interrupt Status Raw/Set register. Writing ‘1’ to a bit-field enables corresponding interrupt to propagate to the processor. Writing ‘0’ has no effect.

#### 12.1.7.4 Mask ON (Disable Interrupt)

Interrupt Enable/Clear register is used to enable the MASK for selected signals in Interrupt Status Raw/Set register. Writing ‘1’ to a bit-field disables corresponding interrupt to the processor. Writing ‘0’ has no effect.

Please note that all interrupts are disabled by default.

There are 50 interrupts that can be mapped to each INTRx at HDVPSS level and everyone of the four INTRx has access to all the 50 available interrupts. One ‘bit’ is allocated for each interrupt in the MMR and spread across two memory mapped registers (Register0 and Register1) to fit in all the 50 interrupts.

The source of interrupts described at HDVPSS level come from Sub-Modules of HDVPSS like VPDMA, DEI, VIP0, etc. Figure 12-13 shows interrupt mapping from module level to HDVPSS level.

### 12.1.8 Clocking

The following section discusses the steps needed to enable HDVPSS clocking.

#### 12.1.8.1 Enable PRCM for HDVPSS Module

Please refer to the *PRCM* chapter to enable PRCM for HDVPSS.

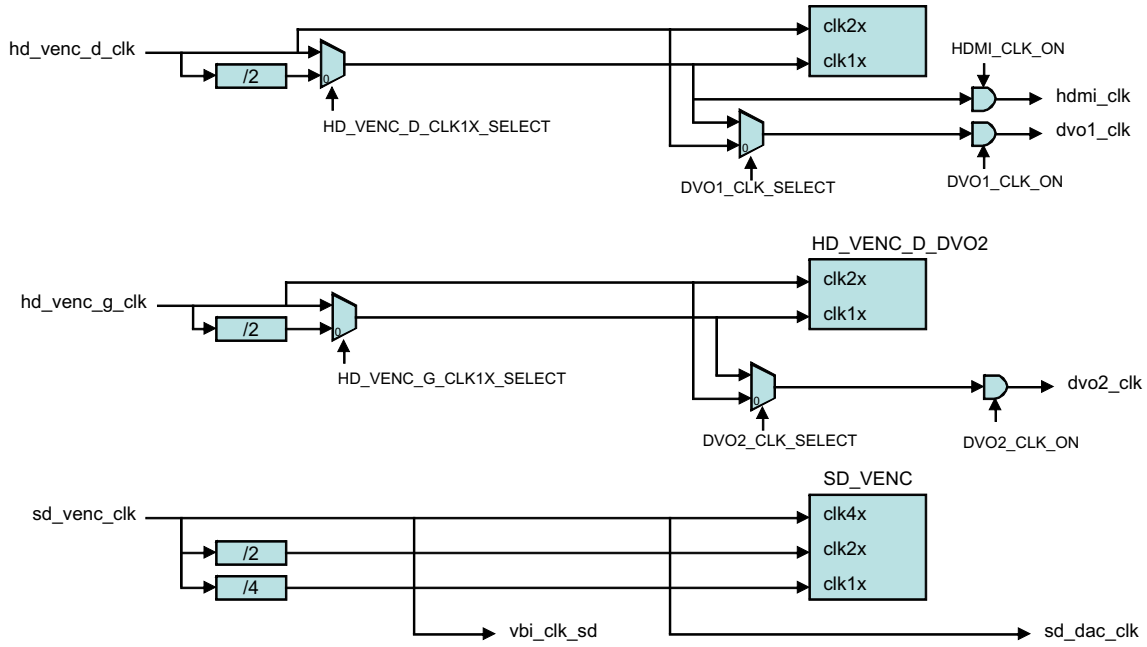
#### 12.1.8.2 Enable HDVPSS Internal Clocks

In HDVPSS, some of the data paths and modules are divided into different clock domains. This enables the user to switch off the paths/modules that are not used, at HDVPSS level. The CLKC→CLKC Module Clock Enable Register (address: 0x48100100) is used to enable the paths that fall in separate clock domains (as mentioned in the CLKC register).

#### 12.1.8.3 VENC Clock Source (HDMI or DVO1/DVO2/SDVENC Pixel Clock)

Figure 12-15 shows the derivation of pixel clock for different VENCs. In this figure, hd_venc_d_clk (external clock source) directly drives the HDMI/DVO1 (hd_venc_d) video encoder and hd_venc_g_clk (external clock source) directly drives the DVO2 (hd_venc_d) video encoder.

**Figure 12-15. Video Encoder Clock/Control Diagram**



The output of the muxes (shown in the above diagram) can be controlled in the CLKC Video Encoder Clock Select (address: 0x48100114) register. Please make sure the required VENCs are enabled in the CLKC Video Encoder Enable (address: 0x48100118) register.

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.1.9 Reset

HDVPSS provides separate resets for each of the paths/modules.

The following sequence is used to reset the entire HDVPSS module:

1. Take VPDMA to standby via force standby MMR write. This disconnects master ports.
2. Ensure all VENCs are disabled via MMR writes.
3. Power down VENCs via appropriate MMR writes.
4. Shut down VENC clocks via MMR writes.
5. Shut down VIP clocks.
6. Shut down all module clocks by writing to all enable bits.
7. Reset all modules and Vencs by writing reset bits.
8. Request IDLE, on IDLE acknowledgement, clocks can be shut down.

Copyright © 2011–2016, Texas Instruments Incorporated

## 12.2 Internal Modules

This section describes the internal modules of the high-definition video processing subsystem (HDVPSS).

### *12.2.1 Chroma Up-Sampler (CHR_US)*

The chroma up-sampler (chr_us) module is used to convert from YCbCr 4:2:0 data format input to YCbCr 4:2:2 format output.

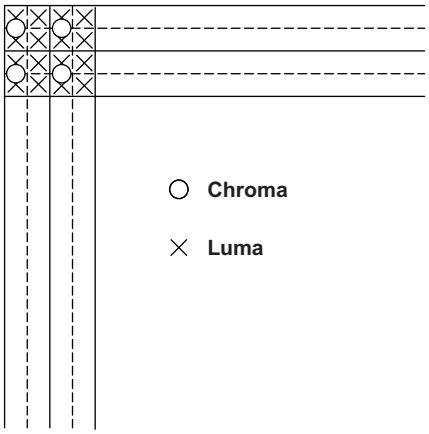
#### 12.2.1.1 Features

- Supports both interlaced and progressive inputs
- 4-tap interpolation filtering
- Filter coefficients are all programmable
- Four sets of coefficients (each set has four coefficients) corresponding to anchor pixels and interpolated pixels of top field and bottom field
- For progressive inputs, the coefficients corresponding to top and bottom field must be identical
- Each coefficient is 14 bit (4.10 format)
- Default filter coefficients are based on Catmull-Rom algorithm
- Capable of removing the half pel vertical offset so all chroma samples are on-grid. This step ensures that the output does not suffer from any kind of rainbow effect due to chroma-upsampling.
- Provides a 10-bit interface in both directions: 10-bit input and 10-bit output
- Support bypass mode for 4:2:2 input

#### 12.2.1.2 Functional Description

The YUV420 input to Chroma Upsampler module must be in the format shown in Figure 12-16, in which the chroma sample lies in the left column of a 2x2 pixel block with half pel vertical shift.

**Figure 12-16. 4:2:0 YCrCb Color Space with Chroma Left-aligned**



The upsampling is performed by an interpolation filter which uses Catmull-Rom algorithm. The Catmull-Rom Filter is based on four anchor pixels representing a four tap filter. The general 4-tap filter Catmull-Rom filter is defined in Figure 12-17.

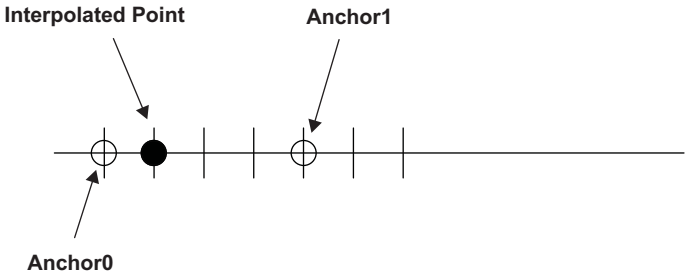
Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-17. Catmull-Rom Filter Definition**

$$[\,1 \quad x \quad x^2 \quad x^3\,] * \begin{bmatrix} 0 & 1 & 0 & 0 \\ -a & 0 & a & 0 \\ 2a & -3+a & 3-2a & -a \\ -a & 2-a & -(2-a) & a \end{bmatrix}$$

In the previous figure, x is the distance to the interpolated point between the two anchor points. In Figure 12-18, the example shows the desired interpolated point to be ¼ of the distance between Anchor0 and Anchor1. Thus, x = ¼.

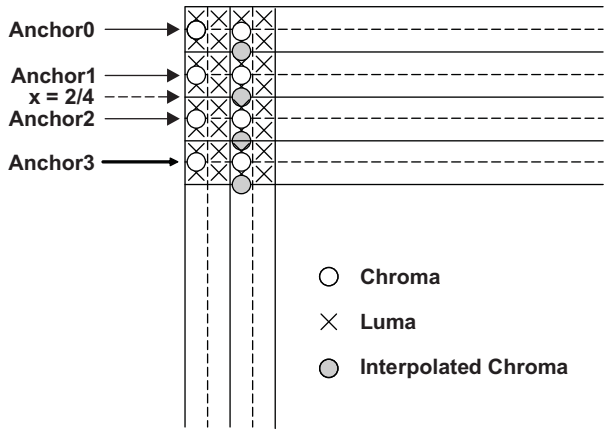
**Figure 12-18. Definition of 'X'**



The variable 'a' determines the characteristics of the filter. a = ½ is generally used because the filter will produce an interpolated output that is an exact match to a linear input curve. In the literature, some people have noted that a=0.75 or a=1.0 may be more pleasing to the eye. In the implementation, the filter coefficients are programmable through MMR.

For the interpolated pixel, the variable x defines the positional offset relative to anchor pixel1. Figure 12-19 shows four anchor pixels with Anchor0 being near the top of the image and Anchor3 near the bottom. x is relative to Anchor1. Positive values of x goes down towards Anchor3. Negative x values imply a direction towards Anchor0. For example, if we want to interpolate a pixel midway between Anchor1 and Anchor2, x would be 2/4=1/2. There are four half pels between Anchor1 and Anchor2. Midway is two pels, so x=2/4.

**Figure 12-19. Anchor Pixels**



Copyright © 2011–2016, Texas Instruments Incorporated

In the implementation, we need to interpolate the anchor pixel to get it on-grid. Then, we also need to interpolate a completely new pixel for YPrPb 4:2:2.

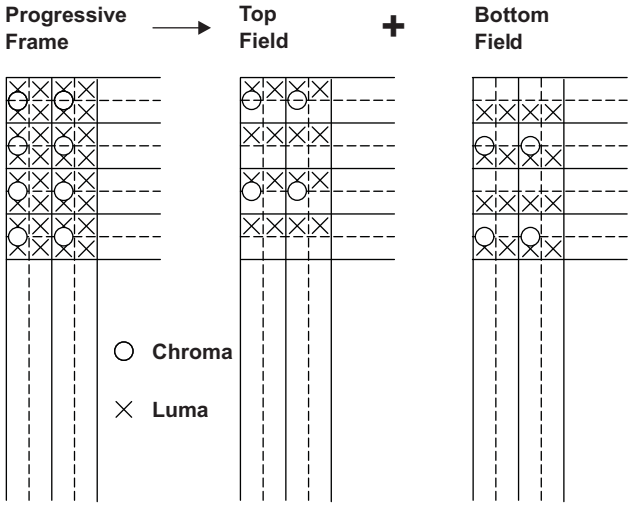
For a progressive input, x = -1/4 for getting the anchor pixel on-grid. x = 1/4 for generating the new pixel.

Lines are scanned from the top of the picture to the bottom.

#### 12.2.1.2.1 For Interlaced YUV420 Input Data

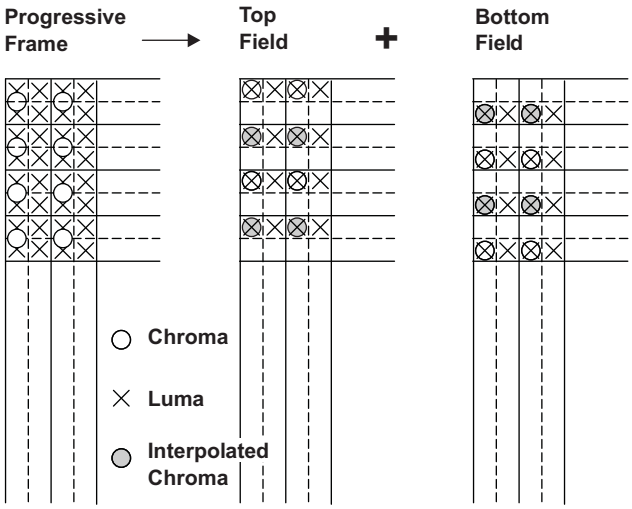
Figure 12-20 shows how 4:2:0 video is split into top and bottom fields in interlaced format. Chroma is attached to alternating Luma lines in the top and bottom fields such that color is equally spread out between the top field and the bottom field. This 4:2:0 interlaced chroma representation is shown in the following figure.

**Figure 12-20. 4:2:0 Interlaced Scan**



In each interlaced field, the chroma anchor points are separated by 4 pixel lines, or 8 half pels. The 4:2:2 chroma interpolated color space representation of interlaced pictures is shown in Figure 12-21.

**Figure 12-21. Ideal 4:2:2 Chroma Upsampling for Interlaced Scan**



Following interpolation, the chroma samples lie on a 4:2:2 grid.

Copyright © 2011–2016, Texas Instruments Incorporated

Anchor pixels for the top field have been sited up by half a pel (x = -1/8). The new interpolated pixel is sited 3 half pels (x=3/8) down. Samples from the top field are distinct from samples in the bottom field.

For the bottom field, anchor pixels are sited 3 half pels up (x = -3/8). The new interpolated pixel is sited 1 half pel down (x=1/8).

The chroma upsampling filter accepts different coefficients for the top field and the bottom field. In the case of progressive input, the coefficients for the top field and bottom field must be the same.

It should be noted that a different implementation could have been chosen to use the same coefficients for the top and bottom fields. Instead of pushing pixels from the top to bottom of a picture, it can be shown that pushing the bottom field through the upsampling filter from the bottom to the top of the picture permits using the same values for x as in the top field case.

#### *12.2.1.2.2 Edge Effects*

Several methods with increasing levels of difficulty resulting in increasing quality can be employed to deal with chroma pixels near the edges. In this module, the edge pixels can be mathematically approximated using the same filter as the rest of the picture. Edge pixels are duplicated going into the filter.

#### *12.2.1.2.3 Modes of Operation (VPDMA)*

In both primary (PRI) and auxiliary (AUX) paths, the mode in which the VPDMA needs to be operated depends whether the chroma upsampler and de-interlacers are enabled or not. Table 12-12 shows the modes of operation.

**Table 12-12. VPDMA Modes of Operation**

| Input data is 4:2:0 | Input data is 4:2:2 |
|---|---|
| Mode A | Mode B |

These modes need to be set in the following register bit-fields of particular instances being used:

CHR_US_reg0.cfg_mode

Line_mode bitfield in VPDMA registers of format RD_LB_CLIENT_CTL_STATUS need to configured as follows:

Mode A corresponds to MMR value 0
Mode B corresponds to MMR value 1

The following are the VPDMA client related bit-fields that need to be configured:

VPDMA_pri_chroma_cstat.line_mode
VPDMA_aux_chroma_cstat.line_mode
VPDMA_sec0_chroma_cstat.line_mode
VPDMA_sec1_chroma_cstat.line_mode
VPDMA_pri_luma_cstat.line_mode
VPDMA_aux_luma_cstat.line_mode
VPDMA_sec0_luma_cstat.line_mode
VPDMA_sec1_luma_cstat.line_mode

**Important Notes:**

1. For VPDMA luma clients, Mode B should always be used.
2. For VPDMA chroma clients, Mode A is used for 420 data and Mode B is used for 422 data.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.1.2.4 Coefficient Configuration

The filter coefficients are left-aligned 14-bit binary values in signed Q4.10 format. The decimal point is between bits 9 and 10 using the convention of the least significant bit being at position zero. The most significant bit, 13, is the sign bit.

In the register map, the most significant nibble of the coefficient is the sign and the integer portion of the value. The next 10 bits represent the fractional portion of the coefficient value.

Chroma upsampling requires two sets of coefficients. Each coefficient set is comprised of four 14-bit Q4.10 values. One set is used for the top field of an interlaced picture, and the other set is used for the bottom field of an interlaced picture. For a progressive picture, both sets must be identical.

The coefficients and settings should be used for the following video source types:

**4:2:2 input (progressive or interlaced input)**

VPDMA line mode = 1

CHR_US_reg0.cfg_mode = 0x1 (mode B)

CHR_US coefficients are not used in this mode, so values are "don't care"

**4:2:0 input (interlaced input):**

VPDMA line mode = 0

CHR_US_reg0.cfg_mode = 0x0 (mode A)
CHR_US_reg0.anchor_fid0_c0 = 0x51
CHR_US_reg0.anchor_fid0_c1 = 0x3d5
CHR_US_reg1.anchor_fid0_c2 = 0x3fe3
CHR_US_reg1.anchor_fid0_c3 = 0x3ff7
CHR_US_reg2.interp_fid0_c0 = 0x3fb5
CHR_US_reg2.interp_fid0_c1 = 0x2e9
CHR_US_reg3.interp_fid0_c2 = 0x18f
CHR_US_reg3.interp_fid0_c3 = 0x3fd3
CHR_US_reg4.anchor_fid1_c0 = 0x16b
CHR_US_reg4.anchor_fid1_c1 = 0x247
CHR_US_reg5.anchor_fid1_c2 = 0xb1
CHR_US_reg5.anchor_fid1_c3 = 0x3f9d
CHR_US_reg6.interp_fid1_c0 = 0x3fcf
CHR_US_reg6.interp_fid1_c1 = 0x3db
CHR_US_reg7.interp_fid1_c2 = 0x5d
CHR_US_reg7.interp_fid1_c3 = 0x3ff9

**4:2:0 input (progressive input):**

VPDMA line mode = 0

CHR_US_reg0.cfg_mode = 0x0 (mode A)
CHR_US_reg0.anchor_fid0_c0 = 0x00C8
CHR_US_reg0.anchor_fid0_c1 = 0x0348
CHR_US_reg1.anchor_fid0_c2 = 0x0018
CHR_US_reg1.anchor_fid0_c3 = 0x3fd8
CHR_US_reg2.interp_fid0_c0 = 0x3fb8
CHR_US_reg2.interp_fid0_c1 = 0x0378
CHR_US_reg3.interp_fid0_c2 = 0x00e8
CHR_US_reg3.interp_fid0_c3 = 0x3fe8
CHR_US_reg4 to CHR_US_reg7 are not used so their values are "don't care".

### 12.2.2 Color Space Converter (CSC)

The color space converter (CSC) module is used to convert video data from one color space to another with nine programmable integer multipliers.

#### 12.2.2.1 Features

- All parameters are programmable
- Each parameter is configurable in signed 13-bits
- Support for Bypass Mode

#### 12.2.2.2 Functional Description

The conversion between the different color spaces requires addition and multiplication operations on color and intensity components. The mathematical expression of the conversion can be written as:

```
Y   = A0*R + B0*G + C0*B + D0
Cb  = A1*R + B1*G + C1*B + D1
Cr  = A2*R + B2*G + C2*B + D2
```

Using YUV to RGB conversion as an example: YUV represents one color space and RGB represents another color space. The conversion can be written in the matrix format shown in Figure 12-22.

**Figure 12-22. Matrix Format**

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix} + \begin{bmatrix} D0 \\ D1 \\ D2 \end{bmatrix}$$

Since HDTV and SDTV have different conversion requirements, both conversions of RGB-to-YCbCr and YCbCr-to-RGB are described. The details of derivations of these matrixes will be given in the following subsections.

##### 12.2.2.2.1 HDTV Application

###### 12.2.2.2.1.1 HDTV Application with Video Data Range

The two equations presented in this section are for the HDTV application. The chromaticity parameters are defined by ITU-R709 standard.

The input video data for these equations should be within the range that is defined for video application.

In an 8-bit system:

- Rd, Gd, Bd, and Yd will be in the range [16-235]
- Cb and Cr will be the range [16-240]
- D = 1

In a 10-bit system:

- Rd, Gd, Bd, and Yd will be in the range [64-940]
- Cb and Cr will be in the range [64-960]
- D = 4

Copyright © 2011–2016, Texas Instruments Incorporated

Conversion from RGB to YCbCr:

**Figure 12-23. Conversion from RGB to YCbCr**

$$\begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} 0.2126 & 0.7152 & 0.0722 \\ -0.1172 & -0.3942 & 0.5114 \\ 0.5114 & -0.4646 & -0.0468 \end{bmatrix} \begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix} D$$

Conversion from YCbCr to RGB:

**Figure 12-24. Conversion from YCbCr to RGB**

$$\begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1.5396 \\ 1 & -0.1831 & -0.4577 \\ 1 & 1.8142 & 0 \end{bmatrix} \begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} + \begin{bmatrix} -197 \\ 82 \\ -232 \end{bmatrix} D$$

#### *12.2.2.2.1.2 HDTV Application with Graphics Data Range*

The two equations presented in this section are for the HDTV application with graphics range data input. The main application is for computer graphics display. The chromaticity parameters are defined by ITU-R709 standard.

The input data ranges for these equations are as follows.

In an 8-bit system:

- Rd, Gd, Bd, Yd, Cb and Cr will be the range [0-255]
- D = 1

In a 10-bit system:

- Rd, Gd, Bd, Yd, Cb and Cr will be in the range [0-1023]
- D = 4

Conversion from RGB to YCbCr:

**Figure 12-25. Conversion from RGB to YCbCr**

$$\begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} 0.1826 & 0.6142 & 0.0620 \\ -0.1006 & -0.3385 & 0.4392 \\ 0.4392 & -0.3990 & -0.0402 \end{bmatrix} \begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} + \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix} D$$

Conversion from YCbCr to RGB:

**Figure 12-26. Conversion from YCbCr to RGB**

$$\begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} = \begin{bmatrix} 1.1644 & -0.0003 & 1.7927 \\ 1.1644 & -0.2132 & -0.5329 \\ 1.1642 & 2.1125 & -0.0001 \end{bmatrix} \begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} + \begin{bmatrix} -248 \\ 77 \\ -289 \end{bmatrix} D$$

#### 12.2.2.2.2 SDTV Application

##### 12.2.2.2.2.1 SDTV Application with Video Data Range

The two equations presented in this section are for the SDTV application. The chromaticity parameters are defined by ITU-R601 standard.

The input video data for these equations should be within the range that is defined for video application.

In an 8-bit system:

- Rd, Gd, Bd, and Yd will be in the range [16-235]
- Cb and Cr will be the range [16-240]
- D = 1

In a 10-bit system:

- Rd, Gd, Bd, and Yd will be in the range [64-940]
- Cb and Cr will be in the range [64-960]
- D = 4

Conversion from RGB to YCbCr:

**Figure 12-27. Conversion from RGB to YCbCr**

$$\begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.172 & -0.339 & 0.511 \\ 0.511 & -0.428 & -0.083 \end{bmatrix} \begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix} D$$

Conversion from YCbCr to RGB:

**Figure 12-28. Conversion from YCbCr to RGB**

$$\begin{bmatrix} Rd \\ Gd \\ Bd \end{bmatrix} = \begin{bmatrix} 1 & -0.0003 & 1.3717 \\ 1 & -0.3365 & -0.6984 \\ 1 & 1.7336 & -0.0016 \end{bmatrix} \begin{bmatrix} Yd \\ Cb \\ Cr \end{bmatrix} + \begin{bmatrix} -176 \\ 132 \\ -222 \end{bmatrix} D$$

#### 12.2.2.3 Bypass Mode

CSC module can be bypassed by setting the following bit-field to 1:

CSC→CSC05.Bypass

### *12.2.3 Compositor Module*

The Compositor (COMP) module is used to blend the input video and graphics sources into a single stream to drive video encoders.

#### 12.2.3.1 Features Supported

COMP supports the following features:

- Three displays: 2 HDs and 1 SD
- Up to five input layers for each HD display: two videos and three graphics
- Up to four input layers for the SD display: one video and three graphics
- Cascade alpha blending for two input layers first and graphic blending later
- Blended outputs to memory from two of the blenders

#### 12.2.3.2 Functional Description

The COMP module has three independently controlled blenders (compositors): two for HD output and one for SD output. Each HD blender can take up to five input layers (two videos and three graphics) to generate one composite output layer. The SD blender can take up to four input layers (one video and three graphics) to generate one composite output layer. This is shown in Figure 12-31.

Each blender is associated with one of the three VENCs to drive the display data as shown.

Blender0 → HDMI/DVO1

Blender1 → DVO2

Blender2 → SD

Following are the input layers available:

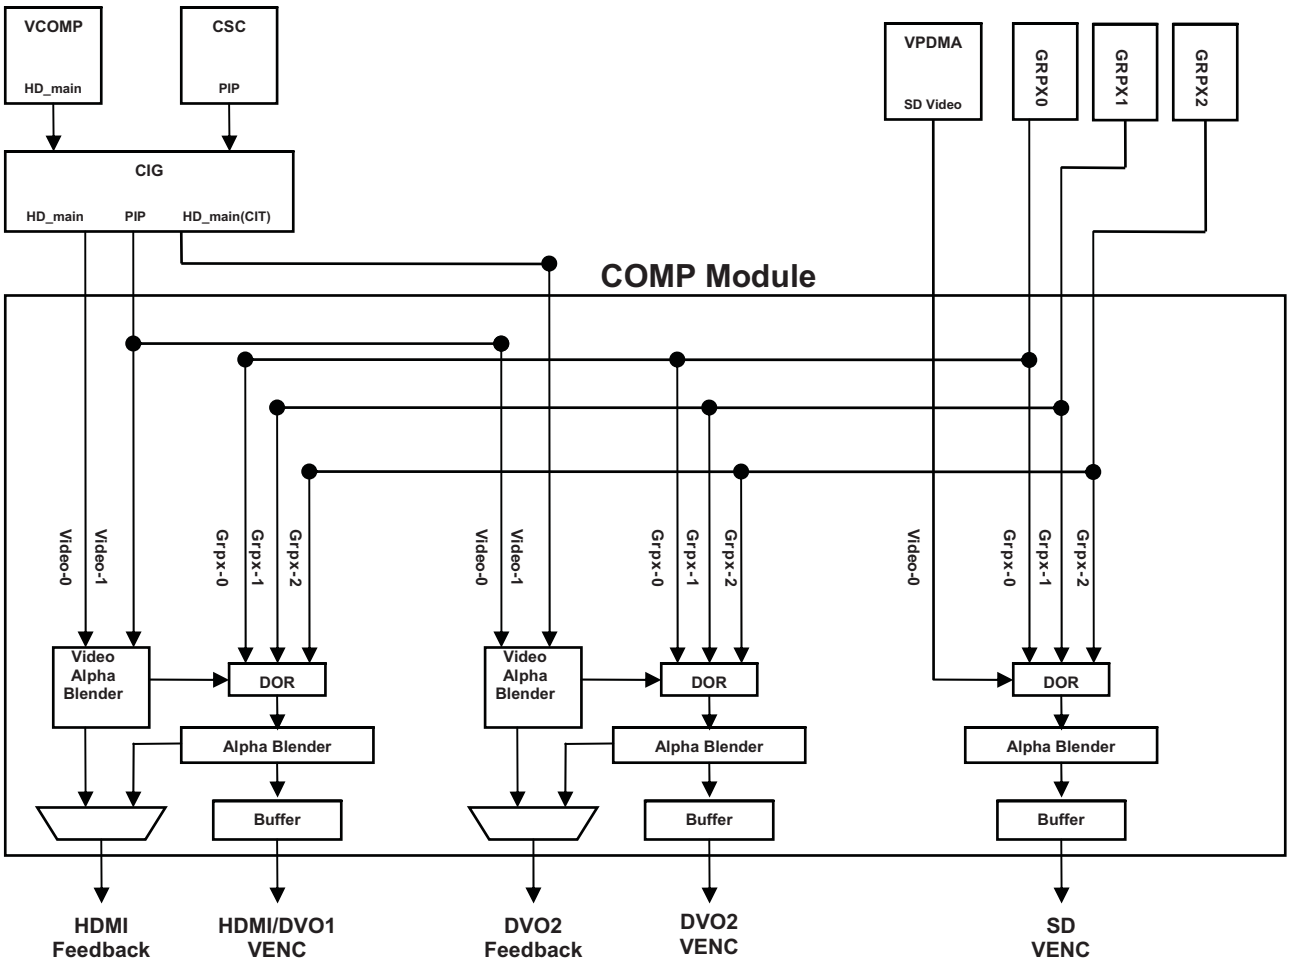
- HD - Main Video Input
- HD - Main Video Input constrained (CIT)
- HD - PIP Video Input
- SD Video Input
- Graphics0 input (GRPX-0)
- Graphics1 input (GRPX-1)
- Graphics2 input (GRPX-2)

Each of the input layers can be associated to one or more VENCs in HD-VPSS as shown in the above figure. All the input layers associated with a VENC should have the same size and type (progressive or interlaced) of the display. This implies that if an input layer is shared with multiple VENCs, all those VENCs should have the same size, type and frame rate.

For example, if the 1080p HDMI output is desired to have main video input and PIP video input with 1 graphics, then the main and PIP video input must be 1080p, and one of the graphics must be 1080p. If another blender is setup 480i, it cannot use either the main or PIP video inputs, and must use a different graphics input.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-31. COMP Module Block Diagram**



All graphic sources have both interlaced or progressive formats. Muxes are used for each display to choose the right format. If the graphics module has interlaced input, it can only provide interlaced output through progressive data path. Therefore, the interlaced input data path can not be used in this case.

Input layers associated to a VENC are grouped together, reordered according to the user programmable display priority order list, and blended using embedded alpha values between overlapped layers. Each composed output is then buffered in a memory (inside COMP) from which the associated VENC pulls the data out at its pixel clock rate.

As mentioned above, each blender can take up to five input layers (four for SD) out of the available seven input layers. The accessibility of each blender to the input layer is shown in Table 12-17.

**Table 12-17. Input Layers and Associated Blenders**

| Input layers and Blenders | Blender0 | Blender1 | Blender2 |
|---|---|---|---|
| HD main video | YES | NO | NO |
| HD main video (CIT) | NO | YES | NO |
| SD video | NO | NO | YES |
| HD pip video | YES | YES | NO |
| Grpx-0 | YES | YES | YES |
| Grpx-1 | YES | YES | YES |
| Grpx-2 | YES | YES | YES |

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.3.3 Input Sources

Each blender in COMP module receives up to five input sources (four for SD) to blend and send the composited output to the corresponding VENC. Five input sources to a blender are as follows :

1. Video-0 (HD main video/ HD main video CIT/ SD video)
2. Video-1 (HD pip video; Not available for SD output)
3. Grpx-0
4. Grpx-1
5. Grpx-2

All the inputs that are connected to a single blender should:

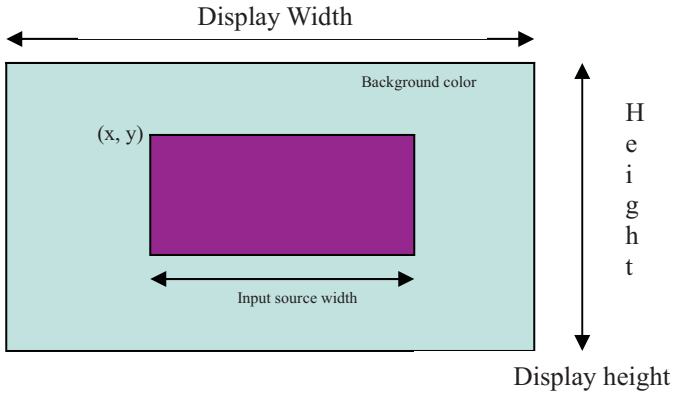
- Have the same size of its corresponding VENC display size. This is done by forming a WINDOW (shown below) in the upstream modules. Please note that it does NOT imply any restriction on the actual input video sizes in external memory to be the same. For example, Video-0 can be 1920x1080 and Video-1 can be 720x480 in the memory.
- Carry their priority levels (if g_reorder =0) to re-order themselves as layers on the final display stream (only for graphic inputs) and
- Carry alpha values used to blend with each other using the above priority levels.

It is necessary to configure upstream modules (to blender) to supply each input of full display size to the blender. If the size of any window is not the same as the display size, background color is inserted in the remaining portion as shown below. The upstream modules include:

1. VCOMP (for HD main video - CIT and non-CIT)
2. CIG (for HD PIP video)
3. VPDMA SD Video (for SD Video)
4. GRPX-0 (for Grpx-0 input)
5. GRPX-1 (for Grpx-1 input)
6. GRPX-2 (for Grpx-2 input)

Display width and display height parameters come from VENC module settings, as shown in Figure 12-32.

**Figure 12-32. Display Width and Height Parameters**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.3.3.1 HD Main Video Window (CIT or non_CIT)

This window is formed in the VCOMP module with two input sources: main and auxiliary. The composition of the input sources and background color is explained in VCOMP module functional description.

VCOMP→reg6. cfg_dsply_numlines = CIG→CIG_REG1.disp_h = Display_Height of VENC associated with HD main video

VCOMP→reg6. cfg_dsply_numpix_per_line = CIG→CIG_REG1.disp_w = Display_Width of VENC associated with HD main video

Background color for HD main window is selected using following bitfields:

VCOMP→reg9.cfg_dsply_bckgrnd_cr_val

VCOMP→reg9.cfg_dsply_bckgrnd_cb_val

VCOMP→reg9.cfg_dsply_bckgrnd_y_val

The alpha value of HD PIP window is configured using following bit-fields:

CIG→CIG_REG2.bl_enable

CIG→CIG_REG2.bl_level

The layer order of HD video windows (main and pip) is configured in COMP <VENC> settings. The <VENC>_vid_bld_ord bitfield is described in the video alpha blender section.

#### 12.2.3.3.2 HD PIP Video Window

CIG module forms the PIP video window after receiving PIP video source from CSC module

CIG→CIG_REG6.pip_disp_h = Display_Height of VENC associated with PIP video

CIG→CIG_REG6.pip_disp_w = Display_Width of VENC associated with PIP video

Background color for PIP window is transparent and carries an alpha value of zero. It gets the background color set by COMP→back_clr at the time of composition.

The alpha value of HD PIP window is configured using following bit-fields:

CIG→CIG_REG9.bl_enable

CIG→CIG_REG9.bl_level

The priority of HD video windows (both the main and PIP windows) is described in Section 12.2.3.4.1.

#### 12.2.3.3.3 SD Video Window

For the SD video window, the SD video input from the memory needs to be the same as the Display_Width of SD_VENC output display.

For the SD video window:

Input source width = Display_Width

Input source height = Display_Height

x=0

y=0

and hence no background color

The alpha value for SD video is 0xFF.

The priority level used SD video is set in: COMP→SD_setting.vid_order (irrespective of COMP→SD_setting.g_reorder bit-field value).

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.3.3.4 Graphics Windows

These windows are formed in the corresponding GPRX modules by configuring below:

GRPX→frame_display_attributes.frame_height = Display_Height of VENC associated with corresponding Grpx

GRPX→frame_display_attributes.frame_width = Display_Width of VENC associated with corresponding Grpx

The origin of a Grpx region input in the window (x,y) is configured as below:

GRPX→region_display_attributes.disp_pos_x = x

GRPX→region_display_attributes.disp_pos_y = y

Background color for Grpx window is transparent and carries an alpha value of zero. It gets the background color set by COMP→back_clr at the time of composition.

The alpha value configuration for blending is explained in GRPX module. Blend type for a region is selected using following bitfield:

GRPX→region_display_attributes.Disp_blend_cfg

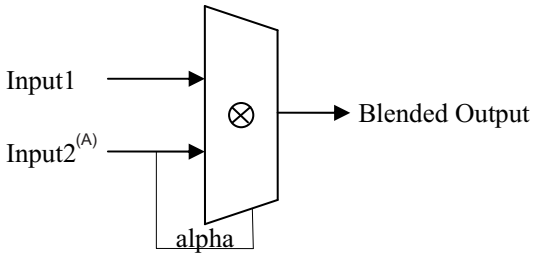
The priority level of a graphics region is set, in corresponding region, using the bitfield mentioned below:

GRPX→region_display_attributes.Disp_prior

### 12.2.3.4 Blender

A Blender in the COMP module works as mentioned in Figure 12-33:

**Figure 12-33. Blender Diagram**



A Input2 is tied to 0 for the SD Blender.

When two input sources, say input1 and input2, are blended, the resulting source is calculated as follows:

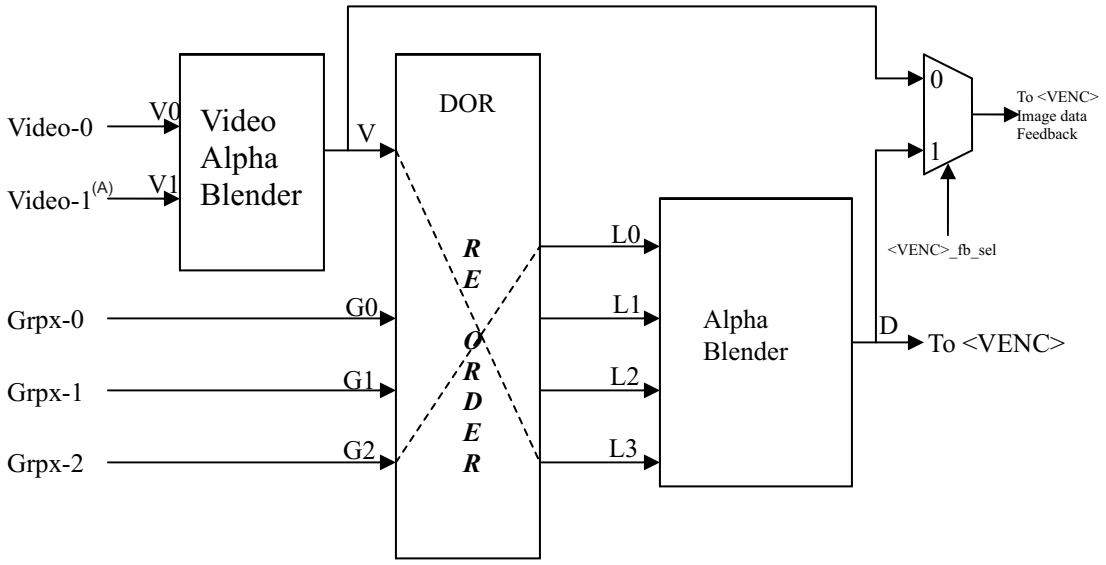
| | | |
|---|---|---|
| Blended Output | =(a)*input1+ (1-a)*input2 | if input1 is top layer and input2 is bottom layer |
| | =(1-b)*input1+ (b)*input2 | if input2 is top layer and input1 is bottom layer |

Copyright © 2011–2016, Texas Instruments Incorporated

Where a and b are alpha values of input1 and input2 windows respectively. The layer order (top or bottom) is decided by priority levels of the two video inputs.

The blending and re-ordering in each blender happens as shown in Figure 12-34

**Figure 12-34. Blending and Reordering**



A Video-1 is tied to 0 for the SD Blender.

#### 12.2.3.4.1 Video Alpha Blender

Two video inputs, Video-0 and Video-1 (sometimes known as MAIN and PIP windows) are first blended together to generate a single video output as shown in the figure above. The priority level, which determines which video to be on top, is decided by COMP→<VENC> settings. <VENC>_vid.bld_ord bitfield.

The alpha values for both the videos are configured in CIG module as described in the sections above.

The alpha value (blended alpha) of the blended video output is calculated as follows.

| | | |
|---|---|---|
| Blended alpha | =alpha_bottom video layer | if alpha_top video layer < 0xFF |
| | =alpha_top video layer | if alpha_top video layer = 0xFF |

Blended alpha (calculated above) is used as alpha value for the Video input to the DOR module described below:

The priority of blended video is configured in COMP→<VENC>Settings.vid_order fit field.

#### 12.2.3.4.2 Display Order Re-shuffling (DOR)

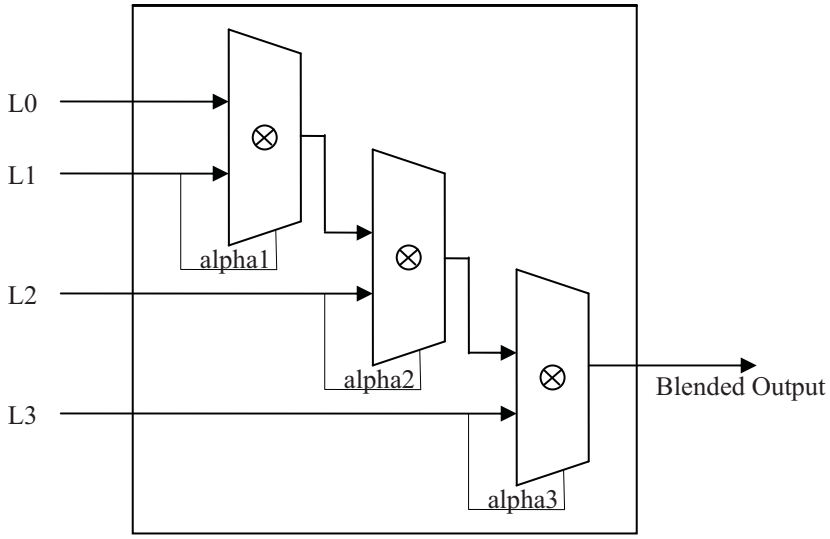
The DOR module is a fully programmable crossbar switch to allow flexible display order change for all input layers. Video layer data is placed in the layer based on its register setting (vid_order bit-field). The graphic data comes with a four-bit priority level configured in the GRPX module. If the global re-order is set (g_reorder=1), the graphics layers are reordered (from top to bottom) based on COMP register settings (g0_order, g1_order, g2_order bit-fields). Otherwise, graphics layers are reordered based on GRPX register (priority) settings as mentioned in the above sections.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.3.4.3 Alpha Blender

The Alpha Blender uses the alpha values of the input layers and blends all of them as per the input order. The block diagram of alpha blender is shown in Figure 12-35.

**Figure 12-35. Alpha Blender Block Diagram**



In Figure 12-35, L0 is the top layer and L3 is the bottom layer. alpha1, alpha2, alpha3 are the blending levels of layers L1, L2, and L3 respectively.

Note: The total number of pixels per frame/field of any source driving the COMP module should be even.

### 12.2.3.5 Feedback Output

Blenders 0 and 2 (associated with DVO1 and DVO2) have a feedback output from blended image data. The feedback image data can be selected from video alpha blending or final alpha blending, and sent to external memory. Since feedback path stalls also stall the entire data pipeline, the amount of the stalls in this path can not be such that they will cause an under-flow to the VENC. Hence, the feedback path needs to be given proper high priority in the system for memory access when the corresponding VENC is also functional. Both the paths (feedback path and Venc data path) are optional.

### 12.2.3.6 Background Color

There is a programmable background color in COMP module. Background color is configured in RGB format with 10-bit in each R, G, and B. Any pixel with an alpha value of 0 will be replaced by this color. If the video bottom layer is disabled, the video top layer will be blended with background color. If both video layers are disabled, the background color is used as output of video alpha blending. For SD channel, only one video stream comes in and it will be blended with the background color.

If the COMP is disabled, or the channel within the COMP driving a particular VENC is disabled, or all inputs to a channel driving particular VENC are disabled, the underflow condition occurs at the VENC. This underflow condition is due to data is not being driven out of the COMP fast enough to keep up with the VENC read rate. Underflow can also happen due to lack of sufficient memory bandwidth or improper VPDMA configuration for any of the input channel. When underflow condition happens, the background color programmed in the COMP module is sent for the underflowed pixels.

### 12.2.4 Constrained Image Generator (CIG)

The Constrained Image Generator (CIG) module is used to generate a resolution constrained version of the high-quality video to meet the CableCard Copy Protection Specification`s requirement on the handling of Constrained Image Trigger (CIT) information.

#### 12.2.4.1 Features

- Generates both constrained and non-constrained output from a single input video source
  - 1/4x vertical/horizontal resolution reduction using 3-tap vertical/horizontal decimation filters
  - 2x vertical/horizontal resolution restoration using 2-tap average interpolation
  - Video Interlacing to match final scan format
- PIP window framer: Positions a PIP window onto a full display screen.
- Individual Chroma keying and blend value application for all outputs
- Can generate interlaced output on both PIP and main window from a progressive input

#### 12.2.4.2 Functional Description

Copy control information (CCI) is passed from the video service provider across the data channel to inform the Set Top Box of the level of copy protection required. Product shall be able to constrain, when required by the CIT CCI bit, the resolution of content that is High Definition to be output through a connection capable of transmitting content in High Definition Analogue Form, to a Constrained Image. The basic requirement of a constrained image is that it contains the visual equivalent of not more than 520,000 Pixels per frame (e.g. an image with resolution of 540 vertical lines by 960 horizontal lines for a 16:9 aspect ratio). A Constrained Image can be output or displayed using video processing techniques such as line doubling or sharpening to improve the perceived quality of the image.

Although not specifically mentioned in these sources, it is also generally accepted that the degraded video will still need to look better than standard DVDs, which generally are encoded at 720x480.

The CIG module takes in a single non-constrained HD video and generates following two outputs:

- The same non-constrained video which may optionally be interlaced
- The same or constrained version of the source video which may optionally be interlaced

The first output is sent to the DVO1 (HDMI)/DVO2 digital output (via COMP/HD_VENC_D) and the second output is sent to the digital HD output HD_DVO2 (via COMP/HD_VENC_A).

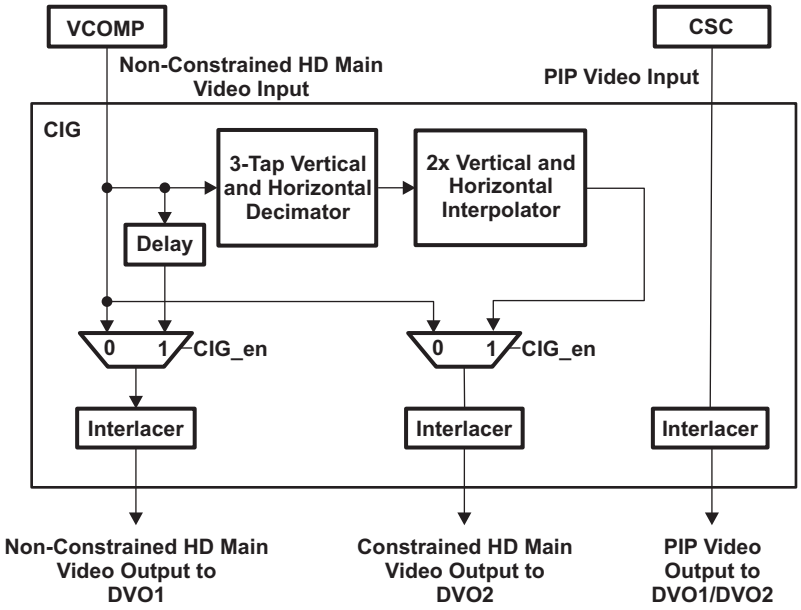
In addition, the CIG module takes in a second video input and positions the video in a full display output screen if the input video is a PIP sized. The PIP video output from CIG module can optionally be interlaced. This path is enabled for following two use cases:

- Displaying un-constrained PIP with constrained/unconstrained main Video (PIP mode)
- Displaying aux video channel output directly on the HD_DVO2 output (Dual-Video Channel mode)

The block diagram of CIG module is shown in Figure 12-36.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-36. CIG Block Diagram**



#### *12.2.4.2.1 Constrained Video Mode*

When the image constraining is required, the CIG requires the incoming unconstrained video to be in progressive scan format in order to apply vertical decimation filter properly. If the output is required to be in interlaced format, the CIG can optionally interlace the outgoing video on both outputs. The PIP video output format (interlaced or progressive) should match the main video output format if it is used as a PIP over the main video.

For the non-constrained video, the output is simply a delayed version (same delay as that of constrained video) of the original video. For the constrained video, ½ decimation filters (3-tap) and 2x interpolation filters (2-tap average) are used to first reduce the overall source resolution by ¼ (½ in vertical ½ in horizontal direction) and to later recover the original display size.

The CIG module performs ½ decimation in both vertical and horizontal directions to achieve the resolution reduction by ¼th (½ in vertical ½ in horizontal direction) on the constrained output and 2x interpolation to restore the total pixel counts. To minimize further filtering of previously optimized image data, a simple 3-taps half-band-filter (¼, ½, ¼) is used for both vertical and horizontal decimation filters while a simple average filter is used for interpolation.

#### *12.2.4.2.2 Interlacer*

The CIG module supports interlacing on each output to generate an interlaced output from the progressive input if needed. The interlacing is performed simply by sending only the current field lines and discarding the others. The current field id is passed on from the upstream module (CSC for HD main video and CSC for PIP video).

#### *12.2.4.2.3 Alpha assignment for Chroma Keying (Transparency) and Blending*

The CIG module receives RGB data and assigns an alpha value to each pixel data based on programmable transparency and blending configurations. When enabled, the blender block in the COMP module uses the configured 8-bit alpha value for both HD main and PIP video windows. Also, it will force a pixel's alpha value to be 0 if the transparency mode is enabled and pixel's color is same as the user-configured transparency color value. A bit masking feature is provided to ignore bottom 1-3 bits when making comparison for transparency color value. The blending alpha value configured in CIG module is carried onto COMP module.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.4.2.4 PIP Video Path

The CIG module includes PIP windowing logic to support composition of an un-constrained PIP window with the constrained video. (Note that if the VCOMP is used to composite two video sources, the Constrain filter is applied to both main and pip video which may not be desired.)

This path can also be used as a non-PIP datapath logic to simply route a second video source to the COMP module.

The PIP path supports independent PIP_DISP_W and PIP_DISP_H to set the output screen size. PIP_W and PIP_H are used to configure the size of the PIP window. When configured as a “fullsize”, then the incoming video must be same as this output size. i.e PIP_DISP_W = PIP_W and PIP_DISP_H = PIP_H. When configured as a non-fullsize, then PIP_X and PIP_Y will position the incoming video onto the output screen. PIP_X, PIP_Y = (0,0) means the PIP window is positioned at top left corner. Note that PIP_X + PIP_W must be less than or equal to PIP_DISP_W. Similiarly, PIP_Y + PIP_H must be less than or equal to PIP_DISP_H.

As mentioned, output interlacing is also supported on this path just in case the incoming video is in progressive scan mode but it needs to be fed into interlaced output. Note that all W/H/X/Y configurations need to be in FRAME mode.

#### 12.2.4.2.5 CIG Bypass Mode

When the image constraining is not required (CIT bit in the encoded bitstream is not set or the application does not require image constraining), the image constraining should be disabled and the input field or frame data should simply be bypassed to the output as shown in Figure 12-36.

To enable the bypass mode:

CIG->CIG_REG0.cig_en = 0

CIG->CIG_REG1 register needs to be configured with correct HD video image size.

Note that the chroma keying and alpha assignment for blending feature as well as output interlacing are still available even in the bypass mode.

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.5 Graphics Module (GRPX)

The graphics module (GRPX) is a region-based graphics processor that composes one or more graphics regions to create a display plane input for the video compositor (COMP) module. For this device, only one region application is supported.

#### 12.2.5.1 Features

- Input:
  - Supports interlace or progressive input format
  - Supports several input formats like RGB 32/24/16-bit, bitmap data (8/4/2/1-bit) with configurable CLUT
  - Supports optional stenciling (1-bit mask) table for each region
- Output:
  - Output data format is ARGB32
  - Provides both progressive and interlaced outputs through different ports simultaneously when input source is progressive
- Multi-region support. Each region can have:
  - Width, height, placement (X and Y) parameters
  - Display priority
  - Scalar enable/disable
  - Scaling ratio attributes
  - Stenciling enable/disable
  - Support for global color and pixel level blending
  - Configurable chroma keying options
  - Bounding box support to reduce artifacts at region boundaries

#### 12.2.5.2 Functional Description

GRPX module reads a RGB or bitmap image data and applies the frame/region attributes to create a graphics plane for the COMP module. The block diagram of GRPX is shown in Figure 12-37.

Two output ports, progressive and interlaced, are available (as shown in Figure 12-37) at the output of GRPX module to output both progressive and interlaced output data to COMP module when the input source is progressive. If the input source is interlaced format, interlaced output is available on both the ports.

One example of the output frame of GRPX module with three regions is shown in Figure 12-38.

As shown in Figure 12-38, a frame is typically composited by rectangular boxes called as regions. Any two regions should not overlap in vertical direction. There is no limitation on number of regions that can be supported in a frame.

The GRPX module is configured in 128-bit words which are logically divided into three groups:

1. Frame configuration attribute – configures display format/sizes (required during initialization)
2. Region configuration attribute – configures all region specific attributes (required on each frame display regions)
3. Scalar configuration attributes (13 words) – configure scaler specific attributes (only required if scaling is enabled)

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-37. GRPX Functional Block Diagram**

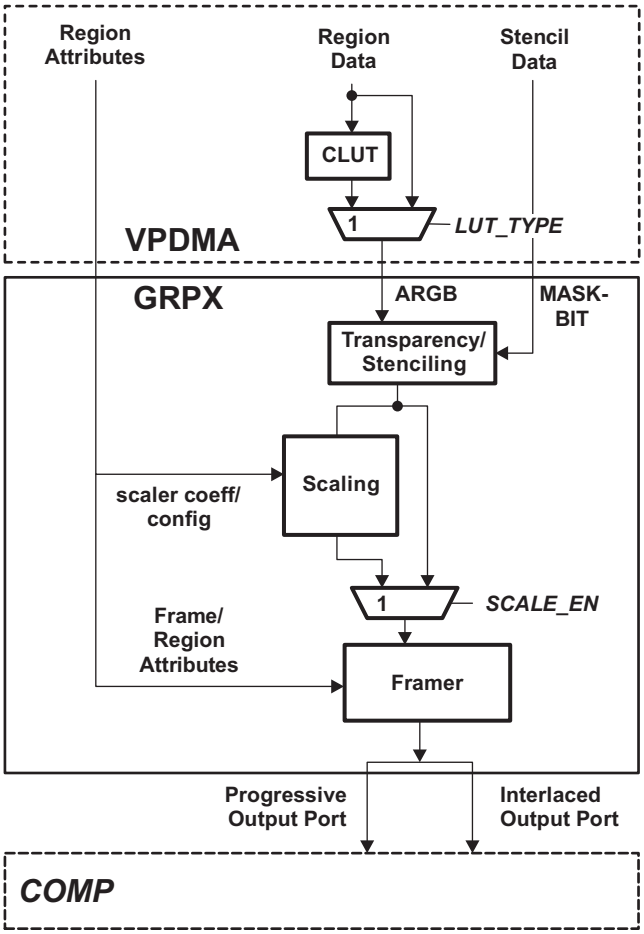


**Figure 12-38. GRPX Output**

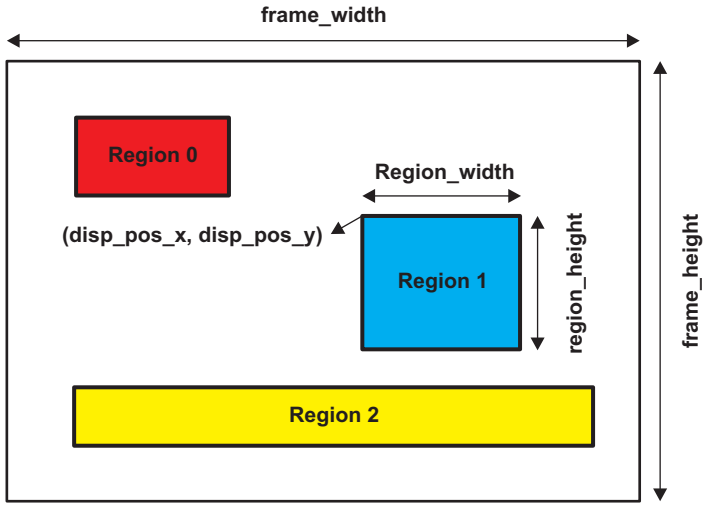


Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.5.2.1 Frame Configuration Attribute

To enable the graphics output plane, a frame configuration attribute has to be written first (typically during the initialization by using a VPDMA configuration descriptor) to set the frame display size (width, height and input data format).

The size of the frame from GRPX module should match the VENC display output size to which the GRPX output is redirected by COMP module. For example, if GRPX0 output is used in DVO2 display output then GRPX0 frame configuration parameters should be same as DVO2 display output frame size.

**Table 12-18. Frame Configuration Attribute (Configuration descriptor payload word 0-3)**

| Attribute | Bits | Description |
|---|---|---|
| Reserved | 31-0 | Reserved |
| frame_height | 47-32 | Frame height (default: 0x0, max 0x7FF)<br>If src_fmt_interlaced is set, frame_height is field_height. (for example, for 480i it should be set to 240).<br>Frame height should be an even number to ensure interlaced outputs are same in height for both fields. |
| frame_width | 63-48 | Frame width (default: 0x0, max 0x780) |
| Reserved | 125-64 | Reserved |
| src_fmt_interlaced | 126 | Format of the source image:<br>0 = Progressive (default)<br>1 = Interlaced |
| Soft reset | 127 | Software reset of GRPX data pipeline:<br>Writing 1 resets GRPX data pipeline<br>Returns 0 on read always |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.5.2.2 Region Configuration Attribute

To display a region, region attribute parameters are set up using the client specific attributes field in the VPDMA data inbound descriptor. Below table shows the details of these parameters.

**Table 12-19. Region Configuration Attribute (Inbound data descriptor word 4-7)**

| Attribute | Bits | Description |
|---|---|---|
| Region_height | 15-0 | Height of the region (number of input region data lines) (max: 0x7FF) |
| Region_width | 31-16 | Width of the region (max: 0x780) |
| disp_pos_y | 47-32 | Position of region (Y origin) (default: 0x00) |
| disp_pos_x | 63-48 | Position of region (X origin) (default: 0x00) |
| Disp_prior | 67-64 | Region display priority |
| Reserved | 70-68 | Reserved |
| Disp_first_region | 71 | 1: First region of the frame |
| Disp_last_region | 72 | 1: First region of the frame |
| scaler_enable | 73 | Scaler enable |
| Reserved | 74 | Reserved |
| stenciling_en | 75 | Stenciling enable for the region |
| Reserved | 78-76 | Reserved |
| bound_box_en | 79 | 0: Bounding box disable<br>1: Bounding box enable |
| bb_alpha | 87-80 | Replace bounding box alpha value when bounding box is enabled. Default value is 0x80. |
| Disp_blend_cfg | 97-88 | Blending configuration<br>95-88: Blending (alpha) value<br>97-96: Blending Type:<br>0 = No blending<br>1 = Region global blending<br>2 = Color (palette) blending<br>3 = Pixel (embedded alpha) blending |
| disp_trans_cfg | 127-101 | Transparency (color keying enable) configuration bits<br>103-102: Transparency LSB bit masking<br>00 = No masking<br>01 = Mask[0] during pixel data comparison to TRANS_COLOR<br>10 = Mask[1:0]<br>11 = Mask[2:0]<br>Example: If TR_LSB_MASK is set to 2'b11, top 5 bits of R/G/B component data are compared to the corresponding 5 bits of TRANS_COLOR R/G/B color.<br>101: Transparency enable<br>0 = Disable<br>1 = Enable transparency for video layer<br>127-104: Transparency color (RGB24) |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.5.2.2.1 Parameter Configuration

Region_height, Region_width, disp_pos_y, disp_pos_x are configured as shown in Figure 12-38.

##### 12.2.5.2.2.1.1 Disp_prior

Each region can be specified to have an inter-graphics-pipeline display priority level which may be used to switch the order between two overlapping regions from two GRPX pipelines. The GRPX simply passes these values along with each pixel data to the COMP module and the COMP uses it to reorder between two GRPX data. This should be used only when both GRPX outputs are tied to the same display output format and rate. The blended output is calculated differently (in the COMP module) for each region based on each its priority level.

##### 12.2.5.2.2.1.2 Disp_first_region

This bit needs to be set to `1` if the region is the first in vertical direction from top of the frame. Region0 in Figure 12-38 is the first region in the frame.

##### 12.2.5.2.2.1.3 Disp_last_region

This bit needs to be set to `1` if the region is the last in vertical direction from top of the frame. Region2 in Figure 12-38 is the last region in the frame.

##### 12.2.5.2.2.1.4 Scaler

The scaler used in GRPX module is consisted of a 5-tap/8-phase horizontal and a 4-tap/8-phase vertical polyphase filters. It supports 0.25x – 4x scaling with a step size of 0.01. Individual regions can have a different set of scaling parameters (coefficients, scale factor, and offset).

The input source format should be progressive if scaling of region is required.

If a region scaling is enabled, the first pixel location (origin) of the region serves as an anchor point for the region display. Since the width and height of the region change after the scaling, application should take care of the correct scaler attributes such that output of the scaler does not go out of the frame display.

Since the scaler stores one or more input lines before outputting any output lines, the following constraints are imposed when multiple regions are displayed on the screen and scaling is enable:

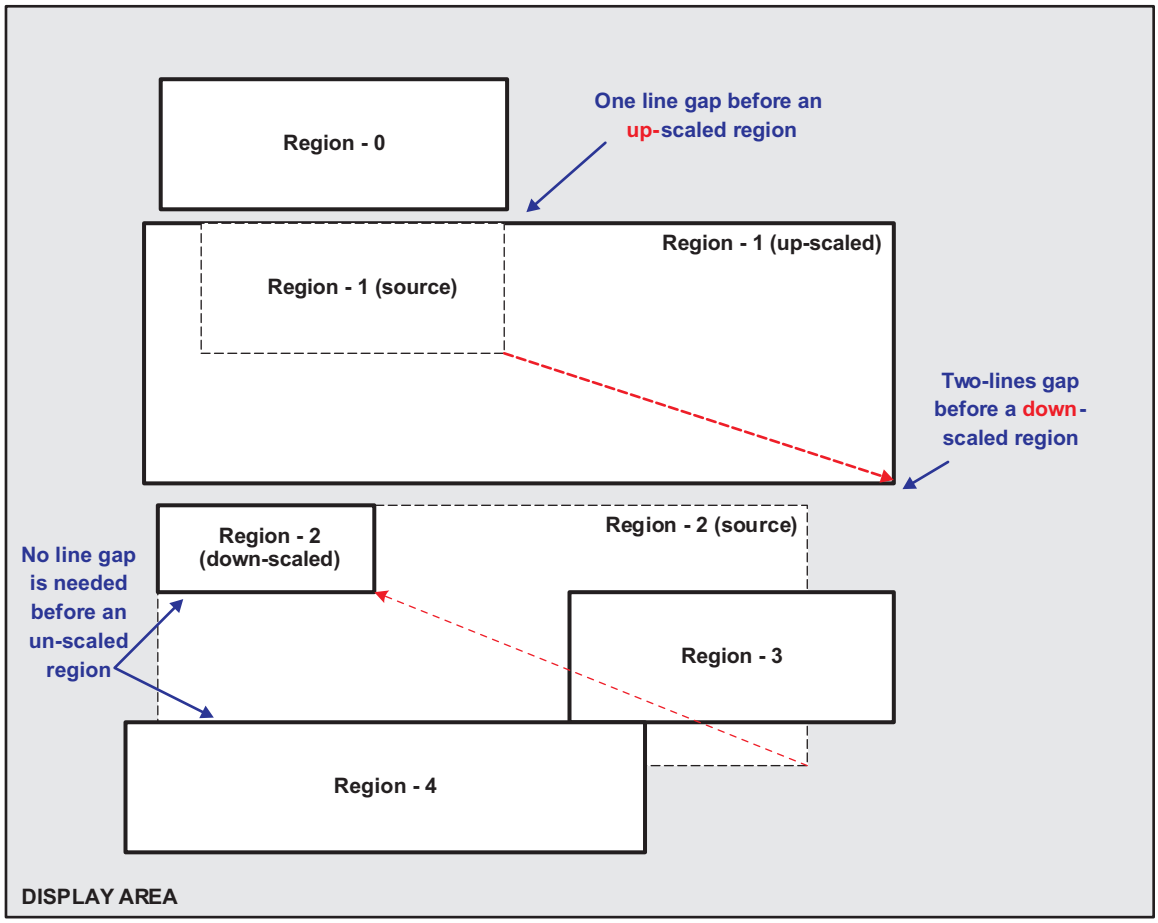
1. One display line gap is required before a vertically up-scaled region
2. Two display line gap is required before a vertically down-scaled region

These constraints do not apply to the first region on the screen. This is illustrated in Figure 12-39.

The minimum size of vertical region is one line, and no multiple regions on a same line is allowed (nor is possible) per “region” graphics definition.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-39. Region Display Position and Gap Requirement Illustration**



Scaler configuration attributes (see Section 12.2.5.2.3) are to be filled for a given scaling ratio when scaler is enabled.

#### *12.2.5.2.2.1.4.1 Anti-flicker Filter Implementation*

When a region is scaled up or down, the poly-phase vertical filter will inherently provide anti-flicker filtering. Even when a region is not needed to be scaled, the scaler can still be enabled to perform low-pass filtering along the vertical direction with scaling ratio=1. Similarly, when the target display of the GRPX is in an interlaced scan mode, the scaler can be used to perform anti-flicker filtering.

#### *12.2.5.2.2.1.5 Stenciling*

The VPDMA sends 1-bit for each pixel (from the region stenciling data buffer) of a region that has “stenciling” feature enabled. This bit is used to force the alpha value of the pixel to ZERO in order to “mask”-off the pixel (i.e., make the pixel transparent). This feature can be used by application to assign an arbitrary mask shape to a rectangular region graphics. Enabling of this feature requires “stenciling_en” bit-field to be set to `1`.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.5.2.2.1.6 Boundary Box Blending

Even with anti-flickering, the flicker around the top and bottom edges of a region may still exists when the anti-flickered region is composed onto the output display in the COMP module. The GRPX supports overwriting alpha values of pixels that make up a 1-pixel wide boundary box of a region with a semi-transparent (alpha) value (default – 0x80) so that the flickering around the edges can be minimized. This feature is enabled when bound_box_en is set to `1`. The alpha value for the boundary box is programmable in the bit-field bb_alpha.

### 12.2.5.2.3 Blending/Transparency Handling

The GRPX supports four blending modes (no-blending, global, pixel/CLUT, pixel) and a transparency mode for each region to determine how alpha value for each pixel is set. The configuration for blending and transparency are in the region attributes and are shown again in Table 12-20.

**Table 12-20. Blending and Transparency Configuration**

| Attribute | Bits | Description |
|---|---|---|
| Disp_blend_cfg | [97:88] | Blending configuration<br>[95:88]: Blending (alpha) value<br>[97:96]: Blending type<br>0 = No Blending<br>1 = Region global blending<br>2 = Color (palette) blending<br>3 = Pixel (embedded alpha) blending |
| disp_trans_cfg | [127:101] | Transparency (color keying enable) configuration bits<br>[103:102]: Transparency LSB bit masking<br>00 = No masking<br>01 = Mask[0] during pixel data comparison to TRANS_COLOR<br>10 = Mask[1:0]<br>11 = Mask[2:0]<br>Example: If TR_LSB_MASK is set to 2'b11, top 5 bits of R/G/B component data are compared to the corresponding 5 bits of TRANS_COLOR R/G/B color.<br>[101]: Transparency enable<br>0 = Disable<br>1 = Enable transparency for video layer<br>[127:104]: Transparency color (RGB24) |

When no-blending is selected, the GRPX forces each alpha to FFh to make the region total opaque. In region global-blending, a programmed alpha value in bits [95:88] (also called as “global blend” value) is assigned to each pixel similar to the no-blending case.

For color or pixel blending, the VPDMA sets the alpha value with CLUT mapping or with embedded Alpha value (argb format source) respectively. In these two modes, the GRPX simply passes the alpha value from the VPDMA to COMP module. Pixel level blending is performed in the COMP module for both color and pixel blending modes.

When transparency is enabled, each pixel color is compared against the transparency color to determine whether the pixel is to be transparent or not. If the colors match, the alpha value is forced to 00h. Otherwise, the alpha value remains as programmed.

The blending level supported is from 0 (transparent) to 255 (totally opaque).

Because the alpha value is also scaled in the same way the color components (RGB) are scaled, all enabled blending/transparency related tasks are performed in the following order:

1. Application of No-blending (force alpha = FFh) or Global-blending (force alpha=programmed global blend level)
2. Transparency check to force alpha = 0 for transparent pixels
3. Stenciling application to force masked pixels (stencil data = 1) with alpha = 0
4. Scaling of Alpha (if scaling enabled)
5. Box Blending (force alpha = programmed box_blend_level)

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.5.2.4 Region Scaler Configuration Attributes

**Table 12-21. Region Scaler Configuration Attributes 1**

| Attribute | Bits | Description |
|---|---|---|
| coefh0_p0 | [9:0] | Coefficient for Horizontal TAP 0 Phase 0 |
| Reserved | [15:10] | reserved |
| coefh0_p1 | [25:16] | Coefficient for Horizontal TAP 0 Phase 1 |
| Reserved | [31:26] | reserved |
| coefh0_p2 | [41:32] | Coefficient for Horizontal TAP 0 Phase 2 |
| Reserved | [47:42] | reserved |
| coefh0_p3 | [57:48] | Coefficient for Horizontal TAP 0 Phase 3 |
| Reserved | [63:58] | reserved |
| coefh0_p4 | [73:64] | Coefficient for Horizontal TAP 0 Phase 4 |
| Reserved | [79:74] | reserved |
| coefh0_p5 | [89:80] | Coefficient for Horizontal TAP 0 Phase 5 |
| Reserved | [95:90] | reserved |
| coefh0_p6 | [105:96] | Coefficient for Horizontal TAP 0 Phase 6 |
| Reserved | [111:106] | reserved |
| coefh0_p7 | [121:112] | Coefficient for Horizontal TAP 0 Phase 7 |
| Reserved | [127:122] | reserved |

**Table 12-22. Region Scaler Attributes 2**

| Attribute | Bits | Description |
|---|---|---|
| coefh1_p0 | [9:0] | Coefficient for Horizontal TAP 1 Phase 0 |
| Reserved | [15:10] | reserved |
| coefh1_p1 | [25:16] | Coefficient for Horizontal TAP 1 Phase 1 |
| Reserved | [31:26] | reserved |
| coefh1_p2 | [41:32] | Coefficient for Horizontal TAP 1 Phase 2 |
| Reserved | [47:42] | reserved |
| coefh1_p3 | [57:48] | Coefficient for Horizontal TAP 1 Phase 3 |
| Reserved | [63:58] | reserved |
| coefh1_p4 | [73:64] | Coefficient for Horizontal TAP 1 Phase 4 |
| Reserved | [79:74] | reserved |
| coefh1_p5 | [89:80] | Coefficient for Horizontal TAP 1 Phase 5 |
| Reserved | [95:90] | reserved |

#### *12.2.5.2.5 VPDMA Configuration*

VPDMA needs to be setup to configure the GRPX module and input data transfer. The initialization sequence for each frame (assuming frame/region attributes change for every frame) should be as follows:

- Frame Attribute Configuration Descriptor
- Region Scalar Co-efficient/Attribute Configuration Descriptor (if required)
- Region Look-Up table Configuration Descriptor (if required)
- Region Stencil Data Descriptor (if required)
- Region Data Descriptor (different from regular data descriptor and it configures region attributes also)

Some of the previous configuration descriptors can be combined into single configuration descriptor (using class 0 type).

If the configuration in any of the previous configuration descriptors is not changed from region to region or frame to frame, it is not required to set up those configuration descriptors each time in the VPDMA LIST. The configuration of descriptors is explained and illustrated in the *VPDMA* chapter.

## 12.2.6 Standard-Definition Video Encoder (SD_VENC)

### 12.2.6.1 Overview

The VENC (video encoder) converts digital component YCbCr/RGB video signals to conform to the various TV standard analog video. CVBS and S-Video outputs are supported.

#### 12.2.6.1.1 Standards

- SMPTE 170M
  - Composite Analog Video Signal – NTSC for Studio Application
- ITU-R BT.470
  - Conventional television systems
- ITU-R BT.601
  - Studio encoding parameters of digital television for standard 4:3 and wide-screen 16:9 aspect ratios
- ITU-R BT.1119
  - Wide-screen signaling for broadcasting (Signaling for wide-screen and other enhanced television parameters)
- EIAJ CPR-1204
  - Transfer Method of Video ID information using Vertical Blanking Interval (525 line system)
- ETSI EN 300 294
  - Television systems; 625-line television Wide Screen Signaling (WSS)
- EIA/CEA-608-E
  - Line 21 Data Services

#### 12.2.6.1.2 Features

- SDTV Feature
  - Master Clock Input - 27 MHz
  - Support Following TV standard
    - NTSC-M
    - NTSC-J
    - NTSC-4.43
    - PAL-B/D/G/H/K/I
    - PAL-M
    - PAL-N
    - PAL-Nc
    - PAL-60
    - SECAM-B/D/G/H/K/L
  - Composite (CVBS)
  - S-Video (Y/C)
  - Macrovision (Rev7.1) Anticopy Protection
  - Non-Interlace
  - CGMS/WSS
  - Line 21 Closed Caption Data Encoding
  - Programmable Sync Amplitude
  - Programmable Color-burst Amplitude
  - Programmable Color Space Converter
  - Programmable Sub-carrier Frequency and SCH phase

Copyright © 2011–2016, Texas Instruments Incorporated

  - Programmable Luma Delay
- 24-bit Input Interface (either RGB 4:4:4 or YCbCr 4:4:4)
- Two channel 12-bit 2x Over-Sampled DAC Output
- Programmable Sync Output
- Master/Slave Operation
- Internal Color Bar Generation
- Support VBI I/F for the generic VBI data insertion

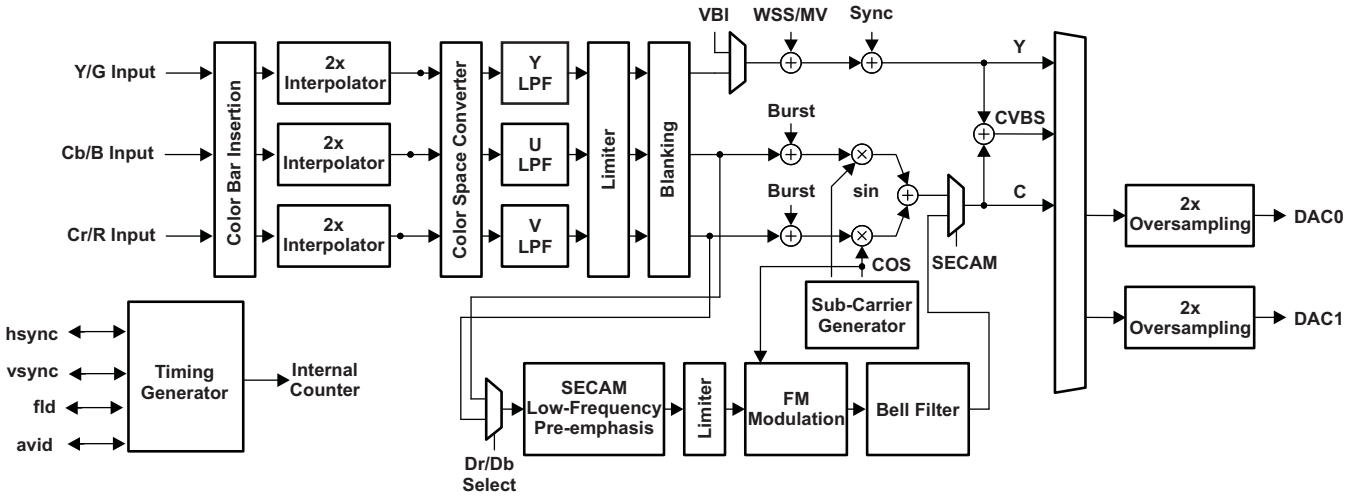
#### 12.2.6.1.3 Features Not Supported

- Square pixel sampling
- Input with embedded sync conforming to ITU-R BT.656
- Analog component video output

### 12.2.6.2 Functional Description

#### 12.2.6.2.1 Block Diagram

**Figure 12-40. VENC Block Diagram**



#### 12.2.6.2.2 Operating Modes

##### 12.2.6.2.2.1 Synchronous Mode

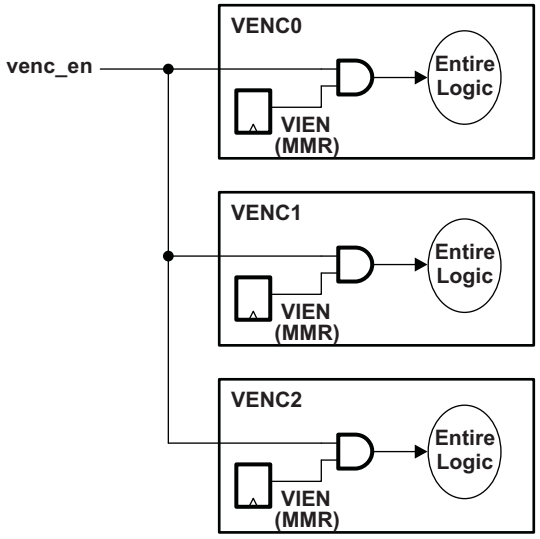
The VENC supports two synchronous modes; master and slave. Each mode can be used in above two video modes.

- Master mode: This mode operates in synchronization with horizontal / vertical sync signals generated in built-in sync signal generator..
- Slave mode: This mode operates in synchronization with sync signals input from outside. Setting the SLV register to 1 enables the slave mode. The external sync inputs are active high by default and their polarity can be independently inverted by registers.

The VENC starts the operation when the external input venc_en is HIGH and the VIEN register is set to 1. The venc_en signal is used for synchronizing multiple video encoders for the multichannel video systems. An external timing manager should take care of the generation of the venc_en signal. When only a single video encoder is used or no synchronization is required among the multiple video encoders, the venc_en can be tied to HIGH. Figure 12-41 provides an example of this synchronization operation.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-41. Example of Multiple VENC Synchronization**

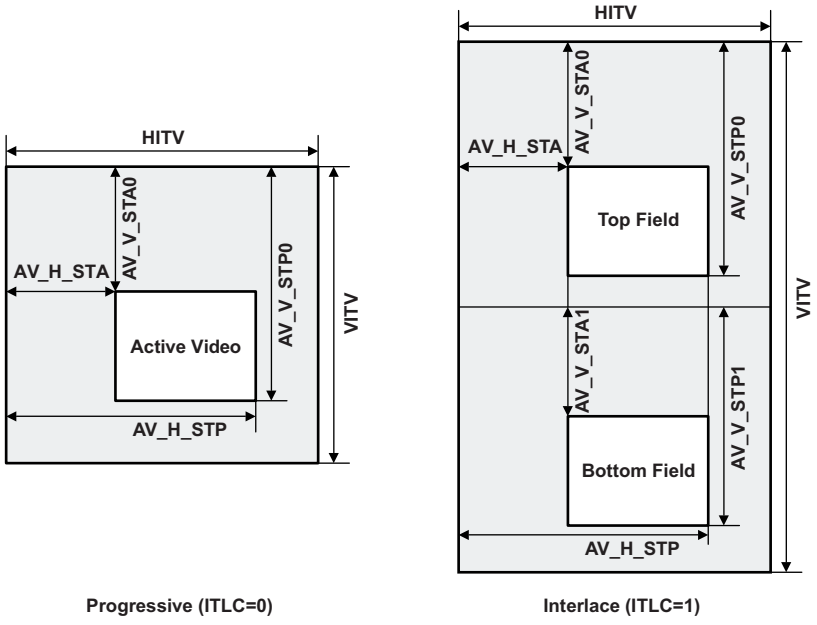


#### 12.2.6.2.3 Timing

##### 12.2.6.2.3.1 Video Timing

The video timing is programmable as shown in Figure 12-42. The HITV and VITV registers set the horizontal and vertical frame sizes. When the target video is interlaced, set ITLC=1. Line per field is VITV/2. Unequal line per field is optionally available. When UEL=1, line per field alternately toggles between (VITV-1)/2 and (VITV+1)/2. The active video position is set by the AV registers.

**Figure 12-42. Video Timing**



Copyright © 2011–2016, Texas Instruments Incorporated

For the analog video output, one of the following TV formats in Table 12-32 also needs to be specified by the FMT register accordingly. The FMT setting specifies the format-dependent timing parameters such as sync rise/fall build-up time, active video rise/fall time, vertical sync and equalizing pulse position, WSS/CC waveform position and so on.

**Table 12-32. TV Formats**

| FMT | Video Format | Type |
|---|---|---|
| 0 | 525i | SDTV |
| 1 | 625i | |

For SDTV (525i/625i), composite video (CVBS) and S-video are available. The output combination from two DACs is described in Section 12.2.6.2.14.2.

#### *12.2.6.2.3.2 Input I/F Timing*

The input I/F consist of venc_dtv_hs (horizontal sync), venc_dtv_vs (vertical sync), venc_dtv_fid (field ID) and venc_dtv_avid (active video). The timing of each signal is programmable. The timing reference is the internal base counter. The internal base counter starts when VIEN register is set to 1 and the venc_en signal is HIGH. The phase between clk1x and the internal base counter is maintained so that the horizontal counter begins increment at phase1x = 1 as shown in Figure 12-43.

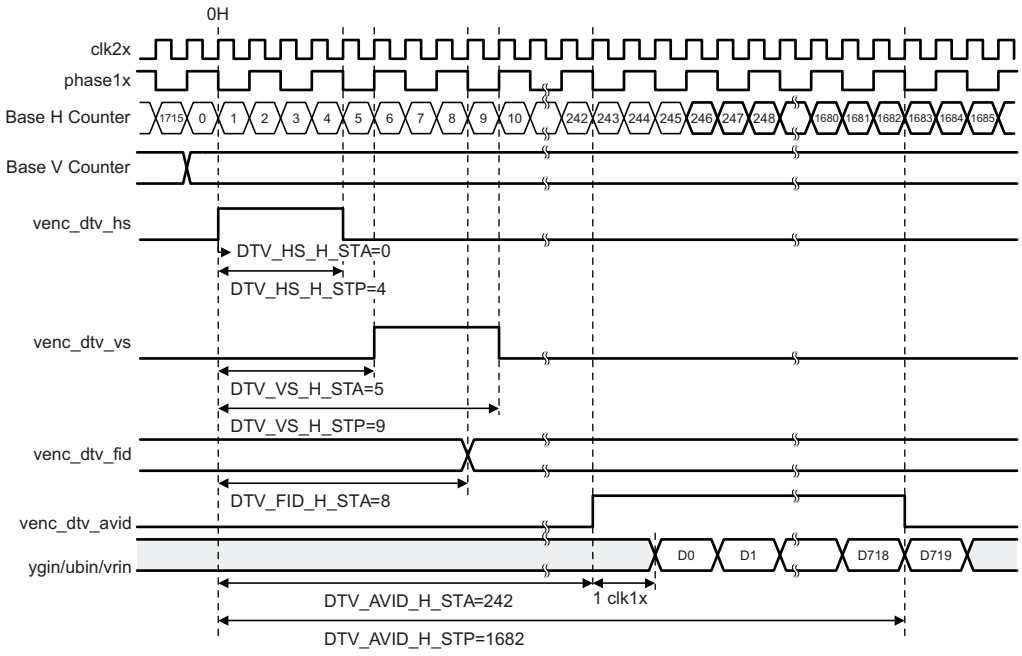
The horizontal timing of each signal is configured in unit of clk2x. The AVID timing should be configured considering the input latency of one cycle of clk1x.

Vertical timing resolution is 1/2H. Independent AVID timings are available for each field for an interlaced format. VS and FID have a unique configuration for both fields

For progressive or non-interlaced formats, the internal base FID is fixed to low. However, it is possible to force toggling venc_dtv_fid at the specified line by setting DTV_FID_F_STA0 register to 1.

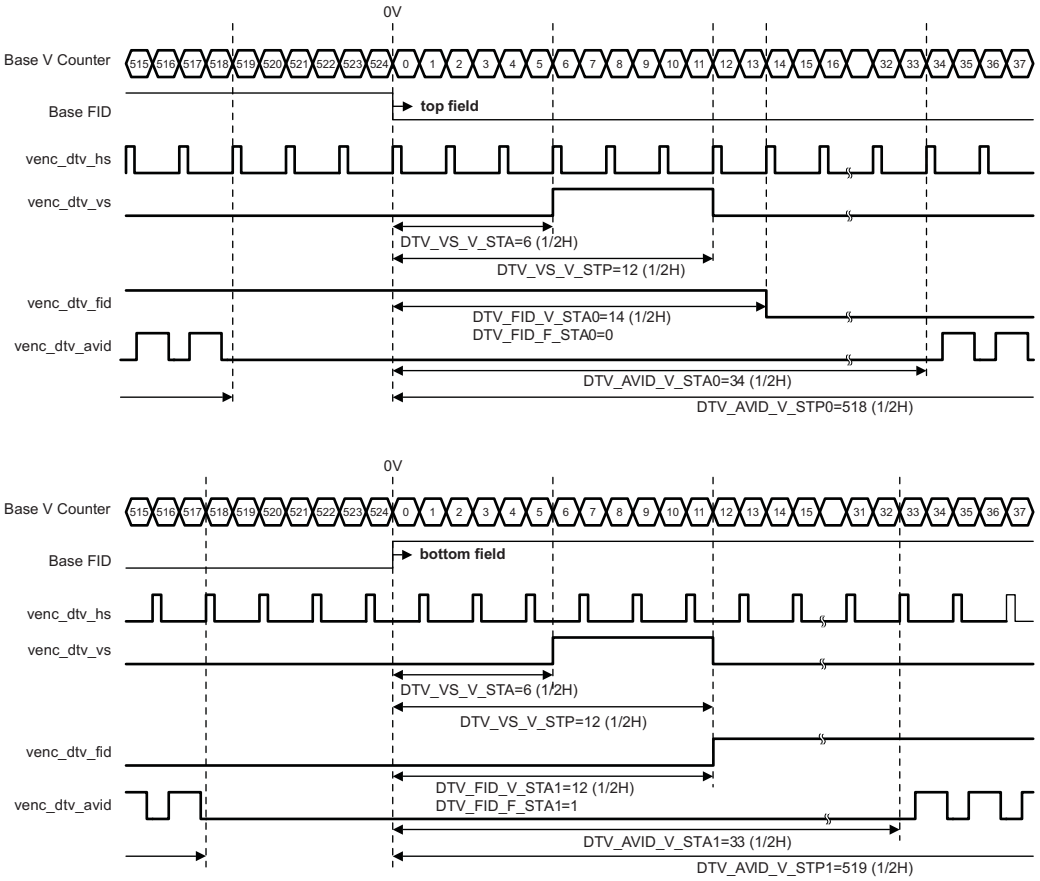
Figure 12-43 and Figure 12-44 show the input I/F timing chart with example settings.

**Figure 12-43. Input I/F Horizontal Timing**



Copyright © 2011–2016, Texas Instruments Incorporated

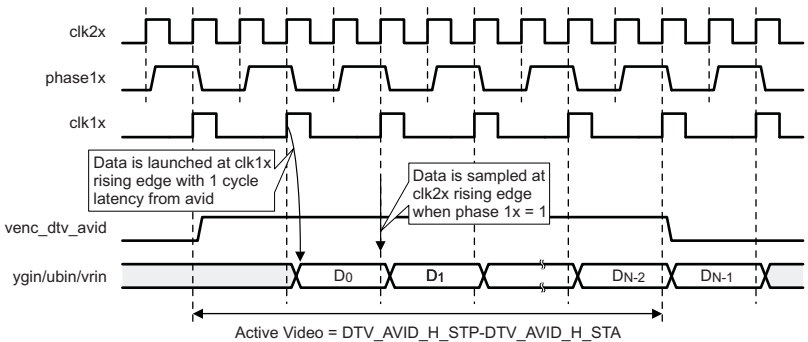
**Figure 12-44. Input I/F Vertical Timing**



The VENC generates a venc_dtv_avid signal for data request purpose for the upstream module. Input data is expected to arrive at the VENC one clk1x cycle (two clk2x cycles) after an avid assertion. The supported input data format is RGB 4:4:4 or YCbCr 4:4:4. Input data is sampled at clk2x rising edge at phase1x=1. Figure 12-45 shows the timing chart of the input interface.

It is possible to sample the input data with an inversion. When the DIIV register is 1, the input data is inverted before sampling.

**Figure 12-45. Input Data Timing**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.3.3 Interrupt Timing

An interrupt pulse is output from the venc_irq port with a single clk2x cycle pulse width every field. Its horizontal and vertical assert position is configured by IRQ_H_STA and IRQ_V_STA registers, respectively.

**Figure 12-46. Interrupt Horizontal Timing**

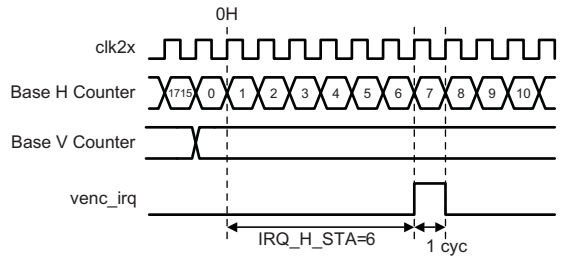


**Figure 12-47. Interrupt Vertical Timing**

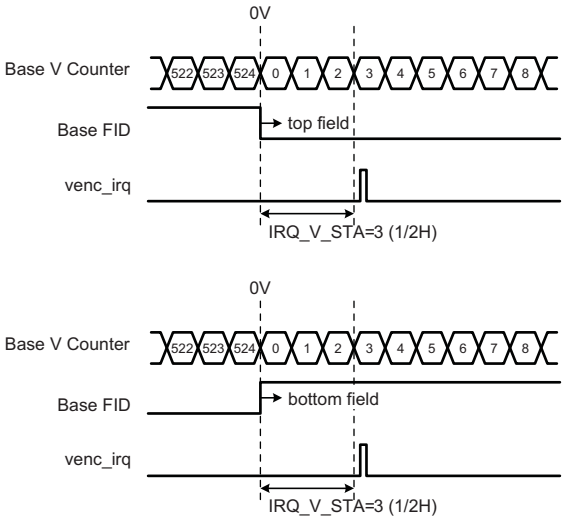

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.3.4 TV Detection Pulse Timing

The VENC supports a TVDET gate pulse generation to connect with the DAC which has the TV detect feature. Its horizontal timing (see Figure 12-48) is configured by TVDETGP_H_STAand TVDETGP_H_STP registers, and vertical timing (see Figure 12-49) is configured by TVDETGP_V_STA and TVDETGP_V_STP registers.

**Figure 12-48. TVDETGP Horizontal Timing**

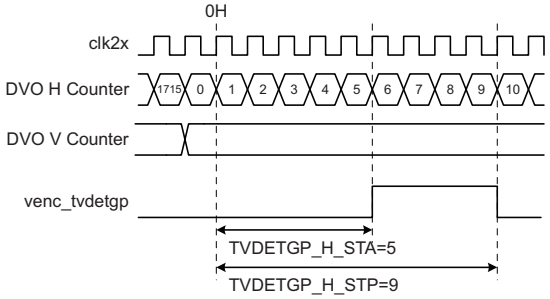

**Figure 12-49. TVDETGP Vertical Timing**

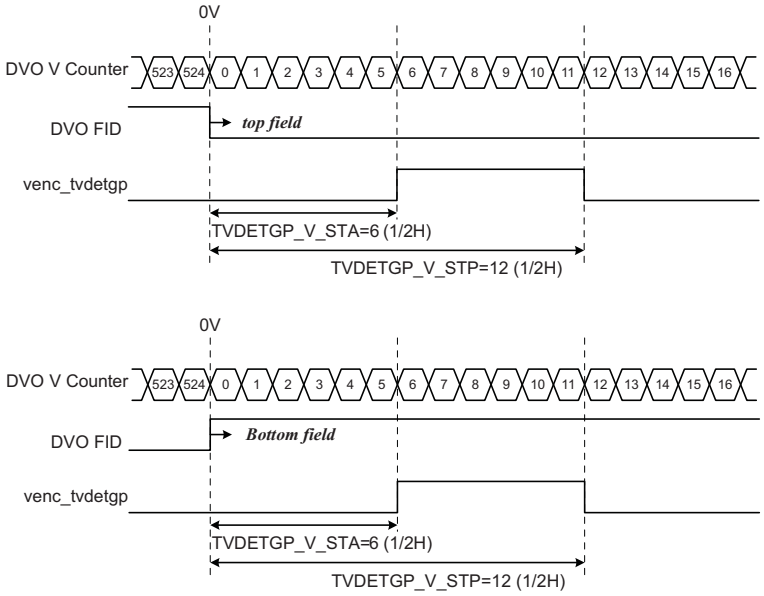

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.3.5 DAC Video Output Timing

##### 12.2.6.2.3.5.1 SDTV Timing

Figure 12-50 shows horizontal timing characteristics of the SDTV DAC video output. The number of pixels per line is determined by the TV scan format register FMT. The horizontal sync pulse width is also fixed depending on the FMT setting. The color burst start/end positions are specified by BST_H_STA and BST_H_STP registers, and the active video start/end positions are specified by AV_H_STA and AV_H_STP registers. The timing reference of these registers is the internal TV counter.

The AV_H registers specify the window position for the active video. There are similar registers to specify the AVID timing which controls the input video timing. They are independent.

Serration and equalization pulses are inserted on the appropriate lines defined in the standard. Color burst is automatically inserted on the appropriate lines defined in the standard. Figure 12-51 and Figure 12-52 show the vertical timing characteristics of NTSC and PAL. The vertical sync duration is selectable from either 3H or 2.5H by the SVSW register. Typically, 3H VSYNC is used for 525i and 2.5H VSYNC is used for 625i, but this is not always the case. For example, PAL-N has 3H VSYNC even though it is a 625i system.

The color burst is not indicated in these figures but its sequence is managed by hardware. The PAL meander sequence is supported for PAL mode.

**Figure 12-50. SDTV Horizontal Timing**

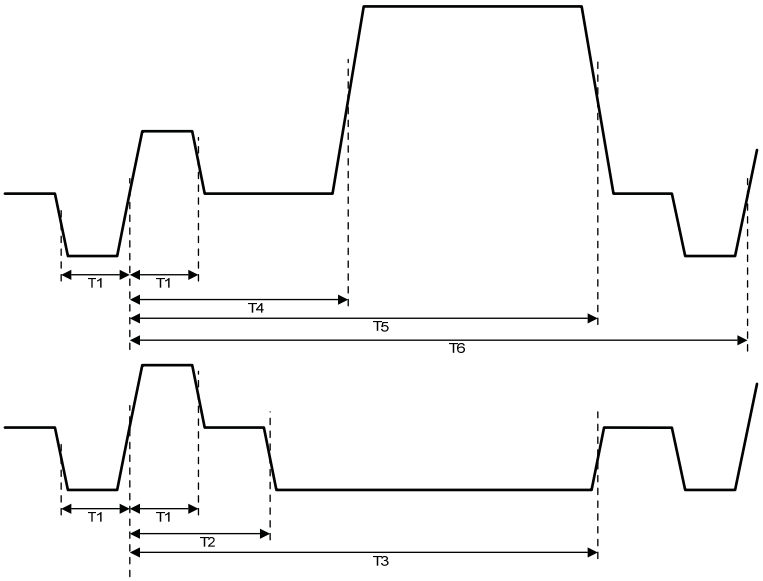

**Table 12-33. SDTV Horizontal Timing Parameter**

| Parameter | Item | 525I (FMT = 0) | 625I (FMT = 1) | Unit |
|---|---|---|---|---|
| T1 | Horizontal Sync Pulse Width | 127 | | clk2x |
| T2 | H Ref to Burst Start | BST_H_STA | | |
| T3 | H Ref to Burst End | BST_H_STP | | |
| T4 | H ref to H Blanking End | AV_H_STA | | |
| T5 | H ref to H Blanking Start | AV_H_STP | | |
| T6 | 1H | HITV | | |
| T7 | Equalizing Pulse Width | 62 | 63 | |
| T8 | Serration Pulse Width | 127 | | |
| T9 | 1/2H | HITV/2 | | |

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-51. 525i Vertical Timing**

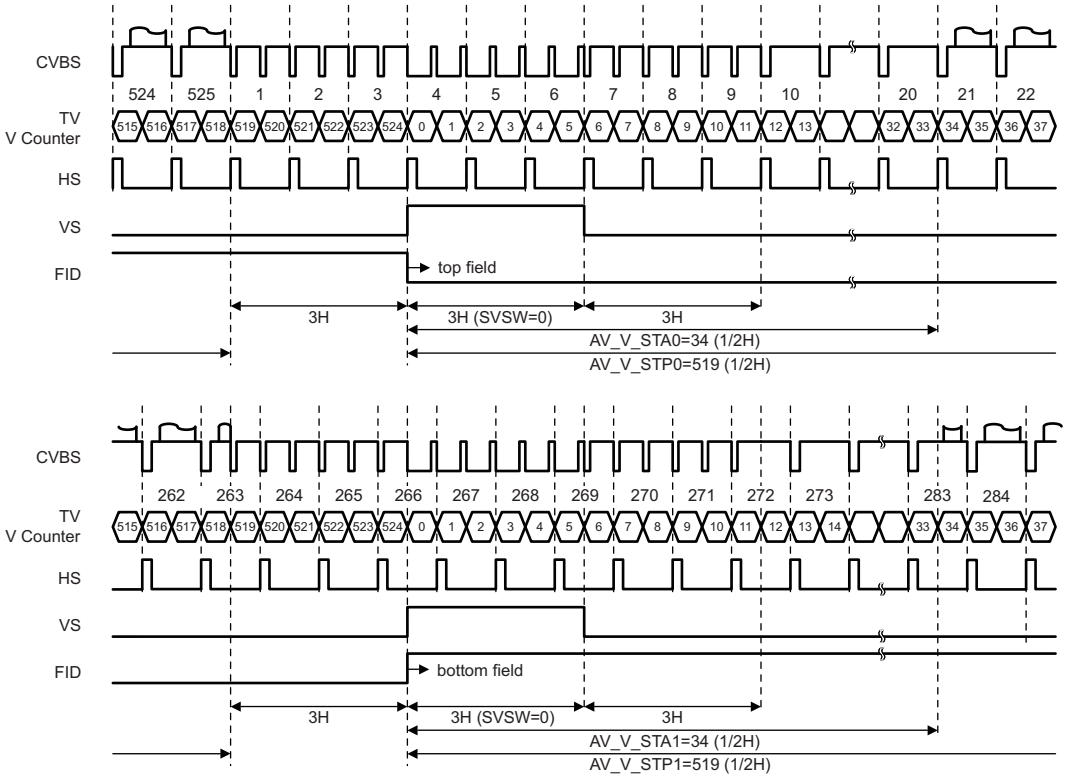

**Figure 12-52. 625i Vertical Timing**

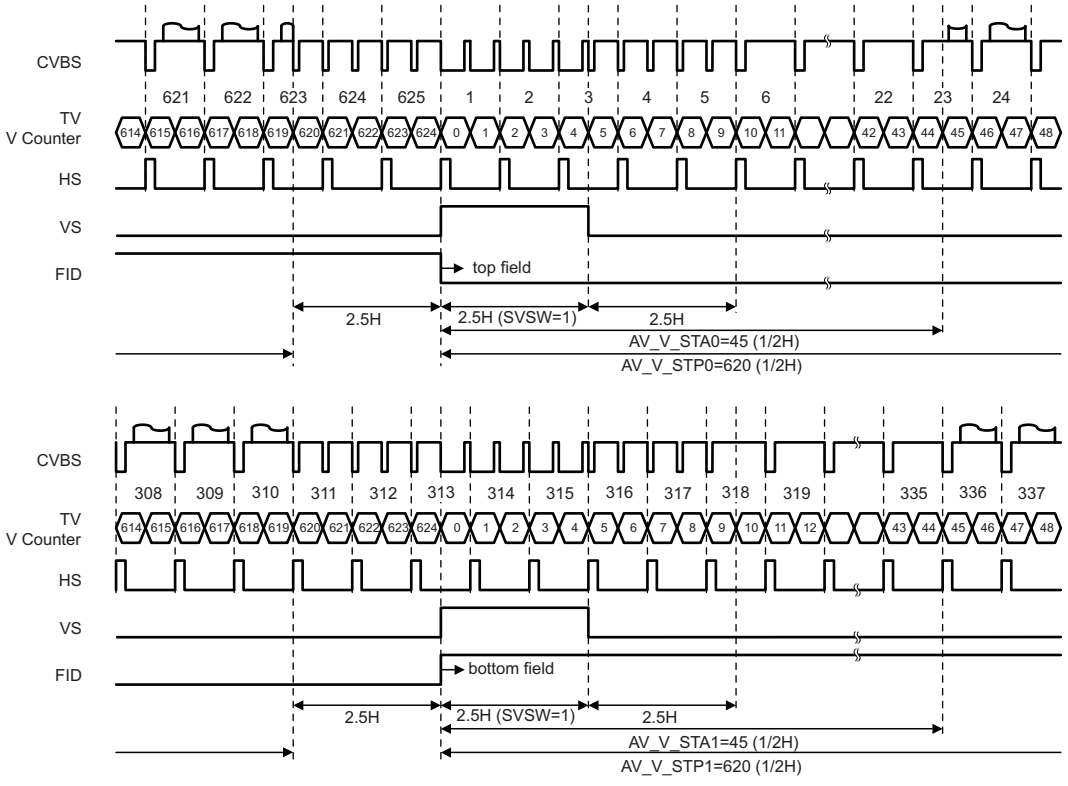

Copyright © 2011–2016, Texas Instruments Incorporated

Figure 12-53 and Figure 12-54 show the DAC video output pipeline delay against the internal base counter. The pipeline delay latency is determined by the input pixel rate. The input pixel rate is specified by the PXLR register. The SDTV input pixel rate is typically 13.5 MHz, which is half of clk2x (PXLR = 0). However, some unusual systems may apply the 27 MHz input pixel rate. It is possible to set PXLR = 1.

**Figure 12-53. SDTV DAC Video Output Pipeline Delay (PXLR = 0)**

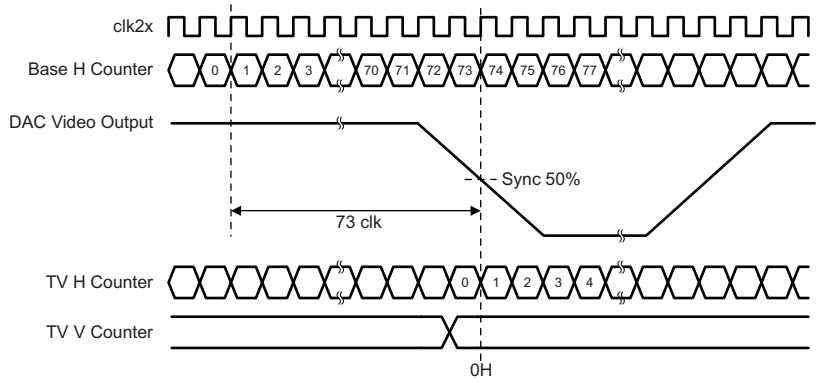

**Figure 12-54. SDTV DAC Video Output Pipeline Delay (PXLR = 1)**

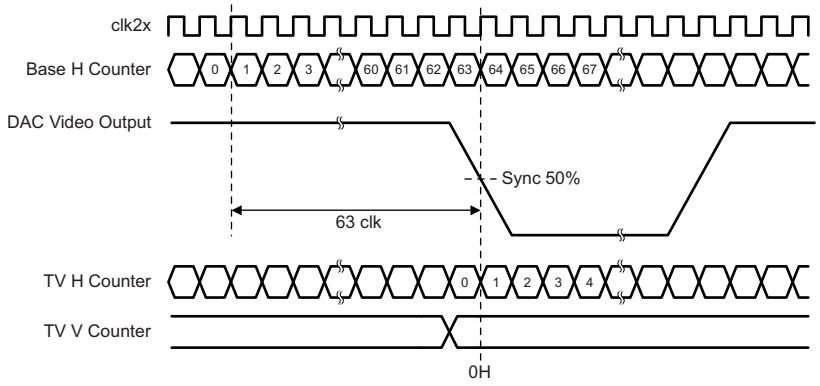

Copyright © 2011–2016, Texas Instruments Incorporated

Figure 12-55 and Figure 12-56 show the non-interlaced operation for 262p and 312p. Table 12-34 shows the register setting for the non-interlaced format. Although it is progressive scan, the ITLC register has to be 1 because the internal hardware still relies on the interlaced timing control. Note that the FID is forced to low for non-interlaced mode.

**Figure 12-55. 262p (Non-Interlaced NTSC) Vertical Timing**

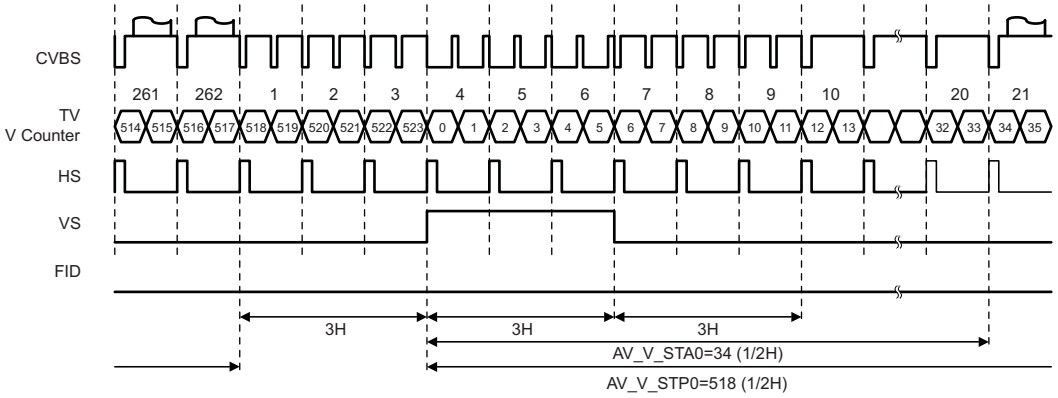

**Figure 12-56. 312p (Non-Interlaced PAL) Vertical Timing**

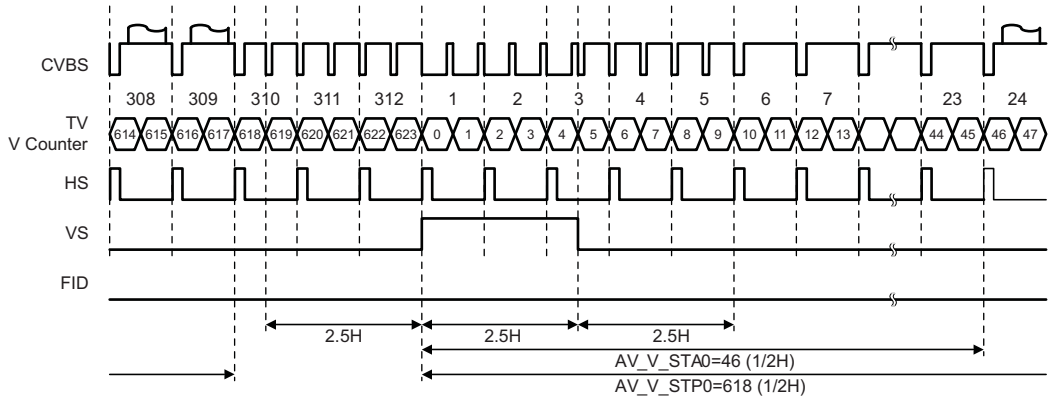

**Table 12-34. Non-Interlaced Format**

| FMT | HITV | VITV | ITLC | UEL | Derived Format |
|---|---|---|---|---|---|
| 0 | 1716 | 525 | 1 | 0 | 525i |
| | | 524 | | | 262H Non-Interlace |
| | | 526 | | | 263H Non-Interlace |
| | | 525 | | 1 | 262H, 263H Non-Interlace |
| 1 | 1728 | 625 | 1 | 0 | 625i |
| | | 624 | | | 312H Non-Interlace |
| | | 626 | | | 313H Non-Interlace |
| | | 625 | | 1 | 312H, 313H Non-Interlace |

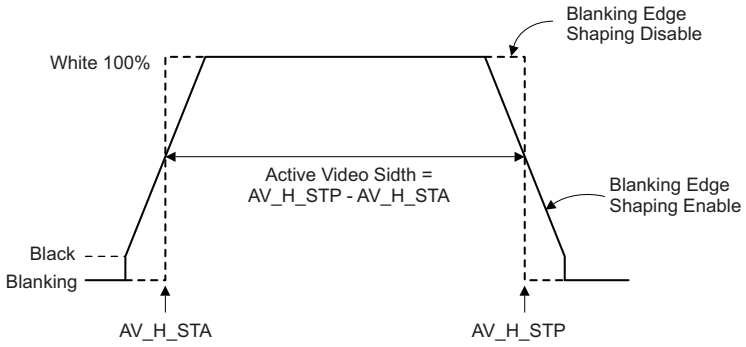
#### 12.2.6.2.3.6 Horizontal Blanking Edge Shaping

Horizontal video blanking edge is shaped so that the output video has the proper blanking transition.

This feature is enabled by default but can be disabled by setting 1 to the BLS register. Figure 12-57 shows the waveforms when blanking edge shaping is enabled and disabled.

**Figure 12-57. Horizontal Blanking Shaping**

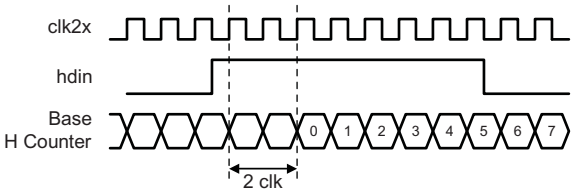


#### 12.2.6.2.3.7 Slave Mode Timings

##### 12.2.6.2.3.7.1 Slave Mode Horizontal Timing

Figure 12-58 shows slave mode horizontal timing. The hdin acts as a horizontal sync input. The internal base horizontal counter is reset after two clk2x cycles upon detecting a rising edge of hdin. The polarity of hdin can be inverted by the HIP register.

**Figure 12-58. Slave Mode Horizontal Timing**



##### 12.2.6.2.3.7.2 Slave Mode Vertical Timings

Figure 12-59, Figure 12-60, and Figure 12-61 show the slave mode vertical timing. The vdin acts as a vertical sync input. The internal base vertical counter is reset when vdin rise transition is detected at hdin rising edge or 0.5H position for the interlaced mode. If vdin is behind hdin assertion. Vertical reset is suspended until the next hdin rise edge or the next 0.5H for the interlaced mode.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-59. Interlaced Slave Vertical Timing (FMD = 0,1)**

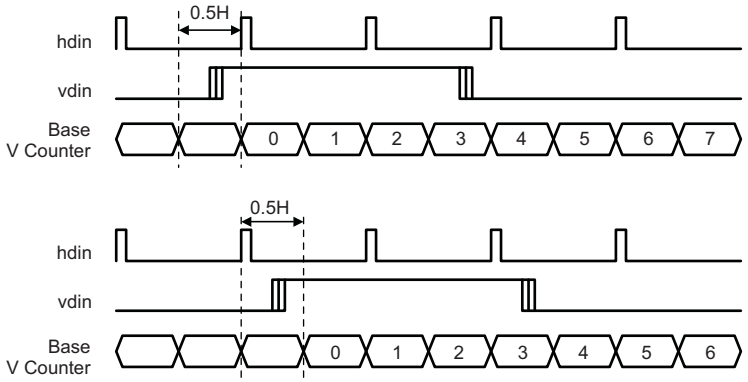


**Figure 12-60. Interlaced Slave Vertical Timing (FMD = 2)**

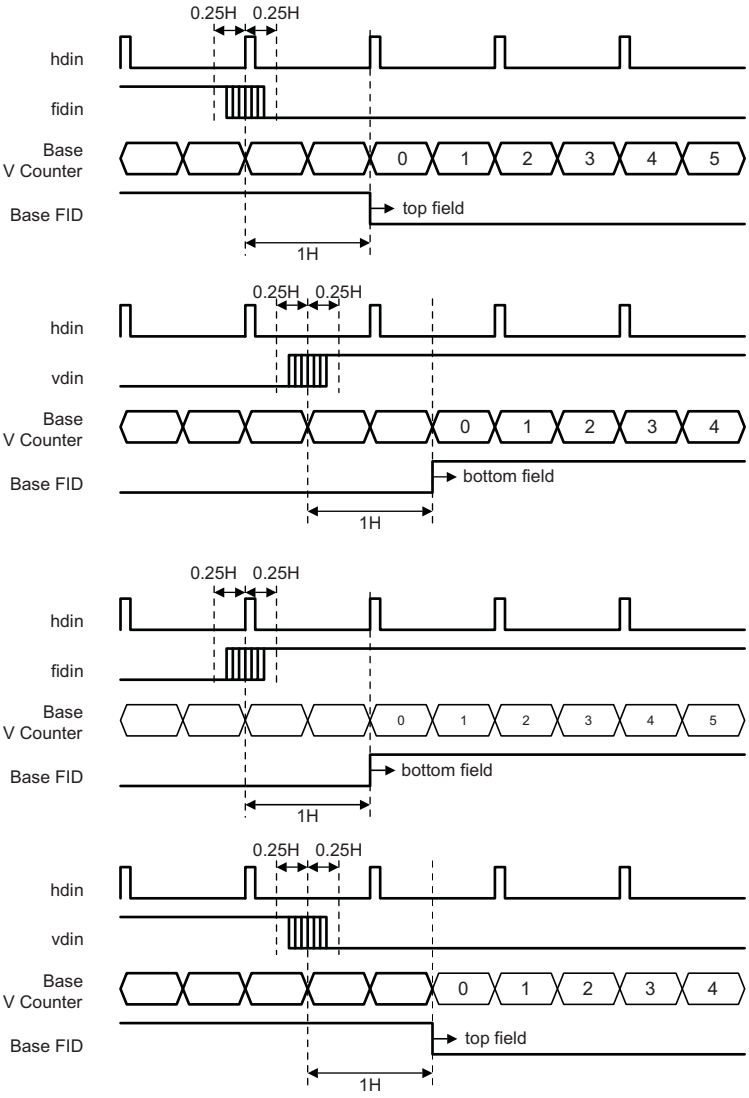
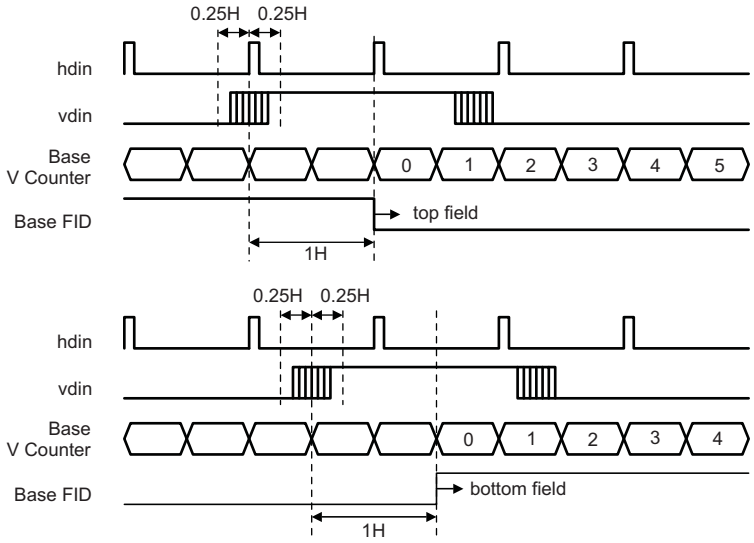


Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-61. Interlaced Slave Vertical Timing (FMD = 3)**



#### *12.2.6.2.3.7.3 Slave Mode Field Detection*

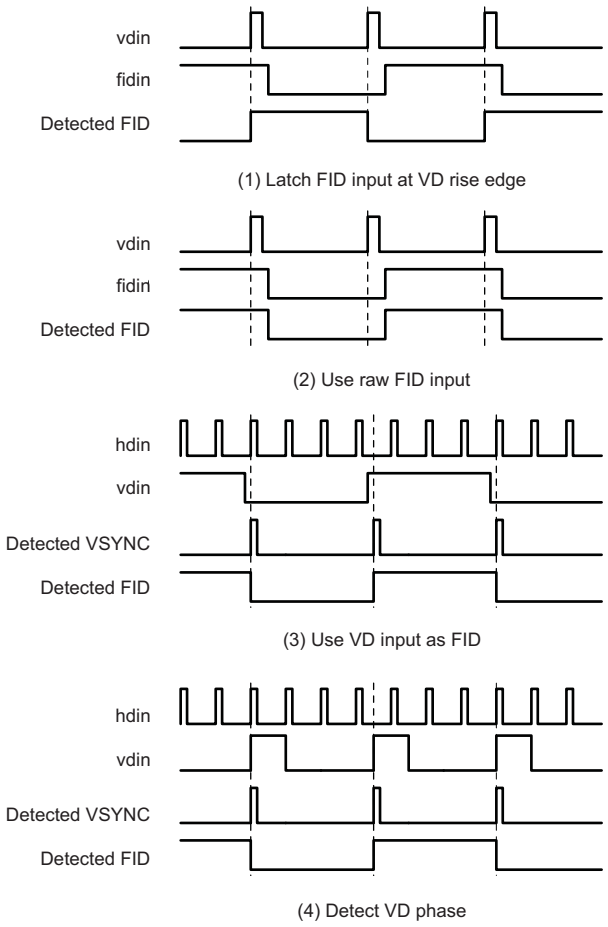
For slave interface mode, the field ID is detected by one of the following methods:

1. Latch FID input at VD rise edge
2. Use raw FID input
3. Use VD input as FID
4. Detect VD phase

These four modes can be selected by the FMD register. Figure 12-62 shows the timing of each mode.

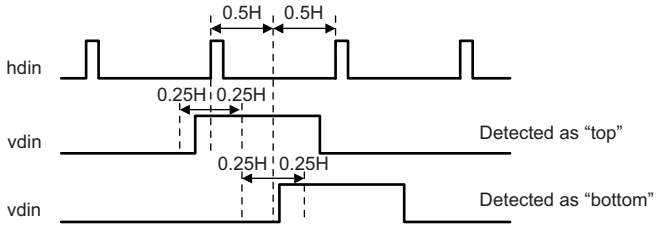
Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-62. Field Detection Mode**



In option4 (Detect VD phase), the timing generator detects VD asserted position in a line. When vdin occurs within 0.25H around hdin, the fid is detected as “top.” Otherwise, the fid is detected as “bottom.” Figure 12-63 shows this detection scheme. When in non-standard mode, field id is always detected as “top” in option4.

**Figure 12-63. Field Detection by VD Phase (FMD=3)**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.4 Color Bar Insertion

When the CBAR register is set to 1, the input pixel data is replaced by the predefined color bar data. The data format of the inserted color bar is 8-bit RGB as shown in Table 12-35. Although the color bar data is generated internally, its timing is based on the AVID signal so it is required to configure the DTV_AVID_STA and DTV_AVID_STP registers appropriately.

When color bar mode is used, the color space conversion matrix should be appropriately programmed so that it can convert the full-range RGB to the desired color format.

**Table 12-35. Color Bar Table**

| Color | G | B | R |
|---|---|---|---|
| White | 255 | 255 | 255 |
| Yellow | 255 | 0 | 255 |
| Cyan | 255 | 255 | 0 |
| Green | 255 | 0 | 0 |
| Magenta | 0 | 255 | 255 |
| Red | 0 | 0 | 255 |
| Blue | 0 | 255 | 0 |
| Black | 0 | 0 | 0 |

#### 12.2.6.2.5 2× Interpolation

Three pixel components, YG, UB and VR, are applied to 2x interpolators. The interpolation is intended to interpolate the SD input pixel which is 1x pixel rate (13.5 MHz) to the 2× clock rate (27 MHz). The interpolator consists of 27 tap symmetric FIR with programmable coefficients. The coefficient register format is s(0.7). The transfer function is expressed as:

$$H(z) = \sum_{n=0}^{26} h(n)\, z^{-n}$$

**Table 12-36. 2× Interpolation Filter Coefficients**

| Coefficients | Value | Default |
|---|---|---|
| h(0), h(26) | UPFC0 | 0 |
| h(1), h(25) | 0 | 0 |
| h(2), h(24) | UPFC1 | 0 |
| h(3), h(23) | 0 | 0 |
| h(4), h(22) | UPFC2 | 0 |
| h(5), h(21) | 0 | 0 |
| h(6), h(20) | UPFC3 | 0 |

| h(12), h(14) | UPFC6 | 78/128 |
| h(13) | 1 | 1 |

Copyright © 2011–2016, Texas Instruments Incorporated

The interpolation is disabled by default and can be enabled by the UPS register.

The interpolator takes 8-bit input (8.0) and generates 12-bit output that has 8-bit integer and 4-bit fractional parts (8.4). After the 2x interpolation, the data processing is done in 12-bit throughout the data pipe. When the interpolation is disabled, the zeros are inserted on 4 LSBs.

#### 12.2.6.2.6 Color Space Converter

The 2x interpolated data then comes into a color space converter (CSC) to be converted into the desired color format. Two independent color space converters are available for CVBS and S-Video paths.

The CSC is implemented based on following equation:

$$\begin{bmatrix} Y_1 \\ Y_2 \\ Y_3 \end{bmatrix} = \frac{1}{64} \begin{bmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{bmatrix} \begin{bmatrix} X_1 + D_1 \\ X_2 + D_2 \\ X_3 + D_3 \end{bmatrix} + \begin{bmatrix} E_1 \\ E_2 \\ E_3 \end{bmatrix}$$

The input is X (8.4) and the output is Y s(12.0). The 3x3 matrix coefficients A, B and C are 13 bit s(6.6). The input offset D is 13 bit s(8.4) and the output offset E is 13 bit s(12.0). The parameters in the equation, A, B, C, D and E, are programmable.

Since the CSC output directly contributes the output video amplitude, the coefficients should be determined considering the final video amplitude. In other words, the CSC can also perform amplification for the video output. The output gain should be included in the matrix coefficients. The input offset D should be applied when input data has an offset like BT601. The output offset E should be used to put pedestal level which is needed for NTSC-M.

Following the above CSC conversion, a limiter is available to constrain the output data to the upper and lower bounds.

The programming example of the CSC will be described later in the sections for each targeted system.

#### 12.2.6.2.7 CVBS Encoding

##### 12.2.6.2.7.1 Color Systems

Targeted color modulation system of SDTV is specified by the CCM register. Table 12-37 shows the supported color systems. Quadrature AM modulation is used for NTSC or PAL systems while FM modulation is used for SECAM. Independent programmability of the timing and color systems enables to generate variant TV formats such as PAL-M, PAL-60 and so on.

**Table 12-37. Color Systems**

| CCM | Color System |
|---|---|
| 0 | NTSC |
| 1 | PAL |
| 2 | SECAM |
| 3 | Reserved |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.7.2 NTSC/PAL Encoding

##### 12.2.6.2.7.2.1 YUV Generation

First, YUV data should be generated by an appropriate color space conversion. The input color format could be YCbCr or RGB. The CSC can convert either format to YUV.

The fundamental YUV formula is defined in the standard as follows:

$$E'_Y = 0.587E'_G + 0.114E'_B + 0.299E'_R$$
$$E'_U = K_b\left(E'_B - E'_Y\right)$$
$$E'_V = K_r\left(E'_R - E'_Y\right)$$

where $K_b$ and $K_r$ are kell factors which have the following values:

$$K_b = \frac{1}{3}\sqrt{\frac{209556997}{96146491}} = 0.492111$$
$$K_r = \sqrt{\frac{221990474}{288439473}} = 0.877283$$

$E_B{}' - E_Y{}'$ and $E_R{}' - E_Y{}'$ are derived using the following equation:

$$\begin{bmatrix} E'_Y \\ E'_B - E'_Y \\ E'_R - E'_Y \end{bmatrix} = \begin{bmatrix} 0.587 & 0.114 & 0.299 \\ -0.587 & 0.886 & -0.299 \\ -0.587 & -0.114 & 0.701 \end{bmatrix} \begin{bmatrix} E'_G \\ E'_B \\ E'_R \end{bmatrix} \equiv \mathbf{M_0} \begin{bmatrix} E'_G \\ E'_B \\ E'_R \end{bmatrix}$$

Using $M_0$, the fundamental YUV formula can be rewritten as follows.

$$\begin{bmatrix} E'_Y \\ E'_U \\ E'_V \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & K_b & 0 \\ 0 & 0 & K_r \end{bmatrix} \bullet \mathbf{M_0} \bullet \begin{bmatrix} E'_G \\ E'_B \\ E'_R \end{bmatrix} \equiv \mathbf{M} \begin{bmatrix} E'_G \\ E'_B \\ E'_R \end{bmatrix}$$

The following are examples of CSC programming for various input and output combinations.

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 12-1. Full-range RGB [0…255] to YUV 10:4 Picture Sync Ratio with 7.5% Setup***

In this example, it is assumed that DAC is configured to have maximum amplitude of 1400 mV.

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{255} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 285 & 55 & 145 \\ -140 & 211 & -71 \\ -250 & -48 & 298 \end{bmatrix} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} 157 \\ 0 \\ 0 \end{bmatrix}$$

$$A = \frac{10}{14} \times 1000(mV) \times 92.5\% \times \frac{4095(LSB)}{1400(mV)} = 1932.6$$

$$S_Y = \frac{10}{14} \times 1000(mV) \times 7.5\% \times \frac{4095(LSB)}{1400(mV)} = 157$$

$$Sync = \frac{4}{14} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 836$$

This coefficient set is preset by default for the CVBS CSC registers.

***Example 12-2. Full-range RGB to YUV 10:4 Picture Sync Ratio with Zero Setup***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{255} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 308 & 60 & 157 \\ -152 & 229 & -77 \\ -270 & -52 & 322 \end{bmatrix} \begin{bmatrix} G \\ B \\ R \end{bmatrix}$$

$$A = \frac{10}{14} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 2089$$

$$S_Y = 0$$

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 12-3. Studio RGB [0…219] to YUV 10:4 Picture Sync Ratio with 7.5% Setup***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{219}\begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64}\begin{bmatrix} 332 & 64 & 169 \\ -163 & 246 & -83 \\ -291 & -56 & 347 \end{bmatrix}\begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} 157 \\ 0 \\ 0 \end{bmatrix}$$

$$A = \frac{10}{14} \times 1000(mV) \times 92.5\% \times \frac{4095(LSB)}{1400(mV)} = 1932.6$$

$$S_Y = \frac{10}{14} \times 1000(mV) \times 7.5\% \times \frac{4095(LSB)}{1400(mV)} = 157$$

***Example 12-4. Studio RGB [0…219] to YUV 10:4 Picture Sync Ratio with Zero Setup***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{219}\begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64}\begin{bmatrix} 358 & 70 & 183 \\ -176 & 266 & -90 \\ -314 & -61 & 375 \end{bmatrix}\begin{bmatrix} G \\ B \\ R \end{bmatrix}$$

$$A = \frac{10}{14} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 2089$$

$$S_Y = 0$$

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 12-5. Full-range RGB [0…255] to YUV 7:3 Picture Sync Ratio with Zero Setup***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{255} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 351 & 68 & 179 \\ -173 & 261 & -88 \\ -308 & -60 & 368 \end{bmatrix} \begin{bmatrix} G \\ B \\ R \end{bmatrix}$$

$$A = \frac{7}{10} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 2047.5$$

$$S_Y = 0$$

$$Sync = \frac{3}{10} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 878$$

***Example 12-6. ITU-R BT.601 YCbCr to YUV 10:4 Picture Sync Ratio with 7.5% Setup***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \begin{bmatrix} 1 & 0 & 0 \\ 0 & K_b & 0 \\ 0 & 0 & K_r \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0.886 & 0 \\ 0 & 0 & 0.701 \end{bmatrix} \begin{bmatrix} 1/219 & 0 & 0 \\ 0 & 1/112 & 0 \\ 0 & 0 & 1/112 \end{bmatrix} \begin{bmatrix} Y - 16 \\ C_b - 128 \\ C_r - 128 \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 565 & 0 & 0 \\ 0 & 482 & 0 \\ 0 & 0 & 679 \end{bmatrix} \begin{bmatrix} Y - 16 \\ C_b - 128 \\ C_r - 128 \end{bmatrix} + \begin{bmatrix} 157 \\ 0 \\ 0 \end{bmatrix}$$

$$A = \frac{10}{14} \times 1000(mV) \times 92.5\% \times \frac{4095(LSB)}{1400(mV)} = 1932.6$$

$$S_Y = \frac{10}{14} \times 1000(mV) \times 7.5\% \times \frac{4095(LSB)}{1400(mV)} = 157$$

Copyright © 2011–2016, Texas Instruments Incorporated

***Example 12-7. Full-range RGB to YUV 10:4 Picture Sync Ratio with Zero Setup (DAC Full-swing)***

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = A \bullet \mathbf{M} \bullet \frac{1}{255} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} S_Y \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 326 & 63 & 166 \\ -160 & 242 & -82 \\ -286 & -56 & 342 \end{bmatrix} \begin{bmatrix} G \\ B \\ R \end{bmatrix} + \begin{bmatrix} 180 \\ 0 \\ 0 \end{bmatrix}$$

Maximum excursion occurs at yellow of the 100% color bar whose amplitude is calculated as follows:

$$\begin{bmatrix} E'_{Yyellow} \\ E'_{Uyellow} \\ E'_{Vyellow} \end{bmatrix} = \mathbf{M} \begin{bmatrix} E'_G = 100 \\ E'_B = 0 \\ E'_R = 100 \end{bmatrix}$$

$$= \begin{bmatrix} 88.6 \\ -88.6Kb \\ 11.4Kr \end{bmatrix}$$

$$MaxAmp_{yellow} = 0.925\left(Y_{yellow} + \sqrt{U_{yellow}{}^2 + V_{yellow}{}^2}\right) + 7.5$$

$$= 130.83(IRE)$$

$$A = \frac{100(IRE)}{40(IRE) + 131(IRE)} \times 0.925 \times 4095(LSB) = 2215$$

$$S_Y = \frac{100(IRE)}{40(IRE) + 131(IRE)} \times 0.075 \times 4095(LSB) = 180$$

$$Sync = \frac{40(IRE)}{40(IRE) + 131(IRE)} \times 4095(LSB) = 958$$

#### 12.2.6.2.7.2.2 LPF

The YUV data from color space converter is applied to the LPF. The LPF is used to bandlimit the signal to conform to the standard. The LPF comprises of 11 tap symmetric FIR with the programmable coefficients. Independent coefficients are available for luma and chroma. The luma LPF takes the input from CSC in s(12.0) and outputs s(12.0). The chroma LPF takes s(11.0) from the CSC (MSB thrown away) and output s(11.0). The coefficient register format is s(0.7). The sampling rate of the FIR filter is half of clk2x clock. The LPFs are disabled by default and can be activated by YLPF and CLPF registers. LPF is available only for the CVBS generation.

**Table 12-38. Luma LPF Filter Coefficient**

| Coefficients | | Value | Default |
|---|---|---|---|
| h(0) | h(10) | YLPFC0 | 0 |
| h(1) | h(9) | YLPFC1 | 0 |
| h(2) | h(8) | YLPFC2 | 0 |
| h(3) | h(7) | YLPFC3 | 0 |
| h(4) | h(6) | YLPFC4 | 32/128 |
| h(5) | | YLPFC5 | 64/128 |

**Table 12-39. Chroma LPF Filter Coefficient**

| Coefficients | | Value | Default |
|---|---|---|---|
| h(0) | h(10) | CLPFC0 | 0 |
| h(1) | h(9) | CLPFC1 | 0 |
| h(2) | h(8) | CLPFC2 | 0 |
| h(3) | h(7) | CLPFC3 | 12/128 |
| h(4) | h(6) | CLPFC4 | 32/128 |
| h(5) | | CLPFC5 | 40/128 |

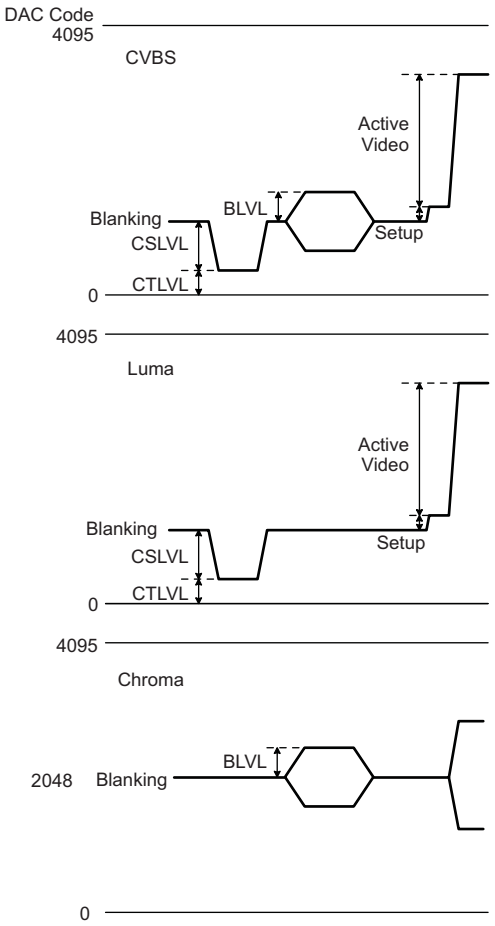
#### 12.2.6.2.7.2.3 Sync/Burst Insertion

Following LPF, sync waveform is inserted onto the luma. The sync tip level and the sync amplitude are programmable as shown in Figure 12-64. The color burst is inserted onto the chroma. The amplitude of the color burst is specified by CBLVL register as follows:

$$ColorBurst = \begin{cases} CBLVL & \ldots \quad NTSC\ (CCM = 0) \\ \sqrt{2} \times CBLVL & \ldots \quad PAL\ (CCM = 1) \end{cases}$$

**Figure 12-64. CVBS Video Amplitude**



Closed caption and WSS signals are also inserted onto the appropriate lines of luma. The pulse amplitude of CC/WSS bit stream is automatically calculated based on the sync amplitude and the picture sync ratio setting. White 100% level is calculated by the following equation:

$$White_{100\%} = \begin{cases} CSLVL \times 10/4 & \ldots \quad CPSR = 0 \\ CSLVL \times 7/3 & \ldots \quad CPSR = 1 \end{cases}$$

The pulse amplitude of CC/WSS is calculated using the ratio of the white level defined in each standard.

The generic VBI-data is also inserted when used. The detail of the VBI-data insertion is described in Section 12.2.6.2.11.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.7.2.4 QAM Modulation

The VENC generates the sub-carrier by internal direct digital synthesizer (DDS). The frequency of sub-carrier is determined by three increment parameters, SCP0, SCP1 and SCP2 as follows:

$$f_{sc} = \frac{1}{1024} \times \left( SCP0 + \frac{SCP1}{SCP2} \right) \times 27MHz$$

Typical settings of these parameters are shown in Table 12-40.

**Table 12-40. Sub-carrier Increment Parameters**

| TV Format | SCP0 | SCP1 | SCP2 | Frequency |
|---|---|---|---|---|
| NTSC-M/J | 135 | 25 | 33 | 3.579545454… MHz |
| NTSC-4.43 | 168 | 2516 | 16875 | 4.433618749… MHz |
| PAL-B/D/G/H/K/I | 168 | 2516 | 16875 | 4.433618749… MHz |
| PAL-M | 135 | 87 | 143 | 3.575611888… MHz |
| PAL-N | 168 | 2516 | 16875 | 4.433618749… MHz |
| PAL-Nc | 135 | 14391 | 16875 | 3.58205625 MHz |
| PAL-60 | 168 | 2516 | 16875 | 4.433618749… MHz |

The sub-carrier to horizontal (SC-H) phase can be controlled by the user. Writing the SCSD register automatically initializes the sub-carrier phase as the value specified in SCSD. The initialization is occurred at the line 4 in the color field 1 for NTSC and the line 1 in the color field 1 for PAL. The phase resolution of DDS is (1/1024)*360°.

Chroma modulation is performed as expressed by:

$$C = \begin{cases} U \sin(2\pi f_{sc}) + V \cos(2\pi f_{sc}) & \ldots \quad NTSC \\ U \sin(2\pi f_{sc}) \pm V \cos(2\pi f_{sc}) & \ldots \quad PAL \end{cases}$$

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.7.3 SECAM Encoding

##### 12.2.6.2.7.3.1 DbDr Generation

First, SECAM YDbDr need to be generated using the CSC. In this example, the input is assumed to be full-range RGB [0…255] and the output is assumed to have 7:3 picture sync ratio with zero setup.

The fundamental SECAM YDbDr equation is expressed as follows:

$$\begin{bmatrix} E'_Y \\ D'_b \\ D'_r \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1.505 & 0 \\ 0 & 0 & -1.902 \end{bmatrix} \bullet \mathbf{M_0} \bullet \begin{bmatrix} E'_G \\ E'_B \\ E'_R \end{bmatrix}$$

Where $D'_b$ has a range of 0 to ±1.33343 and $D'_r$ has a range of 0 to ±1.333302 and needs to be scaled so that the resulted values have the corresponding deviation for the FM modulation.

The deviation calculation is explained in Section 12.2.6.2.7.3.3.

$$\begin{bmatrix} Y \\ D_b \\ D_r \end{bmatrix} = \begin{bmatrix} A_Y & 0 & 0 \\ 0 & A_{D_b} & 0 \\ 0 & 0 & A_{D_r} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1.505 & 0 \\ 0 & 0 & -1.902 \end{bmatrix} \bullet \mathbf{M_0} \bullet \frac{1}{255} \begin{bmatrix} G \\ B \\ R \end{bmatrix}$$

$$= \frac{1}{64} \begin{bmatrix} 302 & 59 & 154 \\ -186 & 280 & -94 \\ 286 & 55 & -341 \end{bmatrix} \begin{bmatrix} G \\ B \\ R \end{bmatrix}$$

$$A_Y = \frac{7}{10} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 2047.5$$

$$A_{D_b} = \frac{0.230(MHz)}{27(MHz)} \times 1024 \times 128 \times \frac{1}{1.33343} = 837.3$$

$$A_{D_r} = \frac{0.280(MHz)}{27(MHz)} \times 1024 \times 128 \times \frac{1}{1.333302} = 1019.4$$

$$Sync = \frac{3}{10} \times 1000(mV) \times \frac{4095(LSB)}{1400(mV)} = 878$$

Where $D_b$ has a range of 0 to ±1117 and $D_r$ has a range of 0 to ±1359.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.7.3.2 Low-Frequency Pre-Emphasis

The YDbDr from CSC is applied to the LPF for a proper attenuation. The LPF function is already described in Section 12.2.6.2.7.2.2. The low-pass filtered Dr and Db are then applied to low-frequency pre-emphasis. The pre-emphasis is implemented by an IIR filter whose transfer function is expressed by:

$$H(z) = \frac{2.75 - 2.5z^{-6}}{1 - 0.75z^{-6}}$$

Then, a limiter clips the DbDr to conform to the maximum deviation requirement specified in SECAM standard. Figure 12-65 shows an example of the limiter configuration.

**Figure 12-65. Limiter Configuration**

$$-350kHz \le \Delta f_{OB} \le 506kHz$$

$$\text{CULCLP} = -\frac{0.35(MHz)}{27(MHz)} \times 1024 \times 128 = -1699$$

$$\text{CUUCLP} = +\frac{0.506(MHz)}{27(MHz)} \times 1024 \times 128 = +2456$$

$$-506kHz \le \Delta f_{OR} \le 350kHz$$

$$\text{CVLCLP} = -\frac{0.506(MHz)}{27(MHz)} \times 1024 \times 128 = -2456$$

$$\text{CVUCLP} = +\frac{0.35(MHz)}{27(MHz)} \times 1024 \times 128 = +1699$$

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.7.3.3 FM Modulation

The low-frequency, pre-emphasized DbDr is then applied to FM modulation. The frequency of the FM modulated sub-carrier is determined by the following equation:

$$f_{FM} = \frac{1}{1024} \times \frac{D_x}{128} \times 27MHz$$

Prior to the modulation, the offsets corresponding to the nominal subcarrier frequency of Db and Dr are added to the low-frequency, pre-emphasized DbDr. The Db and Dr offsets are set by the sub-carrier parameter register SCP1 and SCP2, respectively, as shown in Figure 12-66.

**Figure 12-66. Sub-carrier Parameter Registers**

$$f_{OB} = 4.25MHz$$

$$\text{SCP1} = \frac{4.25(MHz)}{27(MHz)} \times 1024 \times 128 = 20632$$

$$f_{OR} = 4.40625MHz$$

$$\text{SCP2} = \frac{4.40625(MHz)}{27(MHz)} \times 1024 \times 128 = 21390$$

The amplitude of the FM modulated sub-carrier is specified by the CBLVL register. While the CBLVL register specifies the burst amplitude for NTSC/PAL mode, it works differently in SECAM as the sub-carrier amplitude.

For color synchronization, the VENC does not support field identification, but line identification.

The phase of the sub-carrier is reset every line.

#### 12.2.6.2.7.3.4 Bell Filter

A high-frequency pre-emphasis is performed on the FM modulated sub-carrier. The filter has a bell characteristic expressed by:

$$H(z) = \frac{8 - 2.25z^{-4} - 5.5z^{-6}}{1 - 0.5z^{-2}}$$

Finally, SECAM chroma is available from the bell filter output.

#### 12.2.6.2.7.4 Luma Delay

The Y signal delay on the CVBS path can be adjusted by the CYDLY register. It adjusts the Y delay right before mixing Y and C to generate CVBS. The adjustable range is from –8 to 7 cycle of clk2x. S-Video Y is not affected.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.8 WSS

The VENC can insert 14-bit video information (WSS) on line 23 of every frame to conform to the ITU-R BT.1119-2 (ETSI EN 300 294) Wide Screen Signaling specification for the 625i system. The 14-bit transmitted data is specified in the 20-bit WSS_DATA register. The WSS_EN register enables attribute insertion. Figure 12-67 shows the WSS_DATA register usage.

**Figure 12-67. WSS_Data Register Usage**

| 19 14 | 13 11 | 10 8 | 7 4 | 3 0 |
|---|---|---|---|---|
| Unused | GROUP4 | GROUP3 | GROUP2 | GROUP1 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Transmission order is LSB first, that is, WSS_DATA[0] is transmitted first then WSS_DATA[1] follows.

The amplitude of the WSS symbol is automatically determined as five-seventh (5/7) of white 100%. As described earlier, the white level is calculated by the sync amplitude and picture-sync ratio registers (CSLVL and CPSR for CVBS).

#### 12.2.6.2.9 CGMS

The VENC can insert 14-bit CGMS data on line 20 and line 283 to conform to the EIAJ CPR-1024 for 525i. The 14-bit VID data and the corresponding 6-bit CRC are set in the 20-bit WSS_DATA register. The CRC should be calculated by user based on the following equation.

$G(x) = x^6 + x + 1$, where $x^6$, x are preset to 1

The WSS_EN register enables attribute insertion. Figure 12-68 shows the WSS_DATA register usage.

**Figure 12-68. WSS_Data Register Usage**

| 19 14 | 13 6 | 5 2 | 1 0 |
|---|---|---|---|
| CRC | WORD2 | WORD1 | WORD0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Transmission order is LSB first, that is, WSS_DATA[0] is transmitted first and then WSS_DATA[1] follows. WSS_DATA and WSS_EN registers are exclusively used for WSS and CGMS insertion depending on the timing format.

The amplitude of CGMS data is automatically determined as 70% of white (70IRE).

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.10 Closed Caption

The VENC supports closed caption encoding. Closed caption data is transmitted on the line 21 of the odd (top) field and the line 284 of the even (bottom) field in 525i mode. It is possible to specify the fields on which closed captioning is enabled by L21EN register.

Closed caption encoding for 625i system is also supported. Closed caption is inserted on line 22 of the odd field and line 335 of the even field for 625i systems.

The data should be written to the L21DO or L21DE register for odd or even fields, respectively. When data is written to L21DO, CAOST read status bit is changed to 1. When data is written to L21DE, CAEST becomes 1. These bits are automatically cleared to 0 when a caption data transmission is completed on the line 21 in odd field or the line 284 in even field (line 22 and 335 for 625i).

When the caption data register (L21DO or L21DE) is not written before the caption data transmission timing of the corresponding field, an ASCII code specified by L21DF register is used for transmission. A null character should be typically set to L21DF register.

The width of each data register is 8 bits, which consists of 7-bit data and the parity bit. It is your responsibility to calculate the parity bit. The amplitude of closed caption pulse is automatically determined as 50% of white (50IRE).

#### 12.2.6.2.11 Raw VBI-data Insertion Mode

The VBI waveform which is not supported by VENC hardware can be inserted using raw VBI-data insertion mode. In this mode, the VBI waveform is synthesized by software according to the waveform requirements of the selected data type. The VBI_IF module sends VBI waveform to the VENC at the specified VBI lines.

The raw VBI-data insertion mode is enabled VBIEN register is set to 1. Otherwise, the VBI_IF module is basically in a reset state.

The VENC asserts venc_vbi_req pulses to the VBI_IF module during VBI period. The horizontal timing of venc_vbi_req can be configured by VBI_H_STA and VBI_H_STP registers. The reference timing of these registers is the internal TV counter. The vertical timing is determined by the AV window position which is specified by AV_V_STA and AV_V_STP registers. The timing is shown in Figure 12-69 and Figure 12-70.

The VBI_IF module keeps tracks of VBI line numbers by counting the number of venc_vbi_req pulses. On the specified VBI line number, the VBI_IF will send the samples from the payload to the VENC with vbi_venc_val set to HIGH. The data width of vbi_venc_data is only 8bit so zeros are padded to the 4 LSBs when inserted.

Note that CC/WSS and Macrovision have the priority over the VBI data when VBI data insertion is activated on the lines which have these pulses. The vbi_venc_val is disregarded at the lines CC/WSS and Macrovision are enabled.

#### 12.2.6.2.12 Macrovision

The VENC supports analog copy protection Macrovision Rev7.1 to the SDTV CVBS and S-Video output. Due to strict security control by Macrovision, any information such as Macrovision register map, usage, and so on, are not directly distributed to the customers. These information are supposed to be given by Macrovision upon a certain certification.

#### 12.2.6.2.13 Register Setting for Various Video Standards

Table 12-41 is a list of the typical register setting for various video standards.

#### 12.2.6.2.14 DAC Output

##### 12.2.6.2.14.1 DAC Output Level

The VENC has two channel 12-bit digital outputs for DAC input. The DAC output code can be optionally inverted by the DAIV register.

##### 12.2.6.2.14.2 DAC Output Configuration

It is your choice to specify which DAC outputs which video signal. DA0S-DA1S registers specify the DAC output signal as shown in Table 12-42.

**Table 12-42. DAC Output Select**

| DAxS | DAC Output |
|---|---|
| 0 | CVBS |
| 1 | S-Video Y |
| 2 | S-Video C |
| 3-15 | Reserved |

##### 12.2.6.2.14.3 DAC Oversampling

The VENC is capable of 2x oversampling for the final DAC output. The 2x DAC oversampling eases the external analog filter cost as it can eliminate the unwanted image around the sampling frequency of clk2x. Setting DAUPS enables 2x oversampling. The oversampling filter is comprised of a 27 tap symmetric FIR filter with the programmable coefficients. The transfer function is expressed as:

$$H(z) = \sum_{n=0}^{26} h(n)\ z^{-n}$$

The clk4x is used in the oversampler as a DAC sampling clock. Its frequency should be double of clk2x if the hardware is configured to support 2x oversampling. Otherwise, the clk4x should be identical to clk2x. Whether or not to support 2x oversampling can be configured by INC_DUPS parameter in the Verilog HDL.

**Table 12-43. DAC 2x Oversampling Filter Coefficients**

| Coefficients | Value | Default |
|---|---|---|
| h(0), h(26) | DUPFC0 | 0 |
| h(1), h(25) | 0 | 0 |
| h(2), h(24) | DUPFC1 | 0 |
| h(3), h(23) | 0 | 0 |
| h(4), h(22) | DUPFC2 | 0 |
| h(5), h(21) | 0 | 0 |
| h(6), h(20) | DUPFC3 | 0 |
| h(7), h(19) | 0 | 0 |
| h(8), h(18) | DUPFC4 | 6/128 |
| h(9), h(17) | 0 | 0 |
| h(10), h(16) | DUPFC5 | -20/128 |
| h(11), h(15) | 0 | 0 |
| h(12), h(14) | DUPFC6 | 78/128 |
| h(13) | 1 | 1 |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.6.2.14.4 DAC Power Down

DAC power down is managed by the DA0E-DA1E registers. The corresponding DAC should be enabled by setting these registers to 1. Otherwise, DAC should be in power down state. Both DACs can be power down independently. By default, these registers are set to 0 to disable all DACs.

#### 12.2.6.2.14.5 DAC DC Output Mode

A test mode to output the specified DC level on the DAC output pins is available. Setting DADC register to 1 switches DAC output from normal video signal to DALVL register. In this mode, both DACs have same DC output of DALVL D/A converted value.

**Figure 12-71. DAC I/F Logic**

### 12.2.7 High-Definition Video Encoder (HD_VENC)

The HD VENC module encodes the active video data from COMP module and sends it to 30-bit wide DVO (Digital Video Output) port by generating timing signals to control the data flow.

#### 12.2.7.1 Features Supported

- The DVO port will support the output data rate up to 1080p formats (148.5 MHz × 30bits)
- The DVO support 10/20/30-bit wide output with embedded sync or discrete sync
- Fully programmable DVO timing generation (VS,HS,FID) to support any format flat display panel
- Fully programmable internal timing generation - VS, HS, FID, HBI, VBI, and ACT_VID for internal video compositor
- Programmable Color Space Converter: 10-bit data path.
- Gamma correction table

#### 12.2.7.2 Functional Overview

HD VENC primarily has two blocks: OSD and encoder. The OSD module is used to get the data from the COMP module using the sync signals generated by encoder module. In the device, HD VENC supports either digital (HD_VENC_G [HDMI/DVO1] or HD_VENC_D[DVO2]).

Table 12-44 lists the possible display ports and corresponding VENC names. The basic block diagram of HD VENC module is shown in Figure 12-72.

**Table 12-44. Display Ports and VENC Names**

| Display Port Name | Type | HDVENC Used | Port Name for PINMUX | Features Supported |
|---|---|---|---|---|
| HDMI/DVO1 | Digital | HD_VENC_D | VOUT1 | All features in digital data flow path |
| DVO2 | Digital | HD_VENC_D | VOUT0 | All features in digital data flow path |
| SDVENC | Analog | SD_VENC | Not Applicable | Please check SD VENC userguide for details. |

**Figure 12-72. HD VENC Block Diagram**

### 12.2.7.3 Video Data Interface to OSD

#### *12.2.7.3.1 OSD Interface Overview*

The interface between OSD and video display encoder are consisting of a 30-bit data bus, a pixel clock and five sync signals. By default 30-bit RGB video data will be passed from OSD to encoders on every rising edge of the pixel clock during active video period. The maximum frequency of the pixel clock is 148.5 MHz.

Table 12-45 lists all the control signals of this interface.

**Table 12-45. OSD Interface Signals**

| Signal Names | Descriptions |
|---|---|
| dtv_fid | Field ID signal. This signal will toggle between “1” and “0” on every field in interlace mode. It will toggle between “1” and “0” on every frame in progressive mode.<br>Programmability: controlled by register CFG13 (END_F1) and CFG10 (LINES). |
| dtv_vs | Vertical sync signal. This signal is a one-line long pulse. This pulse indicates the first line of each field in interlace mode. In progressive mode, it indicates the first line of each frame.<br>Programmability: location of this signal is controlled V_BLANK1, VBLANK2, and FD1. |
| dtv_vbi | Vertical blank interval signal. This signal goes to “1” during non-active video period; it stays at “0” during active video period.<br>Programmability: controlled by register CFG16/17. (For OSD interface only) |
| dtv_hs | Horizontal sync signal. This is the horizontal sync signal.<br>Programmability; the start location and width of this signal are both programmable. They are controlled by CFG17. (For OSD interface only) |
| dtv_hbi | This is a four-pixels-wide and active-high signal. It appears once every video line.<br>Programmability: The location of this pulse is programmable. (For OSD interface only) |
| dtv_actvid | This is active-video qualification signal. When this signal is high, encoder is expecting active video data output from OSD after one clock delay.<br>Programmability: The fully programmable. (For OSD interface only) |

**Note:** The dtv_vs, dtv_vbi, dtv_hs and dtv_hbi signals are generated by the encoder but are not used by the HDVPSS design. Therefore, all parameters related to these signals do not need to be specified.

Copyright © 2011–2016, Texas Instruments Incorporated

The following figures illustrate the protocol of this interface. Figure 12-73 illustrates all the signals that are related to frame/field sync.

**Figure 12-73. Vertical Sync Signals for OSD**

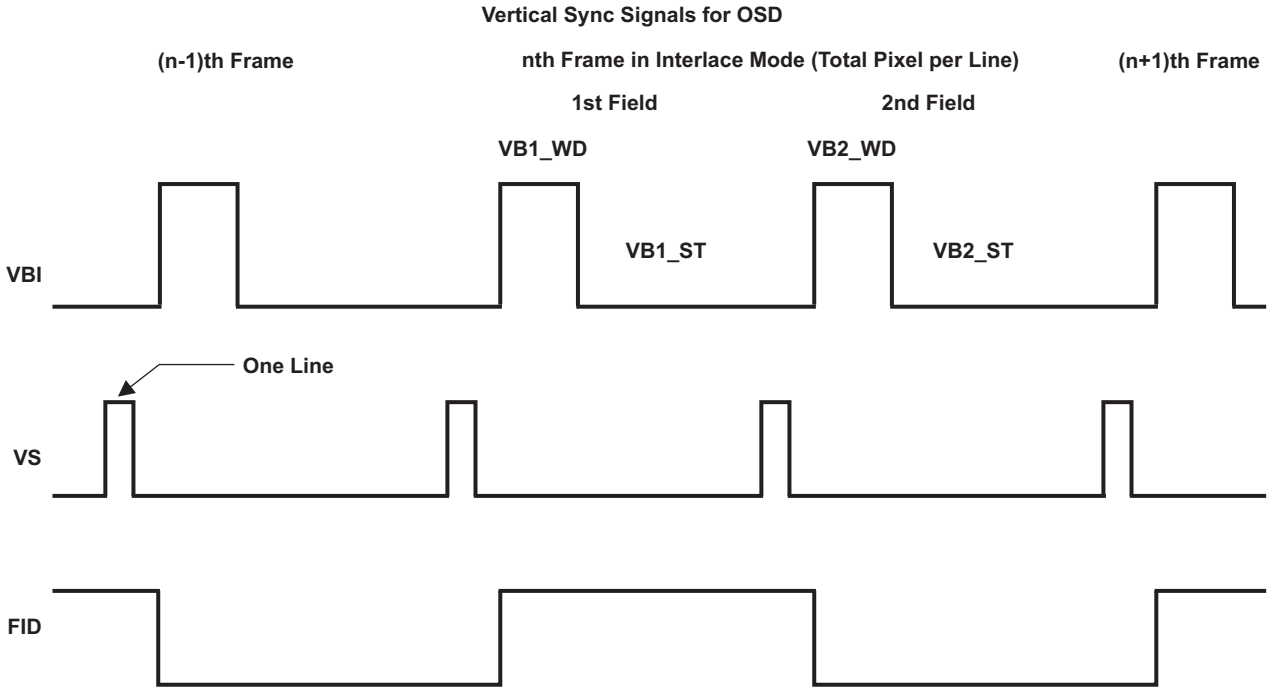

Figure 12-74 illustrates all the signals that are related to line sync. The programmable parameters with corresponding register names are indicated in the diagram.

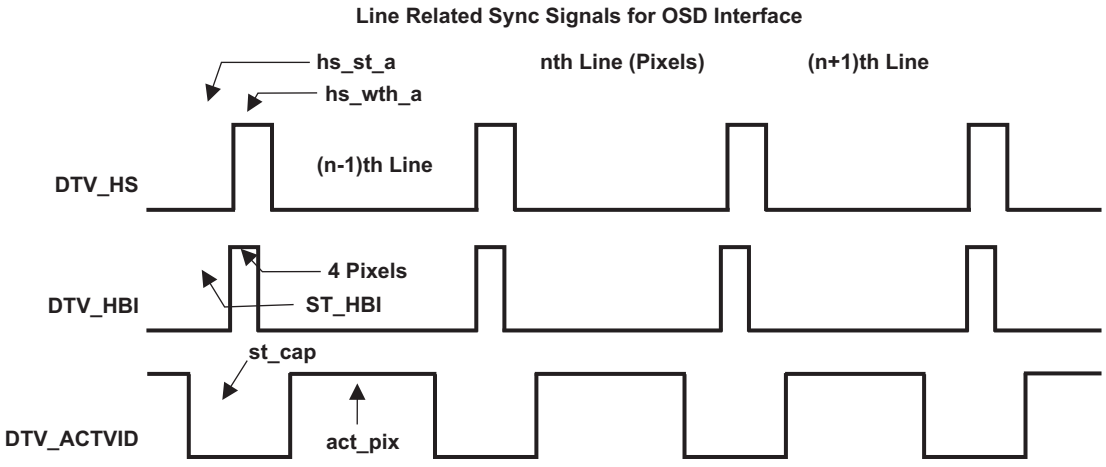
**Figure 12-74. Horizontal Sync-related Signal for OSD**



Copyright © 2011–2016, Texas Instruments Incorporated

Figure 12-75 is the OSD-to-encoder data bus timing diagram. ACT_VID is the active video data qualification signal. Encoder will capture data from OSD after one clock delay when the ACT_VID goes to “high”.

The input 30-bit video data can also be in YCbCr 444 format. On chip processor will set the register bit “Y_RGBn” in CFG0 register to select RGB or YCbCr color spaces.

**Figure 12-75. Video Data Interface Between OSD and Encoder**

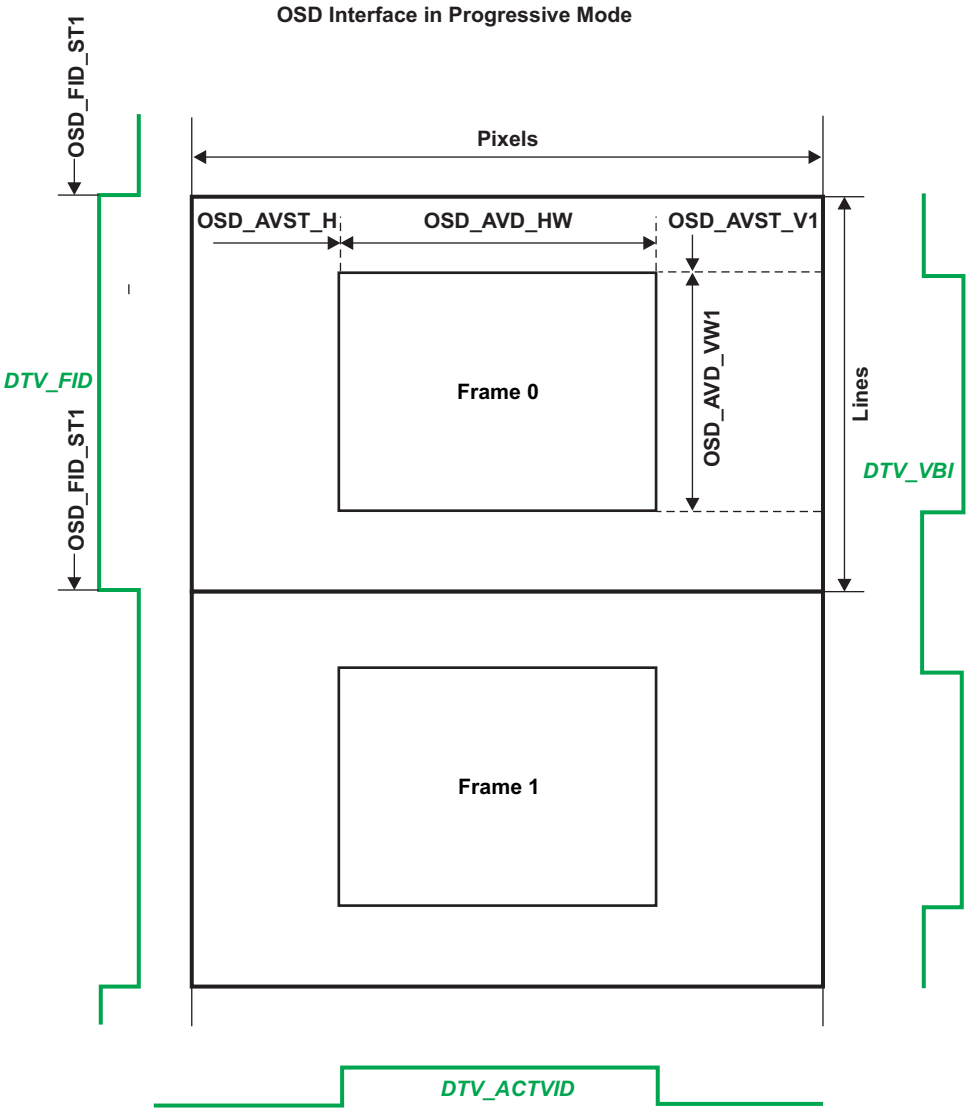
#### 12.2.7.3.2 OSD Interface Configuration for Progressive Display

Figure 12-76 illustrates the OSD interface in the configuration for progressive display mode.

The corresponding register settings are described in the register section.

The green color signals are the signals outputting to OSD.

**Figure 12-76. OSD Interface in Progressive Mode**



Copyright © 2011–2016, Texas Instruments Incorporated

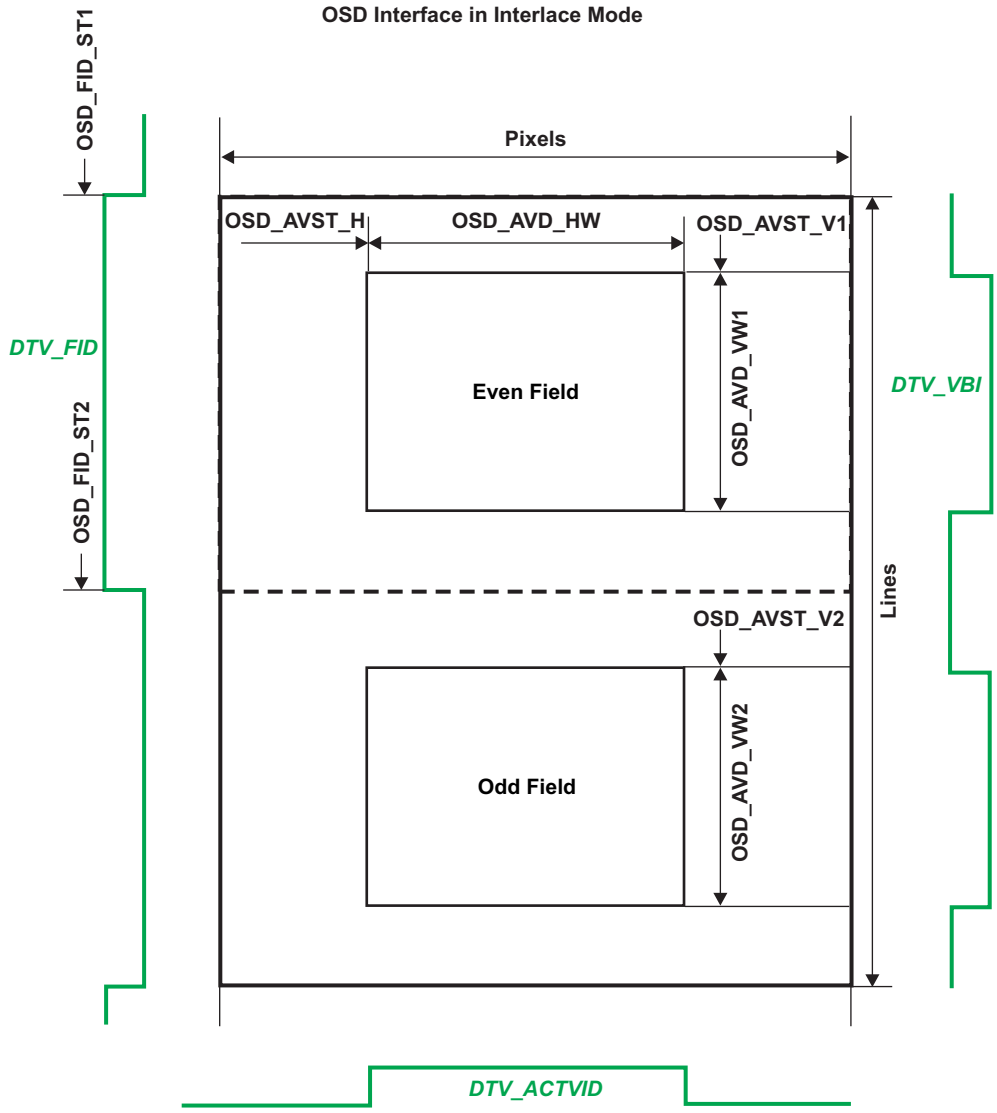
#### 12.2.7.3.3 OSD Interface Configuration for Interlace Display

Figure 12-77 illustrates the OSD interface in the configuration for interlace display mode.

The corresponding register settings are described in the register section.

The green color signals are the signals outputting to OSD.

**Figure 12-77. OSD Interface in Interlace Mode**



Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.7.4 Display Timing Generation (DTG)

The DTG (Display Timing Generator) block will generate all the sync and display timing signals for both OSD interface and DVO interface.

Due to the fast development of display panel technology and lack of the interface standard, the sync timing for DVO will be designed highly flexible. This will make sure that the device can interface to the most panels used by digital TV industry; meanwhile, maintains the simplicity for the software programming.

The details of OSD interface and DVO interface are described in the corresponding sections.

### 12.2.7.5 DVO (Digital Video Output)

#### *12.2.7.5.1 Output Formats of DVO*

Table 12-46 lists all formats that the DVO supports.

**Table 12-46. DVO Formats**

| Formats | DVO_D0 | DVO_D1 | DVO_D2 |
|---|---|---|---|
| Single-stream 656 | YCbCr | (Unused) | (Unused) |
| Dual-stream 656 | Y | CbCr | (Unused) |
| Tri-stream 656 | Y/G | Cb/B | Cr/R |
| YUV422 20bit output with discrete sync | Y | CbCr | (Unused) |
| 30bit output with discrete sync | Y/G | Cb/B | Cr/R |

During the two discrete sync modes, following are the sync signals that DVO outputs:

1. DVO_HS
2. DVO_VS
3. DVO_ACTVID
4. DVO_FID

#### *12.2.7.5.2 Embedded Sync Word Definitions of DVO*

DVO of the device supports single/dual/tri stream with embedded sync (SAV/EAV).

The active video data in single/dual stream formats are in 4:2:2 YCbCr format.

DVO of the device also supports 10-bit video, the embedded sync SAV/EAV in 10bit format as: 3FF, 000, 000, XXX. All the possible values for XXX are listed in Table 12-47.

**Table 12-47. Definition of SAV and EAV words**

| BITS | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | SAV/EAV | Hex |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Function | 1 | F | V | H | P3 | P2 | P1 | P0 | x | x | | |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | SAV | 200 |
| 1 | 1 | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | EAV | 276 |
| 2 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | SAV | 2AC |
| 3 | 1 | 0 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | EAV | 2D8 |
| 4 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | SAV | 31C |
| 5 | 1 | 1 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | EAV | 368 |
| 6 | 1 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | SAV | 3B0 |
| 7 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | EAV | 3C4 |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.7.5.3 DVO Interface Configuration

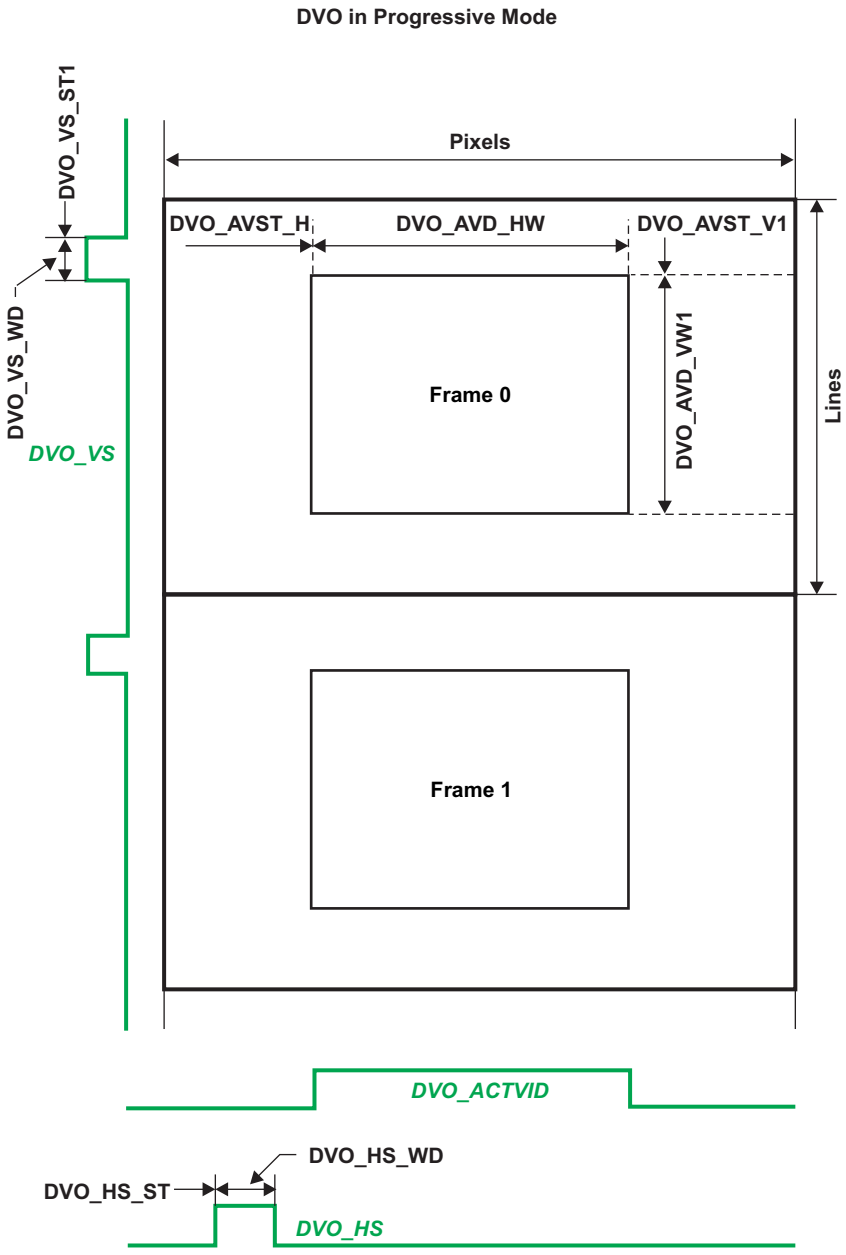
The design goal of the DVO of the device is to interface to all standard and non-standard panels seamlessly. To archive this goal, the DVO of the device has been refined with ultimate flexibility; meanwhile maintaining simplicity for the software programming. Following subsections present all the interface signals for both progressive and interface display devices.

##### 12.2.7.5.3.1 DVO Interface for Progressive Display

The progressive display format is the display format for most flat panel display devices, such LCD, Plasma, and DLP. Figure 12-78 illustrates the progressive configuration of DVO port. The configuration register settings are described in the register section.

The green color signals are the signals outputting from the DVO port.

**Figure 12-78. Progressive Configuration of DVO**



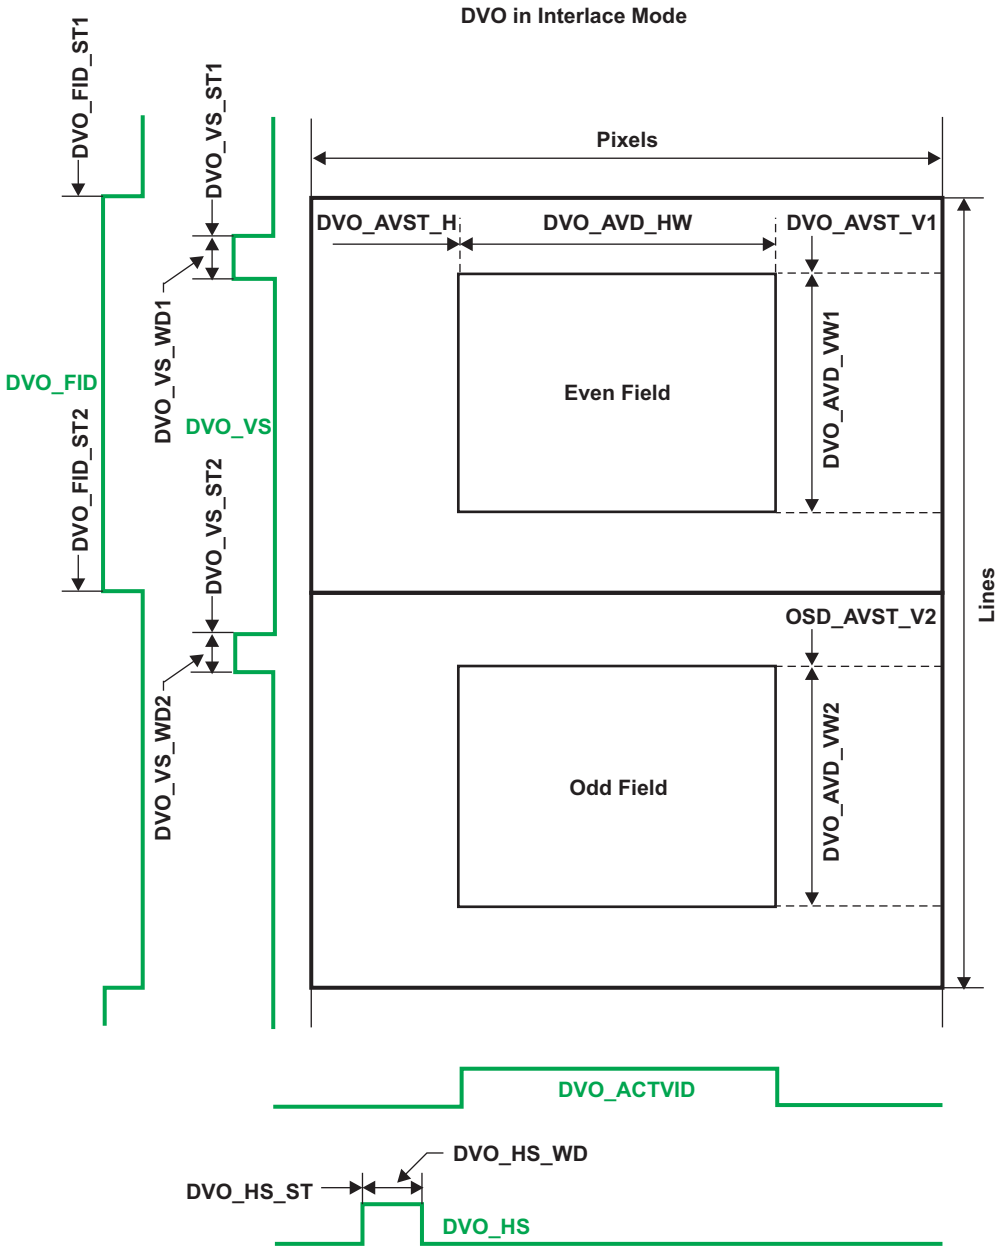
Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.7.5.3.2 DVO Interface for Interlace Display

Figure 12-79 illustrates the interlace configuration of DVO port. The configuration register settings are described in the register section.

The green color signals are the signals outputting from the DVO port.

**Figure 12-79. Interlace Configuration of DVO**



Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.7.6 JEIDA Format of DVO

A new output format of DVO has been added and a corresponding control bit “JED” has also been added.

This bit is used to make DVO interfacing to certain LCD panels seamlessly. Table 12-48 illustrates the JEIDA and VESA (the normal/default format we use) format.

**Table 12-48. JEIDA and VESA Format**

| VESA Mode | | JEIDA Mode | |
|---|---|---|---|
| **RGB Data** | **DVO Port** | **RGB Data** | **DVO Port** |
| G/B/R[9] | DV_OUT0/1/2[9] | G/B/R[3] | DV_OUT0/1/2[9] |
| G/B/R[8] | DV_OUT0/1/2[8] | G/B/R[2] | DV_OUT0/1/2[8] |
| G/B/R[7] | DV_OUT0/1/2[7] | G/B/R[9] | DV_OUT0/1/2[7] |
| G/B/R[6] | DV_OUT0/1/2[6] | G/B/R[8] | DV_OUT0/1/2[6] |
| G/B/R[5] | DV_OUT0/1/2[5] | G/B/R[7] | DV_OUT0/1/2[5] |
| G/B/R[4] | DV_OUT0/1/2[4] | G/B/R[6] | DV_OUT0/1/2[4] |
| G/B/R[3] | DV_OUT0/1/2[3] | G/B/R[5] | DV_OUT0/1/2[3] |
| G/B/R[2] | DV_OUT0/1/2[2] | G/B/R[4] | DV_OUT0/1/2[2] |
| G/B/R[1] | DV_OUT0/1/2[1] | G/B/R[1] | DV_OUT0/1/2[1] |
| G/B/R[0] | DV_OUT0/1/2[0] | G/B/R[0] | DV_OUT0/1/2[0] |

The JEIDA mode is only used in three-channel RGB with discrete sync output format.

### 12.2.7.7 VBI Data Service

Following are the commonly used VBI-data-services on analog component video interface, these functions are supported by the hardware inside the encoder.

- Type-A and Type-B data packets based on CEA-805-A standard, which include CGMS-A/APS(Analog Protection System)/AFD(Active Format Description)/RCI(Re-distribution Control Information)
- International VBI data support based on the international standard IEC-62375, which is mainly for the applications outside of north-American.

A typical VBI data package usually consists of three segments, they are illustrated in Figure 12-80.

**Figure 12-80. Typical VBI Data Package**

Each segment has its-own programmable symbol. Number of symbol for each segment is also programmable. The minimum element of a symbol is one pixel clock. For different display formats, different pixel clocks have been used. All of these require the VBI data encoder can be used for different display interface formats.

Two programmable VBI data encoders have been designed to service all the above functional requirement. These VBI data line encoders are symbol based, it can accommodate different symbol modulations.

- The first VBI line will be used for type-A data packet of CEA-805-A standard or IEC-62375 standard.
- The second VBI line will be used for type-B data packet of CEA-805-A standard

Copyright © 2011–2016, Texas Instruments Incorporated

Table 12-49 shows the first line encoder's programmable capacity. The payload symbol can be programed in the phase-modulation representation. It can be used for type-A VBI data service of CEA-805-A or IEC-62375.

**Table 12-49. Programmable Capacity of First Line Encoder**

| Start Symbol | Header Symbol | Payload Symbol |
|---|---|---|
| Max. = 64 | Max. = 64 | Max. = 128 |

Table 12-50 shows the second line encoder's programmable capacity, it can be used for type-B VBI data service of CEA-805-A. The payload has been increased to accommodate large data packets.

**Table 12-50. Programmable Capacity of Second Line Encoder**

| Start Symbol | Header Symbol | Payload Symbol |
|---|---|---|
| Max. = 64 | Max. = 64 | Max. = 128 |

Although these two line encoders are targeting to some specific VBI applications, but they are flexible enough to be used by some other applications. For example, both encoder data-lines can be transmitted on any line in a frame or a field (by set the line number to register VBI_L1).

These VBI data line encoders can support up to two VBI lines in a frame or a field. If the host-CPU updates the VBI data registers at the frame rate (or field rate), the encoders are able to send out two VBI lines per frame or per field.

### 12.2.7.8 Processing Blocks

The main processing blocks in encoder module are:

- Gamma Correction (Gamm)
- Color Space Conversion (CSC)

#### *12.2.7.8.1 Gamma Correction (Gamm)*

The gamma correction modules perform a gamma or color correction independently for each color in RGB color space by using configurable LUT (Look-Up Table) in RAM. Each Gamm module reads 10-bit input and outputs 10-bit value from its corresponding Look-up Table entry. The RAM has 1024 32-bit words and contains three LUTs for each color as shown in Table 12-51.

**Table 12-51. Gamma Correction LUT**

| | bit[9:0] | bit[19:10] | bit[29:20] | bit[31:30] |
|---|---|---|---|---|
| Address at 0x0000 | LUT_G[0] | LUT_B[0] | LUT_R[0] | reserved, return 0 during read |
| Address at 0x0004 | LUT_G[1] | LUT_B[1] | LUT_R[1] | reserved, return 0 during read |
| Address at 0x0008 | LUT_G[2] | LUT_B[2] | LUT_R[2] | reserved, return 0 during read |
| ... | ... | ... | ... | ... |
| Address at 0x0FFC | LUT_G[1023] | LUT_B[1023] | LUT_R[1023] | reserved, return 0 during read |

- If CFG0.RD_MEM = '1', processor can read and write these LUTs as regular memory.
- If CFG0.RD_MEM = '0', processor can only write to these LUTs as regular memory.

Copyright © 2011–2016, Texas Instruments Incorporated

Table 12-52 shows the memory map address of configuration register and the LUT memories.

**Table 12-52. Memory Map Addresses for Configuration Register and LUT Memories**

| Descriptions | Start Address[12:0] | End Address[12:0] |
|---|---|---|
| HD VENC MMR | 0x0000 | 0x0FFF |
| LUT RAM | 0x1000 | 0x1FFF |

Gamm module can be bypassed by setting CFG0.BYPS_GC bit-field to 1.

#### *12.2.7.8.2 Color Space Conversion (CSC)*

The color space conversion (CSC) module is used to convert the input data from one color space to another by using a programmable 3 × 3 matrix. See the *Color Space Converter* section for more details. The CSC module can be bypassed by setting CFG0.BYPS_CS bit-field to 1.

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.8 VIP Parser

The VIP Parser module is used to capture the video data into the HDVPSS module.

#### 12.2.8.1 Features

The device has two identical instances of the VIP subsystem. Each VIP instance has one VIP parser.

For one VIP Parser instance, the video capture requirements include:

- Two Pixel Clock Input Domains are supported (Port A and Port B)
  - Each Pixel Clock Input Domain has separate clock and framing signals.
  - Each Pixel Clock Input Domain can support embedded (BT.656 style) or discrete (BT.601 style) sync.
  - Pixel Clock Input Domain Port A supports up to one 24-bit input data bus, including BT.1120 style embedded sync for 16 and 24 bit data.
  - Pixel Clock Input Domain Port B supports one 8-bit input data bus. At the SOC level, the same device pins may be shared between Ports A and B. One 24 bit chip level set of device pins is shared. Port A has access to all 24 bits. Port B only has access to 8 bits.
- Embedded Sync data interface mode supports single or multiplexed sources
- Discrete Sync data interface mode supports only single source input
- The two Pixel Clock Input Domains can be individually configured in any combination of Embedded or Discrete Sync
- Vertical ancillary data is supported for each input source. For discrete sync modes where vertical ancillary data is not specified using signals, vertical ancillary data will appear in active video buffer.
- A maximum of 8 + 1 (8 normal line sources + 1 split-line source) multiplexed sources are supported for a single Pixel Clock Input Domain using TI Line Mux Mode
- Multiplexed data can only appear in embedded sync mode
- Where possible, blanking pixels that may contain embedded vertical ancillary data will be stored in a dedicated buffer per each video source
- Optional selection of channel (Luma or Chroma or both) from which Vertical Ancillary data is extracted for YUV422 source
- For RGB source, Vertical Ancillary data can be found in one of the R, G, or B channels. The VIP Parser can select the channel from which Vertical Ancillary data is extracted.
- Ancillary Data can appear in the Horizontal Blanking as well as the Vertical Blanking. Typically, only Vertical Blanking Ancillary Data is captured. However, Horizontal Blanking Ancillary Data can be captured as well using HSYNC style discrete sync capture mode.
- Video up to WUXGA (1920 × 1200) can be supported using Port A in 16- or 24-bit mode.

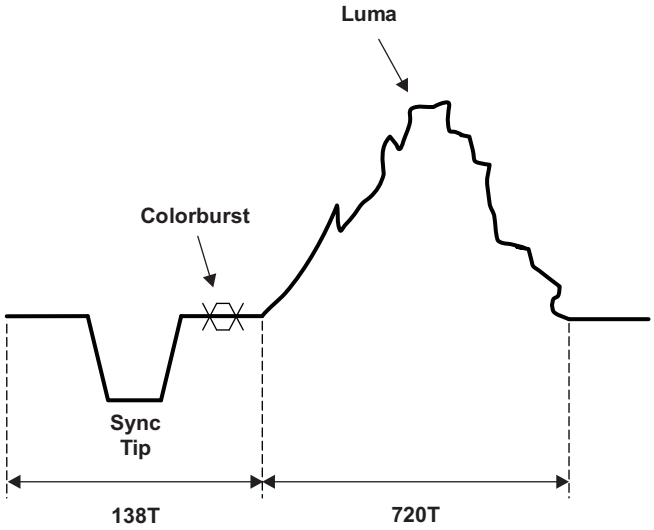
#### 12.2.8.2 Functional Description

##### 12.2.8.2.1 Analog Video

A digital interface stream is based on analog video. The waveform for a line of NTSC analog video is shown in Figure 12-81.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-81. NTSC Analog Video Waveform for One Horizontal Line**



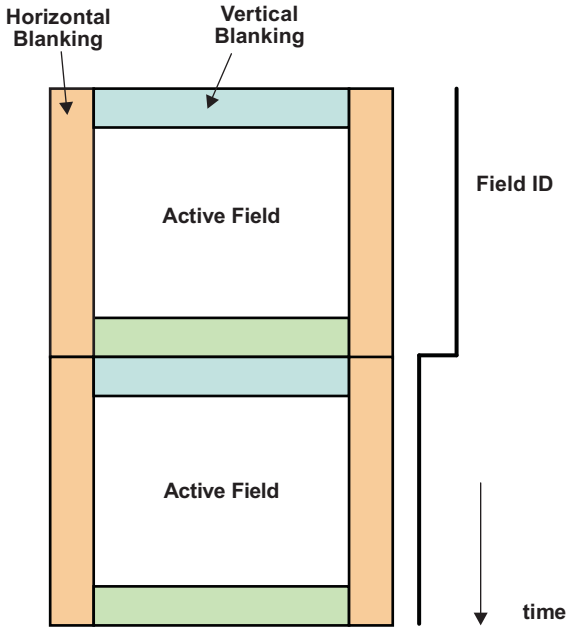
T is a time constant. For NTSC, T=1/13.5 MHz = 74ns.

#### *12.2.8.2.2 Digitized Video*

Digitized video is based on scan lines in found in analog video. BT.601 uses various sync signals to specify when a new field and a new line starts. BT.656 and BT.1120 uses sync words embedded in the data stream to specify start of field and start of line.

An image can be digitized into regions shown in Figure 12-82.

**Figure 12-82. Digitized Video**



With the capability to encode sync words inside the data stream, there is more flexibility for adding non-video related data, called Ancillary Data. Also, code words embedded in the digital stream can be used as a type of identifier for multiplexing several sources of video into one data stream. Such a multi-camera multiplex is useful in the digital security markets.

Copyright © 2011–2016, Texas Instruments Incorporated

Figure 12-83 shows End-of-Active-Video (EAV) and Start-of-Active-Video (SAV) code words added to a video transmission. The period between the EAV and SAV is equivalent to Horizontal Blanking. The period between the SAV to the next EAV is active video or vertical blanking.

In the BT.656 or BT.1120 embedded code word scheme, three bits of the EAV/SAV code word are important: F (field), H (horizontal blanking), and V (vertical blanking).

**Figure 12-83. Code Word Embedded Video Format**

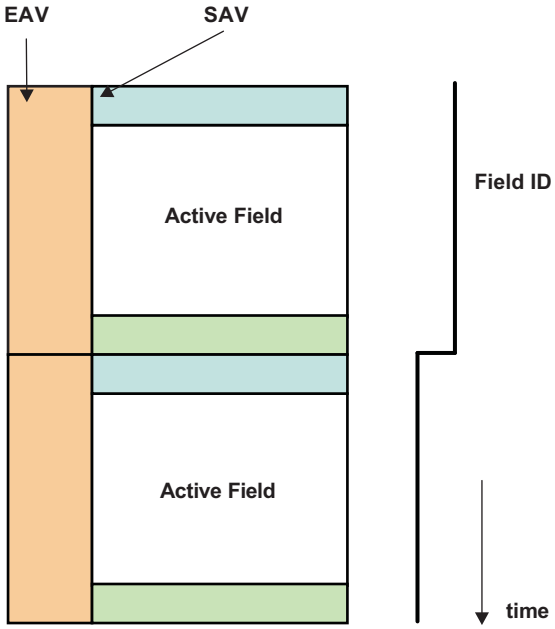


Figure 12-84 shows the values of F, V, and H flags at different locations in the picture. The Field flag represents the state of the Field ID for the picture. For progressive frames, F is always '0.' The V flag specifies vertical blanking areas. The H flag specifies horizontal blanking portions of the picture.

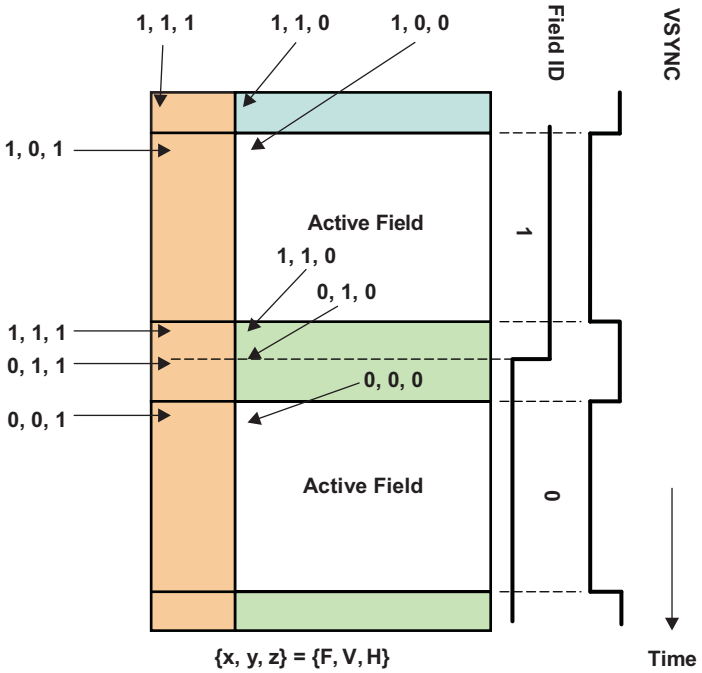
**Figure 12-84. Digitized Video with F, V, and H Flags in EAV/SAV**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.3 Frame Buffers

The VIP/VPDMA supports Frame Buffers in DDR for Active Video and Ancillary Data.

4:2:2 data is always saved in packed pixel buffers.

4:2:0 data is saved in Planar Luma buffers and Planar CbCr pair buffers.

A Luma Frame Buffer is a Planar storage area. Each line is the width in pixels (1Byte/pixel) of the output picture size format. The frame buffer contains the number of active video lines in the output picture size format.

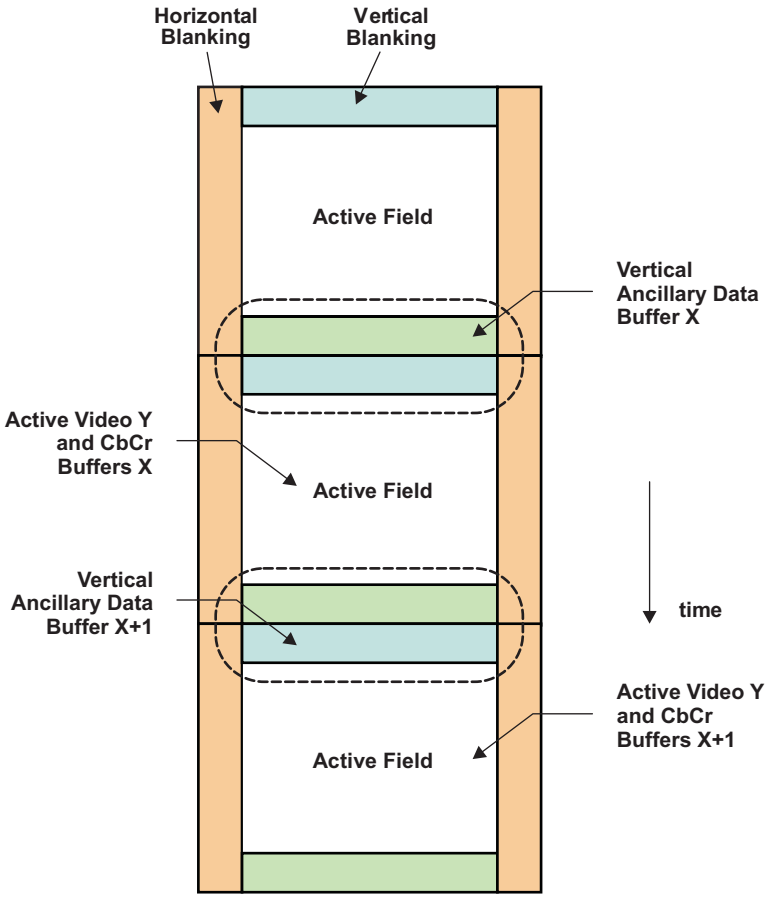
A Chroma Pair Frame Buffer is Planar storage of CbCr pixel pairs, with each pixel being a byte. For 4:2:0 storage, N lines in the output picture active video results in N/2 lines of CbCr pairs being stored.

The Ancillary Data buffer is different than the Active Video Frame Buffers. The Ancillary Data buffer only stores Vertical Blanking Ancillary Data. The number of lines in the Ancillary Data buffer is the same as the number of Vertical Blanking lines. Typically, only one channel is extracted from the Vertical Blanking data, so the width of the Ancillary Data buffer is the same as the width of the Luma Buffer.

In 8-bit input mode, it is possible for both Luma and Chroma sites to be extracted for Vertical Ancillary data. Each color component is strobed on separate input clock cycles. In this case, the line width of the Ancillary data is twice the Luma line width of the picture. Both Luma and Chroma sites cannot be extracted for 16-bit input mode because both Luma and Chroma are sent on the same input clock cycle and the Ancillary port to the VPDMA VPI is only 8 bits wide.

Figure 12-85 shows how the planar data regions are stored in DDR. The vertical blanking data is stored in a set of Planar Buffers. Note that the bottom of the Vertical Ancillary Data from the previous field or frame is stored in the same buffer as the top of the Vertical Ancillary Data from the current field or frame.

**Figure 12-85. Planar Buffer Storage Description**



Copyright © 2011–2016, Texas Instruments Incorporated

The Luma representing Active Video is stored in a set of Planar Buffers. The CbCr Chroma Pairs are stored in a set of Planar Buffers.

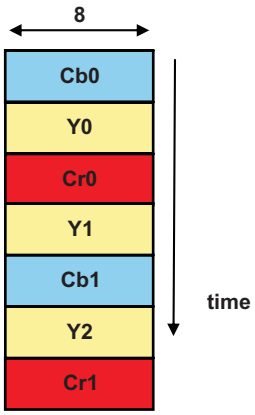
#### 12.2.8.2.4 Input Data Interface

This section describes how the data (luma and chroma data for YUV422 format capture & R,G and B data for RGB888 format capture) is muxed for the interface modes described below.

##### 12.2.8.2.4.1 8b Interface Mode

In 8b data interface mode, the input pixels are multiplexed according to Figure 12-86. The Chroma Format is 4:2:2. Sites with Cb/Cr pixels are known as Chroma sites. Those sites with Y pixels are known as Luma sites.

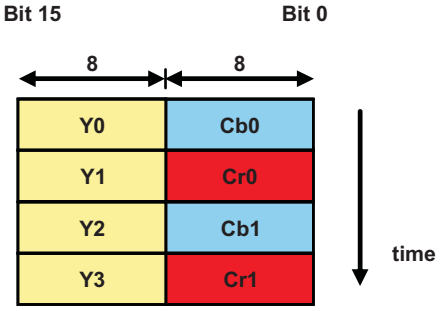
**Figure 12-86. 8b Interface Discrete Sync Pixel Multiplexing**



##### 12.2.8.2.4.2 16b Interface Mode

In 16b interface mode, Luma is on 8 bits of the data bus and Cb/Cr chroma pixels alternate on the other 8 bits of the data bus as shown in Figure 12-87.

**Figure 12-87. 16b Interface Discrete Sync Pixel Multiplexing**



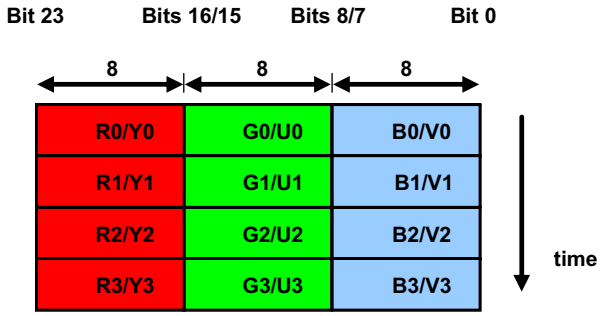
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.4.3 24b Interface Mode

RGB or YUV444 data is sent in 24b Interface Mode. The three components are packed into the data bus and sent to the VPDMA. The 24-bit Luma VPI client to the VPDMA carries all three components. This data is saved to the DDR in packed mode. That is, the three components are not separated by hardware. The 24-bit data bus is shown in Figure 12-88.

Ancillary data is saved in the Ancillary Data buffer. The ctrl_chan_sel configuration register is used to select whether the ancillary data is from the R/Y, G/U, or B/V channels.

**Figure 12-88. 24b Interface RGB or YUV444 Discrete Sync**

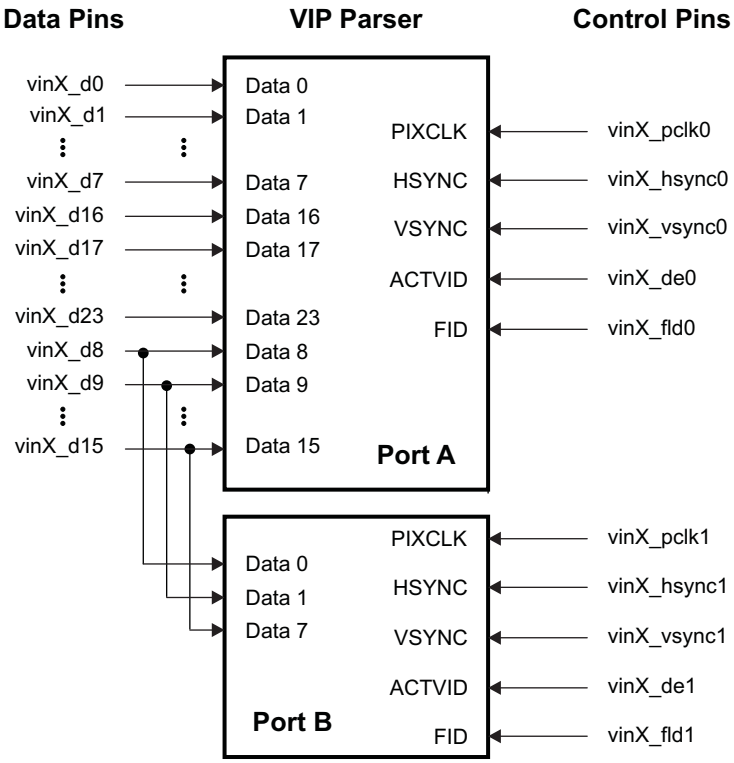


#### 12.2.8.2.5 Input Ports and Sharing of the 24 Bit Data Bus

The VIP Parser supports two independent Pixel Clock Input Domains, which shall be called Port A and Port B. Port A supports a single 24-bit data bus at the instance level and Port B supports a single 8-bit data bus at the instance level.

For the device, a single set of 24 device pins are used to drive both Ports A and B, as shown in the following figure.

**Figure 12-89. 24 Device Pins for Ports A and B**



Copyright © 2011–2016, Texas Instruments Incorporated

The configuration for each device input port is described in Table 12-53.

**Table 12-53. Valid Input Port Configurations**

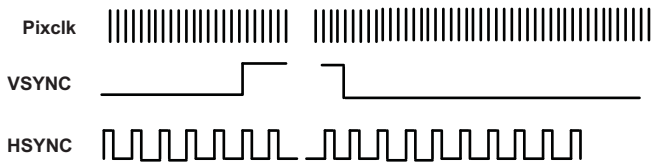
| Port A | Port B |
|---|---|
| 8 Bit | Off |
| 16 Bit | Off |
| 24 Bit | Off |
| 8 Bit | 8 Bit |
| 16 Bit | 8 Bit |
| Off | 8 Bit |

Each Port can individually be configured as Discrete Sync or Embedded Sync.

#### 12.2.8.2.5.1 Signal Relationships

A digital representation of video can be realized by using HSYNC and VSYNC signals to identify frame start and line start. Suppose HSYNC and VSYNC are active high, Figure 12-90 shows the general relationship of these signals.

**Figure 12-90. Discrete Sync Signals**



Every Pixclk cycle carries either an active pixel or a blanking pixel. VSYNC pulses between two fields (or frames, in the case of progressive video). HSYNC pulses to signify the beginning of every line. An ACTVID signal can be used as a data valid to specify active video.

Discrete Sync cannot be used with any multi-camera multiplexed stream inputs. In the device, if Port A is configured for 24 bit discrete sync, then Port B must be disabled since there are no more data input pins left over for Port B.

If Port A is not 24 bits, then the 8-bit Port B can be configured and enabled for either discrete or embedded sync.

Discrete sync basic mode is used to determine the type of vertical blanking signal. DISCRETE_BASIC_MODE='0' means that the vertical blanking interval is specified by the signaling. In the cases where there is no awareness of vertical blanking start and end, vertical blanking data is saved in the Active Video Buffer (DISCRETE_BASIC_MODE='1').

#### 12.2.8.2.5.2 General 5 Pin Interfaces

Discrete Sync signal handling varies among different sending devices. The information that must be conveyed includes the pixel data value, field ID, horizontal blanking, and vertical blanking. Many devices can be configured to adjust the timing of the signals relative to each other.

In this section, DATA will be depicted as 8 bits. However, discrete sync does optionally support 16b and 24b data input. Type 1 is named after a generic five pin interface between the sending and receiving devices.

In Figure 12-91, P0 represents the first pixel in the horizontal blanking interval following the last vertical blanking line of the previous field or frame. HSYNC specifies the horizontal blanking region and VSYNC specifies that the P0 pixel is in the vertical sync area. HSYNC can be a strobe that is active one or more cycles and can deassert before the actual end of horizontal blanking or HSYNC may be active for the full duration of horizontal blanking.

Likewise, VSYNC can be a strobe that is active one or more cycles and can deassert before the actual end of vertical blanking or VSYNC may be active for the full duration of vertical blanking.

Copyright © 2011–2016, Texas Instruments Incorporated

FID can change at this pixel or it may change later. For interlaced source, though, the FID will be inverted for this pixel at the same time point in the next field. So, it does not really matter when FID is captured. Many sending devices allow the location of FID changes to be programmable.

In this diagram and all others in this document, the active polarities of the interface signals can be either high or low. For the sake of uniformity in this document, all polarities are drawn active high. Also, different vendors have different datasheet names for the interface signals.

**Figure 12-91. Type 1, First Horizontal Blanking Pixel**

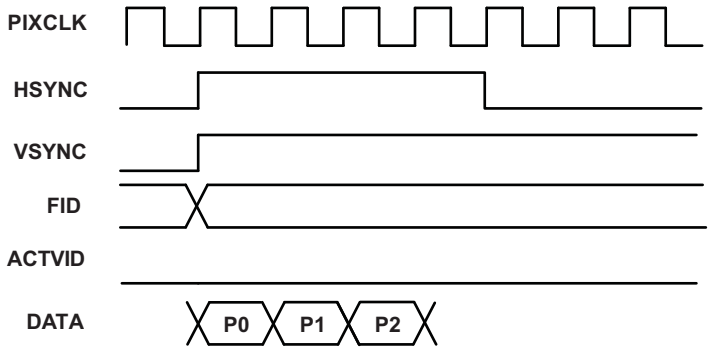


Figure 12-92 shows the P0 pixel being the first Chroma Channel data value in the Vertical Ancillary Data region. HSYNC is definitely de-asserted by now since P0 is no longer in horizontal blanking. ACTVID may or may not be active for Vertical Ancillary Data. Some devices consider these pixels to be Active (as in non-horizontal blanking). Other devices consider only video to be ACTIVE Video.

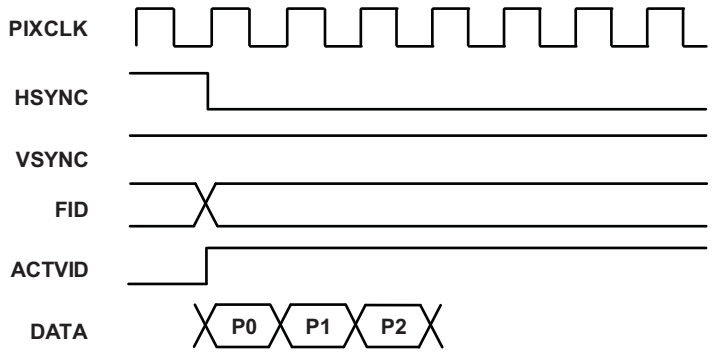
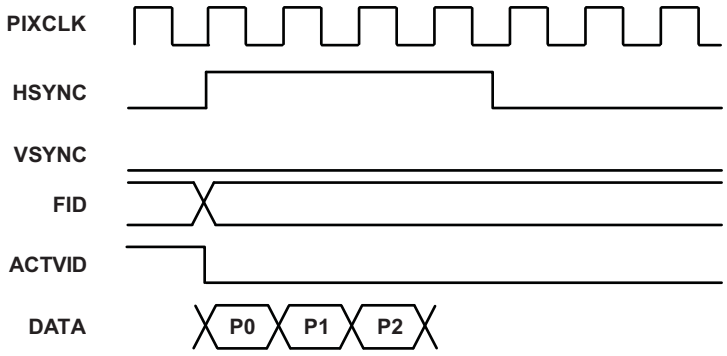
**Figure 12-92. Type 1, First Vertical Ancillary Data Pixel**



Copyright © 2011–2016, Texas Instruments Incorporated

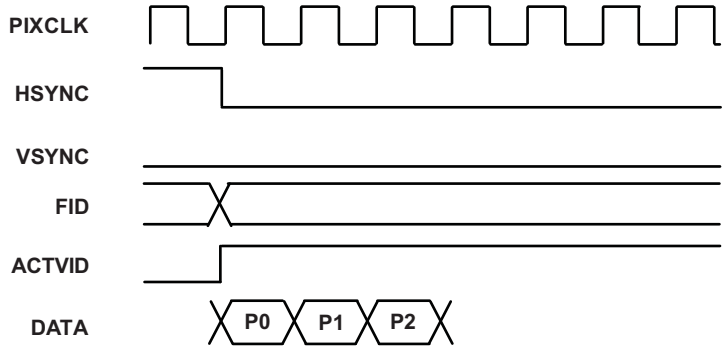
Following the vertical blanking region, the video portion of the field or frame starts. Figure 12-93 shows the horizontal blanking area in this video portion of the field or frame. P0 is the first pixel in the horizontal blanking. HSYNC is active for one or more pixel clocks. VSYNC is inactive in this video area. FID can change here. ACTVID is low since P0 is horizontal blanking.

**Figure 12-93. Type 1, Horizontal Blanking in Video Region**



In Figure 12-94, P0 represents the first Chroma pixel in the Active video line. HSYNC is inactive, since P0 is in the active video region. Likewise, VSYNC is inactive. FID may or may not change here. ACTVID is high to signal capturing of video pixels.

**Figure 12-94. Type 1, First Video Pixel**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.3 Signal Subsets—4 Pin VSYNC, ACTVID, and FID

A sending device may use only a subset of the signals described in Section 12.2.8.2.5.1. The sending device just needs to convey important signals required to capture the field or frame. It can be shown that various selections of four pins can be used to satisfy all Type 1 conditions.

Three pins, VSYNC, ACTVID, and FID, plus a pixel clock can be used to support discrete sync. VSYNC would bump the capture buffer. An inactive to active level of ACTVID specifies a line of data to capture. FID determines the field ID polarity. The scenario in which the sending device wants the receiving end to capture Vertical Ancillary Data using 4-pin signaling is shown in Figure 12-95.

**Figure 12-95. 4-Pin Reduced ACTVID Signaling with Vertical Ancillary Data**

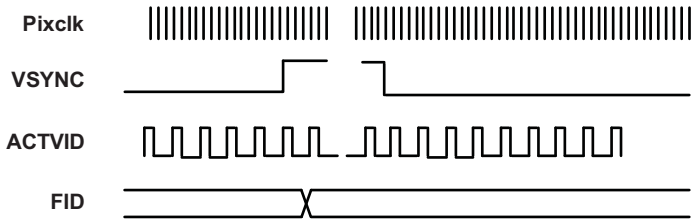


Figure 12-96 describes the case using the 4-pin interface in which the sending device does not send Vertical Ancillary Data.

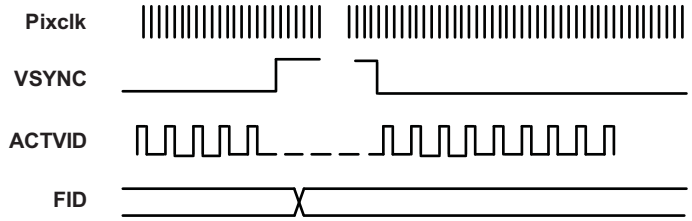
**Figure 12-96. 4-Pin Reduced ACTVID Signaling with No Vertical Ancillary Data**

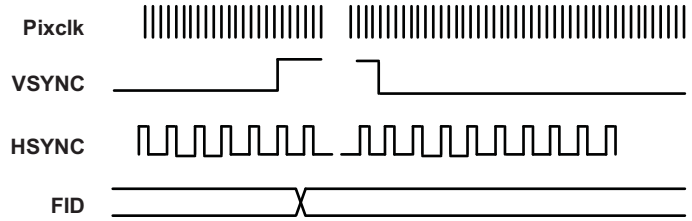


#### 12.2.8.2.5.4 Signal Subsets—4 Pin VSYNC, HSYNC, and FID

In this style of Discrete Sync, as shown in Figure 12-97, four pins are used including the Pixel Clock. HSYNC signals the beginning of the line. All data in the line is captured, including Horizontal Blanking Data. In fact, this signaling mode is the only one that allows Horizontal Blanking Data to be captured.

Of course, by capturing the horizontal blanking pixels in the frame buffers, there is no way to be certain exactly where the blanking ends and the active video starts. One would have to rely solely on video format specs to find the active video inside the frame buffer.

**Figure 12-97. 4-Pin Reduced HSYNC Signaling with Vertical Ancillary Data**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.5 Vertical Sync

Vertical Sync is used to indicate lines that are in the vertical blanking interval. The VSYNC also separates fields or frames. To be spec compliant, VSYNC should be active for a few lines at the bottom of the picture. The exact number of vertical blanking lines at the bottom depends on the specification for the picture format (480i, 480p, 720p, 1080i, 1080p).

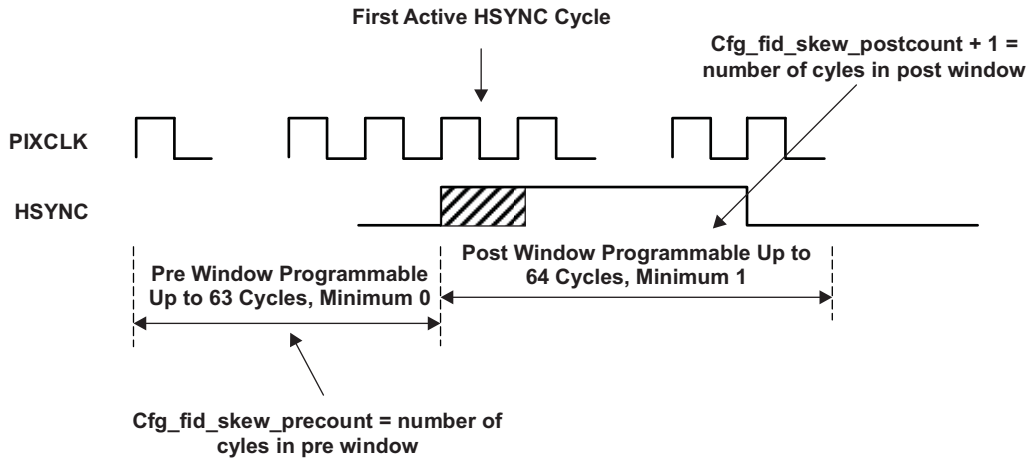
Likewise, the number of vertical blanking lines at the top of the picture depends on the video format specification corresponding to the incoming picture.

In the VIP parser, lines associated with an Active VSYNC are stored in the vertical ancillary data buffers using the ANC VPI port to the VPDMA. Lines without an Active VSYNC are stored in the active video Luma and Chroma-pair buffers using the Y and UV VPI ports, respectively, to the VPDMA.

When using HSYNC signaling instead of ACTVID, the VSYNC signal may be derived from an analog source such as an NTSC/PAL decoder. In this case, VSYNC may not transition on the exact cycle as HSYNC. Thus, the VIP Parser supports a window region around HSYNC in which VSYNC transitions will be detected. A VSYNC transition occurring within the window is identified the same way as if VSYNC transitioned on the same cycle as HSYNC going active.

The window is defined by a pre-window, which is determined by the cfg_fid_skew_precount register. There is also a post-window that is defined by cfg_fid_skew_postcount. Note that although the configuration registers are named fid_skew, they are also used for defining the VSYNC transition window. The window region definition is shown in Figure 12-98.

**Figure 12-98. VSYNC Pre and Post Window**



The results of VSYNC behavior in the transition window are shown in Figure 12-99. A low to high transition in the window is equivalent to VSYNC going low to high on the active HSYNC cycle.

Likewise, a high to low transition in the window is equivalent to VSYNC going high to low on the active HSYNC cycle.

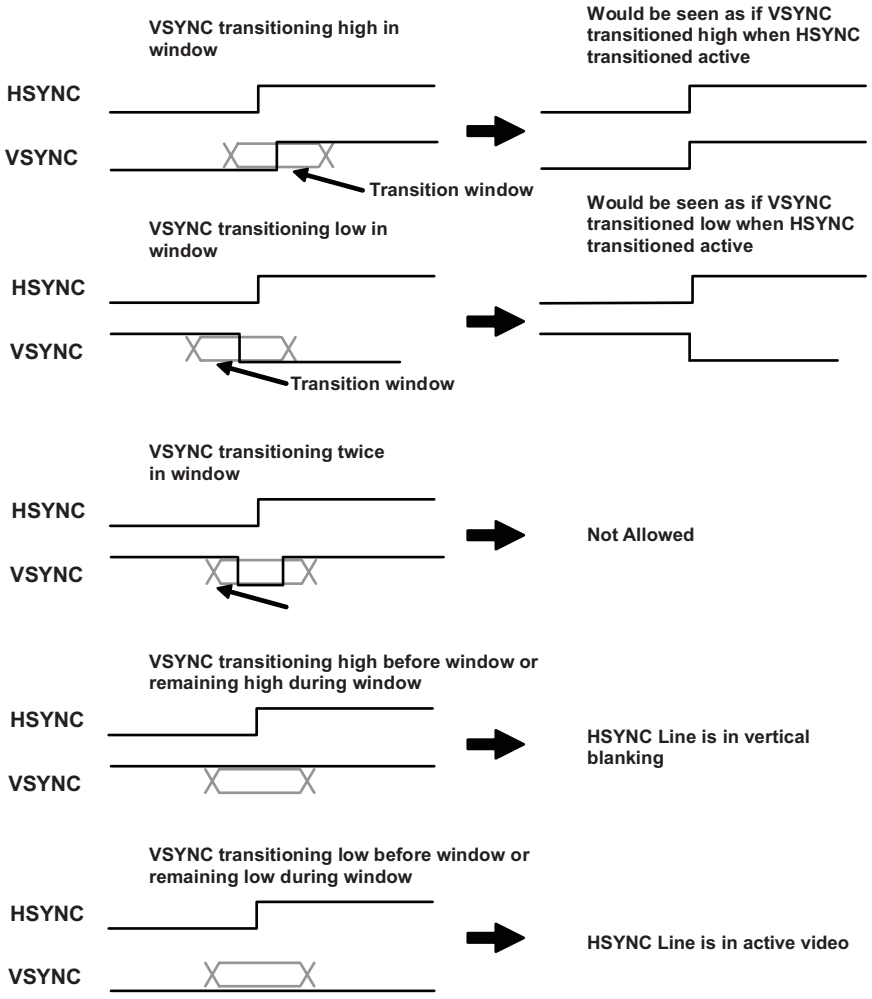
Two transitions of VSYNC within the VSYNC window is not allow and is undefined behavior.

If VSYNC is high throughout the transition window, then the HSYNC line is in vertical blanking.

If VSYNC is low throughout the transition window, then the HSYNC line is in active video.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-99. VSYNC Equivalence When Using Transition Window**



Note that VSYNC skew generally only applies to input signals that have been sampled from an analog source, as in a NTSC/PAL decoder. If the VSYNC is a VBLANK-type signal or if the sending device is another all-digital IC such as another device or Davinci part, then the VSYNC signal does not have a skew since VSYNC will be aligned to HSYNC. In this case, setting cfg_fid_skew_precount = ‘0’ and cfg_fid_skew_postcount = ‘0’ defines a minimum size window which will capture the value of VSYNC on the same cycle that HSYNC goes active.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.6 Field ID Determination Using Dedicated Signal

For Progressive Source, FIELD ID is always '0.'

For Interlace Source, we need to extract FIELD ID consistently.

In some cases, vertical sync is active on the first pixel of a line in the vertical blanking period and it stays active until the last line in the vertical blanking period.

However, the pixel where the FIELD ID signal transitions can be quite variable and depends on the external chip driving the VIP Parser. Many parts that generate digitized raw video have a programmable feature to specify when FIELD ID changes. From our standpoint, the good news is that FIELD ID is valid at the same point for every field. That is, if FIELD ID is read at one particular place in a field, the polarity of the signal will be reversed at the same location in the next field. So, FIELD ID can be corrected with a programmable polarity configuration bit that is XORed with the captured value.

For discrete sync mode, FIELD ID will be registered on the first active pixel capture cycle of each line in both styles of HSYNC and ACTVID usage as specified in Figure 12-100 and Figure 12-101.

**Figure 12-100. FID Registering When Using HSYNC**

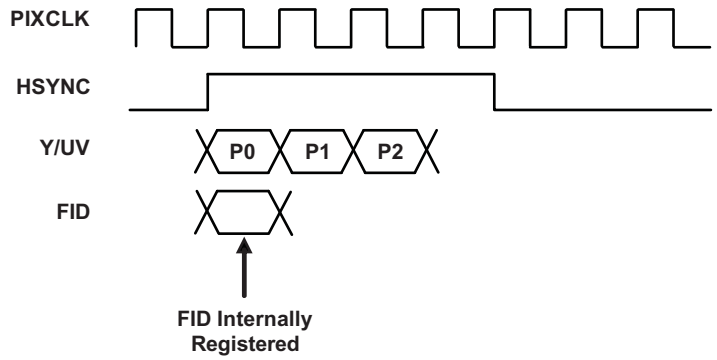


**Figure 12-101. FID Registering When Using ACTVID**

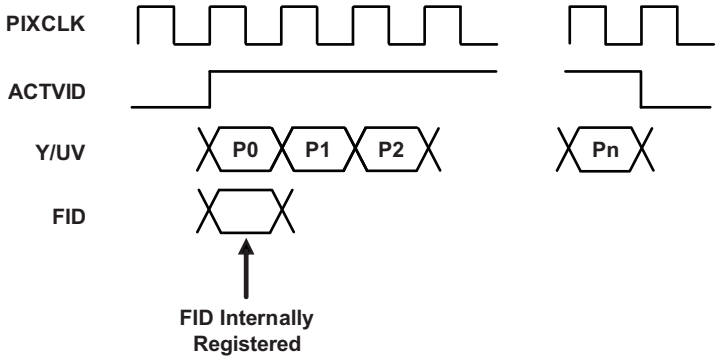


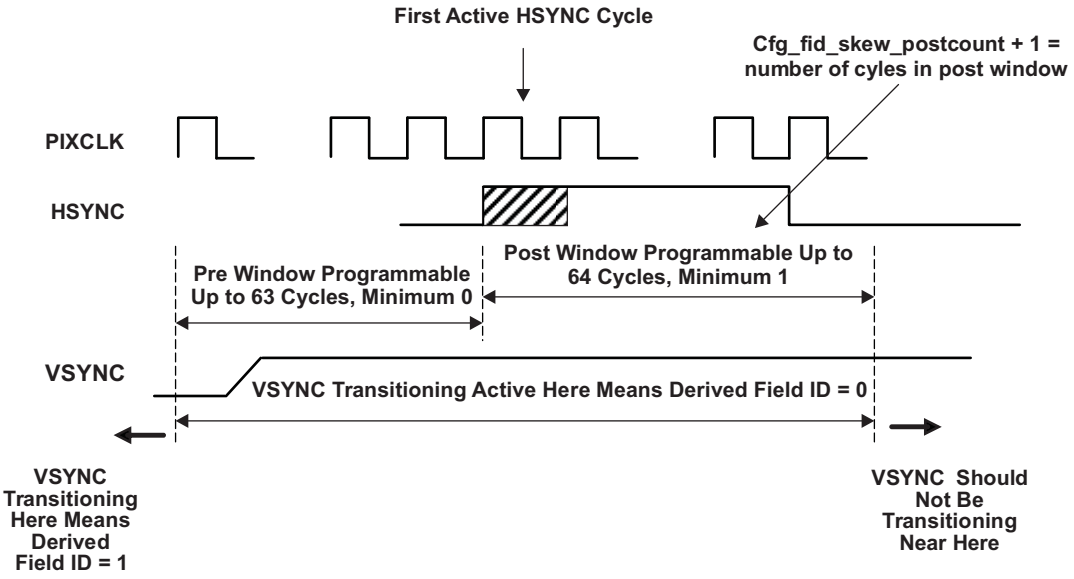
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.7 Field ID Determination Using VSYNC Skew

In order to save a device pin, there is a case where a skew may be inserted into VSYNC (with respect to HSYNC) when HSYNC is used as a start of line indicator as described in Figure 12-97. In this case, no FIELD ID signal is sent by the source chip. A description of Field ID determination by VSYNC skew is shown in Figure 12-102.

The active polarity of VSYNC falling within n pixel clock cycles of the first active cycle of HSYNC indicates the field id. If VSYNC is active before this time window, then the field_id = '1' for the next picture. If VSYNC becomes active within this window, then field_id = '0' for the next picture.

**Figure 12-102. Field ID Determination By VSYNC Skew**



When using FID determination by VSYNC skew, the value for VSYNC is also determined by transitions in the window as shown in Figure 12-99.

The VIP Parser supports a configuration FID polarity bit. For FID determination by VSYNC Skew, the fid determination functions as described in Table 12-54.

**Table 12-54. Polarity Table for FID Determination By VSYNC Skew**

| Cfg_fid_polarity | Transition in Pre/Post Range | FID Determination |
|---|---|---|
| 0 | No | 1 |
| 0 | Yes | 0 |
| 1 | No | 0 |
| 1 | Yes | 1 |

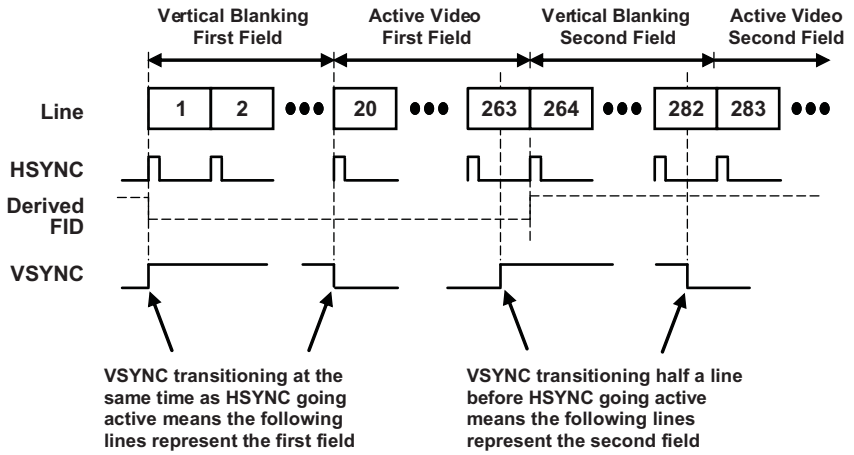
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.8 Rationale for FID Determination By VSYNC Skew

FID determination by VSYNC skew is a method for field ID determination derived from the analog NTSC and PAL interlaced specifications. Under this method, the sending device will not be providing a FID signal. NTSC has 525 total lines split between two fields. PAL has 625 total lines split between two fields. Each of these interlaced standards support an odd number of lines.

Let's consider just the 525 active line NTSC signal. For the sake of consistency, let's call Line 1 the first line of the 2-field pair and Line 525 the last line of the 2-field pair.

**Figure 12-103. Example of 525-line FID Determination By VSYNC Skew**



A waveform is shown in Figure 12-103. VSYNC is defined to go active at the same time as HSYNC for the first line of the first field in a two-field picture pair. For this first field, VSYNC will go inactive after Line 20.

For the second field, VSYNC will go active in the middle of Line 263 to signal that Line 264 is the start of a vertical blanking interval. When HSYNC for Line 264 arrives, coinciding with the vertical blanking interval for the beginning of the second field, VSYNC has already been active for half of Line 263. For the second field, VSYNC will go inactive midway through Line 282 to indicate that Line 283 is active video. When HSYNC for Line 283 appears, VSYNC has already been inactive for half a line.

By seeing whether VSYNC transitions at the beginning of a line or whether it transitions at the midway point of a line, one can determine whether the upcoming group of lines represents the first field or the second field. The derived FID is shown in dashed lines.

The analog NTSC specification defines the field ID changing part way into the vertical blanking. That is, the first few lines of vertical blanking belong to the previous field and the next several lines of vertical blanking belong to the upcoming field. The VIP Parser saves one channel of the entire vertical blanking interval between two active video fields into a single buffer. The hardware does not discriminate between whether the vertical blanking lines belong to the bottom of the previous field or those belonging to the start of the next field. This usage model is consistent with vertical ancillary data capture for embedded sync mode of operation.

Obviously, FID Determination by VSYNC skew cannot be used when framing does not use the VSYNC signal but rather relies on the ACTVID signal instead.

#### 12.2.8.2.5.9 ACTVID Framing

Instead of an HSYNC signal, the VIP Parser can use ACTVID framing as described in Figure 12-96. Under ACTVID Framing, VSYNC is used to separate vertical blanking lines from active video lines.

FID determination by VSYNC Skew is not allowed for ACTVID framing because there is no HSYNC input signal in this mode. Also, the VSYNC transition window is not employed. VSYNC is captured at the first pixel of each ACTVID grouping of pixels. Lines are separated by ACTVID transitioning inactive.

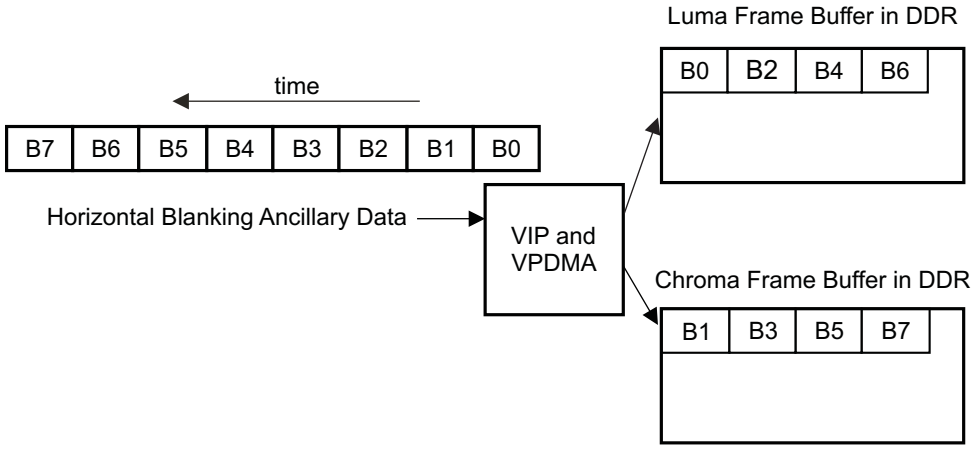
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.5.10 Ancillary Data Storage in Descrete Sync Mode

Ancillary data appearing in horizontal blanking is called Horizontal Blanking Ancillary Data. Ancillary Data in vertical blanking is called Vertical Blanking Ancillary Data.

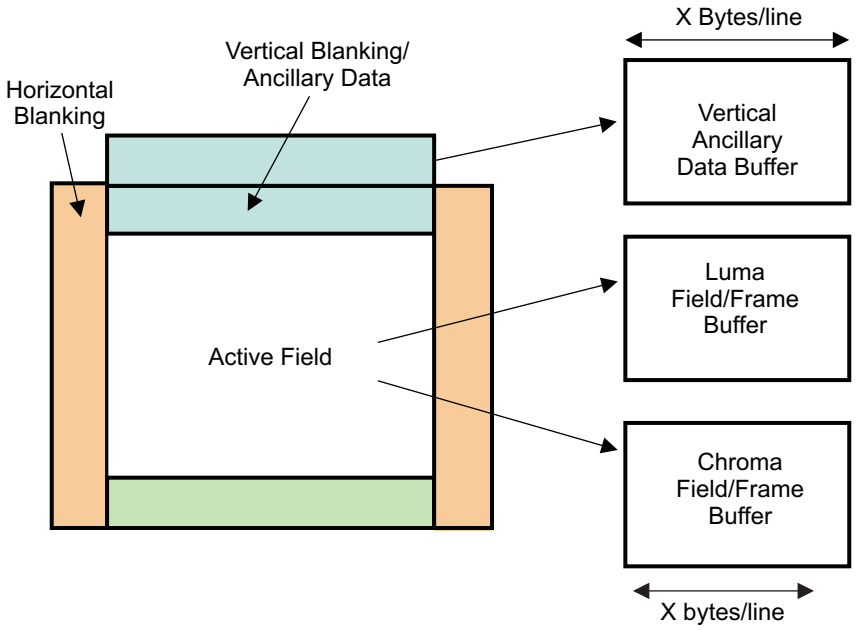
Horizontal Blanking Ancillary Data is not commonly used. For the ACTVID data valid mode described in Figure 12-95, there is no way to capture Horizontal Blanking Ancillary Data. Using the HSYNC mode in Figure 12-97, all blanking pixels are captured. However, the horizontal ancillary data is byte-by-byte distributed between the Luma and Chroma frame buffers. Chroma sited bytes are saved in the Chroma frame buffer and Luma sited bytes are saved in the Luma frame buffer. Some CPU effort would be needed in order to extract ancillary data from the desired Luma or Chroma channel frame buffers. Also, the video on each line starts after the horizontal blanking period. This situation is shown in Figure 12-104.

**Figure 12-104. Horizontal Ancillary Data Packing When HSYNC Used as Sync Signal**



With Interlaced source material, Vertical Blanking Ancillary data will be stored in a separate Vertical Ancillary Data Buffer as shown in Figure 12-105. The Channel from which vertical ancillary data is extracted is a configuration option. For an input image of x active pixels per line, each line of Vertical Blanking Ancillary Data will have x bytes. Unlike the horizontal case, the CPU parsing this Ancillary Data will see a contiguous section of Vertical Ancillary Data that is not intermixed with Video data.

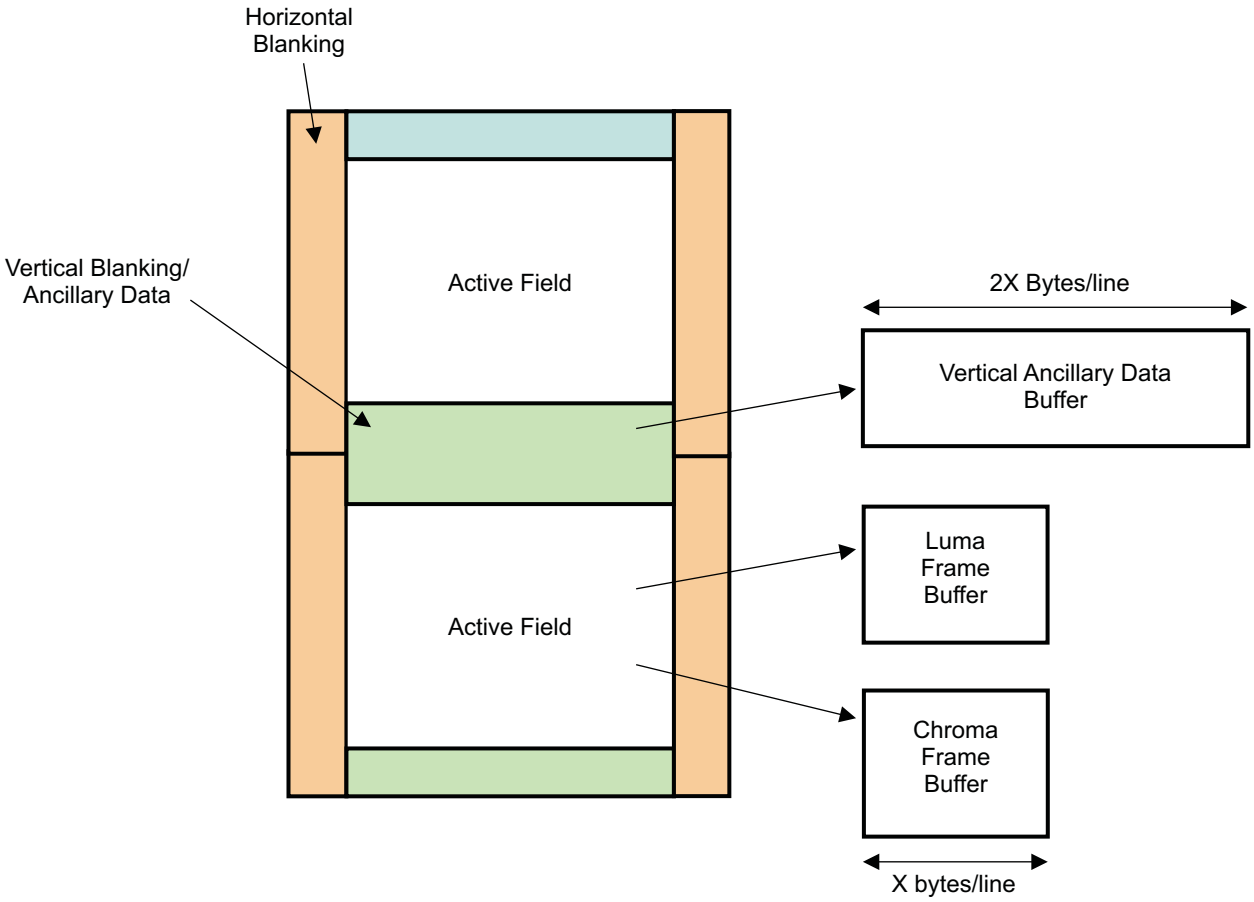
**Figure 12-105. Interlaced Field Vertical Blanking Ancillary Data Storage**



Copyright © 2011–2016, Texas Instruments Incorporated

For Progressive source video, the FIELD ID does not change. So, the Vertical Ancillary Data Buffer will contain all the information beginning from the vertical blanking of the previous frame. This situation is shown in Figure 12-106.

**Figure 12-106. Progressive Frame Vertical Blanking Ancillary Data Storage**

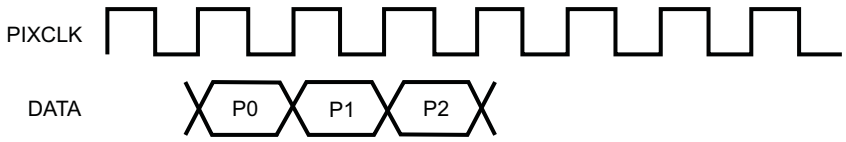


### 12.2.8.2.6 BT.656 Style Embedded Sync

#### 12.2.8.2.6.1 Data Input

Like Discrete Sync Input, Embedded Sync mode takes data from the 24b input bus. Input data can be 8, 16, or 24 bits wide. A sample is retrieved each and every Pixel Clock cycle. There is no valid signal gating data entry. Figure 12-107 shows a valid data sample each Pixel Clock period.

**Figure 12-107. Embedded Sync Data Entry**



#### 12.2.8.2.6.2 Sync Words

In embedded sync mode, code words are inserted into the stream at pixel clock rates. For external devices that send out 10 bits (single pixel interface) or 20 bits (parallel Y-Cb/Cr interface) of data, only the 8 (single pixel interface) or 16 (parallel 8bY-8bCb/Cr interface) most significant bits of each pixel are used.

Copyright © 2011–2016, Texas Instruments Incorporated

The key code words are Start of Active Video (SAV) and End of Active Video (EAV). Three flags are found in these code words: F (field), V (vertical sync), and H (horizontal sync). These flags signify the position in the frame corresponding to the data immediately following the codeword. The flags determine whether the code is EAV or SAV and where they lie in the picture. The first byte of the code word is 0xFF. The second and third bytes are 0x00. The bit ordering of the fourth byte is detailed in Table 12-55.

**Table 12-55. Fourth Byte of EAV/SAV Code Word**

| 7 (fixed) | 6 (F) | 5 (V) | 4 (H) | 3 (P3=V^H) | 2 (P2=F^H) | 1 (P1=F^V) | 0 (P0=F^V^H) | Description |
|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | SAV, Field 0, Active Video |
| 1 | 0 | 0 | 1 | 1 | 1 | 0 | 1 | EAV. Field 0, Horizontal Blanking |
| 1 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | SAV, Field 0, Vertical Blanking |
| 1 | 0 | 1 | 1 | 0 | 1 | 1 | 0 | EAV, Field 0, Horizontal Blanking in Vertical Blanking Region |
| 1 | 1 | 0 | 0 | 0 | 1 | 1 | 1 | SAV, Field 1, Active Video |
| 1 | 1 | 0 | 1 | 1 | 0 | 1 | 0 | EAV, Field 1, Horizontal Blanking |
| 1 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | SAV, Field 1, Vertical Blanking |
| 1 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | EAV, Field 1, Horizontal Blanking in Vertical Blanking Region |

An example of the input ordering of the embedded code word, followed by active video, is shown in Figure 12-108. The input data mode is 8 bits for the example.

**Figure 12-108. Code Word Format Example Followed by Video Data**

#### 12.2.8.2.6.3 Error Correction

The FVH flags are sent with four protection bits to support double error detection, single error correction. A non-correctable detected error is simply ignored. An option exists for the protection bits to correct a single bit error in the FVH flags. The correction table is shown in Table 12-56. n/c means that the error condition is detected, but it is non-correctable.

**Table 12-56. Error Correction Matrix**

| P3, P2, P1, P0 | F, V, and H Flags | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 000 | 001 | 010 | 011 | 100 | 101 | 110 | 111 |
| 0000 | 000 | 000 | 000 | n/c | 000 | n/c | n/c | 111 |
| 0001 | 000 | n/c | n/c | 111 | n/c | 111 | 111 | 111 |
| 0010 | 000 | n/c | n/c | 011 | n/c | 101 | n/c | n/c |
| 0011 | n/c | n/c | 010 | n/c | 100 | n/c | n/c | 111 |
| 0100 | 000 | n/c | n/c | 011 | n/c | n/c | 110 | n/c |
| 0101 | n/c | 001 | n/c | n/c | 100 | n/c | n/c | 111 |
| 0110 | n/c | 011 | 011 | 011 | 100 | n/c | n/c | 011 |
| 0111 | 100 | n/c | n/c | 011 | 100 | 100 | 100 | n/c |
| 1000 | 000 | n/c | n/c | n/c | n/c | 101 | 110 | n/c |

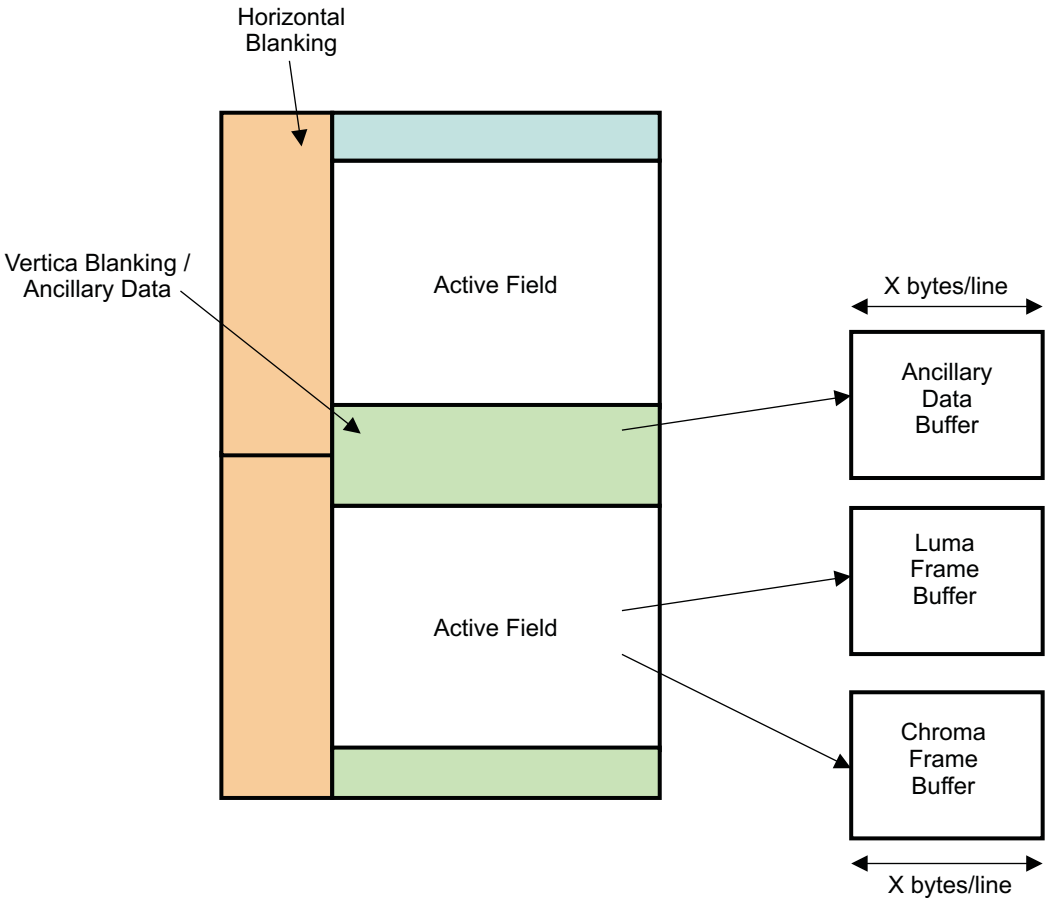
#### 12.2.8.2.6.4 Embedded Sync Ancillary Data

With Embedded Sync streams, only Vertical Ancillary Data can be extracted. The Vertical Ancillary Data buffer is the same width as the corresponding Luma and Chroma buffers. The channel from which Vertical Ancillary Data is extracted is a configuration option.

Horizontal Ancillary data cannot be extracted using embedded sync mode.

The Vertical Ancillary Data is captured starting from the end of the previous active video. See Figure 12-109 for a more detailed description of embedded sync packing.

**Figure 12-109. Embedded Sync Packing**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.6.5 Embedded Sync RGB 24-bit Data

YUV streams are separated into a planar Luma buffer, a planar Chroma Pair (CbCr) buffer, and a planar Vertical Ancillary Data buffer. RGB streams, on the other hand, are stored in a packed R-G-B format, as shown in Figure 12-110.

The BT.1120 standard defines a method of carrying RGB streams. After the SAV code, 8 bits of R, 8 bits of G, and 8 bits of B data are clocked in one cycle. A 24 bit data bus is required. The channel in which to search for the embedded sync codes and the FVH control code is determined by a configuration selection. Only vertical ancillary data from one channel (R, G, or B), which happens to be the channel where control codes are found, are captured. Vertical ancillary data in the other two channels are ignored.

**Figure 12-110. RGB Frame Storage**

#### 12.2.8.2.7 Source Multiplexing

##### 12.2.8.2.7.1 Multiplexing Scenarios

Some applications require multiple camera sources to be used at the same time. For example, video surveillance systems can record and display multiple camera sources. For this type of device, one solution would be to support N 8b or 16b data interfaces for each of N cameras. However, this solution does not efficiently minimize pin count. One set of 8b or 16b interfaces has the bandwidth to support more than one video source, depending on the resolution of the video. Table 12-57 is explanatory only and shows the number of sources that can be multiplexed in one VIP for 8b and 16b interface modes. Note that it does not reflect the capabilities of the VIP Parser design. In addition, the interface pixel clock rates are shown. The VPDMA limits 16 camera sources to be saved to DDR per Pixel Clock Input Domain.

**Table 12-57. Multiplexing Configurations and Pixel Clock Rates**

| | Max Channels In Single 16b Data Interface Mode | Max Channels In Dual 8b Data Interface Mode - Interleaved Channels per Single 8b Port. One 16b VIP can be configured to support two such 8b ports. | Interface Clock Rate (MHz) |
|---|---|---|---|
| HD Interlaced | 2 | 1 | 148.5 |
| D1 Interlaced | 8 | 4 | 108.1 |
| CIF Interlaced | n/a | n/a | n/a |
| HD Progressive | 1 | n/a | 148.5 |
| D1 Progressive | 4 | 2 | 108.1 |
| CIF Progressive (1) | 32 | 16 | 162.2 |

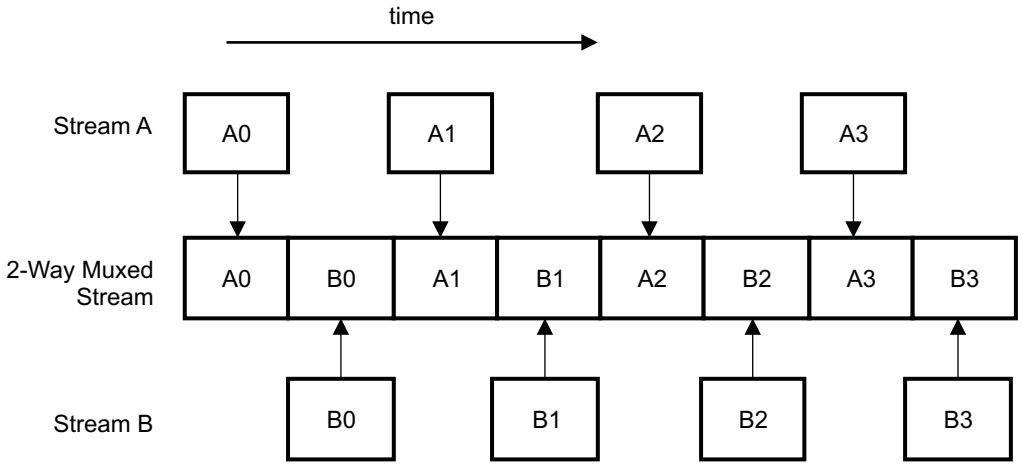
(1) Blanking pixels are not used in the CIF clock rate calculations. Addition of blanking pixels would require a slightly higher clock rate.

**NOTE:** These Channel Density values reflect 1 VIP subsystem.

##### 12.2.8.2.7.2 2-Way Multiplexing

For 2-Way Multiplexing, two embedded sync streams are interleaved a pixel at a time as shown in Figure 12-111.

**Figure 12-111. 2-Way Multiplexing**



The sync codeword, FF-00-00-XY, is replicated in both source streams. In 2-Way Multiplexing, the sizes of both camera sources must be the same. Likewise, the Vertical Ancillary Data size for both sources must be identical. However, the two streams are not necessarily sending the same pixel site in adjacent clock cycles.

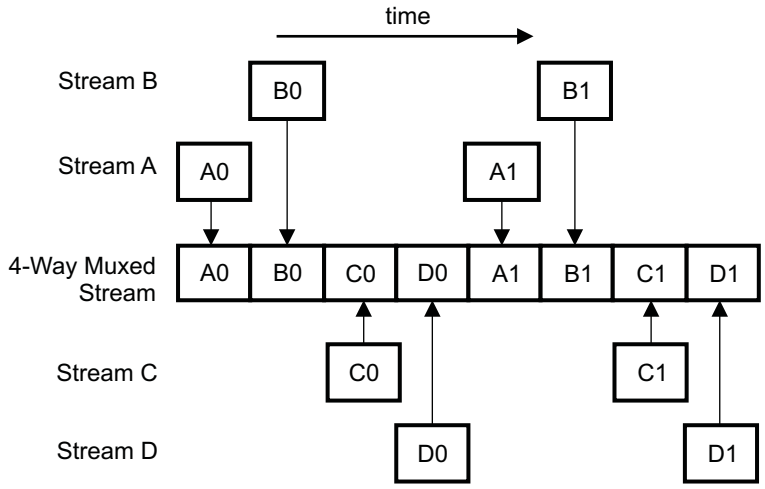
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.7.3 4-Way Multiplexing

For 4-Way Multiplexing, four embedded sync streams are multiplexed into one as seen in Figure 12-112.

Again, the sync codeword is in all four sources. Like 2-Way Multiplexing, the sizes of the four camera sources are the same and the sizes of the Vertical Ancillary Data regions are the same. The four streams are not necessarily sending the same pixel site in adjacent clock cycles.

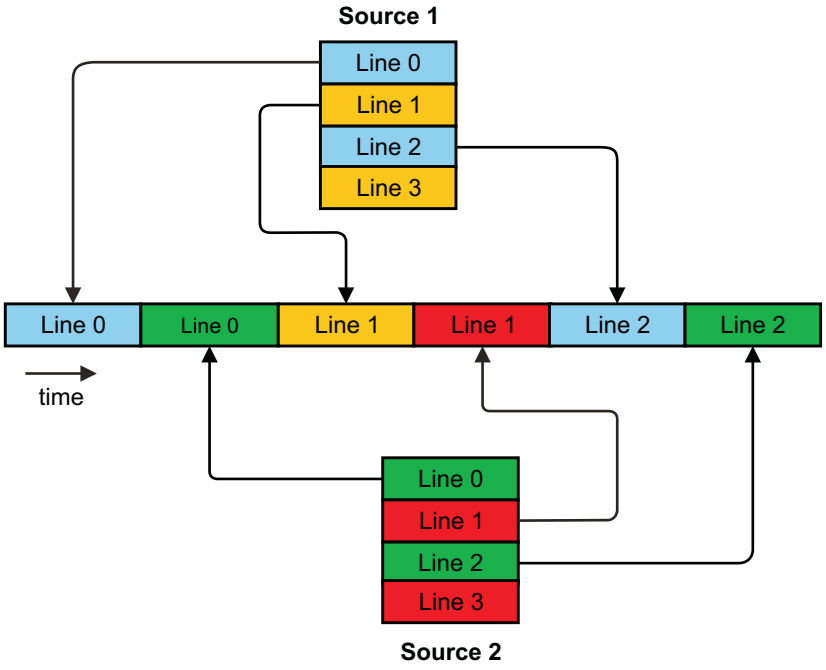
**Figure 12-112. Example of 4-Way Multiplexing**



#### 12.2.8.2.7.4 Line Multiplexing

In Line Multiplexing, n-different sources are sent into the VIP a complete line at a time using a modified version of embedded sync. An example of Line Multiplexing for two sources is shown in Figure 12-113.

**Figure 12-113. Example of Line Multiplexing**



The width and height of each source in Line Multiplexed data can be different. For instance, one source can be PAL while another one can be NTSC. A line is comprised of YUV422 pixels in repeating patterns of CbYCrY.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.7.5 Super Frame Concept in Line Multiplexing

Older TI DSPs do not natively support Line Multiplexing, which is thus far proprietary to the TVP5158 video decoder. When connected to older DSPs, the CPU must parse through the pixel data and in order to create frame buffers. Hence, the '5158 team came up with the concept of a super frame. Different camera sources are interleaved on a line-by-line basis. The beginning of each line carries a Metadata tag that provides key information about that line.

This Metadata tag is preceded by a SAV codeword in which F=0, V=0, and H=0. In other words, the older DSPs would see this line as a normal active video line.

At the end of the line, an EAV code is inserted with an appropriate number of padding pixels following it. This EAV code has F=0, V=0, and H=1.

In older DSPs, a set of like sized buffers are defined to store raw video frames. When a line's V bit changes, the current buffer is closed and an interrupt is given to the CPU. An empty buffer is used to store the incoming line's pixels. With the 5158's SAVs and EAVs having the V flag always set to 0, the older DSPs would never advance their buffer pointer.

Hence, there is a dummy vertical blanking line. The external device would insert an artificial vertical blanking line with a SAV having F=0, V=1, and H=0. It also inserts a dummy EAV with F=0, V=1, and H=1. This dummy line causes the older DSPs to change input buffer and signals the CPU to parse the captured data and build frame buffers.

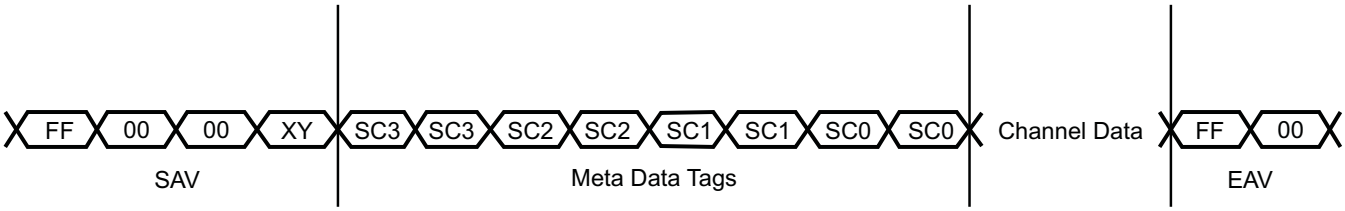
The startcodes used for the Metadata wrapped lines and the dummy lines form the Super Frame.

The dss_vip_parser has logic to parse out the super frame, analyze the Metadata tags, and frame buffer the line contents appropriately.

#### 12.2.8.2.7.6 8-bit Data Interface in Line Multiplexing

Figure 12-114 is an example of an 8-bit line multiplexing interface. Channel Data is the CbYCrY sequence representing a line. Preceding Channel Data is the four byte Meta Data tags. Note that the Meta Data bytes are replicated in both the Luma and the Chroma sites. The entire structure is bounded by a traditional SAV/EAV code in which the V flag is 0.

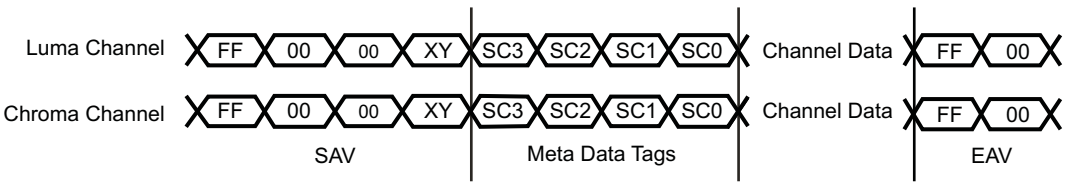
**Figure 12-114. 8-bit Line Mux Interface**



#### 12.2.8.2.7.7 16-bit Data Interface in Line Multiplexing

Figure 12-115 describes the 16-bit line multiplexing interface. Channel Data is the active line. All the Y pixels are in the Luma Channel. The CbCr pixels are in the Chroma Channel. Each cycle, a 16 bit value representing one Luma sample and one Chroma sample enters the VIP Parser. The Meta Data tags are replicated in both channels. Likewise, the SAV/EAV startcodes are found in both channels. The V flags for the SAV/EAV startcodes are always 0.

**Figure 12-115. 16-bit Line Mux Interface**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.7.8 Split Lines in Line Multiplex Mode

Suppose an external device is sending two dissimilar sources in Line Multiplex mode. One narrower source has X pixels per line. The wider source has 2X pixels per line. In an older DSP, the capture buffer for the Super Frame must be configured to be the width of the largest incoming line. So, lines from the narrower source would take up only half of the allocated space in the capture buffer resulting in wasted DDR memory space.

The Meta Data has provisions for the external device to split a line. The Beginning of Line (BOL) and End of Line (EOL) flags tag a split line as described in Table 12-58.

**Table 12-58. Split Line Table**

| BOL | EOL | Function |
|---|---|---|
| 0 | 0 | Undefined |
| 0 | 1 | Line Segment is the second half of a line |
| 1 | 0 | Line Segment is the first half of a line |
| 1 | 1 | Line has not been segmented into two. |

#### 12.2.8.2.7.9 Meta Data

Table 12-59 shows the bitfields in the Meta Data start codes.

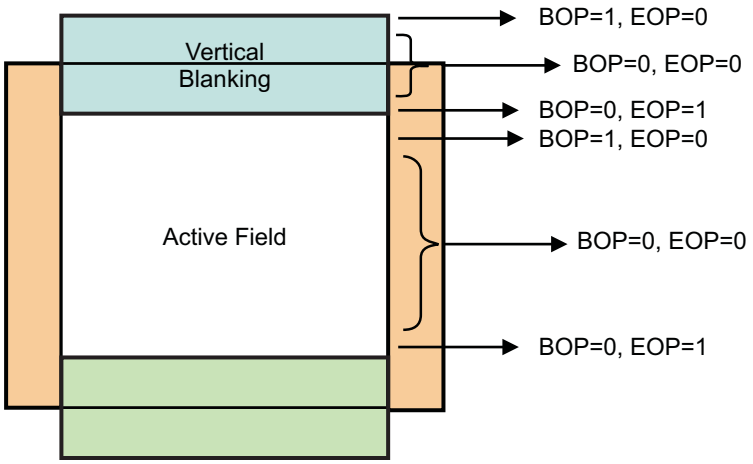
**Table 12-59. Meta Data Layout**

| Byte | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| SC3 | 1 | BOP | EOP | RSVD | CH_ID[3:0] | | | |
| SC3 | 1 | BOP | EOP | RSVD | CH_ID[3:0] | | | |
| SC2 | 0 | BOL | EOL | VDET | LINE_ID[10:7] | | | |
| SC1 | ~LINE_ID[6] | LINE_ID[6:0] | | | | | | |
| SC0 | PAD | F | V | H | P3 | P2 | P1 | P0 |

BOP tags the line as a startline in a period. A period is defined as the contiguous lines in a vertical blanking period or the contiguous lines in a field or frame. For the vertical blanking period case, the vertical blanking at the bottom of the previous field or frame combined with the vertical blanking at the top of the current field or frame is combined to create one period.

EOP tags the line as an endline in a period. Figure 12-116 shows the definition of the two types of Periods as outlined by BOP and EOP.

**Figure 12-116. BOP/EOP Definition of a Period**



Copyright © 2011–2016, Texas Instruments Incorporated

For the Split Line at the top of a Period, the BOP bit is set for both halves of the split line. Likewise, for the Split Line at the bottom of a Period, the EOP bit is set for both halves of the split line.

CH_ID is the channel ID, which tags the camera source that generated the incoming line. A maximum of 16 camera sources are support per Pixel Input Clock Domain.

LINE_ID is the line number, starting from 0 and incrementing by one for each subsequent line from the same source. The TVP5158 only supports SD sources or smaller, so only 9 bits of the line ID (bits 8:7) will be used by this external device.

PAD is a flag which tags the line as an artificially inserted padding line. When PAD is '0', the line should be discarded.

F, V, H, P3, P2, P1, and P0 are the bits representing the normal XY code. F is the Field ID associated with line, V signals when the line is in the vertical blanking, H specifies that the line is in the Horizontal Blanking, and P3:P0 are the protection bits.

Since only active video and vertical ancillary data lines are encapsulated in the Meta Data, the H bit in the SC0 byte should never be '1'.

#### *12.2.8.2.7.10 TI Line Mux Mode, Split Lines, and Channel ID Remapping*

The VIP Parser supports a maximum of 8 different Channel IDs per Port. The Channel IDs must be in the range {0:7} (3 bits). In the source multiplex, only one source can be a split line source and have the same Channel ID as one of the non-split line sources.

This scenario involves an external NTSC decoder which supports 8 D1 cameras. The external NTSC decoder will downscale the 8 sources to SIF format. However, one camera source will be sent in the multiplex as both the downscaled version and the original D1 sized version. They will both have the same Channel ID. However, the D1 version will be sent as a split-line. The source multiplex will thus have 9 maximum streams.

The dss_vip_parser, for TI Line Mux Mode only, will left shift the Channel ID by one. Bit 0 is used as an indicator whether the Source is a split-line source or a normal non-split line source. Only one of the nine inputs can be a split line source.

**Table 12-60. TI Line Mux Mode Channel ID Remapping**

| Source Input Channel ID | Channel ID Sent to VPDMA | |
|---|---|---|
| | Non-split Line | Split Line |
| 0x0 | 0x0 | 0x1 |
| 0x1 | 0x2 | 0x3 |
| 0x2 | 0x4 | 0x5 |
| 0x3 | 0x6 | 0x7 |
| 0x4 | 0x8 | 0x9 |
| 0x5 | 0xA | 0xB |
| 0x6 | 0xC | 0xD |
| 0x7 | 0xE | 0xF |

All subsequent references to the Camera Source, such as in a VPDMA return descriptor, will reference the remapped Channel ID.

The SrcIDx size status registers and the Source FID status registers reflect the remapped Channel ID when the port is in TI Line Mux mode.

#### 12.2.8.2.8 Channel ID Extraction for 2x/4x Multiplexed Source

##### 12.2.8.2.8.1 Channel ID Extraction Overview

For 2-way and 4-way multiplexed source, the Channel ID is either embedded in the four protection bits inside the EAV/SAV code words or in the horizontal blanking pixel data. A configuration setting determines where the VIP Parser would search for the Channel ID.

##### 12.2.8.2.8.2 Channel ID Embedded in Protection Bits for 2- and 4-Way Multiplexing

The four-bit channel ID is an identifier corresponding with the source number (camera) of the incoming video. As shown in Table 12-61, the Channel ID is placed in the code fourth byte of the EAV/SAV code words normally used for protection bits. With 4 bits, the maximum number of sources that can be defined in this range is 16. However, only Channel IDs in the range {0:7} are supported. Obviously, error correction cannot be performed on the FVH flags since the protection bits are no longer there.

**Table 12-61. Channel ID Embedded in EAV/SAV**

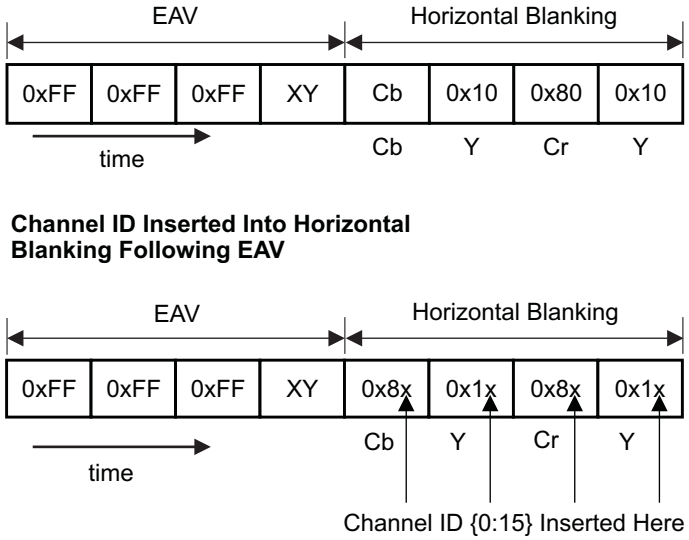
| 7 (fixed) | 6 (F) | 5 (V) | 4 (H) | 3 (ch_id[3]) | 2 (ch_id[2]) | 1 (ch_id[1]) | 0 (ch_id[0]) | Description |
|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 0 | 0 | Ch_id = {0:15} | | | | SAV, Field 0, Active Video |
| 1 | 0 | 0 | 1 | Ch_id = {0:15} | | | | EAV, Field 0, Horizontal Blanking |
| 1 | 0 | 1 | 0 | Ch_id = {0:15} | | | | SAV, Field 0, Vertical Blanking |
| 1 | 0 | 1 | 1 | Ch_id = {0:15} | | | | EAV, Field 0, Horizontal Blanking in Vertical Blanking Region |
| 1 | 1 | 0 | 0 | Ch_id = {0:15} | | | | SAV, Field 1, Active Video |
| 1 | 1 | 0 | 1 | Ch_id = {0:15} | | | | EAV, Field 1, Horizontal Blanking |
| 1 | 1 | 1 | 0 | Ch_id = {0:15} | | | | SAV, Field 1, Vertical Blanking |
| 1 | 1 | 1 | 1 | Ch_id = {0:15} | | | | EAV, Field 1, Horizontal Blanking in Vertical Blanking Region |

##### 12.2.8.2.8.3 Channel ID Embedded in Horizontal Blanking Pixel Data for 2- and 4-Way Multiplexing

In Horizontal Blanking and Vertical Blanking, non-ancillary data pixels should be Y=0x10 and Cb=Cr=0x80. When the Channel ID is embedded in the Horizontal Blanking for 2 and 4-way multiplexing, the lower nibbles of all Luma and Chroma pixels are replaced by the 4 bit Channel ID. This scenario is shown in Figure 12-117. The maximum number of values defined by this 4-bit range is $2^4$ = 16. However, only Channel IDs in the range {0:7} are supported.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-117. Channel ID Inserted Into Horizontal Blanking**



#### 12.2.8.2.9 Embedded Sync Mux Modes and Data Bus Widths

Legal combinations of Embedded Sync Mux Modes and Data Bus Widths are described in Table 12-62.

**Table 12-62. Valid Embedded Sync Mux Mode and Data Bus Width Combinations**

| | 1x Mux | 2x Mux | 4x Mux | Line Mux |
|---|---|---|---|---|
| 8 Bit | √ | √ | √ | √ |
| 16 Bit | √ | n/a | n/a | √ |
| 24 Bit | √ | n/a | n/a | n/a |

#### 12.2.8.2.10 Interrupts

The VIP parser provides one interrupt line to the HDVPSS. The source for this interrupt can be one or more of 22 events.

When an interrupt occurs and is determined to be from the VIP parser, VIP parser level of masks, clears, and status registers must be checked and updated first.

The VIP Parser Interrupt Mask, Interrupt Clear, and Interrupt Status register layout is shown in Table 12-63.

**Table 12-63. Register Layout**

| 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 |
|---|---|---|---|---|---|---|---|---|---|---|
| PrtB Disable Comple | PrtA Disable Complete | PrtB Anc ProtoVio | PrtB YUV ProtoVio | PrtA Anc ProtoVio | PrtA YUV ProtoVio | PrtB Src0Size | PrtA Src0Size | PrtB DisConn | PrtB Conn | PrtA Disconn |
| **10** | **9** | **8** | **7** | **6** | **5** | **4** | **3** | **2** | **1** | **0** |

Copyright © 2011–2016, Texas Instruments Incorporated

Table 12-64 describes each of the interrupts supported by the VIP Parser.

**Table 12-64. VIP Parser Interrupts**

| Interrupt | Description |
|---|---|
| PrtBDisableComplete | When Port B is disabled in the middle of the frame, this interrupt is activated when complete frame is sent out of Port B following disable. |
| PrtADisableComplete | When Port A is disabled in the middle of the frame, this interrupt is activated when complete frame is sent out of Port A following disable. |
| PrtBANCProtocolVio | This interrupt is enabled when the protocol checker on the output of the dss_vip_parser encounters a violation on the Ancillary VPI of Port B. |
| PrtBYUVProtocolVio | This interrupt is enabled when the protocol checker on the output of the dss_vip_parser encounters a violation on the Active Video VPI of Port B. |
| PrtAANCProtocolVio | This interrupt is enabled when the protocol checker on the output of the dss_vip_parser encounters a violation on the Ancillary VPI of Port A. |
| PrtAYUVProtocolVio | This interrupt is enabled when the protocol checker on the output of the dss_vip_parser encounters a violation on the Active Video VPI of Port A. |
| PrtBSrc0Size | The output size for Srcnum=0 on Port B differs from the SRC0_NUMLINES and SRC0_NUMPIX register settings |
| PrtASrc0Size | The output size for Srcnum=0 on Port A differs from the SRC0_NUMLINES and SRC0_NUMPIX register settings |
| PrtBDisConn | Port B Link Disconnect for Srcnum 0 |
| PrtBConn | Port B Link Connect for Srcnum 0 |
| PrtADisConn | Port A Link Disconnect for Srcnum 0 |
| PrtAConn | Port A Link Connect for Srcnum 0 |
| OpPrtBAnc | Overflow at Ancillary Data VPDMA interface for the Port B |
| OpPrtBYUV | Overflow at Luma VPDMA interface for Port B |
| OpPrtAAnc | Overflow at Ancillary Data VPDMA interface for the Port A |
| OpPrtAYUV | Overflow at Luma VPDMA interface for Port A |
| InPrtB | Overflow at Input Async FIFO for Port B |
| InPrtA | Overflow at Input Async FIFO for Port A |
| PrtBVdet | Video Detect Interrupt for Port B |
| PrtAVdet | Video Detect Interrupt for Port A |

- A ‘1’ in the Status register associated with an Interrupt source shows that the interrupt source is pending. The Status register is read-only. To clear a bit in the Status register, the associated bit in the Clear register must be written with a ‘1.’
- A ’1’ the bit position of the Mask register associated with an Interrupt source ensures that the hardware interrupt will never be passed on to the DSS interrupt controller. A ‘0’ in the bit position of the Mask register associated with an Interrupt source will cause the DSS interrupt controller to see a VIP Parser interrupt in the event the hardware in the parser triggers it.
- A ‘1’ in the bit position of the Clear register associated with an Interrupt source clears the hardware interrupt status register until the next time the hardware triggers it. After a Clear, the CPU should set the bit back to a ‘0.’ Otherwise, the hardware would not be able to set any subsequent interrupts of the same type.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.11 VDET Interrupt

For Line Multiplexing Embedded Sync mode only, the Meta Data Header includes a Video Detect (VDET) flag. The TVP5158 sets this VDET flag whenever NTSC or PAL sync is found. Some other external devices using Line Multiplexing mode may not use VDET. However, when VDET changes, a VDET interrupt is issued to the DSS interrupt controller. Each Pixel Clock Input Domain has a separate VDET interrupt.

The VDET status register is comprised of 32 bits, each bit representing the value of the VDET flag found in the Meta Data of the Channel ID. Bit 0 is the VDET value from Channel ID 0, Bit 1is is VDET value from Channel ID 1, etc. There is a separate status register for each Pixel Input Clock Domain.

In Line Mux mode, the meta-data field defining the srcnum is 5 bits wide. The TVP5158 spec only defines the last three bits of this field and the upper two bits are reserved. When set to ‘1’, the cfg_tvp5158_chan_id_type register tells the VIP Parser to ignore the top two bits of the field any only use the lower three bits, giving a maximum of eight srcnums. This bit should always be set to '1' in TI Line Mux mode.

#### 12.2.8.2.12 Source Video Size

These status registers provide the size of the last active video frame in 16 different input sources per port. There is no interrupt activated on the change in the source size in any of the input sources. These read-only registers only inform the application of the width and the height of the last active field or frame associated with each channel ID.

#### 12.2.8.2.13 Clipping

The source for the clipping feature can be either embedded sync or discrete sync. Embedded sync streams use 2 reserved codewords as sync codes, 0x00 and 0xFF. These sync codes define different regions in the incoming data. Discrete sync streams have no limitation on the allowed quantization values. All 8 bits, from 0x00 to 0xFF are legal quantization values.

Suppose the input is discrete sync and the device converts the discrete sync raw video into a embedded sync stream (by adding appropriate embedded sync headers) and stores it on the network or hard disk. In this case, the processor checks every raw video byte to ensure that the reserved 0x00 and 0xFF codewords are not used in the raw video before the stream is saved. Otherwise, when the stored stream is read back by some device as an embedded sync stream, illegal codes are found.

The hardware has the capability to clip illegal codewords into legal ones. This clipping is only needed for discrete sync sourced inputs to the HDVPSS VIP module.

Embedded sync sourced input streams do not need to be clipped as they are presumably already following the rules for embedded sync.

For the embedded sync interface, input values 0x00 and 0xFF are reserved for the sync detection, so these values cannot be used in the rest of the system. The VIP Parser supports one configuration bit that, when enabled, changes all 0x00 to 0x01 and 0xFF to 0xFE in the vertical ancillary data. Another configuration bit, when enabled, changes all 0x00 to 0x01 and 0xFF to 0xFE in the active video portion of the input picture.

Note that if the clipping is enabled for ancillary data, the post processing software will never be able to find a data packet sync header, since the 00-FF-FF sequence will be changed to 01-FE-FE.

For 24- bit YUV, clipping is done on each 8 bit channel. If data[23:16]==0xFF, the clipped value will be 0xFE. If data[23:16]==0x00, the clipped value will be 0x01. Likewise, clipping is done for data bit ranges 15:8 and 7:0

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.14 Current and Last FID Value

The FID values for the current field or frame are reported in the Status Registers. When a new field or frame enters, the current FID values are saved into the previous FID status registers and the new FID value is loaded into the current FID register

Following a reset, the previous and current FID status registers are set to '1.' The first two fields or frames are ignored. On the third input field or frame after a reset, the previous FID is loaded with the current FID ('1'), and the current FID is loaded with the actual FID. By the fourth field or frame after a reset, both the previous and current FID values should represent the values found in the input stream.

The FID values are reported for each camera source in both Pixel Input Clock Domains.

#### 12.2.8.2.15 Disable Handling

When the VIP port is used in single-channel embedded or discrete sync interface, output of the VIP can be connected to the scalar or other modules. When connected with these modules, it may be required to work on frame boundary or it may cause lock up without reset. This feature makes sure that VIP is always disabled at the frame boundary.

In a scenario, assume that the VIP Parser has been processing a single input stream. Then, VIP port is disabled by setting ENABLE to '0'. The VIP Parser will continue to output data downstream until it sends out an end frame pixel and the downstream module accepts the end frame pixel.

#### 12.2.8.2.16 Picture Size Interrupt

Each VIP port can be set up to trigger an interrupt if the picture size varies from a pre-programmed expected picture size. This interrupt is supported only for the Active Video portion of the input video and not for the Vertical Ancillary portion. Also this interrupt is only support for source number 0 in multi channel capture.

The interrupts are named PrtASrc0Size and PrtBSrc0Size. They are described in Table 12-64.

For Port A, the expected active video picture size values are programmed in SRC0_NUMLINES and SRC0_NUMPIX in the VIP_PARSER_xtra_port_a register. For Port B, the expected active video picture size values are programmed in SRC0_NUMLINES and SRC0_NUMPIX in VIP_PARSER_xtra_port_b register.

Note that the Picture Size Interrupt reflects the Active Video size going out of the VIP port. If cropping is enabled for Srcnum=0, the Picture Size is the post-cropped size.

#### 12.2.8.2.17 Ancillary and Video Data Cropping

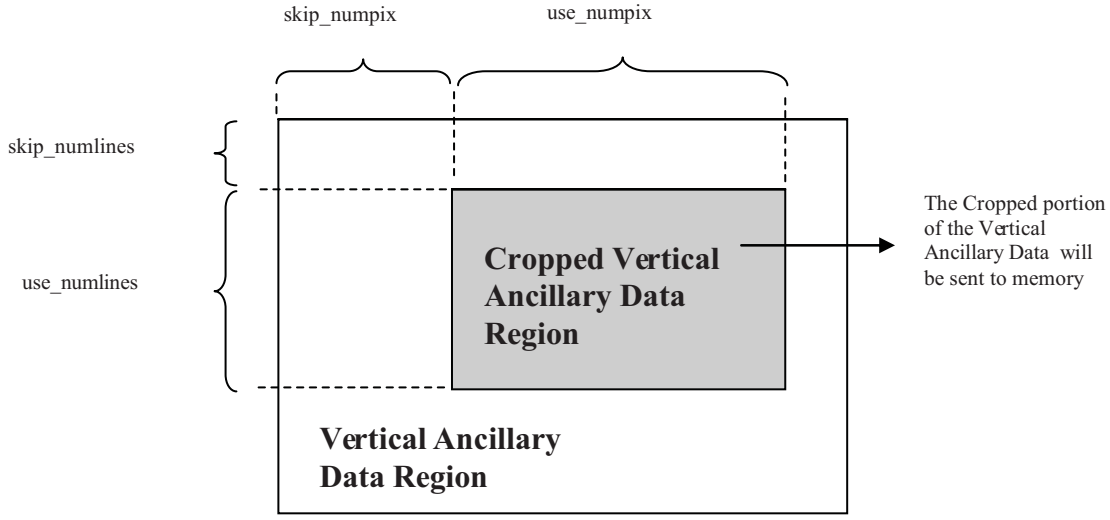
Each VIP port supports cropping of video and ancillary data. The size of the cropping window for video and ancillary data can be configured independently. This feature is supported for only one source number in a VIP port.

For the Vertical Ancillary Data from Port A, cropping is enabled by setting the ANC_BYPASS_N bit in VIP_PARSER_xtra2_port_a register. The Source Number from Port A that gets cropped is defined by the ANC_TARGET_SRCNUM in VIP_PARSER_xtra2_port_a register.

ANC_SKIP_NUMPIX, ANC_USE_NUMPIX, ANC_SKIP_NUMLINES, and ANC_USE_NUMLINES define the region of the selected Source Number that is cropped and sent to memory. The Vertical Ancillary Data Cropping region is described in Figure 12-118.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-118. Vertical Ancillary Data Cropping Region**

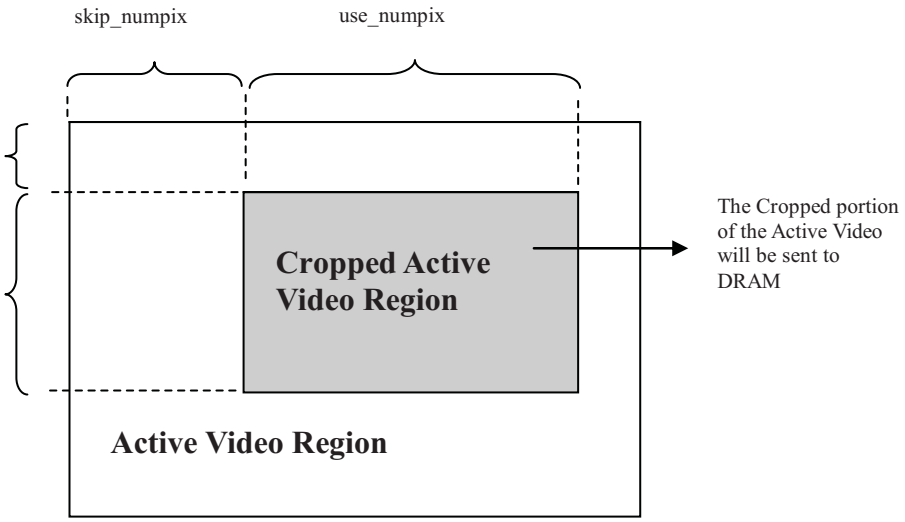


Note that when the VIP is configured to receive data over 8-bit interface, ancillary data from both Luma and Chroma can be captured by configuring ANC_CHAN_SEL_8b to '1x'. Thus, the number of data elements per line in this case is twice the equivalent number of Luma pixels per line. In other words, for this particular dual channel capture example, if there are 720 Luma pixels per line, then the total number of Vertical Ancillary Data Pixels in the source picture can be 2x720=1440 pixels.

For Active Video from Port A, cropping is enabled by setting the ACT_BYPASS_N bit in VIP_PARSER_xtra4_port_a register. The Source Number from Port A that gets cropped is defined by the ACT_TARGET_SRCNUM in VIP_PARSER_xtra2_port_b register.

ACT_SKIP_NUMPIX, ACT_USE_NUMPIX, ACT_SKIP_NUMLINES, and USE_NUMLINES define the region of the selected Source Number that is cropped and sent to memory. The Cropped Active Video region is described in Figure 12-119.

**Figure 12-119. Active Video Region**



Cropping for Port B works in a similar way to Port A. Since picture data is in 4:2:2 format, SKIP_NUMPIX and USE_NUMPIX must be evenly divisible by 2. If the output of vip_parser is sent to a 4:2:2 to 4:2:0 converter, then USE_NUMLINES must also be evenly divisible by 2.

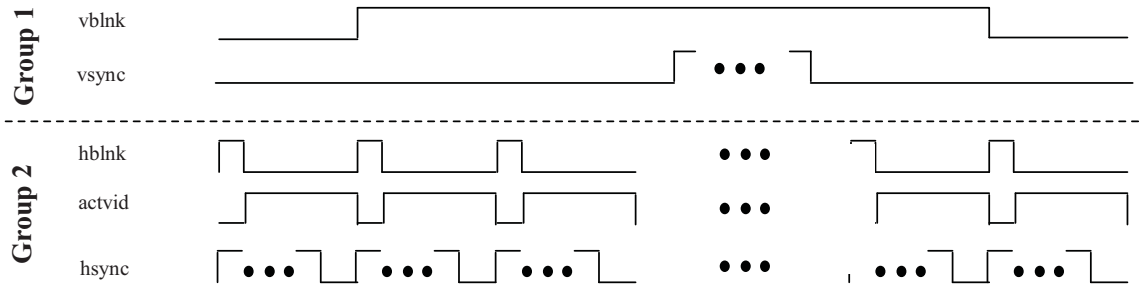
#### 12.2.8.2.18 Discrete Sync Signals

External ICs generally produce discrete sync interface signals seen in Figure 12-120.

**Figure 12-120. Discrete Sync Interface Signals**



**vbnk** represents the vertical blanking interval. Generally, vertical blanking is at the top of a NTSC/PAL field. In certain standards, the last few lines of a field or frame are in vertical blanking in addition to the beginning few lines in the following field or frame.

v**sync** is the vertical sync indicator. vsync is active during a portion of the vertical blanking. Generally, vsync is defined to transition from inactive to active sometime during vertical blanking. This signal then transitions to an inactive state before the end of vertical blanking. Certain standards define the line numbers where vsync transitions.

**hblank** is the horizontal blanking interval for each line. The horizontal blanking is the same number of pixels whether the line is in the active video region or in the vertical blanking region of the scan.

**actvid** is the region of a line that is active video. It is exactly inverse of the hblank signal. The number of pixels in the actvid region is the same for a line in vertical blanking as a line in active video.

**hsync** transitions from inactive to active for the first pixel of each line, which is a horizontal blanking pixel. hsync will transition to the inactive state before the end of the line.

**Group 1** signals define the vertical separation between fields or frames. Group 2 signals define the separation between lines. Note that the VIP module defines three discrete sync control signals: Actvid, Hsync, and Vsync. One of the Group 1 signals can be tied to the Vsync input. The Actvid signal from Group 2 is tied to the Actvid input. One of the other two Group 2 signals, hblank or hsync, can be tied to the Hsync input.

**USE_ACTVID_HSYNC_N** defines whether the line separation method uses the signal from the ACTVID or the HSYNC input of the VIP module. DISCRETE_BASIC_MODE determines whether discrete sync works as described in Section 12.2.8.2.5.1. In summary, choose one signal from Group 1 and one signal from Group 2. There should be a way to capture the external data.

Copyright © 2011–2016, Texas Instruments Incorporated

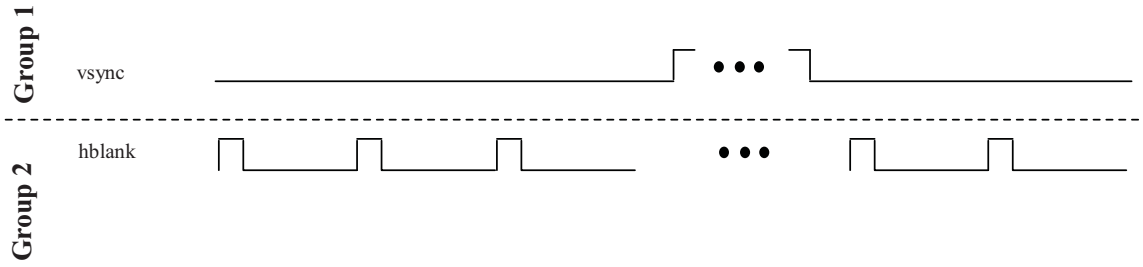
#### 12.2.8.2.18.1 vsync and hblank Input Signals

Figure 12-121 shows vsync from Group 1 and hblank from Group 2 being used. Set USE_ACTVID_HSYNC_N='0' and DISCRETE_BASIC_MODE='1'.

Also, since VIP is not aware of vertical blanking interval start and end, all lines, including both vertical ancillary and active video, will appear in the memory. Lines starting after an inactive to active transition on vsync will delineate a start of frame. Every data element on the Pixel clock's active edge will be stored in the Active Video Buffer.

Note that the vsync signal cannot transition active on the same cycle that hsync transitions active for fast pixel clock rates, since a system clock cycle is needed to insert a new frame indicator into the frame buffer.

**Figure 12-121. vsync and hblank Input Signals**

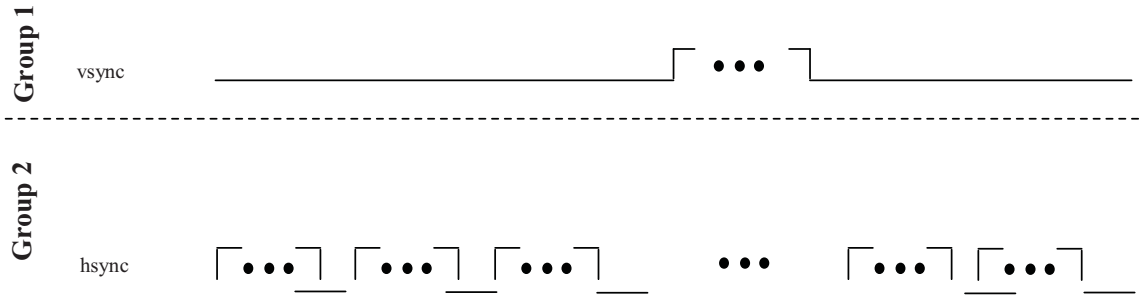


#### 12.2.8.2.18.2 vsync and hsync Input Signals

Figure 12-122 shows vsync from Group 1 and hsync from Group 2 being used. Set USE_ACTVID_HSYNC_N='0' and DISCRETE_BASIC_MODE='1'. Since the VIP is not aware of when VBI data starts and ends, all lines, including both vertical ancillary and active video, will appear in the memory. Lines starting after an inactive to active transition on vsync will delineate a start of frame. Every data element on the Pixel clock's active edge will be stored in the Active Video Buffer. Note that this scenario is the same as the vsync and hblank.

Like the vsync and hblank case, it also holds true that the vsync signal cannot transition active on the same cycle that hsync transitions active for fast pixelclock rates since a system clock cycle is needed to insert a new frame indicator into the framebuffer.

**Figure 12-122. vsync and hsync Input Signals**



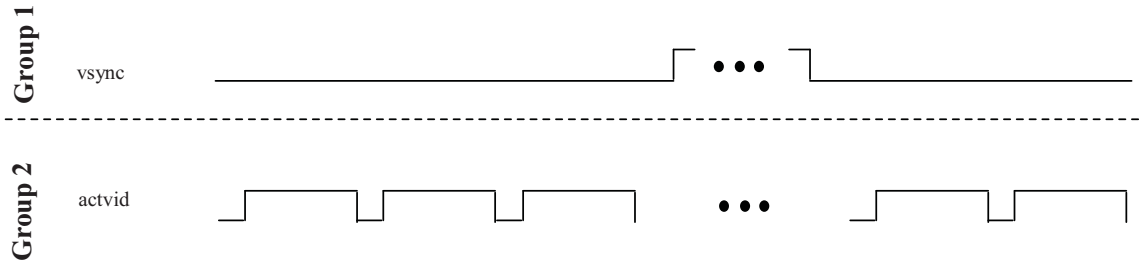
Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.18.3 vsync and actvid Input Signals

Figure 12-123 shows vsync from Group 1 and actvid from Group 2 being used. Set USE_ACTVID_HSYNC_N='1' and DISCRETE_BASIC_MODE='1'. Again, since VIP is not aware of when VBI data starts and ends, all lines, including both vertical ancillary and active video, will appear in the memory. Lines starting after an inactive to active transition on vsync will delineate a start of frame. Lines are denoted by an inactive to active transition of actvid. Pixel will be saved only when actvid is active.

Note that vsync must transition active between the actvid delineated data. vsync cannot transition active when actvid is active.

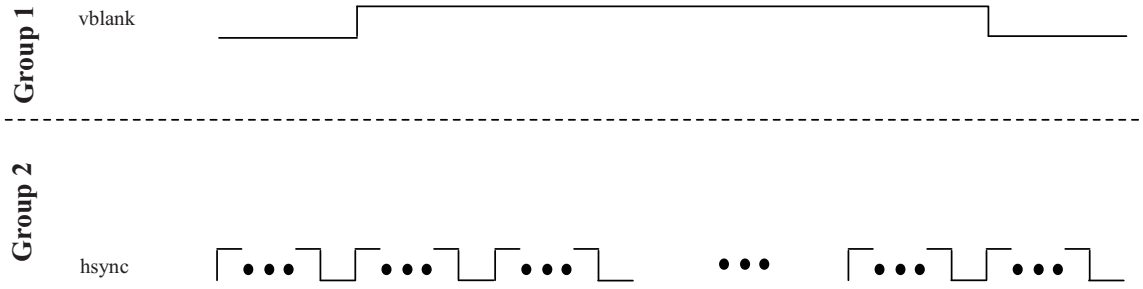
**Figure 12-123. vsync and actvid Input Signals**



#### 12.2.8.2.18.4 vblank and hsync Input Signals

Figure 12-124 shows vblank from Group 1 and hsync from Group 2 being used. In this scenario, set USE_ACTVID_HSYNC_N='0' and DISCRETE_BASIC_MODE='0'. Again, since VIP is aware of the start and end of vertical blanking interval start and end, vertical ancillary and active video data will appear in different memory buffers. Lines starting from inactive to active transition on vblank will delineate a start of the frame. When vblank is active, all data elements on pixel clock's active edge will appear in ancillary data buffer and when vblank is inactive, all data elements on pixel clock's active edge will appear in video data buffer.

**Figure 12-124. vblank and hsync Input Signals**

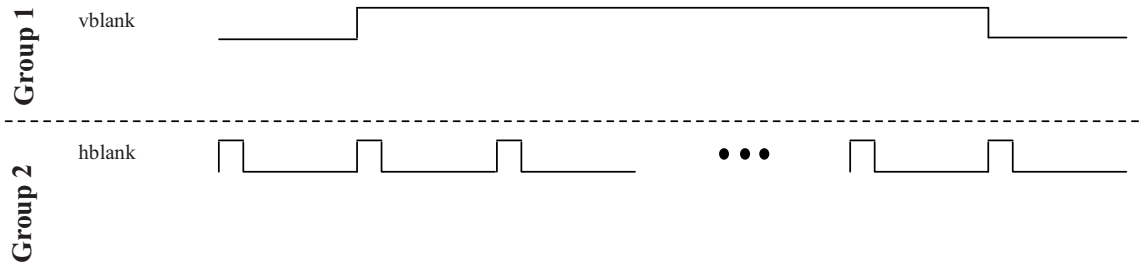


Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.18.5 vblank and hblank Input Signals

Figure 12-125 shows the vblank from group1 and hblank from group2 signals being used. In this case, set USE_ACTVID_HSYNC_N='0' and DISCRETE_BASIC_MODE='0'. Again, since VIP is aware of the start and end of vertical blanking interval start and end, vertical ancillary and active video data will appear in different memory buffers. Lines starting from inactive to active transition on vblank will delineate a start of the frame. When vblank is active, all data elements on pixel clock's active edge will appear in ancillary data buffer and when vblank is inactive, all data elements on pixel clock's active edge will appear in video data buffer.

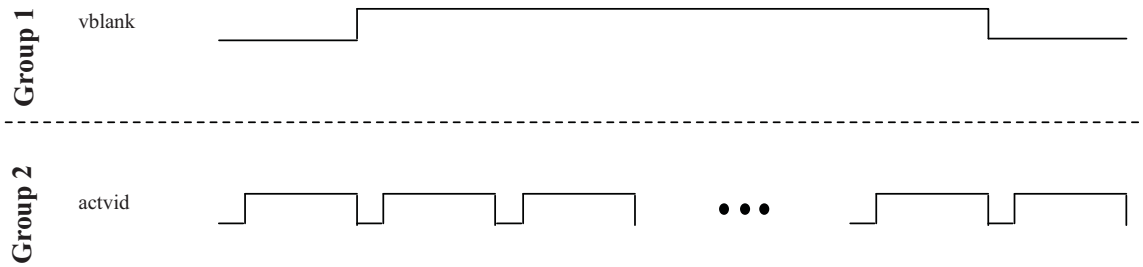
**Figure 12-125. vblank and hblank Input Signals**



#### 12.2.8.2.18.6 vblank and actvid Input Signals

Figure 12-126 shows vblank from Group 1 and actvid from Group 2 being used. Set USE_ACTVID_HSYNC_N='1' and DISCRETE_BASIC_MODE='0'. Again, since VIP is aware of the start and end of vertical blanking interval start and end, vertical ancillary and active video data will appear in different memory buffers. Lines starting from inactive to active transition on vblank will delineate a start of the frame. When vblank and actvid are active, all data elements on pixel clock's active edge will appear in ancillary data buffer and when vblank is inactive and active is active, all data elements on pixel clock's active edge will appear in video data buffer.

**Figure 12-126. vblank and actvid Input Signals**

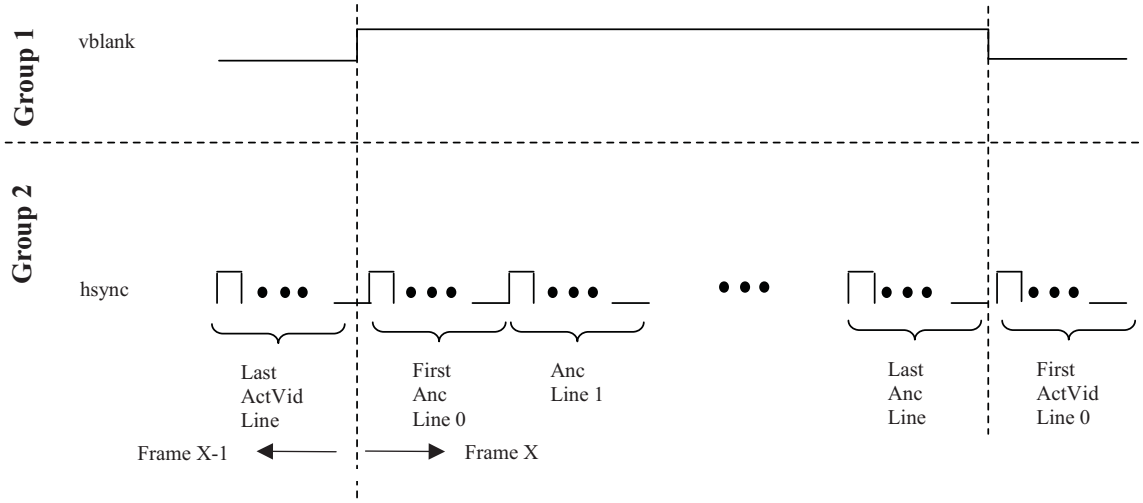


Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.8.2.18.7 Line and Pixel Capture Examples

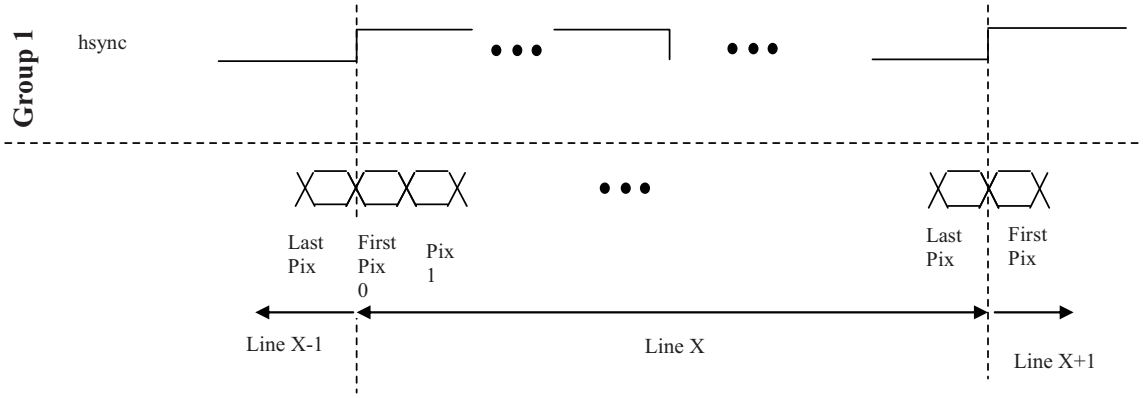
When DISCRETE_BASIC_MODE = '0', vblank is used. All the lines where the start of line is under an active vblank are sent to the Ancillary Data buffer. All the lines where the start of line is not under an active vblank are sent to the Active Video framebuffer. This situation is shown in Figure 12-127.

**Figure 12-127. Line and Pixel Capture, vblank and hsync**



The start of line is the pixel represented by the inactive to active transition on Hsync when USE_ACTVID_HSYNC_N = '1'. Figure 12-128 illustrates the delineation of a line when using USE_ACTVID_HSYNC_N = '1.'

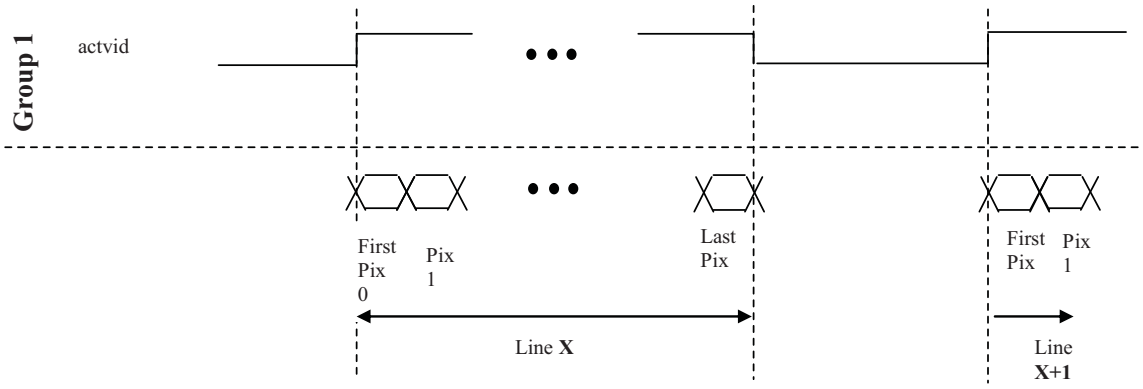
**Figure 12-128. Line and Pixel Capture, hsync**



Copyright © 2011–2016, Texas Instruments Incorporated

The start of line is the pixel represented by the inactive to active transition on actvid when USE_ACTVID_HSYNC_N = '0.' Note that actvid stays active for the entire duration of active video portion of the line. This scenario is shown in Figure 12-129.

**Figure 12-129. Line and Pixel Capture, actvid**



In 8-bit mode, note that the 4:2:2 YUV input color component order is Cb, Y followed by Cr and Y. For 16 and 24-bit input modes, all the components are sent in the same cycle.

#### 12.2.8.2.19 VIP Overflow Detection and Recovery

It is possible that an overflow can occur in the VIP_PARSER. Overflow detection is determined by reading the VIP_PARSER_fiq_status register and checking for bits 8, 7, 5, 4, 3 and 2. If video is being captured, and any of these bits are set, it indicates that not all of the incoming video data was sent to DDR. VIP Overflow can be caused by one of the following:

1. External pixel clock is faster than processing clock
2. DDR bandwidth is temporarily over-consumed
3. VIP scaler is being used inline with external video input, and is upscaling.
   - VIP scaler in this use case can only be used for downscaling
4. VIP scaler is being used inline with external video input, but has not been configured with scaler coefficients
   - VIP scaler will not accept video input if it is not first configured with scaler coefficients. This will cause overflow
5. VIP scaler is being used inline, but has not been enabled
6. External cables are connected or disconnected while the system is running, resulting in corrupted video streams going into the VIP
7. Bad external video cable, which causes corrupted video streams going into the VIP

Items 6 and 7 are typically seen as noise events, where it is likely that multiple horizontal syncs per line and/or multiple vertical syncs per frame will be observed. These result in high peak throughput requirements, leading to DDR bandwidth being temporarily over-consumed, and thus VIP overflow.

The high level recovery method for VIP Overflow on port a is outlined below. Port b is similar :

1. Set yuv_srcnum_stop_immediately = 0xFFFF_FFFF
2. Set anc_srcnum_stop_immediately = 0xFFFF_FFFF
3. Set ENABLE = 0
4. Set CLR_ASYNC_FIFO_RD and CLR_ASYNC_FIFO_WR to 1
5. Set SW_RESET to 1
6. Reset Other VIP modules
   - Write 1 to either bit 16 or bit 17 (depending on VIP0 or VIP1) of the clkc_rst register
7. Abort VPDMA channels
   - Write to list attribute to stop list 0
   - Write to list address register location of abort list
   - Write to list attribute register list 0 and size of abort list
8. Set SW_RESET to 0
9. Un-reset Other VIP modules
   - Write 0 to either bit 16 or bit 17 (depending on VIP0 or VIP1) of the clkc_rst register
10. (Delay)
11. SC coeff downloaded (if VIP_SCALER is being used)
12. (Delay)
13. Set yuv_srcnum_stop_immediately = 0x0000_0000
14. Set anc_srcnum_stop_immediately = 0x0000_0000
15. Set ENABLE = 1
16. Set CLR_ASYNC_FIFO_RD and CLR_ASYNC_FIFO_WR to 0

### 12.2.9 De-Interlacer (DEI) Module

The de-interlacer (DEI) module is used to generate progressive data output from interlaced input format (also known as, deinterlacing).

#### 12.2.9.1 Features

- Motion-adaptive deinterlacing
  - Supports 4-field Motion detection
  - Motion sensitivity adaptive to the frequency of luma texture
- Edge-Directed Interpolation (EDI)
  - Edge detection using luma pixels in a 2x7 window
  - Half-pixel resolution edge vectors
  - Edge-directed luma and chroma interpolation
  - Soft-switch between edge directed interpolation and vertical interpolation depending on the confidence factor
- Film Mode Detection (FMD)
  - 3-2 pull down detection
  - 2-2 pull down detection
  - Hysteresis controls how fast FMD can enter/exit film mode (software function)
- Bad Edit Detection (BED)
- The module can pass the inputs data directly to the outputs in a bypass configuration. No internal processing is performed.

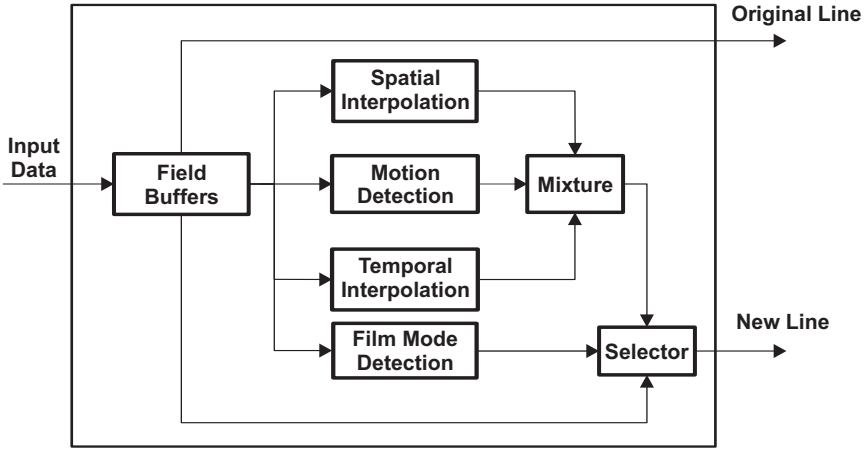
#### 12.2.9.2 Functional Description

The following figure illustrates the block-diagram of motion-adaptive Deinterlacer. The general concept behind motion adaptive deinterlacing is that spatial filtering works very well for images with motion, while temporal filtering works very well for static images. So, the intuitive way is to combine them together. Motion detection is used to switch or fade between the use of spatial deinterlacing and temporal deinterlacing, as shown in the following formula.

$$\hat{y}(j, i, n) = \alpha y_{spat}(j, i, n) + (1 - \alpha) y_{temp}(j, i, n)$$

where $y_{spat}(j, i, n)$ is the spatial interpolation output, $y_{temp}(j, i, n)$ is temporal interpolation output, $\alpha$ is the motion detection output ranging from 0 to 1, $\hat{y}(j, i, n)$ is the final output from deinterlacer, and j, i, n are the vertical, horizontal, and temporal indexes, respectively. From the previous formula, the final output is controlled by the motion detector output, $\alpha$. The higher the motion, the higher value of $\alpha$, and the output favors spatial interpolation. If the motion is absent or very low, the temporal interpolation has higher weight.

**Figure 12-130. Block Diagram of Motion-Adaptive Deinterlacer**



Copyright © 2011–2016, Texas Instruments Incorporated

Temporal interpolation can be disabled by programmable control registers. In that case we have:

$\hat{y}(j, i, n) = y_{spat}(j, i, n)$

Chroma interpolation is handled in the same manner as luma with regards to the above equations. There is a separate control for disabling temporal interpolation for chroma, such that luma can perform the full mixture, and chroma can only be spatial. If luma temporal interpolation is disabled, chroma temporal interpolation is also disabled.

The Figure 12-130 provides a simple description of how a motion-adaptive deinterlacer operates. The actual interpolation used is edge directed interpolation. Edge directed interpolation is only performed spatially prior to the output mixing.

#### 12.2.9.2.1 Modes of Operation

The DEI can be operated in bypass mode and deinterlacer mode.

##### 12.2.9.2.1.1 Bypass Mode

In the bypass mode, input luma and chroma are buffered and sent to the stage after DEI without processing.

To set DEI in the bypass mode, the bypass bit must be set accordingly in the configuration register.

##### 12.2.9.2.1.2 Film Mode Detection (FMD)

Film mode detection is performed by both hardware and software. In every field, the hardware accumulates difference between two neighboring frames (two top fields or two bottom fields), difference between two adjacent fields, and combing artifact. At the end of DEI data processing, an interrupt will be sent to the processor. The processor needs to read three status registers from DEI, calculate whether the film mode has been entered or existed, and update film mode lock and jam direction (fmd_cfg0) MMR of DEI before the next field starts. Since it is a time sensitive processing, the FMD interrupt has to be a high priority interrupt to the processor.

Film mode detection can be performed on a full picture size or a smaller window specified by a few MMR registers. The interrupt is always asserted at the end of the entire DEI data processing and is not affected by the window size and location.

Implementing film mode detection algorithm in software allows more flexibility at the cost of timing critical interface between DEI and the processor. For example, customers may find later that supporting 3-2-2-3 pull down is needed. This feature can be easily added by upgrading only the FMD software.

FMD feature is supported by the DEI module. More details about FMD mode, they are discussed in the DEI_H section.

See the appendix for configuration details on FMD.

##### 12.2.9.2.1.3 Deinterlacer Mode

In the deinterlacer mode, DEI takes in alternative field YUV data and sends out a sequential frame YUV data by interpolation techniques mentioned below.

DEI supports four interpolation modes when converting interlaced pictures to progressive pictures.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.9.2.2 Modes of Interpolation

##### 12.2.9.2.2.1 Interpolation Mode 0

In mode 0, the interpolated field is created by simple line averaging from the original YUV data. That is, the interpolated line is created by averaging its top and bottom line. Setting of MDT mode has no effect on output pictures.

##### 12.2.9.2.2.2 Interpolation Mode 1

In mode 1, the interpolated field is created by averaging pixels from fields before and after the current field. In other words, if the current field is a top field, the interpolated bottom field picture is created by averaging pixels from bottom field pictures before and after the current field. MDT setting has no effect on the result.

##### 12.2.9.2.2.3 Interpolation Mode 2 (EDI)

Mode 2 is an edge assisted interlace mode with edges detected from the luma information of a 2 × 7 (H × W) frame window. It detects seven possible edges between 45 and 135 degrees. Edges with slopes greater than 135 degrees are treated as 135 degree lines, and edges with slopes less than 45 degrees are treated as 45 degree lines.

Luma for missing lines are interpolated using original luma along the detected edge.

Motion value (MV) from the MDT module is used to select coefficients from a look up table on how 2D interpolation from the current field and 3D interpolation from two fields adjacent to the current fields are blended. The way to perform blending for chroma is slightly different than for luma, because the MV is based on luma and extra care needs to be taken when blending is applied to chroma.

At this mode, edge-directed interpolation is applied to luma only. Vertical interpolation is performed for chroma data.

##### 12.2.9.2.2.4 Interpolation Mode 3 (EDI)

The edge detection method used in this mode is similar to interpolation mode 2. The only difference is that the edge-directed interpolation is performed on both Luma and Chroma. Chroma is interpolated similarly according to the edge vectors obtained based on luma information. The reason chroma is interpolated slightly different is because of the down-sampled chroma data.

#### 12.2.9.2.3 Motion Detection (MDT)

Motion values from the MDT module are calculated only based on luma information. The motion value is used to determine how 2D and 3D interpolated results should be blended. The motion value is also used in the Film Mode Detection (FMD) module to determine field and frame differences between frames, which are in turn used in film mode detection.

The motion detection module in DEI supports 4-field mode.

Motion value (MV) is first estimated from y_f0 and y_f2 (current and two field delayed Y). The max value of MV and one field delayed data of MV, MV_f1, is used to create the overall MV per pixel. Since this motion detection method utilizes three fields of luma data and one field delayed MV, it is called 4-field mode as MVs come from four fields of luma data.

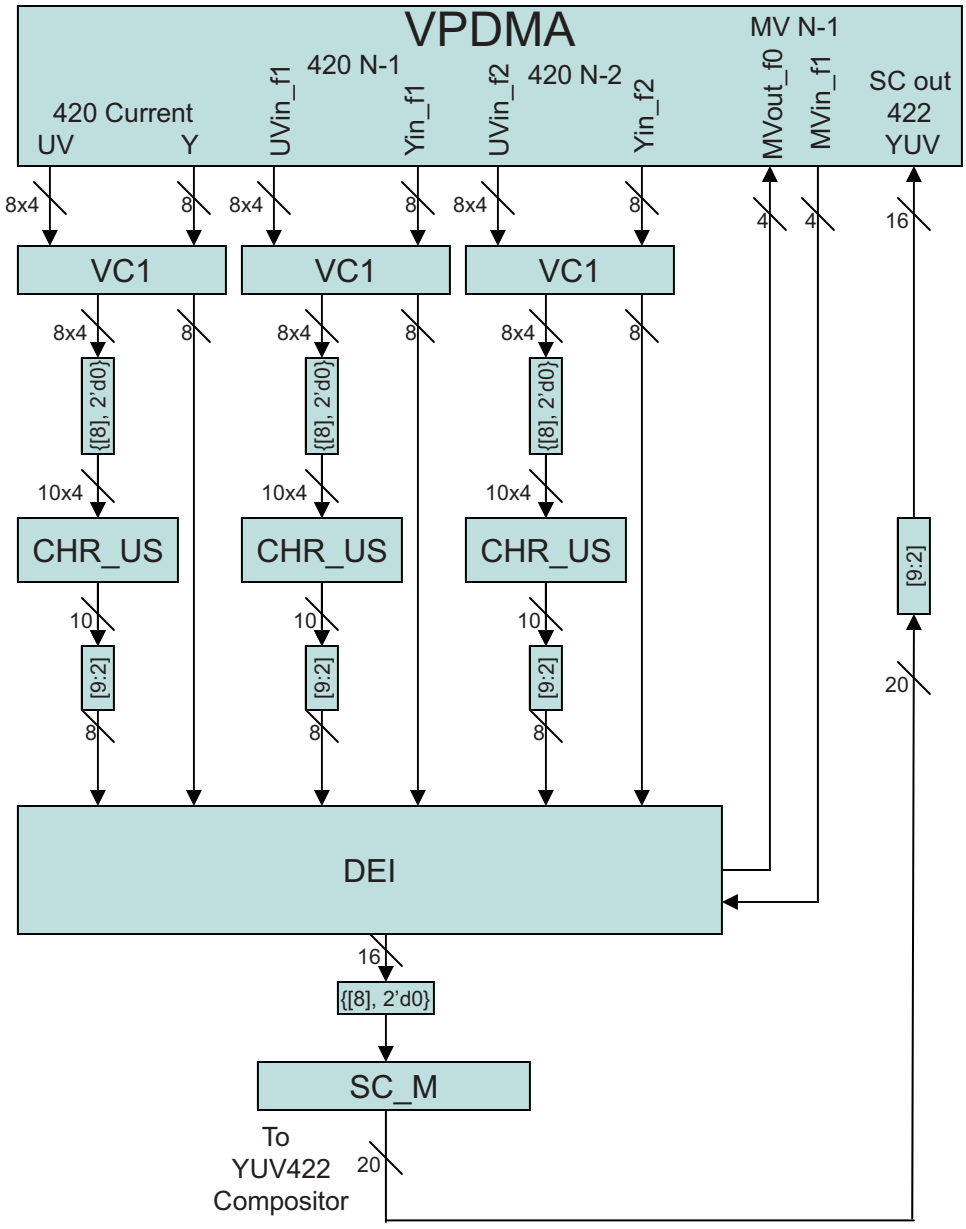
There is one field delay between the YUV inputs and the YUV outputs. The “current_field” that the interpolator works on is the YUV_f1 data.

#### 12.2.9.2.4 Data Buffer Management

VPDMA is used to transfer the data in and out of DEI as shown in the following figure.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-131. VPDMA Transfer Ports**



The following are the VPDMA ports (from DEI to memory) available:

- Inputs
  - Current (N)
    - Y (current Luma)
    - UV (current Chroma
  - One field delay (N-1)
    - Yin_f1 (1-field delayed Luma)
    - UVin_f1 (1-field delayed Chroma)
    - MVin_f1 (1-field delayed Motion Vectors)
  - Two field delay (N-2)
    - Yin_f2 (2-field delayed Luma)
    - UVin_f2 (2-field delayed Chroma)

Copyright © 2011–2016, Texas Instruments Incorporated

- Outputs
  - Current
    - Scalar output (422 interleaved output from scalar)
    - MVout_f0 (Motion vectors)

In the previously listed ports, except Y and UV (current) and Scalar output (current) (referred to as main data), all the other ports directly interact with DEI through VPDMA and are referred to as auxiliary data for DEI module. All the Y and UV ports in auxiliary data require 8 bits/pixel while MV port requires 4 bits/pixel.

#### 12.2.9.2.4.1 4-field MDT-based Interpolation Mode

In this mode, the required external memories are three fields of Luma input, three fields of chroma input, and two fields of 4-bit MV.

- Inputs
  - Y
  - UV
  - Yin_f1
  - Yin_f2
  - UVin_f1
  - UVin_f2
  - MVin_f1
- Outputs
  - MVout_f0
  - Output Scalar

**Figure 12-132. Auxiliary Data**

### 12.2.9.3 Interrupts

The following two interrupts are generated by the module.

**Table 12-65. Module Interrupts**

| Interrupt | Description |
|---|---|
| dei_fm_int | Interrupt indicating film mode is enabled and software needs to read Film Mode statistics registers and update the Film Mode lock and jam direction configuration registers. This is required to be a high priority interrupt. |
| dei_error_int | Interrupt indicating an error condition has occurred |

#### *12.2.9.3.1 Interrupt Description*

Two interrupts from DEI module are mapped to HD-VPSS level interrupt handler. Those are discussed below.

##### *12.2.9.3.1.1 dei_fm_int*

This interrupt is controlled by enabling film mode detection. Once enabled, this interrupt will occur on every input field and tells software that it needs to read the fmd_reset, fmd_frame_diff, fmd_field_diff and fmd_caf registers and execute the Film Mode software program to determine whether to lock film mode and the jamming direction.

This interrupt needs to be serviced as a high priority interrupt. The position the interrupt is generated within a field can be controlled through configuration registers (fmd_window_enable, fmd_window_minx, fmd_window_miny, fmd_window_maxx and fmd_window_maxy). If the window is enabled, the statitics will be gathered over the window bounded by the other register settings, and the interrupt will be generated at the bottom of the window, meaning, the window can be set at the top of the field to generate the interrupt as soon as possible. This interrupt needs to be serviced before the next field is input to the deinterlacer.

The interrupt is fired at the end of the defined film mode window. If the FMD window is not enabled, the entire frame size is used, and the interrupt will occur at the end of the field. Software services the interrupt and then applies “lock and jam” MMR controls to put the design in film mode. This must occur before the next field input. If the entire window is used, there is very little time to perform this servicing and register setting when the design is used in a memory to memory mode. When in a memory to memory mode, and particularly if the “field_flush” control bit is low, the film mode window must be used, and set to provide as much time as possible between the end of the film window and the end of the actual input field. Generally speaking, the film window should end 1 or 2 lines from the bottom of the real field to provide 1 or 2 line times to service the interrupt and apply the lock and jam registers for the next input field. While this means that the entire window is not used for calculating film mode statistics, excluding the last 1 or 2 lines should have negligible impact.

##### *12.2.9.3.1.2 dei_error_int*

This interrupt will occur under the following conditions:

(a) The field ID of the current input frame is the same as the field ID of the last frame. The field ID corresponds to whether the input field is the “top” (all even lines) or “bottom” (all odd lines) field. Two subsequent input frames must have opposite field IDs.

(b) An end of frame input has occurred on the input field data (VPI end of frame for current field), but the internal counters have not counted to either the programmed width or height. This indicates that the input data to the Deinterlacer does not match the programmed width and height the Deinterlacer is expecting.

(c) A start of frame input has occurred on the input field data (VPI start of frame for current field), but the internal counters are not at 0. This indicates that a new video field was started before the last video field was completed.

In any of these cases, the input video data is not matching what the deinterlacer programming is expecting. Software should reconfigure the deinterlacer to match the proper input video timing.

Copyright © 2011–2016, Texas Instruments Incorporated

## 12.2.10 Noise Filter (NF)

### 12.2.10.1 Overview

Noise is one of the most important factors affecting video quality. Random noise can be sensor noise, A/D conversion noise, analog transmission noise, etc. Since human eyes are very sensitive to oscillating signals, the visual quality degenerates significantly even when the noise level is small. Video coding efficiency also suffers from noise because the video encoder has trouble in matching noisy blocks and has to spend extra bits to encode useless noise. Noise reduction plays a fundamental role in improving visual quality and coding efficiency.

There are normally two types of noise reduction techniques – spatial filter and temporal filter. Spatial filter processes each frame individually. Even though each frame becomes clean, the video may still look noisy due to frame-to-frame intensity changing. Temporal filter can remove the frame-to-frame intensity changing. But for moving areas, ghosting artifacts may occur because the pixel-to-pixel correspondence between two consecutive frames is impacted due to the processing. In the noise reduction algorithm of the NF module, a combination of spatial and temporal filter is applied to overcome the shortcomings of both techniques.

It is desirable to have the spatial and temporal filters adaptive to the noise level of the video. If the filters are too weak, the noise may be still obvious. If the filters are too strong, edges and details may be blurred and ghosting artifacts may appear. Noise levels may vary a lot within a video sequence. Automated noise estimation is necessary to measure the noise level of each video clip and adjust the parameters of the filters properly.

This document describes the Video Noise Filter (NF) which is used to reduce noise in a video sequence in order to improve video image quality and compression efficiency.

### 12.2.10.2 Features

The NF module has the following features:

- Spatial and temporal video noise filtering
- Built-in noise measurement
- Adaptive to noise and motion
- YCbCr 4:2:0 Video format support

### 12.2.10.3 Functional Description

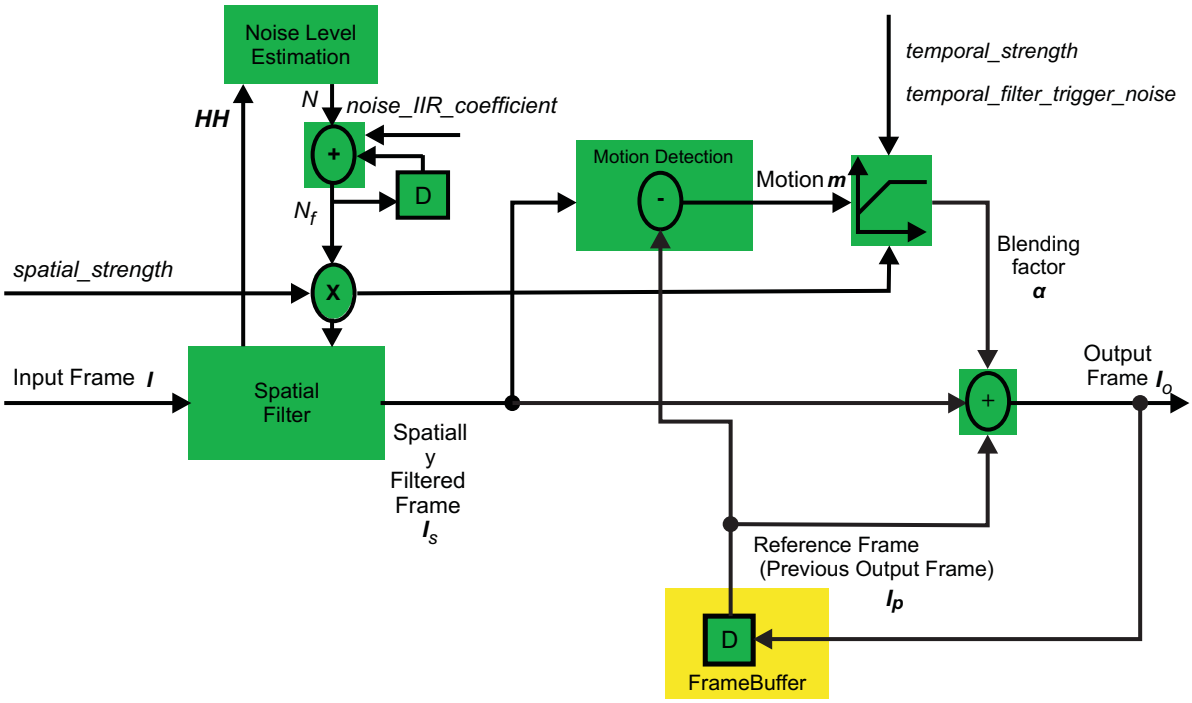
The Video Noise Filter implemented in this device is a combination of spatial and temporal IIR filters. The spatial filter is performed with neighboring pixels in the current frame while the temporal filter is performed with a past filtered frame to suppress both spatial and temporal noises.

The spatial and temporal filters are adaptive to the noise level of the video to deal with varying noise levels in different video contents. Noise estimation is performed by the hardware to measure the noise level of each video clip and to automatically adjust the parameters of the filters properly. Figure 12-133 shows the algorithmic block diagram of the noise filter.

The implementation of the video noise filter uses tile-based processing. The algorithm divides a frame into 32x32 tiles and process each of them independently. If the width or height of the frame is not a multiple of 32, 0x0s (for Luma) and 0x80s (for Chroma) will be padded into rightmost and/or bottommost tiles.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 12-133. Noise Filter Architecture Block Diagram**



### 12.2.10.3.1 Spatial Filter

The algorithm kernel size of the spatial filter is 3 (row) x 7 (column). With edge pixels replicated as shown in Figure 12-134, a 3x7 sliding window is used to process the entire 32x32 tile.

**Figure 12-134. Top-left Corner of a Tile After the Boundary Replication**

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 00 | 00 | 00 | 00 | 01 | 02 | 03 | 04 | 05 | 06 |
| 00 | 00 | 00 | 00 | 01 | 02 | 03 | 04 | 05 | 06 |
| 10 | 10 | 10 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| 20 | 20 | 20 | 20 | 21 | 22 | 23 | 24 | 25 | 26 |
| 30 | 30 | 30 | 30 | 31 | 32 | 33 | 34 | 35 | 36 |
| 40 | 40 | 40 | 40 | 41 | 42 | 43 | 44 | 45 | 46 |

For each 3x7 input, one pixel comes out as output as shown in 3x7 Pixel Output.

**3x7 Pixel Output**

| | | | | | | |
|---|---|---|---|---|---|---|
| | | | | | | X |
| | | | O | | | X |
| | | | | | | X |

For U and V channels, this filtering needs to be performed only at even rows and even columns due to the 4:2:0 format.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.10.3.2 Temporal Filter

The temporal filter is motion- and noise- adaptive. The motion at each pixel is measured as the sum of the absolute differences between the spatially filtered pixel (Ys, Us, Vs) of the current frame and the output pixel (Yp, Up, Vp) of the previous frame.

**m = |Ys – Yp|+|Us – Up|+|Vs – Vp|**

**Figure 12-135. Motion versus Blending Factor Function**

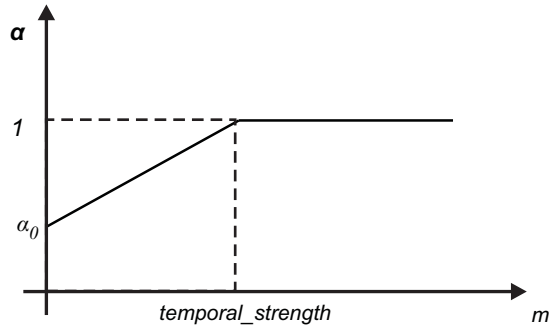


Figure 12-135 shows how the motion value, **m**, translates into the blending factor α. It can be written as:

$\alpha = \alpha_0 + (1 - \alpha_0) * m /$ temporal_strength if m < temporal strength

=1 if m >= temporal strength

where temporal_strength is a register to control the strength of the temporal filter. Setting it to 0 means the temporal filter is essentially bypassed. The discussions on the parameter $\alpha_0$ will be detailed in Section 12.2.10.3.4.

The output pixel value of the temporal filter is:

$\mathbf{I_o = \alpha I_s + (1 - \alpha) I_p}$

where $\mathbf{I_s}$ is the spatially filtered pixel value at the current frame and $\mathbf{I_p}$ is the pixel value of previous output frame.

#### 12.2.10.3.3 Noise Estimation

For each tile, the noise level *tileNoise* is the average of absolute pixel differences between the input frame **I** and the previous output frame $\mathbf{I_p}$. In the averaging, the absolute pixel differences which are smaller than *max_noise* are only taken to avoid strong moving edges. The noise level of a frame *Frame_noise* is the average noise level of all *tileNoises* in a frame. Some tiles that contain inaccurate noise level need to be excluded from the averaging calculation. They are:

(a) The boarder tiles on the four edges of a frame. They may contain zeroes that are padded to make the frame size a multiple of 32.

(b) Pure dark or pure white tiles. The max and min Y values of a tile are used to determine if a tile is pure black or pure while one. If maxY<pure_black_threshold, it is a pure black tile. If minY>255 - pure_white_threshold, it is a pure white tile.

Y, U, V channels have their own noise level respectively, denoted as *Frame_noise_Y*, *Frame_noise_U*, *Frame_noise_V*.

#### 12.2.10.3.4 Threshold and $\alpha_0$

At the end of each frame, the accumulated noise level *Frame_noise_Y*, *Frame_noise_U*, *Frame_noise_V* are processed to generate the thresholds for the spatial filter and the $\alpha_0$ of the temporal filter. The noise level will first pass an IIR low pass filter as shown in the following example.

```
Frame_noise_filtered=Frame_noise_previous* noise_IIR_coefficient +Frame_noise *(1-
 noise_IIR_coefficient )
```

Copyright © 2011–2016, Texas Instruments Incorporated

This IIR low pass filter will make the measured noise level change slowly across frames. The register *noise_IIR_coefficient* controls how fast it changes.

The thresholds of the spatial filter will be the filtered frame noise scaled by *spatial_strength*.

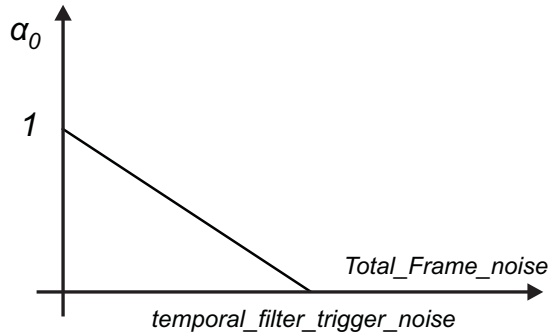
```
Threshold = spatial_strength * Frame_noise_filtered
```

$\alpha_0$ is the offset of the motion vs blending factor function. It is controlled by the total noise level *Total_Frame_noise* as shown in Figure 12-136. The total noise of all three channels is

```
Total_Frame_noise = Frame_noise_Y + Frame_noise_U + Frame_noise_V
```

where *temporal_filter_trigger_noise* is a register to control the slope of the function in Figure 12-136. This function will make $\alpha_0$ to be close to 1 if the measured noise level is low, and therefore the temporal filter to be very weak to avoid ghosting artifacts.

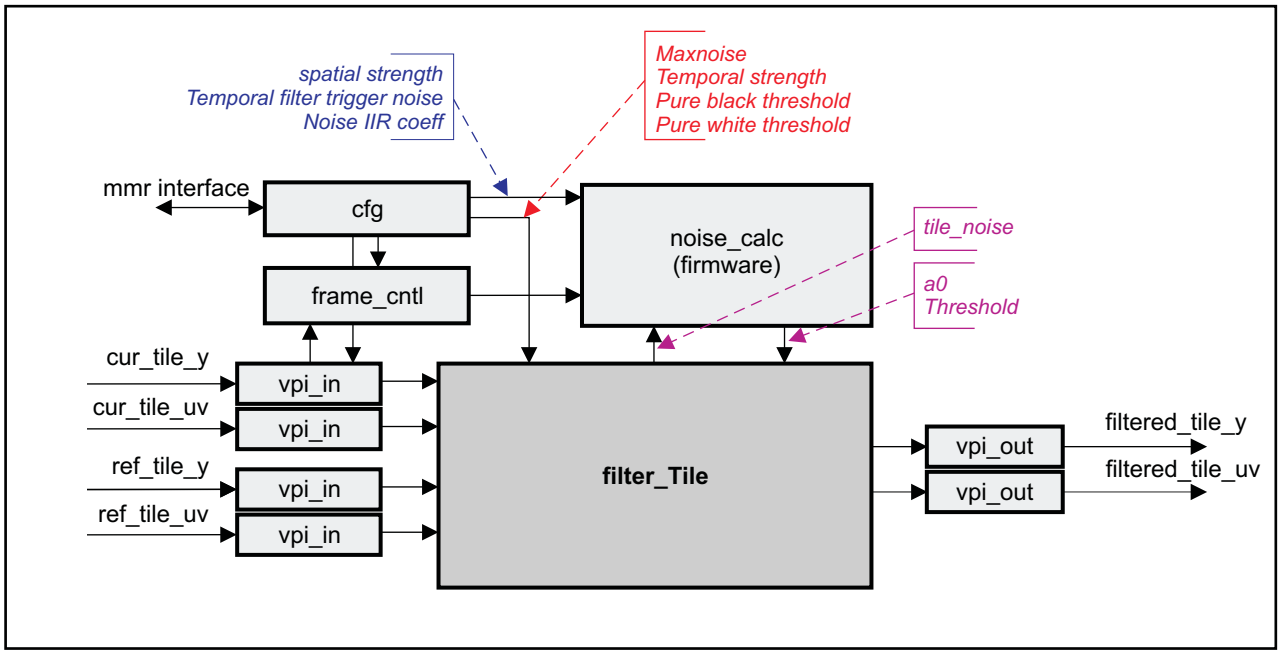
**Figure 12-136. $\alpha_0$ versus *totalFrame_noise* function**



### 12.2.10.3.5 Hardware Implementation

The NF hardware consists of the main filter_Tile processing unit which contains the main spatial and temporal filter logics and a number of support logics which include mainly MMR configuration module, VPI data in and out interface modules, frame noise calculation module (noise_calc) as shown in Figure 12-137.

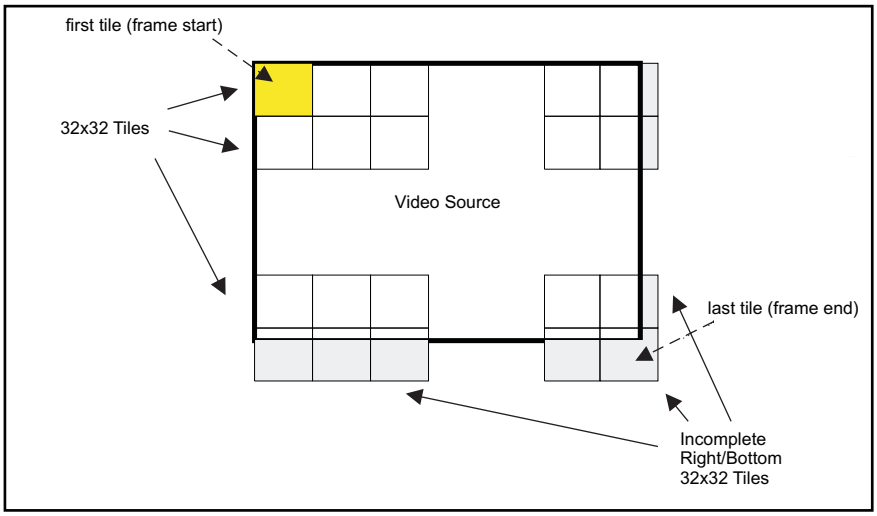
**Figure 12-137. Hardware Implementation Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

The NF always works on blocks of 32x32 Luma and 32x16 Chroma tiles (U and V channels together). The video source size (width/height) configured in NF_REG1 can be non-multiples of 32. But, the VPDMA/CHR_DS still must send full size tiles to the NF module. Any pixels outside the valid video size (see Figure 12-138) are replaced internally by the vpi_in sub-block with 0x0 for luma and 0x80 for chroma data.

**Figure 12-138. Incomplete Boundary Tile Data Masking**



Note that ref_tile in the above diagram refers to the (N-1)th output field/frame (previous filtered_tile) while cur_tile refers to the Nth input field/frame.

The arrival of the very first tile of each video frame is used to trigger the frame processing set up and the timing of the last tile sent out is used to trigger the last frame noise calculation and saving.

The noise_calc module (which implements the task of “firmware” described in Section 12.2.10.3.4) keeps track of each tile’s noise output and generates a frame noise at the end of last tile processing.

#### *12.2.10.3.6 Video Source Multiplexing*

The hardware has 32 sets of frame noise registers to allow video source switching for up to 32 sources without the software having to read and re-initialize the frame noise values every time the video source is switched. The software simply sets the “nf_video_index” parameter of NF_REG0 register to indicate which stream the NF module is currently processing. The NF then uses the selected frame noise data to generate the threshold for the spatial filter and the $\alpha_0$ of the temporal filter for next frame processing and updates the frame noise data at the end of the frame.

If more than 32 sets of video sources are to be processed through the NF, then the software needs to manually read the saved frame noise (indexed by “frame_noise_read_index” of NF_REG7) from NF_REG8 and NF_REG9. The read noise values can then be reloaded next time the same video source is to be processed by writing to data to the NF_REG8 and NF_REG9 and also by setting the “nf_frame_noise_init_en” parameter of NF_REG0.

NF_REG0 (nf_frame_noise_update_en) bit can be used to disable the saving of collected Frame noise information in cases where sliced based filtering is used and the same filter setup is desired for all slices. In this case, the update should only be done at the beginning or end of the frame – once per frame.

Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.10.4 Configuration Examples

#### *12.2.10.4.1 Example of 16-Channel Use Case*

For example, when NF is used to process 16 channels, the steps below show how we should configure for channel 12.

Frame 0, Initialization:

1. nf_video_index = 12
2. nf_frame_noise_init_en=1
3. Initialize NF_REG8 and NF_REG9 (Frame_noise_y, Frame_noise_u, Frame_noise_v) with the desired initialization values.
4. nf_frame_noise_update_en =1

Complete frame processing (the steps 1, 2, and 3 above are used to set the initialization values for noise measurement, and step 4 means the measured noise value per field/frame will be updated through the IIR filter.)

Clear the initialization flags at Frame 1:

nf_frame_noise_init_en=0

At this point, to read the measured noise levels:

Set frame_noise_read_index = 12

Read stored Frame_noise_y/u/v through NF_Reg8 and Reg9

#### *12.2.10.4.2 Basic Configurations*

NF can be easily configured to perform spatial-temporal filtering, spatial-only filtering, temporal-only filtering, or at by-pass mode. Table 12-66 shows how NF should be configured for each basic mode. Note that the temporal bypass mode here is mainly used for debug purpose, and it is not a true bypass mode.

**Table 12-66. NF Configuration for Each Basic Mode**

| Register Name | Spatial-Temporal | Spatial Only | Temporal Only | Spatial Bypass | Temporal Bypass |
|---|---|---|---|---|---|
| nf_en | 1 | 1 | 1 | 1 | 1 |
| nf_ref_cfg | b'00 | Any value, but preferred to set as b'10 or b'11 to disable DMA for reference frame | b'00 | Any value, but preferred to set as b'10 or b'11 to disable DMA for reference frame | b'00 |
| nf_bypass_cfg | b'00 | b'00 | b'00 | b'01 (or b'11) | b'10 |
| spatial_strength X 6 | | | 0 | | |
| temporal_strength | | 0 | | | |

## 12.2.11 Scaler (SC)

The scaler module is used to resize YCbCr422 video images.

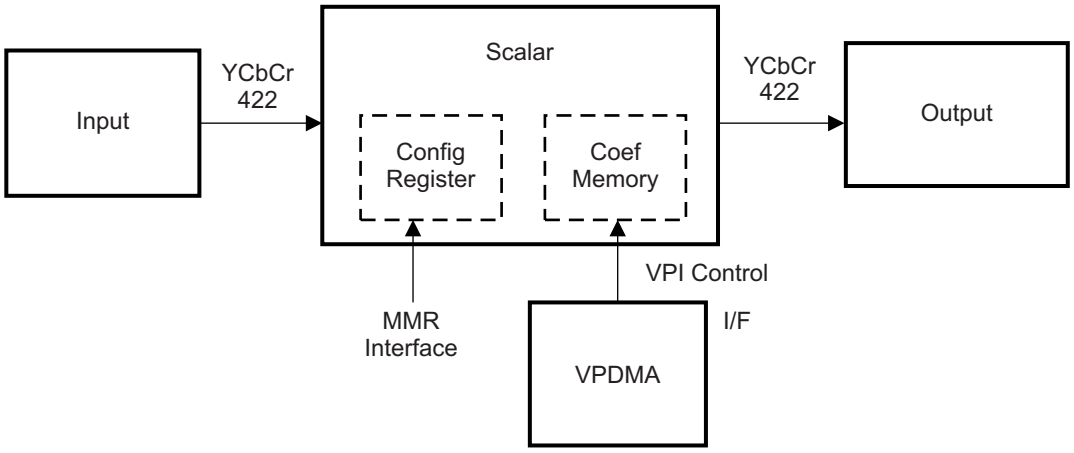
### 12.2.11.1 Features

- Independent vertical and horizontal up/down scaling
- Polyphase filter vertical up/down scaling
- Running average vertical down scaling for memory optimization
- Decimation and polyphase filtering for horizontal scaling
- Non-linear scaling for stretched/compressed left and right sides
- Input image trimmer for pan/scan support
- Pre-scaling peaking filter for enhanced sharpness
- Scale field as frame
- Interlacing of scaled output
- Full 1080p input and output support
- YCbCr422 input and output
- Maximum horizontal scaling ratio only limited by output line buffer (2047 pixels)
- Scaling filter Coefficient memory download via VPI (Video Port Interface) Control interface

### 12.2.11.2 Functional Description

Scaler takes in a 10-bit YCbCr 422 video frame from an upstream module, performs vertical/horizontal scaling, and outputs a YCbCr422 scaled image to a next downstream module. All configurations are done via the MMR interface except for the scaler coefficient memory configuration that is done via the common VPI control interface bus by VPDMA. Figure 12-139 shows the high level block diagram of the scaler module.

**Figure 12-139. High Level Block Diagram**



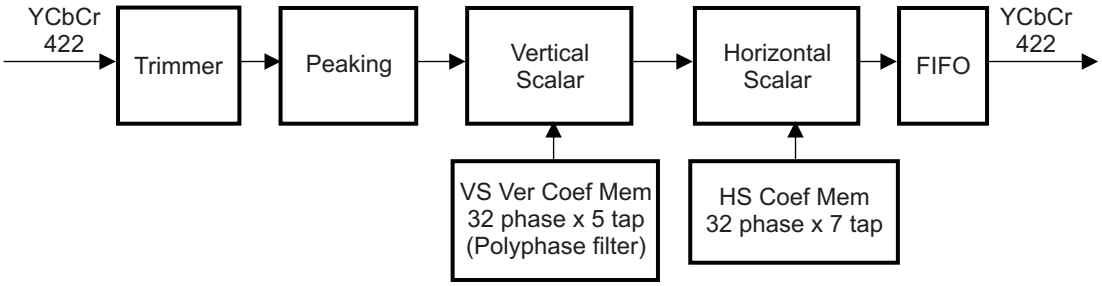
Copyright © 2011–2016, Texas Instruments Incorporated

The SC (Figure 12-140) is used in the video path and in all other video write-back data paths in the HDVPSS module.

Scaling is performed in following three steps:

1. Trimming and Pre-peaking filtering
2. Vertical Scaling (Polyphase/Running Average Filter)
3. Horizontal polyphase scaling

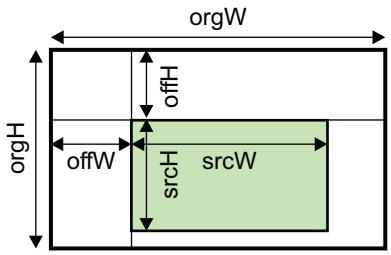
**Figure 12-140. SC Block Diagram**



#### *12.2.11.2.1 Trimmer*

The trimmer can be programmed to re-define a new source image within the input video frame sent from an upstream module before it is sent to the scaling sub-modules. This feature enables small area zoom out, source pan/scan, or removal of unwanted area in the video (such as black box/curtains/noisy line-21 video) without modifying the VPDMA parameters.

**Figure 12-141. Input Image Trimming**

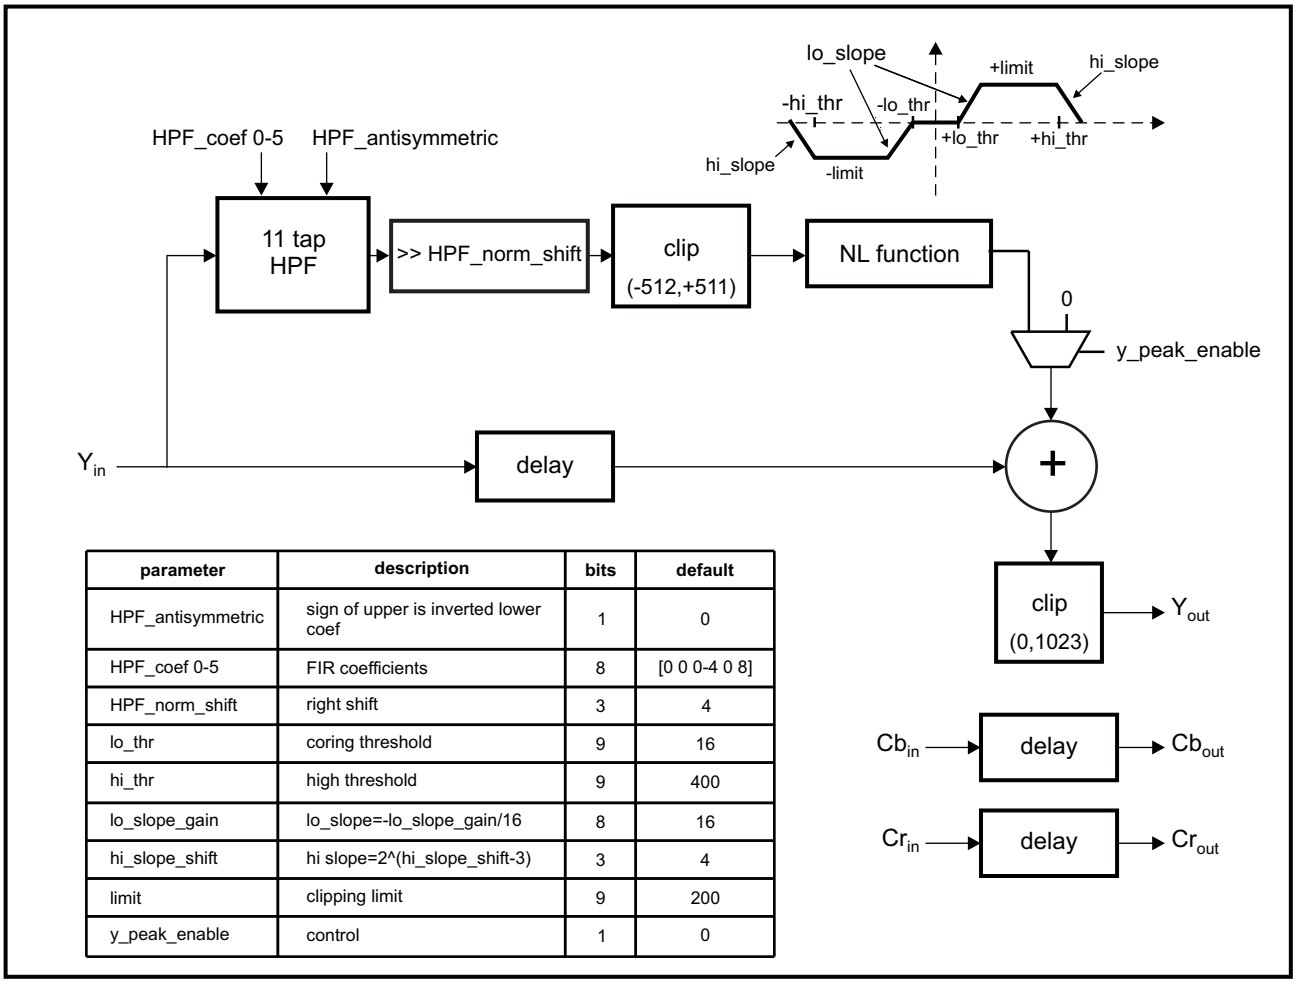


Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.11.2.2 Peaking

The peaking block increases the amplitude of high frequency luminance information in horizontal direction to increase the sharpness of a video image before it is scaled. As shown in Figure 12-142, the high-frequency luminance is increased using an 11-tap High-Pass filter with adjustable gain. The non-linear coring function removes low-level noise and the modified luminance is then added to the original luminance signal. The implementation details are shown in Figure 12-142.

**Figure 12-142. Filter Implementation and Parameter Description**

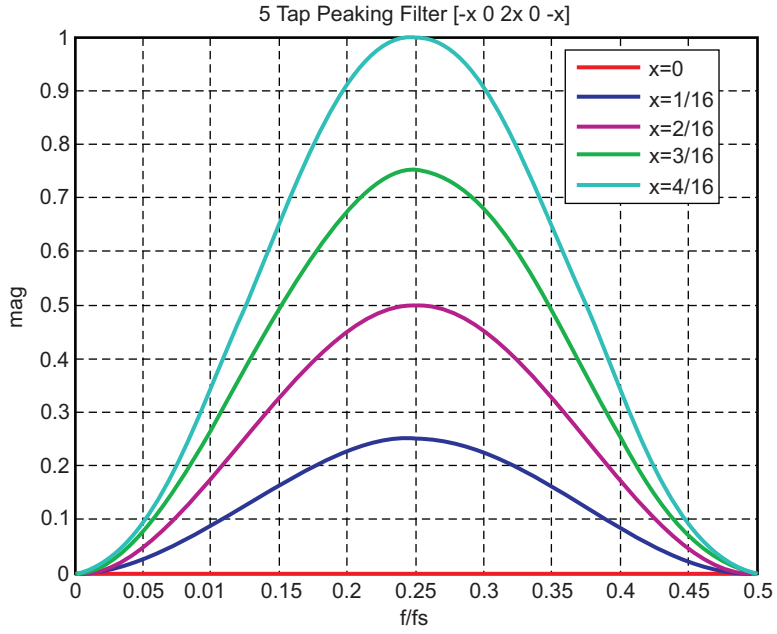


| parameter | description | bits | default |
|---|---|---|---|
| HPF_antisymmetric | sign of upper is inverted lower coef | 1 | 0 |
| HPF_coef 0-5 | FIR coefficients | 8 | [0 0 0-4 0 8] |
| HPF_norm_shift | right shift | 3 | 4 |
| lo_thr | coring threshold | 9 | 16 |
| hi_thr | high threshold | 9 | 400 |
| lo_slope_gain | lo_slope=-lo_slope_gain/16 | 8 | 16 |
| hi_slope_shift | hi slope=2^(hi_slope_shift-3) | 3 | 4 |
| limit | clipping limit | 9 | 200 |
| y_peak_enable | control | 1 | 0 |

Copyright © 2011–2016, Texas Instruments Incorporated

Parameters for the Peaking filters are defined in CFG_SC19-22. The frequency responses of the peaking-filter with different sets of coefficients are shown in Figure 12-143. If the source of the input video is NTSC or PAL format, the peaking filter can be configured to reject the color subcarrier frequency.

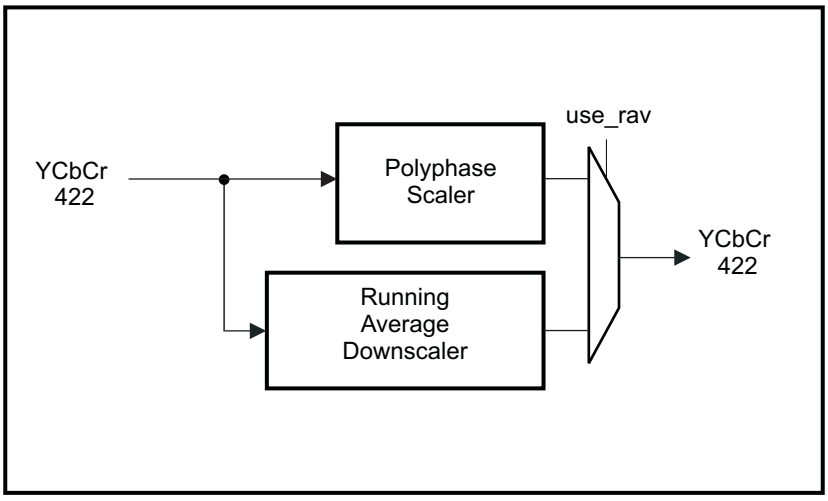
**Figure 12-143. Peaking Filter at fs/4**



### 12.2.11.2.3 Vertical Scaler

The vertical scaler has a poly-phase and a running average filter as shown in Figure 12-144. While the poly-phase filter can be used for any up-scaling and preferably downscaling to 3/16 scale factor, the running average filter is used only for downscaling to a ½ or less size. Selection between these two scalers is based on the user setting of “use_rav” parameter, according to the user preference of the tradeoff between sharpness preserving and introduced artifacts.

**Figure 12-144. Vertical Scaler Block Diagram**

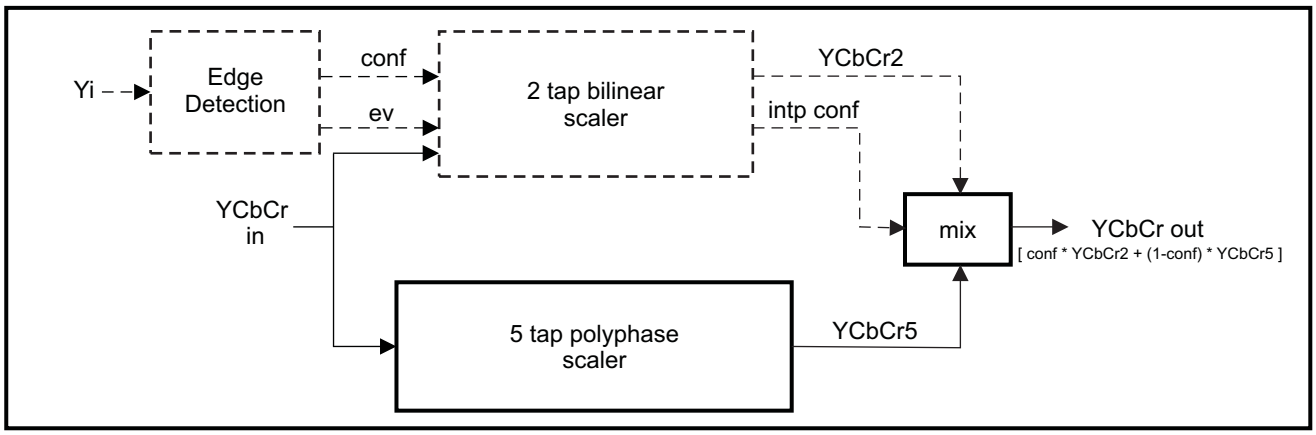


Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.11.2.3.1 Polyphase Scaler (in Vertical Scaler)

The vertical polyphase scaler is mainly implemented using a 32-phase 5-tap polyphase filter.

**Figure 12-145. Mixed 2-tap and 5-tap vertical interpolation**

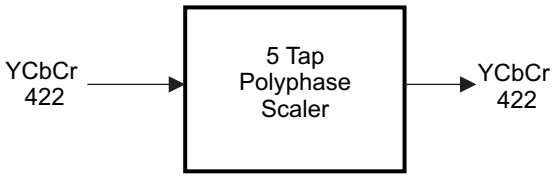


**NOTE:** In SC_M modules present in this device, edge detection and 2-tap bilinear filter modules are not available.

##### 12.2.11.2.3.1.1 Polyphase Filter Selection

The scaler (SC) uses 5-tap polyphase filtering for vertical up-scaling.

**Figure 12-146. Vertical Polyphase Scaler Block Diagram (SC)**



#### 12.2.11.2.3.2 Running Average Filter

When a poly-phase filter is used, usually it has to have many taps in order to achieve acceptable quality for very small downscaling ratio, which requires the use of many line buffers. In HDVPSS, we have a weighted Running Average filter for downscaling when the scaling factor is small (for example, when the scaling ratio is less than 0.5). This highly optimized design requires only one line buffer for luma and one for chroma, which still achieving acceptable quality. The output of the running average filter is based on weighted average of pixels in the current and previous rows in vertical direction. Initializations of accumulators affect the weights.

#### 12.2.11.2.3.3 Vertical Scaler Configuration Parameters

**Table 12-67. Vertical Scaler Configuration Parameters**

| Parameter | Bits | Typical | Controls | Description |
|---|---|---|---|---|
| interlace_in | 1 | | Frame or Field | 0 = progressive, 1 = interlace |
| interlace_out | 1 | | | 0 = progressive 1 = interlace |
| invt_fid | 1 | | | Invert field ID input |
| use_rav | 1 | | Scaler Mode | 0 = use polyphase scaler<br>1 = use running average scaler |
| row_acc_inc | 11.16 | | Bilinear & Polyphase Scalers | round(2^16*(srcH)/(tarH)) |
| row_acc_offset | 11.16 | 0 | | Initial row accumulator value for progressive frame and top field |
| row_acc_offset_b | 11.16 | 0 | | Initial row accumulator value for bottom field |
| ev_thr | 3.2 | 0xC | Bilinear Scaler | Edge vector threshold used in luma soft switch |
| delta_ev_thr | 4 | 1 | | Range of luma soft switch based on edge vector |
| delta_luma_thr | 4 | 4 | | Range for luma soft switch based on pixel differences (max limit = 8) |
| delta_chroma_thr | 4 | 4 | | Range for chroma soft switch based on pixel differences (max limit = 8) |
| chroma_intp_thr | 10 | 64 | | Threshold used in chroma soft switch based on pixel differences |
| luma polyphase filter coefficients | s1.11 | | | 32 phases × 7 taps × 13 bits array (interpolation only: scale factor = 1) |
| chroma polyphase filter coefficients | s1.11 | | | 32 phases × 7 taps × 13 bits array (interpolation only: scale factor = 1) |
| sc_factor_rav | 10 | | Running Average Scaler | Scale factor = round(1024 × tarH/srcH) |
| row_acc_init_rav | 10 | | | Initial row accumulator value for progressive frame and top field |
| row_acc_init_rav_b | 10 | | | Initial row accumulator value for bottom field |
| luma polyphase filter coefficients | s1.11 | | Polyphase Scaler | 32 phases × 5 taps × 13 bits array (dependent on scale factor) |
| chroma polyphase filter coefficients | s1.11 | | | 32 phases × 5 taps × 13 bits array (dependent on scale factor) |

**Note:** Bi-linear scaler is not present in this device.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.11.2.4 Horizontal Scaler

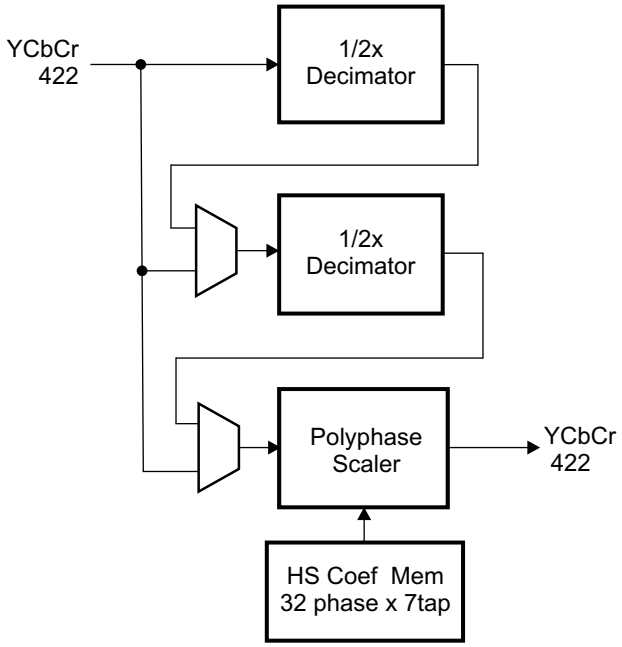
The horizontal scaler is implemented using a 32-phase × 7-tap polyphase filter preceded by two sets of x1/2 decimators. The general configuration of the Horizontal scaler is performed as follows:

- For up scaling, the input video is interpolated using the polyphase scaler.
- For downscaling, it is recommended that input video is decimated by 2 until the modified scale factor falls between 1/2 and 1. Then, a polyphase filter is configured with coefficients selected based on the mod_scale_factor calculated as shown below from one of nine different sets of coefficients: (8,9,10,11,12,13,14,15,16)/16.

```
if (scale_factor>=1/2) {
    dcm_2x=0;
    dcm_4x=0;
    mod_scale_factor=scale factor;
} else if (scale_factor>=1/4) {
    dcm_2x=1;
    dcm_4x=0;
    mod_scale_factor=2*scale_factor;
} else {
    dcm_2x=0;
    dcm_4x=1;
    mod_scale_factor=4*scale_factor;
}
```

In auto mode (auto_hs == 1), scaler will operate as per above recommendation. In addition to this, for (auto_hs==1), polyphase filtering will be bypassed when (scale_factor == 1) or (scale_factor == ½) or (scale_factor == ¼). If (auto_hs==0) is used, user must provide proper values for dcm_2x, dcm_4x, proper values for all inputs to polyphase filter in the registers as well as appropriate coefficient sets. There is no constraint on polyphase filtering in terms of scaling ratio. However, there are constraints on input and output image width for scaler. Frame dimensions are limited from 64x64 to 2047x2047.

**Figure 12-147. Horizontal Scaler Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 12.2.11.2.4.1 Half Decimation Filter

The half-decimation filter is an 11-tap filter with following coefficients – (14, 0, -29, 0, 79, 128, 79, 0, -29, 0, 14). For processing left and right edge pixels, the first and last data are repeated to pre-fill and extend the filter data pipeline respectively.

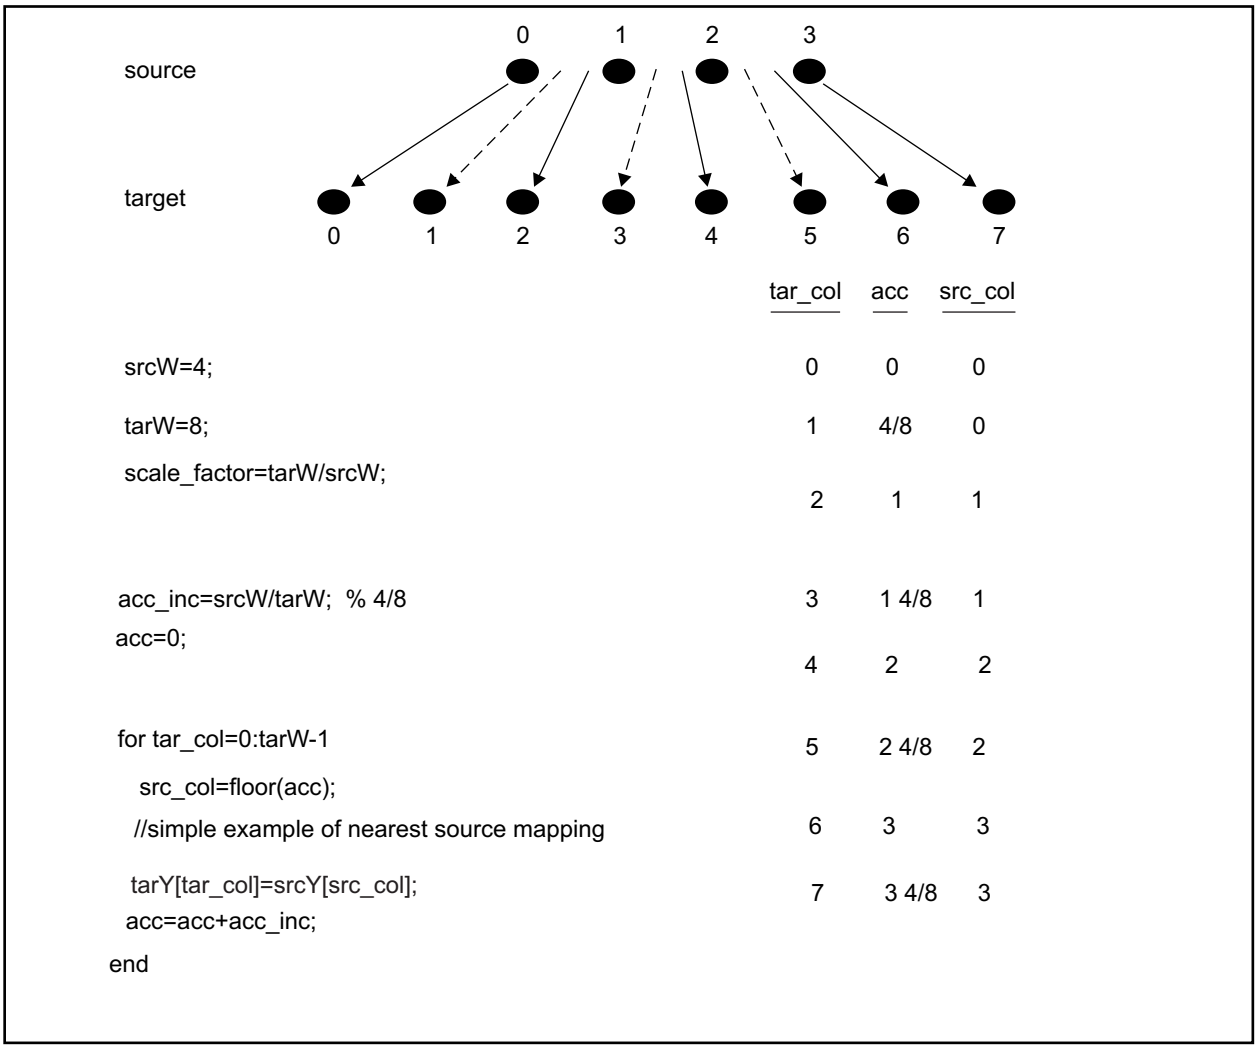
These coefficients are hard-coded into scaler design and user cannot modify these.

#### 12.2.11.2.4.2 Polyphase Filter

The horizontal scaling is done by stepping across the target row and interpolating target pixels based on source pixels. Accumulator points to the source pixel that corresponds to the target pixel.

Figure 12-148 shows an up-scaling example.

**Figure 12-148. Polyphase Filtering Example**



Copyright © 2011–2016, Texas Instruments Incorporated

### 12.2.11.2.4.3 Nonlinear Horizontal Scaling

The horizontal scaler supports non-linear scaling to maintain the same aspect ratio for inner picture while stretching picture edges to fill the screen when displaying a 4x3 picture onto a 16x9 display. When setting up a non-linear scaling application, the inner picture is defined as the center square portion of the image with width and height equal to the height of the source image. Remaining side regions are then scaled non-linearly. Figure 12-149 shows a non-linear scaling case:

**Figure 12-149. Non-linear Scaling Example**

#### 12.2.11.2.5 Coefficient Memory

##### 12.2.11.2.5.1 Overview

The scaler requires initialization of eight coefficient SRAMS prior to processing a video frame. These coefficients are stored in the external DDR memories and downloaded by the VPDMA. The VPDMA writes the coefficient data through the VPI Control Interface bus.

The eight coefficient SRAMs are:

- HS horizontal polyphase scaler, Luma and Chroma (7tap)
- VS vertical polyphase scaler, Luma and Chroma (5tap or 3tap)
- VS vertical bilinear scaler, top line Luma and Chroma (7tap)
- VS vertical bilinear scaler, bottom line Luma and Chroma (7tap)

Only the SC_H requires the VS vertical bilinear scaler coefficients and has the memories to store them. Nevertheless, SC will accept the VPI Write command to these memories although it does not store the data.

##### 12.2.11.2.5.2 Physical Coefficient SRAM Layout

Each of the six legacy coefficient SRAMs is 32 phases × 91 bits. A single coefficient value is 13 bits. Therefore, one word of the SRAM contains 7 coefficient values as shown in Figure 12-150, and 224 coefficient values are stored in each SRAM.

**Figure 12-150. SRAM Layout for 7tap Coefficient**

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Phase 0 | C6 | C5 | C4 | C3 | C2 | C1 | C0 |
| | | | | | | | |
| Phase 31 | C223 | C222 | C221 | C220 | C219 | C218 | C217 |

The two vertical polyphase SRAMs are 32 phases × 65 bits. A single coefficient is 13 bits. Therefore, one word of SRAM contains 5 coefficient values as shown in Figure 12-151.

**Figure 12-151. SRAM Layout for 5tap Coefficient**

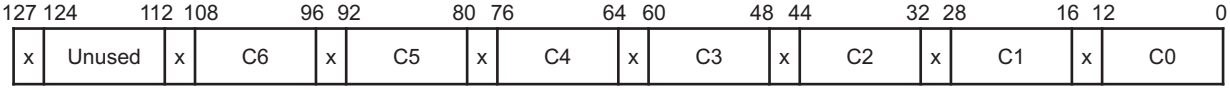
#### 12.2.11.2.5.3 Scaler Coefficients Packing on 128-bit VPI Control I/F

A coefficient value is 13 bits wide and takes a single half word. Thus, one VPI Control write carries one phase's worth of coefficients. The last half-word in a quad-word is not used for 7tap coefficients.

**Figure 12-152. VPI Control I/F Coef Data Format (7tap)**



The Vertical Polyphase scaler coefficients have only five or three values per phase, so the last three (or five) entries are unused. The Vertical Polyphase coefficient packing is shown in Figure 12-153 and Figure 12-154.

**Figure 12-153. VPI Control I/F Coef Data Format (5tap)**

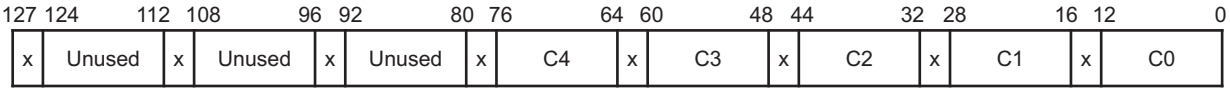


**Figure 12-154. VPI Control I/F Coef Data Format (3tap)**

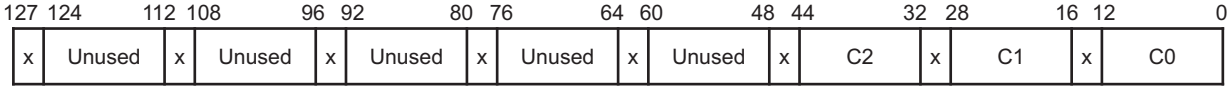
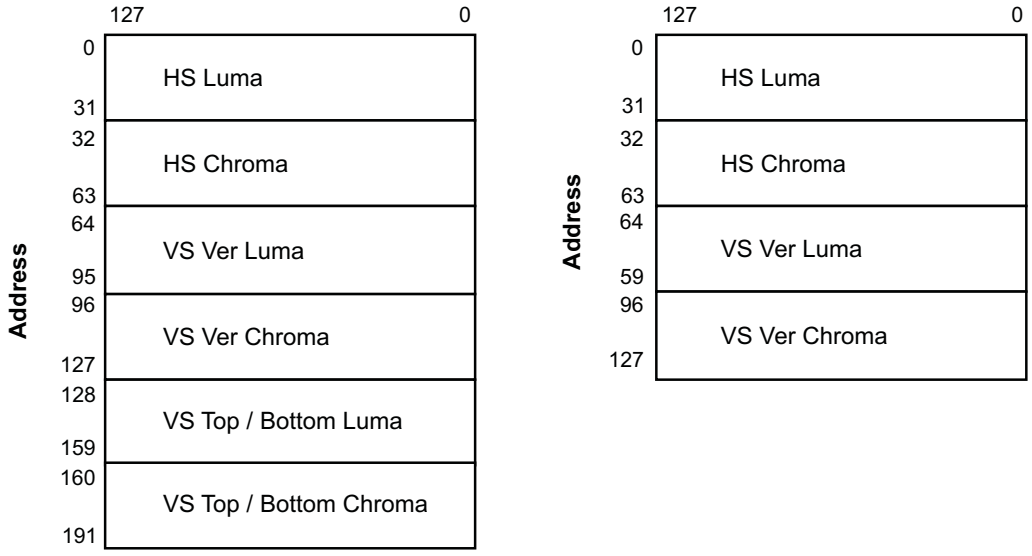


#### 12.2.11.2.5.4 VPI Control I/F Memory Map for Scaler Coefficients

The memory map of the VPI Control I/F for the Scaler coefficients is shown in Figure 12-155. All coefficients can be filled up by a single VPI Control write command. The update address feature of VPI Control I/F enables individual access to a certain location of memories. The VS top and bottom coefficients of SC_H are written concurrently through VPI Control Write.

**Figure 12-155. VPI Control I/F Memory Map (Write)**

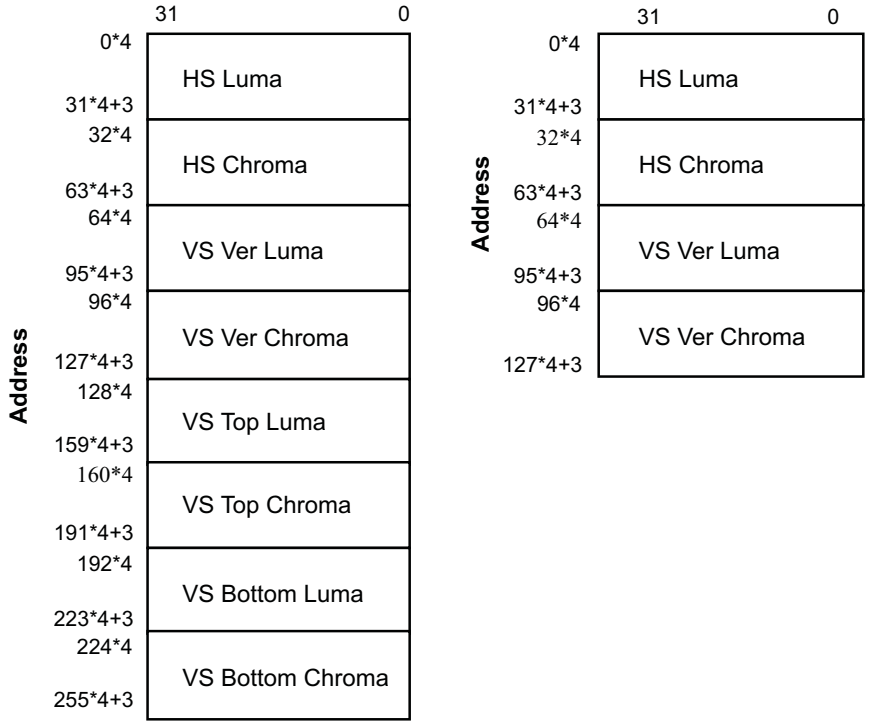


**(a) sc_h** **(b) sc_m**

Copyright © 2011–2016, Texas Instruments Incorporated

The module supports the VPI Control Read to read back the contents in the coefficient memories for debug purpose. Figure 12-156 shows the memory map of the VPI Control Read. As the VPI Control Read has only 32 bit data bus, it requires the word addressing while the write does the quad-word addressing. The VS top and bottom coefficients can be accessed separately for the read.

**Figure 12-156. VPI Control I/F Memory Map (Read)**



### 12.2.11.2.5.5 VPI Control Interface

VPDMA is used to configure the coefficient memories of scaler through VPI control interface. Since the coefficient memories are not shadowed (unlike the MMR registers), VPI control write access needs to be done only during the gap between video frame processing times. If a write request is made while the Scaler is active, the access will be held off by the hardware until the last data of the currently processed frame is sent out. Care must be given to the order of the DMA descriptors so that blocking of VPI control bus does not occur.

#### 12.2.11.2.5.6 Coefficient Table Selection Guide

The scaler filter coefficient tables are pre-generated using a Matlab program for various scaling factor ranges. Table 12-71 is a general selection guide table for coefficient data files.

**Table 12-71. Coefficient Data Files**

| Scaler | Scale Factor | Coeff table |
|---|---|---|
| HS Polyphase Filter | All upscaling | ppfcoef_scale_eq_1_32_phases_flip.dat |
| HS Polyphase Filter | All upscaling | ppfcoef_scale_eq_1_32_hases_flip.dat |
| | ½ or ¼ down scaling | ppfcoef_scale_eq_1_32_phases_flip.dat |
| | > 15/16 | ppfcoef_scale_eq_15div16_32_phases_flip.dat |
| | > 14/16 | ppfcoef_scale_eq_14div16_32_phases_flip.dat |
| | > 13/16 | ppfcoef_scale_eq_13div16_32_phases_flip.dat |
| | > 12/16 | ppfcoef_scale_eq_12div16_32_phases_flip.dat |
| | > 11/16 | ppfcoef_scale_eq_11div16_32_phases_flip.dat |
| | > 10/16 | ppfcoef_scale_eq_10div16_32_phases_flip.dat |
| | > 9/16 | ppfcoef_scale_eq_9div16_32_phases_flip.dat |
| | > 8/16 | ppfcoef_scale_eq_8div16_32_phases_flip.dat(1) |
| VS Polyphase Filter | Upscaling | ppfcoef_scale_eq_1_32_phases_ver_5tap_flip.dat |
| | > 15/16 | ppfcoef_scale_eq_15div16_32_phases_ver_5tap_flip.dat |
| | > 14/16 | ppfcoef_scale_eq_14div16_32_phases_ver_5tap_flip.dat |
| | > 13/16 | ppfcoef_scale_eq_13div16_32_phases_ver_5tap_flip.dat |
| | > 12/16 | ppfcoef_scale_eq_12div16_32_phases_ver_5tap_flip.dat |
| | > 11/16 | ppfcoef_scale_eq_11div16_32_phases_ver_5tap_flip.dat |
| | > 10/16 | ppfcoef_scale_eq_10div16_32_phases_ver_5tap_flip.dat |
| | > 9/16 | ppfcoef_scale_eq_9div16_32_phases_ver_5tap_flip.dat |
| | > 8/16 | ppfcoef_scale_eq_8div16_32_phases_ver_5tap_flip.dat |
| | else | For down-scaling <8/16, RAV filter is recommended. In this case, coefficients for vertical scaling need not be loaded. |

(1) HS Scaler has two sets of ½-decimator to perform downscaling ratios below ½ and ¼.

The above mentioned .dat files are available in Section 12.2.11.4.

### 12.2.11.3 Code

#### 12.2.11.3.1 Generate Coefficient Memory Image

The following Perl script is used to generate a coefficient memory image for a given set of scaling factors.

```
#!/usr/local/bin/perl

#$dir="coef/";                    # directory which contains the coef files
#$cfg_file="sc_config1.cfg";      # configuration file name
#$spl_file="sc_config_supl.cfg";  # supplemental configuration file name $cfg_file=$ARGV[0];  #
configuration file name $spl_file=$ARGV[1];  # supplemental configuration file name
$dir=$ARGV[2];       # directory which contains the coef files

$coef_width=13;  # coef bit width
$coef_ntap=7;    # coef tap
$coef_nphase=32; # coef phase
$coef_norm=11;   # coef norm

#-----------------------------------------------------------
# read config file to get srcH/tarH/interlace_i/interlace_o
#-----------------------------------------------------------
open(INFILE, "<$cfg_file") or die "### ERROR: Cannot open $cfg_file";
