# TMS320DM8127 and TMS320DM814x DaVinci™ Digital Media Processor

# Technical Reference Manual

Literature Number: SPRUGZ8G
14 November 2011–Revised June 2016

# Contents

**Preface** ..... **153**

**1 Chip Level Resources** ..... **155**

1.1 ARM® Cortex™-A8 Microprocessor Unit (MPU) Subsystem Overview ..... 156
1.1.1 ARM Cortex-A8 RISC Processor ..... 156
1.1.2 Embedded Trace Module (ETM) ..... 157
1.1.3 ARM Cortex-A8 Interrupt Controller (AINTC) ..... 157
1.1.4 ARM Cortex-A8 PLL (PLL_ARM) ..... 157
1.1.5 ARM MPU Interconnect ..... 157
1.2 Media Controller Subsystem ..... 158
1.2.1 Dual Cortex-M3 MPU Subsystem Overview ..... 158
1.2.2 Dual Cortex-M3 MPU Subsystem Integration ..... 159
1.2.3 Dual Cortex-M3 MPU Subsystem Functional Description ..... 162
1.2.4 Shared Cache ..... 164
1.2.5 Shared Cache MMU ..... 164
1.2.6 L2 MMU ..... 165
1.2.7 Registers ..... 166
1.3 C674x DSP ..... 180
1.3.1 Introduction ..... 180
1.3.2 TMS320C674x Megamodule ..... 181
1.3.3 Memory Map ..... 183
1.3.4 Advanced Event Triggering (AET) ..... 183
1.4 HD Video Coprocessor Subsystem ..... 183
1.4.1 HDVICP2 Overview ..... 183
1.4.2 ICONTs ..... 185
1.4.3 vDMA ..... 185
1.4.4 iME3 ..... 185
1.4.5 iPE3 ..... 185
1.4.6 MC3 ..... 185
1.4.7 CALC3 ..... 186
1.4.8 iLF3 ..... 186
1.4.9 ECD3 ..... 186
1.4.10 SL2 Interface ..... 186
1.4.11 Message Bus ..... 186
1.4.12 HDVICP2 Local Interconnect ..... 186
1.4.13 MailBox ..... 186
1.4.14 HDVICP2 System Control ..... 186
1.5 System MMU ..... 188
1.5.1 MMU Overview ..... 188
1.5.2 MMU Integration ..... 188
1.5.3 MMU Functional Description ..... 189
1.5.4 MMU Low-level Programming Models ..... 202
1.5.5 MMU Registers ..... 205
1.6 SGX530 Graphics Subsystem ..... 218
1.6.1 SGX Overview ..... 218
1.6.2 SGX Integration ..... 221

Copyright © 2011–2016, Texas Instruments Incorporated

1.6.3 SGX Functional Description ..... 223
1.6.4 SGX Register Manual ..... 225
1.7 Device Interrupts and EDMA Events ..... 240
1.7.1 Interrupt Controllers ..... 240
1.7.2 Interrupt Requests to Cortex-A8 MPU INTC ..... 241
1.7.3 Interrupt Requests to C674x INTC ..... 244
1.7.4 Interrupt Requests to Media Controller INTC ..... 248
1.7.5 EDMA Channel Synchronization Events ..... 252
1.8 Inter-Processor Communication ..... 255
1.8.1 Reset Requirements ..... 255
1.8.2 Features ..... 255
1.8.3 Overview and Strategy ..... 256
1.8.4 IPC Component Configuration ..... 259
1.9 Mailbox ..... 260
1.9.1 Overview ..... 260
1.9.2 System Mailbox Integration ..... 260
1.9.3 Functional Description ..... 262
1.9.4 Programming Guide ..... 266
1.9.5 Mailbox Registers ..... 270
1.10 Spinlock ..... 290
1.10.1 Overview ..... 290
1.10.2 Integration ..... 291
1.10.3 Functional Description ..... 292
1.10.4 Programming Guide ..... 294
1.10.5 Spinlock Registers ..... 296
1.11 Error Location Module ..... 300
1.11.1 Error Location Module Overview ..... 300
1.11.2 ELM Integration ..... 301
1.11.3 ELM Functional Description ..... 302
1.11.4 ELM Basic Programming Model ..... 305
1.11.5 ELM Registers ..... 312
1.12 Bus Interconnect ..... 324
1.12.1 Interconnect Overview ..... 324
1.12.2 L3 Interconnect ..... 328
1.12.3 L4 Interconnects ..... 408
**2 Power, Reset, and Clock Management (PRCM) Module ..... 462**
2.1 Introduction ..... 463
2.1.1 Device Power-Management Architecture Building Blocks ..... 463
2.1.2 Module-Level Clock Management ..... 464
2.1.3 Clock Domain ..... 467
2.1.4 Power Management ..... 469
2.2 Power Reset Clock Management Structure ..... 472
2.2.1 Introduction ..... 472
2.3 Clock Generation and Management ..... 474
2.3.1 Types of Clocks ..... 474
2.3.2 Clock Structure ..... 474
2.3.3 Main PLL Clock Structure ..... 477
2.3.4 USB PLL Clock Structure ..... 479
2.3.5 DDR PLL Clock Structure ..... 480
2.3.6 SERDES and Ethernet Clock Structure ..... 480
2.3.7 Video PLL Clock Structure ..... 481
2.3.8 Audio PLL Clock Structure ..... 483
2.3.9 Timer Clock Structure ..... 486

Copyright © 2011–2016, Texas Instruments Incorporated

2.3.10 Device Clocking from External Sources ..... 488
2.3.11 Clock Output Pin ..... 489
2.4 Oscillator ..... 490
2.5 DPLLS ..... 491
2.5.1 DPLLS Frequency Range ..... 492
2.5.2 DPLLS Fractional M-divider Programming ..... 492
2.5.3 DPLLS Clock Functions ..... 492
2.5.4 DPLLS Frequency Factors ..... 493
2.6 DPLLLJ ..... 493
2.6.1 DPLLLJ Fractional M-divider Programming ..... 495
2.6.2 DPLLLJ Clock Functions ..... 495
2.6.3 DPLLLJ Frequency Range (MHz) ..... 496
2.6.4 DPLLLJ Frequency Factors ..... 496
2.6.5 Mode of Operations ..... 496
2.6.6 BYPASS Mode ..... 497
2.6.7 M2 & N2 Change On-the-Fly ..... 498
2.6.8 Gating and Power Down of Output Clocks ..... 498
2.6.9 M2PWDNZ / CLKDCOLDOPWDNZ bits ..... 498
2.6.10 Connected Outputs of DPLLS ..... 499
2.6.11 Connected Outputs of DPLLLJ ..... 499
2.7 Reset Management ..... 499
2.7.1 Overview ..... 499
2.7.2 Reset Concepts and Definitions ..... 499
2.7.3 Power On Reset (PORz) ..... 501
2.7.4 External Warm Reset (RESETz) ..... 501
2.7.5 Emulation Cold Reset (ICEPICK POR) ..... 501
2.7.6 Emulation Warm Reset ..... 501
2.7.7 Reset Requestor ..... 501
2.7.8 Software Controlled Reset ..... 501
2.7.9 Test Reset (TRSTz) ..... 501
2.7.10 Reset Priority ..... 502
2.7.11 Reset Characteristics ..... 502
2.7.12 Trace Functionality Across Reset ..... 502
2.7.13 Reset Isolation ..... 503
2.7.14 Reset Output ($\overline{\text{RSTOUT_WD_OUT}}$) ..... 503
2.7.15 Power-on-Reset (PORz) Sequence ..... 504
2.7.16 RESETz Sequence ..... 504
2.7.17 Power-Up/Down Sequence ..... 505
2.7.18 IO State ..... 505
2.7.19 MPU Subsystem POR Sequence ..... 505
2.7.20 MPU Subsystem Warm Sequence ..... 506
2.7.21 HDVICP Power-On Reset Sequence ..... 507
2.7.22 HDVICP Software Warm Reset Sequence ..... 509
2.7.23 C674x DSP Power-On Reset Sequence ..... 509
2.7.24 C674x DSP Warm Reset Sequence ..... 510
2.7.25 Media Controller Power-On Reset Sequence ..... 510
2.7.26 Media Controller Warm Reset Sequence ..... 512
2.8 Voltage and Power Domains ..... 512
2.8.1 Voltage Domains ..... 513
2.8.2 Power Domains ..... 514
2.8.3 Device Modules and Power Management Attribute List ..... 515
2.8.4 Power Domain Power-Down Sequence ..... 515
2.8.5 Power Domain Power-Up Sequence ..... 515

Copyright © 2011–2016, Texas Instruments Incorporated

2.9 Voltage Management Functional Description ..... 517
2.9.1 Overview ..... 517
2.9.2 Internal LDOs Control ..... 518
2.10 PRCM Registers ..... 518
2.10.1 PLLSS Registers ..... 520
2.10.2 PRM_DEVICE Registers ..... 707
2.10.3 CM_DEVICE Registers ..... 710
2.10.4 OCP_SOCKET_PRM Registers ..... 712
2.10.5 CM_DPLL Registers ..... 713
2.10.6 CM_ACTIVE Registers ..... 733
2.10.7 CM_DEFAULT Registers ..... 735
2.10.8 CM_HDVICP Registers ..... 743
2.10.9 CM_ISP Registers ..... 747
2.10.10 CM_DSS Registers ..... 751
2.10.11 CM_SGX Registers ..... 754
2.10.12 PRM_ACTIVE Registers ..... 756
2.10.13 PRM_DEFAULT Registers ..... 761
2.10.14 PRM_HDVICP Registers ..... 766
2.10.15 PRM_ISP Registers ..... 771
2.10.16 PRM_DSS Registers ..... 775
2.10.17 PRM_SGX Registers ..... 780
2.10.18 CM_ALWON Registers ..... 785
2.10.19 PRM_ALWON Registers ..... 848

**3 Control Module ..... 851**

3.1 Control Module ..... 852
3.1.1 MMR_LOCK Register (Locked/Unlocked States) ..... 852
3.1.2 Pin Multiplexing (Pin Mux) ..... 853
3.1.3 BOOT Status ..... 854
3.1.4 DSP / EDMA Memory Management Unit Configuration ..... 854
3.1.5 Interrupt and DMA Controller Crossbars ..... 854
3.1.6 Device Level Peripheral Configuration ..... 855
3.1.7 Reset Isolation ..... 855
3.2 CONTROL_MODULE Registers ..... 856
3.2.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h] ..... 862
3.2.2 CONTROL_HWINFO Register (offset = 4h) [reset = 0h] ..... 863
3.2.3 CONTROL_SYSCONFIG Register (offset = 10h) [reset = 0h] ..... 864
3.2.4 CONTROL_STATUS Register (offset = 40h) [reset = 0h] ..... 865
3.2.5 BOOTSTAT Register (offset = 44h) [reset = 0h] ..... 867
3.2.6 DSPBOOTADDR Register (offset = 48h) [reset = 800000h] ..... 868
3.2.7 MMR_LOCK0 Register (offset = 60h) [reset = 1A1C8144h] ..... 869
3.2.8 MMR_LOCK1 Register (offset = 64h) [reset = FDF45530h] ..... 870
3.2.9 MMR_LOCK2 Register (offset = 68h) [reset = 1AE6E320h] ..... 871
3.2.10 MMR_LOCK3 Register (offset = 6Ch) [reset = 2FFA927Ch] ..... 872
3.2.11 MMR_LOCK4 Register (offset = 70h) [reset = 143F832Ch] ..... 873
3.2.12 CONTROL_SEC_CTRL Register (offset = 100h) [reset = 1Bh] ..... 874
3.2.13 DEVOSC Register (offset = 468h) [reset = 0h] ..... 875
3.2.14 AUXOSC Register (offset = 46Ch) [reset = 2h] ..... 876
3.2.15 PCIE_CFG Register (offset = 480h) [reset = 0h] ..... 877
3.2.16 DEVICE_ID Register (offset = 600h) [reset = B8F202Eh] ..... 878
3.2.17 DEV_FEATURE Register (offset = 604h) [reset = 0h] ..... 879
3.2.18 INIT_PRIORITY_0 Register (offset = 608h) [reset = 0h] ..... 881
3.2.19 INIT_PRIORITY_1 Register (offset = 60Ch) [reset = 0h] ..... 882
3.2.20 MMU_CFG Register (offset = 610h) [reset = 80h] ..... 883

Copyright © 2011–2016, Texas Instruments Incorporated

3.2.21 TPTC_CFG Register (offset = 614h) [reset = AAh] ..... 884
3.2.22 DSP_IDLE_CFG Register (offset = 61Ch) [reset = 28h] ..... 885
3.2.23 USB_CTRL0 Register (offset = 620h) [reset = 3C006007h] ..... 886
3.2.24 USB_STS0 Register (offset = 624h) [reset = 0h] ..... 888
3.2.25 USB_CTRL1 Register (offset = 628h) [reset = 3C006007h] ..... 889
3.2.26 USB_STS1 Register (offset = 62Ch) [reset = 0h] ..... 891
3.2.27 MAC_ID0_LO Register (offset = 630h) [reset = 0h] ..... 892
3.2.28 MAC_ID0_HI Register (offset = 634h) [reset = 0h] ..... 893
3.2.29 MAC_ID1_LO Register (offset = 638h) [reset = 0h] ..... 894
3.2.30 MAC_ID1_HI Register (offset = 63Ch) [reset = 0h] ..... 895
3.2.31 SW_REVISION Register (offset = 640h) [reset = 0h] ..... 896
3.2.32 DCAN_RAMINIT Register (offset = 644h) [reset = 0h] ..... 897
3.2.33 AUD_CTRL Register (offset = 64Ch) [reset = 0h] ..... 898
3.2.34 GMII_SEL Register (offset = 650h) [reset = 0h] ..... 899
3.2.35 OCMEM_PWRDN Register (offset = 654h) [reset = 0h] ..... 900
3.2.36 MEDIA_CONTROLLER_MEM_PWRDN Register (offset = 65Ch) [reset = 0h] ..... 901
3.2.37 SD_DAC_CTRL Register (offset = 670h) [reset = 18800C6h] ..... 902
3.2.38 SD_DAC0_CAL Register (offset = 674h) [reset = 0h] ..... 904
3.2.39 SD_DAC1_CAL Register (offset = 678h) [reset = 0h] ..... 905
3.2.40 SD_DAC0_REGCTRL Register (offset = 67Ch) [reset = 0h] ..... 906
3.2.41 SD_DAC0_REGSTATUS Register (offset = 680h) [reset = 0h] ..... 907
3.2.42 SD_DAC1_REGCTRL Register (offset = 684h) [reset = 0h] ..... 908
3.2.43 SD_DAC1_REGSTATUS Register (offset = 688h) [reset = 0h] ..... 909
3.2.44 EMIF_CLK_GATE Register (offset = 694h) [reset = 0h] ..... 910
3.2.45 SMRT_CTRL Register (offset = 6A0h) [reset = 0h] ..... 911
3.2.46 ARM_CORTEX_A8_HW_DBG_SEL Register (offset = 6A4h) [reset = 0h] ..... 912
3.2.47 ARM_CORTEX_A8_HW_DBG_INFO Register (offset = 6A8h) [reset = 0h] ..... 913
3.2.48 PRCM_DEBUG_ALWON_DEFAULT Register (offset = 6B0h) [reset = 3F7B0010h] ..... 914
3.2.49 PRCM_DEBUG_PD_DOMAIN_STATUS Register (offset = 6B4h) [reset = 871C7180h] ..... 916
3.2.50 PCIE_PLLCFG0 Register (offset = 6D8h) [reset = 40007000h] ..... 919
3.2.51 PCIE_PLLCFG1 Register (offset = 6DCh) [reset = 0h] ..... 921
3.2.52 PCIE_PLLCFG2 Register (offset = 6E0h) [reset = 0h] ..... 922
3.2.53 PCIE_PLLCFG3 Register (offset = 6E4h) [reset = 4000000h] ..... 923
3.2.54 PCIE_PLLCFG4 Register (offset = 6E8h) [reset = 0h] ..... 925
3.2.55 PCIE_PLLSTATUS Register (offset = 6ECh) [reset = 0h] ..... 927
3.2.56 PCIE_RXSTATUS Register (offset = 6F0h) [reset = 0h] ..... 928
3.2.57 PCIE_TXSTATUS Register (offset = 6F4h) [reset = 0h] ..... 929
3.2.58 SATA_PLLCFG0 Register (offset = 720h) [reset = C0007160h] ..... 930
3.2.59 SATA_PLLCFG1 Register (offset = 724h) [reset = 812C0000h] ..... 931
3.2.60 SATA_PLLCFG2 Register (offset = 728h) [reset = 0h] ..... 932
3.2.61 SATA_PLLCFG3 Register (offset = 72Ch) [reset = 4000000h] ..... 933
3.2.62 SATA_PLLCFG4 Register (offset = 730h) [reset = 0h] ..... 936
3.2.63 SATA_TXSTATUS Register (offset = 73Ch) [reset = 0h] ..... 938
3.2.64 SATA_TESTCFG Register (offset = 740h) [reset = 0h] ..... 939

## About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

## Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers may be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing non-default values to the Reserved bits could cause unexpected behavior and should be avoided.

## Glossary

SLYZ022 — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

## 1.1 ARM® Cortex™-A8 Microprocessor Unit (MPU) Subsystem Overview

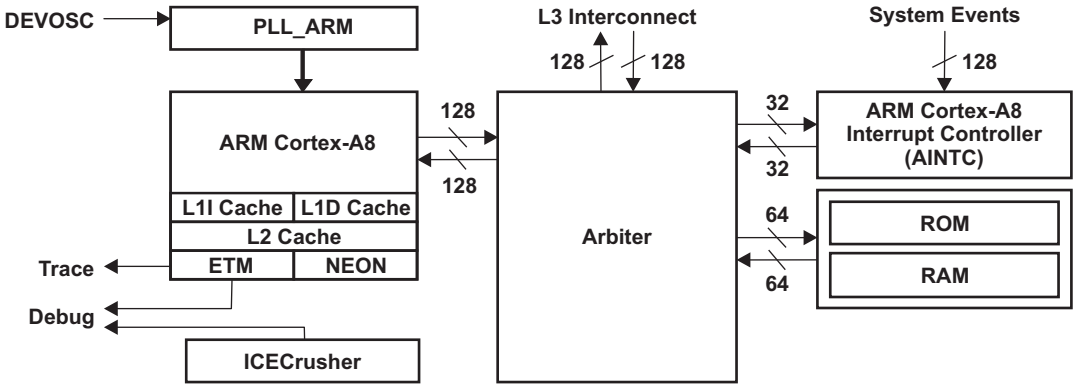
The ARM® Cortex™-A8 Subsystem is designed to allow the ARM Cortex-A8 master control of the device. In general, the ARM Cortex-A8 is responsible for configuration and control of the various subsystems, peripherals, and external memories.

The ARM Cortex-A8 Subsystem includes the following features:

- ARM Cortex-A8 RISC processor:
  - ARMv7 ISA plus Thumb2™, JazelleX™, and Media Extensions
  - Neon™ Floating-Point Unit
  - Enhanced Memory Management Unit (MMU)
  - Little Endian
  - 32K-Byte L1 Instruction Cache
  - 32K-Byte L1 Data Cache
  - 256K-Byte L2 Cache with ECC
- CoreSight Embedded Trace Module (ETM)
- ARM Cortex-A8 Interrupt Controller (AINTC)
- Embedded PLL Controller (PLL_ARM)
- Internal RAM
- Internal ROM

Figure 1-1 shows the ARM Cortex-A8 Subsystem for the device.

**Figure 1-1. ARM Cortex-A8 Subsystem**



### 1.1.1 ARM Cortex-A8 RISC Processor

The ARM Cortex-A8 processor is a member of ARM Cortex family of general-purpose microprocessors. This processor is targeted at multi-tasking applications where full memory management, high performance, low die size, and low power are all important. The ARM Cortex-A8 processor supports the ARM debug architecture and includes logic to assist in both hardware and software debug. The ARM Cortex-A8 processor has a Harvard architecture and provides a complete high-performance subsystem, including:

- ARM Cortex-A8 Integer Core
- Superscalar ARMv7 Instruction Set
- Thumb-2 Instruction Set
- Jazelle RCT Acceleration
- CP14 Debug Coprocessor
- CP15 System Control Coprocessor
- NEON™ 64-/128-bit Hybrid SIMD Engine for Multimedia
- Enhanced VFPv3 Floating-Point Coprocessor

Copyright © 2011–2016, Texas Instruments Incorporated

- Enhanced Memory Management Unit (MMU)
- Separate Level-1 Instruction and Data Caches
- Integrated Level-2 Cache
- 128-bit Interconnect with Level 3 Fast (L3) System Memories and Peripherals
- Embedded Trace Module (ETM).

### 1.1.2 Embedded Trace Module (ETM)

To support real-time trace, the ARM Cortex-A8 processor provides an interface to enable connection of an embedded trace module (ETM). The ETM consists of two parts:

- The Trace port which provides real-time trace capability for the ARM Cortex-A8.
- Triggering facilities that provide trigger resources, which include address and data comparators, counter, and sequencers.

The ARM Cortex-A8 trace port is not pinned out and is, instead, only connected to the system-level Embedded Trace Buffer (ETB). The ETB has a 32KB buffer memory. ETB enabled debug tools are required to read/interpret the captured trace data.

### 1.1.3 ARM Cortex-A8 Interrupt Controller (AINTC)

The ARM Cortex-A8 subsystem contains an interrupt controller (AINTC) that prioritizes all service requests from the system peripherals and generates either IRQ or FIQ to the ARM Cortex-A8 processor.

### 1.1.4 ARM Cortex-A8 PLL (PLL_ARM)

The ARM Cortex-A8 subsystem contains an embedded PLL Controller (PLL_ARM) for generating the subsystem's clocks from the device Clock input.

### 1.1.5 ARM MPU Interconnect

The ARM Cortex-A8 processor is connected through the arbiter to the L3 interconnect port. The L3 interconnect port is 128-bits wide and provides access to the other device modules.

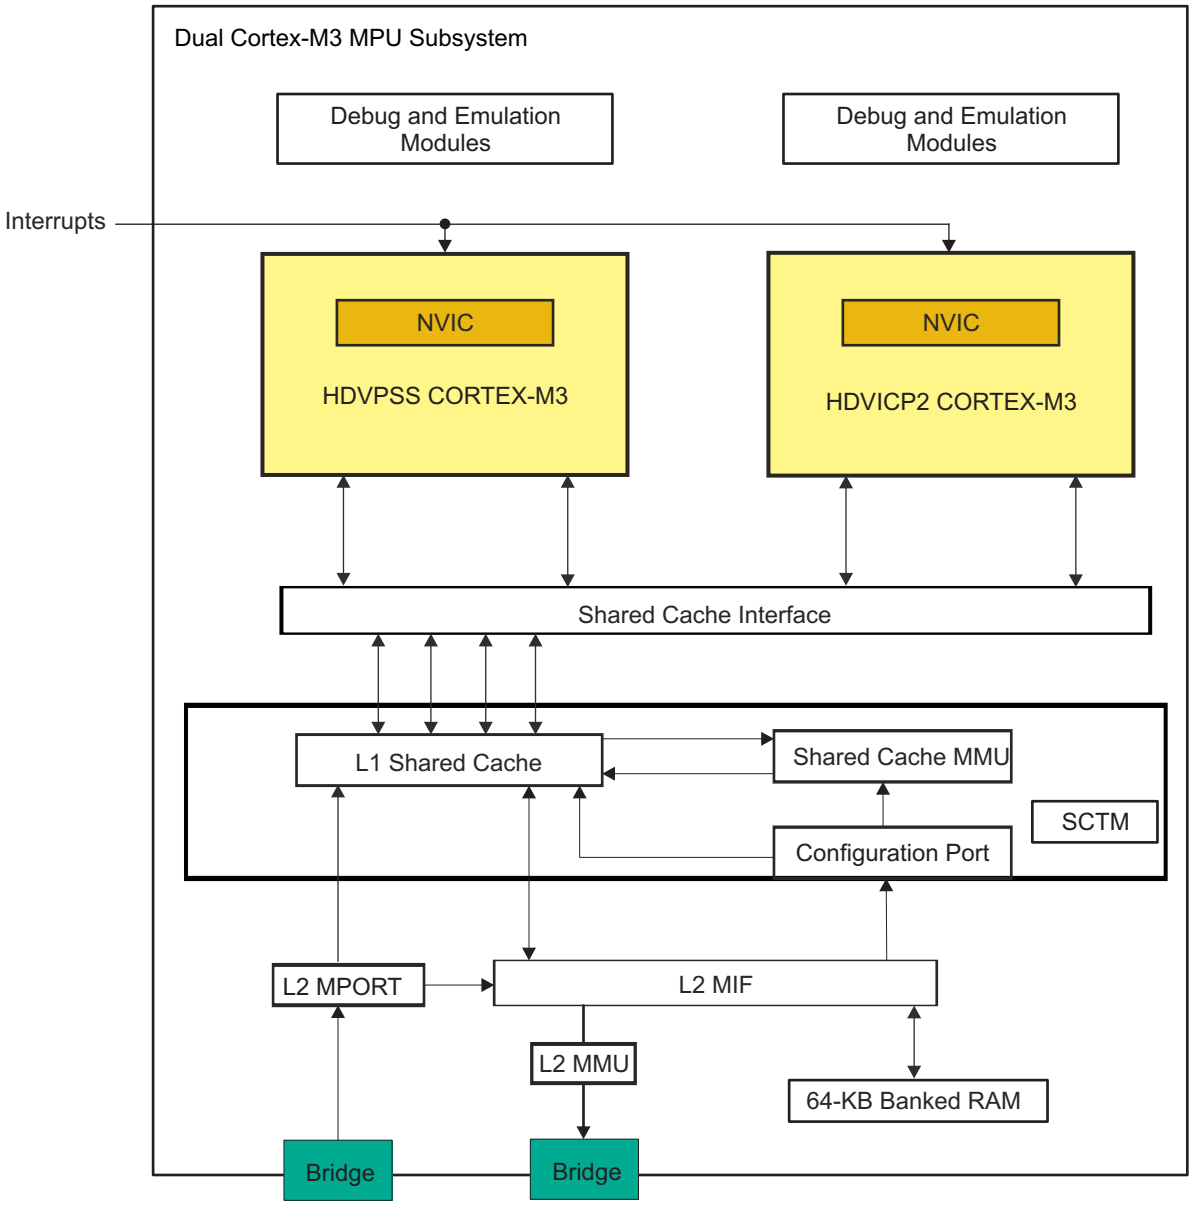
## 1.2 Media Controller Subsystem

### 1.2.1 Dual Cortex-M3 MPU Subsystem Overview

#### 1.2.1.1 Introduction

The Dual Cortex™-M3 MPU subsystem controls and manages the HDVPSS and HDVICP2 subsystems. It contains two ARM® Cortex-M3 processors (CPUs) that share a common L1 cache - Shared cache. Figure 1-2 is a high-level block diagram of the dual Cortex-M3 MPU subsystem.

**Figure 1-2. Dual Cortex-M3 MPU Subsystem Overview**



#### 1.2.1.2 Features

The dual Cortex-M3 MPU subsystem integrates the following:

- Two ARM Cortex-M3 microprocessor:
  - ARMv7-M and Thumb®-2 instruction set architecture

Copyright © 2011–2016, Texas Instruments Incorporated

  - Hardware division and single-cycle multiplication computational acceleration
  - Integrated nested vector interrupt controller (NVIC)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Shared cache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- L2 MIF (Master Interface) – splitter for access to memory or configuration port
- Configuration port - used for shared cache maintenance and shared cache MMU configuration
- Shared cache
  - 32KB divided into 16 banks
  - 4-way
  - Cache configuration – lock/freeze/preload
  - Internal MMU (memory management unit):
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- SCTM - Counter Timer Module
- Banked RAM memory
- Emulation/debug: Emulation feature embedded in Cortex-M3
- L2 MMU: 32 entries with walking table logic
- Power management

### 1.2.2 Dual Cortex-M3 MPU Subsystem Integration

Figure 1-3 shows the signals that interface with other modules.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-3. Dual Cortex-M3 MPU Subsystem Integration Overview**

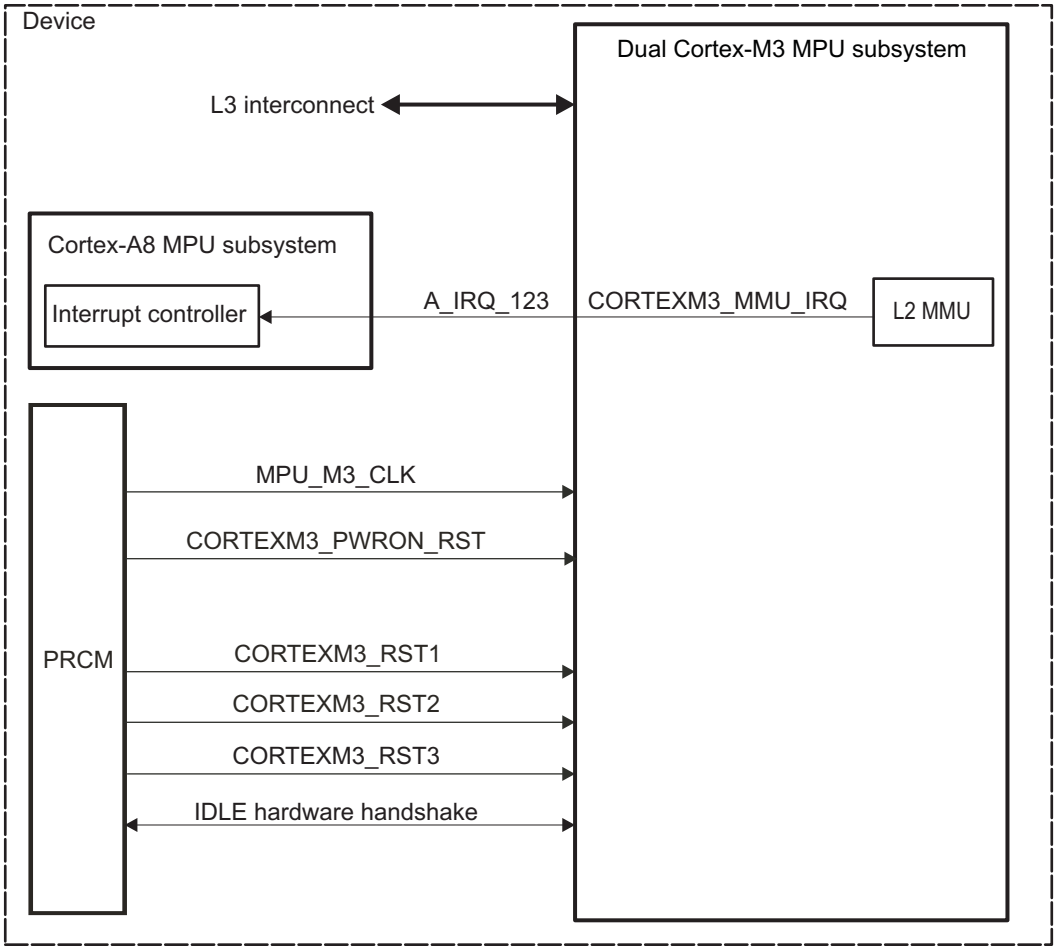


Table 1-1 and Table 1-4 summarize the integration of the module in the device.

**Table 1-1. Integration Attributes**

| Module Instance | Attributes | |
|---|---|---|
| | Power Domain | Interconnect |
| CORTEXM3 | PD_ALWAYS_ON | L3 |

**Table 1-2. Hardware Requests**

| Interrupt Requests | | | | |
|---|---|---|---|---|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| L2MMU | CORTEXM3_MMU_IRQ | A_IRQ_123 | Cortex-A8 MPU INTC | L2 MMU Fault Interrupt |

**Table 1-3. Clocks**

| Module Instance | Source Signal Name | Destination Signal Name | Source | Description |
|---|---|---|---|---|
| CORTEXM3 | MPU_M3_CLK | MPU_M3_CLK | PRCM module | Interface and Functional Clock |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-4. Resets**

| Module Instance | Source Signal Name | Destination Signal Name | Source | Description |
|---|---|---|---|---|
| CORTEXM3 | CORTEXM3_PWRON_RST | CORTEXM3_PWRON_RST | PRCM module | Power-on reset, used to reset the whole Media Controller Subsystem |
| | CORTEXM3_RST1 | CORTEXM3_RST1 | PRCM module | Reset signal to the HDVPSS |
| | CORTEXM3_RST2 | CORTEXM3_RST2 | PRCM module | Reset signal to the HDVICP2 |
| | CORTEXM3_RST3 | CORTEXM3_RST3 | PRCM module | Reset signal to the shared cache and L2 MMU |

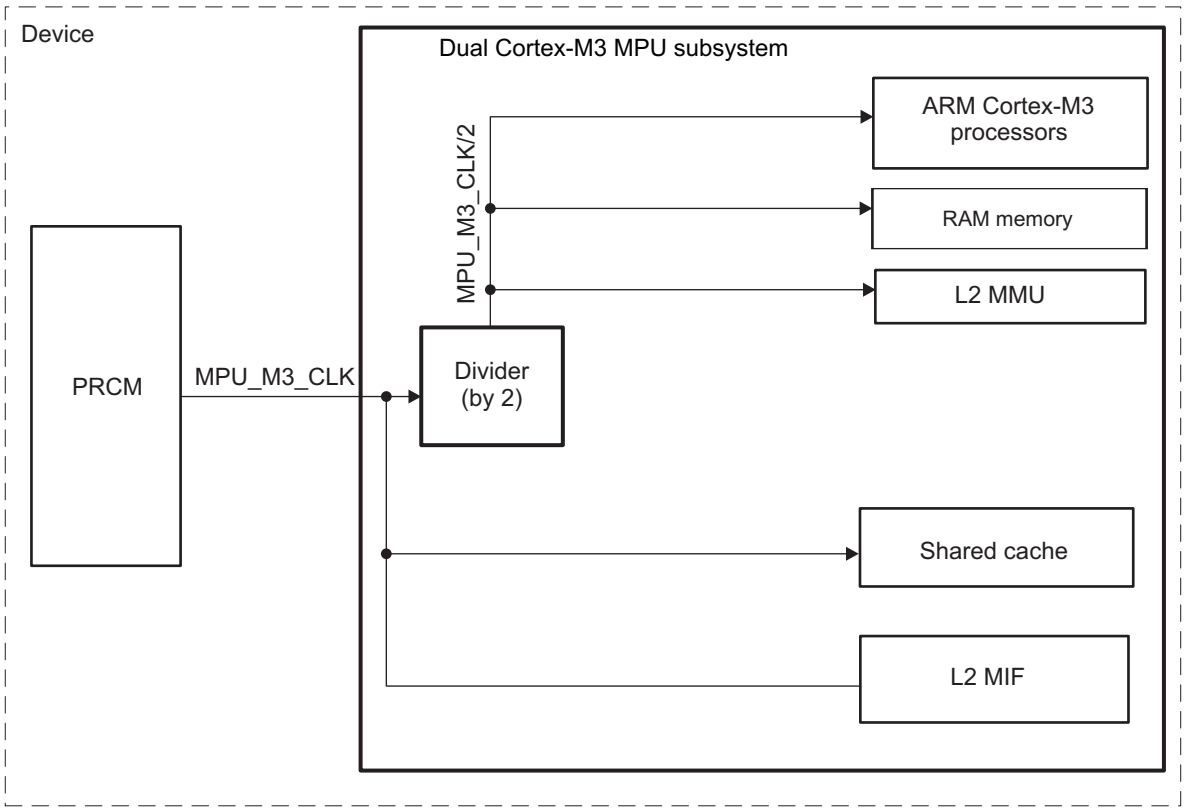
### 1.2.2.1 Dual Cortex-M3 MPU Subsystem Clock and Reset Distribution

#### *1.2.2.1.1 Clock Distribution*

The dual Cortex-M3 subsystem receives only one clock, MPU_M3_CLK, which is divided in two for each ARM Cortex-M3 processor, RAM memory and the L2 MMU module. The shared cache and the L2 MIF are directly clocked by the MPU_M3_CLK, without any division.

Figure 1-4 shows the clocking scheme of the MPU subsystem.

**Figure 1-4. Dual Cortex-M3 MPU Subsystem Clocking Scheme**



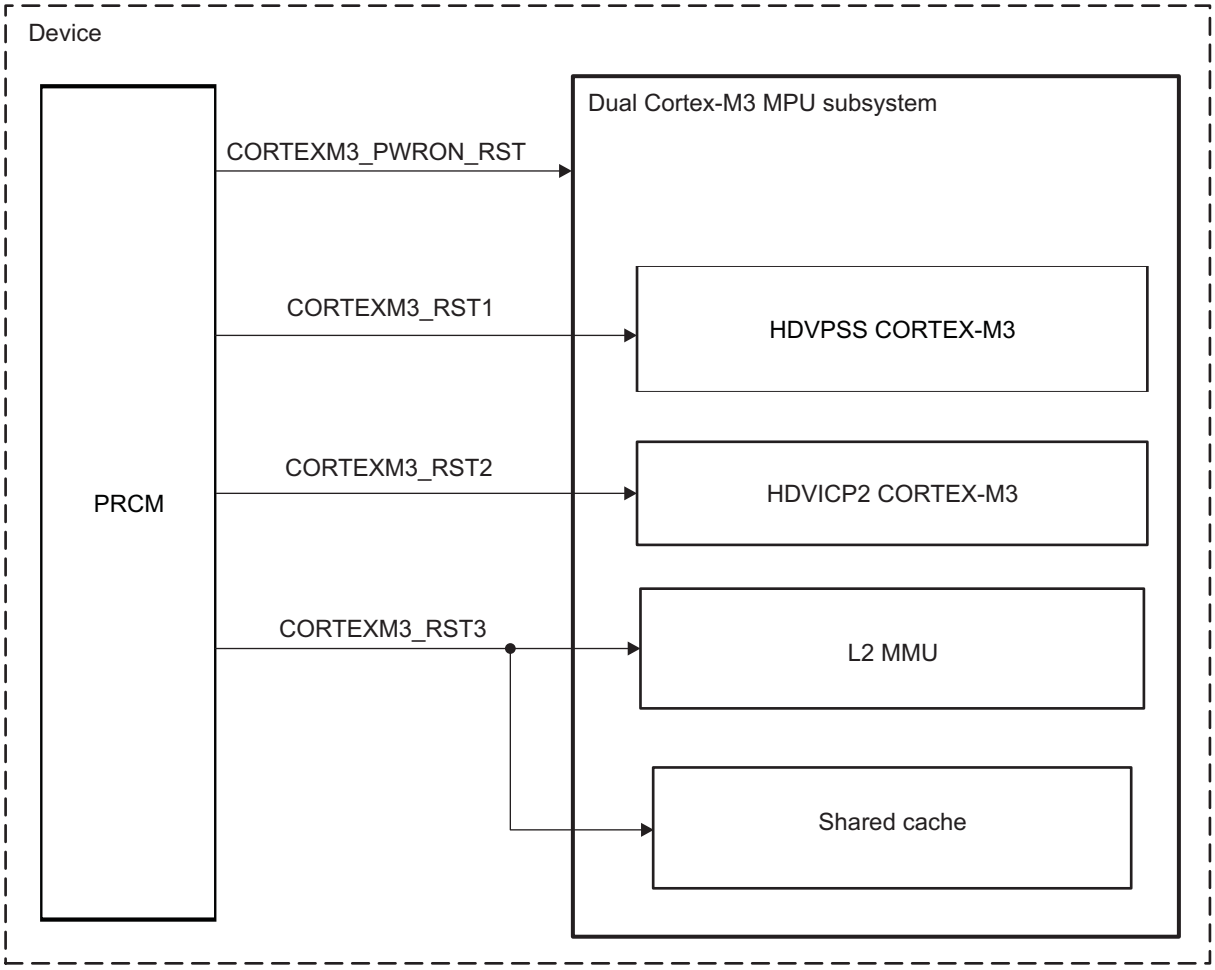
#### *1.2.2.1.2 Reset Distribution*

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two ARM Cortex-M3 processors and the rest of the dual Cortex-M3 MPU subsystem be reset independently. These three reset signals are: CORTEXM3_RST1, CORTEXM3_RST2, and CORTEXM3_RST3.

Figure 1-5 shows the reset scheme of the MPU subsystem.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-5. Dual Cortex-M3 MPU Subsystem Reset Scheme**



## *1.2.3 Dual Cortex-M3 MPU Subsystem Functional Description*

### 1.2.3.1 Dual Cortex-M3 MPU Subsystem Block Diagram

The dual Cortex-M3 MPU subsystem integrates the following group of submodules:

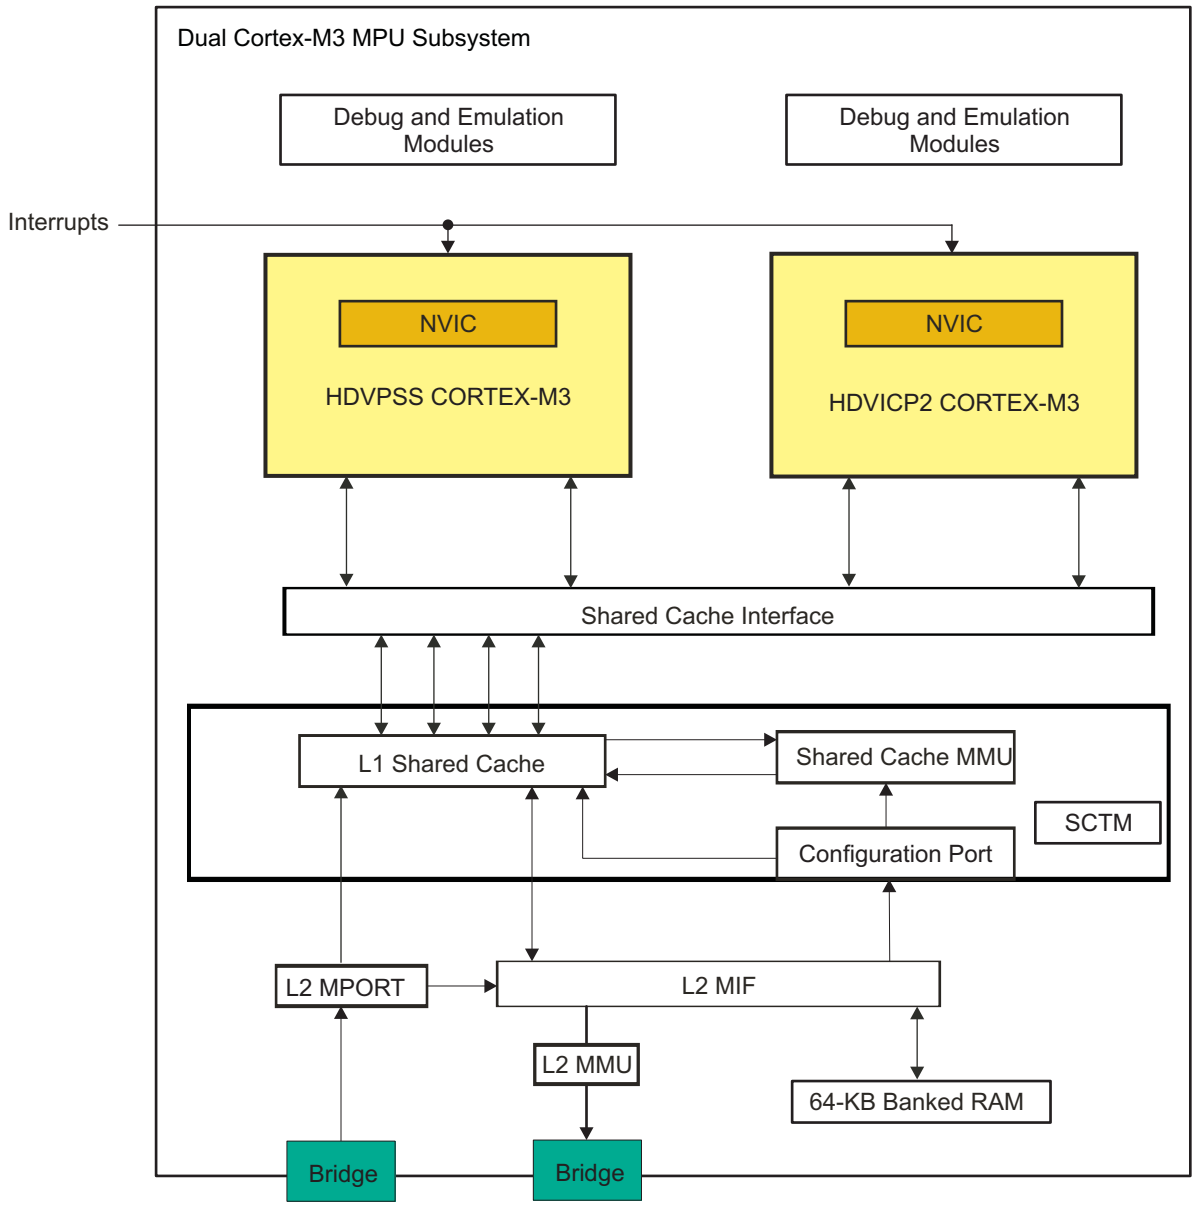
- Two ARM Cortex-M3 processors: Two cores, one core dedicated to HDVPSS and the other core dedicated to HDVICP2. For a description of the ARM Cortex-M3 processor, see the ARM Cortex-M3 Technical Reference Manual, available through your TI representative.
- Interrupt controller (NVIC): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M3 receives the same interrupts except for a few internal interrupts.
- Shared cache interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the ARM Cortex-M3 processors (two for each processor).The instruction and data connections from each ARM Cortex-M3 are multiplexed, but the ARM Cortex-M3 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cache ability is provided through the MMU inside the cache.
- Shared cache: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- Shared cache MMU: Provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the shared cache MMU is done only under privilege mode. The shared cache MMU can be programmed by the Cortex-A8 MPU subsystem through the Cortex-M3 slave port.

Copyright © 2011–2016, Texas Instruments Incorporated

- SCTM: Counter Timer Module, embedded in the Shared cache. Interconnect configuration port: Ca-che maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the shared cache MMU. Interconnect accesses are generated from the L2 MIF.
- L2 MMU: Provides address translation for all the accesses done from the Cortex-M3 to the level 3 (L3) interconnect. The L2 MMU can be programmed by the Cortex-A8 MPU subsystem through the Cortex-M3 slave port.
- L3 interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the dual Cortex-M3 MPU subsystem, see the Memory Map section of the device data manual.
- Banked RAM memory. The address range of the on-chip banked RAM memory is from 0x5502 0000 to 0x5503 FFFF.

Figure 1-6 shows the block diagram of the dual Cortex-M3 MPU subsystem.

**Figure 1-6. Dual Cortex-M3 MPU Subsystem**



Copyright © 2011–2016, Texas Instruments Incorporated

### 1.2.4 Shared Cache

Table 1-5 describes the shared cache configuration in the dual Cortex-M3 MPU subsystem platform.

**Table 1-5. Shared Cache Configuration**

| Parameter | Value |
|---|---|
| Way | 4 |
| Size | 32KB |
| Bank Elements | 32b |
| Bank Number | 16 |
| Slave Interface Data Size | 32b |
| Master Interface Data Size | 64b |
| Line size | 256b |
| MMU lookup | Included |
| Number of slaves | 4 |
| Number of masters | 1 |
| Number of fill/prefetch buffers | 4 prefetch buffers |
| Slave Types | Shared cache interface |

Shared cache allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

### 1.2.5 Shared Cache MMU

The MMU for the shared cache provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Table 1-6 describes the MMU configuration in the dual Cortex-M3 MPU subsystem.

**Table 1-6. Shared Cache MMU Configuration**

| Parameter | Harware Configurable |
|---|---|
| Number of large pages | 4 entries |
| Size of large pages | 32MB or 512MB |
| Number of medium pages | 2 entries |
| Size of medium pages | 128KB or 256KB |
| Number of small pages | 10 entries |
| Size of small pages | 4KB or 16KB |
| Number of patch pages | Not included |
| Size of line pages | 256-bit |
| Number of comparison interfaces | 4 |
| Number of comparator sets | 1 |
| Write pipeline data comparison | Disabled |
| Number of unicache maintenance interfaces | 3 |
| Size of entry address | 32-bit |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.2.6 L2 MMU

An additional MMU provides address translation for the accesses done from the dual Cortex-M3 MPU subsystem to the L3 interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with ARMv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion
- 2-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16MB, 1MB, 64KB, 4KB)
- Page table alignment on 128-byte boundary for ARM11™ compatibility

The configuration of the MMU can be done from one of the Cortex-M3 cores or from the L3 interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access. When an MMU fault occurs, an interrupt is generated. This interrupt is connected to the Cortex-M3 cores, but it is generated outside of the dual Cortex-M3 MPU subsystem and is connected to the dual Cortex™-A8 MPU subsystem. When an MMU fault occurs, no other access can be done through the L2 MMU; the current faulty access is stalled, thereby stalling one or both Cortex-M3 cores. The dual Cortex-A8 MPU that received the MMU fault must clean up the fault to resume the execution of the code (or reset Cortex-M3).

| CACHE_MMU_MMUCONFIG | RW | MMU Configuration Register | 0000 0CB8h |

#### 1.2.7.1 Configuration Registers (CACHE_CFG)

The Configuration Registers (CACHE_CFG) is described in docato-extra-info-title Configuration Registers (CACHE_CFG) Field DescriptionsTable 1-8 .

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-8. Configuration Registers (CACHE_CFG) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:2 | Reserved | Reserved | R | 0 |
| 1 | BYPASS | bypass cache | RW | 0 |
| | | 0x0: everything is non-cacheable | | |
| | | 0x1: everything is cacheable | | |
| 0 | Reserved | Reserved | R | 0 |

### 1.2.7.2 Interrupt Register (CACHE_INT)

The Interrupt Register (CACHE_INT) is described in Table 1-9.

**Table 1-9. Interrupt Register (CACHE_INT) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:9 | Reserved | Reserved | R | 0 |
| 8:5 | PORT | slave interface number that has recorded an error | RW W1toClr | 0 |
| 4 | READ | interface read response error | RW W1toClr | 0 |
| 3 | WRITE | interface write response error | RW W1toClr | 0 |
| 2 | MAINT | maintenance is completed | RW W1toClr | 0 |
| 1 | PAGEFAULT | AMMU page fault | RW W1toClr | 0 |
| 0 | CONFIG | configuration error | RW W1toClr | 0 |

### 1.2.7.3 Interface Configuration Register (CACHE_OCP)

The Interface Configuration Register (CACHE_OCP) is described in Table 1-10.

**Table 1-10. Interface Configuration Register (CACHE_OCP) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:6 | Reserved | Reserved | R | 0 |
| 5 | CLEANBUF | clean write and prefetch buffers in cache | RW | 0 |
| | | 0x0: do not clean | | |
| | | 0x1: clean | | |
| 4 | PREFETCH | always prefetch data | RW | 0 |
| | | 0x0: follow MMU policies | | |
| | | 0x1: always prefetch | | |
| 3 | CACHED | follow cacheable sideband signals | RW | 1 |
| | | 0x0: reads always not allocated, writes write through if cached | | |
| | | 0x1: slave sideband signals determine policy | | |
| 2 | WRALLOCATE | follow write allocate sideband signals | RW | 0 |
| | | 0x0: no writes are allocated independent to sideband | | |
| | | 0x1: follow sideband | | |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-10. Interface Configuration Register (CACHE_OCP) Field Descriptions (continued)**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 1 | WRBUFFER | write throughs and write back no allocate are buffered | RW | 0 |
| | | 0x0: write throughs and write back no allocated are not buffered | | |
| | | 0x1: write throughs and write back no allocated are buffered | | |
| 0 | WRAP | OCP wrap mode (critical word first) | RW | 0 |
| | | 0x0: disabled | | |
| | | 0x1: enabled | | |

### 1.2.7.4 Maintenance Configuration Register (CACHE_MAINT)

The Maintenance Configuration Register (CACHE_MAINT) is described in Table 1-11.

**Table 1-11. Maintenance Configuration Register (CACHE_MAINT) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:6 | Reserved | Reserved | R | 0 |
| 5 | INTERRUPT | generate interrupt when maintenance operation is complete | RW | 0 |
| | | 0x0: do not generate interrupt | | |
| | | 0x1: generate interrupt | | |
| 4 | INVALIDATE | invalidate lines in region defined by maintenance start/end addresses | RW | 0 |
| | | 0x0: do nothing | | |
| | | 0x1: invalidate | | |
| 3 | CLEAN | evict dirty lines in region defined by maintenance start/end addresses | RW | 0 |
| | | 0x0: do nothing | | |
| | | 0x1: clean | | |
| 2 | UNLOCK | unlock region defined by maintenance start/end addresses | RW | 0 |
| | | 0x0: do nothing | | |
| | | 0x1: unlock | | |
| 1 | LOCK | lock region defined by maintenance start/end addresses | RW | 0 |
| | | 0x0: do nothing | | |
| | | 0x1: lock | | |
| 0 | PRELOAD | preload region defined by maintenance start/end addresses | RW | 0 |
| | | 0x0: do nothing | | |
| | | 0x1: preload | | |

### 1.2.7.5 Maintenance Start Configuration Register (CACHE_MTSTART)

The Maintenance Start Configuration Register (CACHE_MTSTART) is described in Table 1-12.

**Table 1-12. Maintenance Start Configuration Register (CACHE_MTSTART) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | START_ADDR | start address of maintenance operations, reset to 0 when finished | RW | 0 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.2.7.6 Maintenance End Configuration Register (CACHE_MTEND)

The Maintenance End Configuration Register (CACHE_MTEND) is described in Table 1-13.

**Table 1-13. Maintenance End Configuration Register (CACHE_MTEND) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | END_ADDR | end address of maintenance operations, reset to 0 when finished | RW | 0 |

### 1.2.7.7 Cache Test Address Register (CACHE_CTADDR)

The Cache Test Address Register (CACHE_CTADDR) is described in Table 1-14.

**Table 1-14. Cache Test Address Register (CACHE_CTADDR) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | ADDRESS | address of cache visibility when read CTDATA register, autoincrements | RW | 0 |

### 1.2.7.8 Cache Test Data Register (CACHE_CTDATA)

The Cache Test Data Register (CACHE_CTDATA) is described in Table 1-15.

**Table 1-15. Cache Test Data Register (CACHE_CTDATA) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | DATA | cache data at address of CTADDR register, CTADDR autoincrements each time CTDATA is read | RW | 0 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.2.7.9 Counter Timer Control Register (CACHE_SCTM_CTCNTL)

he Counter Timer Control Register (CACHE_SCTM_CTCNTL) is described in Table 1-16.

**Table 1-16. Counter Timer Control Register (CACHE_SCTM_CTCNTL) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:26 | NUMSTM | Number of timers that can export via STM | R | 0 |
| 25:18 | NUMINPT | Number of event input signals | R | 1Fh |
| 17:13 | NUMTIMR | Number of timers in the module | R | 2 |
| 12:7 | NUMCNTR | Number of counters in the module | R | 8 |
| 6:3 | REVISION | Revision ID of SCTM | R | TI internal data |
| 2:1 | IDLEMODE | Idle mode control | RW | 2 |
| | | 0x0: Force Idle mode | | |
| | | 0x1: Ths SCTM will acknoledge the idle request, but never transition to the idle state | | |
| | | 0x2: Ths SCTM uses the smart idle protocol. This is the default mode | | |
| | | 0x3: Since the SCTM does not support internal wakeup, this mode is identical to smart_idle | | |
| 0 | ENBL | SCTM global enable | RW | 0 |
| | | 0x0: Ths mode is disable. Only the configuration interface is functional. All other logic is reset | | |
| | | 0x1: The module is enabled and individual counter/timers can be configured | | |

### 1.2.7.10 Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL)

The Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL) is described in Table 1-17.

**Table 1-17. Counter Timer STM Control Register (CACHE_SCTM_CTSTMCNTL) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:11 | Reserved | Reserved | R | 0 |
| 10 | XPORTACT | Indicates if a frame is currently being written to the STM | R | 0 |
| 9:5 | NUMXPORT | The total number of counters designated for export. This will be used as the count in the CSM and CCM headers. The value written should be the total number of counters designated for export -1 | RW | 0 |
| 4 | CCMXPORT | SW control of CCM message export | RW | 0 |
| 3 | CCMVAIL | SCTM supports CCM export | R | 0 |

| | | Read 0x1: The STM function of the SCTM is enabled | | |

### 1.2.7.11 Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID)

The Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID) is described in Table 1-18.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-18. Counter Timer STM Master ID Register (CACHE_SCTM_CTSTMMSTID) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:7 | Reserved | Reserved | R | 0 |
| 6:0 | MASTID | HW Master ID for this module. | RW | 0 |

### 1.2.7.12 Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL)

The Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL) is described in Table 1-19.

**Table 1-19. Counter Timer STM Interval Register (CACHE_SCTM_CTSTMINTVL) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:16 | Reserved | Reserved | R | 0 |
| 15:0 | INTERVAL | Periodic export interval | RW | 0 |

### 1.2.7.13 Counter Timer STM Count Select Register 0 (CACHE_SCTM_CTSTMSEL0)

The Counter Timer STM Count Select Register 0(CACHE_SCTM_CTSTMSEL0) is described in Table 1-20.

**Table 1-20. Counter Timer STM Count Select Register 0(CACHE_SCTM_CTSTMSEL0) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | COUNTSEL | The counter selection bit-field | RW | 0 |

### 1.2.7.14 Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i)

The Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i) is described in Table 1-21.

**Table 1-21. Counter Timer Interval Number Debug Event Register (CACHE_SCTM_TINTVL_R_i) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:0 | INTERVAL | Interval match value for the timers in the SCTM | RW | 0 |

### 1.2.7.15 Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM)

The Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM) is described in Table 1-22.

**Table 1-22. Counter Timer Number Debug Event Register (CACHE_SCTM_CTDBGNUM) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:3 | Reserved | Reserved | R | 0 |
| 2:0 | NUMEVT | Number of input selectors for debug events | R | 0 |

### 1.2.7.16 Counter Timer Global Enable Register 0 (CACHE_SCTM_CTGNBL0)

The Counter Timer Global Enable Register 0 (CACHE_SCTM_CTGNBL0) is described in Table 1-23.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-23. Counter Timer Global Enable Register 0(CACHE_SCTM_CTGNBL0) Field Description**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:8 | Reserved | Reserved | R | 0 |
| 7:0 | ENABLE | The counter enable bit-field | RW | 0 |

### 1.2.7.17 Counter Timer Global Reset Register 0 (CACHE_SCTM_CTGRST0)

The Counter Timer Global Reset Register 0 (CACHE_SCTM_CTGRST0) is described in Table 1-24.

**Table 1-24. Counter Timer Global Reset Register 0(CACHE_SCTM_CTGRST0) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:8 | Reserved | Reserved | R | 0 |
| 7:0 | RESET | The counter reset bit-field | RW | 0 |

### 1.2.7.18 Counter Timer Control Register 0-31 (CACHE_SCTM_CTCRWT_i)

he Counter Timer Control Register 0-31 (CACHE_SCTM_CTCRWT_i) is described in Table 1-25.

**Table 1-25. Counter Timer Control Register 0-31(CACHE_SCTM_CTCRWT_i) Field Descriptions**

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|

## 1.3 C674x DSP

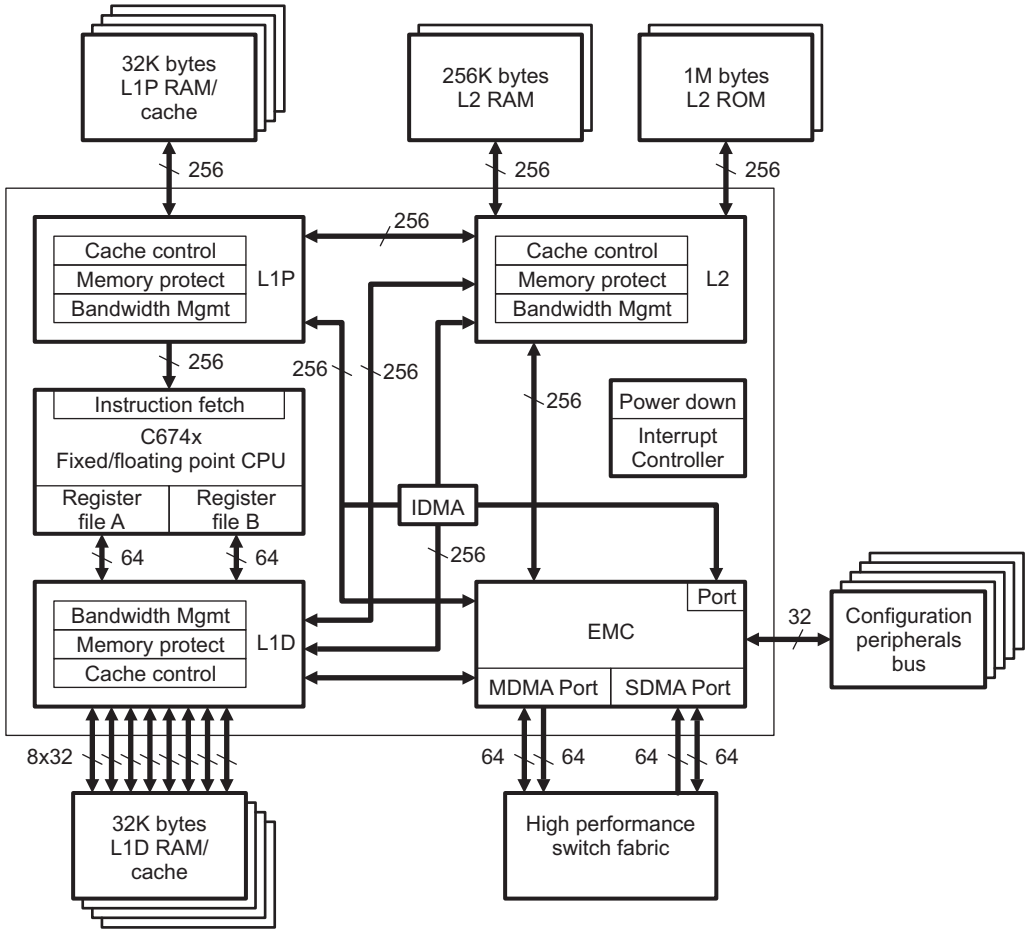
### 1.3.1 Introduction

The DSP subsystem (Figure 1-7) includes TI's standard TMS320C674x megamodule and several blocks of internal memory (L1P, L1D, and L2). This chapter provides an overview of the DSP subsystem and the following considerations associated with it:

- Memory mapping
- Interrupts
- Power management

For more information on the TMS320C674x megamodule, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5), the *TMS320C674x DSP CPU and Instruction Set Reference Guide* (SPRUFE8), and the *TMS320C674x DSP Cache User's Guide* (SPRUG82).

**Figure 1-7. TMS320C674x Megamodule Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

### 1.3.2 TMS320C674x Megamodule

The C674x megamodule (Figure 1-7) consists of the following components:

- TMS320C674x CPU
- Internal memory controllers:
  - Level 1 program memory controller (PMC)
  - Level 1 data memory controller (DMC)
  - Level 2 unified memory controller (UMC)
  - Extended memory controller (EMC)
  - Internal direct memory access (IDMA) controller
- Internal peripherals:
  - Interrupt controller (INTC)
  - Power-down controller (PDC)
  - Bandwidth manager (BWM)
- Advanced event triggering (AET)

For more information about each of these controllers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

#### 1.3.2.1 Internal Memory Controllers

The C674x megamodule implements a two-level internal cache-based memory architecture with external memory support. Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). L1 memory is accessible to the CPU without stalls. Level 2 memory (L2) can also be split into L2 RAM (normal addressable on-chip memory) and L2 cache for caching external memory locations. The internal direct memory access controller (IDMA) manages DMA among the L1P, L1D, and L2 memories.

#### 1.3.2.2 Internal Peripherals

The C674x megamodule includes the following internal peripherals:

- DSP interrupt controller (INTC)
- DSP power-down controller (PDC)
- Bandwidth manager (BWM)
- Internal DMA (IDMA) controller

This section briefly describes the INTC, PDC, BWM, and IDMA controller. For more information on these internal peripherals, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

##### 1.3.2.2.1 Interrupt Controller (INTC)

The C674x megamodule includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps DSP device events to 12 CPU interrupts. All DSP device events are listed in Section 1.7.3. The INTC is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

###### 1.3.2.2.1.1 Interrupt Controller Registers

For more information on the DSP interrupt controller (INTC) registers, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

##### 1.3.2.2.2 Power-Down Controller (PDC)

The C674x megamodule includes a power-down controller (PDC). The PDC can power-down all of the following components of the C674x megamodule and internal memories of the DSP subsystem:

Copyright © 2011–2016, Texas Instruments Incorporated

- C674x CPU
- Level 1 program memory controller (PMC)
- Level 1 data memory controller (DMC)
- Level 2 unified memory controller (UMC)
- Extended memory controller (EMC)
- Internal direct memory access (IDMA) controller
- L1P memory
- L1D memory
- L2 memory

This device supports the static power-down feature from the C674x megamodule. The *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5) describes the power-down control in more detail.

- Static power-down: The PDC initiates power-down (clock gating) of the entire C674x megamodule and all internal memories immediately upon command from software.

Static power-down (clock gating) affects all components of the C674x megamodule and all internal memories. Software can initiate static power-down by way of a register bit in the power-down controller command register (PDCCMD) of the PDC. For more information on the PDC, see the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

#### *1.3.2.2.3 Bandwidth Manager (BWM)*

The bandwidth manager (BWM) provides a programmable interface for optimizing bandwidth among the requesters for resources, which include the following:

- EDMA3-initiated DMA transfers (and resulting coherency operations)
- DSP subsystem IDMA-initiated transfers (and resulting coherency operations)
- Programmable cache coherency operations
  - Block based coherency operations
  - Global coherency operations
- CPU direct-initiated transfers
  - Data access (load/store)
  - Program access

The resources include the following:

- L1P memory
- L1D memory
- L2 memory
- Resources outside of the C674x megamodule: external memory, on-chip peripherals, registers

Since any given requestor could potentially block a resource for extended periods of time, the bandwidth manager is implemented to assure fairness for all requesters.

The bandwidth manager implements a weighted-priority-driven bandwidth allocation. Each requestor (EDMA3, DSP subsystem IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system. There are a total of nine priority levels, where priority zero is the highest priority and priority eight is the lowest priority. When requests for a single resource contend, access is granted to the highest-priority requestor. When the contention occurs for multiple successive cycles, a contention counter assures that the lower-priority requestor gets access to the resource every 1 out of *n* arbitration cycles, where *n* is programmable. A priority level of -1 represents a transfer whose priority has been increased due to expiration of the contention counter or a transfer that is fixed as the highest-priority transfer to a given resource.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.3.2.2.4 Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the C674x megamodule. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port. The IDMA cannot transfer data to or from the internal DSP memory-mapped register space. The IDMA is fully described in the *TMS320C674x DSP Megamodule Reference Guide* (SPRUFK5).

### 1.3.3 Memory Map

Refer to your device-specific data manual for the addresses of the memory-map registers.

#### 1.3.3.1 DSP Internal Memory

See the *System Memory* chapter for a description of the DSP internal memory.

#### 1.3.3.2 External Memory

See the *System Interconnect* chapter and the *System Memory* chapter for a description of the additional memory and peripherals that the DSP has access to.

### 1.3.4 Advanced Event Triggering (AET)

The C674x megamodule supports advanced event triggering (AET). This capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- Counters: count the occurrence of an event or cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

## 1.4 HD Video Coprocessor Subsystem

### 1.4.1 HDVICP2 Overview

The HDVICP2 is the image and video imaging hardware accelerator subsystem.

The HDVICP2 supports resolutions up to 1080 p/i with full performance of 60 fps (or 120 fields). The HDVICP2 subsystem supports the following codec standards natively; that is, all functions of standards are accelerated (without any intervention of the digital signal processor [Media Controller]):

- H.264: BP/MP/HP Encode and Decode
- H.264: Fast Profile/RCDO Encode and Decode
- MPEG-4: SP/ASP Encode/Decode (No support for GMC)
- DivX 5.x & higher Encode/Decode (No lower version; for example, 3.11 and 4.x)
- H.263: Profile 0 and 3 for Decode, Profile 0 for Encode
- Sorenson Spark: V0 and V1 Decode (No encode support)
- MPEG-2 SP/MP Encode/Decode
- MPEG-1 Encode/Decode
- VC1/WMV9/RTV : SP/MP/AP Encode and Decode
- ON2 VP6/VP7 Decode
- RV 8/9/10 Decode
- AVS 1.0 Encode and Decode

Copyright © 2011–2016, Texas Instruments Incorporated

- JPEG (also MJPEG) Baseline Encode/Decode
- H264 Annex H (MVC)

The HDVICP2 subsystem is composed of:

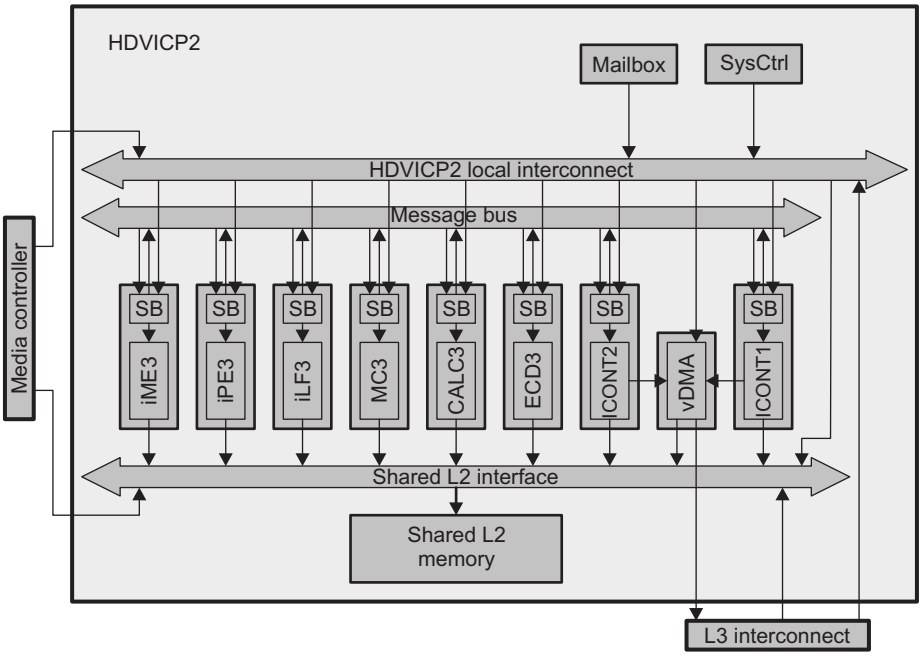
- A primary and a secondary sequencer: ICONT1 & ICONT2, which include its memories and an interrupt controller. Both these sequencers, ICONT1 and ICONT2, are identical.
- A video DMA engine: vDMA
- An entropy coder/decoder: ECD3
- A motion compensation engine: MC3
- A transform and quantization calculation engine: CALC3
- A loop filter acceleration engine: iLF3
- A motion estimation acceleration engine: iME3
- An intraprediction estimation engine: iPE3
- Shared level 2 (L2) interface and memory (of size 256 Kbytes)
- Local interconnect
- A message interface for communication between SyncBoxes
- Mailbox
- A debug module for trace event and software instrumentation: SMSET

TI has chosen eXpress DSP Digital Media (xDM) standard as the principle software interface to HDVICP2. The xDM standard defines application programming interfaces (APIs) through which an application invokes a particular class of codec, such as video, imaging, speech, and audio (aka VISA). The video and imaging classes for encode and decode apply to HDVICP2.

#### 1.4.1.1 HDVICP2 Functional Description

Figure 1-8 shows the block diagram of the HDVICP2 subsystem.

**Figure 1-8. HDVICP2 Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.4.1.2 SyncBox

The SyncBox is a configurable module that is in charge of scheduling all embedded hardware modules within the HDVICP2 subsystem. It handles all aspects of synchronization, data sharing, and parameters passing between accelerators. It also offers the possibilities to use asynchronous messages.

### *1.4.2 ICONTs*

The ICONT module is an ARM968E-S based microcontroller with 32KB of instruction tightly coupled memory (TCM) and 16KB of data tightly coupled memory. It includes an interrupt controller (INTC), a local data mover, its own SyncBox module for synchronizing tasks with other modules and its associated SyncBox handler.

Two identical instances of the ICONT, ICONT1 and ICONT2, are present in the HDVICP2 subsystem. They can typically be used to perform high-level processing (at frame and slice level), control at macroblock-level bounding box computation and other vDMA processing tasks.

Software can map processing equally on either ICONT.

### *1.4.3 vDMA*

The vDMA is a DMA engine to perform data transfer between external memories and shared L2 memory. The VDMA can also perform memory copies inside SL2 and inside external memory.

### *1.4.4 iME3*

The iME3 accelerator is used to perform motion estimation for Video encoding. iME3 has its own embedded SyncBox module for synchronizing tasks with other modules.

The iME3 compares a current macroblock to a reference area and provides an area in the reference region (in terms of offsets) which is least different to the current macroblock. It can also interpolate a block with half or quarter pixel precision, thus producing 4 (half pixel) or 16 (quarter pixel) interpolated blocks from the original block. Additionally, the IME3 supports searching of the best matching block within the interpolated planes.

### *1.4.5 iPE3*

The iPE3 accelerator is used to perform the intraprediction estimation for video encoding. The iPE3 has its own embedded SyncBox module for synchronizing tasks with other modules and an LSE to transfer data from internal memories to shared L2 memory.

The iPE3 supports two modes, depending on the video standard:

- Spatial intraprediction estimation for H264 and AVS. It creates intraprediction macroblocks with given intramodes from the original macroblock and provides a cost estimation between the original macroblock and each pseudo intraprediction macroblock, and then chooses a mode with the smallest cost to recommend it as an optimal intraprediction mode.
- Spatial activity for MPEG-1/2/4 and VC-1. It calculates the spatial activity of the original luminance samples with the specified block size. This mode is designed to provide information about the original Luma pixels. The values can be used to decide the coding parameters of the macroblock such as the coding mode and the quantization parameter.

### *1.4.6 MC3*

The MC3 accelerator is used to perform the motion compensation. The MC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It creates an interprediction macroblock with given motion vectors and modes from the reference data.

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.4.7 CALC3

The CALC3 accelerator is used to perform forward and inverse transform and quantization calculation. CALC3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It can perform transform/inverse transform, Q/iQ and DC/AC prediction.

### 1.4.8 iLF3

The iLF3 accelerator is used to perform deblocking filtering and boundary strength computation. The iLF3 has its own embedded SyncBox module for synchronizing tasks with other HWAs.

### 1.4.9 ECD3

The ECD3 accelerator is designed to encode and decode the stream. ECD3 has its own embedded SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It supports Huffman codes and arithmetic codes.

For encode, the ECD3 encodes the macroblock information and residual data into a bitstream. For decode, the ECD3 decodes the bitstream and recovers the macroblock information and residual data.

### 1.4.10 SL2 Interface

The shared L2 interface, SL2IF, is an arbitrator that allows 18 initiators to access to an interleaved set of eight memory banks.

The SL2IF has two sets of interfaces:

- Eighteen 128-bit interfaces for accesses from module's to shared L2 memories.
- Eight 128-bit memory interfaces for direct accesses to the memory banks.

### 1.4.11 Message Bus

The message bus is an arbitrator that allows eight initiators to access eight targets. It is used to dispatch messages generated by the SyncBox of the different IPs.

### 1.4.12 HDVICP2 Local Interconnect

The HDVICP2 local interconnect provides connectivity between two external host interconnects (Media Controller and L3), two local sequencers (ICONT1 and ICONT2) and video hardware accelerators (iME3, iLF3, ECD3, CALC3, MC3, iPE3), video DMA engine (vDMA), and local modules (mailbox and sysctrl).

### 1.4.13 MailBox

The function of the mailbox is to support a 2-way communication between two hosts through interrupts. It allows the software to establish a communication channel between processors through a set of registers and associated interrupt signals by sending and receiving messages.

The mailbox embedded inside the HDVICP2 subsystem implements a 2-way communication between three external users and one internal user. This communication is ensured through three pairs of mailboxes and four-message FIFO depth for each message queue.

**NOTE:** The internal user is one of the two ICONTs. ICONT1 and ICONT2 are connected on a shared interrupt line. The choice between ICONT1 and ICONT2 is done by masking mailbox interrupt on ICONT1 or ICONT2. ICONT1 and ICONT2 can access the mailbox through the HDVICP2 local interconnect.

### 1.4.14 HDVICP2 System Control

The SYSCTRL module of HDVICP2 is in charge of:

Copyright © 2011–2016, Texas Instruments Incorporated

- Controlling clocks to the modules via software control and the hardware power handshaking state.
- Controlling power, reset, and clock management (PRCM) module power handshaking.
- Providing status of the above operation.
- Supporting synchronization through external event.

Copyright © 2011–2016, Texas Instruments Incorporated

## 1.5 System MMU

### 1.5.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management).

The device contains the following MMUs:

- System MMU for: C674x™ (via its MDMA Port), EDMA Transfer Controller 0 (TPTC0), and EDMA Transfer Controller 1 (TPTC1).
- L1 Shared cache MMU and L2 MMU in Media Controller Subsystem
- ARM® Cortex™-A8 MMU
- SGX530™ MMU

This user guide provides a detailed description of System MMU and L2 MMU present in the Media Controller Subsystem. For more details on Cortex A8 MMU, see the ARM® Cortex™-A8 Core Technical Reference Manual (contact your TI representative). For more details on the L1 Shared cache MMU present in the Media Controller subsystem, please refer to the *Media Controller Subsystem* section.

### 1.5.2 MMU Integration

The MMU communicates accesses from the requestor (e.g., C674x MDMA bus requests) to the L3 main interconnect, performing virtual to physical address translation. The MMU will assert an interrupt when a translation fault occurs; or for other error conditions. For MMU interrupt details, refer to the device datasheet.

Figure 1-9 shows the System MMU integration. Requests initiated by the EDMA Transfer Controllers 0 and 1 (TPTC0, and TPTC1) can optionally be routed through the System MMU. These requestors' use (or not) of the MMU is independently controllable via the Control Module MMU_CFG register bitfields (TC0MMU and TC1MMU, respectively). The C674x DSP MDMA port accesses will always be routed through the MMU so no configuration bit is instantiated in the MMU_CFG register for C674x DSP. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3 interconnect to the MMU and will again go through the L3 interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3 interconnect to the requested physical address, thus minimizing bus request latency as illustrated in Figure 1-9.

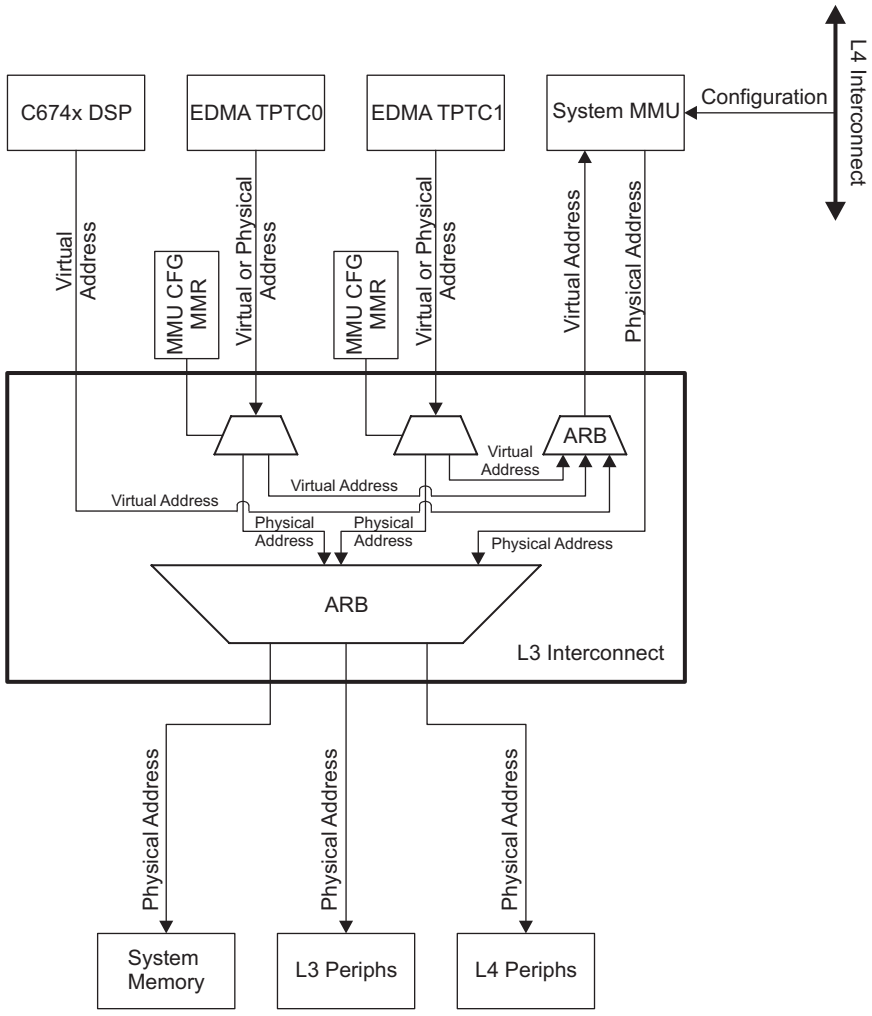
**Figure 1-9. MMU Intergration**



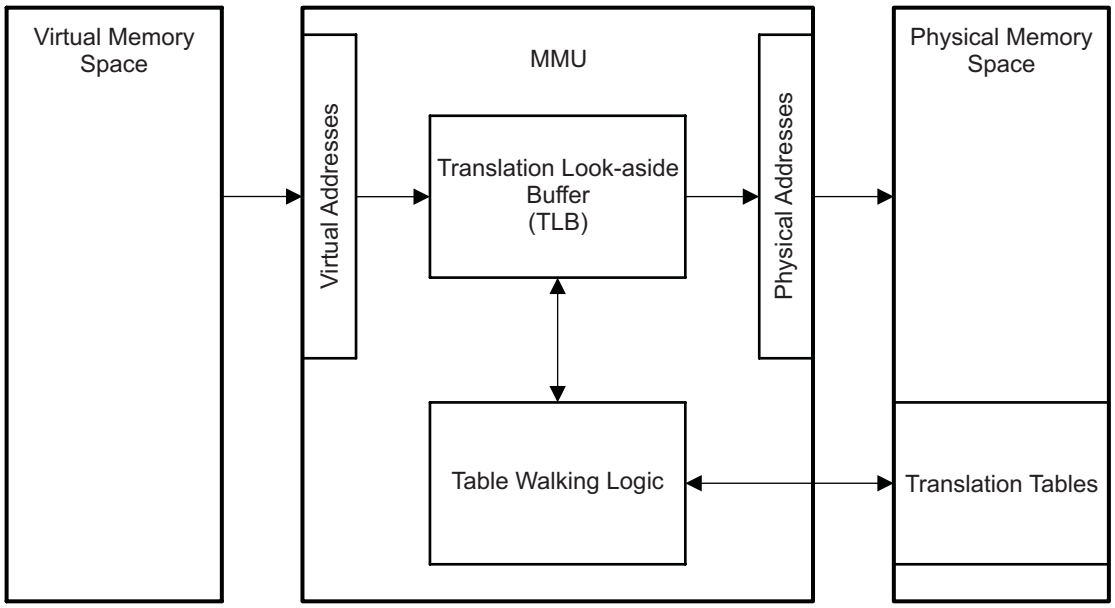
## *1.5.3 MMU Functional Description*

### 1.5.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. The MMU can be programmed through the L4 interconnect.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-10. MMU Block Diagram**



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Translation Tables.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

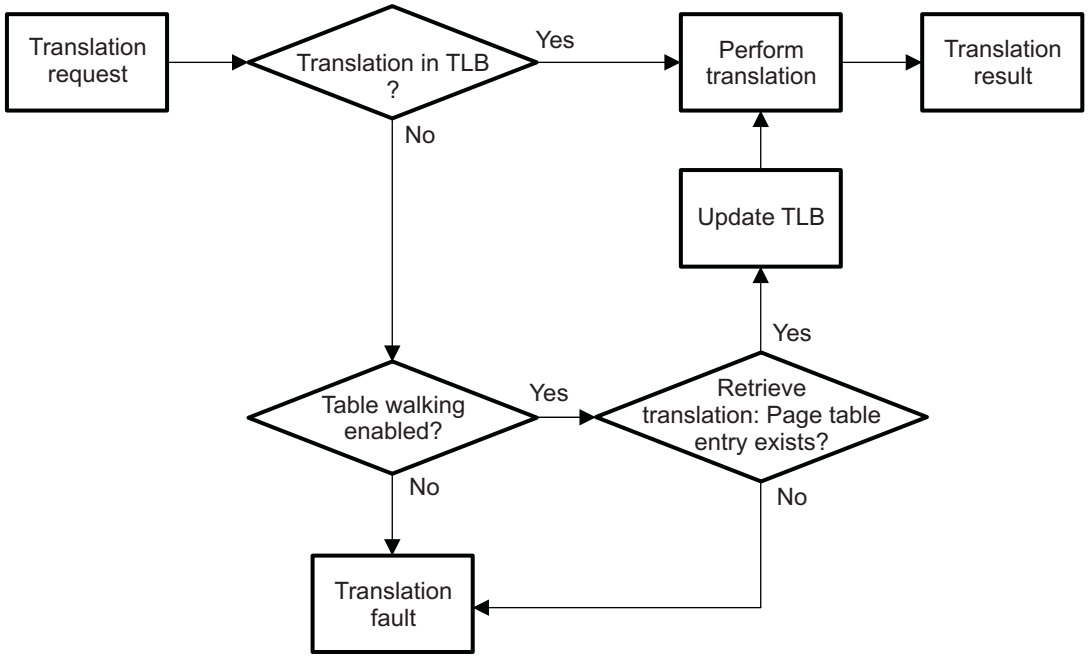
#### *1.5.3.1.1 MMU Address Translation Process*

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 1-11 summarizes the process.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-11. MMU Address Translation Process**



#### 1.5.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

##### 1.5.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages reduces the flexibility of the typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

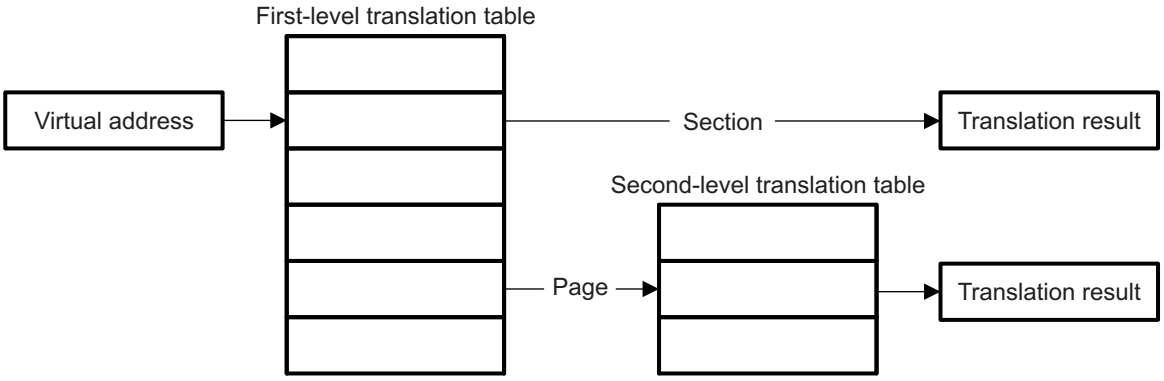
- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on

Copyright © 2011–2016, Texas Instruments Incorporated

smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used.

**Figure 1-12. Translation Hierarchy**



The structure of the first and second-level translation tables and their entries are described in more detail in First-Level Translation Table and Two-Level Translation.

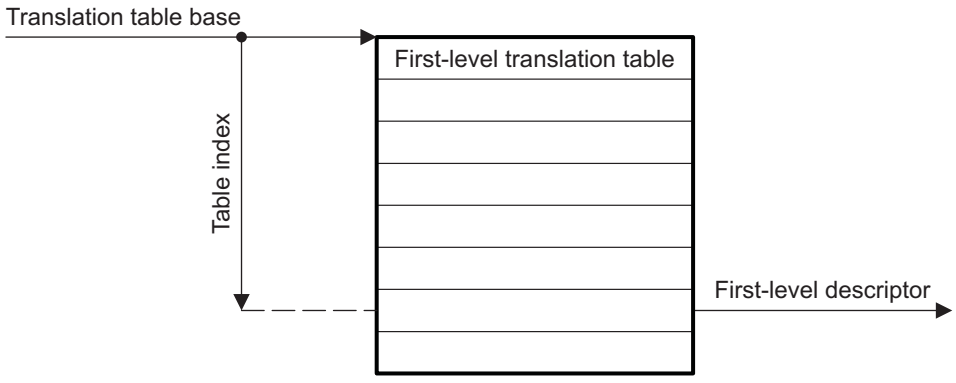
#### *1.5.3.1.2.2 First-Level Translation Table*

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address.

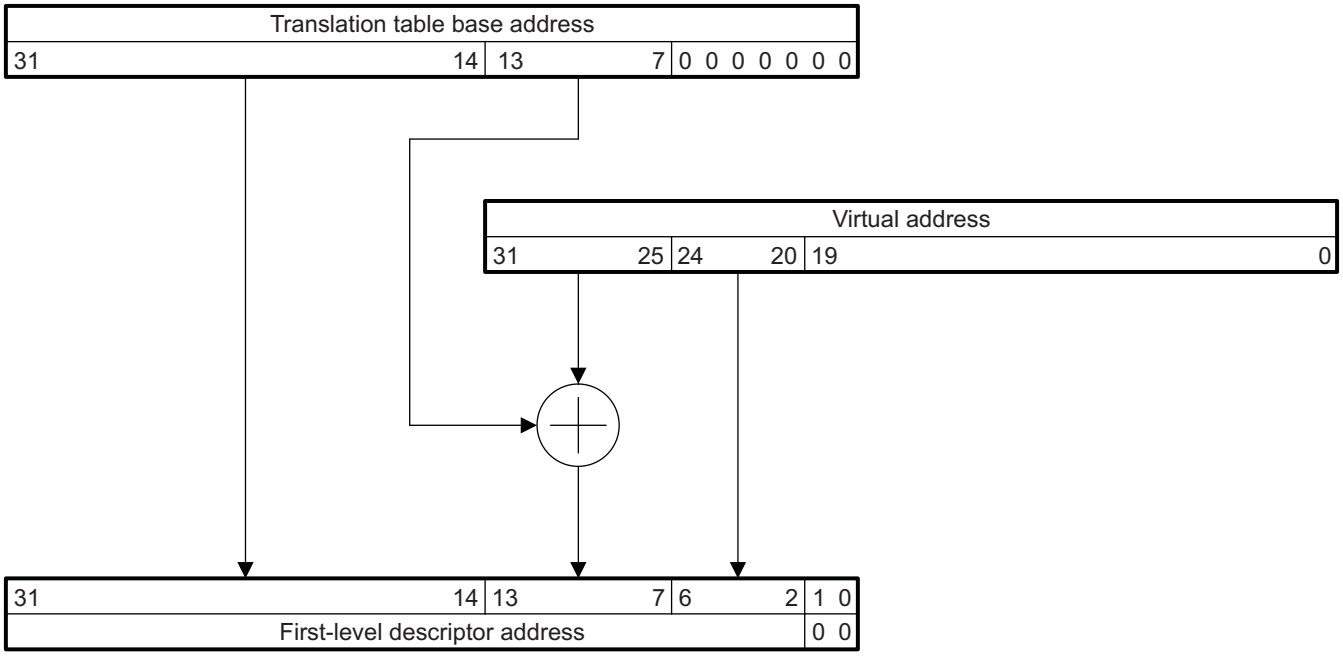
**Figure 1-13. First-Level Descriptor Address Calculation**



To summarize, the translation table base and the translation table index together define the first-level descriptor address. The precise mechanism used to calculate this address is shown below.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-14. Detailed First-Level Descriptor Address Calculation**



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is:

0x8000:0000 + (0x123 <<2) = 0x8000:048C.

#### *1.5.3.1.2.3 First-Level Descriptor Format*

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages.

**Table 1-42. First-Level Descriptor Format**

| 31:24 | 23:20 | 19 | 18 | 17 | 16 | 15 | 14:12 | 11:10 | 9:2 | 1 | 0 | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| X | | | | | | | | | | 0 | 0 | Fault |
| Second-level Translation Table Base Address | | | | | | | | | X | 0 | 1 | Page |
| Section Base Address | | X | 0 | M | X | E | X | ES | X | 1 | 0 | Section |
| Super Section base Address | | X | 1 | M | X | E | X | ES | X | 1 | 0 | Supersection |
| X | | | | | | | | | | 1 | 1 | Fault |

**M = Mixed region:** Don't care when E=0. Set to 0 to ensure future compatibility.

**E = Endianness:** Set to 0 for little-endian. Big-endian mode is not supported.

**ES = Element Size:** Don't care when E=0. Set to 00 to ensure future compatibility.

**X = Don't care.** Set to 0 to ensure future compatibility.

#### *1.5.3.1.2.4 First-Level Page Descriptor Format*

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.2.5 First-Level Section Descriptor Format

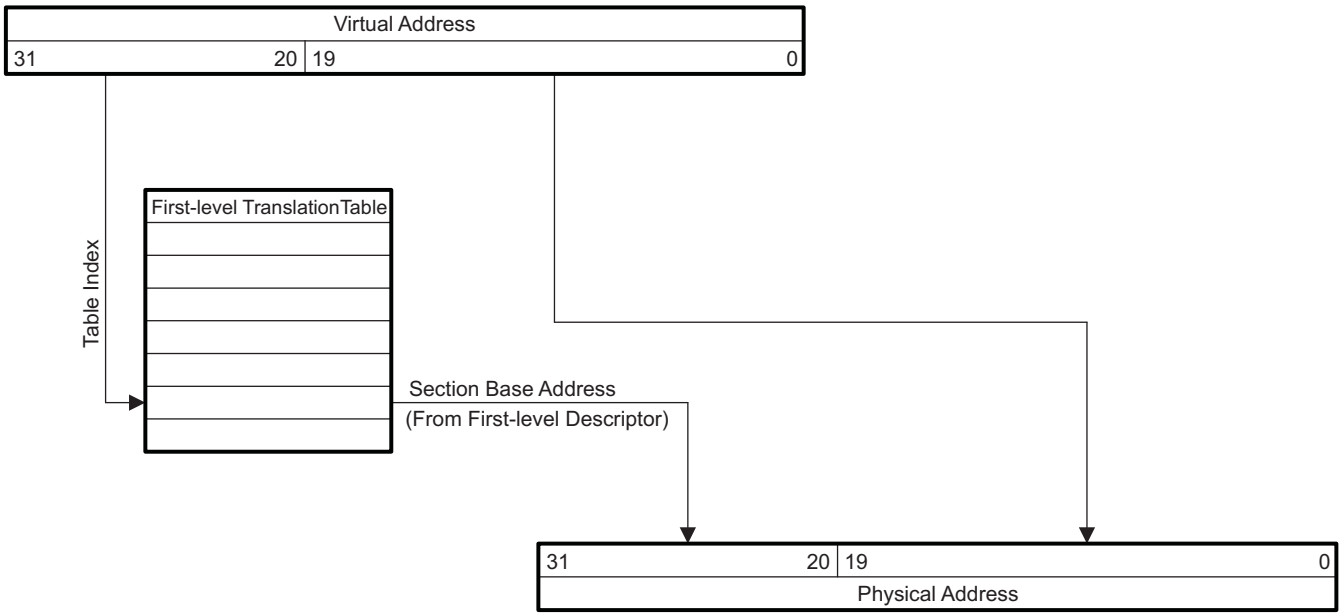
Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

**NOTE:** Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

#### 1.5.3.1.2.6 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table.

**Figure 1-15. Section Translation Summary**

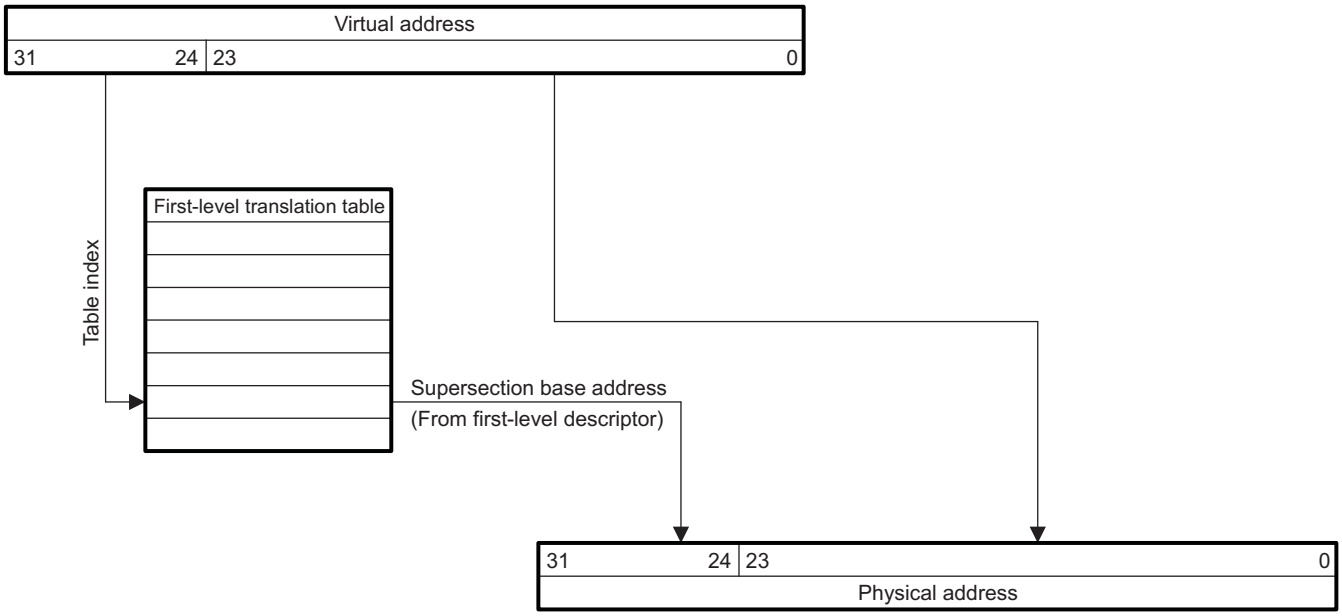


Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.2.7 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

**Figure 1-16. Supersection Translation Summary**

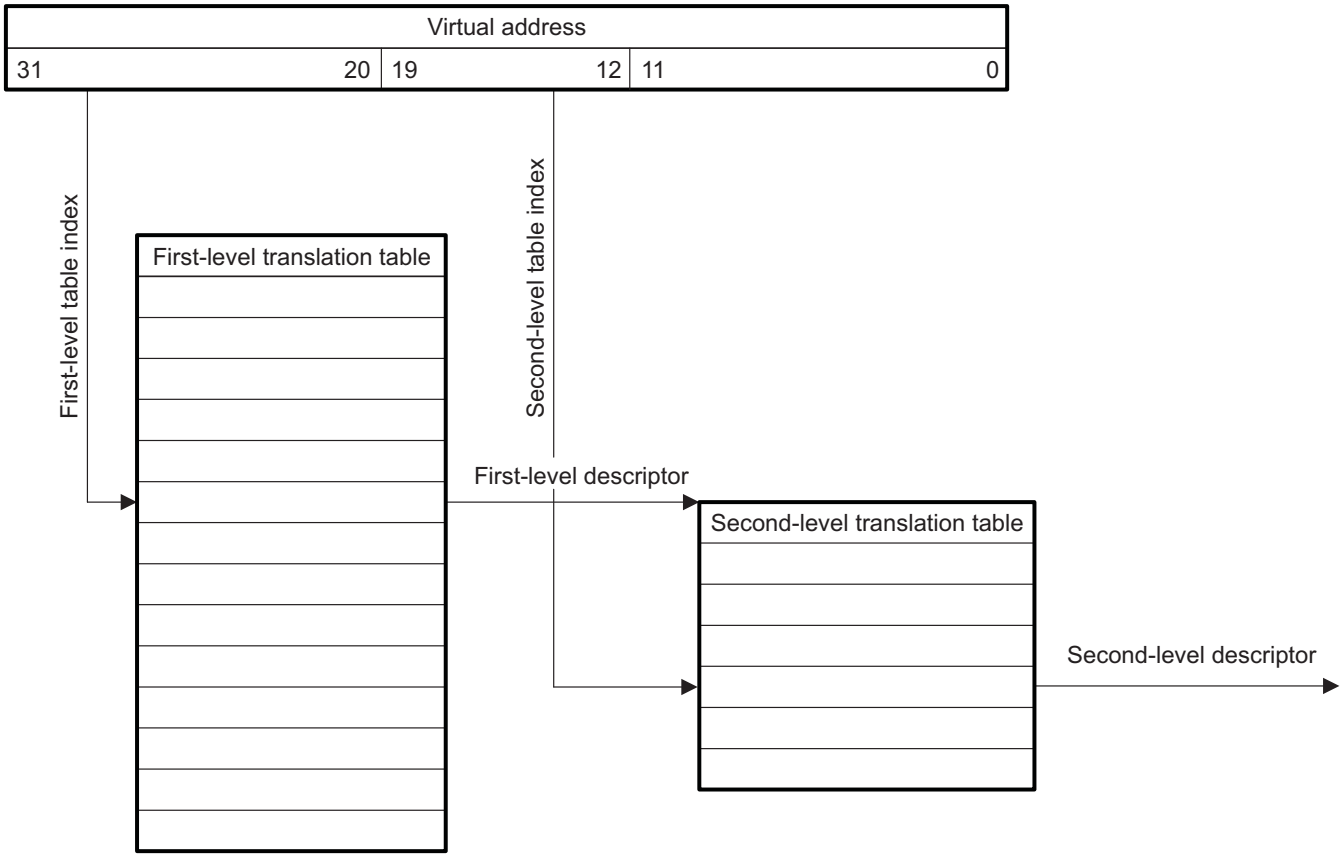


Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.2.8 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address.

**Figure 1-17. Two-Level Translation**



Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

**NOTE:** In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way."

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.2.9 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

**Table 1-43. Second-Level Descriptor Format**

| 31:16 | 15:12 | 11 | 10 | 9 | 8:6 | 5:4 | 3:2 | 1 | 0 | |
|---|---|---|---|---|---|---|---|---|---|---|
| X | | | | | | | | 0 | 0 | Fault |
| Large Page Base Address | X | M | X | E | X | ES | X | 0 | 1 | Large Page |
| Small Page Base Address | | M | X | E | X | ES | X | 1 | X | Small Page |

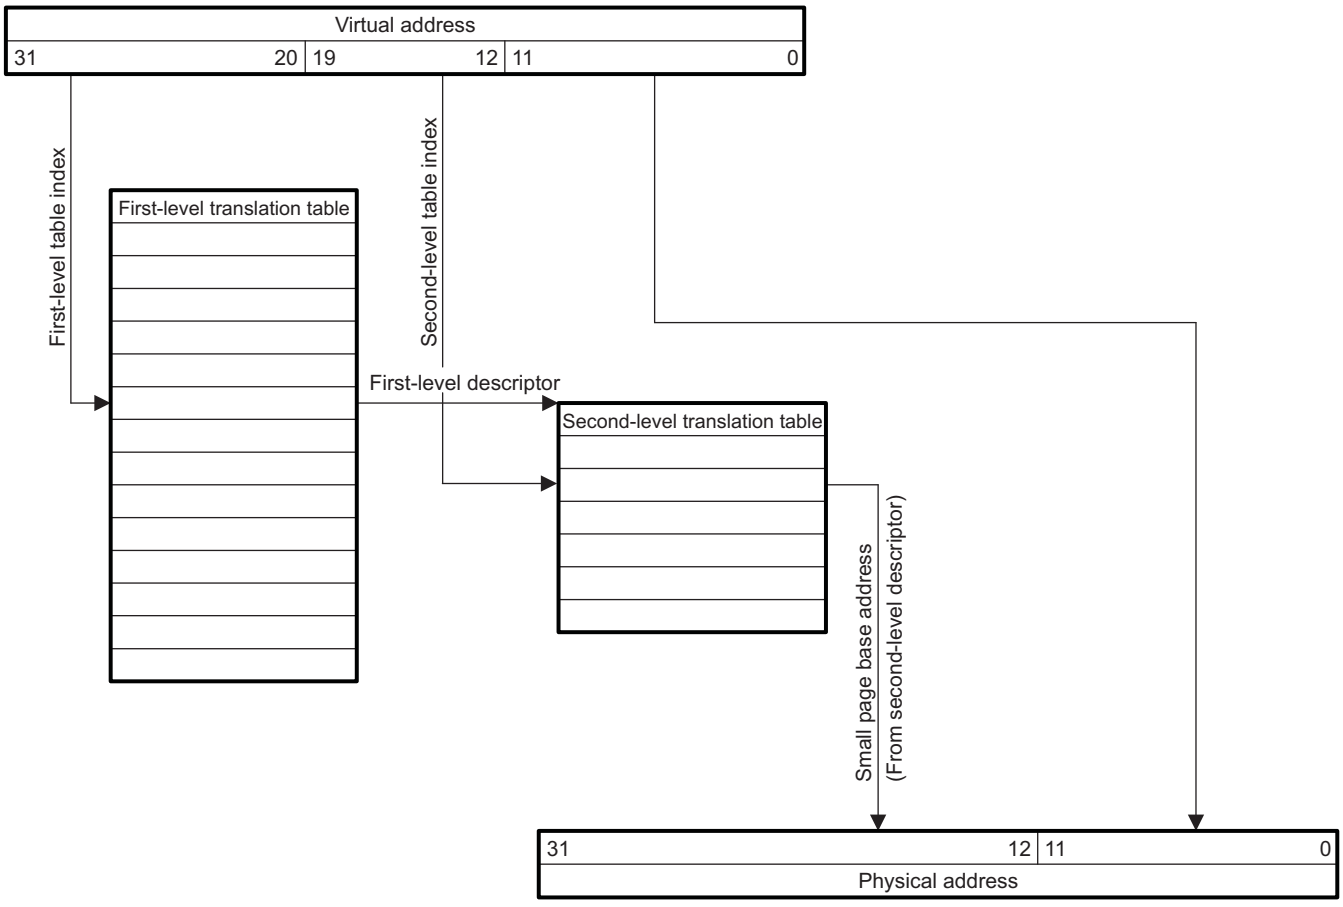
**M = Mixed region:** Don't care when E=0. Set to 0 to ensure future compatibility.

**E = Endianness:** Set to 0 for little-endian. Big-endian mode is not supported.

**ES = Element Size:** Don't care when E=0. Set to 00 to ensure future compatibility.

**X = Don't care.** Set to 0 to ensure future compatibility.

**Figure 1-18. Small Page Translation Summary**

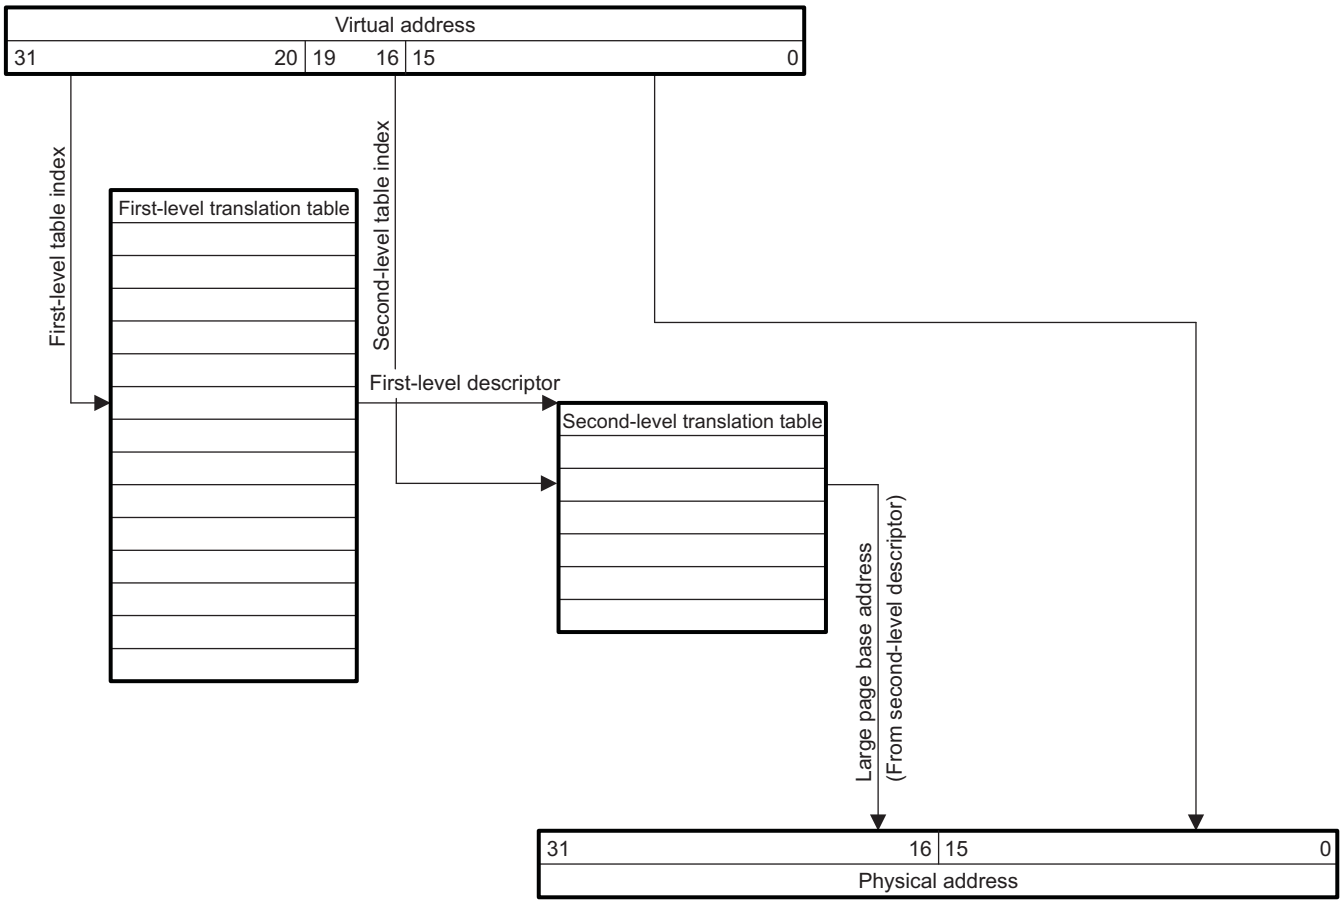


Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.2.10 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page.

**Figure 1-19. Large Page Translation Summary**



Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.3.1.3 Translation Lookaside Buffer

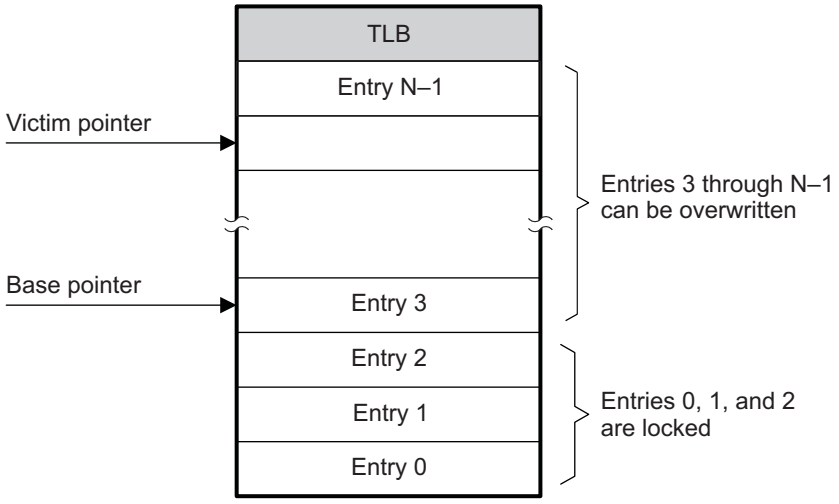
Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where n < Total Number N of TLB Entries , can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 1-20 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

**NOTE:** The last TLB entry (Entry N-1) always remains unprotected.

**Figure 1-20. TLB-Entry Lock Mechanism**



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

##### 1.5.3.1.3.1 TLB Entry Format

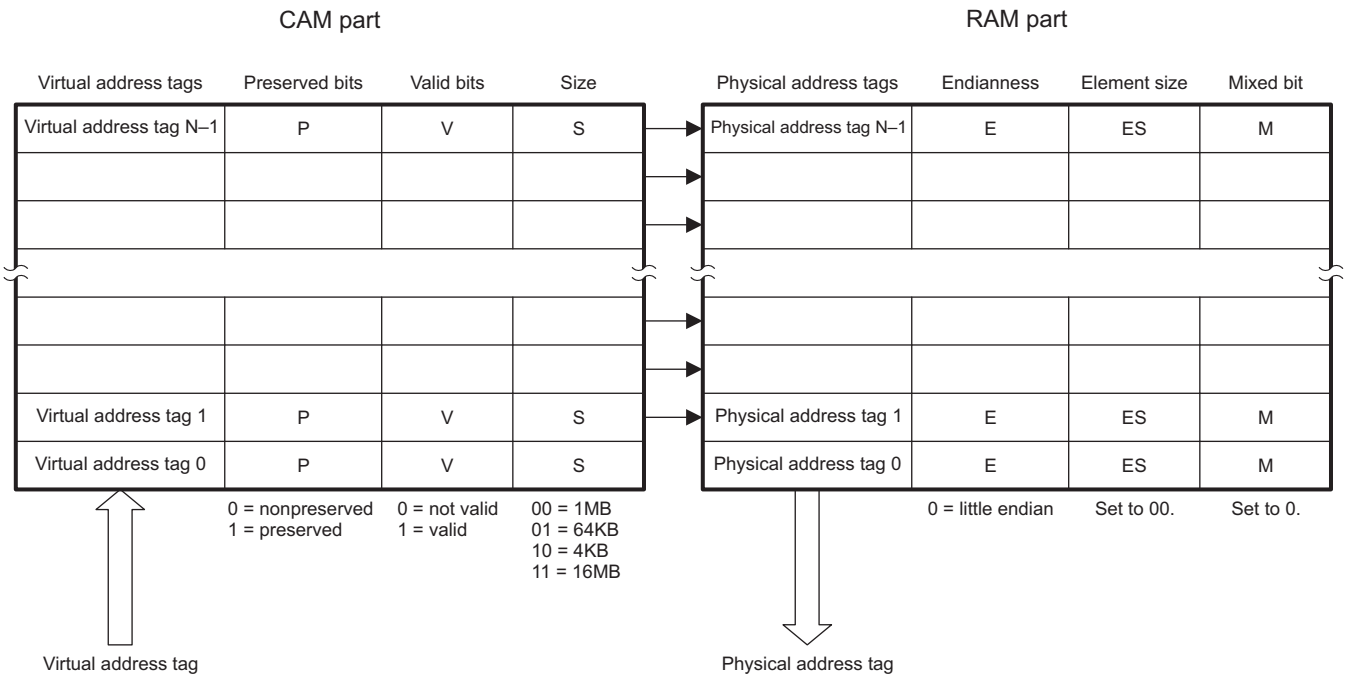
TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in First-Level Translation Table. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-21. TLB-Entry Structure**



### 1.5.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the MMU_SYSCONFIG register. This is a system configuration register that controls the various parameters of the L3 interface.

### 1.5.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See the Clocks and Resets tables for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

### 1.5.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

### 1.5.3.5 MMU Local Power Management Features

**Table 1-44. MMU Local Power Management Features**

| Feature | Register |
|---|---|
| Idle modes | MMU_SYSCONFIG[4:3] IDLEMODE |
| Clock activity | MMU_SYSCONFIG[9:8] CLOCKACTIVITY |
| Clock autogating | MMU_SYSCONFIG[0] AUTOIDLE |

**NOTE:** The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

### 1.5.3.6 MMU Interrupt Requests

**Table 1-45. Events**

| Event Flag | Event Mask | Description |
|---|---|---|
| MMU_IRQSTATUS[4] MULTIHITFAULT | MMU_IRQENABLE[4] MULTIHITFAULT | Error due to multiple matches in the TLB |
| MMU_IRQSTATUS[3] TABLEWALKFAULT | MMU_IRQENABLE[3] TABLEWALKFAULT | Error due to error response received during a Table Walk |
| MMU_IRQSTATUS[2] EMUMISS | MMU_IRQENABLE[2] EMUMISS | |
| MMU_IRQSTATUS[1] TRANSLATIONFAULT | MMU_IRQENABLE[1] TRANSLATIONFAULT | Error due to invalid descriptor in the translation tables (translation fault) |
| MMU_IRQSTATUS[0] TLBMISS | MMU_IRQENABLE[0] TLBMISS | Error due to unrecoverable TLB miss (hardware TWL disabled) |

### 1.5.3.7 MMU Error Handling

**Table 1-46. Error Handling**

| Item | Condition | Action |
|---|---|---|
| 1 | Table-walk read has an error response. | Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis |
| 2 | MMU is disabled during table-walk. | Not permitted; can result in loss of the current transaction but must not deadlock the MMU.<br>Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending. |
| 3 | MMU is disabled during an address translation. | Not permitted; can result in access to an unintended location, but must not deadlock MMU.<br>This condition should be avoided by ensuring that no accesses are pending. |
| 4 | TLB is accessed during an address translation or a table walk. | Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur. |
| 5 | TLB is flushed during address translation or a table walk. | Permitted; the flush is processed first, followed by the TWL update. |
| 6 | MMU is disabled while an interrupt is pending. | Not permitted; all pending interrupts should be processed before disabling the MMU. |

## 1.5.4 MMU Low-level Programming Models

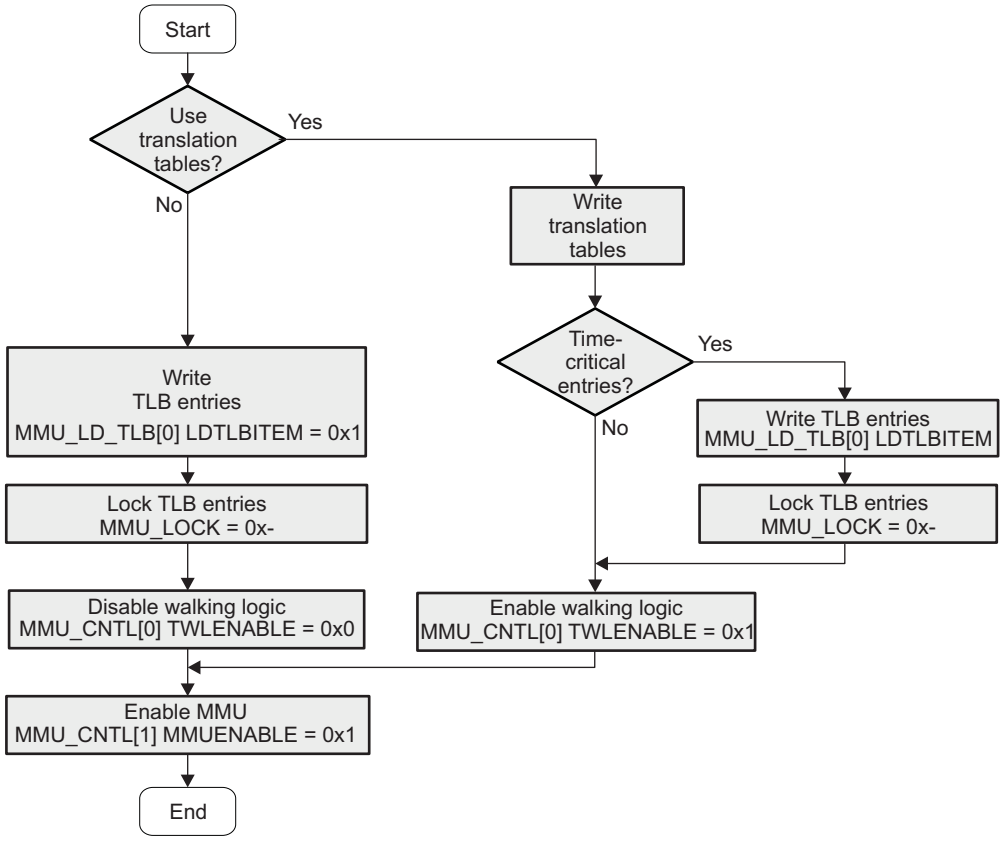
This section covers the low-level hardware programming sequences for configuration and usage of the module.

### 1.5.4.1 MMU Global Initialization

#### 1.5.4.1.1 Main Sequence - MMU Global Initialization

The System MMU can be enabled or disabled in MMU_CFG register (refer to the *Control Module* chapter). Figure 1-22 shows the procedure to initialize the MMU after a power-on or software reset.

**Figure 1-22. MMU Global Initialization**



#### 1.5.4.1.2 Subsequence - Configure a TLB entry

**Table 1-47. Configure a TLB Entry**

| Step | Registe/Bitfield/Programming Model | Value |
|---|---|---|
| Load the Virtual Address Tag | MMU_CAM[31:12] VATAG | 0x- |
| Protect the TLB entry against flush | MMU_CAM[3] P | 0x1 |
| Validate the TLB entry | MMU_CAM[2] V | 0x1 |
| Define the page size | MMU_CAM[1:0] PAGESIZE | 0x- |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.5.4.2 Operational Modes Configuration

#### *1.5.4.2.1 Main Sequence - Writing TLB Entries Statically*

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

**Table 1-48. MMU Writing TLB Entries Statically**

| Step | Register/ Bitfield / Programming Model | Value |
|---|---|---|
| Execute software reset | MMU_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait for reset to complete | MMU_SYSSTATUS[0] RESETDONE | =0x1 |
| Enable power saving via automatic interface clock gating | MMU_SYSCONFIG[0] AUTOIDLE | 0x1 |
| Configure TLB entries | Refer to table Configure a TLB Entry | |
| Load the physical Address of the page | MMU_RAM[31:12] PHYSICALADDRESS | 0x- |
| Define the endianness of the page (little endian or big endian) | MMU_RAM[9] ENDIANNESS | 0x- |
| Select the element size | MMU_RAM[8:7] ELEMENTSIZE | 0x- |
| Define mixed page attribute | MMU_RAM[6] MIXED | 0x- |
| Specify the TLB entry you want to write | MMU_LOCK[8:4] CURRENTVICTIM | 0x- |
| Load the specified entry in the TLB | MMU_LD_TLB[0] LDTLBITEM | 0x1 |
| Enable multihit fault and TLB miss | MMU_IRQENABLE[4] MULTIHITFAULT | 0x1 |
| | MMU_IRQENABLE[0] TLBMISS | 0x1 |
| Enable memory translations | MMU_CNTL[1] MMUENABLE | 0x1 |

#### *1.5.4.2.2 Main Sequence - Protecting TLB Entries*

The first n TLB entries (with n < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

**Table 1-49. Protecting TLB Entries**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Locks the TLB entries | MMU_LOCK[14:10] BASEVALUE | 0x- |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.4.2.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

**Table 1-50. Deleting TLB Entries**

| Step | Registe/Bitfield/Programming Model | Value |
|---|---|---|
| Flush all nonprotected TLB entries | MMU_GFLUSH[0] GLOBALFLUSH | 0x1 |
| Flush all TLB entries specified by the CAM register | MMU_FLUSH_ENTRY[0] FLUSHENTRY | 0x1 |

#### 1.5.4.2.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

**Table 1-51. Read TLB Entries**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Set the current victim pointer | MMU_LOCK[8:4] CURRENTVICTIM | 0x- |
| Read RAM parts of the TLB entry | MMU_READ_RAM | |
| Read CAM parts of the TLB entry | MMU_READ_CAM | |

Copyright © 2011–2016, Texas Instruments Incorporated

## 1.5.5 MMU Registers

### 1.5.5.1 MMU Instance Summary

**Table 1-52. MMU Instance Summary**

| Module Name | Size |
|---|---|
| System MMU | 4KB |

### 1.5.5.2 MMU Registers

**Table 1-53. MMU Registers**

| Register Name | Type | Register Width (Bits) | Address Offset |
|---|---|---|---|
| MMU_REVISION | R | 32 | 00h |
| MMU_SYSCONFIG | RW | 32 | 10h |
| MMU_SYSSTATUS | R | 32 | 14h |
| MMU_IRQSTATUS | RW | 32 | 18h |
| MMU_IRQENABLE | RW | 32 | 1Ch |
| MMU_WALKING_ST | R | 32 | 40h |
| MMU_CNTL | RW | 32 | 44h |
| MMU_FAULT_AD | R | 32 | 48h |
| MMU_TTB | RW | 32 | 4Ch |
| MMU_LOCK | RW | 32 | 50h |
| MMU_LD_TLB | RW | 32 | 54h |
| MMU_CAM | RW | 32 | 58h |
| MMU_RAM | RW | 32 | 5Ch |
| MMU_GFLUSH | RW | 32 | 60h |
| MMU_FLUSH_ENTRY | RW | 32 | 64h |
| MMU_READ_CAM | R | 32 | 68h |
| MMU_READ_RAM | R | 32 | 6Ch |
| MMU_EMU_FAULT_AD | R | 32 | 70h |
| MMU_FAULT_PC | R | 32 | 80h |

#### 1.5.5.2.1 MMU_REVISION

The MMU_REVISION register is shown in Figure 1-23 and described in Table 1-54.

**Figure 1-23. MMU_REVISION**

| 31 | 0 |
|---|---|
| REVISION | |
| R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-54. MMU_REVISION Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | REVISION | 0 | IP Revision. |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.5.2.2 MMU_SYSCONFIG

The MMU_SYSCONFIG register is shown in Figure 1-24 and described in Table 1-55.

**Figure 1-24. MMU_SYSCONFIG**

| 31 | 16 |
|---|---|
| Reserved | |
| R-0 | |

| 15 | 10 | 9 | 8 | 7 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | | CLOCKACTIVITY | | Reserved | | IDLEMODE | | Reserved | SOFTRESET | AUTOIDLE |
| R-0 | | R/W-0 | | R-0 | | R/W-0 | | R-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 1-55. MMU_SYSCONFIG Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-10 | Reserved | 0 | Write 0's for future compatibility. Reads returns 0. |
| 9-8 | CLOCKACTIVITY | 0 | Clock activity during wake-up mode 00 Functional and Interconnect clocks can be switched off. |
| 7-5 | Reserved | 0 | Write 0's for future compatibility. Reads returns 0 |
| 4-3 | IDLEMODE | | Idle Mode |
| | | 0 | Force-idle. An idle request is acknowledged unconditionally. |
| | | 1h | No-idle. An idle request is never acknowledged. |
| | | 2h | Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. |
| | | 3h | Reserved do not use. |
| 2 | Reserved | 0 | Write 0's for future compatibility. Reads returns 0. |
| 1 | SOFTRESET | 1-0 | Software reset. This bit is automatically reset by the hardware. During reads, it always return 0. |
| | | | Read 0x0: always return 0 |
| | | | Write 0x0: no functional effect |
| | | | Write 0x1: The module is reset |
| | | | Read 0x1: never happens |
| 0 | AUTOIDLE | | Internal interconnect clock gating strategy. |
| | | 0 | Interconnect clock is free-running. |
| | | 1 | Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity. |

| R-0 | | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-57. MMU_IRQSTATUS Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-5 | Reserved | 0 | Write 0's for future compatibility read returns 0. |
| 4 | MULTIHITFAULT | 1-0 | Error due to multiple matches in the TLB. |
| | | | Read 0x0: MultiHitFault false. |
| | | | Write 0x0: MultiHitFault status bit unchanged. |
| | | | Write 0x1: MultiHitFault status bit is reset. |
| | | | Read 0x1: MultiHitFault is true ("pending"). |
| 3 | TABLEWALKFAULT | 1-0 | Error response received during a Table Walk. |
| | | | Read 0x0: TableWalkFault false. |
| | | | Write 0x0: TableWalkFault status bit unchanged. |
| | | | Write 0x1: TableWalkFault status bit is reset. |
| | | | Read 0x1: TableWalkFault is true ("pending"). |
| 2 | EMUMISS | 1-0 | Unrecoverable TLB miss during debug (hardware TWL disabled). |
| | | | Read 0x0: EMUMiss false. |
| | | | Write 0x0: EMUMiss status bit unchanged. |
| | | | Write 0x1: EMUMiss status bit is reset. |
| | | | Read 0x1: EMUMiss is true ("pending"). |
| 1 | TRANSLATIONFAULT | 1-0 | Invalid descriptor in translation tables (translation fault). |
| | | | Read 0x0: TranslationFault false. |
| | | | Write 0x0: TranslationFault status bit unchanged. |
| | | | Write 0x1: TranslationFault status bit is reset. |
| | | | Read 0x1: TranslationFault is true ("pending"). |
| 0 | TLBMISS | 1-0 | Unrecoverable TLB miss (hardware TWL disabled). |
| | | | Read 0x0: TLBMiss false. |
| | | | Write 0x0: TLBMiss status bit unchanged. |
| | | | Write 0x1: TLBMiss status bit is reset. |
| | | | Read 0x1: TLBMiss is true ("pending"). |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-60. MMU_CNTL Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-4 | Reserved | 0 | Write 0's for future compatibility Reads return 0. |
| 3 | EMUTLBUPDATE | | Enable TLB update on emulator table walk. |
| | | 0 | Emulator TLB update disabled. |
| | | 1 | Emulator TLB update enabled. |
| 2 | TWLENABLE | | Table Walking Logic enable. |
| | | 0 | TWL disabled. |
| | | 1 | TWL enabled. |
| 1 | MMUENABLE | | MMU enable. |
| | | 0 | MMU disabled. |
| | | 1 | MMU enabled. |
| 0 | Reserved | 0 | Write 0's for future compatibility Reads return 0. |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.5.5.2.8 MMU_FAULT_AD

The MMU_FAULT_AD register is shown in Figure 1-30 and described in Table 1-61.

**Figure 1-30. MMU_FAULT_AD**

| 31 | 0 |
|---|---|
| FAULTADDRESS | |
| R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-61. MMU_FAULT_AD Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | FAULTADDRESS | 0-FFFF FFFFh | Virtual address of the access that generated a fault. |

#### 1.5.5.2.9 MMU_TTB

The MMU_TTB register is shown in Figure 1-31 and described in Table 1-62.

**Figure 1-31. MMU_TTB**

| 31 | 7 | 6 | 0 |
|---|---|---|---|
| TTBADDRESS | | Reserved | |
| R/W-0 | | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-62. MMU_TTB Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-7 | TTBADDRESS | 0-3FF FFFFh | Translation Table Base Address. |
| 6-0 | Reserved | 0 | Write 0's for future compatibility Reads return 0. |

#### 1.5.5.2.10 MMU_LOCK

The MMU_LOCK register is shown in Figure 1-32 and described in Table 1-63.

**Figure 1-32. MMU_LOCK**

| 31 | 15 | 14 | 10 | 9 | 8 | 4 | 3 | 0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-66. MMU_RAM Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-12 | PHYSICALADDRESS | 0-F FFFFh | Physical address of the page. |
| 11-10 | Reserved | 0 | Write 0's for future compatibility Reads return 0. |
| 9 | ENDIANNESS | | Endianness of the page. |
| | | 0 | Little Endian. |
| | | 1 | Reserved. |
| 8-7 | ELEMENTSIZE | | Element size of the page (8, 16, 32, no translation) |
| | | 0 | Value is don't care when ENDIANNESS is set to 0 (Little Endian). Should set to 0 to ensure future compatibility. |
| | | 1 | Though value is don't care, not recommended. Value should be set to 0x0 to ensure future compatibility. |
| | | 2h | Though value is don't care, not recommended. Value should be set to 0x0 to ensure future compatibility. |
| | | 3h | Though value is don't care, not recommended. Value should be set to 0x0 to ensure future compatibility. |
| 6 | MIXED | | Mixed page attribute (use CPU element size). |
| | | 0 | Value is don't care when ENDIANNESS is set to 0 (Little Endian). Should set to 0 to ensure future compatibility. |
| | | 1 | Though value is don't care, not recommended. Value should be set to 0 to ensure future compatibility. |
| 5-0 | Reserved | 0 | Write 0's for future compatibility Reads return 0. |

#### 1.5.5.2.14 MMU_GFLUSH

The MMU_GFLUSH register is shown in Figure 1-36 and described in Table 1-67.

**Figure 1-36. MMU_GFLUSH**

| 31 1 | 0 |
|---|---|
| Reserved | GLOBALFLUSH |
| R-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-67. MMU_GFLUSH Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|

## 1.6 SGX530 Graphics Subsystem

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

**NOTE:** The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

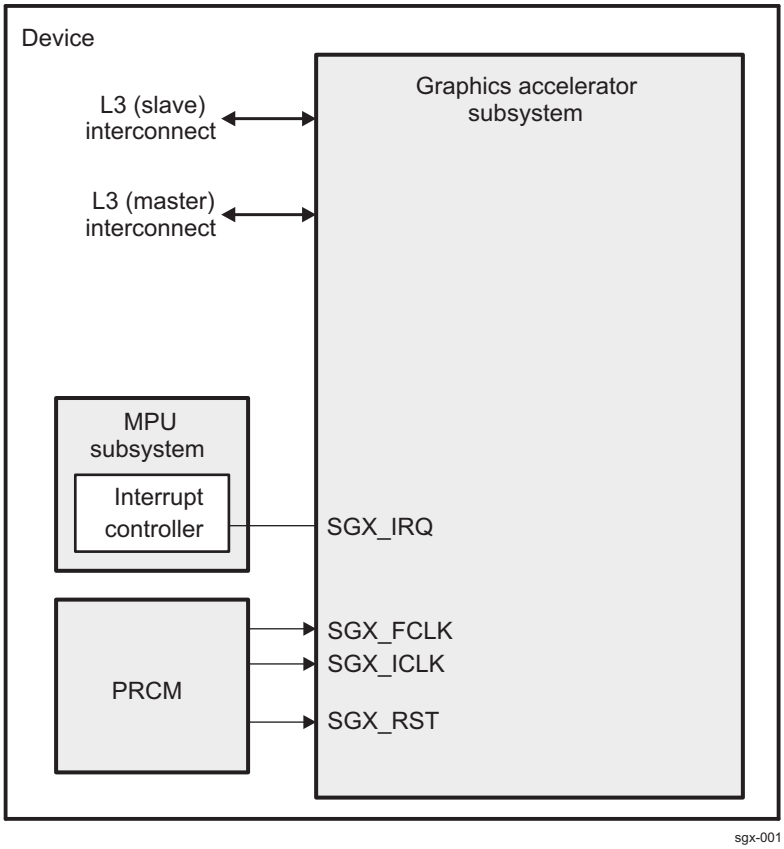
POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

### *1.6.1 SGX Overview*

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 1-42 shows the SGX subsystem in the device.

**Figure 1-42. Graphics Accelerator Highlight**



The SGX graphics accelerator can simultaneously process various multimedia data types:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

Copyright © 2011–2016, Texas Instruments Incorporated

This is achieved through a multithreaded architecture using two levels of scheduling and data partitioning enabling zero-overhead task switching.

The SGX subsystem is connected to the L3 interconnect by a 128-bit master and a 32-bit slave interface.

#### 1.6.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

#### 1.6.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear, anisotropic
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing

Copyright © 2011–2016, Texas Instruments Incorporated

  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).
  **Note**: Performance is limited when the on-chip memory is not available.

#### 1.6.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

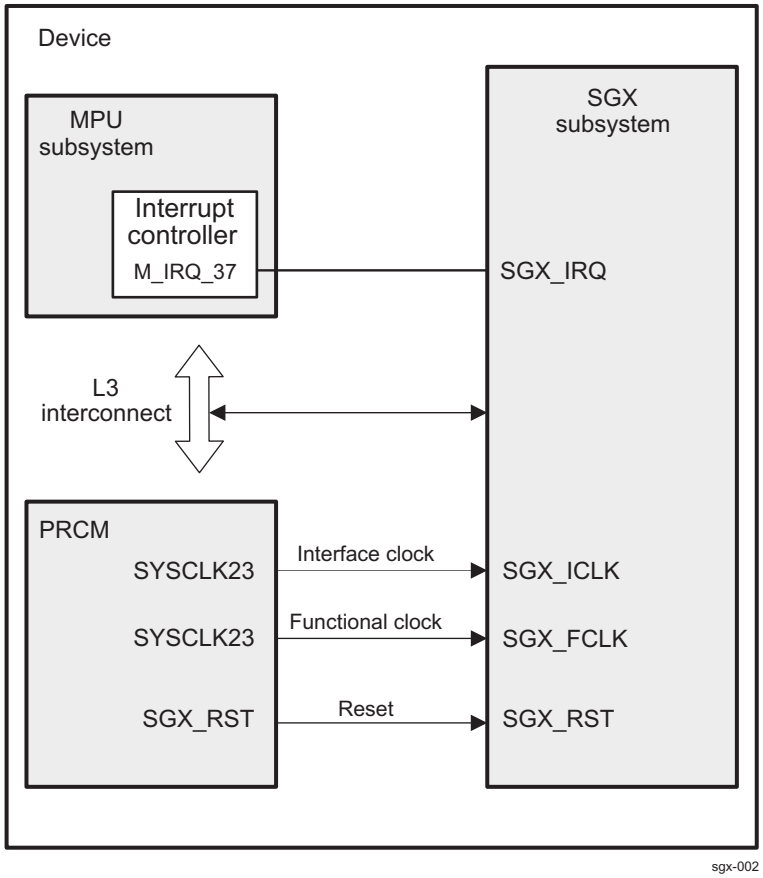
### 1.6.2 SGX Integration

Figure 1-43 highlights the SGX subsystem integration in the device.

**Figure 1-43. SGX Subsystem Integration**



#### 1.6.2.1 Clocking, Reset, and Power-Management Scheme

##### 1.6.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SYSCLK23). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device.

**Table 1-73. Clock Descriptions**

| Functional Name | Signal Name | I/O[1] | Description |
|---|---|---|---|
| SGX_FCLK | SYSCLK23 | I | Functional clock → Functional clock domain |
| SGX_ICLK | SYSCLK23 | I | Interface clock → Interface clock domain |

(1) I =Input; O=Output

- SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports.
- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

**To Enable the SGX Functional and Interface Clock**

Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x2
Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x2
Poll for the PRCM.CM_SGX_SGX_CLKCTRL IDLEST to be 0x0

Copyright © 2011–2016, Texas Instruments Incorporated

**To Disable the SGX Functional and Interface Clock**

Program the PRCM.CM_SGX_SGX_CLKCTRL.MODULEMODE to 0x0
Program the PRCM.CM_SGX_CLKSTCTRL.CTLKTRCTRL to 0x0

The SGX_ICLK and SGX_FLCK are sourced from SYSCLK23 Depending on the DPLL_SGX and the PRCM.CM_SYSCLK23_CLKSEL[CLKSEL] settings, SGX can support a frequency up to 200 MHz. SGX530 Clocks can be divided from the original DPLL_SGX frequency. The divider can be programmed from /1../8 using the PRCM.CM_SYSCLK23_CLKSEL[CLKSEL] bits

#### *1.6.2.1.2 Resets*

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_SGX_RSTCTRL[0] SGX_RST bit.

#### *1.6.2.1.3 Power Management*

The SGX subsystem has its own power domain (SGX power domain). See the *Power, Reset, and Clock Management* chapter for additional information about the SGX power domain.

As described in the *SGX Integration* chapter, the SGX subsystem receives two clock signals from the PRCM module. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see the *Power, Reset, and Clock Management* chapter.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains. SGX is in the same voltage domain as that of the Core logic. For more information refer to the Power, Reset, Clock Management chapter.

### 1.6.2.2 Hardware Requests

#### *1.6.2.2.1 Interrupt Request*

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_37.

Copyright © 2011–2016, Texas Instruments Incorporated

## 1.6.3 SGX Functional Description

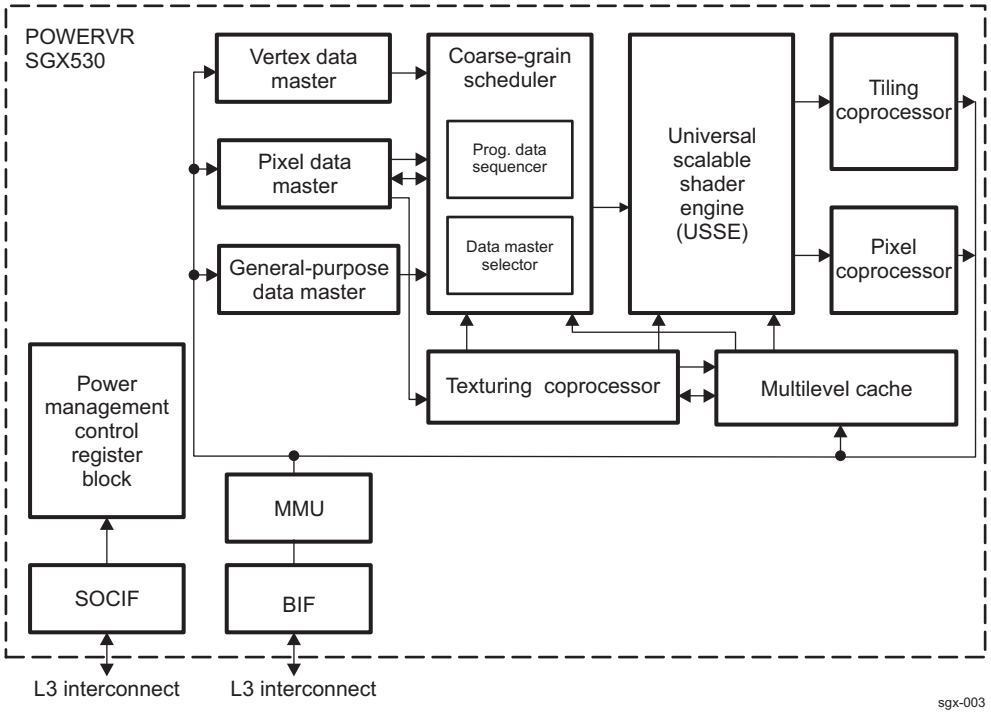
### 1.6.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable data sequencer (PDS)
  - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 1-44 shows a block diagram of the SGX cores.

**Figure 1-44. SGX Block Diagram**



### 1.6.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an

Copyright © 2011–2016, Texas Instruments Incorporated

input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

### 1.6.4 SGX Register Manual

**CAUTION**

All SGX registers are limited to 32-bit data accesses, 8- and 16-bit accesses are not allowed because they can corrupt register content.

#### 1.6.4.1 SGX OCP Register Summary

**Table 1-74. SGX Registers Mapping Summary**

#### 1.6.4.1.8 Interrupt 1 Status Event Register (OCP_IRQSTATUS_1)

The Interrupt 1 Status Event Register (OCP_IRQSTATUS_1) is shown in Figure 1-52 and described in Table 1-82.

**Figure 1-52. Interrupt 1 Status Event Register (OCP_IRQSTATUS_1)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | TARGET_SINTERRUPT_STATUS |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-82. Interrupt 1 Status Event Register (OCP_IRQSTATUS_1) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | TARGET_SINTERRUPT_STATUS | | Interrupt 1 - slave port status event. |
| | | 0 | Read: No event pending. |
| | | 1 | Read: Event pending and interrupt enabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Clear event. |

#### 1.6.4.1.9 Interrupt 2 Status Event Register (OCP_IRQSTATUS_2)

The Interrupt 2 Status Event Register (OCP_IRQSTATUS_2) is shown in Figure 1-53 and described in Table 1-83.

**Figure 1-53. Interrupt 2 Status Event Register (OCP_IRQSTATUS_2)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | TARGET_SINTERRUPT_STATUS |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-83. Interrupt 2 Status Event Register (OCP_IRQSTATUS_2) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | TARGET_SINTERRUPT_STATUS | | Interrupt 1 - slave port status event. |
| | | 0 | Read: No event pending. |
| | | 1 | Read: Event pending and interrupt enabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Clear event. |

#### 1.6.4.1.10 Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0)

The Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0) is shown in Figure 1-54 and described in Table 1-84.

**Figure 1-54. Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | INIT_MINTERRUPT_ENABLE |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-84. Enable Interrupt 0 Register (OCP_IRQENABLE_SET_0) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | INIT_MINTERRUPT_ENABLE | | Enable interrupt 0 - master port. |
| | | 0 | Read: Interrupt is enabled. |
| | | 1 | Read: Interrupt is disabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Enable interrupt. |

#### 1.6.4.1.11 Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1)

The Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1) is shown in Figure 1-55 and described in Table 1-85.

**Figure 1-55. Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | TARGET_SINTERRUPT_ENABLE |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-85. Enable Interrupt 1 Register (OCP_IRQENABLE_SET_1) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | TARGET_SINTERRUPT_ENABLE | | Enable interrupt 1 - slave port interrupt. |
| | | 0 | Read: Interrupt is enabled. |
| | | 1 | Read: Interrupt is disabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Enable interrupt. |

#### 1.6.4.1.12 Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2)

The Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2) is shown in Figure 1-56 and described in Table 1-86.

**Figure 1-56. Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | THALIA_IRQ_ENABLE |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-86. Enable Interrupt 2 Register (OCP_IRQENABLE_SET_2) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | THALIA_IRQ_ENABLE | | Enable interrupt 2 - Thalia (core) interrupt. |
| | | 0 | Read: Interrupt is enabled. |
| | | 1 | Read: Interrupt is disabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Enable interrupt. |

#### 1.6.4.1.13 Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0)

The Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0) is shown in Figure 1-57 and described in Table 1-87.

**Figure 1-57. Disable Interrupt 0 Register (OCP_IRQENABLE_CLR_0)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | INIT_MINTERRUPT_DISABLE |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

#### 1.6.4.1.14 Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1)

The Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1) is shown in Figure 1-58 and described in Table 1-88.

**Figure 1-58. Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | TARGET_SINTERRUPT_DISABLE |
| R-0 | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-88. Disable Interrupt 1 Register (OCP_IRQENABLE_CLR_1) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | TARGET_SINTERRUPT_DISABLE | | Disable interrupt 1 - slave port. |
| | | 0 | Read: Interrupt is enabled. |
| | | 1 | Read: Interrupt is disabled. |
| | | 0 | Write: No action. |
| | | 1 | Write: Disable interrupt. |

#### 1.6.4.1.15 Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2)

The Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2) is shown in Figure 1-59 and described in Table 1-89.

**Figure 1-59. Disable Interrupt 2 Register (OCP_IRQENABLE_CLR_2)**

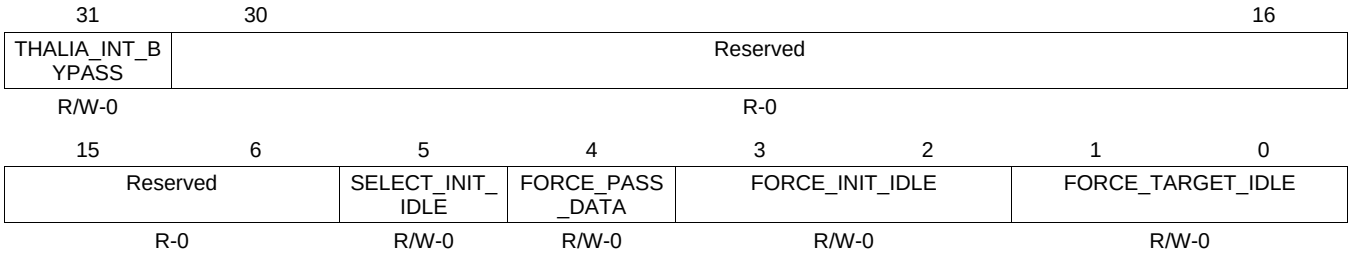
#### 1.6.4.1.18 Configuration of Debug Modes Register (OCP_DEBUG_CONFIG)

The Configuration of Debug Modes Register (OCP_DEBUG_CONFIG) is shown in Figure 1-62 and described in Table 1-92.

**Figure 1-62. Configuration of Debug Modes Register (OCP_DEBUG_CONFIG)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-92. Configuration of Debug Modes Register (OCP_DEBUG_CONFIG) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | THALIA_INT_BYPASS | | Bypass OCP IPG interrupt logic. |
| | | 0 | Don't Bypass. |
| | | 1 | Bypass core interrupt to IO pin, ie disregard the interrupt enable setting in IPG register. |
| 30-6 | Reserved | 0 | Reserved. |
| 5 | SELECT_INIT_IDLE | | To select which idle the disconnect protocol should act on 0. |
| | | 0 | Whole SGX Idle. |
| | | 1 | OCP initiator idle only |
| 4 | FORCE_PASS_DATA | | Forces the initiator to pass data independent of disconnect protocol. |
| | | 0 | Normal mode. Don't force. |
| | | 1 | Never fence request to OCP. |
| 3-2 | FORCE_INIT_IDLE | | Forces the OCP master port to Idle. |
| | | 0 | Normal mode. No force. |
| | | 1h | Force port to be always Idle. |
| | | 2h | Forces target port to never be in Idle mode. |
| | | 3h | Normal mode. No force. |
| 1-0 | FORCE_TARGET_IDLE | | Forces the OCP target port to Idle. |
| | | 0 | Normal mode. No force. |
| | | 1h | Force port to be always Idle. |
| | | 2h | Forces target port to never be in Idle mode. |
| | | 3h | Normal mode. No force. |

| R-0 | | R-0 | | R-0 | R-0 | | |

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

**Table 1-93. Debug Status Register (OCP_DEBUG_STATUS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31 | CMD_DEBUG_STATE | | Target command state machine |
| | | 0 | Idle. |
| | | 1 | Accept command. |
| 30 | CMD_RESP_DEBUG_STATE | | Target response state machine. |
| | | 0 | Send accept. |
| | | 1 | Wait accept. |
| 29 | TARGET_IDLE | 0-1 | Target idle. |
| 28 | RESP_FIFO_FULL | 0-1 | Target response FIFO full. |
| 27 | CMD_FIFO_FULL | 0-1 | Target command FIFO full. |
| 26 | RESP_ERROR | 0-1 | Respond to OCP with error, which could be caused by either address misalignment or invalid byte enable. |
| 25-21 | WHICH_TARGET_REGISTER | 0-1Fh | Indicates which OCP target registers to read. |
| 20-18 | TARGET_CMD_OUT | | Command received from OCP. |
| | | 0 | Command WRSYS received. |
| | | 1h | Command RDSYS received. |
| | | 2h | Command WR_ERROR received. |
| | | 3h | Command RD_ERROR received. |
| | | 4h | Command CHK_WRADDR_PAGE received. Not used. |
| | | 5h | Command CHK_RDADDR_PAGE received. Not used. |
| | | 6h | Command TARGET_REG_WRITE received. |
| | | 7h | Command TARGET_REG_READ received. |
| 17 | INIT_MSTANDBY | 1-0 | Status of init_MStandby signal. |
| 16 | INIT_MWAIT | 1-0 | Status of init_MWait signal. |
| 15-14 | INIT_MDISCREQ | | Disconnect status of the OCP interface. |
| | | 0 | State is FUNCT. |
| | | 1h | State is SLEEP TRANS |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-93. Debug Status Register (OCP_DEBUG_STATUS) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| | | 2h | Reserved. |
| | | 3h | State is IDLE. |
| 13 | INIT_MDISCACK | | Memory request FIFO full. |
| | | 0 | Read: No event pending. |
| | | 1 | Read: Event pending. |
| | | 0 | Write: Clear the event. |
| | | 1 | Write: Set the event and interrupt if enabled (debug only) |
| 12 | INIT_SCONNECT2 | | Defines whether to wait in M_WAIT state for MConnect FSM. |
| | | 0 | Skip M_WAIT state. |
| | | 1 | Wait in M_WAIT state. |
| 11 | INIT_SCONNECT1 | | Defines the busy-ness state of the slave. |
| | | 0 | Slave is drained. |
| | | 1 | Slave is loaded. |
| 10 | INIT_SCONNECT0 | | Disconnect from slave. |
| | | 0 | Disconnect request from slave. |
| | | 1 | Connect request from slave. |
| 9-8 | INIT_MCONNECT | | Initiator MConnect state. |
| | | 0 | State is M_OFF. |
| | | 1h | State is M_WAIT. |
| | | 2h | State is M_DISC. |
| | | 3h | State is M_CON. |
| 7-6 | TARGET_SIDLEACK | | Acknowledge the SIdleAck state machine. |
| | | 0 | State is FUNCT. |
| | | 1h | State is SLEEP TRANS. |
| | | 2h | Reserved. |
| | | 3h | State is IDLE. |
| 5-4 | TARGET_SDISCACK | | Acknowledge the SDiscAck state machine. |
| | | 0 | State is FUNCT. |
| | | 1h | State is SLEEP TRANS. |
| | | 2h | Reserved. |
| | | 3h | State is IDLE. |
| 3 | TARGET_SIDLEREQ | | Request the target to go idle. |
| | | 0 | Don't go idle, or go active. |
| | | 1 | Go idle. |
| 2 | TARGET_SCONNECT | | Target SConnect state. |
| | | 0 | Disconnect interface. |
| | | 1 | Connect OCP interface. |
| 1-0 | TARGET_MCONNECT | | Target MConnect state. |
| | | 0 | Target is in M_OFF state. |
| | | 1h | Target is in M_WAIT disconnect state. |
| | | 2h | Target is in M_DISC state. |
| | | 3h | Target is in M_CON state. |

## 1.7 Device Interrupts and EDMA Events

### 1.7.1 Interrupt Controllers

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The ARM Cortex-A8, C674x DSP, and Media Controller are capable of servicing these interrupts via their integrated interrupt controllers. In addition, the C674x DSP and Media Controller interrupt controllers are preceded by an Interrupt Controller Crossbar that provides flexibility in mapping the device interrupts to processor interrupts. For more information about crossbars, see the *Control Module* chapter.

**Cortex™-A8 MPU Subsystem Interrupt Controller**

The ARM Cortex-A8 Interrupt Controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either IRQs or FIQs to the Cortex-A8. The AINTC has the capability to handle up to 128 requests, and the priority of the interrupt inputs is programmable. Table 1-94 lists the interrupt sources for the AINTC.

For detailed information about this module, see the *ARM Interrupt Controller (AINTC)* chapter.

**DSP subsystem (DSPSS) Interrupt Controller**

The C674x DSPx interrupt controller combines up to 128 interrupts into 12 prioritized interrupts presented to the CPU. The default sources of the 128 interrupts are shown in Table 1-95. In addition, device interrupts 15 through 95 can alternatively be sourced through the DSP's Interrupt Crossbar from one of the 31 multiplexed device interrupts shown in Table 1-96. The DSP_INTMUX_x registers in the Control Module are used to select between the default interrupt and the multiplexed interrupt. The interrupt controller also controls the generation of the CPU exceptions, NMI, and emulation interrupts.

For detailed information about this module, refer to Chapter 7 of the TMS320C674x DSP Megamodule.

**Media Controller Interrupt Controllers**

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M3. The interrupt mapping is the same for the two cores to facilitate parallel processing. The default sources of the 79 interrupts are shown in Table 1-97. In addition, device interrupts 23 through 79 can alternatively be sourced through the Media Controller's Interrupt Crossbar from one of the 63 multiplexed device interrupts shown in Table 1-98. The Media_Controller_INTMUX_x registers in the Control Module are used to select between the default interrupt and the multiplexed interrupt. The NVIC supports:

- 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to ARM *Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Figure 1-64 shows the top-level block diagram of the interrupt controllers in this device.

### 1.7.5 EDMA Channel Synchronization Events

The EDMA channel controller supports up to 64 channels which service peripherals and memory. Each EDMA channel is mapped to a default EDMA synchronization event as shown in Table 1-99. In addition, each EDMA channel can alternatively be mapped through a crossbar to one of the 31 multiplexed EDMA synchronization events shown in Table 1-100. The EDMA3CC_EVTMUX_x registers in the Control Module are used to select between the default event and the multiplexed events for each channel.

For more detailed information on the EDMA module and how EDMA events are enabled, captured, processed, linked, chained, cleared, and more, see the *Enhanced Direct Memory Access Controller* chapter.

Figure 1-65 shows the top-level block diagram of the EDMA channel synchronization events.

## 1.8 Inter-Processor Communication

This SoC is a heterogeneous multi-core device, which requires software to efficiently manage and communicate between the cores. The following are the main features that need to be implemented by any such software:

1. Device management of the slave processors from the host processor.
2. Inter-processor communication between the cores for transfer and exchange of information between them.

In this SoC, the host processor is usually the Cortex A8. This processor is responsible for boot-loading the slave processors (Video-M3, VPSS-M3).

Boot-loading includes power management of the slaves (power-up/down and other power management), reset control (reset/release of the slave processor) and setting the entry point of the slave executable into the appropriate register.

For implementing efficient Inter-Processor Communication between the multiple cores on the device, certain hardware features are provided:

- Mailbox interrupts
- Hardware Spinlocks

### *1.8.1 Reset Requirements*

This SoC has a power on reset (POR) and warm reset. For the POR reset, the A8 is taken out of reset and it boots from its boot ROM. Once booted, the A8 will boot load the VPSS M3 and Video M3.

### *1.8.2 Features*

Different methods of IPC are used between the various processing elements in the SoC:

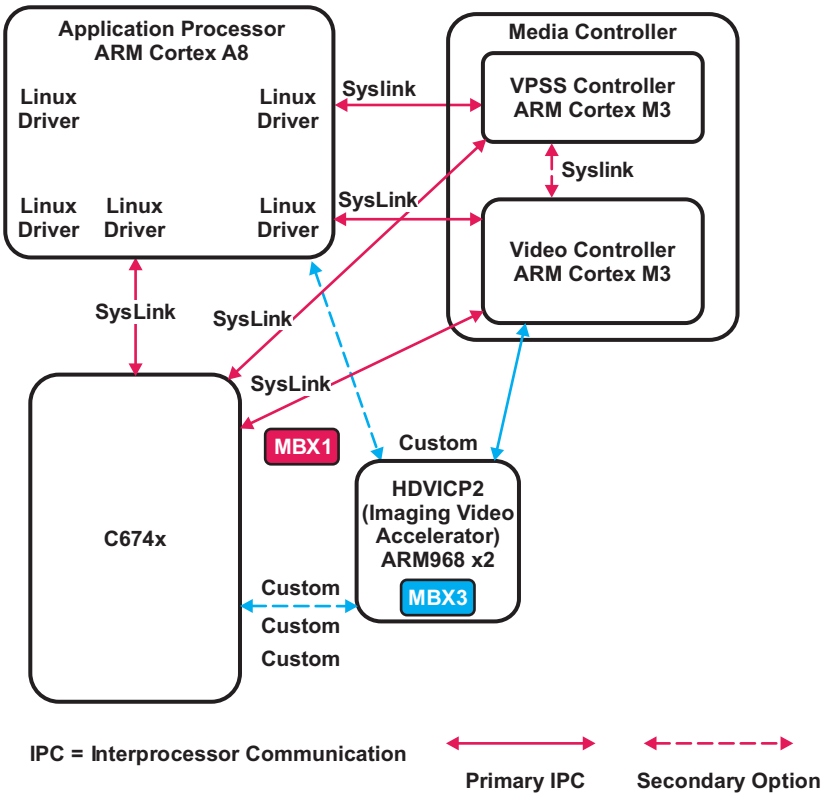
- Custom IPC – This is an IPC that doesn't use any standard IPC software.
- SysLink – This is a new implementation of the BIOS Link that allows communication between the processors in the SoC. SysLink includes ProcMgr module for device management of the slave cores (Video-M3, VPSS-M3, C674x™). The Notify method is the API for responding to interrupts. SysLink also incorporates full IPC features including MessageQ, RingIO, and FrameQ.

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.8.3 Overview and Strategy

Figure 1-66 depicts the processing elements that are part of the SoC.

**Figure 1-66. IPC Overview Diagram**



The SoC contains Mailbox and Spinlock hardware to facilitate the IPC mechanism.

Mailboxes provide a mechanism for one processor to write a value to a register and send an interrupt to another processor. One system level mailbox is provided for the IPCs between the A8, the C674x™, and the Media M3s. The HDVICP2 has its own mailbox within its IP module. The SoC shall provide Spinlocks to facilitate Mutexes for access to shared resources in the system.

Mailboxes and Spinlocks will be discussed in more detail later in this document.

It is intended that the following IPC mechanisms shall be used between various processors:

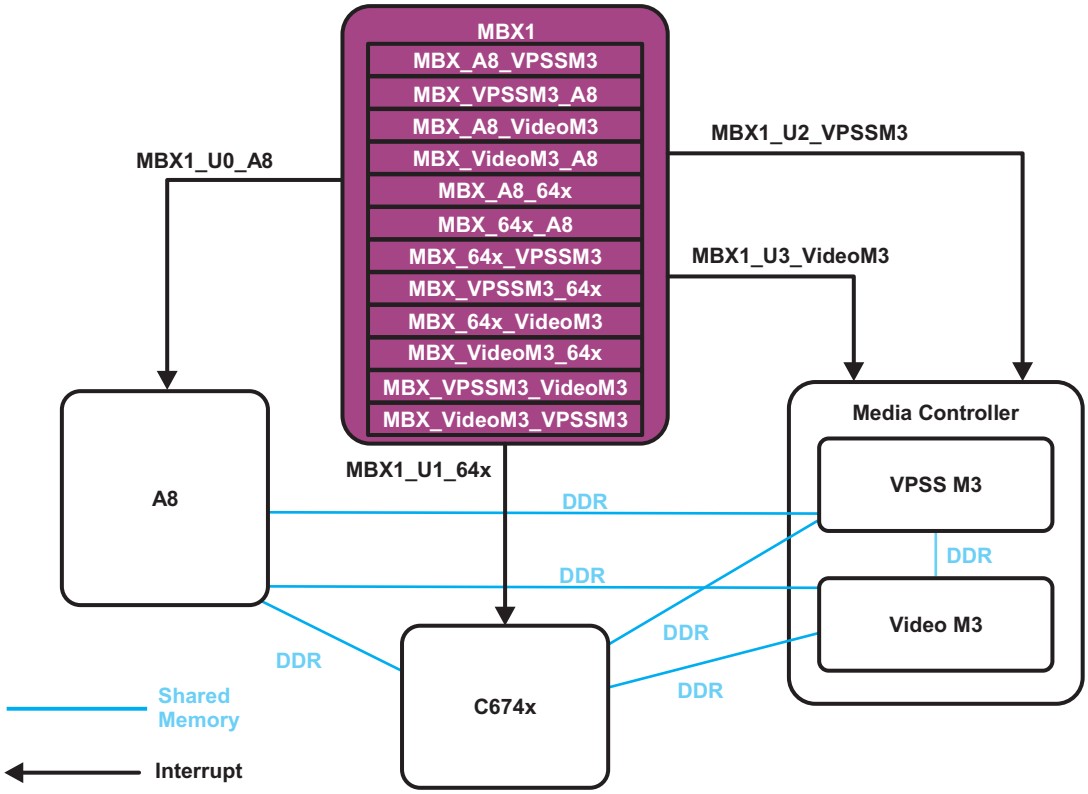
- SysLink / IPC
  - A8 to C674x™
  - A8 to Video M3
  - A8 to VPSS M3
  - Video M3 to VPSS M3
  - C674x™ to VideoM3
  - C674x™ to VPSS M3
- Custom
  - Video M3 to HDVICP2

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.8.3.1 System IPCs

Figure 1-67 depicts how Mailbox 1 (MBX1) will be used for system IPCs. Four interrupts are generated from the mailbox that allows the A8, C674x™, VPSS M3, and Video M3 to communicate. DDR is used as the shared memory interface. An IPC can be created between any of the processors listed. The A8 will communicate to the C674x™, Video M3 and VPSS M3 using SysLink.

**Figure 1-67. System IPCs**

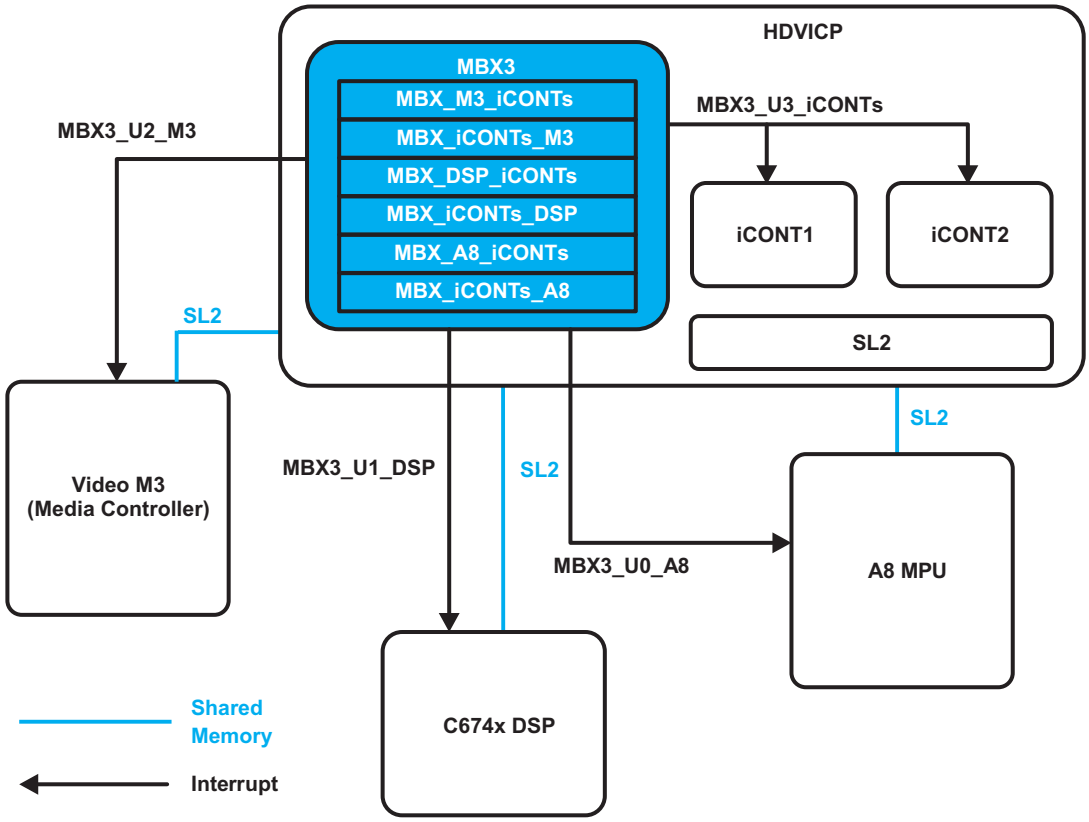


Copyright © 2011–2016, Texas Instruments Incorporated

### 1.8.3.2 HDVICP2 IPC

Figure 1-68 depicts how Mailbox 3 (MBX3) will be used for the IPC between the HDVICP2 and the other processors that may control it. The plan of record is that only one processor will be chosen to control the HDVICP2 at a time. The Video M3 is the primary processor that will control the HDVICP2. Interrupts from the mailbox are provided as shown in Figure 1-68. IPCs will use the Shared Level 2 memory that is part of the HDVICP2 module. This is necessary since the HDVICP2 processors cannot access DDR or the L3/L4 switch fabric. The HDVICP2 software will reside beneath the xDM API.

**Figure 1-68. HDVICP2 IPC**



Copyright © 2011–2016, Texas Instruments Incorporated

## 1.8.4 IPC Component Configuration

### 1.8.4.1 Shared Memory

Shared memory will be used as necessary for the IPCs of the system and it is important that cache coherency is maintained.

### 1.8.4.2 IPC Interrupt Module - Mailboxes

Interrupts used by IPCs are generated from mailbox modules.

All mailboxes use interrupts with both an active high level and active low level. The appropriate type of interrupt is connected to each processor based on the characteristics of that processor.

Each mailbox provides two messages per mailbox submodule.

### 1.8.4.3 Hardware Spinlocks

Spinlocks are pared down semaphores designed to provide direct access mutex support without the need for interrupt generator or queues. Spinlocks can be used very effectively as a mechanism to protect data structures in shared memory space that might be accessed by multiple processing cores simultaneously. They can be utilized if the following conditions apply:

1. The time to hold the lock is predictable and small. (How small is a hardware/software system design consideration. For example a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted or suspended or interrupted while holding the lock. (This would make the hold time large and unpredictable).
3. The lock is lightly contended, i.e., the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions hold, then the locking code can retry a failed attempt to acquire the lock until success.

The spin lock unit is responsible for providing hardware assistance for synchronizing the processes running on multiple processors in the device:

- The application processor (ARM Cortex-A8)
- C674x™

Note that the HDVICP2 can’t access the L3/L4 switch fabric, so IPCs to the HDVICP2 can’t use spinlocks.

Hardware spinlocks are used by SysLink and IPC products to provide multi-core mutual-exclusion between the processors on this SoC. This is used to protect access to control structures in shared memory. In addition spinlocks can provide a mutual exclusion mechanism that could be used in a system level resource manager.

This SoC has 128 spinlocks for the system.

**Table 1-101. Hardware Spinlock Configuration**

| Hardware Spinlocks | Name | Configuration |
|---|---|---|
| 0.127 | SPINLOCK_0 .. SPINLOCK_127 | No configurable options |

## 1.9 Mailbox

### 1.9.1 Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A8 microprocessor unit (Cortex-A8 MPU) and digital signal processor (DSP) communications.
- HDVICP2 mailbox - used for communication between one internal to the HDVICP2 subsystem user (imaging controller 1 - iCont1, or imaging controller 2 - iCont2) and three external to the HDVICP2 subsystem users (Cortex-A8 MPU, DSP and Video M3). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Four users for the system mailbox instance (Cortex-A8 MPU, DSP and Media Controller Subsystem) or four users for the HDVICP2 mailbox instance (iCont1/iCont2, Cortex-A8 MPU, DSP and Video-M3 MPU)
- Four mailbox message queues for the system mailbox instance/six mailbox message queues for the HDVICP2 mailbox instance
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Four interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the HDVICP2 mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

### 1.9.2 System Mailbox Integration

This section describes the system mailbox integration in the device, including information about clocks, resets, and hardware requests. Figure 1-69 shows the system mailbox integration.

Table 1-102 through Table 1-104 summarize the system mailbox integration in the device.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-69. System Mailbox Integration**

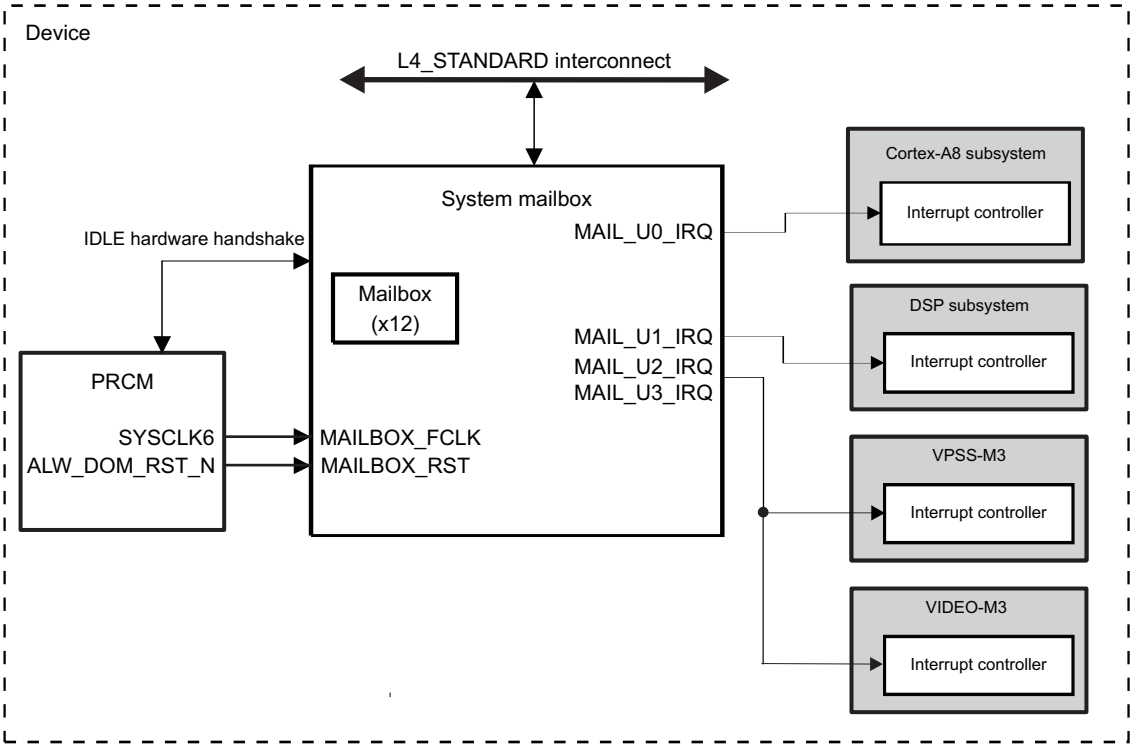

**Table 1-102. Integration Attributes**

| Module Instance | Attributes | |
|---|---|---|
| | Power Domain | Interconnect |

**Table 1-104. Hardware Requests (continued)**

| Module Instance | Source Signal Name | Destination Signal | Destination | Description |
|---|---|---|---|---|
| | MAIL_U1_IRQ | D_IRQ_56 | DSP | System Mailbox user 1 interrupt |

### 1.9.3 Functional Description

This device has the following mailbox instances:

- System mailbox
- HDVICP2 mailbox

Table 1-105 shows Mailbox Implementation in this device, where u is the user number and m is the mailbox number.

**Table 1-105. Mailbox Implementation**

| Mailbox Type | User Number(u) | Mailbox Number(m) | Messages per Mailbox |
|---|---|---|---|
| System mailbox | 0 to 3 | 0 to 11 | 4 |
| HDVICP2 mailbox | 0 to 3 | 0 to 5 | 4 |

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (12 for the system mailbox instance, six for the HDVICP2 mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

The system mailbox module includes the following user subsystems:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)

The HDVICP2 mailbox module includes the following user subsystems, where x=0,1,2.:

- User 0: Cortex-A8 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)
- User 2: HDVICP2 subsystem - only available to the HDVICP2 mailbox instance (u = 3)

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers. Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_STANDARD interconnect.

For the HDVICP2 mailbox instance, a user can query its interrupt status register as follows:

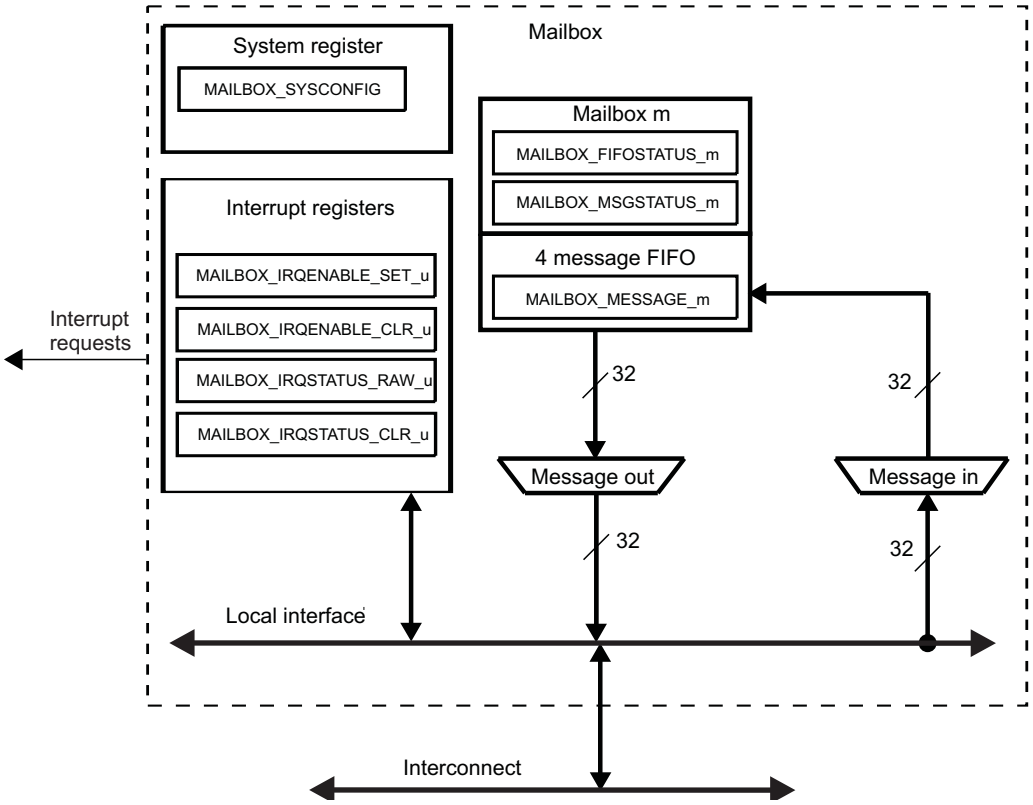
- Cortex-A8 MPU and DSP - through the L3 interconnect
- iCont1/iCont2 and DSP - private access (directly through the HDVICP2 and DSP local interconnect respectively)

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.9.3.1 Mailbox Block Diagram

Figure 1-70 shows the mailbox block diagram.

**Figure 1-70. Mailbox Block Diagram**



### 1.9.3.2 Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0].SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going
- Read 0: the software reset is complete

The software must ensure that the software reset completes before doing mailbox operations.

### 1.9.3.3 Power Management

Table 1-106 describes power-management features available for the mailbox module.

**Table 1-106. Local Power Management Features**

| Feature | Registers | Description |
|---|---|---|
| Clock autogating | NA | Feature not available |
| Slave idle modes | MAILBOX_SYSCONFIG[3:2].SIDLEMODE | Force-idle, no-idle and smart-idle modes are available |
| Clock activity | NA | Feature not available |
| Master standby modes | NA | Feature not available |
| Global wake-up enable | NA | Feature not available |
| Wake-up sources enable | NA | Feature not available |

Copyright © 2011–2016, Texas Instruments Incorporated

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

#### 1.9.3.4 Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user. Table 1-107 lists the event flags, and their mask, that can cause module interrupts.

**Table 1-107. Interrupt Events**

| Non-Maskable Event Flag[(1)] | Maskable Event Flag | Event Mask Bit | Event Unmask Bit | Description |
|---|---|---|---|---|
| MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm | MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm | MAILBOX_IRQENABLE_CLR_u[0+m*2]. | | |
| MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm | MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm | MAILBOX_IRQENABLE_CLR_u[0+m*2]. NEWMSGSTATUSUUMBm | MAILBOX_IRQENABLE_SET_u[0+m*2]. NEWMSGSTATUSUUMBm | Mailbox m receives a new message |
| MAILBOX_IRQSTATUS_RAW_u[1+m*2].NOTFULLSTATUSUMBm | MAILBOX_IRQSTATUS_CLR_u[1+m*2].NOTFULLSTATUSUMBm | MAILBOX_IRQENABLE_CLR_u[1+m*2]. NOTFULLSTATUSUMBm | MAILBOX_IRQENABLE_SET_u[1+m*2]. NOTFULLSTATUSUMBm | Mailbox m message queue is not full |

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

**CAUTION**

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register. Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 1.9.3.5 Assignment

#### *1.9.3.5.1 Description*

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where u is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

**CAUTION**

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

### 1.9.3.6 Sending and Receiving Messages

#### *1.9.3.6.1 Description*

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded. Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it. Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned. The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

#### 1.9.3.7 16-Bit Register Access

##### *1.9.3.7.1 Description*

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02). All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

**CAUTION**

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

### *1.9.4 Programming Guide*

#### 1.9.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

##### *1.9.4.1.1 Global Initialization*

###### *1.9.4.1.1.1 Surrounding Modules Global Initialization*

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 1.9.2 for further information.

**Table 1-108. Global Initialization of Surrounding Modules for System Mailbox**

| Surrounding Modules | Comments |
|---|---|
| PRCM | Mailbox functional/interface clock must be enabled. |
| Interrupt Controllers | Cortex-A8 MPU or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem. |

**Table 1-109. Global Initialization of Surrounding Modules for HDVICP2 Mailbox**

| Surrounding Modules | Comments |
|---|---|
| PRCM | Mailbox functional/interface clock must be enabled. |
| Interrupt Controllers | Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPUor DSP subsystem or HDVICP2 Subsystem |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-110. Global Initialization of Surrounding Modules for HDVICP2-1 Mailbox**

| Surrounding Modules | Comments |
|---|---|
| PRCM | Mailbox functional/interface clock must be enabled. |
| Interrupt Controllers | Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2-1 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem or HDVICP2-1 Subsystem |

**Table 1-111. Global Initialization of Surrounding Modules for HDVICP2-2 Mailbox**

| Surrounding Modules | Comments |
|---|---|
| PRCM | Mailbox functional/interface clock must be enabled. |
| Interrupt Controllers | Cortex-A8 MPU or DSP or iCont1/iCont2 of HDVICP2-2 Subsystem interrupt controller must be configured to enable the interrupt request generation to the Cortex-A8 MPU or DSP subsystem or HDVICP2-2 Subsystem |

#### 1.9.4.1.1.2 Mailbox Global Initialization

##### 1.9.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 1-112. Mailbox Global Initialization**

| | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Perform a software reset | MAILBOX_SYSCONFIG[0].SOFTRESET | 1 |
| Wait until reset is complete | MAILBOX_SYSCONFIG[0].SOFTRESET | 0 |
| Set idle mode configuration | MAILBOX_SYSCONFIG[3:2].SIDLEMODE | 0x- |

#### 1.9.4.1.2 Operational Modes Configuration

##### 1.9.4.1.2.1 Main Sequence - Sending a Message (Polling Method)

**Table 1-113. Sending a Message (Polling Method)**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| IF : Is FIFO full ? | MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB | =1h |
| Wait until at least one message slot is available | MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB | =0h |
| ELSE | | |
| Write message | MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM | ----h |
| ENDIF | | |

##### 1.9.4.1.2.2 Main Sequence - Sending a Message (Interrupt Method)

**Table 1-114. Sending a Message (Interrupt Method)**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| IF : Is FIFO full ? | MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB | =1h |
| Enable interrupt event | MAILBOX_IRQENABLE_SET_u[1+ m*2] | 1h |
| User(processor) can perform anothr task until interrupt occurs | | |
| ELSE | | |
| Write message | MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM | ----h |
| ENDIF | | |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.9.4.1.2.3 Main Sequence - Receiving a Message (Polling Method)

**Table 1-115. Receiving a Message (Polling Method)**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| IF : Number of messages is not equal to 0 | MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB | !=0h |
| Read message | MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM | ----h |
| ENDIF | | |

#### 1.9.4.1.2.4 Main Sequence - Receiving a Message (Interrupt Method)

**Table 1-116. Receiving a Message (Interrupt Method)**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Enable interrupt event | MAILBOX_IRQENABLE_SET_u[0 + m*2] | 1h |
| User(processor) can perform anothr task until interrupt occurs | | |

### 1.9.4.1.3 Events Servicing

#### 1.9.4.1.3.1 Sending Mode

Table 1-117 describes the events servicing in sending mode.

**Table 1-117. Events Servicing in Sending Mode**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Read interrupt status bit | MAILBOX_IRQSTATUS_CLR_u[1 + m*2] | 1 |
| Write message | MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM | ----h |
| Write 1 to acknowledge interrupt | MAILBOX_IRQSTATUS_CLR_u[1 + m*2] | 1 |

#### 1.9.4.1.3.2 Receiving Mode

Table 1-118 describes the events servicing in receiving mode.

**Table 1-118. Events Servicing in Receiving Mode**

| Step | Register/Bitfield/Programming Model | Value |
|---|---|---|
| Read interrupt status bit | MAILBOX_IRQSTATUS_CLR_u[0 + m*2] | 1 |
| IF : Number of messages is not equal to 0 ? | MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB | !=0h |
| Read message | MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM | ----h |
| ELSE | | |
| Write 1 to acknowledge interrupt | MAILBOX_IRQSTATUS_CLR_u[0 + m*2] | 1 |
| ENDIF | | |

### 1.9.5 Mailbox Registers

Table 1-119 lists the Mailboxes available on the device. The previous register set is applicable to these mailboxes. See the device-specific data manual for the memory address of these mailboxes.

**Table 1-119. Mailboxes**

| Mailbox Type | User Number(u) | Mailbox Number(m) | Messages per Mailbox |
|---|---|---|---|
| System Mailbox | 0 to 3 | 0 to 11 | 4 |
| HDVICP2-1Mailbox | 0 to 3 | 0 to 5 | 4 |
| HDVICP2-2 Mailbox | 0 to 3 | 0 to 5 | 4 |

Table 1-120 lists the memory-mapped registers for the Mailbox Registers. See the device-specific data manual for the memory address of these registers.

**Table 1-120. Mailbox Registers Mapping Summary**

| Offset | Acronym | Register Description | Section |
|---|---|---|---|
| 0000h | MAILBOX_REVISION | Mailbox Revision Register | Section 1.9.5.1 |
| 0010h | MAILBOX_SYSCONFIG | Mailbox System Configuration Register | Section 1.9.5.2 |
| 0040h + (4h * m) | MAILBOX_MESSAGE_m (1) | Mailbox Message Register | Section 1.9.5.3 |
| 0080h + (4h * m) | MAILBOX_FIFOSTATUS_m (1) | Mailbox FIFO Status Register | Section 1.9.5.4 |
| 00C0h + (4h * m) | MAILBOX_MSGSTATUS_m (1) | Mailbox Message Status Register | Section 1.9.5.5 |
| 0100h + (10h * u) | MAILBOX_IRQSTATUS_RAW_u (2) | Mailbox IRQ RAW Status Register | Section 1.9.5.6 |
| 0104h + (10h * u) | MAILBOX_IRQSTATUS_CLR_u (2) | Mailbox IRQ Clear Status Register | Section 1.9.5.7 |
| 0108h + (10h * u) | MAILBOX_IRQENABLE_SET_u (2) | Mailbox IRQ Enable Set Register | Section 1.9.5.8 |
| 010Ch + (10h * u) | MAILBOX_IRQENABLE_CLR_u (2) | Mailbox IRQ Enable Clear Register | Section 1.9.5.9 |
| 0140h | RESERVED | Reserved | |

### 1.9.5.1 Revision Register (MAILBOX_REVISION)

This register contains the IP revision code. The Mailbox Revision Register (MAILBOX_REVISION) is shown in Figure 1-71 described in Table 1-121.

**Figure 1-71. Revision Register (MAILBOX_REVISION)**

| 31 | 0 |
|---|---|
| REVISION | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-121. Revision Register (MAILBOX_REVISION) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | REVISION | 0-FFFF FFFFh | IP Revision |

### 1.9.5.2 System Configuration Register (MAILBOX_SYSCONFIG)

This register controls the various parameters of the communication interface. The Mailbox System Configuration Register (MAILBOX_SYSCONFIG) is shown in Figure 1-72 and described in Table 1-122.

**Figure 1-72. System Configuration Register (MAILBOX_SYSCONFIG)**

| 31 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|
| Reserved | | SIDLEMODE | | Reserved | SOFTRESET |
| R-0 | | R/W-0 | | R-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-122. System Configuration Register (MAILBOX_SYSCONFIG) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-4 | Reserved | 0 | Reserved |
| 3-2 | SIDLEMODE | 0 | Force-idle. An idle request is acknowledged unconditionally |
| | | 1 | No-idle. An idle request is never acknowledged |
| | | 2 | Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module based on the internal activity of the module |
| | | 3 | Reserved do not use |
| 1 | Reserved | 0 | Reserved |
| 0 | SOFTRESET | 0 | Soft/Hard reset done. |
| | | 1 | Reset is ongoing. |
| | | 0 | No action. |
| | | 1 | Start the soft reset sequence. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.9.5.3 Message Register (MAILBOX_MESSAGE_m)

The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue. The Mailbox Message Register (MAILBOX_MESSAGE_m) is shown in Figure 1-73 and described in Table 1-123.

**Figure 1-73. Message Register (MAILBOX_MESSAGE_m)**

| 31 | 0 |
|---|---|
| MESSAGEVALUEMBM | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-123. Message Register (MAILBOX_MESSAGE_m) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | MESSAGEVALUEMBM | 0-FFFF FFFFh | Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue. |

### 1.9.5.4 FIFO Status Register (MAILBOX_FIFOSTATUS_m)

The FIFO status register has the status related to the mailbox internal FIFO. The Mailbox FIFO Status Register (MAILBOX_FIFOSTATUS_m) is shown in Figure 1-74 and described in Table 1-124.

**Figure 1-74. FIFO Status Register (MAILBOX_FIFOSTATUS_m)**

| 31 | 1 | 0 |
|---|---|---|
| MESSAGEVALUEMBM | | FIFOFULLMBM |
| R/W-0 | | R-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-124. FIFO Status Register (MAILBOX_FIFOSTATUS_m) Field Descriptions**

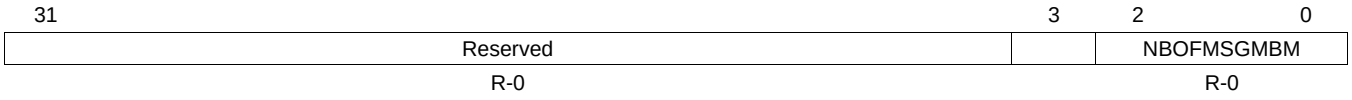
| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | MESSAGEVALUEMBM | 0-7FFF FFFFh | Message in Mailbox. The message register stores the next to be read message of the mailbox. Reads remove the message from the FIFO queue. |
| 0 | FIFOFULLMBM | | Full flag for Mailbox |
| | | 0 | Mailbox FIFO is not full |
| | | 1 | Mailbox FIFO is full |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.9.5.5 Message Status Register (MAILBOX_MSGSTATUS_m)

The message status register has the status of the messages in the mailbox. The Mailbox Message Status Register (MAILBOX_FIFOSTATUS_m) is shown in Figure 1-75 and described in Table 1-125.

**Figure 1-75. Message Status Register (MAILBOX_MSGSTATUS_m)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-125. Message Status Register (MAILBOX_MSGSTATUS_m) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-3 | Reserved | 0 | Reserved. |
| 2-0 | NBOFMSGMBM | 0-7h | Number of unread messages in Mailbox. Limited to four messages per mailbox. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.9.5.6 IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)

The interrupt status register has the raw status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit sets this bit. This register is mainly used for debug purpose. The Mailbox IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u) is shown in Figure 1-76 and described in Table 1-126.

**Figure 1-76. IRQ RAW Status Register (MAILBOX_IRQSTATUS_RAW_u)**

### 1.9.5.7 IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u)

The interrupt status register has the status combined with irq-enable for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. The Mailbox IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u) is shown in Figure 1-77 and described in Table 1-127.

**Figure 1-77. IRQ Clear Status Register (MAILBOX_IRQSTATUS_CLR_u)**

### 1.9.5.8 IRQ Enable Set Register (MAILBOX_IRQENABLE_SET_u)

The interrupt enable register enables to unmask the module internal source of interrupt to the corresponding user. This register is write 1 to set. The Mailbox IRQ Enable Set Register (MAILBOX_IRQENABLE_SET_u) is shown in Figure 1-78 and described in Table 1-128.

**Figure 1-78. IRQ Enable Set Register (MAILBOX_IRQENABLE_SET_u)**

## 1.10 Spinlock

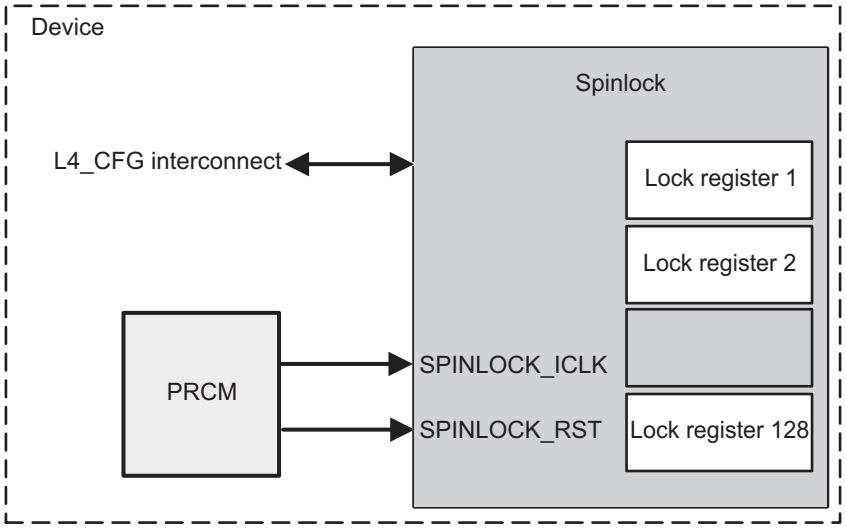
### 1.10.1 Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A8 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Media Controller subsystem

The Spinlock module implements 128 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

**Figure 1-80. Spinlock Module**



Copyright © 2011–2016, Texas Instruments Incorporated

### 1.10.2 Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 1-81 shows the Spinlock integration.

**Figure 1-81. Spinlock Integration**

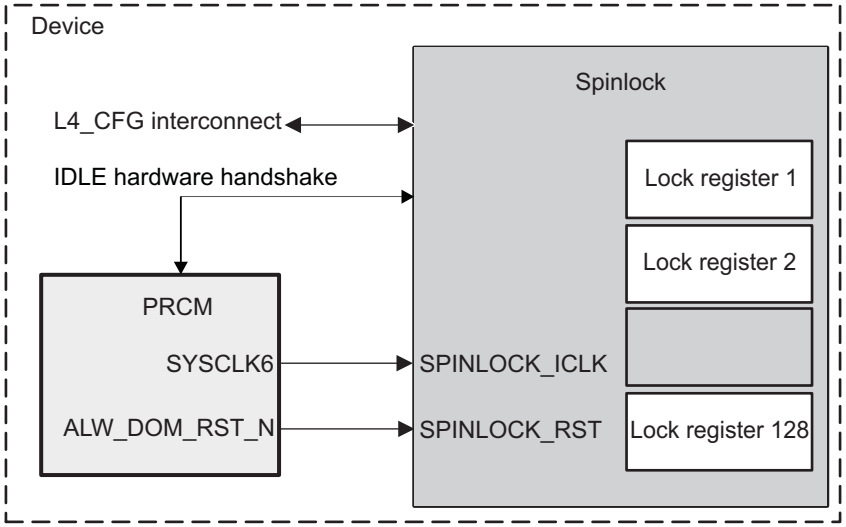


Table 1-130 and Table 1-131 summarize the integration of the module in the device.

**Table 1-130. Integration Attributes**

| Module Instance | Attributes | |
|---|---|---|
| | Power Domain | Interconnect |
| SPINLOCK | PD_ALWAYS_ON | L4_STANDARD |

**Table 1-131. Clocks and Resets**

| Clocks | | | | |
|---|---|---|---|---|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SPINLOCK | SPINLOCK_ICLK | SYSCLK6 | PRCM | Spinlock interface clock. This clock is used for all interface and functional operations. |
| **Resets** | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SPINLOCK | SPINLOCK_RST | ALW_DOM_RST_N | PRCM | Spinlock hardware reset. This reset is asynchronously applied to the Spinlock registers. |

The Spinlock module does not support any interrupt and DMA requests.

## 1.10.3 Functional Description

### 1.10.3.1 Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. This bit also indicates that the software reset is complete when its value is reset to 0. The software must ensure that the software reset completes before doing Spinlock operations.

### 1.10.3.2 Power Management

Table 1-132 describes power-management features available to the Spinlock module.

**Table 1-132. Local Power Management Features**

| Feature | Registers | Description |
|---|---|---|
| Clock auto gating | [0] AUTOGATING bit | This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity. |
| Slave idle modes | [4:3] SIDLEMODE bit field | This bit field indicates that the module uses smart-idle mode. |
| Clock activity | [8] CLOCKACTIVITY bit | This bit indicates that the interface clock is not required by the module during idle mode and may be switched off. |
| Global wake-up enable | [2] ENAWAKEUP bit | This bit indicates that the wake-up generation feature (at module level) is disabled. |

**NOTE:** All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
  - Already powered off
  - Notified that Spinlock is not available and the notification is acknowledged
- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 128 locks can be read from the register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

### 1.10.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

- The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
- The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
- The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

### 1.10.3.4 Functional Operation

The Spinlock module supports 128 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock i (where i = 0 to 127) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock i is Taken, a read returns 1 and does not change the state of the lock. A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

**CAUTION**

Only 32-bit reads and writes are supported.

**Figure 1-82. SPINLOCK_LOCK_REG_i Register State Diagram**

## 1.10.4 Programming Guide

### 1.10.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 1.10.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

#### 1.10.4.1.2 Global Initialization of Surrounding Modules

**Table 1-133. Global Initialization of Surrounding Modules**

| Surrounding Modules | Comments |
|---|---|
| PRCM | Spinlock interface clock must be enabled. For more information, Refer PRCM User Guide. |
| Interconnect | For more information about the L4-Standard interconnect configuration, Refer Bus Topology. |

### 1.10.4.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

#### 1.10.4.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

**Table 1-134. Spinlock System Bug Recovery**

| Step | Register | Value |
|---|---|---|
| IF: SPINLOCK_SYSTATUS[0] IU0 = = 1? | SPINLOCK_SYSTATUS[0] IU0 | |
| Free the 128 locks | SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 127) | 0 |
| END | | |

#### 1.10.4.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be re-attempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before re-attempting to acquire the lock. Figure 1-83 shows the described above procedure.

### 1.10.5 Spinlock Registers

Table 1-135 lists the memory-mapped registers for the Spin Lock Module. See the device-specific data manual for the memory address of these registers.

**Table 1-135. Spin Lock Module Registers Offset**

| Address Offset | Acronym | Description | Section |
|---|---|---|---|
| 00h | SPINLOCK_REV | Revision Register | Section 1.10.5.1 |
| 010h | SPINLOCK_SYSCFG | System Configuration Register | Section 1.10.5.2 |
| 014h | SPINLOCK_SYSSTAT | System Status Register | Section 1.10.5.3 |
| 800h + (4h × i) | SPINLOCK_LOCK_REG_i | Lock Register | Section 1.10.5.4 |

#### 1.10.5.1 Revision Register (SPINLOCK_REV)

The Spin Lock Revision Register (SPINLOCK_REV) is shown in Figure 1-84 and described in Table 1-136.

**Figure 1-84. Revision Register (SPINLOCK_REV)**

| 31 | 0 |
|---|---|

## 1.11 Error Location Module

### 1.11.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

#### 1.11.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.11.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 1-88 shows the integration of the ELM subsystem in the device.

**Figure 1-88. ELM Integration**

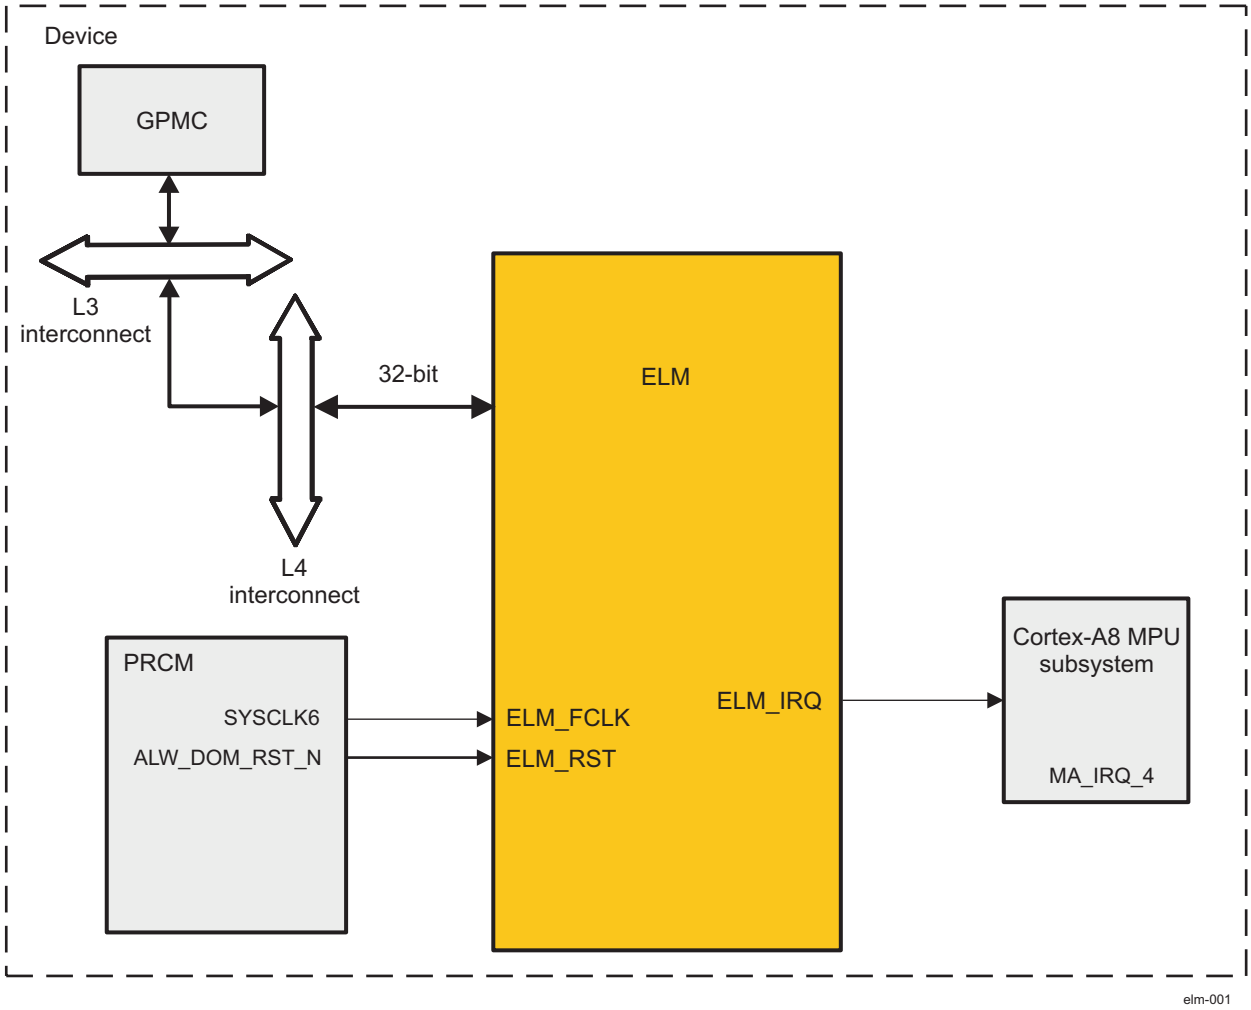

**Table 1-140. Integration Attributes**

| Module Instance | Attributes | | |
|---|---|---|---|
| | Power Domain | Wake-Up Capability | Interconnect |
| ELM | PD_ALWAYS_ON | No | NA |

| Interrupt Requests | | | | |
|---|---|---|---|---|
| **Module Instance** | **Source Signal Name** | **Destination Signal Name** | **Destination** | **Description** |
| ELM | ELM_IRQ | MA_IRQ_4 | Cortex-A8 | BCH error-location module interrupt |

## 1.11.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

### 1.11.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

### 1.11.3.2 ELM Power Management

Table 1-143 describes the power-management features available to the ELM module.

**Table 1-143. Local Power Management Features**

| Feature | Registers | Description |
|---|---|---|
| Clock autogating | ELM_SYSCONFIG[0] AUTOGATING bit | This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity. |
| Slave idle modes | ELM_SYSCONFIG[4:3] SIDLEMODE bit field | Force-idle, No-idle, and Smart-idle modes are available. |
| Clock activity | ELM_SYSCONFIG[8] CLOCKACTIVITY bit | The clock can be switched-off or maintained during the wake-up period. |
| Master Standby modes | N/A | |
| Global Wake-up Enable | N/A | |
| Wake-up Sources Enable | N/A | |

Copyright © 2011–2016, Texas Instruments Incorporated

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

### 1.11.3.3 ELM Interrupt Requests

Table 1-144 lists the event flags, and their masks, that can cause module interrupts.

**Table 1-144. Events**

| Event Flag | Event Mask | Map to | Description |
|---|---|---|---|
| ELM_IRQSTATUS[8] PAGE_VALID | ELM_IRQENABLE[8] PAGE_MASK | ELM_IRQ | Page interrupt |
| ELM_IRQSTATUS[7] LOC_VALID_7 | ELM_IRQENABLE[7] LOCATION_MASK_7 | ELM_IRQ | Error-location interrupt for syndrome polynomial 7 |
| ELM_IRQSTATUS[6] LOC_VALID_6 | ELM_IRQENABLE[6] LOCATION_MASK_6 | ELM_IRQ | Error-location interrupt for syndrome polynomial 6 |
| ELM_IRQSTATUS[5] LOC_VALID_5 | ELM_IRQENABLE[5] LOCATION_MASK_5 | ELM_IRQ | Error-location interrupt for syndrome polynomial 5 |
| ELM_IRQSTATUS[4] LOC_VALID_4 | ELM_IRQENABLE[4] LOCATION_MASK_4 | ELM_IRQ | Error-location interrupt for syndrome polynomial 4 |
| ELM_IRQSTATUS[3] LOC_VALID_3 | ELM_IRQENABLE[3] LOCATION_MASK_3 | ELM_IRQ | Error-location interrupt for syndrome polynomial 3 |
| ELM_IRQSTATUS[2] LOC_VALID_2 | ELM_IRQENABLE[2] LOCATION_MASK_2 | ELM_IRQ | Error-location interrupt for syndrome polynomial 2 |
| ELM_IRQSTATUS[1] LOC_VALID_1 | ELM_IRQENABLE[1] LOCATION_MASK_1 | ELM_IRQ | Error-location interrupt for syndrome polynomial 1 |
| ELM_IRQSTATUS[0] LOC_VALID_0 | ELM_IRQENABLE[0] LOCATION_MASK_0 | ELM_IRQ | Error-location interrupt for syndrome polynomial 0 |

### 1.11.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Copyright © 2011–2016, Texas Instruments Incorporated

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

#### 1.11.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

**Table 1-145. ELM_LOCATION_STATUS_i Value Decoding Table**

| ECC_CORRECTABLE Value | ECC_NB_ERRORS Value | Status | Number of Errors Detected | Action Required |
|---|---|---|---|---|
| 1 | 0 | OK | 0 | None |
| 1 | ≠ 0 | OK | ECC_NB_ERRORS | Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results. |
| 0 | Any | Failed | Unknown | Software-dependant |

#### 1.11.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Copyright © 2011–2016, Texas Instruments Incorporated

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

**NOTE:** Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

## *1.11.4 ELM Basic Programming Model*

### 1.11.4.1 ELM Low Level Programming Model

#### *1.11.4.1.1 Processing Initialization*

**Table 1-146. ELM Processing Initialization**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Resets the module | ELM_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is done. | ELM_SYSSTATUS[0] RESETDONE | 0x1 |
| Configure the slave interface power management. | ELM_SYSCONFIG[4:3] SIDLEMODE | Set value |
| Defines the error-correction level used | ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL | Set value |
| Defines the maximum buffer length | ELM_LOCATION_CONFIG[26:16] ECC_SIZE | Set value |
| Sets the ELM in continuous mode or page mode | ELM_PAGE_CTRL | Set value |
| **If** continuous mode is used | All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7) | 0x0 |
| Enables interrupt for syndrome polynomial i | ELM_IRQENABLE[i] LOCATION_MASK_i | 0x1 |
| **else** (page mode is used) | One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7) | 0x1 |
| Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt. | All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1 | Set value |
| **endif** | | Set value |
| Set the input syndrome polynomial i. | ELM_SYNDROME_FRAGMENT_0_i | Set value |
| | ELM_SYNDROME_FRAGMENT_1_i | Set value |
| | ELM_SYNDROME_FRAGMENT_5_i | Set value |
| | ELM_SYNDROME_FRAGMENT_6_i | Set value |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-146. ELM Processing Initialization (continued)**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Initiates the computation process | ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID | 0x1 |

#### 1.11.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 1-147 and Table 1-148 describe the processing completion for continuous and page modes, respectively.

**Table 1-147. ELM Processing Completion for Continuous Mode**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Wait until process is complete for syndrome polynomial i:<br>Wait until the ELM_IRQ interrupt is generated, or poll the status register. | | |
| Read for which i the error-location process is complete. | ELM_IRQSTATUS[i] LOC_VALID_i | 0x1 |
| **if** the process fails (too many errors) | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE | 0x0 |
| It is software dependant. | | |
| **else** (process successful, the engine completes) | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE | 0x1 |
| Read the number of errors. | ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS | |
| Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.<br>It is the software responsibility to correct errors in the data buffer. | ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION | |
| | ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION | |
| | ... | |
| | ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION | |
| **endif** | | |
| Clear the corresponding i interrupt. | ELM_IRQSTATUS[i] LOC_VALID_i | 0x1 |

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

**Table 1-148. ELM Processing Completion for Page Mode**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Wait until process is complete for syndrome polynomial i:<br>Wait until the ELM_IRQ interrupt is generated, or poll the status register. | | |
| Wait for page completed interrupt:<br>All error locations are valid. | ELM_IRQSTATUS[8] PAGE_VALID | 0x1 |
| **Repeat** the following actions the necessary number of times. That is, once for each valid defined block in the page. | | |
| Read the process exit status. | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE | |
| **if** the process fails (too many errors) | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE | 0x0 |
| It is software dependant. | | |
| **else** (process successful, the engine completes) | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE | 0x1 |
| Read the number of errors. | ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS | |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-148. ELM Processing Completion for Page Mode (continued)**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. | ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION | |
| | ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION | |
| | ... | |
| | ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION | |
| **endif** | | |
| **End Repeat** | | |
| Clear the ELM_IRQSTATUS register. | ELM_IRQSTATUS | 0x1FF |

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

### 1.11.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

**Table 1-149. Use Case: Continuous Mode**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Resets the module | ELM_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is done. | ELM_SYSSTATUS[0] RESETDONE | 0x1 |
| Configure the slave interface power management: Smart idle is used. | ELM_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Defines the error-correction level used: 8 bits | ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL | 0x1 |
| Defines the maximum buffer length: 528 bytes (2x528 = 1056) | ELM_LOCATION_CONFIG[26:16] ECC_SIZE | 0x420 |
| Sets the ELM in continuous mode | ELM_PAGE_CTRL | 0 |
| Enables interrupt for syndrome polynomial 0 | ELM_IRQENABLE[0] LOCATION_MASK_0 | 0x1 |
| Set the input syndrome polynomial 0. | ELM_SYNDROME_FRAGMENT_0_i (i=0) | 0xFB0D0980 |
| | ELM_SYNDROME_FRAGMENT_1_i (i=0) | 0xE44F767B |
| | ELM_SYNDROME_FRAGMENT_2_i (i=0) | 0x16ABE115 |
| | ELM_SYNDROME_FRAGMENT_3_i (i=0) | 0x0000000A |
| Initiates the computation process | ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0) | 0x1 |
| Wait until process is complete for syndrome polynomial 0:<br>IRQ_ELM is generated or poll the status register. | | |
| Read that error-location process is complete for syndrome polynomial 0. | ELM_IRQSTATUS[0] LOC_VALID_0 | 0x1 |
| Read the process exit status:<br>All errors were successfully located. | ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0) | 0x1 |
| Read the number of errors:<br>Four errors detected. | ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0) | 0x4 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-149. Use Case: Continuous Mode (continued)**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers:<br>Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452. | ELM_ERROR_LOCATION_0_i (i=0) | 0x1AF |
| | ELM_ERROR_LOCATION_1_i (i=0) | 0x426 |
| | ELM_ERROR_LOCATION_2_i (i=0) | 0x775 |
| | ELM_ERROR_LOCATION_3_i (i=0) | 0xD7C |
| Clear the corresponding interrupt for polynomial 0. | ELM_IRQSTATUS[0] LOC_VALID_0 | 0x1 |

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 1-150 are given in decimal format.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-150. 16-bit NAND Sector Buffer Address Map**

| NAND Memory Address | Message bit addresses in the memory word | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | 4215 | 4214 | 4213 | 4212 | 4211 | 4210 | 4209 | 4208 | 4223 | 4222 | 4221 | 4220 | 4219 | 4218 | 4217 | 4216 |
| 1 | 4175 | 4174 | 4173 | 4172 | 4171 | 4170 | 4169 | 4168 | 4183 | 4182 | 4181 | 4180 | 4179 | 4178 | 4177 | 4176 |
| ... | | | | | | | | | | | | | | | | |
| 47 | 3463 | 3462 | 3461 | 3460 | 3459 | 3458 | 3457 | 3456 | 3471 | 3470 | 3469 | 3468 | 3467 | 3466 | 3465 | 3464 |
| 48 | 3447 | 3446 | 3445 | 3444 | 3443 | 3442 | 3441 | 3440 | 3455 | 3454 | 3453 | 3452 | 3451 | 3450 | 3449 | 3448 |
| 49 | 3431 | 3430 | 3429 | 3428 | 3427 | 3426 | 3425 | 3424 | 3439 | 3438 | 3437 | 3436 | 3435 | 3434 | 3433 | 3432 |
| 50 | 3415 | 3414 | 3413 | 3412 | 3411 | 3410 | 3409 | 3408 | 3423 | 3422 | 3421 | 3420 | 3419 | 3418 | 3417 | 3416 |
| ... | | | | | | | | | | | | | | | | |
| 255 | 135 | 134 | 133 | 132 | 131 | 130 | 129 | 128 | 143 | 142 | 141 | 140 | 139 | 138 | 137 | 136 |
| 256 | 119 | 118 | 117 | 116 | 115 | 114 | 113 | 112 | 127 | 126 | 125 | 124 | 123 | 122 | 121 | 120 |
| 257 | 103 | 102 | 101 | 100 | 99 | 98 | 97 | 96 | 111 | 110 | 109 | 108 | 107 | 106 | 105 | 104 |
| 258 | 87 | 86 | 85 | 84 | 83 | 82 | 81 | 80 | 95 | 94 | 93 | 92 | 91 | 90 | 89 | 88 |
| 259 | 71 | 70 | 69 | 68 | 67 | 66 | 65 | 64 | 79 | 78 | 77 | 76 | 75 | 74 | 73 | 72 |
| 260 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 |
| 261 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 |
| 262 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| 263 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

### 1.11.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 1-151. Use Case: Page Mode**

| Step | Register/ Bit Field / Programming Model | Value |
|---|---|---|
| Resets the module | ELM_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is done. | ELM_SYSSTATUS[0] RESETDONE | 0x1 |

### 1.11.5 ELM Registers

**Table 1-152. ELM Registers Mapping Summary**

| Address Offset | Acronym | Description | Section |
|---|---|---|---|
| 000 | ELM_REVISION | ELM Revision Register | Section 1.11.5.1 |
| 010h | ELM_SYSCONFIG | ELM System Configuration Register | Section 1.11.5.2 |
| 014h | ELM_SYSSTATUS | ELM System Status Register | Section 1.11.5.3 |
| 018h | ELM_IRQSTATUS | ELM Interrupt Status Register | Section 1.11.5.4 |
| 01Ch | ELM_IRQENABLE | ELM Interrupt Enable Register | Section 1.11.5.5 |
| 020h | ELM_LOCATION_CONFIG | ELM Location Configuration Register | Section 1.11.5.6 |
| 080h | ELM_PAGE_CTRL | ELM Page Definition Register | Section 1.11.5.7 |
| 400h + (40h × i) | ELM_SYNDROME_FRAGMENT_0_i | ELM_SYNDROME_FRAGMENT_0_i Register | Section 1.11.5.8 |
| 404h+ (40h × i) | ELM_SYNDROME_FRAGMENT_1_i | ELM_SYNDROME_FRAGMENT_1_i Register | Section 1.11.5.9 |
| 408h + (40h × i) | ELM_SYNDROME_FRAGMENT_2_i | ELM_SYNDROME_FRAGMENT_2_i Register | Section 1.11.5.10 |
| 40Ch + (40h × i) | ELM_SYNDROME_FRAGMENT_3_i | ELM_SYNDROME_FRAGMENT_3_i Register | Section 1.11.5.11 |
| 410h + (40h × i) | ELM_SYNDROME_FRAGMENT_4_i | ELM_SYNDROME_FRAGMENT_4_i Register | Section 1.11.5.12 |
| 414h + (40h × i) | ELM_SYNDROME_FRAGMENT_5_i | ELM_SYNDROME_FRAGMENT_5_i Register | Section 1.11.5.13 |
| 418h + (40h × i) | ELM_SYNDROME_FRAGMENT_6_1 | ELM_SYNDROME_FRAGMENT_6_1 Register | Section 1.11.5.14 |
| 800h + (100h × i) | ELM_LOCATION_STATUS_i | ELM_LOCATION_STATUS_i Register | Section 1.11.5.15 |
| 880h-8BCh + (100h × i) | ELM_ERROR_LOCATION_0-15_i | ELM_ERROR_LOCATION_0-15_i Registers | Section 1.11.5.16 |

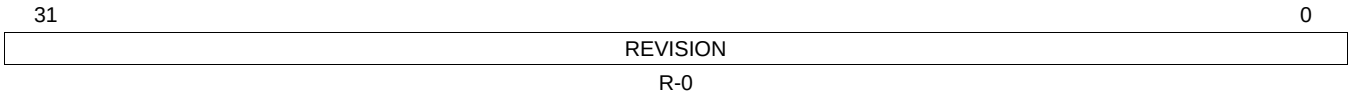
### 1.11.5.1 ELM Revision Register (ELM_REVISION)

This register contains the IP revision code. The ELM Revision Register (ELM_REVISION) is shown in Figure 1-89 and described in Table 1-153.

**Figure 1-89. ELM Revision Register (ELM_REVISION)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

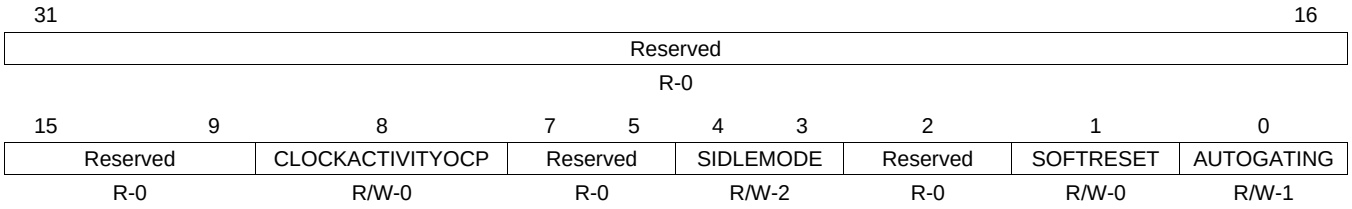
**Table 1-153. ELM Revision Register (ELM_REVISION) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | REVISION | 0-FFFF FFFFh | IP Revision |

### 1.11.5.2 ELM System Configuration Register (ELM_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The ELM System Configuration Register (ELM_SYSCONFIG) is shown in Figure 1-90 and described in Table 1-154.

**Figure 1-90. ELM System Configuration Register (ELM_SYSCONFIG)**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-154. ELM System Configuration Register (ELM_SYSCONFIG) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | Reserved |
| 8 | CLOCKACTIVITY OCP | | OCP Clock activity when module is in IDLE mode (during wake up mode period). |
| | | 0 | OCP Clock can be switch-off |
| | | 1 | OCP Clock is maintained during wake up period |
| 7-5 | Reserved | 0 | Reserved |
| 4-3 | SIDLEMODE | | Slave interface power management (IDLE req/ack control). |
| | | 0 | FORCE Idle. IDLE request is acknowledged unconditionally and immediately. (Default *Dumb* mode for safety) |
| | | 1h | NO idle. IDLE request is never acknowledged. |
| | | 2h | SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. |
| | | 3h | Reserved - do not use |
| 2 | Reserved | 0 | Reserved |
| 1 | SOFTRESET | | Module software reset. This bit is automatically reset by hardware (During reads, it always returns 0.). It has same effect as the OCP hardware reset. |
| | | 0 | Normal mode. |
| | | 1 | Start soft reset sequence. |
| 0 | AUTOGATING | | Internal OCP clock gating strategy. (No module visible impact other than saving power.) |
| | | 0 | OCP clock is free-running. |
| | | 1 | Automatic internal OCP clock gating strategy is applied based on the OCP interface activity. |

### 1.11.5.3 ELM System Status Register (ELM_SYSSTATUS)

The ELM System Status Register (ELM_SYSSTATUS) is shown in Figure 1-91 and described in Table 1-155.

**Figure 1-91. ELM System Status Register (ELM_SYSSTATUS)**

| 31 | 1 | 0 |
|---|---|---|
| Reserved | | RESETDONE |
| R-0 | | R-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-155. ELM System Status Register (ELM_SYSSTATUS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-1 | Reserved | 0 | Reserved |
| 0 | | | Internal reset monitoring (OCP domain). Undefined since:<br>From hardware perspective, the reset state is 0.<br>From software user perspective, when the accessible module is 1. |
| | | 0 | Reset is on-going |
| | | 1 | Reset is done (completed) |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.11.5.4 ELM Interrupt Status Register (ELM_IRQSTATUS)

This register doubles as a status register for the error-location processes. The ELM Interrupt Status Register (ELM_IRQSTATUS) is shown in Figure 1-92 and described in Table 1-156.

**Figure 1-92. ELM Interrupt Status Register (ELM_IRQSTATUS)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Reserved | | | | | | | | | | | | | | | |
| R-0 | | | | | | | | | | | | | | | |

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| Reserved | | | | | | | PAGE_VALID |
| R-0 | | | | | | | R/W-0 |

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| LOC_VALID_7 | LOC_VALID_6 | LOC_VALID_5 | LOC_VALID_4 | LOC_VALID_3 | LOC_VALID_2 | LOC_VALID_1 | LOC_VALID_0 |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-156. ELM Interrupt Status Register (ELM_IRQSTATUS) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | Reserved |
| 8 | PAGE_VALID | | Error-location status for a full page, based on the mask definition. |
| | | 0 | Read: Error locations invalid for all polynomials enabled in the ECC_INTERRUPT_MASK register. |
| | | 1 | Read: All error locations valid. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 7 | LOC_VALID_7 | | Error-location status for syndrome polynomial 7. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 6 | LOC_VALID_6 | | Error-location status for syndrome polynomial 6. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 5 | LOC_VALID_5 | | Error-location status for syndrome polynomial 5. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 4 | LOC_VALID_4 | | Error-location status for syndrome polynomial 4. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 3 | LOC_VALID_3 | | Error-location status for syndrome polynomial 3. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |

**Table 1-156. ELM Interrupt Status Register (ELM_IRQSTATUS) Field Descriptions (continued)**

| Bit | Field | Value | Description |
|---|---|---|---|
| 2 | LOC_VALID_2 | | Error-location status for syndrome polynomial 2. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 1 | LOC_VALID_1 | | Error-location status for syndrome polynomial 1. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |
| 0 | LOC_VALID_0 | | Error-location status for syndrome polynomial 0. |
| | | 0 | Read: No syndrome processed or process in progress. |
| | | 1 | Read: Error-location process completed. |
| | | 0 | Write: No effect. |
| | | 1 | Write: Clear interrupt. |

| LOCATION_MASK_7 | LOCATION_MASK_6 | LOCATION_MASK_5 | LOCATION_MASK_4 | LOCATION_MASK_3 | LOCATION_MASK_2 | LOCATION_MASK_1 | LOCATION_MASK_0 |
| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-157. ELM Interrupt Enable Register (ELM_IRQENABLE) Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-9 | Reserved | 0 | Reserved |
| 8 | PAGE_MASK | | Page interrupt mask bit |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 7 | LOCATION_MASK_7 | | Error-location interrupt mask bit for syndrome polynomial 7. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 6 | LOCATION_MASK_6 | | Error-location interrupt mask bit for syndrome polynomial 6. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 5 | LOCATION_MASK_5 | | Error-location interrupt mask bit for syndrome polynomial 5. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 4 | LOCATION_MASK_4 | | Error-location interrupt mask bit for syndrome polynomial 4. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 3 | LOCATION_MASK_3 | | Error-location interrupt mask bit for syndrome polynomial 3. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 2 | LOCATION_MASK_2 | | Error-location interrupt mask bit for syndrome polynomial 2. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 1 | LOCATION_MASK_1 | | Error-location interrupt mask bit for syndrome polynomial 1. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |
| 0 | LOCATION_MASK_0 | | Error-location interrupt mask bit for syndrome polynomial 0. |
| | | 0 | Disable interrupt. |
| | | 1 | Enable interrupt. |

### 1.11.5.8 ELM_SYNDROME_FRAGMENT_0_i Register

The ELM_SYNDROME_FRAGMENT_0_i Register is shown in Figure 1-96 and described in Table 1-160.

**Figure 1-96. ELM_SYNDROME_FRAGMENT_0_i Register**

| 31 | 0 |
|---|---|
| SYNDROME_0 | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-160. ELM_SYNDROME_FRAGMENT_0_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_0 | 0-FFFF FFFFh | Syndrome bits 0 to 31. |

### 1.11.5.9 ELM_SYNDROME_FRAGMENT_1_i Register

The ELM_SYNDROME_FRAGMENT_1_i Register is shown in Figure 1-97 and described in Table 1-161.

**Figure 1-97. ELM_SYNDROME_FRAGMENT_1_i Register**

| 31 | 0 |
|---|---|
| SYNDROME_1 | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-161. ELM_SYNDROME_FRAGMENT_1_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_1 | 0-FFFF FFFFh | Syndrome bits 32 to 63. |

### 1.11.5.10 ELM_SYNDROME_FRAGMENT_2_i Register

The ELM_SYNDROME_FRAGMENT_2_i Register is shown in Figure 1-98 and described in Table 1-162.

**Figure 1-98. ELM_SYNDROME_FRAGMENT_2_i Register**

| 31 | 0 |
|---|---|
| SYNDROME_2 | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-162. ELM_SYNDROME_FRAGMENT_2_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_2 | 0-FFFF FFFFh | Syndrome bits 64 to 95. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.11.5.11 ELM_SYNDROME_FRAGMENT_3_i Register

The ELM_SYNDROME_FRAGMENT_3_i Register is shown in Figure 1-99 and described in Table 1-163.

**Figure 1-99. ELM_SYNDROME_FRAGMENT_3_i Register**

| 31 | 0 |
|---|---|
| SYNDROME_3 | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-163. ELM_SYNDROME_FRAGMENT_3_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_3 | 0-FFFF FFFFh | Syndrome bits 96 to 127. |

### 1.11.5.12 ELM_SYNDROME_FRAGMENT_4_i Register

The ELM_SYNDROME_FRAGMENT_4_i Register is shown in Figure 1-100 and described in Table 1-164.

**Figure 1-100. ELM_SYNDROME_FRAGMENT_4_i Register**

| 31 | 0 |
|---|---|
| SYNDROME_4 | |
| R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-164. ELM_SYNDROME_FRAGMENT_4_i Register Field Descriptions**

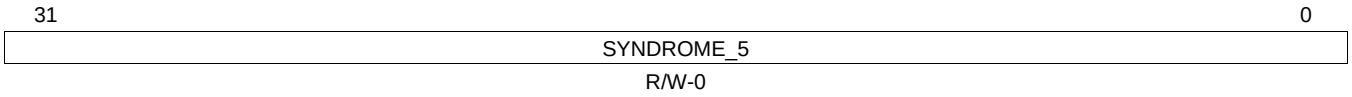
| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_4 | 0-FFFF FFFFh | Syndrome bits 128 to 159. |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.11.5.13 ELM_SYNDROME_FRAGMENT_5_i Register

The ELM_SYNDROME_FRAGMENT_5_i Register is shown in Figure 1-101 and described in Table 1-165.

**Figure 1-101. ELM_SYNDROME_FRAGMENT_5_i Register**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

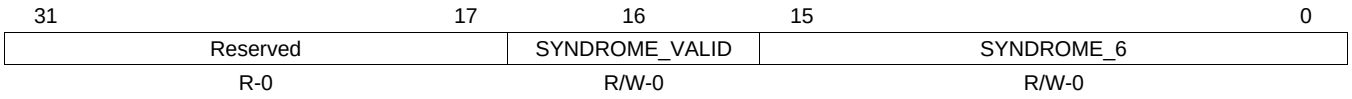
**Table 1-165. ELM_SYNDROME_FRAGMENT_5_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-0 | SYNDROME_5 | 0-FFFF FFFFh | Syndrome bits 160 to 191. |

### 1.11.5.14 ELM_SYNDROME_FRAGMENT_6_i Register

The ELM_SYNDROME_FRAGMENT_6_i Register is shown in Figure 1-102 and described in Table 1-166.

**Figure 1-102. ELM_SYNDROME_FRAGMENT_6_i Register**



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

**Table 1-166. ELM_SYNDROME_FRAGMENT_6_i Register Field Descriptions**

| Bit | Field | Value | Description |
|---|---|---|---|
| 31-17 | Reserved | 0 | Reserved |
| 16 | SYNDROME_VALID | | Syndrome valid bit. |
| | | 0 | This syndrome polynomial should not be processed. |
| | | 1 | This syndrome polynomial must be processed. |
| 15-0 | SYNDROME_6 | 0-FFFFh | Syndrome bits 192 to 207. |

## 1.12 Bus Interconnect

### *1.12.1 Interconnect Overview*

**NOTE:** The L3 interconnect is instantiation of the NoC interconnect from Arteris, Inc. Arteris® is a registered trademark of Arteris, Inc.

This document contains materials that are ©Arteris, Inc., and that constitute proprietary information of Arteris, Inc.

All materials and trademarks are used under license from Arteris, Inc. For additional information, see the Arteris Reference manuals, or contact Arteris, Inc.

NoC is an abbreviation for Network On Chip.

**NOTE:** The L4 interconnects are instantiations of the Sonics3220™ interconnect from Sonics, Inc.

This document contains materials that are ©2003-2009 Sonics, Inc., and that constitute proprietary information of Sonics, Inc.

SonicsMX™ and Sonics3220, are trademarks or registered trademarks of Sonics, Inc. All such materials and trademarks are used under license from Sonics, Inc. For additional information, see the SonicsMX or Sonics3220 Reference manuals, or contact Sonics, Inc.

SMX is an abbreviation for SonicsMX.

#### 1.12.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

**NOTE:** A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).

Copyright © 2011–2016, Texas Instruments Incorporated

- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behavior is defined by the protocol semantics.
- Sideband signal: Any signal whose behavior is not associated to a precise transaction or data flow.
- Out-of-band error: Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors.

**NOTE:** Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 1-169 lists the commands encoded.

**Table 1-169. MCmd Qualifier Description**

| MCmd[2:0] | Transaction Type |
|---|---|
| 0 0 0 | Idle |
| 0 0 1 | Write |
| 0 1 0 | Read |
| 0 1 1 | ReadEx |
| 1 0 0 | Read link |
| 1 0 1 | Write nonposted |
| 1 1 0 | Write conditional |
| 1 1 1 | Write broadcast |

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 1-170.

**Table 1-170. MReqInfo Qualifier Description**

| Qualifiers | Description |
|---|---|
| MReqType | 0: Data access |
| | 1: Opcode fetch |
| MReqSupervisor | 0: User mode |
| | 1: Supervisor mode |
| MReqDebug | 0: Functional access |
| | 1: Debug access |

Copyright © 2011–2016, Texas Instruments Incorporated

- Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 1-171.

**Table 1-171. SResp Qualifier Description**

| SResp[1:0] | Description |
|---|---|
| 0 0 | No response |
| 0 1 | Data valid/accept |
| 1 0 | Not used |
| 1 1 | Error |

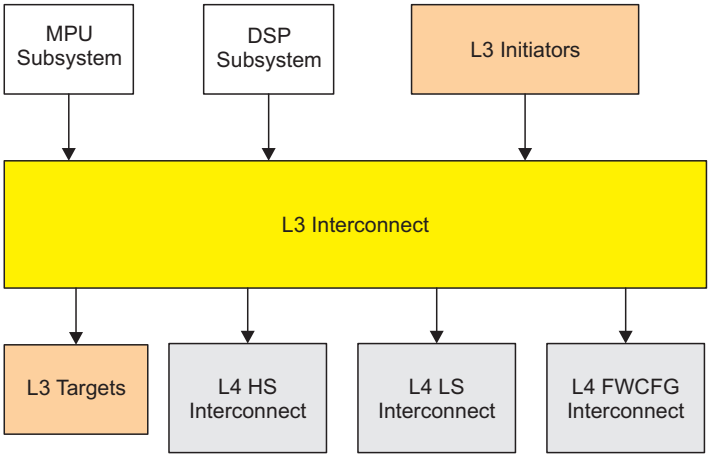
### 1.12.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core.
- L2 is included in the DSP subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and three L4 interconnects. It enables communication among the modules and subsystems in the device.

Figure 1-105 shows an overview of the L3 and L4 interconnect architecture.

**Figure 1-105. Interconnect Overview**



Copyright © 2011–2016, Texas Instruments Incorporated

- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- The L4 is composed of the following:
  - L4 HS: Includes the majority of the configuration interface for level 3 (L3) system modules and peripheral interconnect
  - L4 LS : Includes the main peripherals that require enhanced direct memory access (EDMA) access
  - L4 FWCFG: Includes peripherals attached to the WKUP power domain.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default settings are fully functional; they enable all possible functional data paths and a minimal default protection setting. However, the interconnect parameters can be modified to fit user expectations.

### 1.12.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

#### 1.12.2.1 L3 Interconnect Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3 interconnects are:

- Network interface units (NIUs): Master NIUs for the initiator agents (IAs) and slave NIUs for the target agents (TAs)
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting satistical events on the L3 interconnect

Figure 1-106 is an overview of the L3 interconnect and the peripherals attached to it.

### 1.12.2.3 L3 Interconnect Functional Description

#### *1.12.2.3.1 Module Use in L3 Interconnect*

The L3 interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUX to mask interrupts: Three, one for each clock domain
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration.
- Some rate adapters for control of throughput ratio

#### *1.12.2.3.2 Module Distribution*

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 1-174 and Table 1-175 list all the modules and subsystems with their associated agents. The agents are listed for each L3 interconnect domain.

##### *1.12.2.3.2.1 L3 Interconnect Agents*

Any initiator or target core is connected to the L3 interconnect through an NIU. NIUs act as entry points to the L3 interconnect, and also include various programming registers. Table 1-174 lists the supported master NIU ports.

**Table 1-174. Master NIUs**

| Master NIU | Description |
|---|---|
| L3_MN_MPU | Cortex A8 microprocessor subsystem unit 128-bit port |
| L3_MN_HDVICP | HDVICP subsystem port 1 128-bit initiator port |
| L3_MN_ISS | Imaging subsystem 128-bit initiator port |
| L3_MN_MMU | Memory management unit 128-bit initiator port |
| L3_MN_DSP1 | DSP subsystem 128-bit initiator port1 (GEM MDMA) |
| L3_MN_EXPSLOT0 | Expansion slot 0 128-bit initiator port |
| L3_MN_TPTC_RD1/2/3/4 | TPTC 128-bit read initiator ports |
| L3_MN_TPTC_WR1/2/3/4 | TPTC 128-bit write initiator ports |
| L3_MN_HDVPSS1 | Display subsystem port 1 - 128-bit initiator |
| L3_MN_HDVPSS2 | Display subsystem port 2 - 128-bit initiator |
| L3_MN_DSP2 | DSP subsystem 128-bit initiator port 2 (GEM CFG) |
| L3_MN_SGX | SGX 530 2D graphics accelerator 128-bit initiator port |
| L3_MN_MEDIACONTROLLER | Media Controller 64-bit initiator port |
| L3_MN_PCIE | PCIe 64-bit initiator port |
| L3_MN_3PGSW | 3PGSW 32-bit initiator port |
| L3_MN_FDIF | Face Detection Interface 32-bit initiator port |
| L3_MN_SATA | SATA controller 32-bit initiator port |
| L3_MN_DAP | Debug access point 32-bit initiator port |
| L3_MN_USB1/2 | USB CPP DMA/QUEUE Manager 32-bit initiator port |
| L3_MN_PATA | PATA 32-bit initiator port |

**Table 1-174. Master NIUs (continued)**

| Master NIU | Description |
|---|---|
| L3_MN_IEEE1500 | IEEE1500 32-bit initiator port |
| L3_MN_MLB | MLB 32-bit initiator port |

Table 1-175 lists the supported slave NIU ports.

**Table 1-175. Slave NIUs**

| Slave NIU | Description |
|---|---|
| L3_SN_DMM0 | Direct memory manager 0 (DMM0) 128-bit target port |
| L3_SN_DMM1 | DMM1 128-bit target port |
| L3_SN_SL2 | HDVICP SL2IF 128-bit target port |
| L3_SN_EXPSLOT0 | Expansion slot 0 128-bit target port |
| L3_SN_DSP | DSP (GEM SDMA) 128-bit target port |
| L3_SN_TPTC_CFG | 4 32-bit TPTC configuration target ports |
| L3_SN_TPCC_CFG | 32-bit TPCC configuration target port |
| L3_SN_SGX | 2D Graphics accelerator (SGX530) 64-bit target port |
| L3_SN_OCMRAM0 | OCM RAM 64-bit target port |
| L3_SN_MEDIACONTROLLER | Media Controller 64-bit target port |
| L3_SN_PCIE | PCIe 64-bit target port |
| L3_SN_VCP | VCP2 64-bit target port |
| L3_SN_HDVICP | HDVICP Host 1 Control 32-bit target port |
| L3_SN_ISS | ISS 32-bit target port |
| L3_SN_MMCHS2 | MMCHS 32-bit target port |
| L3_SN_L3_INSTR | L3 Instrumentation 32-bit target port |
| L3_SN_L4F | 2 L4_FAST peripheral 32-bit target ports |
| L3_SN_DAP | Debug subsystem target port |
| L3_SN_L4S | 2 L3_SLOW peripheral 32-bit target port |
| L3_SN_GPMC | General Purpose Memory Controller 32-bit target port |
| L3_SN_MCASP0/1/2 | McASP 32-bit target ports |
| L3_SN_HDMI | HDMI 32-bit target port |
| L3_SN_USB | USB 32-bit target port |
| L3_SN_L4 Firewall | L3 Firewalls target port |
| L3_SN_MCBSP | McBSP 32-bit target port |

#### *1.12.2.3.2.2 L3 Connectivity Matrix*

The L3 interconnect is divided into two main clock domains plus one small domain dedicated to DRAM performance monitorring:

- L3F clock domain (220 MHz)
- L3S clock domain (110 MHz)
- L3M cock domain (200MHz clock domain for performance monitoring)

The two main clock domains (L3F and L3S) are sychronous and balanced to each other. The third clock domain L3M, dedicated to performance monitoring is asynchronous to all other domains.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.12.2.3.2.2.1 Clock Domain Mapping of the L3 Interconnect Modules

Each clock domain (L3F, L3S, and L3M) has its own host, flag mux, slave NIUs, and bandwidth regulators.

**Table 1-176. L3 Clock Domains and Elements**

#### 1.12.2.3.2.3 Master NIU Identification

An master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 1-177). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3 interconnect error logging

**Table 1-177. ConnID Values**

| 4 Bit ConnID Value (security) (hex) | 6 Bit ConnID Value (debug) (hex) | Master NIU |
|---|---|---|
| 0x0 | 0 | Cortex-A8 MPU |

#### 1.12.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. It is used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 1.12.2.5.1.4, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following masters: HDVICP, TPTC_RD2/4, TPTC_WR2/4, MMU, ISS and SGX.

#### 1.12.2.3.4 Flag Muxing

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU interrupt controller without interfering with the interconnect traffic. Flag mux unit contains software registers that are able to eventually mask some interrupts in order to prevent the unit from seeing them and to help with debug.

There are four registers in this group:

- One register to mask application error sources
- One status register to check which application error sources are active
- One register to mask debug error sources
- One status register to check which debug error source are active

By default none of the flags are masked.

There are four flag muxes in Centaurus L3 Interconnect, one per each clock domain plus additional flag mux collecting flags from the three previous ones. In concequnce L3 will generate two flags: APPLICATION error and DEBUG error.

The unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) are used to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number. Flag mux inputs for the different sources can be see in Table 1-230.

#### 1.12.2.3.5 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Copyright © 2011–2016, Texas Instruments Incorporated

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Table 1-268).

Filters are programmed through the Table 1-268 configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 1-250). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 1-250).

There are five statistic collectors embedded in Centaurus L3, one dedicated to DRAM load monitoring and four statistic collectors dedicated to master latency monitoring.

#### 1.12.2.3.6 L3 Interconnect Error Handling

Error logging is enabled in the L3 interconnect. The three major types of errors are:

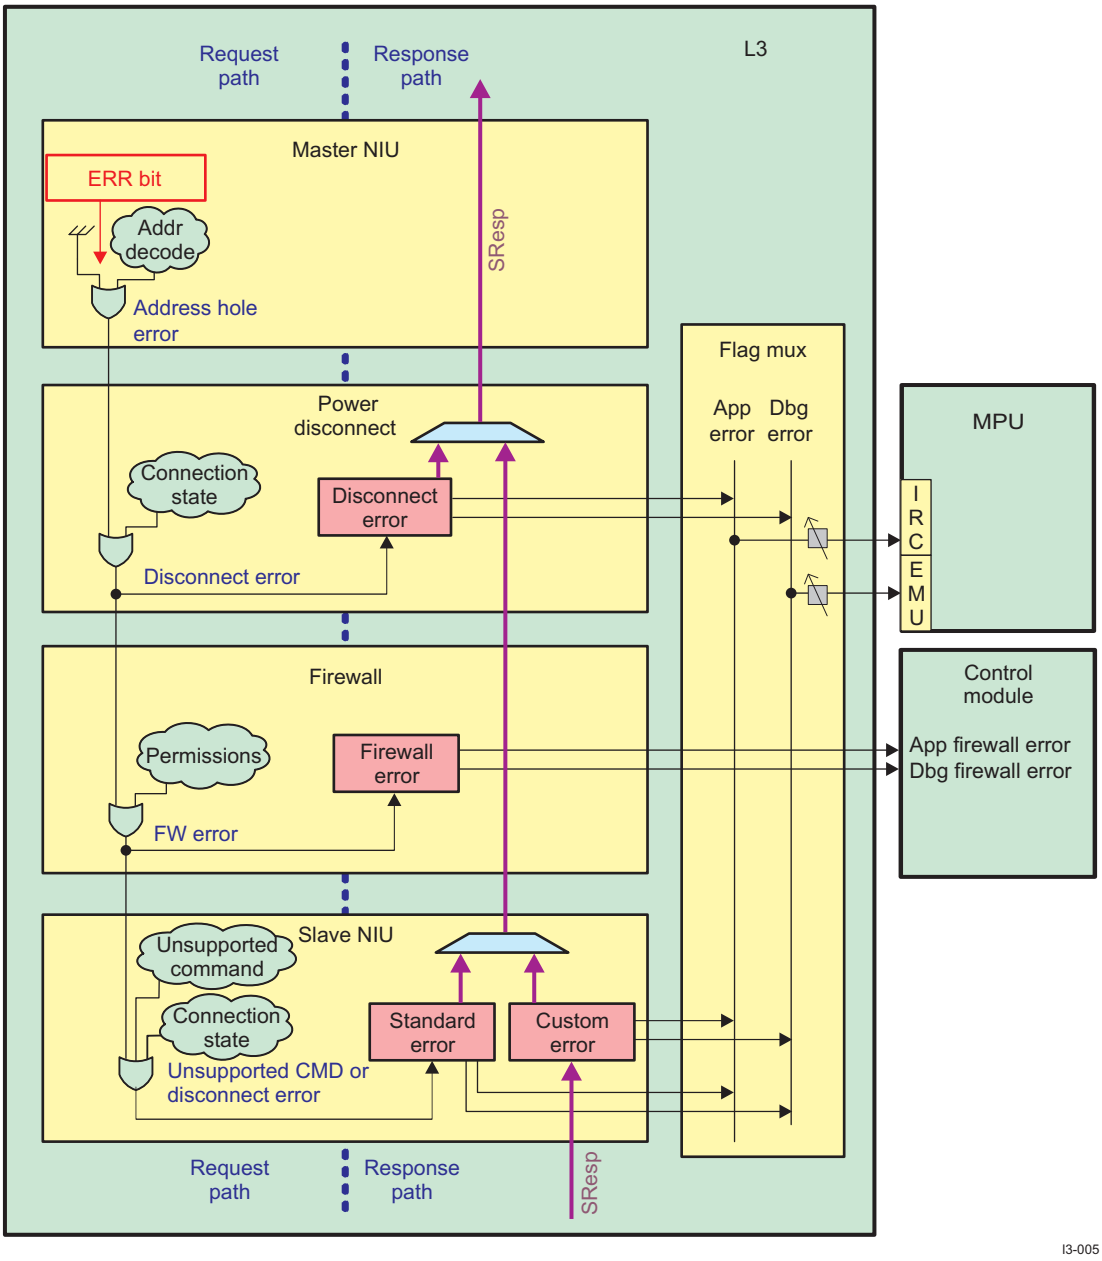
- Slave NIU errors
- Firewall errors (see , *L3Firewall Error Logging*)
- Flag mux errors

##### 1.12.2.3.6.1 Global Error-Routing Scheme

Figure 1-108 shows the L3 global error-routing scheme.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-108. L3 Global Error-Routing Scheme**



### *1.12.2.3.6.2 Slave NIU Error Logging*

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 1-178).

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-178. L3 Connectivity and Holes Error Routing**

| Master | Connectivity and Holes Errors Logged Into Slave NIUs |
|---|---|
| DAP | GPMC |
| Dual Cortex M3 (Media Controller) | |
| Expansion slot | |
| JTag interface (IEEE1500) | |
| MMU | |
| MPU (Modena) | |
| PCIe | |
| SATA | |
| MLB | |
| SGX | |
| TPTC_RD1/2/3/4 | |
| TPTC_WR1/2/3/4 | |
| USB2 | |
| SW3PG | OCMC RAM0 |
| HDVPSS1/2 | |
| HDVICP | |
| FACEDETECT | |
| PATA | |
| DSP (GEM_CFG) | USB Targ |
| DSP (GEM_MDMA) | MMU Targ |
| USB1 | DSP (GEM_SDMA) |

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module.
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
  - None: Error logging for this type of error is disabled.
  - Error: Error is logged for this type of error.
  - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
  - Application error - Fault[0]
  - Debug error - Fault[1]

  By default, all slave NIUs are configured with standard and custom error levels set to FAULT, active high. The errors are reported on the two flag muxes (see Figure 1-108), depending on the access type, application or debug. For more information, see Section 1.12.2.3.6.3, *Flag Mux Error Logging*.

  The slave NIU power-disconnect component also has error logging enabled. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the slave is awake. This is inefficient but it simplifies NIU implementation and should not be a problem,

Copyright © 2011–2016, Texas Instruments Incorporated

because errors are supposed to occur only during software debug.

#### 1.12.2.3.6.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- L3_FLAGMUX_MASK0: Masks application error sources
- L3_FLAGMUX_MASK1: Masks debug error sources
- L3_FLAGMUX_REGERR0: Checks which application error sources are active
- L3_FLAGMUX_REGERR1: Checks which debug error sources are active

The two L3_FLAGMUXMASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

Table 1-179 describes the mapping of the flags to the corresponding sources.

**Table 1-179. Interconnect Flag Mapping**

| | Flag Mux Input | Source |
|---|---|---|
| L3F Flag Mux | 0 | MMU |
| | 1 | DMM port1 |
| | 2 | DMM port2 |
| | 3 | TPTC3 |
| | 4 | TPTC4 |
| | 5 | DSP (GEM_SDMA) |
| | 6 | TPTC2 |
| | 7 | TPTC1 |
| | 8 | TPCC |
| | 9 | SL2 port1 |

#### *1.12.2.3.6.4 Severity Level of Standard and Custom Errors*

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors (see Table 1-191).
- The L3_TARG_STDERRLOG_MAIN register is the main register for error-logging management. It shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

### 1.12.2.4 L3 Interconnect Programming Guide

#### *1.12.2.4.1 L3 Interconnect Low-Level Programming Models*

This section describes the low-level hardware programming sequences for configuring and using the L3 interconnect module.

##### *1.12.2.4.1.1 Global Initialization*

###### *1.12.2.4.1.1.1 Global Initialization of Surrounding Modules*

This section identifies the requirements for initializing the surrounding modules when the L3 interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3interconnect. For more information, see Section 1.12.2.2, *L3 Interconnect Integration* .

**Table 1-180. Global Initialization of Surrounding Modules**

| Surrounding Modules | Comments |
|---|---|
| PRCM | For information about the configuration of the PRCM module, see the *PRCM* chapter. |
| Control module | For information about the configuration of the control module, see the *Control Module* chapter. |
| MPU INTC | The MPU INTC must be configured to enable interrupts from the L3 interconnect module. See the *ARM Interrupt Controller (AINTC)* chapter. |
| EDMA | For information about the configuration of the EDMA, see the *EDMA* chapter. |
| L3 interconnect | For information about the configuration of the interconnect, see the *L3 Interconnect* section. |

#### *1.12.2.4.2 Operational Modes Configuration*

##### *1.12.2.4.2.1 L3 Interconnect Error Analysis Mode*

###### *1.12.2.4.2.1.1 Main Sequence: L3 Interconnect Error Analysis Mode*

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 1-109 shows the software sequence required in most cases.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-109. Typical Error Analysis Sequence**

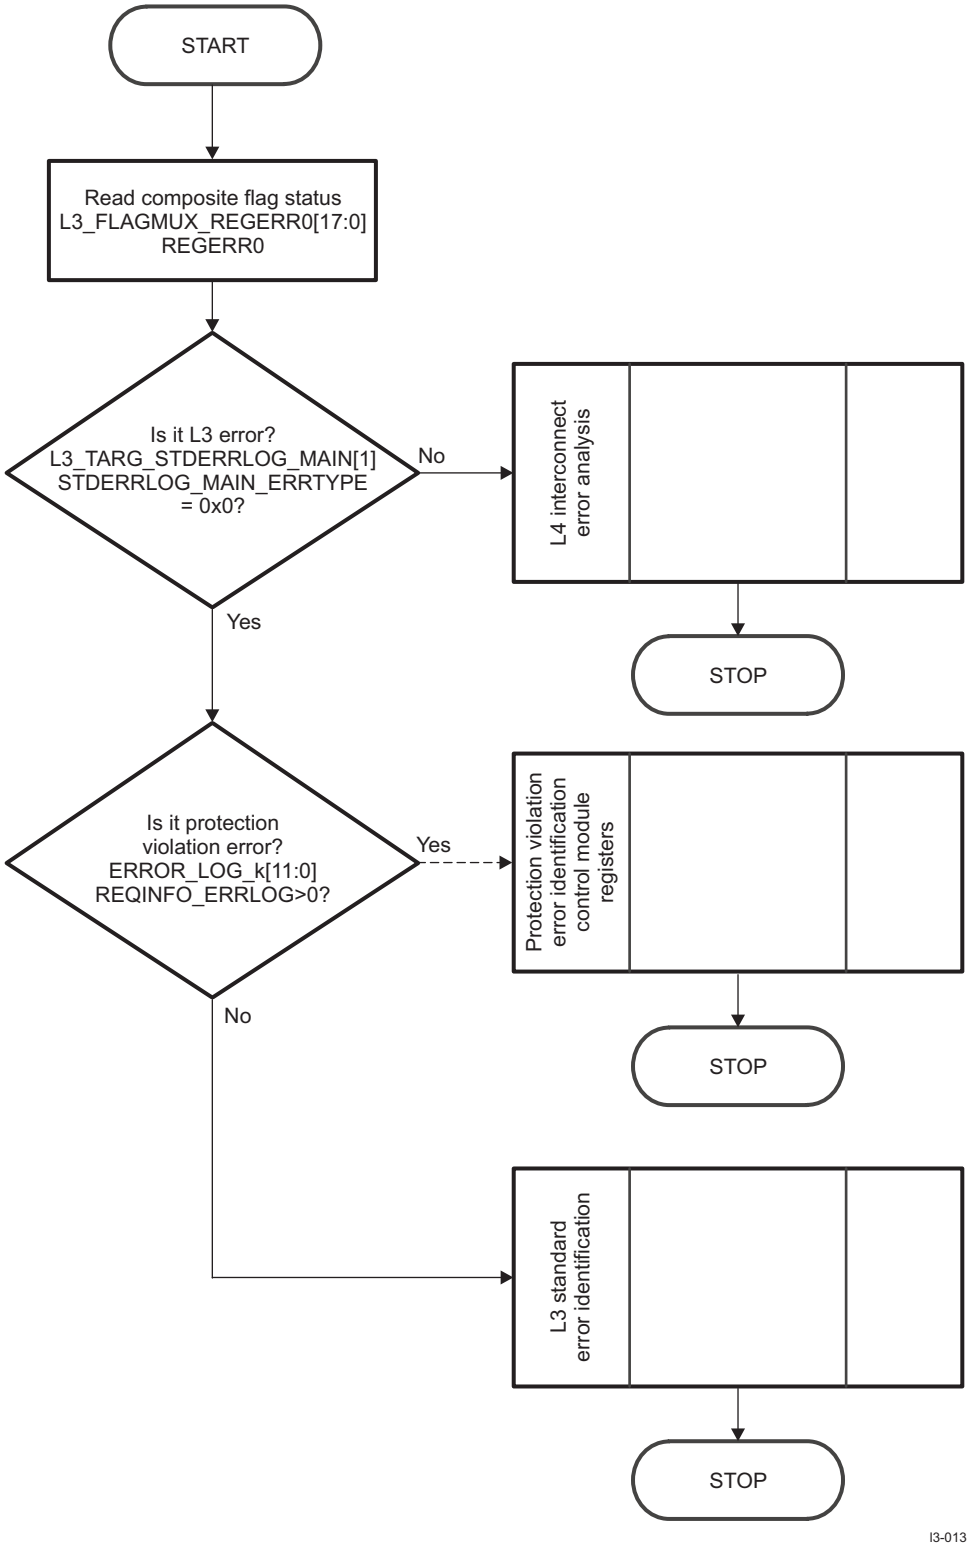

Table 1-181 lists the subprocess call summary for error analysis mode in the main sequence.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-181. Subprocess Call Summary for Main Sequence – Error Analysis Mode**

| Subprocess | Cross-Reference |
|---|---|
| L4 interconnect error analysis | See Section 1.12.2.4.2.1, *L4 Interconnect Error Analysis Mode.* |
| L3 interconnect protection violation error identification | See Section 1.12.2.4.2.1.1.2, *Subsequence: L3 Interconnect Protection Violation Error Identification.* |
| L3 interconnect unsupported command/address hole error identification | See Section 1.12.2.4.2.1.1.3, *Subsequence: L3Interconnect Unsupported Command/Address Hole Error Identification.* |
| L3 interconnect reset FLAGMUX and module | See Section 1.12.2.4.2.1.1.4, *Subsequence: L3 Interconnect Reset FLAGMUX and Module.* |

#### *1.12.2.4.2.1.1.1 Subsequence: L3 Custom Error Identification*

The procedure listed in Table 1-182 describes custom error identification.

**Table 1-182. Custom Error Identification**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| IF: Is custom error detected? | L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE | =0x1 |
| Read info field of the response packet. | L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO | xxx |
| Read the address of the initiator that caused error. | L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[5:0] STDERRLOG_CUSTOMINFO_MSTADDR | xxx |
| Read the type of operation (read/write). | L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE | xxx |
| ENDIF | | |

#### *1.12.2.4.2.1.1.2 Subsequence: L3 Interconnect Protection Violation Error Identification*

The procedure listed in Table 1-183 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

**Table 1-183. Protection Violation Error Identification**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Read the burst violation. | ERROR_LOG_k[23] 2D_BURST_VIOLATION | xxx |
| Read the initiator ID. | ERROR_LOG_k[3:0] ConnID | xxx |
| Read the command that caused the error. | ERROR_LOG_k[7] MCMD | xxx |
| Read the address of the request that caused the error. | ERROR_LOG_k[31:12] SLVOFS_LOGICAL | xxx |
| **IF**: Is it an application error? | L3_FLAGMUX_REGERR0 [10:0] REGERROR0 | 0x0 |
| Clear the status bit. | L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| **ELSE IF** | L3_FLAGMUX_REGERR1[10:0] REGERROR1 | = 0x1 |
| Clear the status bit. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| **ENDIF** | | |
| Clear the burst violation. | ERROR_LOG_k[23] 2D_BURST_VIOLATION | 0x0 |
| Clear the error status. | ERROR_LOG_k[21:17] REGION_START_ERRLOG | 0x00 |

#### *1.12.2.4.2.1.1.3 Subsequence: L3 Interconnect Standard Error Identification*

The procedure listed in Table 1-184 describes the identification of standard errors inside the L3 interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-184. L3 Standard Error Identification**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| **IF**: Is an error detected? | L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT | = 0x1 |
| Read the corresponding flag. | L3_FLAGMUX_REGERR0[10:0] REGERROR0 | xxx |
| Read the corresponding flag. | L3_FLAGMUX_REGERR1[10:0] REGERROR1 | xxx |
| Localize the slave NIU that generated the error. | See Table 1-179, *Interconnect Flag Mapping*. | |
| **ELSE** | | |
| Clear the error log. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| Clear the severity error status. | L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0 | 0x2 |
| **ENDIF** | | |

#### *1.12.2.4.2.1.1.4 Subsequence: L3 Interconnect FLAGMUX Configuration*

The procedure listed in Table 1-185 gives information about the configuration of FLAGMUX masks.

**Table 1-185. FLAGMUX Configuration**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Set the FLAGMUX masks to mask an event. | L3_FLAGMUX_MASK0[10:0] MASK0<br>L3_FLAGMUX_MASK1[10:0] MASK1 | xxx |
| Read the REGERR bits to see if an error is recorded. | L3_FLAGMUX_REGERR0[10:0] REGERR0<br>L3_FLAGMUX_REGERR1[10:0] REGERR1 | xxx |
| Clear the slave NIU error log and the FLAGMUX error. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0 | 0x1 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.12.2.5 L3 Interconnect Register Manual

#### *1.12.2.5.1 L3 Register Group Summary*

The registers in the L3 interconnect are divided into eight groups:

- HOST registers (See Table 1-187)
- TARG registers (See Table 1-206)
- FLAGMUX registers (See Table 1-231)
- BW registers (See Table 1-241)
- STATCOLL registers (See Table 1-250)

##### *1.12.2.5.1.1 L3 Host Register Summary and Description*

**Table 1-186. HOST Instance Summary**

| Module Name | Base Address | Size |
|---|---|---|
| L3F | 0x4400 0000 | 8MB |
| L3M | 0x4440 0000 | 8MB |
| L3S | 0x44800 0000 | 8MB |

Copyright © 2011–2016, Texas Instruments Incorporated

### 1.12.2.5.1.1.1 L3 HOST Register Summary

**Table 1-187. HOST Registers Summary**

| Register Name | Type | Register Width (Bits) | Address Offset for L3F | L3F L3 Physical Address | Address Offset for L3M | L3M L3 Physical Address | Address Offset for L3S | L3S L3 Physical Address |

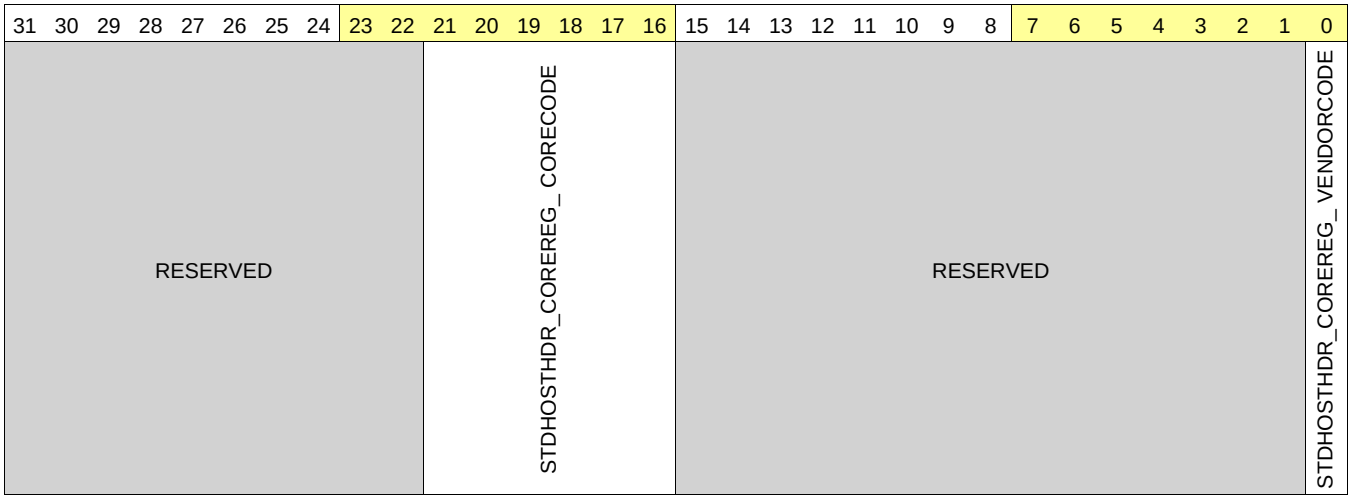
### 1.12.2.5.1.2.2 L3 TARG Registers Description

**Table 1-213. L3_TARG_STDHOSTHDR_COREREG**

| | | | |
|---|---|---|---|
| **Address Offset** | 0x0000 0000 | | |
| **Physical Address** | See Table 1-206 through Table 1-212 | **Instance** | See Table 1-206 through Table 1-212 |
| **Description** | | | |
| **Type** | R | | |



| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:22 | RESERVED | | R | 0x000 |
| 21:16 | STDHOSTHDR_COREREG_ CORECODE | The Core Code field is a constant reporting a vendor-specific core generator code. Type: Constant. Reset value: 0x13. | R | 0x13 |
| 15:1 | RESERVED | | R | 0x0000 |
| 0 | STDHOSTHDR_COREREG_ VENDORCODE | The Vendor Code field is a constant reporting the core generator vendor code. Type: Constant. Reset value: 0x1.<br>Read 0x0: Third-party vendor.<br>Read 0x1: | R | 1 |

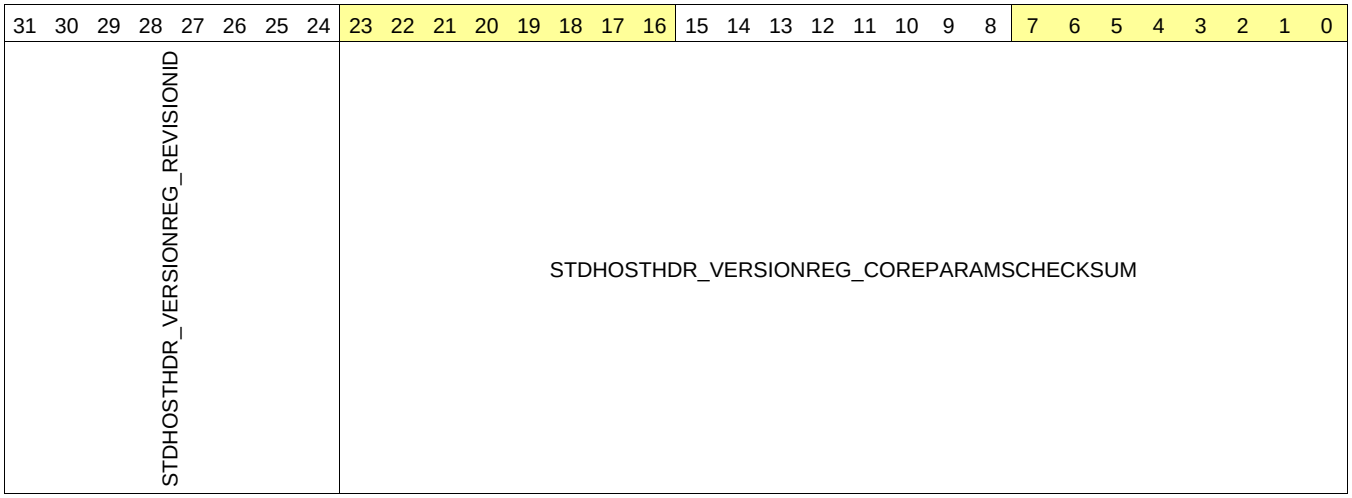
### Table 1-214. L3_TARG_STDHOSTHDR_VERSIONREG

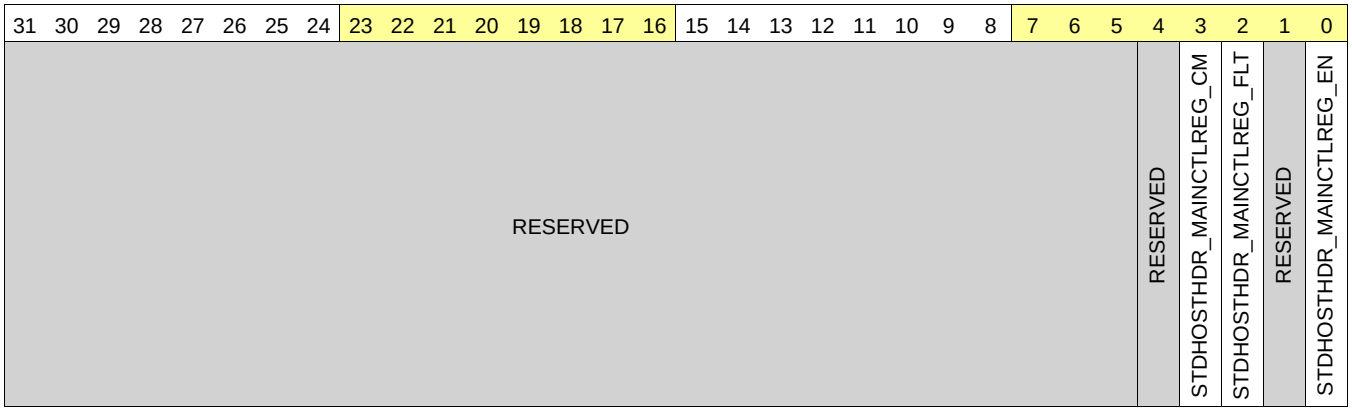
| | | | |
|---|---|---|---|
| **Address Offset** | 0x0000 0004 | | |
| **Physical Address** | See Table 1-206 through Table 1-212 | **Instance** | See Table 1-206 through Table 1-212 |
| **Description** | | | |
| **Type** | R | | |



| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:24 | STDHOSTHDR_VERSIONREG_REVISIONID | The Revision Identifier field is a constant reporting the core generator revision number. Type: Constant. Reset value: 0x0. | R | 0x00 |
| 23:0 | STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM | Reserved. Type: Reserved. Reset value: Reserved. | R | 0x000000 |

### Table 1-215. L3_TARG_STDHOSTHDR_MAINCTLREG

| | | | |
|---|---|---|---|
| **Address Offset** | 0x0000 0008 | | |
| **Physical Address** | See Table 1-206 through Table 1-212 | **Instance** | See Table 1-206 through Table 1-212 |
| **Description** | | | |
| **Type** | RW | | |

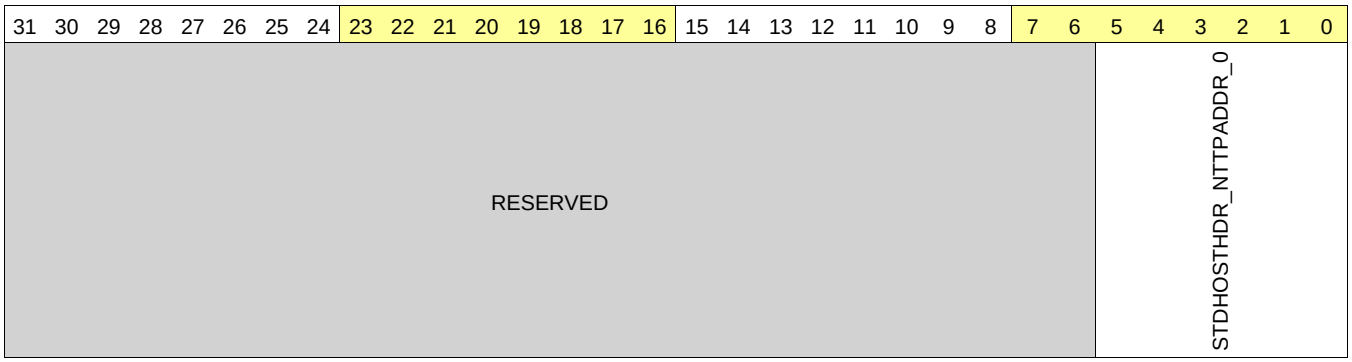


Copyright © 2011–2016, Texas Instruments Incorporated

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:5 | RESERVED | Reserved | R | 0x0000000 |
| 4 | RESERVED | Reserved | R | 0 |
| 3 | STDHOSTHDR_MAINCTLREG_CM | Reserved for internal testing. Must be set to 0. Type: Control. Reset value: 0x0. | R | 0 |
| 2 | STDHOSTHDR_MAINCTLREG_FLT | Asserted when a Fault condition is detected: if the unit includes Error Logging, Flt is asserted when the FltCnt register field indicates a Fault, and deasserted when FltCnt is reset. If no Error Logging is implemented, this bit becomes unit-dependent. In all cases, Flt bit and Flt pin (service network) have the same logical level. Type: Status. Reset value: X. | R | 0 |
| 1 | RESERVED | Reserved | R | 0 |
| 0 | STDHOSTHDR_MAINCTLREG_EN | Sets the global core enable. Note: A disabled master does not generate any NTTP requests, and a disabled slave replies with an error packet to any request it receives. Type: Control. Reset value: 0x1. | RW | 1 |

## Table 1-216. L3_TARG_STDHOSTHDR_NTTPADDR_0

| | | | |
|---|---|---|---|
| **Address Offset** | 0x0000 0010 | | |
| **Physical Address** | See Table 1-206 through Table 1-212 | **Instance** | See Table 1-206 through Table 1-212 |
| **Description** | | | |
| **Type** | R | | |



| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:6 | RESERVED | Reserved | R | 0x0000000 |
| 5:0 | STDHOSTHDR_NTTPADDR_0 | Sets the RX port address. Type: Control. Reset value: 0x15. | R | 0x03 |

### 1.12.3 L4 Interconnects

This section details the device L4 interconnects.

#### 1.12.3.1 L4 Interconnect Overview

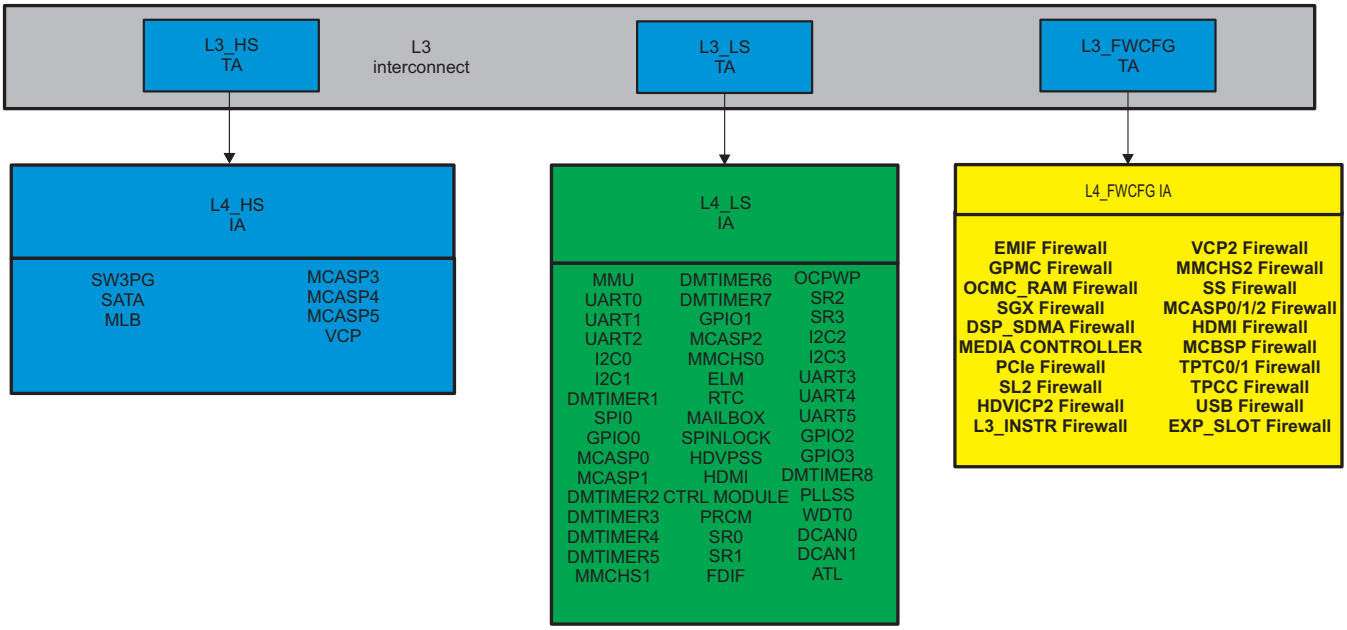
The device uses two separate L4 interconnect structures to connect peripheral modules, and one additional L4 interconnect for the firewalls. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 1-110 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_HS: Configuration peripheral interconnect, for configuration of high speed masters. Located in the 220MHz clock domain.
- L4_LS: Main peripheral interconnect for peripherals that requre DMA accesses. This is a configuration interconnect for the low speed masters, located in the 110 MHz clock domain.
- L4_FWCFG: Firewall configuration interconnect located in the 110 MHz clock domain.

**Figure 1-110. L4 Interconnect Overview**



The main features of the L4 interconnects are:

- From one to two 32-bit initiator ports for each L4 interconnect instance.
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little endian
- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- Protection logic that provides user-configurable access control to targets by each initiator
- L4LS and L4HS are each with its own PRCM interface
- All peripherals are protected by firewall

#### 1.12.3.2 L4 Interconnect Integration

Table 1-290 and Table 1-291 summarize the integration of the module in the device.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-290. Integration Attributes**

| Module Instance | Attributes |
|---|---|
| | Power Domain |
| L4_HS | Always on power domain |
| L4_LS | Always on power domain |
| L4_FWCFG | Always on power domain |

**Table 1-291. Clocks and Resets**

| Clocks | | | |
|---|---|---|---|
| **Module Instance** | **Destination Signal Name** | **Source** | **Description** |
| L4_HS | L4HS_CLK | PRCM module | Functional and interface clock |
| L4_LS | L4LS_CLK | PRCM module | Functional and interface clock |
| L4_FWCFG | L4FWCFG_CLK | PRCM module | Functional and interface clock |
| **Resets** | | | |
| **Module Instance** | **Destination Signal Name** | **Source** | **Description** |
| L4_HS | L4HS_RST | PRCM module | Reset of L4_HS interconnect |
| L4_LS | L4LS_RST | PRCM module | Reset of L4_LS interconnect |
| L4_FWCFG | L4FWCFG_RST | PRCM module | Reset of L4_FWCFG interconnect |

### 1.12.3.3 L4 Interconnect Functional Description

#### *1.12.3.3.1 Module Distribution*

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 1-292 through Table 1-297 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

##### *1.12.3.3.1.1 L4_HS Interconnect Agents*

Table 1-292 lists the L4 HS TAs.

**Table 1-292. L4 HS TAs**

| Module Target Name | Description |
|---|---|
| L4HS_TA_SW3PG | SW3PG L4 HS target port |
| L4HS_TA_SATA | SATA L4 HS target port |
| L4HS_TA_MLB | MLB L4 HS target port |
| L4HS_TA_MCASP3 | MCASP3 L4 HS target port |
| L4HS_TA_MCASP4 | MCASP4 L4 HS target port |
| L4HS_TA_MCASP5 | MCASP5 L4 HS target port |
| L4HS_TA_VCP | VCP L4 HS target port |

Two ports communicate beteween L3 and the L4 HS interconnect to allow L3 Initiators to access L4HS targets. Table 1-293 lists the L4HS initiator TAs.

For the list of initiators authorized to access the L4 peripheral peripherals, see *Connectivity Matrix*.

**Table 1-293. L4 HS IAs**

| Module Iniator Name | Description |
|---|---|
| L4HS_IA_0 | L3 enhanced direct memory access (EDMA) RD interconnect port |
| L4HS_IA_1 | L3 EDMA WR interconnect port |

##### *1.12.3.3.1.2 L4_LS Interconnect Agents*

The L4_LS interconnect handles only transfers to peripherals in the core power domain. Table 1-294 lists the TAs.

**Table 1-294. L4_LS TAs**

| Module Target Name | Description |
|---|---|
| L4LS_TA_MMU | System MMU L4LS target port |
| L4LS_TA_UART0 | UART0 L4LS target port |
| L4LS_TA_UART1 | UART1 L4LS target port |
| L4LS_TA_UART2 | UART2 L4LS target port |
| L4LS_TA_I2C0 | I2C0 L4LS target port |
| L4LS_TA_I2C1 | I2C1 L4 LS target port |
| L4LS_TA_DMTIMER1 | TIMER1 L4 LS target port |
| L4LS_TA_SPI0 | SPI0 L4LS target port |
| L4LS_TA_GPIO0 | GPIO0 L4LS target port |
| L4LS_TA_MCASP0 | MCASP0 L4LS target port |
| L4LS_TA_MCASP1 | MCASP1 L4LS target port |
| L4LS_TA_DMTIMER2 | TIMER2 L4LS target port |
| L4LS_TA_DMTIMER3 | TIMER3 L4LS target port |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 1-294. L4_LS TAs (continued)**

| Module Target Name | Description |
|---|---|
| L4LS_TA_DMTIMER4 | TIMER4 L4LS target port |
| L4LS_TA_DMTIMER5 | TIMER5 L4LS target port |
| L4LS_TA_DMTIMER6 | TIMER6 L4LS target port |
| L4LS_TA_DMTIMER7 | TIMER7 L4LS target port |
| L4LS_TA_GPIO1 | GPIO1 L4LS target port |
| L4LS_TA_MCASP2 | MCASP2 L4LS target port |
| L4LS_TA_MMCHS0 | MMCHS0 L4LS target port |
| L4LS_TA_ELM | ELM L4LS target port |
| L4LS_TA_RTC | RTC L4LS target port |
| L4LS_TA_MAILBOX | MAILBOX L4LS target port |
| L4LS_TA_SPINLOCK | SPINLOCK L4LS target port |
| L4LS_TA_HDVPSS | HDVPSS L4LS target port |
| L4LS_TA_HDMIPHY | HDMIPHY L4LS target port |
| L4LS_TA_CONTROL | Control Module L4LS target port |
| L4LS_TA_PRCM | PRCM L4LS target port |
| L4LS_TA_SR0 | Smart Reflex 0 L4LS target port |
| L4LS_TA_SR1 | Smart Reflex 1 L4 LS target port |
| L4LS_TA_OCPWP | OCPWP L4 LS target port |
| L4LS_TA_SR2 | Smart Reflex 2 L4 LS target port |
| L4LS_TA_SR3 | Smart Reflex 3 L4 LS target port |
| L4LS_TA_I2C2 | I2C2 L4 LS target port |
| L4LS_TA_I2C3 | I2C3 L4 LS target port |
| L4LS_TA_SPI1 | SPI1 L4 LS target port |
| L4LS_TA_SPI2 | SPI2 L4 LS target port |
| L4LS_TA_SPI3 | SPI3 L4 LS target port |
| L4LS_TA_UART3 | UART3 L4 LS target port |
| L4LS_TA_UART4 | UART4 L4 LS target port |
| L4LS_TA_UART5 | UART5 L4 LS target port |
| L4LS_TA_GPIO2 | GPIO2 L4 LS target port |
| L4LS_TA_GPIO3 | GPIO3 L4 LS target port |
| L4LS_TA_DMTIMER8 | TIMER8 L4 LS target port |
| L4LS_TA_PLLSS | PLL Subsystem L4 LS target port |
| L4LS_TA_WDT0 | Watchdog timer 0 L4 LS target port |
| L4LS_TA_DCAN0 | DCAN0 L4 LS target port |
| L4LS_TA_DCAN1 | DCAN1 L4 LS target port |
| L4LS_TA_ATL | ATL L4 LS target port |
| L4LS_TA_FDIF | FDIF L4 LS target port |
| L4LS_TA_MMCHS1 | MMCHS1 L4 LS target port |

For the list of initiators authorized to access the L4_LS peripherals, see *Connectivity Matrix*.

**Table 1-295. L4_LS IAs**

| Module Iniator Name | Description |
|---|---|
| L4LS_IA_0 | L3 interconnect port |
| L4LS_IA_1 | L3 interconnect port |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.12.3.3.1.3 L4_FWCFG Interconnect Agents

The L4 FWCFG interconnect handles transfers only to peripherals in the FWCFG. Table 1-296 lists the TAs. Table 1-297 lists the L4FWCFG initiator agents.

**Table 1-296. L4 FWCFG TAs**

| Module Target Name | Description |
|---|---|
| L4FWCFG_TA_EMIF | EMIF firewall |
| L4FWCFG_TA_GPMC | GPMC firewall |
| L4FWCFG_TA_OCMC_RAM | OCMC RAM firewall |
| L4FWCFG_TA_SGX | SGX firewall |
| L4FWCFG_TA_DSP_SDMA | DSP SDMA firewall |
| L4FWCFG_TA_MEDIA_CONTROLLER | Media Controller firewall |
| L4FWCFG_TA_PCIE | PCIe firewall |
| L4FWCFG_TA_SL2 | HDVICP2-0 SL2 firewall |
| L4FWCFG_TA_HDVICP2 | HDVICP2-0 CFG firewall |
| L4FWCFG_TA_VCP2 | VCP2 firewall |
| L4FWCFG_TA_MMCHS2 | MMCHS2 firewall |
| L4FWCFG_TA_ISS | ISS firewall |
| L4FWCFG_TA_MCASP0/1/2 | MCASP0/1/2 firewall |
| L4FWCFG_TA_HDMI | HDMI firewall |
| L4FWCFG_TA_MCBSP | MCBSP firewall |
| L4FWCFG_TA_TPTC0/1 | TPTC0/1 firewall |
| L4FWCFG_TA_TPCC | TPCC firewall |
| L4FWCFG_TA_USB | USB firewall |
| L4FWCFG_TA_EXP_SLOT | Expansion slot firewall |
| L4FWCFG_TA_L3_INSTR | L3 Instrumentation firewall |

**Table 1-297. L4_FWCFG IAs**

| Module Iniator Name | Description |
|---|---|
| L4FWCFG_IA_0 | L3 interconnect port |

#### 1.12.3.3.2 Power Management

Each L4 has a single power management interface connected to a power control bridge. Power control bridge is managing the different internal power interfaces. It has na external slave interface to the PRCM, an internal master interface to L4 power interface and one interface to each power bridge. The power disconnect bridge is responsible for returning OCP responses or asking for target wake up. The bridge is under the control of the PRCM.

As part of the Always On power domain L4 interconnects do not support idle state or retention.

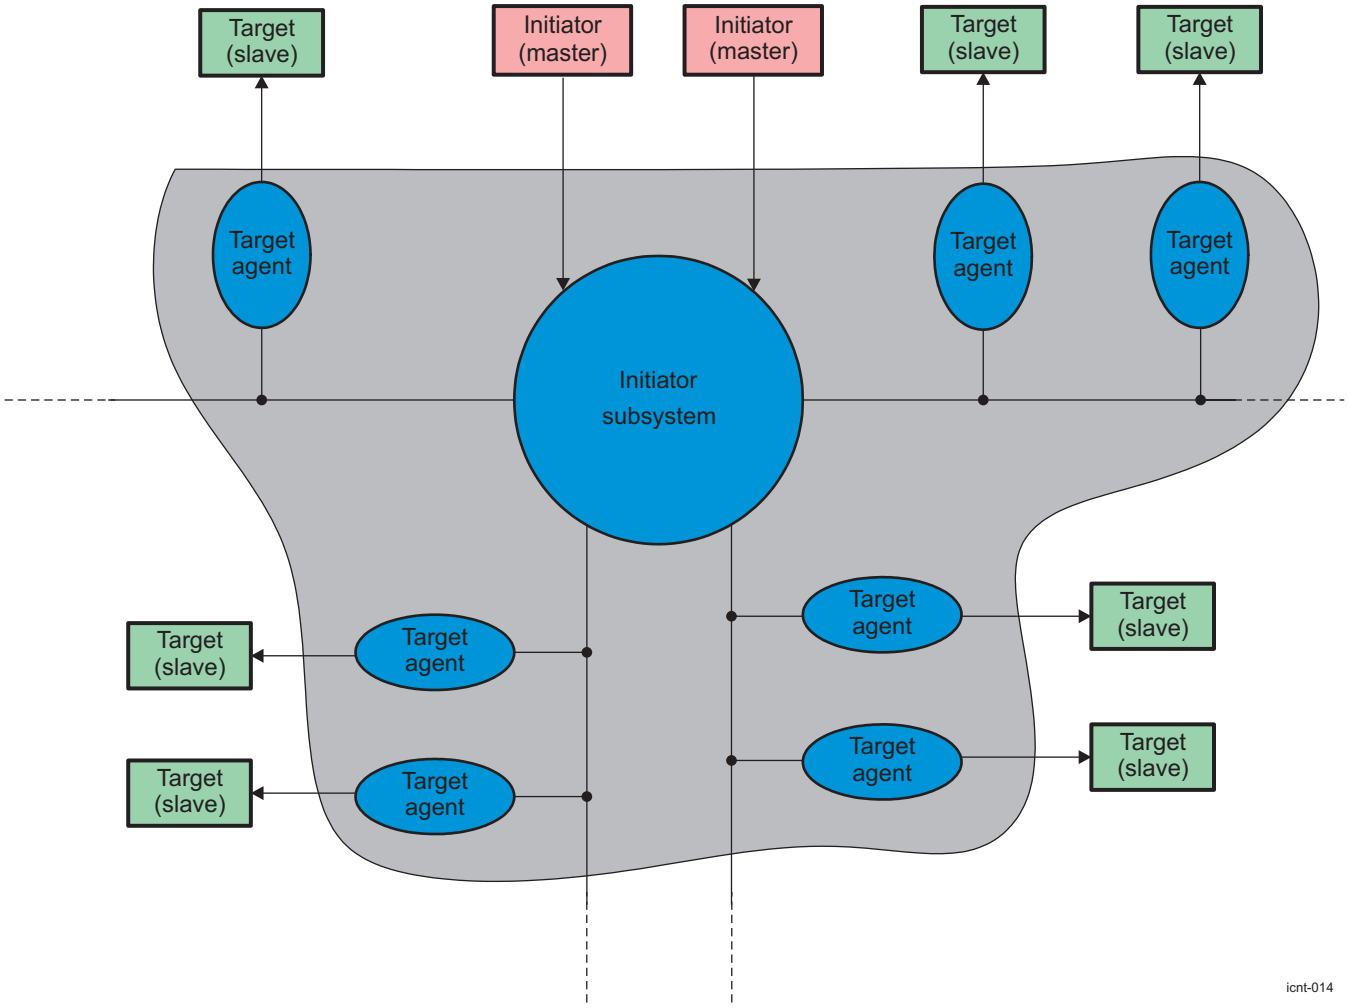
For more information about L4 interconnects power managemnet, clocking and resets see *Chapter: Power Reset and Clock management*.

#### 1.12.3.3.3 L4 Firewalls

Figure 1-111 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-111. L4 Initiator-Target Connectivity**



**NOTE:** As Figure 1-111 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators
  - Eight protection groups for L4_HS and L4_LS interconnect
- Segments divided into regions of 4KB
  - 29 regions for the L4_HS interconnect
  - 128 regions for the L4_LS interconnect
  - 47 regions for the L4_FWCFG interconnect.

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

All L4 interconnect information, such as numbers of protection groups, regions, and segments, is available in the L4_LA_INITIATOR_INFO_L register.

Copyright © 2011–2016, Texas Instruments Incorporated

#### 1.12.3.3.3.1 Protection Group

A protection group is defined by its initiators and REQ_INFO is allowed. Two registers define these two settings:

- The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k_L is a 1-bit vector that defines which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 1-298 lists all the ConnID available at the L4 levels.
- The ENABLE field L4_AP_PROT_GROUP_ROLES_k_L lists all possible REQ_INFO combinations associated with the L4_AP_PROT_GROUP_MEMBERS_k_L register. Setting a Req bit in this register determines the initiators type of access. Two REQ_INFOs are used in L4 interconnects: MReqDebug and MReqSupervisor.

**NOTE:** Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

L indicates the region number.

**Table 1-298. L4 ConnID Definition**

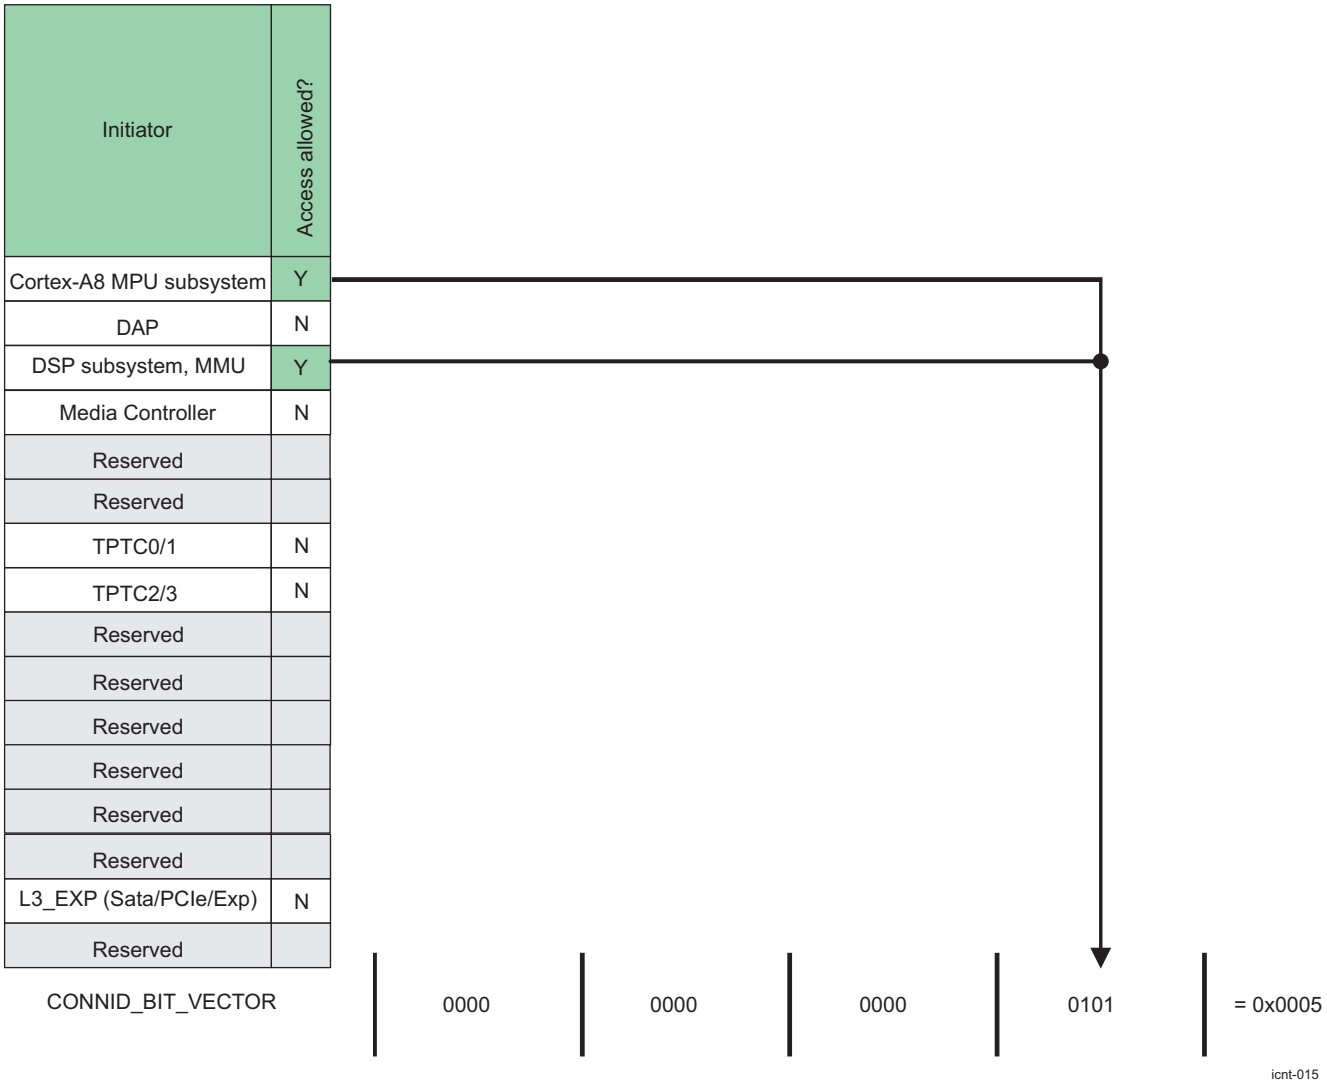
Figure 1-112 is an example of CONNID_BIT_VECTOR.

**Figure 1-112. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k**



Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A8 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_l_H.PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of CONNID_BIT_VECTOR and ENABLE fields are exported by the control module at reset or are user writable (see Figure 1-112 for more information).

Table 1-299 and Table 1-301 list the default configuration of the various groups for each L4 interconnect. For each group, some modules/regions are associated with it with default initiator members.

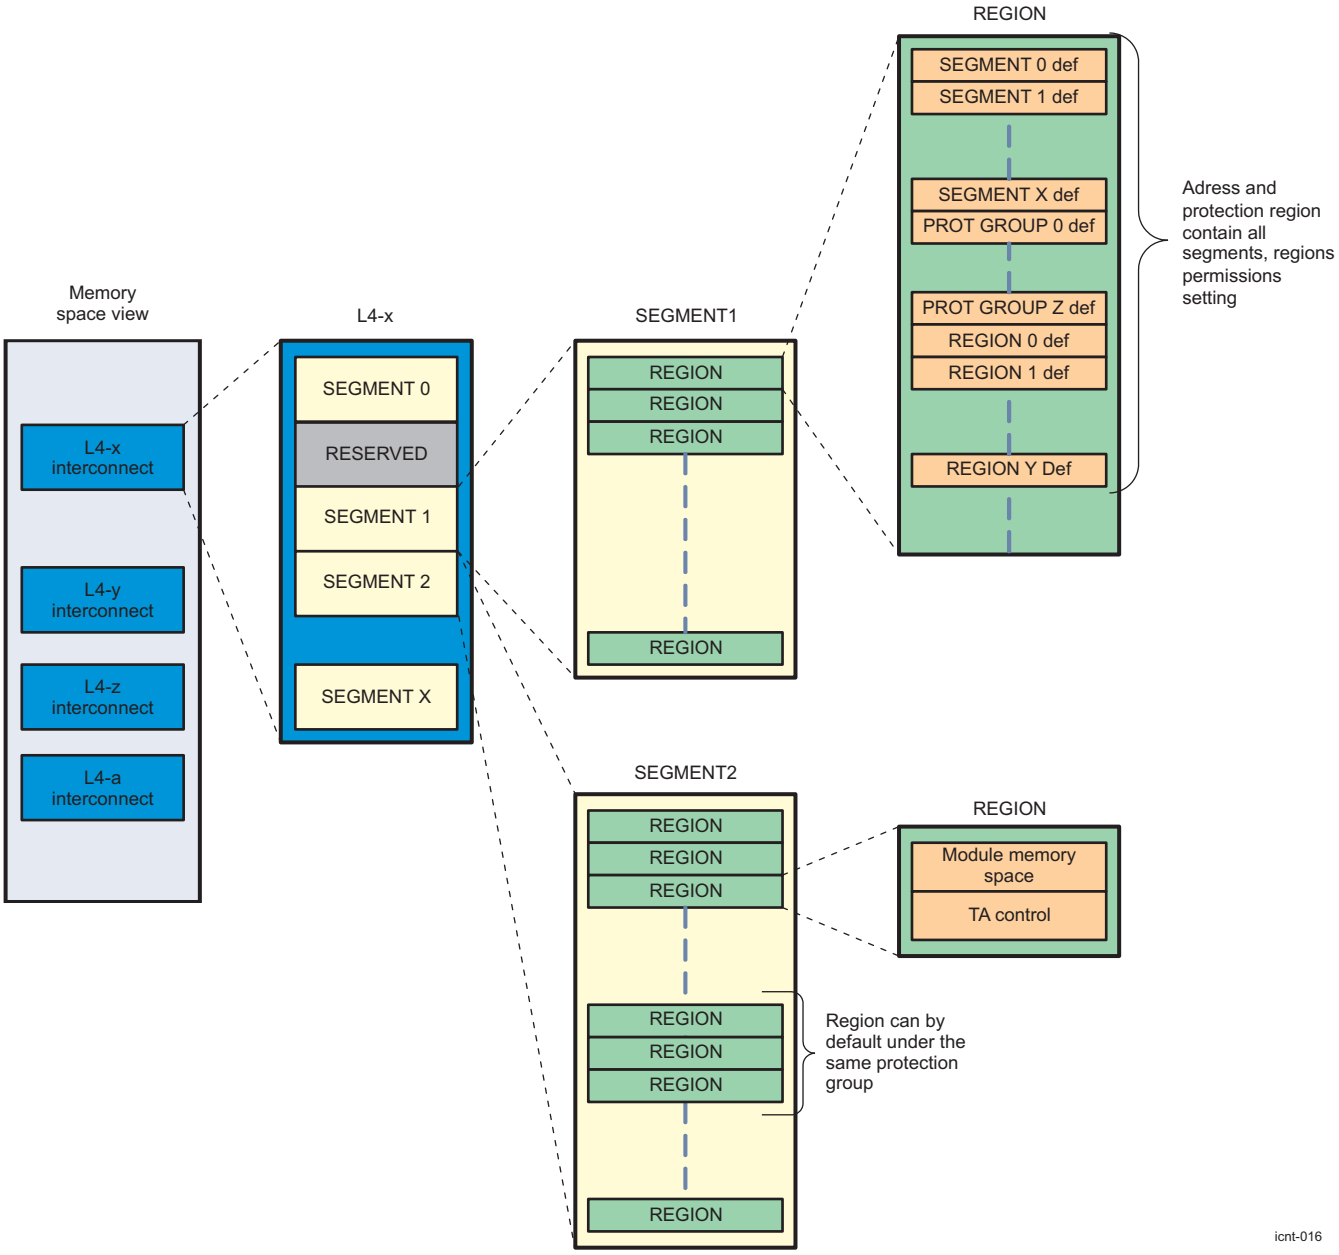
#### *1.12.3.3.3.2 Segments and Regions*

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 1-113. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-113. L4 Segmentation**



All interconnect address spaces are covered by regions. Table 1-302 through Table 1-304 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

**NOTE:** Module refers to the configuration registers of the module.

TA refers to the interconnect configuration registers of the TA associated with the module.

#### 1.12.3.3.3 L4 Address and Protection Register Settings

Table 1-305 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

**Table 1-305. L4 Address and Protection Register Description Overview**

| Register Type | Register Name | Bits | Field | Description |
|---|---|---|---|---|
| Segment | L4_AP_SEGMENT_i_L (1) | 23:0 | BASE | Segment base address |
| | L4_AP_SEGMENT_i_H (1) | 4:0 | SIZE | Segment size equals to $2^{SIZE}$ |
| Protection groups | L4_AP_PROT_GROUP_MEMBERS_k_L (2) | 15:0 | CONNID_BIT_VECTOR | For L4ConnID, see Table 1-298. |
| | L4_AP_PROT_GROUP_ROLES_k_L (2) | 31:0 | ENABLE | See for REQ_INFO description(3) |
| | L4_AP_PROT_GROUP_ROLES_k_H | 31:0 | ENABLE | See for REQ_INFO description(3) |
| Region setting | L4_AP_REGION_l_L (4) | 23:0 | BASE | Defines the base address of region with respect to its segment base address |
| | L4_AP_REGION_l_H (4) | 31:28 | MADDRSPACE | Target OCP MAddrSpace value |
| | | 26:24 | SEGMENT_ID | Segment ID number of the region |
| | | 22:20 | PROT_GROUP_ID | Protection group member attached to the region |
| | | 18:17 | BYTE_DATA_WIDTH_EXP | Determines the number of byte in an access |
| | | 14:8 | PHY_TARGET_ID | Physical target ID |
| | | 6:1 | SIZE | Size of the region equals to $2^{SIZE}$ |
| | | 0 | ENABLE | Enables the region protection |

(1) i = 0 to 1 forHS_AP
i = 0 to 2 for LS_AP
(2) k = 0 to 7 for HS_AP
k = 0 to 7 for LS_AP
(3) For L4 interconnects, only MReqDebug and MReqSupervisor are available.
(4) l = 0 to 28 for HS_AP
l = 0 to 127 for LS_AP

The value of L4_AP_PROT_GROUP_ROLES_k is exported at the chip boundary. Those values are latched in the register at reset or by using the load firewall mechanism, which allows to latch exported values simply by writing into a register of the control module, this avoids resetting the interconnect in this case. The values of the other protection registers can be modified on the fly.

#### 1.12.3.3.4 L4 Error Detection and Reporting

##### 1.12.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** L4_IA denotes the IA for all L4 interconnects: L4_LS, L4_HS and FWCFG.

L4_TA denotes the TA for all L4 interconnects: L4_LS, L4_HS and FWCFG.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 1.12.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 1.12.3.3.4.2, *Time-Out*).

Table 1-306 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

**Table 1-306. L4 CODE Bit Field Definition**

| CODE (bits 1:0) | Error Type | REQ_INFO | Secondary | ConnID | CMD |
|---|---|---|---|---|---|
| 0 | No error | | | | |
| 1 | Unsupported command | x | x | x | x |
| 2 | Address hole | x | x | x | x |
| 3 | Protection violation | x | | x | x |

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type access (REQ_INFO qualifier) that caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ID of the initiator that caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] register logs the address for error conditions.

  A L4_IA_ERROR_LOG_L[31] MULTI bit is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

#### *1.12.3.3.4.2 Time-Out*

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

Copyright © 2011–2016, Texas Instruments Incorporated

The error is logged in the L4_TA_AGENT_STATUS_L[10:8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, the TA must be reset by the system software. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. Selection is done by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 1-307 lists all values in number of L4 clock cycles.

**Table 1-307. L4 Time-Out Link and TA Programming**

| | L4_TA_AGENT_CONTROL_L REQ_TIMEOUT[2:0] | | | | |
|---|---|---|---|---|---|
| **L4_LA_NETWORK_CONTROL_L TIMEOUT_BASE[2:0]** | **0** | **1** | **2** | **3** | **4** |
| 0 | All L4 time-out features are disabled. | | | | |
| 1 | Locally disabled | 64 | 256 | 1024 | 4096 |
| 2 | | 256 | 1024 | 4096 | 16,384 |
| 3 | | 1024 | 4096 | 16,384 | 65,536 |
| 4 | | 4096 | 16,384 | 65,536 | 262,144 |

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of one to three time-base periods.

On detection of a time-out condition, the TA logs the error in L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the corresponding IA, which forward it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

#### *1.12.3.3.4.3 Error Reporting*

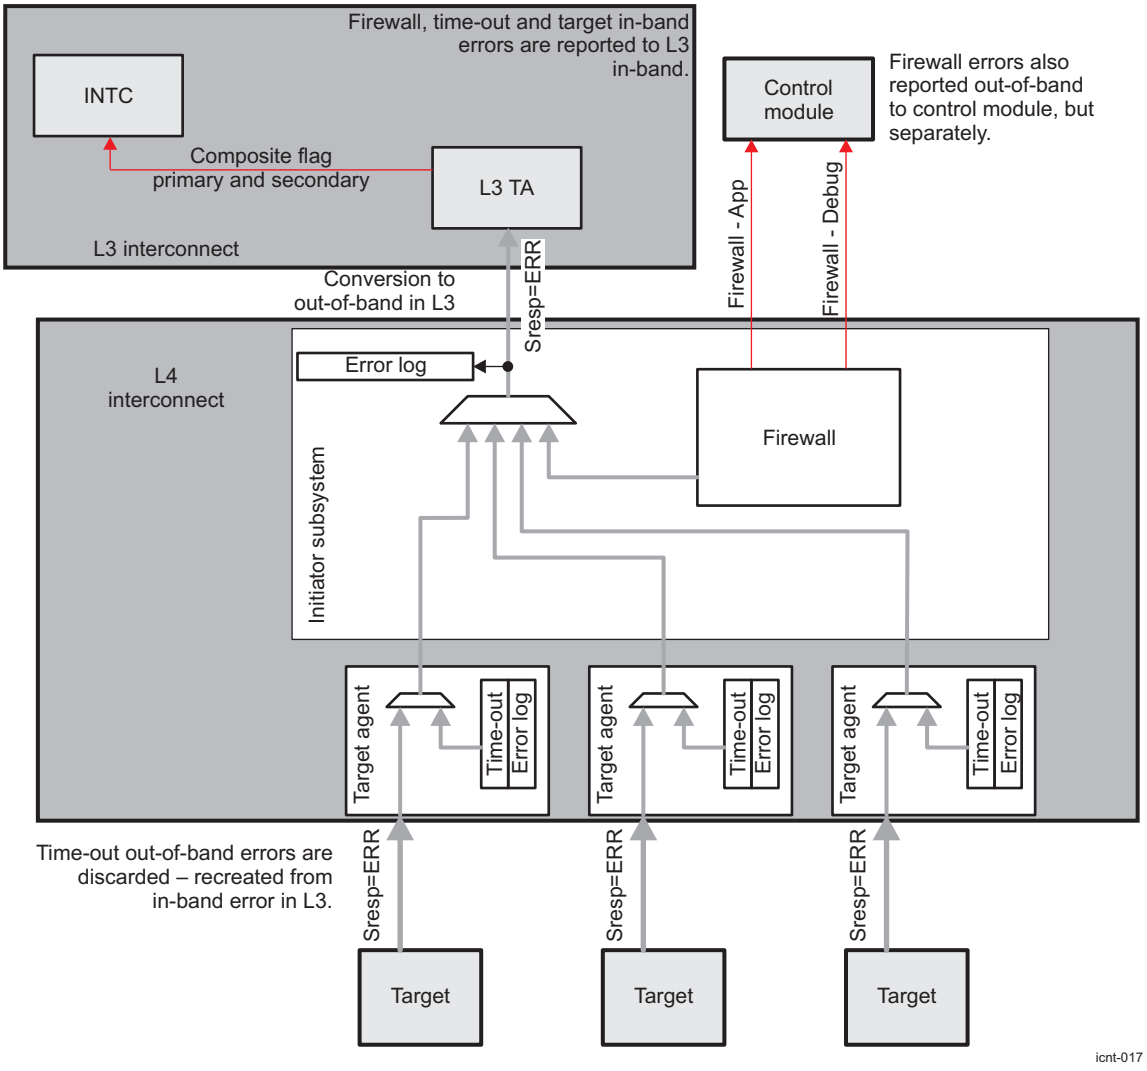
Figure 1-114 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to L3 Interconnect with SRESP = ERR, as well as being stored in the appropriate registers. Any target error response is send back to the initiator via L3 interconnect.

Protection errors are always reported out-of-band to the Control Module. This asynchronous reporting uses separate flags for debug requests and for non-debug reuqests. Out-of-band firewall error reporting can be disabled by software from the L4_IA_AGENT_CONTROL register.

By setting the register L4_LA_FLAG_MASK_i_L registers errors comming form different initiator ports can be masked independently. The default settings of these registers are 0x3 so that all errors can be reported. In case of error, the L4_LA_FLAG_STATUS_i_L registers can be read to determine the error source.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 1-114. L4 Error Reporting**



### *1.12.3.3.4.4 Error Recovery*

Writing 1 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Writing 0 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit terminates the software reset period.

The attached module must then be reset to complete the recovery.

### 1.12.3.4 L4 Interconnect Programming Guide

#### 1.12.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

##### 1.12.3.4.1.1 Global Initialization

###### 1.12.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see Section 1.12.3.2, *L4 Interconnect Integration* .

**Table 1-308. Global Initialization of Surrounding Modules**

| Surrounding Modules | Comments |
|---|---|
| PRCM | For more information about the configuration of the module, see the *PRCM* chapter. |
| Control module | For more information about the configuration of the module, see the *Control Module* chapter. |
| MPU INTC | The MPU INTC must be configured to enable the interrupts from L4 interconnect module. See the *ARM Interrupt Controller (AINTC)* chapter. |
| EDMA | For more information about the configuration of the EDMA, see the *EDMA* chapter. |
| L3 interconnect | For more information about the interconnect configuration, see the *L3 Interconnect* section. |

##### 1.12.3.4.1.2 Operational Modes Configuration

###### 1.12.3.4.1.2.1 L4 Interconnect Error Analysis Mode

###### 1.12.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers.The number of registers to access depends on the error source.

Figure 1-115 and Figure 1-116 show the software sequence required in most cases.

Table 1-309 and Table 1-310 show the main sequence for error analysis mode and its subprocess call summary, respectively.

#### 1.12.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 1-311).

**Table 1-311. Protection Violation Error Identification**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Read multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | |
| Read initiator ID. | L4_IA_ERROR_LOG_L[13:8] CONNID | |
| Read command that cause the error. | L4_IA_ERROR_LOG_L[3:0] CMD | |
| Read address of request that caused the error. | L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR | |
| **IF**: Is it a primary error? | L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY | =0x1 |
| Write 1 to clear IA status bit. | L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY | 0x1 |
| **ELSE** | | |
| Write 1 to clear IA status bit | L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY | 0x1 |
| **ENDIF** | | |
| Write 1 to clear multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | 0x1 |
| Write 1 to clear in-band error status. | L4_IA_AGENT_STATUS_L[27] INBAND_ERROR | 0x1 |

#### 1.12.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see Table 1-312).

**Table 1-312. Unsupported Command/Address Hole Error Identification**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Read multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | |
| Read initiator ID. | L4_IA_ERROR_LOG_L[13:8] CONNID | |
| Read command that caused the error. | L4_IA_ERROR_LOG_L[3:0] CMD | |
| Read address of request that caused the error. | L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR | |
| Read secondary status. | L4_IA_ERROR_LOG_L[30] SECONDARY | |
| Write 1 to clear secondary status. | L4_IA_ERROR_LOG_L[30] SECONDARY | 0x1 |
| Write 1 to clear multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | 0x1 |
| Write 1 to clear inband error status. | L4_IA_AGENT_STATUS_L[27 INBAND_ERROR | 0x1 |

#### 1.12.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see Table 1-313).

**Table 1-313. Reset TA and Module**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Reset TA. | L4_TA_AGENT_CONTROL_L[0] OCP_RESET | 0x1 |
| Wait until target module clock = 16 cycles. | | |
| Write 0 to clear TA time - out status. | L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT | 0x0 |
| Write 0 to clear TA reset. | L4_TA_AGENT_CONTROL_L[0] OCP_RESET | 0x0 |
| Reset the attached module.(1) | | |

(1) For more information, see the respective module chapter.

#### 1.12.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

##### 1.12.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see Table 1-314).

**Table 1-314. Time-Out Configuration**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Disable time-out. | L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE | 0x0 |
| Clear TA time-out error status.(1) | L4_TA_AGENT_STATUS_L[10:8] REQ_TIMEOUT | 0x1 |
| Set time-out at TA level.(1) | L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT | xxx |
| Set time-out base. | L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE | xxx |

(1) Must be done for each TA.

#### 1.12.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

##### 1.12.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see Table 1-315).

**Table 1-315. Firewall Configuration**

| Step | Register/Bit Field/Programming Model | Value |
|---|---|---|
| Define the members of protection group k.(1) | L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR | xxx |
| Define the access type of a protection group k.(1) | L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE | xx |
| Set region affiliation to protection group.(2) | L4_AP_REGION_l_L[22:20] PROT_GROUP_ID | xxx |

(1) Must be done for each protection group.
(2) Must be done for each region.

## Table 1-352. L4_TA_AGENT_CONTROL_L

| | |
|---|---|
| **Address Offset** | 0x0000 0020 |
| **Physical Address** | See Table 1-331 to Table 1-347. |
| **Description** | Enable error reporting |
| **Type** | RW |

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| RESERVED | | | | | | | SERROR_REP | RESERVED | | | | | | | | | | | | | REQ_TIMEOUT | | | RESERVED | | | | | | | OCP_RESET |

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:25 | RESERVED | Read returns 0. | R | 0x00 |
| 24 | SERROR_REP | Enable logging of error | R | 0x0 |
| 23:11 | RESERVED | Read returns 0. | UNDEFINED_TYPE_STRING | |
| 10:8 | REQ_TIMEOUT | Time-out Bound. Values are:<br>0 - No time-out<br>1 - 1x base cycles.<br>2 - 4x base cycles.<br>3 - 16x base cycles.<br>4 - 64x base cycles. | RW | 0x2 |
| 7:1 | RESERVED | Read returns 0. | R | 0x00 |
| 0 | OCP_RESET | The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
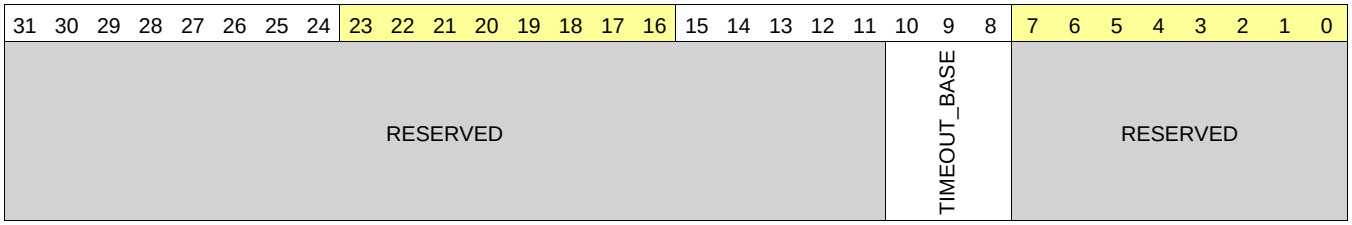
| 5:0 | ADDR_WIDTH | This field specifies the initiator subsystem address width. The ADDR_WIDTH field contains read-only configuration information for the initiator subsystem. | R | 0x18 |

### Table 1-364. L4_LA_NETWORK_CONTROL_L

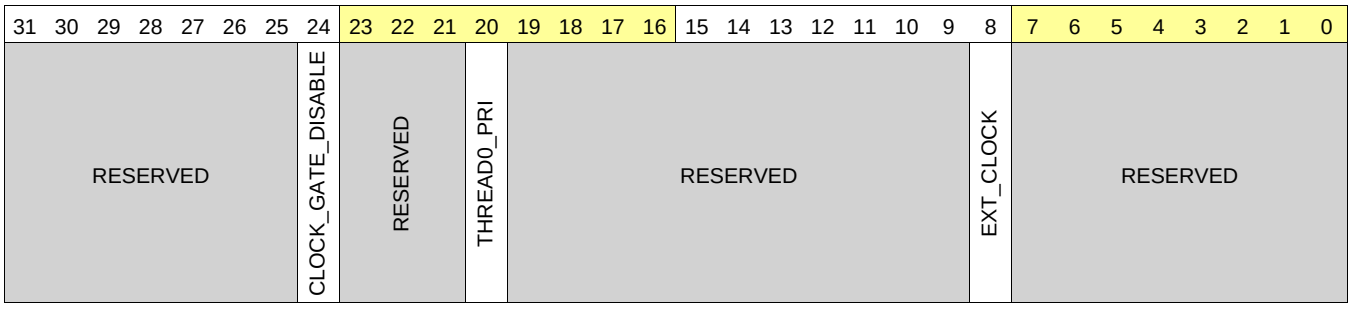
| | |
|---|---|
| **Address Offset** | 0x0000 0020 |
| **Physical Address** | See Table 1-356 |
| **Description** | Control interconnect minimum timeout values. |
| **Type** | RW |



| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:11 | RESERVED | Read returns 0. | R | 0x000000 |
| 10:8 | TIMEOUT_BASE | The TIMEOUT_BASE field indicates the time-out period (that is, base cycles) for the highest frequency time-base signal sent from the L4 initiator subsystem to all target agents that have time-out enabled. Values for the field are:<br>0 - Time-out disabled<br>1 - L4 interconnect clock cycles divided by 64<br>2 - L4 interconnect clock cycles divided by 256<br>3 - L4 interconnect clock cycles divided by 1024<br>4 - L4 interconnect clock cycles divided by 4096 | RW | 0x4 |
| 7:0 | RESERVED | Read returns 0. | R | 0x00 |

### Table 1-365. L4_LA_NETWORK_CONTROL_H

| | |
|---|---|
| **Address Offset** | 0x0000 0024 |
| **Physical Address** | See Table 1-356 |
| **Description** | Control interconnect global power control |
| **Type** | RW |



| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 31:25 | RESERVED | Read returns 0. | R | 0x00 |
| 24 | CLOCK_GATE_DISABLE | When set to 1 this field disables all clock gating. | RW | 0 |
| 23:21 | RESERVED | Read returns 0. | R | 0x0 |

Copyright © 2011–2016, Texas Instruments Incorporated

| Bits | Field Name | Description | Type | Reset |
|---|---|---|---|---|
| 20 | THREAD0_PRI | Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads. | R | 0 |
| 19:9 | RESERVED | Read returns 0. | R | 0x000 |
| 8 | EXT_CLOCK | When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off. | R | 1 |
| 7:0 | RESERVED | Read returns 0. | R | 0x00 |

## 2.1 Introduction

The device power-management architecture ensures maximum performance and operation time for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements. This section contains the following information:

- Power-management architecture building blocks for the device.
- State-of-the-art power-management techniques supported by the power-management architecture of the device.

### *2.1.1 Device Power-Management Architecture Building Blocks*

To provide a versatile architecture supporting multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage management.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

#### 2.1.1.1 Clock Management

The PRCM module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management.

Each module within the device has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks.

The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.
- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is identified by an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity.
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

Figure 2-1 provides a representation of the functional and interface clocks.

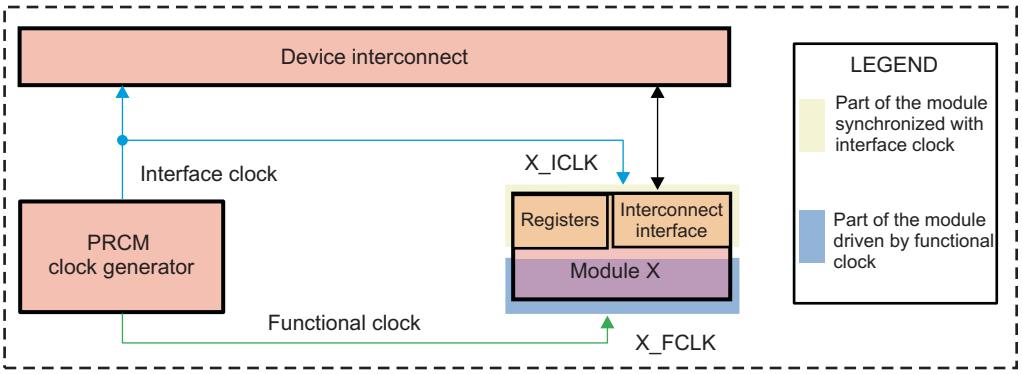
**Figure 2-1. Functional and Interface Clocks**



### 2.1.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or may be gated otherwise. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks. The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module or initiators) or cannot initiate transactions and only responds to the transactions initiated by the master (called slave module or targets). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules

#### 2.1.2.1 Master Standby Protocol

This protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for the purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes. Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the module register bit field <Module>_SYSCONFIG. IDLEMODE or <Module>_SYSCONFIG. STANDBYMODE (see Table 2-1). The behavior, identified by standby mode values, must be configured.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-1. Master Module Standby-Mode Settings**

| Standby Mode Value | Selected Mode | Description |
|---|---|---|
| 0 | Force-standby | The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent the loss of data at the time the clocks are gated. |
| 1h | No-standby | The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it never allows the output clocks of the PRCM module to be gated. |
| 2h | Smart-standby | The module asserts the standby request based on its internal activity status.The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module. |
| 3h | Smart-standby wakeup-capable mode | The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in STANDBY state. The mode is relevant only if the appropriate module mwakeup output is implemented. |

The standby status of a master module is indicated by the CM_<Power_domain>_<Module>_CLKCTRL[x].STBYST bit in the PRCM module. Table 2-2 describes the master module standby status.

**Table 2-2. Master Module Standby Status**

| STBYST Bit Value | Description |
|---|---|
| 0 | The module is functional. |
| 1 | The module is in standby mode. |

### 2.1.2.2 Slave Idle Protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an idle request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module. Similarly, an idled slave module may need to be wakened because of a service request from a master module or as a result of an event (called a wake-up event; for example, interrupt or DMA request) received by the slave module. In this situation the PRCM module enables the clocks to the module and then deasserts the idle request to signal the module to wake up. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the module register bit field <Module>_SYSCONFIG. SIDLEMODE or <Module>_SYSCONFIG. IDLEMODE (see Table 2-3). The behavior, listed in the Idle Mode Value column, must be configured by software.

**Table 2-3. Module Idle Mode Settings**

| Idle Mode Value | Selected Mode | Description |
|---|---|---|
| 0h | Force-idle | The module unconditionally acknowledges the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent the loss of data at the time the clock is switched off. |
| 1h | No-idle | The module never acknowledges any idle request from the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-3. Module Idle Mode Settings (continued)**

| Idle Mode Value | Selected Mode | Description |
|---|---|---|
| 2h | Smart-idle | The module acknowledges the idle request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or direct memory access (DMA) requests are processed. This is the best approach to efficient system power management. |
| 3h | Smart-idle wakeup-capable mode | The module acknowledges the idle request basing its decision on its internal wakeup-capable mode activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module's wakeup output(s) is implemented. |

The idle status of a slave module is indicated by the CM_<Powerdomain>_<Module>_CLKCTRL[x] IDLEST bit field in the PRCM module. Table 2-4 lists the possible idle status for a slave module.

**Table 2-4. Slave Module Idle Status**

| IDLEST Bit | Idle Status | Description |
|---|---|---|
| 0h | Functional | The module is fully functional. The interface and functional clocks are active. |
| 1h | In transition | The module is performing a wake-up or a sleep transition. |
| 2h | Interface idle | The module interface clock is idled. The module may remain functional if using a separate functional clock. |
| 3h | Full idle | The module is fully idle. The interface and functional clocks are gated. |

For the idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM_<Powerdomain>_<Module>_CLKCTRL[x] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the idle request to the module unconditionally (that is, immediately when the software requests). Table 2-5 describes the configurable behavior of MODULEMODE.

**Table 2-5. Slave Module Mode Settings in PRCM**

| MODULE MODE Bit Value | Selected Mode | Description |
|---|---|---|
| 0h | Disabled | The PRCM module unconditionally asserts the module idle request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled). |
| 1h | Reserved | Reserved |
| 2h | Enabled | This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module idle request based on the clock-domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module. |
| 3h | Reserved | Reserved |

In addition to the IDLE and STANDBY protocol, PRCM offers also the possibility to manage optional clocks, through a direct software control: “OPTFCLKEN” bit from programming register.

**Table 2-6. Module Clock Enabling Condition**

| Clock Enabling Condition | Condition: AND | Condition: OR |
|---|---|---|
| Clock associated with STANDBY protocol | Clock domain is ready | MStandby is de-asserted<br>Mwakeup is asserted |
| Clock associated with IDLE protocol, as interface clock | Clock domain is ready | Idle status = FUNCT<br>Idle status = TRANS<br>SWakeup is asserted |
| Clock associated with IDLE protocol, as functional clock | Clock domain is ready | Idle status = FUNCT<br>Idle status = TRANS<br>Idle status = IDLE<br>SWakeup is asserted |
| Optional clock | Clock domain is ready | OPTFCLKEN = Enabled (0x1) |

### 2.1.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module (see Figure 2-2). By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE (GATED) states). Thus, a clock domain allows control of the dynamic power consumption of the device. The device is partitioned into multiple clock domains, and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to individually activate and gate each clock domain of the device.

**Figure 2-2. Generic Clock Domain**

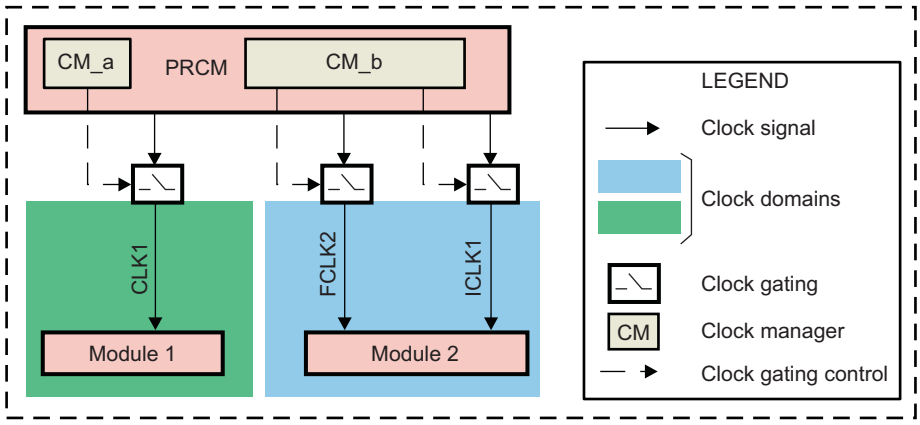

Figure 2-2 is an example of two clock managers: CM_a and CM_b. Each clock manager manages a clock domain. The clock domain of CM_b is composed of two clocks: a functional clock (FCLK2) and an interface clock (ICLK1), while the clock domain of CM_a consists of a clock (CLK1) that is used by the module as a functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use. The PRCM module lets software check the status of the clock domain functional clocks. The CM_<Clock_domain>_CLKSTCTRL[x] CLKACTIVITY_<FCLK/Clock name_FCLK> bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table 2-7 shows the possible states of the functional clock.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-7. Clock Domain Functional Clock States**

| CLKACTIVITY Bit | Status | Description |
|---|---|---|
| 0 | Gated | The functional clock of the clock domain is inactive |
| 1 | Active | The functional clock of the clock domain is running |

### 2.1.3.1 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings. A clock domain can switch between three possible states: ACTIVE, IDLE_TRANSITION, and INACTIVE. Figure 2-3 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

**Figure 2-3. Clock Domain State Transitions**

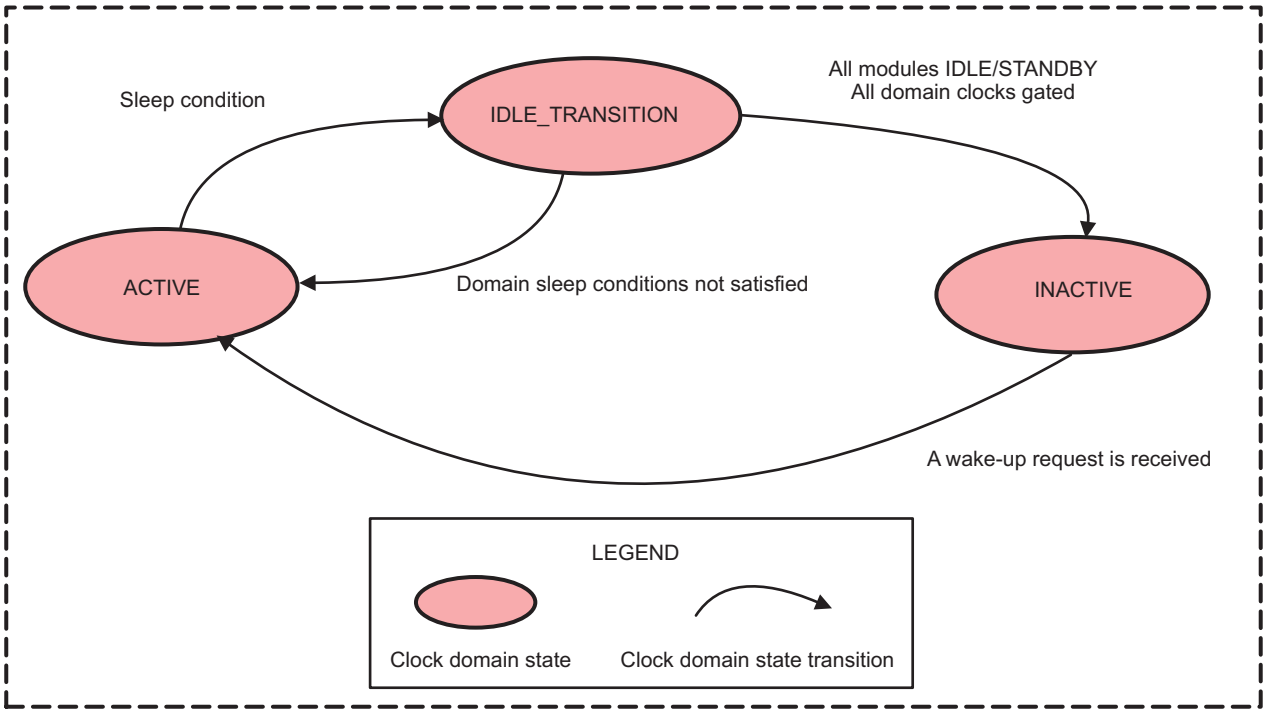

**Table 2-8. Clock Domain States**

| State | Description |
|---|---|
| ACTIVE | Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state. · All interface clocks to the nondisabled slave modules in the clock domain are provided. All functional and interface clocks to the active master modules (that is, not in STANDBY) in the clock domain are provided.· All enabled optional clocks to the modules in the clock domain are provided. |
| IDLE_TRANSITION | This is a transitory state.· Every master module in the clock domain is in STANDBY state · Every idle request to all the slave modules in the clock domain is asserted.· The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active.· All enabled optional clocks to the modules in the clock domain are provided. |
| INACTIVE | All clocks within the clock domain are gated.· Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled or auto) is in IDLE state and set to disabled or auto mode.· Every optional functional clock in the clock domain is gated. |

Copyright © 2011–2016, Texas Instruments Incorporated

Each clock domain transition behavior is managed by an associated register bit field in the CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL PRCM module. Table 2-9 describes the clock transition mode settings in the clock domain.

**Table 2-9. Clock Transition Mode Settings**

| CLKTRCTRL Bit | Selected Mode | Description |
|---|---|---|
| 0 | Reserved | Reserved |
| 1h | SW_SLEEP | A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied |
| 2h | SW_WKUP | A software-forced clock domain wake-up transition is initiated |
| 3h | Reserved | Reserved |

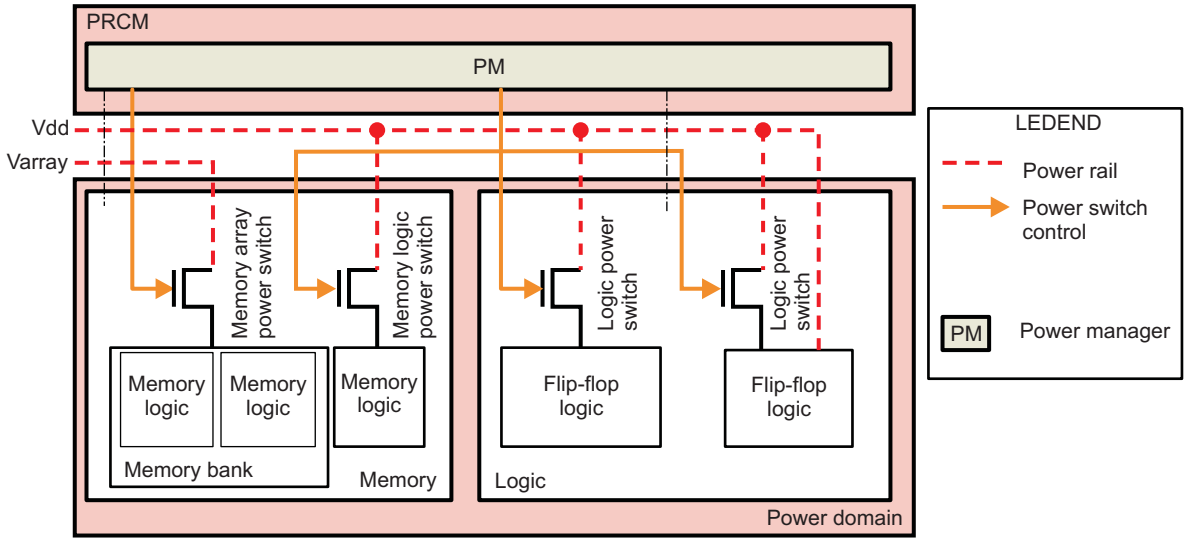
### 2.1.4 Power Management

The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allows the PRCM module to turn on and off specific sections of the device without affecting the others.

#### 2.1.4.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see Figure 2-4). A power domain can be turned on and off without affecting the other parts of the device.

**Figure 2-4. Power Domain Block Diagram**



Copyright © 2011–2016, Texas Instruments Incorporated

To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into a logic area (Table 2-11) and a memory area (Table 2-10).

**Table 2-10. States of a Memory Area in a Power Domain**

| State | Description |
|---|---|
| On | The memory array is powered and fully functional. |
| Off | The memory array is powered down. |

**Table 2-11. States of a Logic Area in a Power Domain**

| State | Description |
|---|---|
| On | Logic is fully powered |
| Off | Logic power switches are off. All the logic (DFF) is lost. |

#### 2.1.4.2 Power Domain Management

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state.

**Table 2-12. Power Domain Control and Status Registers**

| Register/Bit Field | Type | Description |
|---|---|---|
| PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE | Control | Selects the target power state of the power domain. It is OFF or ON. |
| PM_<Power domain>_PWRSTST[1:0] POWERSTATEST | Status | Identifies the current state of the power domain. It is OFF or ON. |
| PM_<Power domain>_PWRSTST[2] LOGICSTATEST | Status | Identifies the current state of the logic area in the power domain. It is OFF or ON. |
| PM_<Power domain>_PWRSTST[5:4] MEMSTATEST | Status | Identifies the current state of the memory area in the power domain. It is OFF or ON. |

#### 2.1.4.3 Power-Management Techniques

The following section describes the state-of-the-art power-management techniques supported by the device.

##### *2.1.4.3.1 Dynamic Voltage and Frequency Scaling*

Dynamic voltage and frequency scaling (DVFS) consists of opportunistically reducing the operating frequency of a logic block so that the operating voltage may be reduced accordingly. Dynamic power is related to the supply voltage so it is generally advantageous to reduce frequency and voltage instead of completing task faster and then going idle. The DVFS technique uses dynamic selection of the optimal operating frequency and voltage to allow a task to be performed in the required length of time. This reduces the active power consumption (power consumed while executing a task) of the device while still meeting task requirements.

**NOTE:** The values in Figure 2-5 are hypothetical. They are ment to clarify the concept only and do not represent valid test results on the device.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 2-5. Comparison of Energy Consumed With/Without DVFS**

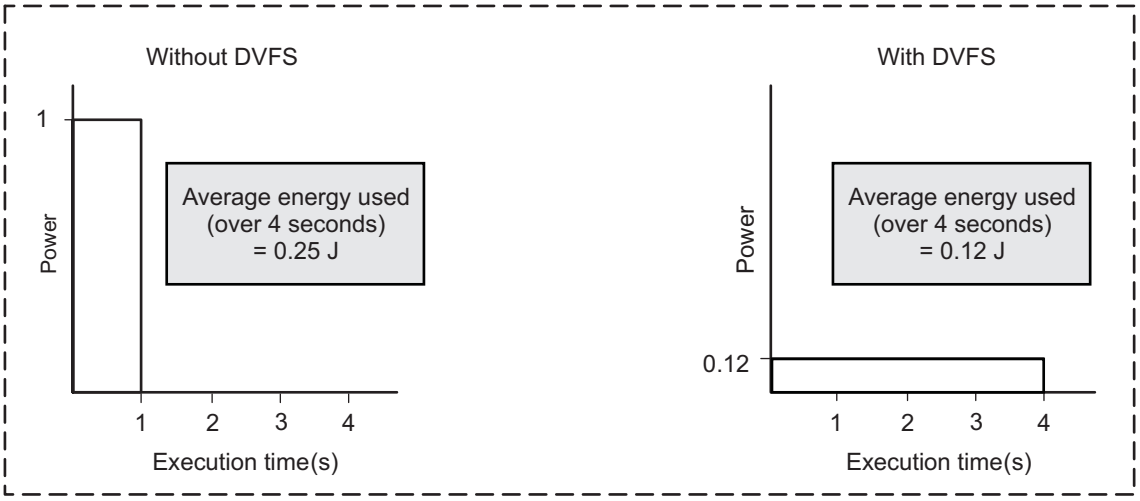


Figure 2-5 shows the DVFS technique by comparing a process executed at maximum frequency and operating voltage without applying DVFS to the same process executed at optimal frequency and voltage using DVFS, based on the task requirements. If a task that must terminate in 4 seconds is performed at maximum operating frequency (left side of the figure), it terminates in 1 second, and the remaining 3 seconds are spent in idle mode. With DVFS (right side of the figure), the operating frequency is reduced to an optimal level; the task takes the full 4 seconds to complete, but power consumption is reduced. In addition, the voltage can be reduced further to save power so the dynamic and leakage power consumption are reduced.

DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching the individual elements of the device to their OPPs, the power consumption of the device for a given task can be minimized.

For practical reasons related to device making (flow, tools), DVFS can be used only for a few discrete steps, not over a continuum of voltage and frequency values. Each step, or OPP, is composed of a voltage (V) and frequency (F) pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally; the voltage corresponds to the minimum voltage allowed for a frequency.

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. The user determines the optimal OPP for a given task and then switches to that OPP to save power.

## 2.2 Power Reset Clock Management Structure

### 2.2.1 Introduction

The PRCM is structured using the architectural concepts presented in the 5000x Power Management Framework. This framework provides:

- A set of modular, reusable FSM blocks to be assembled into the full clock and power management mechanism.
- A register set and associated programming model.
- Functional sub-block definitions for clock management, power management, system clock source generation, and master clock generation.

The device supports an enhanced power management scheme based on:

- Six functional power domains:

Generic power domains:

- Active (DSP)
- AlwaysOn
- ISP (ISS)
- HDVICP
- SGX
- DSS

The PRCM provides the following functional features:

- Software configurable for direct, automatic, or a combination thereof, functional power domain state transition control
- Device power-up sequence control
- Device sleep / wake-up sequence control
- Centralized reset generation and management
- Centralized clock generation and management

The PRCM modules implement these general functional interfaces, further described in Table 2-13:

- OCP configuration ports
- Direct interface to device boundary
- Power switch control signals
- Device control signals
- Clocks control signals
- Resets signals
- A set of power management protocol signals for each module to control and monitor standby, idle and wake-up modes (CM and PRM)
- Emulation signals

**Table 2-13. PRCM Functional Interfaces**

| Interface | Description |
|---|---|
| OCP configuration ports | The OCP port for the PRCM module is used to control power, reset and wake-up Management. |
| OCP slave | PRCM implements a 32-bit OCP target interface. |
| Power switch control signals | The device has power domain switches over the device. This interface provides PRCM control over power domain switches and receives responses from the power domains which indicate the switch status. It also controls the isolation signals. The control for power domain switches is latched in the PRCM Status Registers. |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-13. PRCM Functional Interfaces (continued)**

| Interface | Description |
|---|---|
| Device control signals | This interface provides PRM management of several device-level features which are not specific to any single power domain. This PRCM interface controls signals to/from the device for global control:<br>• Device type coding<br>• I/Os isolation control |
| Clocks control signals | This interface gathers all clock inputs and outputs managed by PRCM modules. |
| Resets signals | This interface gathers all resets inputs and outputs managed by PRCM module. |
| Modules Power Management Control | Modules or subsystems in the device are split over two categories:<br>• **Initiator:** an initiator is a module able to generate traffic on the device interconnects (typically: processors, MMU, eDMA...). The PRCM module handles all initiator modules' power management interfaces: MStandby signal MWait signal.<br>• **Target:** a target is a module that cannot generate traffic on the device interconnects, but that can generate interrupts or DMA request to the system (typically, peripherals). PRCM handles a power management handshake protocol with each module or subsystem. This protocol allows performing proper clock and power transition, taking into account each module activity or state. PRCM module handles all target modules' power management interfaces: SIdleReq signal, SIdleAck signal, FCLKEN signal. It also handles all target modules' wake-up: SWakeup signal (1). |

(1) Only USB and PCIe support SWakeUp.

Copyright © 2011–2016, Texas Instruments Incorporated

## 2.3 Clock Generation and Management

PRCM provides a centralized control for the generation, distribution and gating of most clocks in the device. PRCM gathers externally generated clocks and device internally generated clocks (DPLL clocks) for distribution to the other modules in the device. The PRCM module manages system clock generation.

### 2.3.1 Types of Clocks

The PRCM produces two types of clocks: interface and functional.

**Interface clocks:** these clocks primarily provide clocking for the system interconnect modules and the portions of device's functional modules which interface to the system interconnect modules. In most cases, the interface clock supplies the functional module's system interconnect interface and registers. For some modules, the interface clock is also used as functional clock. In this specification, interface clocks are represented by blue lines.

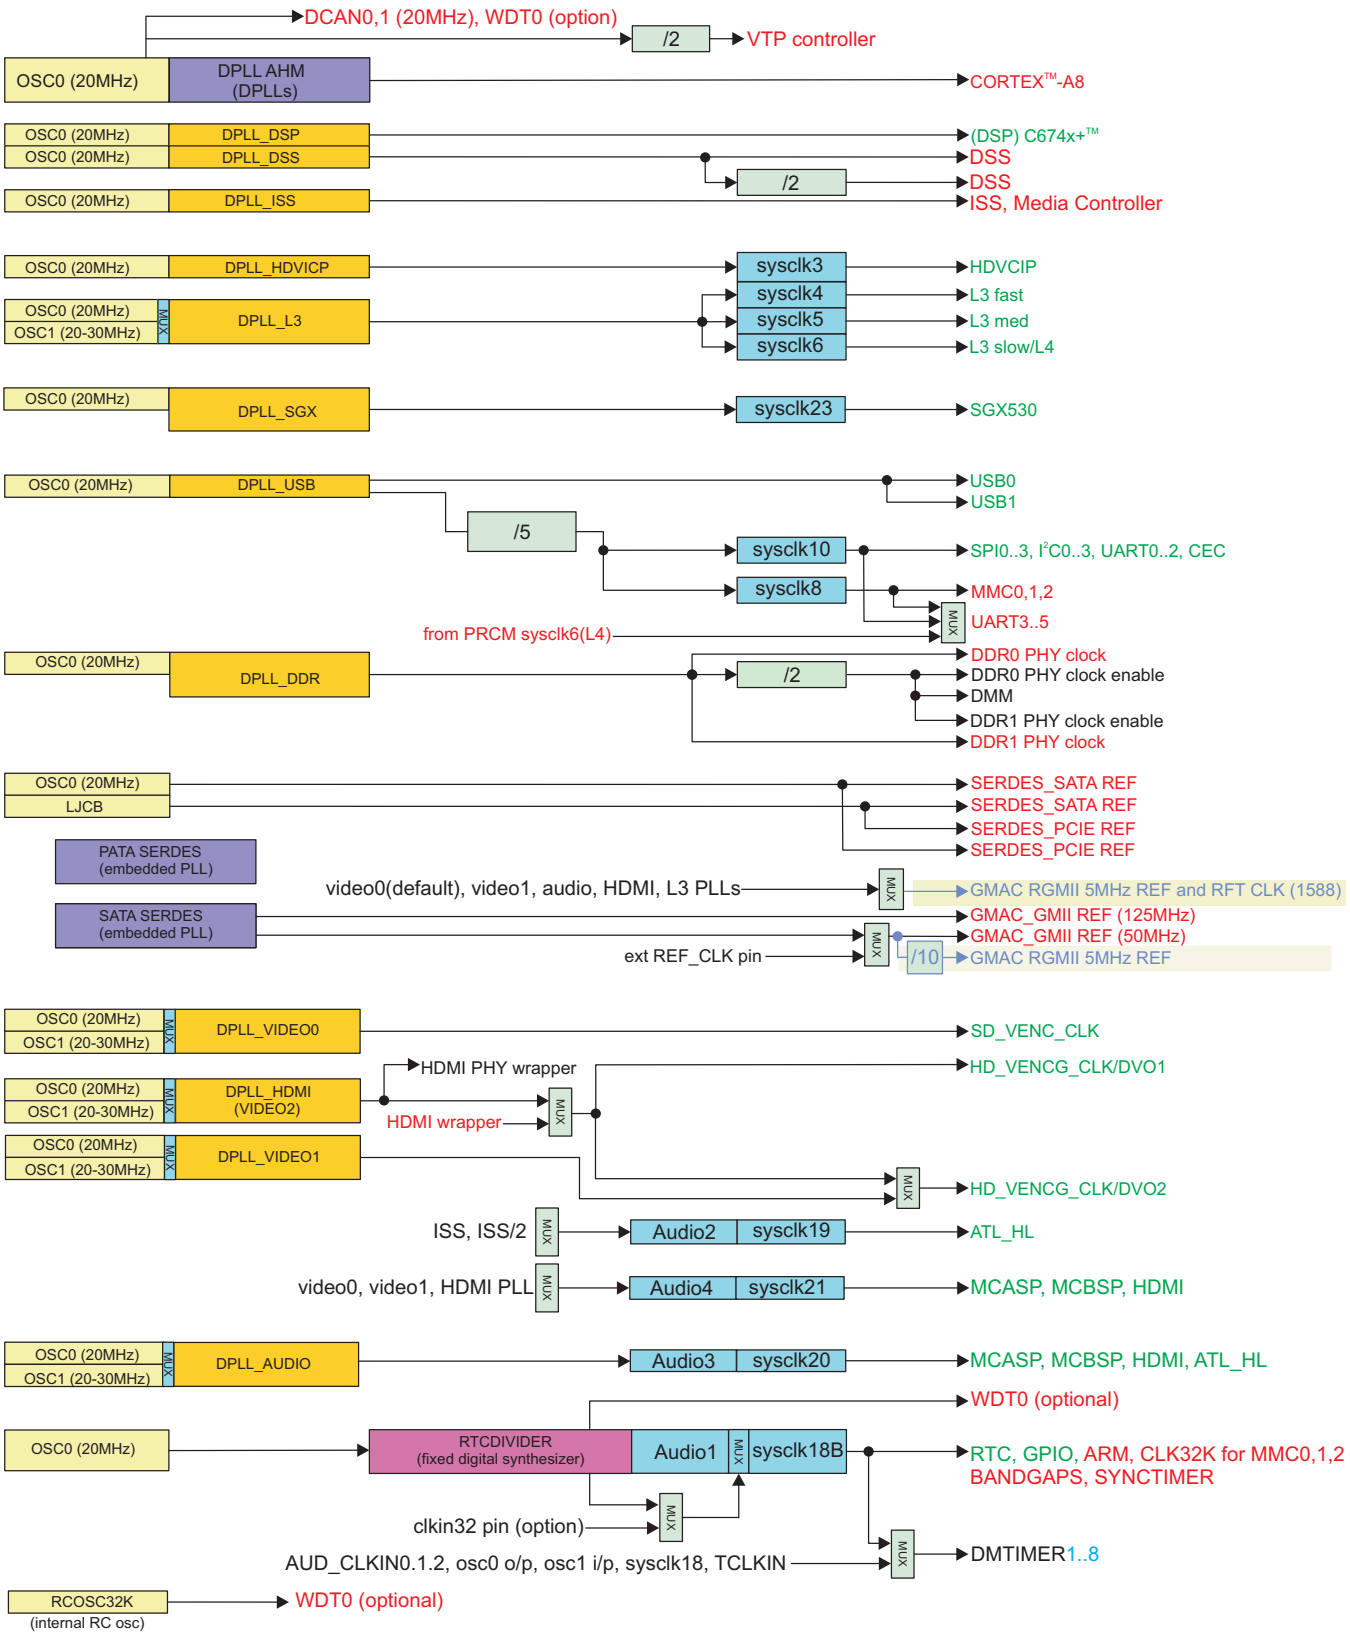
**Functional clock:** this clock supplies the functional part of a module or a sub-system. In some cases, a module or a subsystem may require several functional clocks: 1 or several main functional clock(s), 1 or several optional clock(s). A module needs its main clock(s) to be operational. Optional clocks are used for specific features and can be shutdown without stopping the module.

### 2.3.2 Clock Structure

The device has 12 on-chip PLLs at top level, and three additional inside hard macros (two of them in SERDES, one of them in Cortex™-A8 Subsystem). All of the twelve top level DPLLs are DPLLLJ instances which includes bypass feature inside. The Cortex™-A8 Subsystem is a DPLLS instance. Figure 2-6 shows the detailed clock structure of the device.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 2-6. Clock Structure**



Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-14. PLL Names and Types**

| PLL Name | PLL Type |
|---|---|
| DPLL_MPU(For Cortex™-A8) | DPLLS |
| DPLL_DSP | DPLLLJ |
| DPLL_ISS (DPLL_ISP) | DPLLLJ |
| DPLL_HDVICP | DPLLLJ |
| DPLL_L3 | DPLLLJ |
| DPLL_DDR | DPLLLJ |
| DPLL_USB | DPLLLJ |
| DPLL_SGX530 | DPLLLJ |
| DPLL_AUDIO | DPLLLJ |
| DPLL_HDMI | DPLLLJ |
| DPLL_VIDEO0 | DPLLLJ |
| DPLL_VIDEO1 | DPLLLJ |
| DPLL_DSS | DPLLLJ |
| DPLL_SATA_SERDES | DPLLLJ |
| DPLL_PATA_SERDES | DPLLLJ |

The device has two reference clocks which are generated by on-chip oscillators or externally. The main oscillator on the device is 20 MHz (DEVOSC). Optionally, if DEVOSC is 20 MHz and a precise audio or video frequency is desired, a second oscillator (AUXOSC) may be utilized for video and/or audio PLLs (e.g., 27, 22.5792 MHz or other frequency between 20-30 MHz). For instance, if a precise audio reference clock is needed, AUXOSC would provide this (e.g., 22.5792 for 44.1k audio) and then the video clock must be derived from Video PLL based on a multiply/divide of 20 MHz (pre-divide in PLL allows precise 27 MHz multiples from 20 MHz reference).

It is also possible to have one off-chip VCXO to supply the AUXOSC reference clock and in this case, the on-chip oscillator is bypassed.

In addition to the DEVOSC (20 MHz) and AUXOSC (20-30 MHz) reference clocks, there are an optional external 100 MHz differential clock input for the PCIe SERDES. The SATA SERDES also provides references for EMAC switch IP (125 MHz for GMII, 50 MHz RMII, 5 MHz RGMII).

A separate 250 MHz reference is used for EMAC RGMII mode, this comes from a mux which also feeds the 1588 reference clock. This clock has multiple options (see SERDES and Ethernet clocking diagram), but defaults to VIDEO0 PLL. Therefore to use reset isolation, the user must use VIDEO0 PLL at 250 MHz, which is also a suitable for 1588 reference clock rate.

There is third clock input for the RTC and GPIO0,1,2,3 and MMC0,1,2 debounce. This is an optional 32768 Hz clock input (no on-chip oscillator). Alternatively a fixed divider of the on-chip 20 MHz oscillator (DEVOSC) may be used to generate the 32768 Hz clock (provided by RTCDIVIDER). The 32k clock (regardless of source: pin or RTCDIVIDER source) is also used as optional reference for the eight timers, a reference clock for memory LDOs and bandgaps, and SYNCTIMER. The direct RTCDIVIDER output is also used as optional clock for WDT0 (Cortex™-A8 watchdog and as an optional clock source for ARM functional clock for very low power mode). By the Control Module MMR bits is provided a glitchless clock gating (enable/disable). This allows the clocks to be turn off when the modules are inactive state with a goal to minimize power consumption. During reset however, free running clock should be allowed such that reset can fully propagate.

**NOTE:** The ADPLLS in Cortex™-A8 Subsystem and the two ADPLLJ in SERDES could be controlled by Control Module MMR bits through a wrapper which utilizes the direct mode control ports on the DPLLs.

There are four individual clock mux instances that select between the DEVOSC and AUXOSC in the Main/Video/Audio PLL structures. In addition, the Cortex™-A8 subsystem clock has a mux to select between DEVOSC clock and RTCDIVIDER clock. The mux is controlled by the register MPU_CLKSRC.MPU_SOURCE.

Copyright © 2011–2016, Texas Instruments Incorporated

**CAUTION**

"Glitch-free" muxes have an output which is free from any glitches. It requires the previously selected clock and the newly selected clock to both be free-running for switch-over to occur. Switchover could take 1-2 clock cycles of previously selected and newly selected clock to complete. If newly selected clock is idle, a switchover never occurs (previously selected clock continues to pass through the mux). Do not switch to a non-existent clock.

### 2.3.3 Main PLL Clock Structure

The PLL clock structure includes the DSP, SGX530, HDVICP, L3, ISS, and DSS PLLs. Figure 2-7 shows the clock structure.

**Figure 2-7. Main PLL Clock Structure**

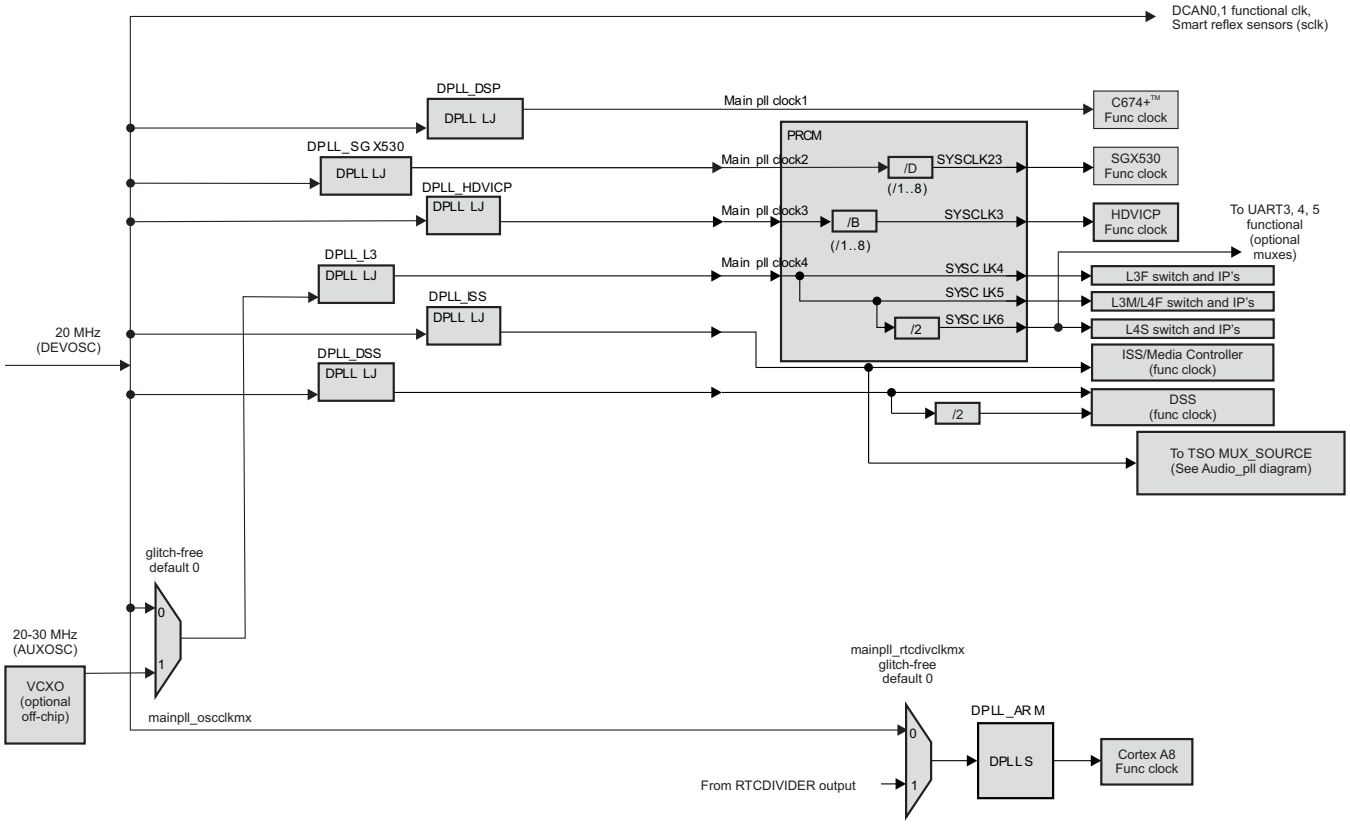


**Table 2-15. Main PLL Clock Source**

| SYSCLK | Source | Destination |
|---|---|---|
| - | DPLL_DSP | To C674x+™SubSystem |
| SYSCLK23 | DPLL_SGX530 | SGX530 functional clock (CORECLK) |
| SYSCLK3 | DPLL_HDVICP | To HDVICP |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-15. Main PLL Clock Source (continued)**

| SYSCLK | Source | Destination |
|---|---|---|
| SYSCLK4 | DPLL_L3 | L3_FAST, OCP clock for Cortex™-A8, HDVICP, expansion slot(master), MMU,C674x+ Subsystem, ISS, TPTCs, C674x+Subsystem, HDVICP SL2, TPCC |
| | | L3_MID, L4_FAST, OCP clock for SGX530 (SYSCLK and MEMCLK), ISS Media Controller, 3PGSW, SATA, PCI ex, VCP2, MLB, FDIF, DAP, OCMC RAM, MMCHS2. |
| SYSCLK6 | | L3_SLOW, L4_SLOW, OCP clock for UART0..2,3..5, I2C, SPI, SDIO, TIMER, GPIO, PRCM, McASP, McBSP, GPMC, HDMI, MLB, WDT0, PATA, Mailbox, Spinlock, , USB SS. |
| | | Func clock for UART3,4,5 (optional), Efuse control, MMU config, P1500, ELM, MMCHS0..1, ATL, FDIF config. |
| | DPLL_ISS (DPLL_ISP) | ISS/Media Controller |
| | DPLL_DSS | DSS (proc, l3) also div2 of this clock (top level divider) goes to DSS proc_d2 and l4 clocks. |

As shown in Table 2-15, each of the DPLLLJs can be configured as appropriate for the desired functional clock of each major core (C674x+ subsystem, HDVICP, ISS, SGX530, DSS, L3/4, A8). They are entirely independent from one another other than the shared reference clock (DEVOSC) except for the DPLL_L3, can optionally choose to use AUXOSC. This is useful as some IPs may use their L4 clock to derive other key frequencies so a slight change to L3/L4 speed could help achieve this while still being in reasonable range for L3/L4 functionality.

The DCAN0..1 functional clocks come from the 20 MHz oscillator to allow fixed rate for baud rate generation and minimal jitter (DEVOSC clock versus PLL clock). Also, the Smart Reflex sensor clock comes from fixed DEVOSC oscillator (20MHz) and the VTP controller clock comes from DEVOSC/2 (fixed /2 divider at top level) such that the frequency of these is the same across all operating points (OPPs).

Table 2-16 lists the divide ratios supported for each of the divider in Main PLL.

**Table 2-16. : Main PLL Supported Configurable Dividers**

| PLL Source | Destination | Control Bit Filed | Divider | Supported Divide Ratios | Default Value |
|---|---|---|---|---|---|
| DPLL_HDVICP | HDVICP Clocks | CM_SYSCLK3_CLKSEL.[CLKSEL] | B | 1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8 | 1/1 |
| DPLL_SGX530 | SGX530 Clocks | CM_SYSCLK23_CLKSEL.[CLKSEL] | D | 1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8 | 1/3 |

**Table 2-17. Clock Multiplexing Used With Main PLLs**

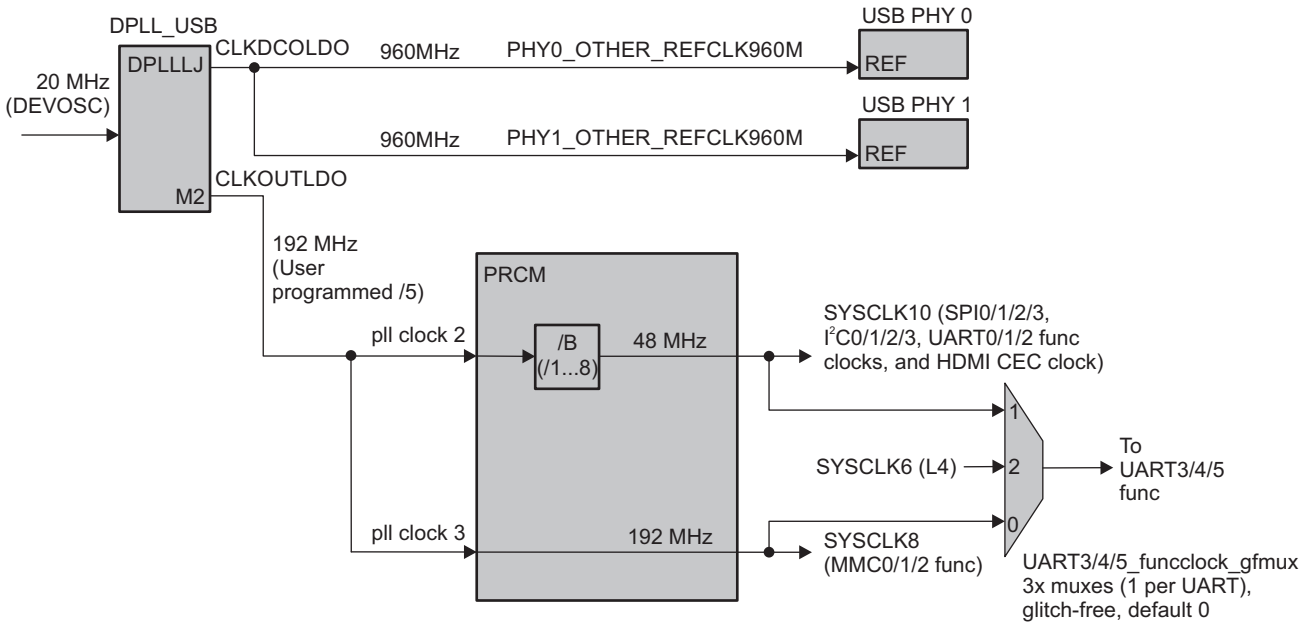
| Mux | Mux Source 0 | Mux Source 1 | Control Bit Field |
|---|---|---|---|
| DPLL_L3 Input Clock Mux | DEVOSC | AUXOSC | OSC_SRC. L3_PLL_SOURCE (control module register) |
| DPLL_MPU Clock Source | DEVOSC | RTC_DIVIDER_OUTPUT | MPU_CLKSRC. MPU_SOURCE |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.3.4 USB PLL Clock Structure

Figure 2-8 shows the clock structure of the USB PHY. The PRCM gets the inputs from the divide by 5 output of the DPLL for clocking the UART, McBSP. These are driven by the DPLL_USB (DPLLLJ), SYSCLK10 which is 48 MHz and goes to SPI0,1,2,3, I2C0,1,2,3, UART0,1,2, UART3,4,5 (optional via glitchless muxes), and the CEC clock of HDMI wrapper. SYSCLK8 is used to generate 192 MHz to UART3,4,5 (optional via glitchless muxes) and MMC0,1,2. Optionally, the PRCM SYSCLK6 (L4 clock) clock output could optionally source each of UART3,4 or 5 functional clocks (this provides additional baud rate options for UART3,4,5, without affecting MMC0,1,2). This mux is controlled by McBSP_UART_CLKSRC register in the PRCM.

**Figure 2-8. USB PLL Clock Structure**



**NOTE:** The /5 divider (M2 post divider) is embedded inside the DPLL_USB module (see Figure 2-19 for details). The /5 divider can be configured in the USBPLL_M2NDIV[22:16] M2 bit field. It is stated as a /5 divider, as the reset (default) value of the M2 bit field is 0x5.

Table 2-18 shows supported divide ratios for dividers in PRCM.

**Table 2-18. USB PLL Supported Dividers**

| PLL Source | Destination | Control Bit Filed | Divider | Supported Divide Ratios | Default Value |
|---|---|---|---|---|---|
| PLL_USB | SPI0..3,I2C0..3, UART0..2, HDMI CEC | CM_SYSCLK10_CLKSEL.[CLKSEL] | B | 1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8 | 1/1 |

**Table 2-19. Clock Multiplexing used with USB PLL**

| Mux | Mux Source 0 | Mux Source 1 | Mux Source 2 | Control Bit Field |
|---|---|---|---|---|
| UART3 clock source | SYSCLK8 | SYSCLK10 | SYSCLK6 | MCBSP_UART_CLKSRC.UART3_CLK_SOURCE |
| UART4 clock source | SYSCLK8 | SYSCLK10 | SYSCLK6 | MCBSP_UART_CLKSRC.UART4_CLK_SOURCE |
| UART5 clock source | SYSCLK8 | SYSCLK10 | SYSCLK6 | MCBSP_UART_CLKSRC.UART5_CLK_SOURCE |

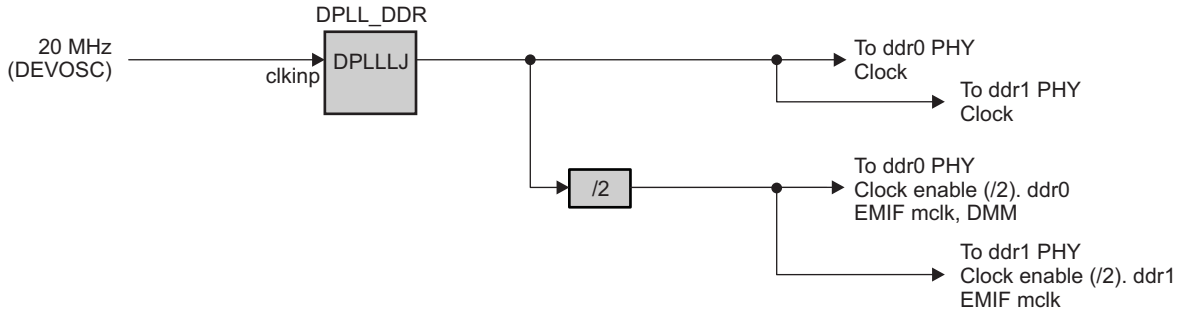
### 2.3.5 DDR PLL Clock Structure

Figure 2-9 shows the DDR PLL. The two DDR PHY interfaces (DDR0 or DDR1) share a single PLL. DMM is synchronous to the DDR EMIF controller.

**Figure 2-9. : DDR PLL Clock Structure**



**NOTE:** Each EMIF must be configured to the same rate due to the shared PLL (If different memory configurations are used even with same rates, there could be some performance impact through DMM for asymmetrical configurations when interleaving).

PRCM does not provide a clock signal to DDR_PHY.

### 2.3.6 SERDES and Ethernet Clock Structure

Figure 2-10 shows the SERDES and Ethernet clocking. The SATA SERDES reference input is driven from the 20 MHz on-chip oscillator. The SATA SERDES also provides reference clocks to the Ethernet GMII (125 MHz) and RMII (50 MHz) and RGMII 5 MHz clock. Ethernet clocking provides several options to receive or output the RMII reference clock from a pin. This mux is controlled by the bit RMII_REFCLK_SRC. REFCLK_SOURCE in the PRCM. Also, several clock sources are required for the 1588 reference clock (cpts_rft_clk), also shown in Figure 2-10.

This 1588 reference clock also feeds the RGMII 250 MHz reference clock in case of RGMII. To use reset isolation, the VIDEO0 PLL option must be used for this clock since the clock mux control is not reset-isolated and VIDEO0 is the default clock. Note that 250 MHz is also a suitable frequency for 1588 reference. Also note that the use of this clock also means that VIDEO0 cannot be set to 54 MHz to support AVDAC use, which is a use case limitation. To use AVDAC, lose the reset isolation feature and select another clock.

The PCIe SERDES always requires its reference clock to be sourced from an external 100 MHz reference from the LJCB input pads.

The SATA SERDES could optionally use the external 100 MHz reference as well (same LJCB inputs as used for PCIe). This may be practical if spread spectrum clocking (SSC) is desired to reduce EMI on the SATA interface and especially if such clock is already present due to PCIe usage. If the clock is not present, then using the DEVOSC 20 MHz as reference for SATA SERDES is another solution.

**NOTE:** The PLL inside of SATA SERDES is isolated from the rest of the SERDES naturally by design. The PLL may remain active while the rest of the SERDES is put in low power mode (feature of SERDES). The control to the PLL within SERDES is located at top level in the control module to allow the ability to keep PLL in its active/configured state for reset-isolation of Ethernet.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 2-10. SERDES and Ethernet Clock Structure**

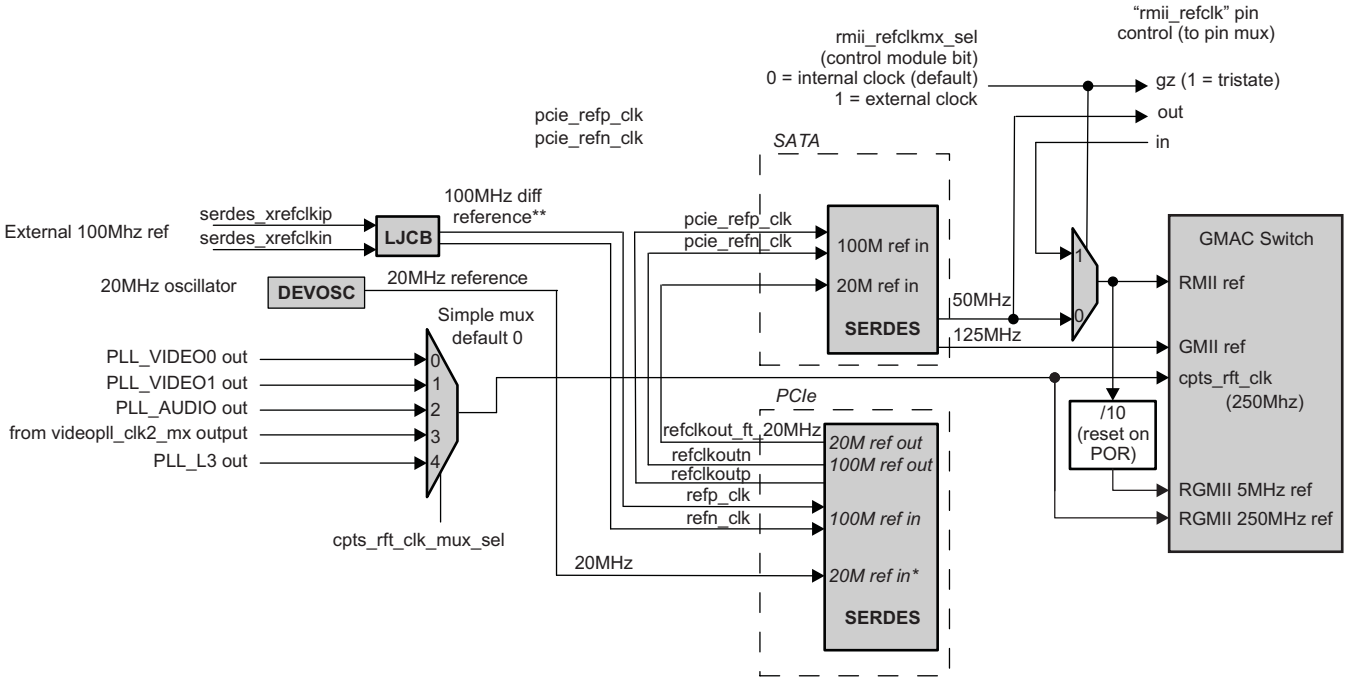


**Table 2-20. Clock Multiplexing Used With SERDES PLL**

| Mux | Mux Source 0 | Mux Source 1 | Mux Source 2 | Mux Source 3 | Mux Source 4 | Bit Field |
|---|---|---|---|---|---|---|
| Cpts_RFT_CLK source Mux | VIDEO0_PLL_ OUT | VIDEO1_PLL_ OUT | AUDIO_PLL_ OUT | VIDEO_PLL_ CLK2 | L3_PLL_ OUT | RMII_REFCLK_ SRC.CPTS_RFT _CLK |
| RMII Ref Clk Mux | 50 MHz SATA SerDes | REFCLK_PIN | | | | RMII_REFCLK_ SRC.REFCLK_ SOURCE |

### 2.3.7 Video PLL Clock Structure

As shown in Figure 2-11, there are three DPLLLJs for video. Each of the video DPLLs (DPLL_VIDEO0, DPLL_VIDEO1, DPLL_HDMI), can be optionally supply from DEVOSC (20 MHz) or AUXOSC (20-30 MHz osc). Deriving 54/27 MHz clocks from 20 MHz DPLL reference is useful in case it is desired to use AUXOSC instead for an precise audio frequency crystal (e.g., 22.5792). Because the device uses DPLLLJ, this is easy to achieve, as the user may pre-divide (e.g,. to 1 or 2 MHz) and then multiply up to 27 or 54MHz.

PLL_VIDEO0 supplies the SD VENC clock to display subsystem directly. This clock is always 54 MHz. DPLL_HDMI provides clock to HD_VENC_D_CLK either directly or via HDMI wrapper logic. This clock is used by the display subsystem to derive DVO1 clock (vout1). HD_VENC_D_CLK needs to support 13.5 MHz, 27 MHz, 54 MHz, 74.25 MHz, 148.5 MHz, 162 MHz and 165 MHz frequencies. It supports 1000/1001 times all of these frequencies (e.g., via fractional multiply adjustment). DPLL_VIDEO1 supplies clock to HD_VENC_G_CLK of display subsystem which is used to derive the DVO2 clock (vout0). This clock has similar frequency requirements as HD_VENC_D_CLK.

Optionally the HD_VENC_G_CLK could also be supplied from DPLL_HDMI. HD_VENC_G (DVO2) has similar frequency requirements, and supports independent frequency from HDMI/DVO1. This addresses the requirements for two digital displays on DVO2 and DVO1 with different resolutions and or timings.

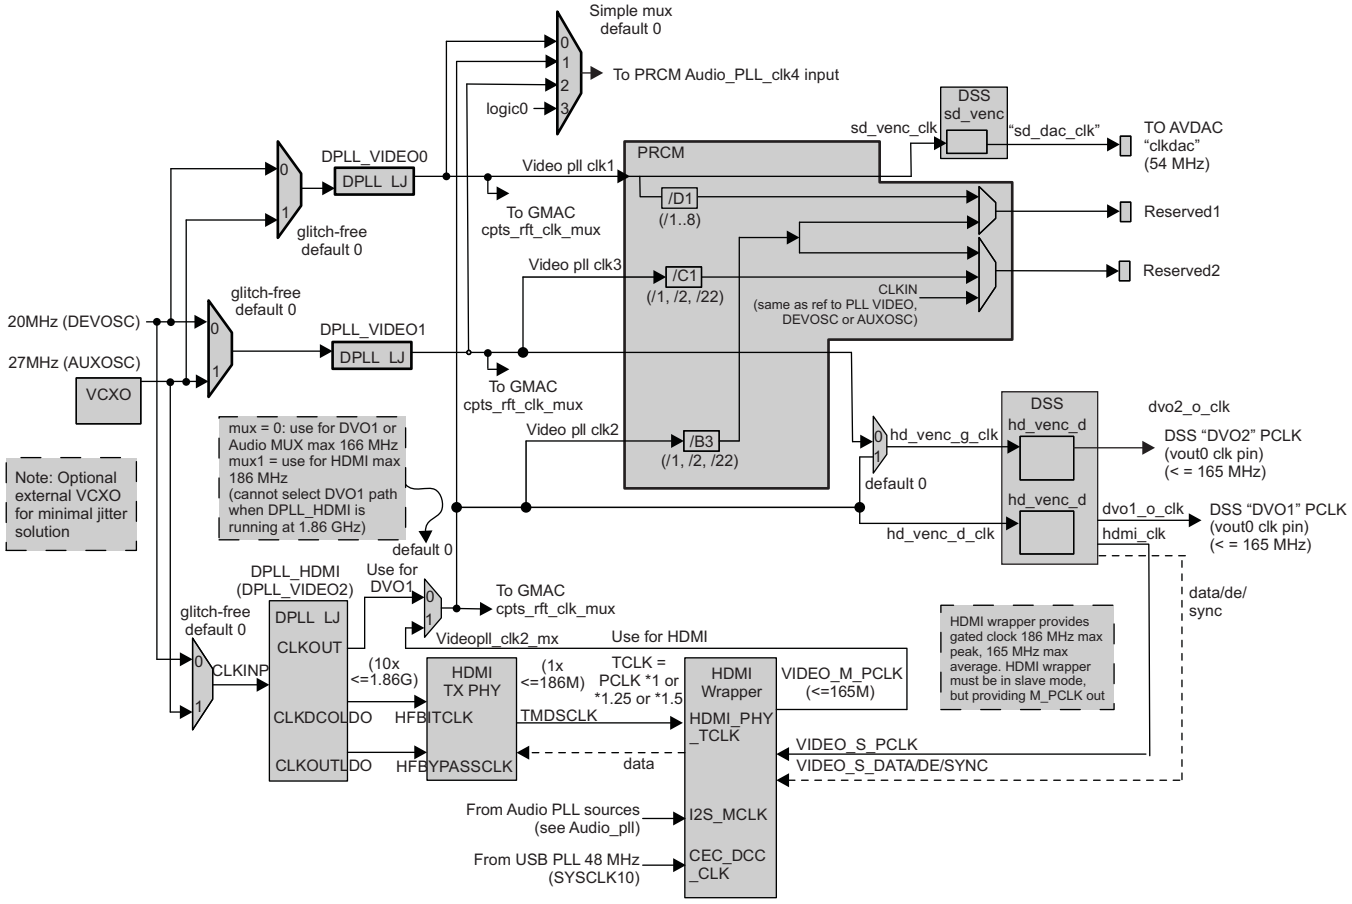
**Figure 2-11. Video Clock Structure**



The device has options for DCXO/VCXO type feature to adjust video frequency on the fly: Use an off-chip VCXO on AUXOSC (can feed clock to AUXOSC_XI pad and run AUXOSC in bypass). This provides the most smooth, low jitter solution.

In each case, software controls the frequency adjustment (via manipulation of off-chip VCXO or other means). There is a 27 or 54 MHz clock generated from each of these PLLs (via PRCM) which is routed back to the STC to generate the error with respect to the clock embedded in the in-coming transport stream.

The HDMI PHY requires a high speed clock (up to 1.85 GHz) from a dedicated DPLLLJ. From this clock a TMDS clock is derived which is 1/10 the high speed clock and which is driven to the HDMI wrapper. The clock to DSS used to generate PCLK is equal to TMDS clock /1, /1.25 or /1.5 depending on deep color mode. The HDMI wrapper provides a shaped clock for this purpose. This clock is muxed into the DSS clock inputs.

**NOTE:** If any of the three video DPLLs are not needed for video, any of these can be optionally used to generate a second audio master frequency, as the sources are muxed and routed to the Audio pll clk4 input of the PRCM and to ATL and McASP 3,4,5 references (see Figure 2-12).

### 2.3.8 Audio PLL Clock Structure

Audio clocking is based on a single dedicated Audio PLL which is a DPLLLJ. It provides several options for other sources of audio clocks including directly using AUXOSC input pad (drive clock onto AUXOSC XI pad and use AUXOSC in bypass), external pins (AUD_CLKIN0,1,2) and optionally using any of the video PLLs (PLL_VIDEO0, PLLVIDEO1, PLL_HDMI, and more, if any of these resources are not used for video).

| 176.4 | 22.5792 | 45.1584 | 67.7376 | 90.3168 | 135.4752 | 180.6336 |
| 192 | 24.5760 | 49.1520 | 73.7280 | 98.3040 | 147.4560 | 196.6080 |

Refer back to Figure 2-12 to see the connection of audio clocks to McASP0,1,2, McBSP and HDMI modules. In addition to the mux options provided inside PRCM, top-level muxes provide for McASP3,4,5 and ATL to share any of the audio clock sources as well as to add path from any of the sources to McASP0,1,2, McBSP or HDMI. Notice also that the McASP peripherals also have a setup of clock muxes to feed various clocks to their AHCLKX and AHCLKR inputs. Since there are six McASPs, rather than pin mux all 12 possible AHCLKX and AHXLKR pins, there are three loosely dedicated pins referred to as

Copyright © 2011–2016, Texas Instruments Incorporated

AUD_CLKIN0,1,2 which are used as optional sources for all of the McASP AHCLK ports as well as for various other timing functions (e.g., dmtimer, STC, etc). Any function which optionally uses an AUD_CLKIN0,1,2 pin as an input timing reference should use the signal coming off the input pad itself (and not through pin muxing logic). This is because some timing sources are also optionally routed as an output to these pins (e.g., ATL clock out and McASP AHCLKX outputs), in which case another peripheral could use that same pin as an input timing reference.

**NOTE:** Similar to the video case, there are several options for implementing adjustments to audio clocks. The smoothest is external VCXO (e.g., on AUXOSC For McASPs one can also use the ATL clock outputs as reference which is adjusted via ATL register writes.

**Table 2-24. Audio PLL Supported Dividers**

| Control Bit Filed | Divider | Supported Divide Ratios | Default Value |
|---|---|---|---|
| CM_APA_CLKSEL[CLKSEL] | A | 1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8 | 1/1 |

A fixed 32,768 Hz clock frequency is provided on PRCM SYSCLK18. This clock has two sources. The Audio PLL Clock1 which is fed from a fixed divider (RTCDIVIDER) on the 20 MHz clock, and the “clkin32” input pin. SYSCLK18 provides clock for: RTC, DMTIMER1..8 (optional via mux), BANDGAPS, synctimer and debounce circuit for MMC0,1,2 and GPIO0,1,2,3.

### 2.3.9 Timer Clock Structure

The output of RTCDIVIDER is also taken directly to optionally feed the WDT0 watchdog (Cortex™-A8 watchdog). The external 32KHz clock is not an option for WDT0. The other option for WDT0 is internal RCOSC32 oscillator. RTCDIVIDER output may also be optionally used as Cortex™-A8 Subsystem functional clock (via mux) for very low power operation (e.g., waiting in loop to bring clocks/system back up to full rate).

The following figures show the optional functional/reference clocks for DMTIMER1..8 and the functional/reference clocks for the watchdog timer (WDT0) and the Synctimer (which is available for generic use).

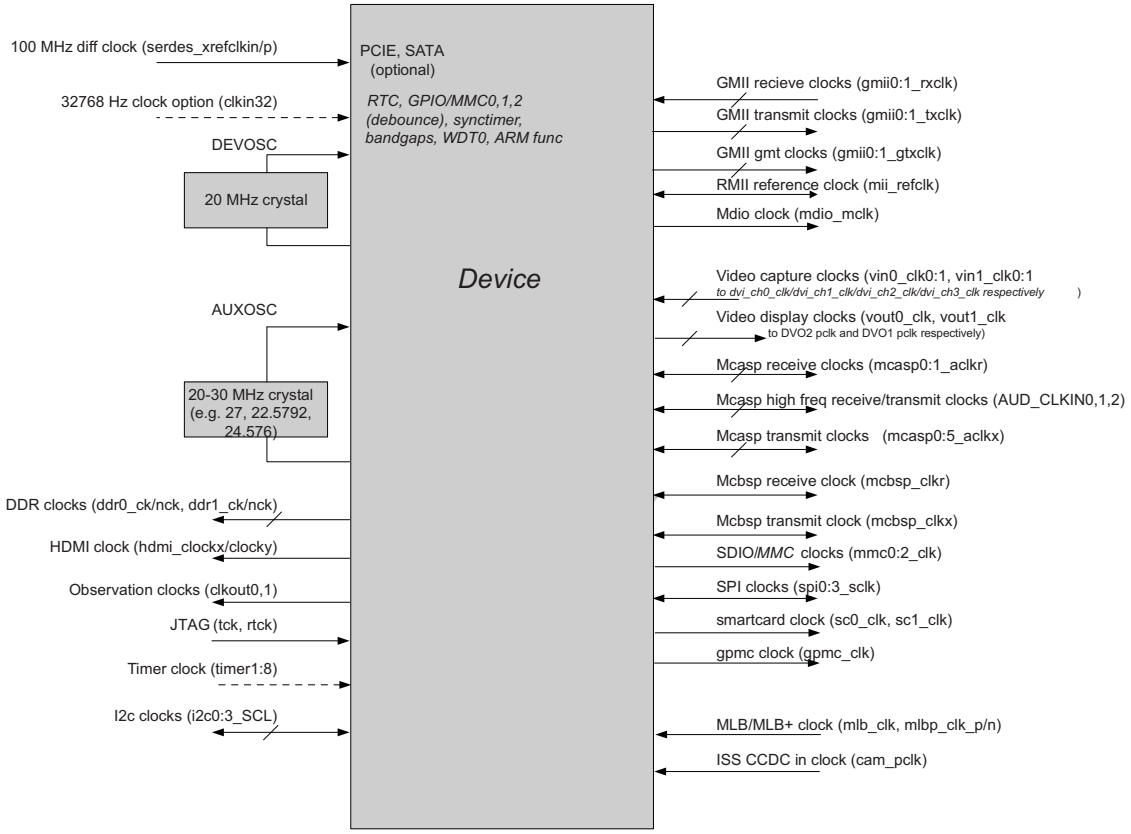
### 2.3.10 Device Clocking from External Sources

As shown in Figure 2-15, AUXOSC (20-30MHz) and DEVOSC (20 MHz) crystals are connected to generate the reference clocks. It is also possible to supply AUXOSC using an off-chip VCXO. A 100 MHz external differential clock must be used for PCIe. SATA uses 20 MHz oscillator as a reference.

Output clock SYSCLK_OUT can deliver clock outputs of each DPLL. The CM_CLKOUT_CTRL register controls the clock selection and division ratios.

Copyright © 2011–2016, Texas Instruments Incorporated

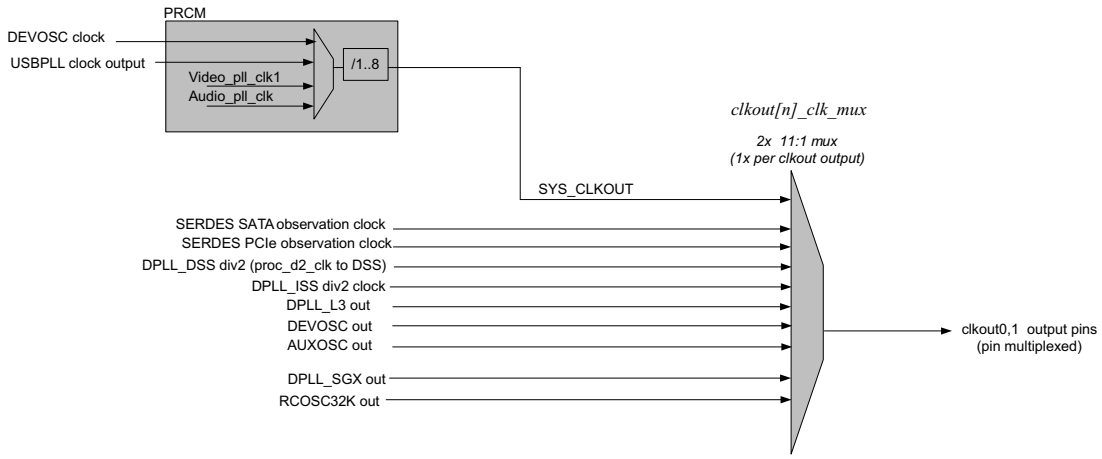
**Figure 2-15. Device Clocking External Clock Sources**



### 2.3.11 Clock Output Pin

The device has two clock output options. When chosen from the mux, the PLL clocks can be divided further before being exported out. The clock out is controlled by the register CM_CLKOUT_CTRL. The CLKOUT also has an enable option CM_CLKOUT_CTRL.CLKOUTEN.

**Figure 2-16. Clock Output Pin Options**



Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-27. Clkout Divider Options**

| Control Bit Filed | Divider | Supported Divide Ratios | Default Value |
|---|---|---|---|
| CM_CLKOUT_CTRL [CLKOUTDIV] | A | 1/1,1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8 | 1/1 |

The clock outputs are controlled by two mux options respectively CLKOUT0 and CLKOUT1. Refer to the CLKOUT_MUX register for more details on the options of CLKOUT multiplexing.

## 2.4 Oscillator

As discussed in previous sections, the device has two conventional on-chip oscillators: DEVOSC and AUXOSC.

Figure 2-17 shows the conventional oscillator connections. DEVOSC is always needed, while AUXOSC is optional for video/audio reference and can run at any desired frequency in range of 20-30 MHz (e.g., typically could be 27 MHz or 22.5792 MHz). Table 2-28 and Table 2-29 show the settings for the two on-chip oscillators.

**Figure 2-17. Oscillator Connection**

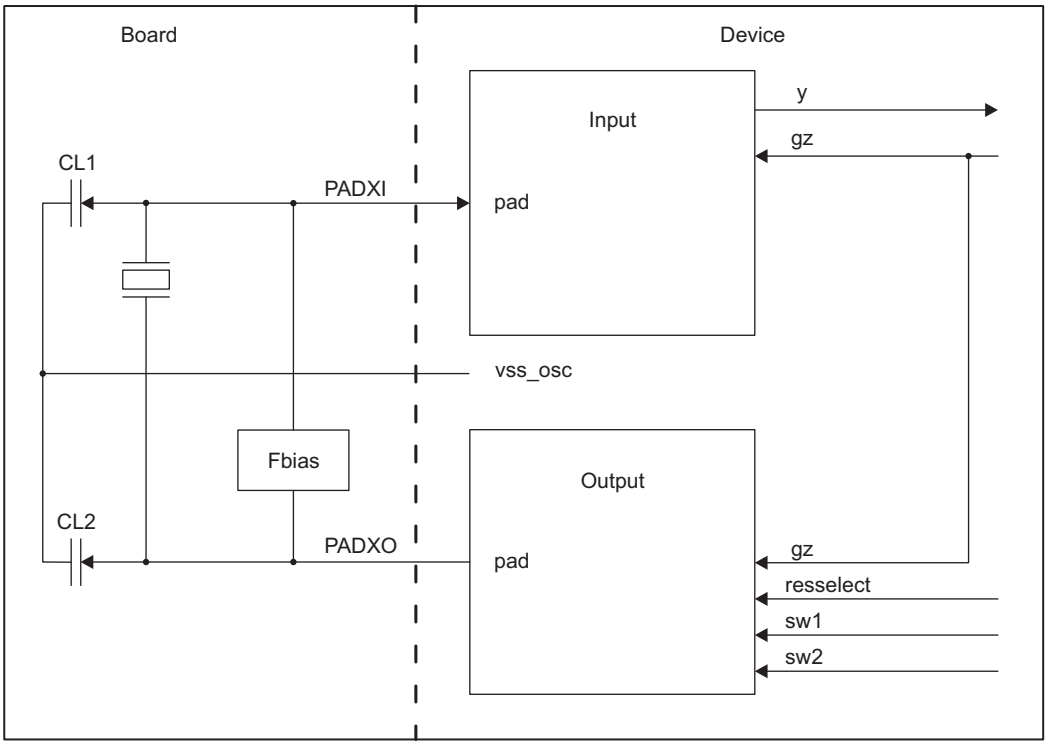


**Table 2-28. AUXOSC Oscillator Settings**

| Pin | Value |
|---|---|
| sw1 | 1 (select 15-35 MHz range) |
| sw2 | 0 (select 15-35 MHz range) |
| gz | MMR (Default 0 - Setting this to “1” disable the oscillator) |
| reselect | MMR (Default 0 - Use internal feedback resistor) |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-29. DEVOSC Oscillator Settings**

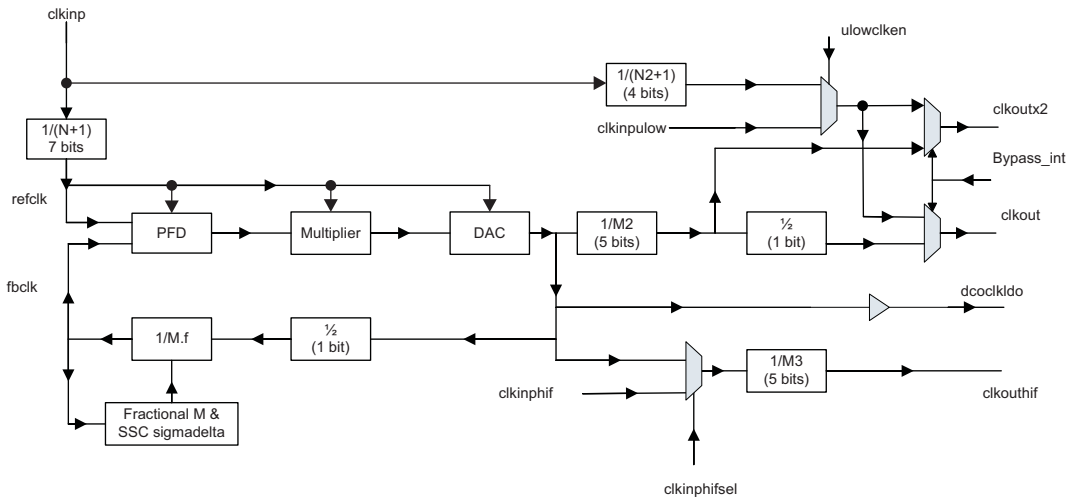
| Pin | Value |
|---|---|
| sw1 | 1 (select 15- 20 MHz range) |
| sw2 | 0 (select 15-20 MHz range) |
| gz | Controlled solely by Sleep control logic (Default 0 - sleep control logic sets to “1” to disable the oscillator while in sleep) |
| reselect | MMR (Default 0 - Use internal feedback resistor) |

**NOTE:** To enter sleep, the software must configure the desired sense of the wakeup (OSC_WAKE pin) and write to AUXOSC.GZ in the control module to force a hardware mechanism to turn off DEVOSC. The DEVOSC is cleanly re-started upon a wakeup event (rising or falling edge on the OSC_WAKE pin depending on configured sense before going into sleep). In case that an external oscillator/vcxo, a clock can directly be connected to XI pin and oscillator is put in bypass mode.

## 2.5 DPLLS

The DPLLS is a high resolution frequency synthesizer PLL with built in level shifters which allows the generation of frequencies upto 1GHz. DPLLLS has a pre-divide feature which allows the user to divide, for instance, a 20 MHz or 27 MHz reference clock to 1 MHz and then multiply up to 1 GHz maximum frequency. All PLLs come up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked. Once it is locked, then PLLs can be taken out of bypass mode. The Cortex™-A8 PLL is of this type.

**Figure 2-18. DPLLS Clocks Structure**



The DPLLS has three input clocks:

- CLKINP : Reference input clock
- CLKINPULOW : Low frequency input clock for bypass mode only
- CLKINPHIF : High Frequency Input Clock for post-divider M3
- The DPLLS has four output clocks:
- CLKOUTHIF: High Frequency Output Clock from Post divider M3
- CLKOUTX2: Secondary 2x Output
- CLKOUT: Primary output clock
- DCOCLKLDO: Oscillator(DCO) output clock with no bypass

The DPLL has internal clocks: REFCLK (Internal reference clock) and BCLK.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.5.1 DPLLS Frequency Range

The internal reference clock, REFCLK, is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK. Here, REFCLK = CLKINP/(N+1).

### 2.5.2 DPLLS Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm.

M is the software-configured Integer Feedback Multiplier Value.

N is the software-configured Input Divider Value.

M2 is the software-configured post-divider value

N2 is the software-configured Bypass divider value.

Frac M is software-configured Fractional Feedback Multiplier.

M3 is the software-configured additional divider

For more information for DPLLS programing and detailed descriptions of DPLLS registers see section *PLLSS Registers* in the device TRM.

### 2.5.3 DPLLS Clock Functions

The DPLL clock functions are shown in the tables Table 2-30:

**Table 2-30. Clock Functions**

| **Output Clocks in Locked Condition** | | |
|---|---|---|
| **REGM4XEN = '0'** | | |
| **Pin Name** | **Frequency** | **Comments** |
| CLKOUT | [M /(N+1)] * CLKINP * [1/M2] | |
| CLKOUTX2 | 2 * [M /(N+1)] * CLKINP * [1/M2] | |
| DCOCLKLDO | 2 * [M /(N+1)] * CLKINP | |
| CLKOUTHIF | CLKINPHIF / M3 | CLKINPHIFSEL = '1' |
| | 2 * [M /(N+1)] * CLKINP * [1/M3] | CLKINPHIFSEL = '0' |
| **REGM4XEN = '1'** | | |
| **Pin Name** | **Frequency** | **Comments** |
| CLKOUT | [4M /(N+1)] * CLKINP * [1/M2] | |
| CLKOUTX2 | 2 * [4M /(N+1)] * CLKINP * [1/M2] | |
| DCOCLKLDO | 2 * [4M /(N+1)] * CLKINP | |
| CLKOUTHIF | CLKINPHIF / M3 | CLKINPHIFSEL = '1' |
| | 2 * [4M /(N+1)] * CLKINP * [1/M3] | CLKINPHIFSEL = '0' |
| **Output Clocks before Lock & during Relock modes** | | |
| **Pin Name** | **Frequency** | **Comments** |
| CLKOUT | CLKINP/(N2+1) | ULOWCLKEN = '0' |
| | CLKINPULOW | ULOWCLKEN = '1' |
| CLKOUTX2 | CLKINP/(N2+1) | ULOWCLKEN = '0' |
| | CLKINPULOW | ULOWCLKEN = '1' |
| DCOCLKLDO | Low | |
| CLKOUTHIF | CLKINPHIF/M3 | CLKINPHIFSEL = '1' |
| | Low | CLKINPHIFSEL = '0' |

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** Since M3 divider is running on the internal LDO domain, in the case when CLKINPHIFSEL='1,' CLKOUTHIF could be active only when internal LDO is ON. Hence, whenever LDOPWDN goes low to high to powerdown LDO (happens when TINITZ activated / when entering slow relock bypass mode), output CLKOUTHIF glitch and stop. To avoid this glitch, it is recommended to gate CLKOUTHIF using control CLKOUTHIFEN before asserting TINITZ entering any slow relock bypass mode.

The Min and Max Values of the Clock generation supported by PLLs across different OPPs.

**NOTE:** For detailed information about PLL frequency limits at all OPPs see section *PLL Frequency Limits* in the device *Datasheet*.

### 2.5.4 DPLLS Frequency Factors

The divide values have to be selected with the ranges in the Table 2-31 so as to generate the required CLOCKOUT in the Frequency Ranges mentioned in the previous sections are satisfied.

**Table 2-31. Frequency Factors**

| Feedback Multiplier | M[1] | 2 - 2047 | 00000000010 - 11111111111 |
|---|---|---|---|
| **Input Divider** | **N + 1** | 1 - 128 | (0000000 - 1111111) + 1 |
| **Bypass Divider** | **N2 + 1** | 1 - 16 | (0000 - 1111) + 1 |
| **Post Divider** | **M2**[2] | 0 - 31 | 00000 - 11111 |
| **Additional Divider** | **M3**[3] | 1 - 31 | 00001 - 11111 |

(1) M = 0 and 1 correspond to MN Bypass mode setting.
(2) When M2 = 0, the M2 post divider is bypassed.
(3) M3 = 0 is an invalid setting.

## 2.6 DPLLLJ

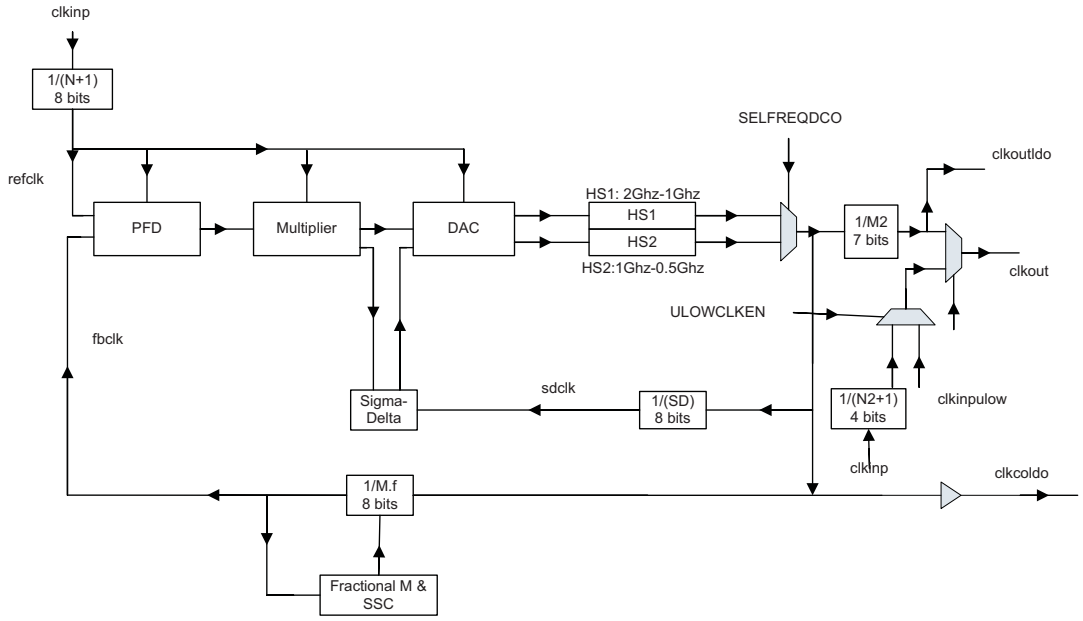
The DPLLLJ is a low-jitter PLL with a 2GHz maximum output. The DPLLLJ has a pre-divide feature which allows users to divide, for instance, a 20 MHz or 27 MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum.

The DPLLLJ also has an 18b fractional multiplier which is useful for configuring very specific frequencies as desired (for example, audio and video).

All PLLs come up in bypass mode at reset. The software needs to program all the DPLL settings appropriately and then wait for theDPLL to be locked. Once the DPLL is locked, then DPLLs can be taken out of bypass mode.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 2-19. DPLLJ Basic Structure**



The following PLLs belong to type DPLLJ:

- DSPPLL
- SGXPLL
- HDVICPPLL
- L3PLL
- ISSPLL
- DSSPLL
- VIDEO0PLL
- VIDEO1PLL
- HDMIPLL
- AUDIOPLL
- USBPLL
- DDRPLL

The DPLL has two input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Bypass input clock

The DPLL has two internal clocks: REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK. Here, REFCLK = CLKINP/(N+1)

DCOCLK (Internal Oscillator clock.): This is the raw clock directly out of the digitally controlled oscillator (DCO) before the post-divider. The PLL output clock is synthesized by an internal oscillator which is phase locked to the REFCLK. There are two oscillators built within DPLLLJ. The oscillators are user selectable based on the synthesized output clock frequency requirement. In locked condition, DCOCLK= CLKINP *[M/(N+1)].

The DPLL has three external output clocks:

- CLKOUTLDO
  Primary output clock in VDDLDOOUT domain. Bypass option not available on this output
  CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)

Copyright © 2011–2016, Texas Instruments Incorporated

- CLKOUT
  Primary output clock on digital core domain
  CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- CLKDCOLDO
  Oscillator (DCO) output clock before post-division in VDDLDOOUT domain. Bypass option is not available on this output.
  CLKDCOLDO = (M / (N+1))*CLKINP

All clock outputs of the DPLL can be gated. The Control module provides the DPLL with a clock gating control signal to enable or disable the clock, and the DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. Output clock gating control for various clockouts: CLKOUTEN/CLKOUTLDOEN/CLKDCOLDOEN.

### 2.6.1 DPLLLJ Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm.

M is the software-configured Integer feedback multiplier value.

N is the software-configured input divider value.

M2 is the software-configured post-divider value

N2 is the software-configured bypass divider value.

SD is the software-configured Sigma2Delta divider.

Frac M is software-configured fractional feedback multiplier.

For more information for DPLLs programing and detailed descriptions of DPLLSJ registers see section *PLLSS Registers* in the device TRM.

### 2.6.2 DPLLLJ Clock Functions

The clock functions are shown in Table 2-32 and Table 2-33 the tables below.

**Table 2-32. Output Clocks in Locked Condition**

| PINNAME | FREQUENCY |
|---|---|
| CLKOUT | [M /(N+1)] * CLKINP * [1/M2] |
| CLKOUTLDO | [M /(N+1)] * CLKINP * [1/M2] |
| CLKDCOLDO | [M /(N+1)] * CLKINP |

**Table 2-33. Output Clocks Before Lock and During Relock Modes**

| PINNAME | FREQUENCY | Conditions |
|---|---|---|
| CLKOUT | CLKINP/N2+1 | ULOWCLKEN = ’0’ |
| | CLKINPLOW | ULOWCLKEN = ’1’ |
| CLKOUTLDO | LOW | |
| CLKDCOLDO | LOW | |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.6.3 DPLLLJ Frequency Range (MHz)

The Min and Max Values of the Clock generation supported by PLLs across different OPPs.

**NOTE:** For detailed information about PLL frequency limits at all OPPs see section *PLL Frequency Limits* in the device *Datasheet*.

### 2.6.4 DPLLLJ Frequency Factors

The divide values have to be selected with the ranges in the Table 2-34 so as to generate the required CLOCKOUT in the Frequency Ranges mentioned in the previous sections are satisfied.

**Table 2-34. DPLLLJ Frequency Factors**

| Multiplier/Divider | | Range | |
|---|---|---|---|
| Feedback Multiplier (Integer) | M | 2 - 4095 | 00000000010 – 11111111111 |
| Feedback Multiplier (Fractional) | Frac M | | 000000000000000000 - 111111111111111111 |
| Input Divider | N+1 | 1-256 | (00000000 – 11111111) + 1 |
| Post Divider | M2[(1)] | 1-127 | 0000001 - 1111111 |
| Sigma2Delta Divider | SD | 2-255 | 000000010-11111111 |
| Bypass Divider | N2+1 | 16-1 | (0000 – 1111) + 1 |

(1) The M2 divider is bypassed when the divisor is equal to 0 or 1.

### 2.6.5 Mode of Operations

**Table 2-35. Modes of Operations**

| Mode | Control Signal | CLKINP | REFCLK | Digital | Analog Bias | DCO OSC | CLKOUT | CLKDCOLDO(CLKOUTLDO) | FreqLock time (Phaselock time) from specific mode to "Active & Locked mode" |
|---|---|---|---|---|---|---|---|---|---|
| OFF | SYSRESET = 1 or TINITZ = 0 | ON or OFF | OFF | ON | OFF | OFF | Bypass clk | LOW | 350REFCLKs (500REFCLKs) |
| Active & Locked | SYSRESET = 0 TINITZ = 1 IDLE = 0 | ON | CLKINP /(N+1) | ON | ON | ON | M/(N+1) * CLKINP * (1/M2) | DCOCLK (DCOCLK/M2) | Locked |
| Idle Bypass low power | SYSRESET = 0 TINITZ = 1 IDLE = 1 | ON | OFF | ON | OFF | OFF | Bypass clk | LOW | 20REFCLKs (150REFCLKs) |
| Lossclk – Bypass low power | SYSRESET = 0 TINITZ = 1 | OFF | OFF | ON | OFF | OFF | Bypass clk | LOW | 20REFCLKs (150REFCLKs) |
| Standby Retention-Bypass low power | STBYRET= 1 ULOWCLK EN=0/1 | ON | OFF | ON | OFF | OFF | Bypass clk | LOW | 7.5us+30REFCLKs (7.5us+125 REFCLKs) |
| MN Bypass | M = 0 or 1 | ON | OFF | ON | OFF | OFF | Bypass clk | LOW | 350REFCLKs (500REFCLKs) |
| Retention | Enter into RETENTION from Idle Bypass Mode | | | OFF | OFF | OFF | Low | LOW | 7.5us + 30REFCLKs (7.5us+125 REFCLKs) |

Copyright © 2011–2016, Texas Instruments Incorporated

**TINITZ:** TINITZ activation (Low) gives softreset to DPLLJ. TINITZ does not reset the entire digital control logic. It forces the FSM into RESET State so that DPLLJ could restart. DPLLJ starts calibration and lock sequence when TINITZ is disabled (Low to High).

**TENABLEDIV:** TENABLEDIV rising edge loads the values of M2REG and N2REG into PLL register (PLL_M2NDIV). It is not necessary to recalibrate PLL with the updated values. The change in values of M2REG reflects appropriately in the output clocks CLKOUT and CLKOUTLDO.

**OFF MODE:** SYSRESET= 1 or TINITZ = 0 PLL is in off mode when SYSRESET/TINITZ is configured to the values SYSRESET= 1 or TINITZ = 0. CLKOUT is bypass clk and CLKOUTLDO, and CLKDCOLDO are low irrespective of the presence of the inputclock.

**ACTIVE and Locked Mode:** SYSRESET = 0 & TINITZ = 1 , IDLE = ‘0’ PLL is in Active and locked mode when SYSRESET = 0 & TINITZ = 1, IDLE = ‘0’

- TENABLE rising edge loads the values of MREG and NREG into the ADPLLJ registers.
- TENABLEDIV rising edge loads the values of M2REG and N2REG into the ADPLLJ register.
- ADPLLJ starts calibration and lock sequence begins from the first CLKINP edge when TINITZ is disabled (low to high).
- TINITZ rising edge should follow the TENABLE rising edge, so that ADPLLJ performs the calibration and lock sequence after the loop control values are loaded.
- The change in values of M2REG reflects appropriately in the output clocks CLKOUT and CLKOUTLDO.
- Following this internal calibration sequence is performed followed by locking sequence. ADPLLJ has two lock outputs viz. FREQLOCK and PHASELOCK.
- The FREQLOCK output indicates frequency lock. FREQLOCK is asserted when internally the normal clk frequency is within + 1 / 2% of the final output frequency. The PHASELOCK output indicates phase tracking between output clocks (CLKOUT, CLKOUTLDO and CLKDCOLDO) and input clock (CLKINP). The FREQLOCK, PHASELOCK gets asserted in the ADPLLJ status register. The ouptut clocks CLKOUT, CLKOUTLDO and CLKDCOLDO are generated as per the register values (M, N, M2, N2) values.

**IDLE Bypass:** TINITZ =1 IDLE =1 The IDLE input signal can force ADPLLJ into bypass mode. Also the internal reference clock REFCLK is gated inside the ADPLLJ digital control logic to save power. In the IDLE mode, the PHASELOCK and FREQLOCK output signals are asserted low.CLKOUT is bypass clk and CLKOUTLDO, CLKDCOLDO are low

### *2.6.6 BYPASS Mode*

After digital power-up and before SYSRESET is active (high), DPLL is in an undefined state. Hence, power-up with SYSRESET active (high). On SYSRESET = ‘1’, VDD should be active, PONIN = ‘1’, PGOODIN = ‘1’ as shown in <MODULE>PLL_PWRCTRL register in PRCM and also the acknowledge signals PONOUT = ‘1’ and PGOODOUT = ‘1’ shown in <MODULE>PLL_STATUS register of PRCM.

CLKOUT is in the bypass mode and would give out bypass clk during and after sysreset.

<MODULE>PLL_CLKCTRL.ULOWCLKEN = ‘1’ – BYPASS CLK = CLKINPULOW

<MODULE>PLL_CLKCTRL.ULOWCLKEN = ‘0’ – BYPASS CLK = CLKINP/(N2+1); N2 =0

The bypass mode CLKOUT could be kept active or inactive during sysreset by controlling the status of <MODULE>PLL_CLKCTRL. CLKOUTEN during SYSRESET = ‘1’.

<MODULE>PLL_CLKCTRL.CLKOUTEN = ‘1’ during SYSRESET = ‘1’ asynchronously enables CLKOUT. And the acknowledge bit in the register is <MODULE>PLL_STATUS.CLKOUTENACK = ‘1’

<MODULE>PLL_CLKCTRL.CLKOUTEN = ‘0’ during SYSRESET = ‘1’ asynchronously disables CLKOUT. And the acknowledge bit in the register <MODULE>PLL_STATUS.CLKOUTENACK = ‘0’

CLKOUTLDO and CLKDCOLDO are low during and after SYSRESET.

Check the status bits CLKOUTENACK, BYPASS, BYPASSACK in the status register <MODULE>PLL_STATUS in the PRCM.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.6.7 M2 & N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly. The output clock CLKOUT/ CLKOUTLDO perform a clean switch from OLD period to NEW period without any clock period being different from OLD or NEW period.

### 2.6.8 Gating and Power Down of Output Clocks

The high to low transition of the input signal CLKOUTEN/ CLKOUTLDOEN/ CLKDCOLDOEN performs synchronous gating of the output clock CLKOUT/ CLKOUTLDO/ CLKDCOLDO respectively.The gating acknowledge output CLKOUTENACK/ CLKOUTLDOENACK/CLKDCOLDOENACK is asserted Low once the gating is complete.

The low to high transition of the input signal CLKOUTEN/ CLKOUTLDOEN/ CLKDCOLDOEN performs synchronous enabling of the output clock CLKOUT/ CLKOUTLDO/ CLKDCOLDO.The gating acknowledge output CLKOUTACK/ CLKOUTLDOACK/CLKDCOLDOACK is asserted High once the enabling is complete.

### 2.6.9 M2PWDNZ / CLKDCOLDOPWDNZ bits

<MODULE>PLL_CLKCTRL. M2PWDNZ active (low) will powerdown the M2 divider. Hence, the output clock CLKOUT is in bypass mode. Also, even after DPLL has locked and <MODULE>PLL_STATUS. FREQLOCK has gone high, and <MODULE>PLL_STATUS. BYPASSACK output continues to remain high. Changing this bit in active locked condition is not supported.

INITIALIZATION should follow the change of these bits <MODULE>PLL_CLKCTRL.CLKDCOLDOPWDNZ / CLKOUTLDOPWDNZ active (low) will powerdown the CLKDCOLDO/CLKOUTLDO output. CLKDCOLDO/CLKOUTLDO is Low in this condition. Changing these bits in active locked condition is not supported. INITIALIZATION should follow change of these bits.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.6.10 Connected Outputs of DPLLS

| PLL Instance | CLKOUT | CLKOUTX2 | DCOCLKLDO | CLKOUTHIF |

## 2.7 Reset Management

### 2.7.1 Overview

The PRCM manages the reset signals to all power domains. And, it manages generation of a single reset output signal through device pin, SYS_RESWARM_RST, for external use. The PRCM has no control over resets generated locally within a module, e.g., via the OCP configuration register bit <IPName>_SYSCONFIG.SOFTRESET.

All PRM reset outputs are asynchronously asserted. These outputs are active-low except for the DPLL resets. Deassertion is synchronous to the clock which runs a counter used to stall, or delay, reset de-assertion upon source deactivation. This clock is SYS_CLK used by all the reset managers. All modules receiving a PRCM generated reset are expected to treat the reset as asynchronous and implement local re-synchronization upon de-activation as needed.

One or more reset managers are required per power domain. Independent management of multiple reset domains is required to meet the reset sequencing requirements of all modules in the power domain.

### 2.7.2 Reset Concepts and Definitions

The PRCM manages many sources of reset signals with different characteristics. Reset signals are categorized as:

- Scope: Global or Local reset.
  - Global reset: Affects the entire logic of the device; all modules are reset. Generally, occurs when the device powers up or an abnormal operation is detected (the eFuse bad device is detected, etc.).
  - Local reset: Affects one power domain, reset domain, or module. Generally, when a power domain transitions from off mode to active mode, or when a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

Copyright © 2011–2016, Texas Instruments Incorporated

- Occurrence: Cold or Warm reset.
  - Cold reset: global reset that affects every module in the device. It usually corresponds to the initial power-on reset.
  - Warm reset: A module may use a warm reset to reset a subset of its logic.
- Source type: Software or Hardware triggered reset
  - Software reset: Triggered by setting a bit in a configuration register of the PRCM module.
  - Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

Each reset source is specified as being a cold or warm type. Cold types sources are applied globally within each receiving entity (i.e., subsystem, module, macro-cell) upon assertion. Cold reset events include: device power-up, power-domain power-up, and E-Fuse programming failures.

Warm reset types are not necessarily applied globally within each receiving entity. This is often done to speed-up reset recovery time, i.e., the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include: software initiated per power-domain, watch-dog time-out, externally triggered, and emulation initiated.

Reset sources, warm or cold types, intended for device-wide effect are classified as global sources. Reset sources intended for regional effect are classified as local sources.

Each reset manager provides two reset outputs. One is a cold reset generated from the group of global and local cold reset sources it receives. The other is a warm+cold reset generated from the combined groups of, global and local, cold and warm reset sources it receives.

The reset manager asserts one, or both, of its reset outputs asynchronously upon reset source assertion. Reset deassertion is extended beyond the time the source gets de-asserted. The reset manager will then extend the active period of the reset outputs beyond the release of the reset source, according to the PRCM's internal constraints and device's constraints. Some reset durations can be software-configured. Most (but not all) reset sources are logged by PRCM's reset status registers. The same reset output can generally be activated by several reset sources and the same reset source can generally activate several reset outputs. All the reset signals output of the PRCM are active low. Several conventions are used in this document for signal and port names. They include:

- "_RST" in a signal or port name is used to denote reset signal.
- "_PWRN_RST" in a signal or port name is used to denote a cold reset source

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.7.3 Power On Reset (PORz)

The source of power on reset is the PORz pin on the device. Everything on device is reset with assertion of power on reset. This reset is non-blockable. Power on Reset is also referred to as a cold reset since it is required to be asserted when the device goes through a power-up cycle. However, a device power-up cycle is not required to initiate a Power-on Reset.

### 2.7.4 External Warm Reset (RESETz)

The source for this reset is the RESETz pin on the device. This signal resets everything except test and emulation logic, and efuse to provide a clean starting stage. This reset is also optionally blocked to the GMAC switch and it's reference clock source PLL (controlled in protected control module MMR). This reset DOES reset PLL, PRCM and EMIF. This reset is different from POR as during Warm reset, reset controller can assume that clocks and power to the chip are stable from assertion through deassertion, whereas for POR they can become stable during assertion. This reset source is fully blockable only via emulation.

### 2.7.5 Emulation Cold Reset (ICEPICK POR)

The source for this reset is on-chip emulation logic. This reset is same as POR reset. Only difference is that ICEPICK POR reset does not affect emulation logic and efuse.

### 2.7.6 Emulation Warm Reset

The source for this reset is on-chip emulation logic. This reset is same as external Warm reset (RESETz).

### 2.7.7 Reset Requestor

There is a watchdog timer on the device that can act as a reset requestor. This reset is not blockable. The watchdog is optionally combined with other device-level resets based on bootstrap latch and goes as chip output as board reset on the RSTOUT_WD_OUT pin. If BTMODE[11] (from gpmc_ad11 pin) is 0, then RSTOUT is asserted when a Watchdog Timer reset, POR, RESET, or Emulation/Software-Global Cold/Warm reset occurs. If BTMODE[11] is 1, then the RSTOUT_WD_OUT is asserted only when a Watchdog Timer reset occurs. The register PRM_RSTST in the PRCM logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software.

### 2.7.8 Software Controlled Reset

The device also has software controlled reset. There is three types of software resets:

- SW Global cold reset (SWGCR)
- SW Global warm reset (SWGWR)
- Local reset (for IPs with CPUs)

### 2.7.9 Test Reset (TRSTz)

This reset is triggered from TRSTz pin on JTAG interface. This is a non-blockable reset and it resets test and emulation logic.

**NOTE:** A PORz reset assertion should cause entire device to reset including all test and emulation logic regardless of the state of TRSTz. Therefore, PORz assertion achieves full reset of the device even if TRSTz pin is pulled permanently high and no special toggling of TRSTz pin is required during power ramp to achieve full POR reset to the device. Further, it should also be perfectly acceptable for TRSTz input to be pulled permanently low during normal functional usage of the device in the end-system to ensure that all test and emulation logic is kept in reset.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.7.10 Reset Priority

If more than one of these reset sources are asserted simultaneously then following priority order should be used:

1. POR
2. TRSTz
3. External Warm reset
4. Emulation
5. Reset requestors
6. Software resets

### 2.7.11 Reset Characteristics

Table 2-36 shows the characteristics of each reset source.

**Table 2-36. Reset Sources**

| Characteristics | Pin POR (PORz) | SW Global Cold Reset | Emu Cold Reset (Icepick POR) | Bad Device (eFUSE) | Pin Warm Reset (RESETz) | Emu Warm Reset | Watchdog Timer | SW Global Warm Reset | TRSTz |
|---|---|---|---|---|---|---|---|---|---|
| Resets PLLs and enable bypass mode | Y | Y | Y | Y | Y | Y | Y | Y | N |
| Resets Dividers | Y | Y | Y | Y | Y | Y | Y | Y | N |
| Resets Fusefarm | Y | N | N | N | N | N | N | N | N |
| Resets chip functional logic | Y | Y | Y | Y | Y | Y | Y | Y | N |
| Resets GMAC switch and related chip logic | Y | N(1) | Y | Y | N(1) | N(1) | N(1) | N(1) | N |
| Resets test and emulation logic | Y | Y | N | N | N | N | N | N | Y |
| Resets Memory (DDR controller/PHY) | Y | Y | Y | Y | Y | Y | Y | Y | N |
| Resets power state for each IP | Y | Y | Y | Y | Y | Y | Y | Y | N |
| Reset source blockable | N | Y | N | N | Y | Y | Y (only emulation) | Y | N |
| Config pins latched4 | Y | N | N | N | Y | N | N | N | N |
| Puts Ios in tristate | Y | Y | Y(2) | Y(2) | Y(2) | Y(2) | Y(2) | Y(2) | N |
| Pin mux registers | Y | Y | Y(3) | Y(3) | Y(3) | Y(3) | Y(3) | Y(3) | N |
| RSTOUTn pin asserted | Y(4) | Y(4) | Y(4) | Y(4) | Y(4) | Y(4) | Y | Y(4) | N |

(1) Only true if GMAC switch reset isolation is enabled in control registers, otherwise is in reset.
(2) Some special IOs like test and emulation related is not in reset.
(3) Some special IOs like test and emulation related muxing is not in reset.
(4) RSTOUT_WD_OUT pin asserted only in case BTMODE[11] = 0 (latched from gpmc_ad11 pin). For pin reset conditions (PORz and RESETz), the pin is asserted only after the bootstrap value is latched (therefore asserts during internal stretched version of the reset, but not during assertion of the external pin).

**NOTE:** The Bandgap macros for the LDO's is in reset on PORz only.

### 2.7.12 Trace Functionality Across Reset

Other than POR, TRSTz and SW cold reset, none of the other resets affect trace functionality. This requires that Debug_SS has required reset isolation for the trace logic. Also the IOs and muxing control (if any) for trace IOs should not get affected by any other reset. Since none of the PLLs getting reset with other resets, clocks are any way stable.

Copyright © 2011–2016, Texas Instruments Incorporated

## 2.7.13 Reset Isolation

### 2.7.13.1 PCIe Reset Isolation

The device supports reset isolation for the PCI Express IP in the limited fashion as described below. It means that the user should be able to control the chip warm reset and PCI express in-band reset independently.

1. **RC (Root Complex), PCIE_SS reset and chip not reset**
   Local reset is asserted to the PCIE_SS from the PRCM. SW needs to make sure that there were no ongoing transactions at this point of time. This can be ensured by first taking the PCIE_SS to IDLE state. After coming out reset the bus enumeration needs to be performed again. Driver SW should behave as if all downstream devices are just connected again
2. **RC (Root Complex), PCIESS not reset and chip reset**
   In Root Complex mode, the chip is master of the PCI Express network. There is no utility of keeping PCIE_SS running if the chip is rebooting. All state information is lost and it is simpler to restart. When resuming, the Root Complex can issue Hot Reset to all downstream devices and start with the bus enumeration stage.
3. **EP (Endpoint), PCIE_SS reset and chip not reset**
   This can happen due to an in-band reset or because of PCIERST getting asserted. PCIE_SS indicates this by interrupting the Cortex™-A8 core. SW should then take the PCIE_SS to IDLE state and then local reset can be asserted to the PCIE_SS.
4. **EP (Endpoint), PCIE_SS not reset and chip reset**
   This is not supported as PCIE is a point to point connection and resetting one endpoint does not impact the complete system. So whenever chip gets reset even PCIE_SS gets reset.

### 2.7.13.2 EMAC Switch Reset Isolation

The device supports reset isolation for the Ethernet Switch IP by register RESET_ISO[0] ISO_CONTROL in the control module. This allows the device to undergo a warm reset without disrupting the switch or traffic being routed through the switch during the reset condition.

If configured by registers in control module that EMAC reset isolation ISO_CONTROL is active, then behavior is as follows:

Any “Warm” reset source (except the software warm reset) is blocked to the EMAC switch logic in the IP (the IP has two reset inputs to support such isolation) and to PLL (and it’s control bits) which is sourcing the EMAC switch clocks as required by the IP (50 or 125MHz reference clocks). Also, the EMAC switch related IO pins must retain their pin muxing and not glitch (continuously controlled by the EMAC switch IP) by blocking reset to the controlling register bits.

If configured by registers in control module that EMAC reset isolation ISO_CONTROL is NOT active (default state), then the warm reset sources are allowed to propagate as normal including to the EMAC Switch IP (both reset inputs to the IP).

All cold or POR resets are always propagate to the EMAC switch IP as normal (as otherwise defined in this document).

## 2.7.14 Reset Output ($\overline{\text{RSTOUT_WD_OUT}}$)

The device has one pin $\overline{\text{RSTOUT_WD_OUT}}$ which reflects chip reset status. This output is always assert asynchronously when any chip watchdog timer reset occurs (any of the 3 chip watchdogs) and if BTMODE[11] bootstrap is 0, then additionally the pin asserts if any of the following reset events occurs:

1. POR (only internal stretched portion of reset event after bootstrap is latched)
2. External Warm reset ($\overline{\text{RSTOUT_WD_OUT}}$ pin, only internal stretched portion of reset event after bootstrap is latched)
3. Emulation reset (Cold or warm from ICEPICK)
4. Reset requestor
5. SW Cold/Warm reset
   This output remains asserted as long as PRCM keeps reset to the host processor asserted.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:**

- The RSTOUT_WD_OUT pin is output only and not bidirectional.
- TRST does not cause RSTOUT_WD_OUT assertion

### 2.7.15 Power-on-Reset (PORz) Sequence

The following is the sequence of actions for PORz:

1. PORz pin at chip boundary gets asserted (goes low).

**NOTE:** The state of the Reset Output during PORz assertion should be a don't care, it should not affect PORz (only implication is if they are both asserted and RSTOUT_WD_OUT is deasserted after PORz gets re-latching of boot config pins and may see warm RESET flag set in PRCM versus POR).

2. All IOs go to tri-state immediately.
3. When power comes-up, PORz value propagates to the PRCM.
4. PRCM fans out reset to the complete chip and all logic which uses async reset gets reset. RSTOUT_WD_OUT goes low to indicate reset-in-progress.
5. External clocks start toggling and PRCM propagates these clocks to the chip keeping PLLs in bypass mode.
6. All logic using sync reset gets reset.
7. When power and clocks to the chip are stable, PORz is de-asserted.
8. Boot Config pins are latched upon de-assertion of PORz pin
9. FuseFarm reset is de-asserted to start eFuse scanning.
10. Once eFuse scanning is complete, reset to the host processor and to all other peripherals (peripherals without local processor) is de-asserted.
11. RSTOUT_WD_OUT is de-asserted.
12. Once host processors finish booting then all remaining peripherals see reset de-assertion.

**NOTE:** All IPs with local CPUs have local reset asserted by default at PORz and reset de-assertion requires host processor to write to corresponding registers in PRCM.

### 2.7.16 RESETz Sequence

The following is the sequence of actions for RESETz:

1. RSTOUT_WD_OUT pin at chip boundary gets asserted (goes low).

**NOTE:** For RESETz sequence to work as described, it is expected that PORz pin is always inactive, otherwise refer to PORz functionality as described in previous section.

2. All IOs (except test and emulation) go to tri-state immediately.
3. PRCM propagates reset to the complete chip and all logic. RSTOUT_WD_OUT goes low to indicate reset-in-progress.
4. Chip clocks are not affected as both PLL and dividers are intact.
5. RESETz gets de-asserted after 30 cycles
6. Boot Config pins are latched upon de-assertion of PORz pin
7. PRCM de-asserts reset to the host processor and all other peripherals without local CPUs.
8. Once host processors finish booting then all remaining peripherals see reset de-assertion.

Copyright © 2011–2016, Texas Instruments Incorporated

**NOTE:** All IPs with local CPUs have local reset asserted by default at RESETz and reset de-assertion requires host processor to write to corresponding registers in PRCM.

### 2.7.17 Power-Up/Down Sequence

The power-up/down sequence is as follows:

1. Each power domain has dedicated warm and cold reset.
2. Warm reset gets asserted each time there is any warm reset source requesting reset. Warm reset is also asserted when power domain moves from ON to OFF state.
3. Cold reset for the domain is asserted in response to cold reset sources. When domain moves from OFF to ON state then also cold reset gets asserted as this is similar to power-up condition for that domain.

### 2.7.18 IO State

All IOs except for JTAG and Reset output (and any special cases mentioned in pinlist) should have their output drivers tri-state, and internal pulls enabled during assertion of all reset sources. JTAG IO is affected only by TRSTz.

**NOTE:** The DSP, HDVICP, and Media Controller are held under reset after global warm reset by assertion of software source of reset. Other domains such are held under reset after global warm reset until the MPU software enables their respective interface clock.

### 2.7.19 MPU Subsystem POR Sequence

The power on reset must be applied when MPU SS is first powered up. Following is the detailed description of MPU power on reset sequence.

1. During the initial power up sequence, the PRCM it asynchronously releases the DPLL_MAIN_RST signal for the main PLL. Once the main PLL reset is released, it starts the PLL initialization. The PLL is configured in bypass mode and it provides the bypass output CLK to all the modules inside MPU SS.
2. The PRCM releases the reset to INTC module inside MPUSS i.e. it asynchronously releases the MPU_AO_RST signal to MPUSS.
   Before the MPU power on reset is de-asserted, the PRCM must ensure that the MPU CLK is running so that MPU can be reset properly.
3. The PRCM releases MPU_PWRON_RST and it waits until MPUSS power-on Reset is complete. That is, the MPU_PWRON_RSTDONE signal is asserted HIGH by the MPUSS.
4. Following the de-assertion of MPU_PWRON_RST signal, the MPU SS de-asserts the nPORESET signal to the Cortex™-A8 CPU and after sufficient number of MPU CLK cycles MPU SS asserts the MPU_PWRON_RSTDONE signal high to indicate to the PRCM that synchronous power on reset sequence is completed inside MPU SS.
5. Once the PRCM sees that this MPU_PWRON_RSTDONE signal is asserted HIGH, PRCM de-asserts the MPU_RST signal and then the MPU starts booting.

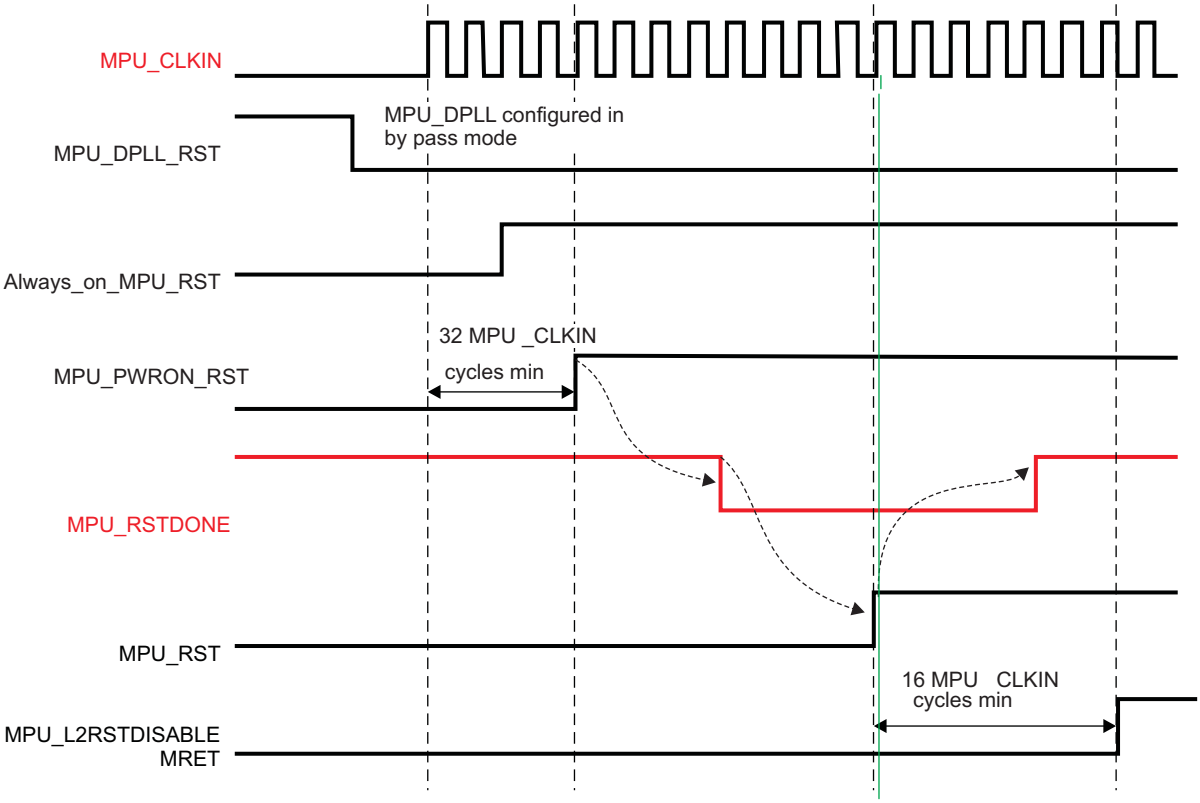
**Figure 2-20. MPU SS POR Sequence**



### 2.7.20 MPU Subsystem Warm Sequence

During the warm reset of MPU, the PRCM asserts the MPU_RST signal only and power on reset signal is not asserted.

The MPU_RST is kept asserted for minimum 32 MPU clock cycles, that is, SYS_CLK in this case since during warm the reset of MPU.

Figure 2-21 illustrates the timing diagram for MPU warm reset sequence.

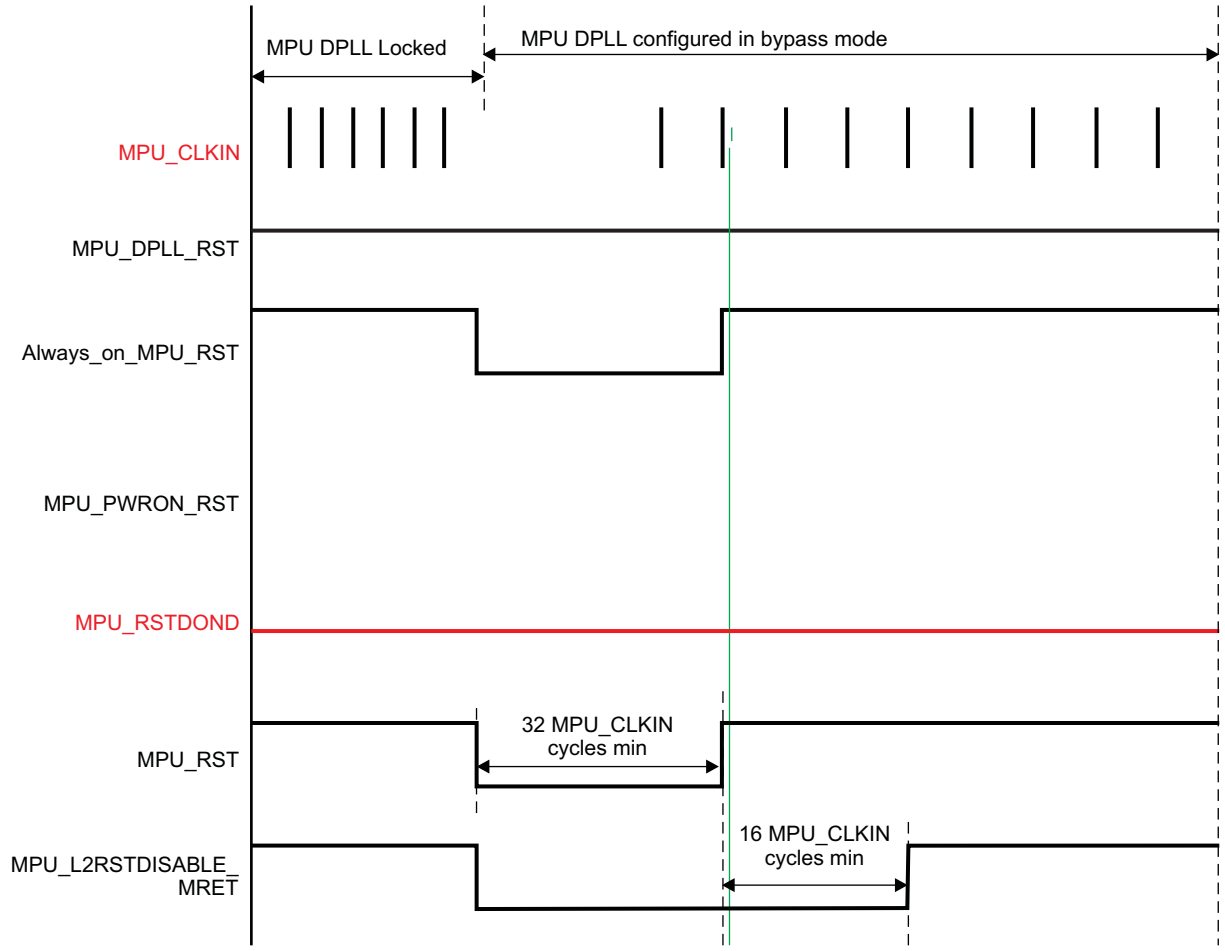
**Figure 2-21. MPU Warm Reset Sequence**

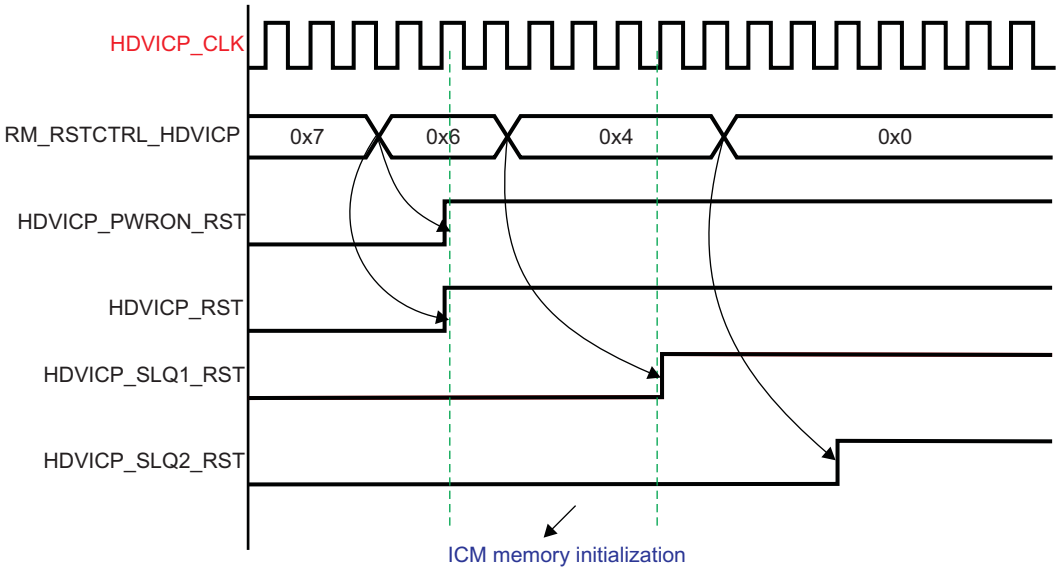


### 2.7.21 HDVICP Power-On Reset Sequence

Figure 2-22 illustrates the POR sequence of the HDVICP subsystem.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 2-22. POR Sequence of the HDVICP2**



POR to HDVICP is applied when PD_HDVICP is powered up.

Whenever the HDVICP is enabled by software control, the following sequence happens:

- The PRCM module provides the functional clock HDVICP_CLK to the HDVICP SUBSYSTEM
- The POR to HDVICP is de-asserted

After POR de-assertion, the sequence is:

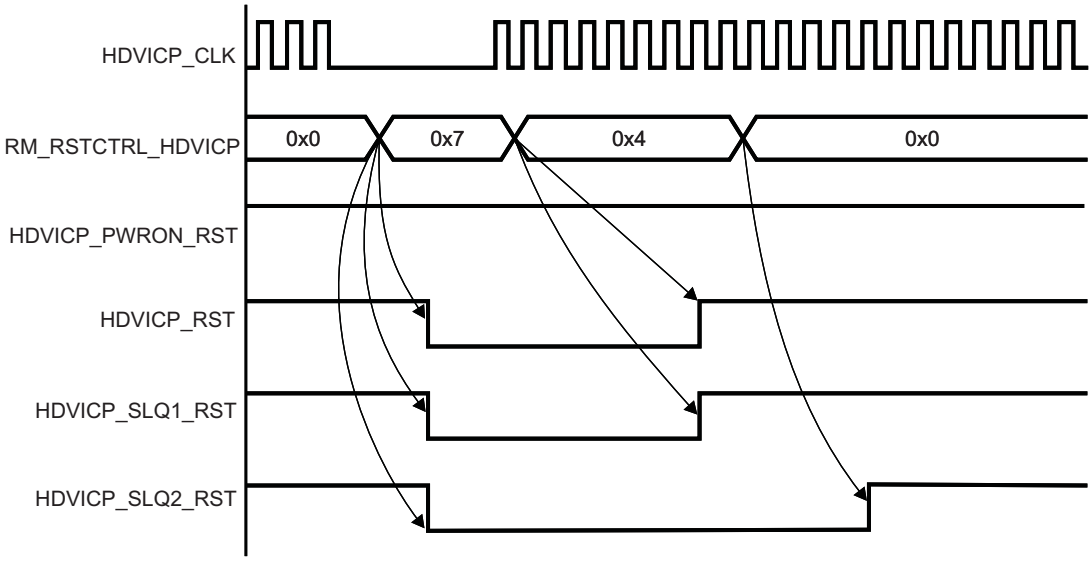
- Software clears the RM_HDVICP_RSTCTRL[2] RST3 bit. This causes the PRCM module to release the HDVICP_PWRN_RST reset, which is used inside HDVICP primarily to reset the emulation logic and the HDVICP_RST reset, which is used to reset all logic inside HDVICP. Then, software can download data into the TCM memory while keeping the sequencer CPUs under reset.
- Software clears the RM_HDVICP_RSTCTRL[0] RST1 bit. This releases the HDVICP_SEQ1_RST reset to the Sequencer1 CPU.
- Software can clear the RM_HDVICP_RSTCTRL[1] RST2 bit. This releases the HDVICP_SEQ2_RST reset to the Sequencer2 CPU.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.7.22 HDVICP Software Warm Reset Sequence

Figure 2-23 illustrates the software warm reset sequence of the HDVICP.

**Figure 2-23. Software Warm Reset Sequence of the HDVICP**



Before asserting the software reset to the HDVICP, the MPU software must ensure that:

- The HDVICP sequencer CPUs are in IDLE state (CM_HDVICP_CLKCTRL[17:16] IDLEST).
- The HDVICP2 is in STANDBY state CM_HDVICP_CLKCTRL[[18] STBYST).
- The functional clock to the HDVICP has been gated by the PRCM module (CM_HDVICP_CLKSTCTRL[8] CLKACTIVITY_HDVICP_CLK).

The software reset sequence occurs when the MPU software:

1. Sets the RM_HDVICP_RSTCTRL[2] RST3, RM_HDVICP_RSTCTRL[1] RST2, and RM_HDVICP_RSTCTRL[0] RST1 bits. This causes the PRCM module to assert the HDVICP_RST, HDVICP_SEQ1_RST, and HDVICP_SEQ2_RST resets to the HDVICP2. HDVICP_PWRN_RST remains deasserted.
2. Enables the functional clock to the HDVICP.
3. clears the RM_HDVICP_RSTCTRL[2] RST3 and RM_HDVICP_RSTCTRL[0] RST1 bits. This causes the PRCM module to release the HDVICP_RST and HDVICP_SEQ1_RST resets to the HDVICP.
4. clears the RM_HDVICP_RSTCTRL[1] RST2 bit. This releases the HDVICP_SEQ2_RST reset to the Sequencer2 CPU.

### 2.7.23 C674x DSP Power-On Reset Sequence

The assumptions about POR de-assertion are:

- The MPU software sets the CM_ACTIVE_GEM_CLKCTRL [1:0] MODULEMODE bit field to enabled.
- The MPU software sets the CM_ACTIVE_GEM_CLKSTCTRL [1:0] CLKTRCTRL bit field to SW_WKUP.
- The PRCM is providing the clocks to C674x DSP.

The POR sequence is:

- The PRCM module releases GEM_POR when the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) reaches its limit.
- The MPU software clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to release the DSP, MMU, and CACHE interface from reset.

Copyright © 2011–2016, Texas Instruments Incorporated

- Once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the GEM_GRST signal.
- On deassertion of the GEM_GRST signal, the C674x subsystem starts the initialization sequence. During the initialization sequence all the internal registers inside the C674x subsystem are properly reset and the reset for the DSP, MMU, and CACHE interface completes.
- The MPU software must configure the MMU once the MMU is out of reset. After the MMU is configured, the MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.

The PRCM module releases GEM_LRST, which causes the DSP to start booting.

### 2.7.24 C674x DSP Warm Reset Sequence

The assumptions about WARM reset de-assertion are:

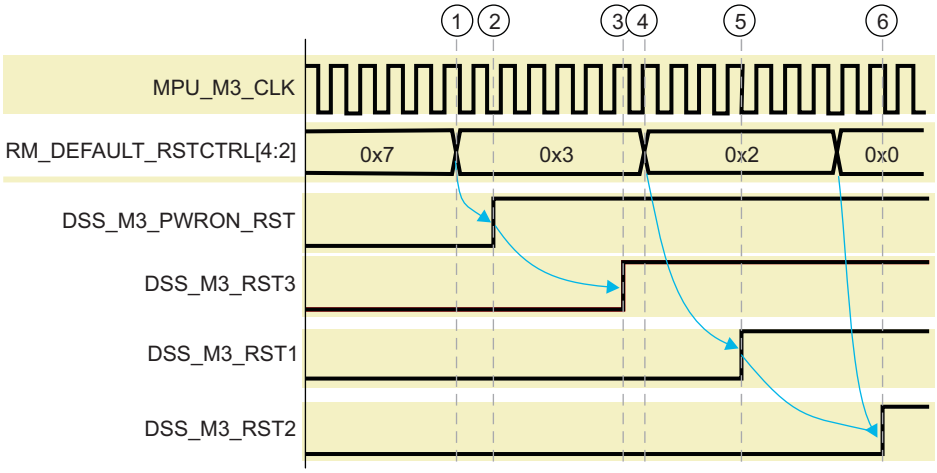
- The DSP is in IDLE state

The sequence is:

1. The MPU software sets the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST and RM_ACTIVE_RSTCTRL[0] GEM_LRST bits.
2. The PRCM module asserts the GEM_GRST and GEM_LRST reset signals.GEM_POR remains deasserted in this case.
3. The MPU software re-enables the C674x DSP Clocks and clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to reset the DSP, MMU, and CACHE interface. The DSP subsystem starts the partial initialization sequence for the warm reset.
4. The MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.
5. The PRCM module releases GEM_LRST, which causes the DSP to start booting.

### 2.7.25 Media Controller Power-On Reset Sequence

**Figure 2-24. Media Controller Power-On Reset Sequence**



The assumptions about POR de-assertion are:

- The Media Controller MPU subsystem is held in reset by the PRCM module and the following are asserted:
  - DSS_PWRN_RST
  - DSS_RST1
  - DSS_RST2
  - DSS_RST3

Copyright © 2011–2016, Texas Instruments Incorporated

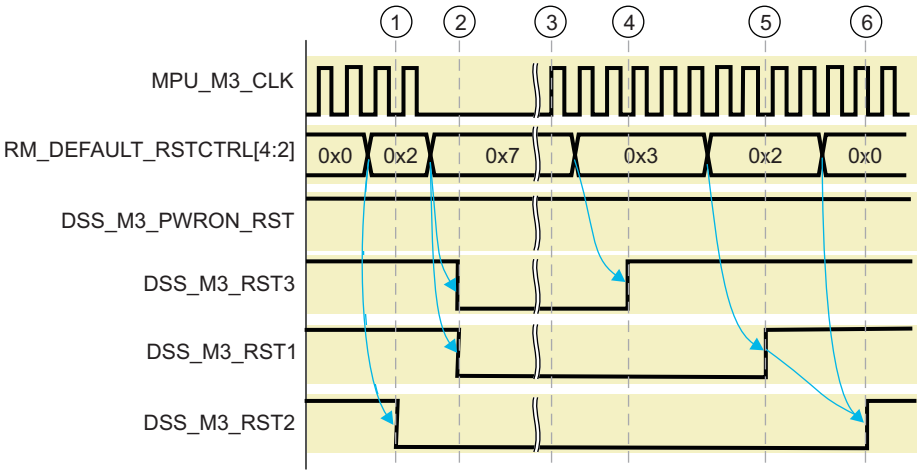
The POR sequence is:

1. Software enables Media Controller MPU subsystem.
2. Software clears the RM_DEFAULT_RSTCTRL[4] RST3 bit in the PRCM module register to release the Media Controller MPU Cache and MMU from reset.
3. Once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the DSS_RST3 signal.
4. Upon the deassertion of the DSS_M3_RST3 signal, the Media Controller MPU subsystem starts the CPU and MMU initialization sequence
5. The MPU software must configure the MMU once the MMU is out of reset. After MMU configuration and cache initialization is done, the MPU software clears the RM_DEFAULT_RSTCTRL[3] RST1 bit in the PRCM module register.
6. The PRCM module releases DSS_RST1, which causes the Media Controller MPU Core 1 to start booting.
7. The MPU software can clear the RM_DEFAULT_RSTCTRL[2] RST2 bit in the PRCM module register so that the PRCM module releases DSS_RST2 to the Media Controller MPU Core 2.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.7.26 Media Controller Warm Reset Sequence

**Figure 2-25. Media Controller MPU Subsystem Software Warm Reset Sequence**



The assumption about Warm reset assertion is:

- The Media Controller MPU Core2 is in IDLE state.

The sequence is:

1. Media Controller MPU Core 1 software or Cortex™-A8 MPU software sets the RM_DEFAULT_RSTCTRL[3] RST2 bit. The PRCM module asserts the DSS_RST2 reset signal to the Media Controller Core 2.
2. The Cortex™-A8 MPU cuts the MPU_M3_CLK and software sets the RM_DEFAULT_RSTCTRL[4] RST3 and RM_DEFAULT_RSTCTRL[2] RST1 bits.
3. The PRCM module asserts the DSS_RST3, DSS_RET_RST, and the DSS_RST1 reset signals. The DSS_PWRN_RST remains deasserted in this case.
4. The MPU software re-enables the MPU_M3_CLK and the initialization sequence starts inside the Media Controller subsystem. Software clears the RM_DEFAULT_RSTCTRL[4] RST3 bit in the PRCM module register.
5. When the reset sequence in Step 4 completes and the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the DSS_RST3, and DSS_RST1 reset signals. Media Controller Core 1 starts rebooting.
6. Software clears the RM_DEFAULT_RSTCTRL[3] RST2 bit in the PRCM module register. The PRCM module releases the DSS_RST2 reset signal to the Media Controller Core 2. Core 2 starts to boot.

## 2.8 Voltage and Power Domains

Table 2-37 shows how the device core logic is partitioned into 4 core logic voltage domains, 4 memory voltage domains and 6 power domains. The table lists which voltage and power domain a functional module belongs. All voltage domains must be supplied during any mode of operation while 5 of the 6 power domains can turned off by internal switch.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-37. Volage and Power Domains**

| Logic Voltage Domain Name | Module |
|---|---|
| ARM | Cortex™-A8, |
| CORE | DCAN0, DCAN1, DDR_PHY_LOGIC0, DDR_PHY_LOGIC1, DMM EDMA, ELM, EMIF0, EMIF1, 2 Channel GMAC Switch, GPIO_CNTL0, GPIO_CNTL1, GPIO_CNTL2, GPIO_CNTL3,GPMC, I2C0, I2C1, I2C2, I2C3, Interconnect, IPC, MCASP0, MCASP1, MCASP2, MCASP3, MCASP4, MCASP5, ATL, MCBSP, MLB, OCMC SRAM, PATA, PBIST, PCI, PRCM, RTC, SATA, SCR, SD/MMC0, SD/MMC1, SD/MMC2, SPI0, SPI1, SPI2, SPI3, Switch fabric, Timer1, Timer2, Timer3, Timer4, Timer5, Timer6, Timer7, Timer8, UART0, UART1, UART2, UART3, UART4, UART5, USB0, USB1, WDT0, VCP, XBAR, Debug_SS |
| | FACEDETECT |
| | SGX530 Subsystem |
| | HDD_SS, HDMI, SD-DAC LOGIC |
| ACTIVE (DSP) | C674x+™ Subsystem. , C674x+™ L2 SRAM, |
| HDVICP | HDVICP, |

### 2.8.1 Voltage Domains

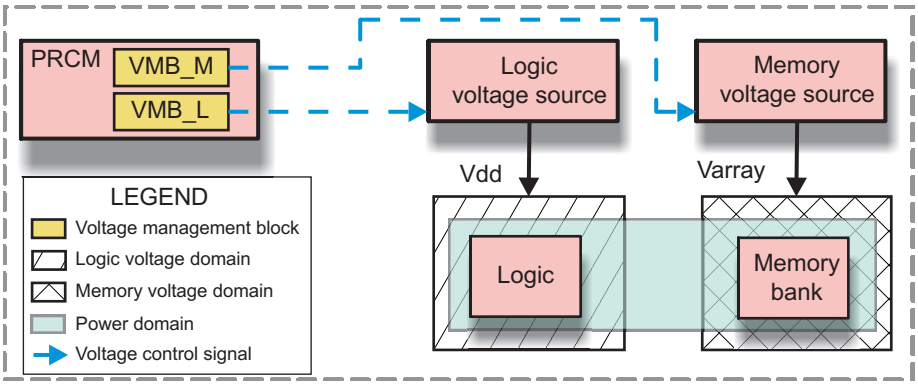
The PRCM module controls the voltage scaling (that is, switching the voltage in discrete steps or in a continuum within a range of possible values) of the power sources of the device. This allows control of the device power consumption according to the performance criteria defined. Higher performance is ensured with higher voltage and clock frequencies (and hence higher power consumption), while lower performance can be supported with lowered power consumption by reducing or completely gating the power supply to specific areas of the device and gating the associated clocks.
A voltage domain is a section of the device supplied by a dedicated voltage source (that is, an internal LDO or external switched mode power supply [SMPS]). A voltage domain may or may not be controlled by the PRCM module. When a voltage domain is controlled by the PRCM module, a dedicated voltage manager is associated. The voltage manager allows regulation of the voltage level of the source for the voltage domain, independently of other voltage domains of the device.
The core logic is divided into four voltage domains. This division permits the system to scale down voltage to some functional blocks while maintaining highest performance on other blocks.

The voltage managers in the PRCM module can be of two types:

- Hardware controlled to automatically switch the domain voltage levels according to the associated hardware conditions.

Figure 2-26 shows a voltage domain.

**Figure 2-26. Generic Voltage Domain**



Copyright © 2011–2016, Texas Instruments Incorporated

### 2.8.2 Power Domains

In order to reduce power due to leakage, the core logic supply voltage to six of the device power domains can be turned OFF with internal power switches. The internal power switches are controlled through memory mapped registers in the PRCM. In an use case whereby all the modules within a power domain are not used that power domain can be place in the OFF state.

Table 2-38 shows the allowable combination power domain ON/OFF states and which power domains are switched via internal power switches. At power-on-reset, all domains except always-on are in the power domain OFF state.

**Table 2-38. Power Domain State Table**

| | POWER DOMAIN | | | | | |
|---|---|---|---|---|---|---|
| MODE | ALWAYS_ON | ISP (ISS) | GFX | DSS | ACTIVE (DSP) | HDVICP |
| No Voltage Supply | N/A | N/A | N/A | N/A | N/A | N/A |
| Power On Reset | ON | OFF | OFF | OFF | OFF | OFF |
| ALL OTHER FUNCTIONAL MODES | ON | DON'T CARE | DON'T CARE | DON'T CARE | DON'T CARE | DON'T CARE |
| Internal Power Switch | NO | YES | YES | YES | YES | YES |

### 2.8.3 Device Modules and Power Management Attribute List

The device modules and power management list are described below:

**Table 2-39. Device Modules**

| Power Domain Name | Module |
|---|---|
| ALWAYS_ON | Cortex™-A8, , DCAN0, DCAN1, DDR_PHY_LOGIC0, DDR_PHY_LOGIC1, DMM EDMA, ELM, EMIF0, EMIF1, 2 Channel GMAC Switch, GPIO_CNTL0, GPIO_CNTL1, GPIO_CNTL2, GPIO_CNTL3,GPMC, I2C0, I2C1, I2C2, I2C3, Interconnect, IPC, MCASP0, MCASP1, MCASP2, MCASP3, MCASP4, MCASP5, ATL,MCBSP, MLB, OCMC SRAM, PATA, PBIST, PCI, PRCM, RTC, SATA, SCR, SD/MMC0, SD/MMC1, SD/MMC2, SPI0, SPI1, SPI2, SPI3, Switch fabric, Timer1, Timer2, Timer3, Timer4, Timer5, Timer6, Timer7, Timer8, UART0, UART1, UART2, UART3, UART4, UART5, USB0, USB1, WDT0, VCP, XBAR, Debug_SS |
| ISS (ISP) | FACEDETECT, ISS |
| SGX530 | SGX530 Subsystem |
| DSS | HDD_SS, HDMI, SD-DAC LOGC |
| ACTIVE (DSP) | C674x+™ Subsystem. , C674x+™ L2 SRAM, |
| HDVICP | HDVICP, SRSense2 |

### 2.8.4 Power Domain Power-Down Sequence

Below is the sequence of steps which happen during power down of a power domain.

All IPs (belonging to a power domain) with STANDBY interface asserts STANDBY. The STANDBY assertion should get triggered by the IP based on its activity on OCP initiator port. The IP should assert STANDBY whenever initiator port is IDLE. Some of the DSPS IPs may not have this feature and they require SW write to standby-mode register to get STANDBY assertion from IP.

1. SW requests all modules in given power domain to go to disable state by programming module control register inside PRCM.
2. PRCM starts and waits for completion of power management handshake with IPs (IdleReq/IdleAck).
3. PRCM gates-off all the clocks to the power domain.
4. SW requests all clock domains in given power domain to go to “force sleep” mode by programming functional clock domain register in PRCM. PRCM has already gated-off clocks and this register programming may look redundant.
5. SW requests PRCM to take this power domain to OFF state by programming PWRSTCTRL register. This step can be skipped if PWRSTCTRL is permanently programmed to OFF state. When this is done, functional clock domain register decides when power domain is taken to OFF state. Only reason not to have OFF state in PWRSTCTRL is to take power domain to just clock gate state without power gating.
6. PSCON specific to this power domain asserts isolation enable for the domain.
7. PRCM asserts warm and cold reset to the power domain.
8. PSCON asserts control signals to switch-off power using on-die switches.
9. On-die switches sends acknowledge back to PSCON.

### 2.8.5 Power Domain Power-Up Sequence

Below is the sequence of steps during power-up of a power domain. This sequence is not relevant to ALWAYS_ON power domain as this domain never goes to OFF state as long as the device is powered. This sequence is repeated each time a domain is taken to ON state from OFF (including first time power-up).

There can be multiple reasons to start power-up sequence for a domain. For example it can be due to an interrupt from one of the IPs which is powered-up.

Copyright © 2011–2016, Texas Instruments Incorporated

1. SW requests required clock domains inside this power domain to go to force wake-up state by programming the functional clock domain register.
2. PRCM enables clocks to the required clock domains.
3. PSCON specific to this power domain asserts control signal to ungate the power.
4. Once power is ungated, on-die switches sends acknowledge back to PSCON.
5. PRCM deasserts cold and warm reset to the power domain.
6. PRCM turns off isolation cells.
7. SW requests PRCM to enable the required module in the power domain by programming the module control register.
8. PRCM initiates and waits for completion of PM protocol to enable the modules (IdleReq/IdleAck).

## 2.9 Voltage Management Functional Description

This section describes the voltage domains and voltage control architecture. It also explains the interactions between the device and the external power IC.

### 2.9.1 Overview

The voltage-management architecture of the device is based on voltage sources managed by the PRCM module. They define the voltage domains within the device (see Section 2.8.1, *Voltage Domains*). This partition of the voltage domains ensures independent voltage control of each voltage domain through dedicated SMPS or LDO. The following voltage domains are managed by the PRCM module:

- VDD_ARM_L
- VDD_CORE_L
- VDD_DSP_L
- VDD_HDVICP_L
- LDO_ARM_M
- LDO_CORE_M
- LDO_DSP_M
- LDO_HDVICP_M
- LDO_ARM_ABB
- LDO_DSP_ABB
- LDO_HDVICP_ABB

**NOTE:** See the device *Datasheet* document for device power supply pin association to the power domain.

Table 2-40 lists the supported DVFS OPPs for each voltage domain. The exact values depend on the silicon; for more information, see the device *Datasheet*.

**Table 2-40. Supported DVFS OPPs Summary**

| Voltage Domain | Operating Point | Control |
|---|---|---|
| VDD_ARM_L (cvdd_arm) | OPP100 | Hardware and software |
| | OPP120 | |
| | OPP166 | |
| VDD_HDVICP_L (cvdd_hdvicp) | OPP100 | Hardware and software |
| | OPP120 | |
| | OPP166 | |
| VDD_CORE_L (cvdd) | OPP100 | Hardware and software |
| | OPP120 | |
| | OPP166 | |
| VDD_DSP_L (cvdd_dsp) | OPP100 | Hardware and software |
| | OPP120 | |
| | OPP166 | |

**NOTE:** For the supported OPPs for each device in the *Davinci* family, see in the device *Datasheet*.

#### DVFS OPPs Dependencies

For detailed information about DVFS OPP dependencies, see the device *Datasheet*.

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.9.2 Internal LDOs Control

#### 2.9.2.1 Memory LDOs

Embedded SRAM LDOs (that is, LDO_CORE_M, LDO_HDVICP_M, LDO_ARM_M and LDO_DSP_M) are used to supply power to the split-rail memory arrays. The PRM generates the controls used to select LDO operating mode: on-active, or off.

Split-rail type SRAMs are used in the device to implement the larger memories. These SRAMs feature memory array and periphery logic which are on separate supplies to allow independent power management. Proper memory operation, however, requires the SRAM array voltage to never be operated at a level lower than the SRAM periphery logic.

Memory LDO can switch to on, and off mode:

- On mode: 1.2 V is the normal voltage reference used through all functional OPPs, whenever memories must be functional. When logic voltage level VDD_x_L (where x can be ARM, CORE, HDVICP and DSP) becomes higher than the associated memory voltage level VDD_x_M, the LDO operates in the tracking mode and follows its respective the VDD_x_L voltage level.
- Off mode: 0 V is set when the device switches to off mode.

**NOTE:** The voltage levels associated with the different modes may depend on the device characteristics.

#### 2.9.2.2 ABB LDOs Control

The ABB LDO supports three voltage modes:

- Bypass mode: In this mode the <x>_ABB LDO is bypassed and outputs the VDD_<x>_L voltages (x refers to ARM, DSP, HDVICP). This mode is activated when ABB is not required, or when voltage domain enters low-power mode.
- ABB Set1: This mode is enabled at OPP_166.
- ABB Set2: This mode is enabled at OPP_120.

The Control module provides the SGX_VBBLDO_CTRL, HDVICP_VBBLDO_CTRL, C674x_DSP_VBBLDO_CTRL, ARM_CORTEX_A8_VBBLDO_CTRL registers for configuration with the following controls:

- LDOBYPASSZ – Bypass the ABB power management
- BBSEL – high selects FBB

The register RAMLDO_CTRL in Control module controls RAM LDOs. It provides following controls:

- AIPOFF - Disable LDO and enables IDDQ mode.
- SRAMALLRET - puts VDDAR in retention mode.
- ABBOFF - shorts VDDAR to VNWA.

## 2.10 PRCM Registers

The following are memory-mapped registers for the PRCM.

**Table 2-41. PRCM Memory Mapped Registers**

| Module Name | Base Address Offset | Size |
|---|---|---|
| PRM_DEVICE | 0x0000 | 256 Bytes |
| CM_DEVICE | 0x0100 | 256 Bytes |
| OCP_SOCKET_PRM | 0x0200 | 256 Bytes |
| CM_DPLL | 0x0300 | 256 Bytes |
| CM_ACTIVE (DSP) | 0x0400 | 256 Bytes |
| CM_DEFAULT | 0x0500 | 256 Bytes |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-41. PRCM Memory Mapped Registers (continued)**

| Module Name | Base Address Offset | Size |
|---|---|---|
| CM_HDVICP | 0x0600 | 256 Bytes |
| CM_ISS | 0x0700 | 256 Bytes |
| CM_DSS | 0x0800 | 256 Bytes |
| CM_SGX530 | 0x0900 | 256 Bytes |
| PRM_ACTIVE (DSP) | 0x0A00 | 256 Bytes |
| PRM_DEFAULT | 0x0B00 | 256 Bytes |
| PRM_HDVICP | 0x0C00 | 256 Bytes |
| PRM_ISP (ISS) | 0x0D00 | 256 Bytes |
| PRM_DSS | 0x0E00 | 256 Bytes |
| PRM_SGX530 | 0x0F00 | 256 Bytes |
| CM_ALWON | 0x1400 | 1 KBytes |
| PRM_ALWON | 0x1800 | 1 KBytes |

### 2.10.1 PLLSS Registers

Table 2-42 lists the memory-mapped registers for the PLLSS. All register offset addresses not listed in Table 2-42 should be considered as reserved locations and the register contents should not be modified.

**Table 2-42. PLLSS REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CONTROL_REVISION | The CONTROL_REVISION register is a read only register containing the revision number of the Control module.<br>A write to this register has no effect. | Section 3.2.1 |
| 4h | CONTROL_HWINFO | The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any). | Section 3.2.2 |
| 10h | CONTROL_SYSCONFIG | The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the OCP Design Guidelines. | Section 3.2.3 |
| 40h | PLLSS_MMR_LOCK | The PLLSS_MMR_LOCK Register is used allow/block writes to the registers in address region Start_Addess_x -End_Address_x.<br>This register has 2 states LOCKED and UNLOCKED<br>When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked.<br>When in UNLOCKED state all writes to Start_Addess_x -End_Address_x is allowed.<br>All reads to Start_Addess_x -End_Address_x should not be blocked by the state of PLLSS_MMR_LOCK registers but they should follow the underlying security specified in each section, e.g.<br>Firewall setting, Non Secure Supervisior etc. | Section 2.10.1.4 |
| 48h | MPUPLL_PWRCTRL | The MPU PLL Power Control register is used to control the power state of the MPU _PLL. | Section 2.10.1.5 |
| 4Ch | MPUPLL_CLKCTRL | The MPU PLL Clock Control register is used to control the different clock control state of the MPU_PLL | Section 2.10.1.6 |
| 50h | MPUPLL_TENABLE | The MPU PLL TENABLE register is used to load the M, N dividers of MPU_PLL | Section 2.10.1.7 |
| 54h | MPUPLL_TENABLEDIV | The MPU PLL TENABLEDIV register is used to load the M2,N2 dividers of MPU_PLL | Section 2.10.1.8 |
| 58h | MPUPLL_M2NDIV | MPU PLL M2NDIV register is for programming M2 and N values of MPU _PLL | Section 2.10.1.9 |
| 5Ch | MPUPLL_MN2DIV | MPU PLL MN2DIV register is for programming M and N2 values of MPU _PLL | Section 2.10.1.10 |
| 60h | MPUPLL_FRACDIV | The MPU PLL FRACDIV register is for controlling the fractional values of MPU _PLL | Section 2.10.1.11 |
| 64h | MPUPLL_BWCTRL | The MPU PLL_BWCTRL register is for controlling the loop bandwidth of MPU _PLL | Section 2.10.1.12 |
| 68h | MPUPLL_FRACCTRL | Controlls the fractional portion of Modena PLL | Section 2.10.1.13 |
| 6Ch | MPUPLL_STATUS | The MPU PLL Status register is for viewing the status of the MPU PLL. | Section 2.10.1.14 |
| 70h | MPUPLL_M3DIV | The MPU PLL_M3DIV register is for controlling the M3 divider of MPU _PLL | Section 2.10.1.15 |
| 74h | MPUPLL_RAMPCTRL | The MPUPLL_RAMPCTRL register is for controlling the ramping of MPU _PLL | Section 2.10.1.16 |
| 80h | DSPPLL_PWRCTRL | The PLL Power Control register is used to control the power state of therespective PLL. | Section 2.10.1.17 |
| 84h | DSPPLL_CLKCTRL | The PLL Clock Control register is used to control the different clock control state of the respective PLL | Section 2.10.1.18 |
| 88h | DSPPLL_TENABLE | Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ. | Section 2.10.1.19 |
| 8Ch | DSPPLL_TENABLEDIV | The PLL TENABLEDIV register is used to load the M2,N2 dividers of respective PLL | Section 2.10.1.20 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-42. PLLSS REGISTERS (continued)**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 90h | DSPPLL_M2NDIV | PLL M2NDIV register is for programming M2 and N values of respective PLL | Section 2.10.1.21 |
| 94h | DSPPLL_MN2DIV | PLL MN2DIV register is for programming M and N2 values of respective PLL | Section 2.10.1.22 |
| 98h | DSPPLL_FRACDIV | The PLL FRACDIV register is for controlling the fractional values of respective PLL | Section 2.10.1.23 |
| 9Ch | DSPPLL_BWCTRL | The PLL_BWCTRL register is for controlling the loop bandwidth of respective PLL | Section 2.10.1.24 |
| A0h | DSPPLL_FRACCTRL | Controlls the fractional portion of respective ADPLLLJ. | Section 2.10.1.25 |

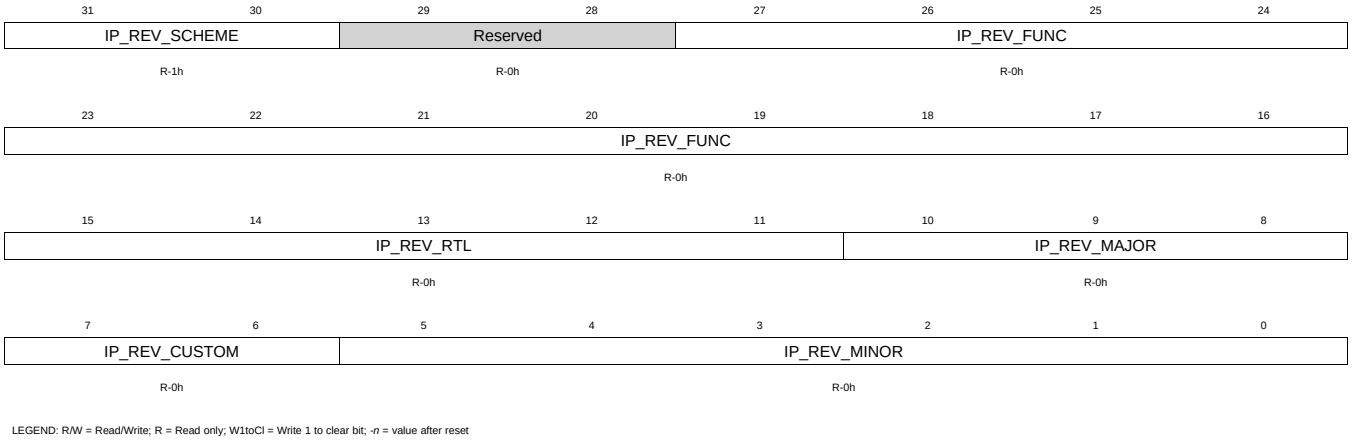
### 2.10.1.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h]

CONTROL_REVISION is shown in Figure 3-2 and described in Table 3-4.

The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.

**Figure 2-27. CONTROL_REVISION Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-43. CONTROL_REVISION Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-30 | IP_REV_SCHEME | R | 1h | Used to distinguish register scheme<br>0x0: Legacy (ASP or WTBU) scheme<br>0x1: Highlander 0.8 scheme |
| 29-28 | Reserved | R | 0h | |
| 27-16 | IP_REV_FUNC | R | 0h | Function indicates a software compatible module family. If there is no level of software compatibility a new Func number (and hence REVISION) should be assigned. |
| 15-11 | IP_REV_RTL | R | 0h | RTL Version (R), maintained by IP design owner. |
| 10-8 | IP_REV_MAJOR | R | 0h | Major Revision (X), maintained by IP specification owner. |
| 7-6 | IP_REV_CUSTOM | R | 0h | Indicates a special version for a particular device. Consequence of use may avoid use of standard Chip Support Library (CSL) / Drivers |
| 5-0 | IP_REV_MINOR | R | 0h | Minor Revision (Y), maintained by IP specification owner. |

### 2.10.1.2 CONTROL_HWINFO Register (offset = 4h) [reset = 0h]

CONTROL_HWINFO is shown in Figure 3-3 and described in Table 3-5.

The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any).

**Figure 2-28. CONTROL_HWINFO Register**

### 2.10.1.3 CONTROL_SYSCONFIG Register (offset = 10h) [reset = 2Ah]

CONTROL_SYSCONFIG is shown in Figure 3-4 and described in Table 3-6.

The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the OCP Design Guidelines.

### 2.10.1.4 PLLSS_MMR_LOCK Register (offset = 40h) [reset = 1F125B64h]

PLLSS_MMR_LOCK is shown in Figure 2-30 and described in Table 2-46.

The PLLSS_MMR_LOCK Register is used allow/block writes to the registers in address region Start_Addess_x -End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x -End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of PLLSS_MMR_LOCK registers but they should follow the underlying security specified in each section, e.g. Firewall setting, Non Secure Supervisior etc.

**Figure 2-30. PLLSS_MMR_LOCK Register**

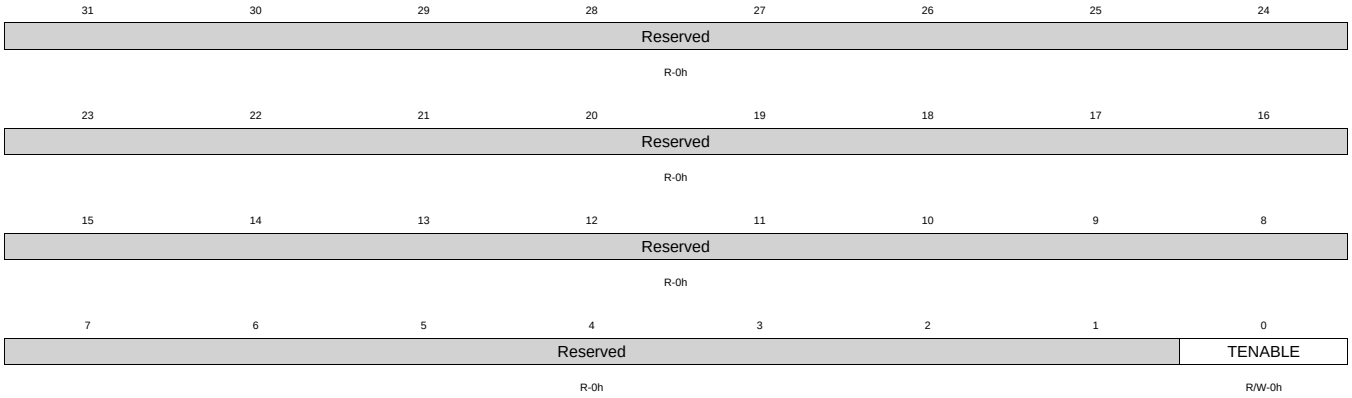
### 2.10.1.29 SGXPLLL_TENABLE Register (offset = B8h) [reset = 0h]

SGXPLLL_TENABLE is shown in Figure 2-55 and described in Table 2-71.

Load the M, N, SD and SELFREQDCO dividers of the particular ADPLLLJ.

**Figure 2-55. SGXPLLL_TENABLE Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-71. SGXPLLL_TENABLE Register Field Descriptions**

### 2.10.1.146 CLKOUT_MUX Register (offset = 2E4h) [reset = 0h]

CLKOUT_MUX is shown in Figure 2-172 and described in Table 2-188.

Control the options for CLKOUT multiplexing. The clock outputs are respectively CLKOUT0 and CLKOUT1.

### 2.10.1.151 DEEPSLEEP_CTRL Register (offset = 324h) [reset = 6A75h]

DEEPSLEEP_CTRL is shown in Figure 2-177 and described in Table 2-193.

The DEEPSLEEP control register is used to control deep sleep power mode. Deep sleep is not supported on this SoC.

**Figure 2-177. DEEPSLEEP_CTRL Register**

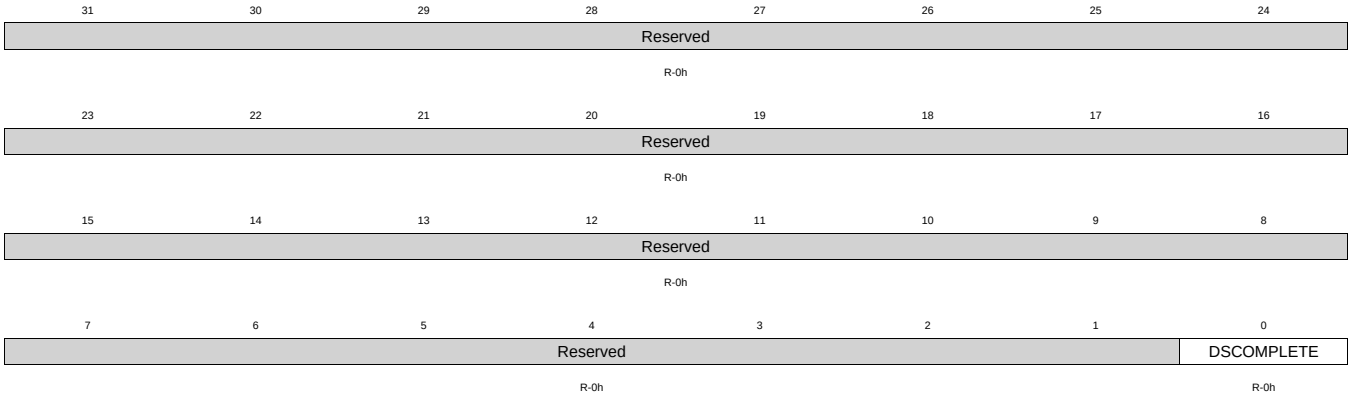
### 2.10.1.152 DEEPSLEEP_STATUS Register (offset = 328h) [reset = 0h]

DEEPSLEEP_STATUS is shown in Figure 2-178 and described in Table 2-194.

The DEEPSLEEP control register logs the internal deepsleep counter value.

**Figure 2-178. DEEPSLEEP_STATUS Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-194. DEEPSLEEP_STATUS Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-1 | Reserved | R | 0h | |
| 0 | DSCOMPLETE | R | 0h | 1' if DSCOUNT value equals the internal deepsleep counter value |

## *2.10.2 PRM_DEVICE Registers*

Table 2-195 lists the memory-mapped registers for the PRM_DEVICE. All register offset addresses not listed in Table 2-195 should be considered as reserved locations and the register contents should not be modified.

**Table 2-195. PRM_DEVICE REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| A0h | PRM_RSTCTRL | Global software cold and warm reset control.<br>This register is auto-cleared.<br>Only write 1 is possible.<br>A read returns 0 only. | Section 2.10.2.1 |
| A4h | PRM_RSTTIME | Reset duration control. | Section 2.10.2.2 |
| A8h | PRM_RSTST | This register logs the global reset sources.<br>Each bit is set upon release of the domain reset signal.<br>Must be cleared by software.<br>[warm reset insensitive] | Section 2.10.2.3 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.2.1 PRM_RSTCTRL Register (offset = A0h) [reset = 0h]

PRM_RSTCTRL is shown in Figure 2-179 and described in Table 2-196.

Global software cold and warm reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.

**Figure 2-179. PRM_RSTCTRL Register**

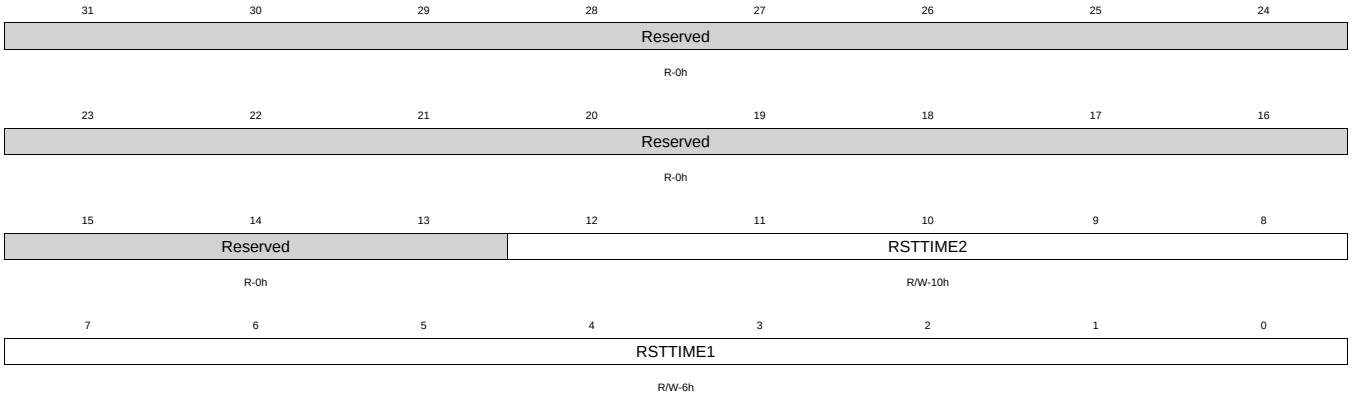
### 2.10.2.2 PRM_RSTTIME Register (offset = A4h) [reset = 1006h]

PRM_RSTTIME is shown in Figure 2-180 and described in Table 2-197.

Reset duration control.

**Figure 2-180. PRM_RSTTIME Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 2-197. PRM_RSTTIME Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.2.3 PRM_RSTST Register (offset = A8h) [reset = 1h]

PRM_RSTST is shown in Figure 2-181 and described in Table 2-198.

This register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

**Figure 2-181. PRM_RSTST Register**

## *2.10.3 CM_DEVICE Registers*

Table 2-199 lists the memory-mapped registers for the CM_DEVICE. All register offset addresses not listed in Table 2-199 should be considered as reserved locations and the register contents should not be modified.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-199. CM_DEVICE REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CM_CLKOUT_CTRL | This register provides the control over SYS_CLKOUT output | Section 2.10.3.1 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.3.1 CM_CLKOUT_CTRL Register (offset = 0h) [reset = 0h]

CM_CLKOUT_CTRL is shown in Figure 2-182 and described in Table 2-200.

This register provides the control over SYS_CLKOUT output

**Figure 2-182. CM_CLKOUT_CTRL Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

## *2.10.4 OCP_SOCKET_PRM Registers*

Table 2-201 lists the memory-mapped registers for the OCP_SOCKET_PRM. All register offset addresses not listed in Table 2-201 should be considered as reserved locations and the register contents should not be modified.

**Table 2-201. OCP_SOCKET_PRM REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | REVISION_PRM | This register contains the IP revision code for the PRCM | Section 2.10.4.1 |

Copyright © 2011–2016, Texas Instruments Incorporated

#### 2.10.4.1 REVISION_PRM Register (offset = 0h) [reset = 10h]

REVISION_PRM is shown in Figure 2-183 and described in Table 2-202.

This register contains the IP revision code for the PRCM

**Figure 2-183. REVISION_PRM Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-8 | Reserved | R | 0h | |
| 7-0 | Rev | R | 10h | IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1 |

### *2.10.5 CM_DPLL Registers*

Table 2-203 lists the memory-mapped registers for the CM_DPLL. All register offset addresses not listed in Table 2-203 should be considered as reserved locations and the register contents should not be modified.

**Table 2-203. CM_DPLL REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 8h | CM_SYSCLK3_CLKSEL | Selects the divider value for SYSCLK3 | Section 2.10.5.1 |
| 24h | CM_SYSCLK10_CLKSEL | Selects the divider value for SYSCLK10 | Section 2.10.5.2 |
| 40h | CM_VPB3_CLKSEL | Selects the divider value for Video PLL B3 divider | Section 2.10.5.3 |
| 44h | CM_VPC1_CLKSEL | Selects the divider value for Video PLL C1 divider | Section 2.10.5.4 |
| 48h | CM_VPD1_CLKSEL | Selects the divider value for Video PLL D1 divider | Section 2.10.5.5 |
| 4Ch | CM_SYSCLK19_CLKSEL | Selects the divider value for SYSCLK19 clock | Section 2.10.5.6 |
| 50h | CM_SYSCLK20_CLKSEL | Selects the divider value for SYSCLK20 clock | Section 2.10.5.7 |
| 54h | CM_SYSCLK21_CLKSEL | Selects the divider value for SYSCLK21 clock | Section 2.10.5.8 |
| 58h | CM_SYSCLK22_CLKSEL | Selects the divider value for SYSCLK22 clock | Section 2.10.5.9 |
| 5Ch | CM_APA_CLKSEL | Selects the divider value for Audio PLL A divider | Section 2.10.5.10 |
| 70h | CM_SYSCLK14_CLKSEL | Selects the Mux select line for SYSCLK14 clock | Section 2.10.5.11 |
| 74h | CM_SYSCLK16_CLKSEL | Selects the Mux select line for SYSCLK16 clock | Section 2.10.5.12 |
| 78h | CM_SYSCLK18_CLKSEL | Selects the Mux select line for SYSCLK18 clock | Section 2.10.5.13 |
| 7Ch | CM_AUDIOCLK_MCASP0_CLKSEL | Selects the Mux select line for McASP0 audio clock | Section 2.10.5.14 |
| 80h | CM_AUDIOCLK_MCASP1_CLKSEL | Selects the Mux select line for McASP1 audio clock | Section 2.10.5.15 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-203. CM_DPLL REGISTERS (continued)**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 84h | CM_AUDIOCLK_MCASP2_CLKSEL | Selects the Mux select line for McASP2 audio clock | Section 2.10.5.16 |
| 88h | CM_AUDIOCLK_MCBSP_CLKSEL | Selects the Mux select line for McBSP audio clock | Section 2.10.5.17 |
| ACh | CM_HDMI_CLKSEL | Selects the Mux select line for HDMI audio clock | Section 2.10.5.18 |
| B0h | CM_SYSCLK23_CLKSEL | Selects the divider value for SYSCLK23 which is the SGX functional clock | Section 2.10.5.19 |

## *2.10.6 CM_ACTIVE Registers*

Table 2-223 lists the memory-mapped registers for the CM_ACTIVE. All register offset addresses not listed in Table 2-223 should be considered as reserved locations and the register contents should not be modified.

**Table 2-223. CM_ACTIVE REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CM_GEM_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states.<br>It also hold one status bit per clock input of the domain. | Section 2.10.6.1 |
| 20h | CM_ACTIVE_GEM_CLKCTRL | This register manages the DSP Subsystem C674x clocks. | Section 2.10.6.2 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.6.1 CM_GEM_CLKSTCTRL Register (offset = 0h) [reset = 1h]

CM_GEM_CLKSTCTRL is shown in Figure 2-203 and described in Table 2-224.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-203. CM_GEM_CLKSTCTRL Register**

## *2.10.7 CM_DEFAULT Registers*

Table 2-226 lists the memory-mapped registers for the CM_DEFAULT. All register offset addresses not listed in Table 2-226 should be considered as reserved locations and the register contents should not be modified.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-226. CM_DEFAULT REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 10h | CM_DEFAULT_PCI_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. | Section 2.10.7.1 |
| 18h | CM_DEFAULT_DUCATI_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. | Section 2.10.7.2 |
| 28h | CM_DEFAULT_DMM_CLKCTRL | This register manages the DMM clocks. | Section 2.10.7.3 |
| 54h | Reserved | | |
| 58h | CM_DEFAULT_USB_CLKCTRL | This register manages the USB clocks. | Section 2.10.7.4 |
| 60h | CM_DEFAULT_SATA_CLKCTRL | This register manages the SATA clocks. | Section 21.6.2 |
| 74h | CM_DEFAULT_DUCATI_CLKCTRL | This register manages the DUCATI clocks. | Section 2.10.7.6 |
| 78h | CM_DEFAULT_PCI_CLKCTRL | This register manages the PCI clocks. | Section 2.10.7.7 |

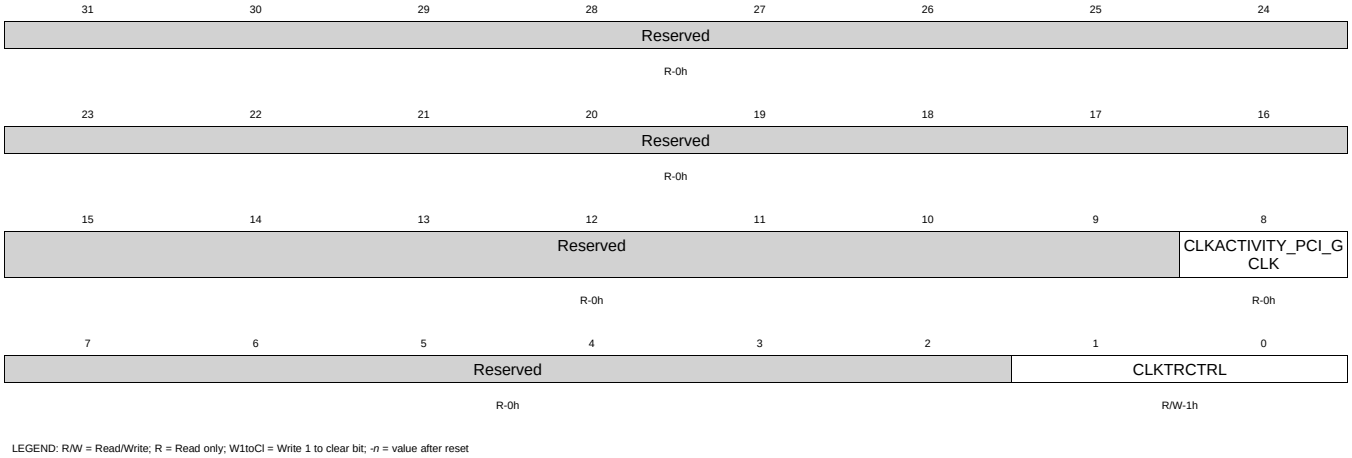
Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.7.1 CM_DEFAULT_PCI_CLKSTCTRL Register (offset = 10h) [reset = 1h]

CM_DEFAULT_PCI_CLKSTCTRL is shown in Figure 2-206 and described in Table 2-228.

This register manages the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-205. CM_DEFAULT_PCI_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 2.10.7.2 CM_DEFAULT_DUCATI_CLKSTCTRL Register (offset = 18h) [reset = 1h]

CM_DEFAULT_DUCATI_CLKSTCTRL is shown in Figure 2-206 and described in Table 2-228.

This register manages the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

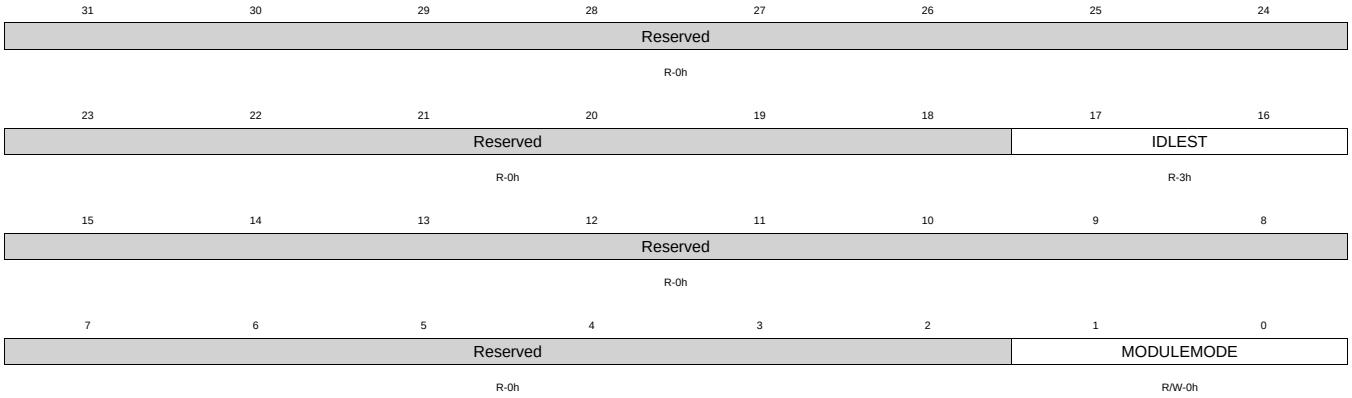
### 2.10.7.3 CM_DEFAULT_DMM_CLKCTRL Register (offset = 28h) [reset = 30000h]

CM_DEFAULT_DMM_CLKCTRL is shown in Figure 2-207 and described in Table 2-229.

This register manages the DMM clocks.

**Figure 2-207. CM_DEFAULT_DMM_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-229. CM_DEFAULT_DMM_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-18 | Reserved | R | 0h | |
| 17-16 | IDLEST | R | 3h | Module idle status.<br>0x0: Func: Module is fully functional, including INTERCONN<br>0x1: Trans: Module is performing transition: wakeup, or sleep, or sleep abortion<br>0x2: Idle: Module is in Idle mode (only INTERCONN part). It is functional if using separate functional clock<br>0x3: Disable: Module is disabled and cannot be accessed |
| 15-2 | Reserved | R | 0h | |
| 1-0 | MODULEMODE | R/W | 0h | Control the way mandatory clocks are managed.<br>0x0: DISABLED: Module is disable by SW. Any INTERCONN access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).<br>0x1: RESERVED<br>0x2: ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.<br>0x3: RESERVED |

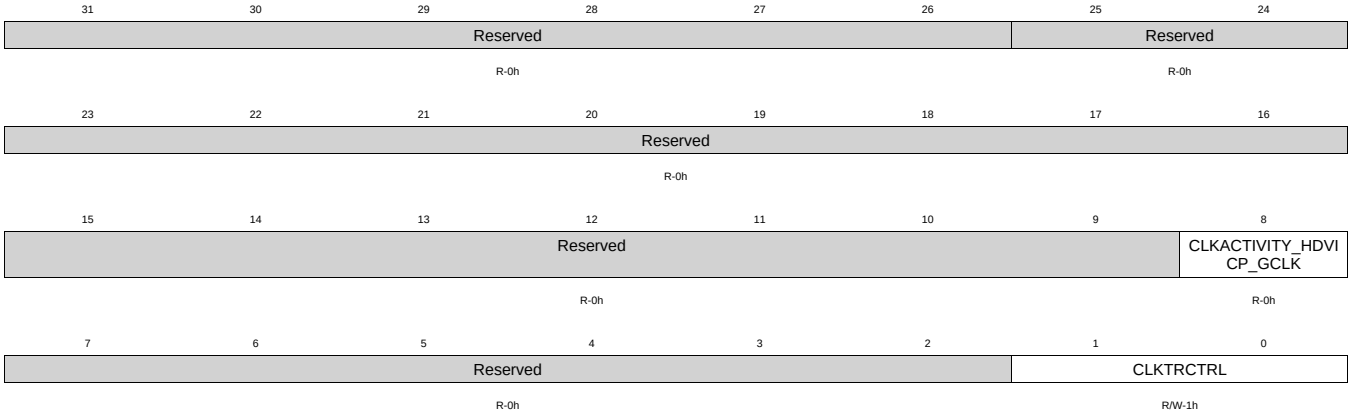
### 2.10.8.1 CM_HDVICP_CLKSTCTRL Register (offset = 0h) [reset = 1h]

CM_HDVICP_CLKSTCTRL is shown in Figure 2-212 and described in Table 2-235.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-212. CM_HDVICP_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

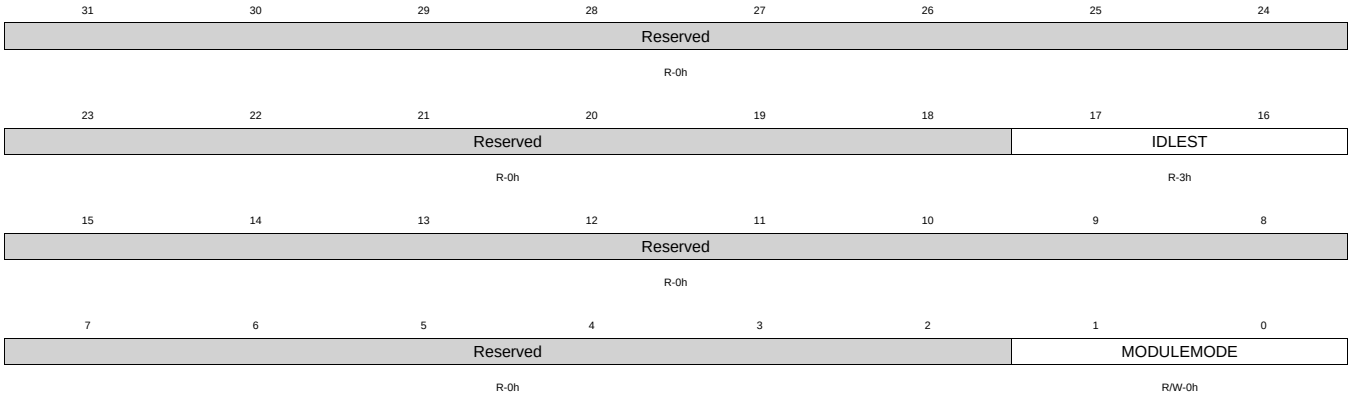
### 2.10.8.3 CM_HDVICP_SL2_CLKCTRL Register (offset = 24h) [reset = 30000h]

CM_HDVICP_SL2_CLKCTRL is shown in Figure 2-214 and described in Table 2-237.

This register manages the SL2 clocks.

**Figure 2-214. CM_HDVICP_SL2_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 2-237. CM_HDVICP_SL2_CLKCTRL Register Field Descriptions**

It is functional if using separate functional clock<br>0x3: Disable : Module is disabled and cannot be accessed |
| 15-2 | Reserved | R | 0h | |
| 1-0 | MODULEMODE | R/W | 0h | Control the way mandatory clocks are managed.<br>0x0: DISABLED: Module is disable by SW. Any INTERCONN access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).<br>0x1: RESERVED<br>0x2: ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.<br>0x3: RESERVED |

## 2.10.9 CM_ISP Registers

Table 2-238 lists the memory-mapped registers for the CM_ISP. All register offset addresses not listed in Table 2-238 should be considered as reserved locations and the register contents should not be modified.

**Table 2-238. CM_ISP REGISTERS**

| Offset | Acronym | Register Description | Section |
|---|---|---|---|
| 0h | CM_ISP_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. | Section 2.10.9.1 |
| 20h | CM_ISP_ISP_CLKCTRL | This register manages the ISP clocks. | Section 2.10.9.2 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 2-238. CM_ISP REGISTERS (continued)**

| Offset | Acronym | Register Description | Section |
|---|---|---|---|
| 24h | CM_ISP_FDIF_CLKCTRL | This register manages the FDIF clocks. | Section 2.10.9.3 |

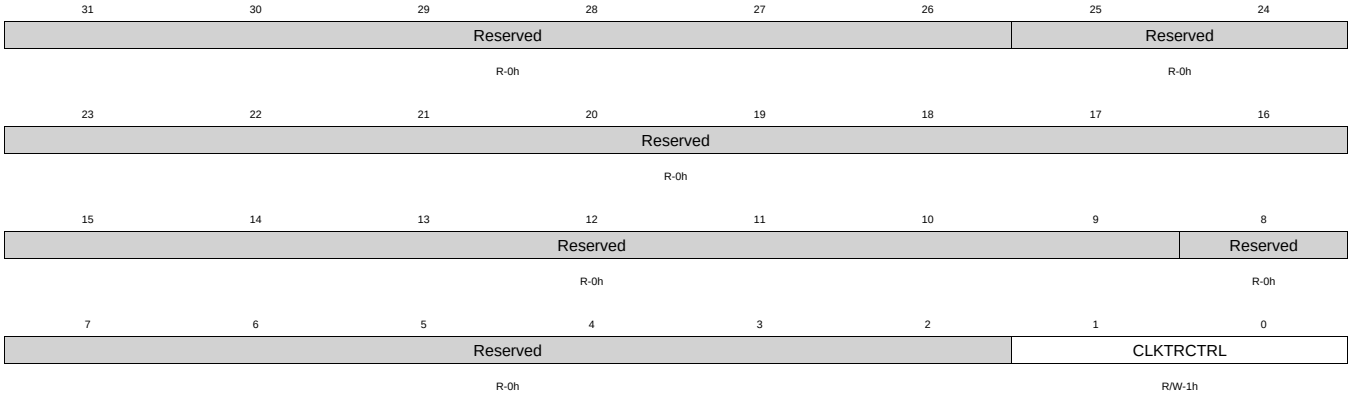
### 2.10.9.1 CM_ISP_CLKSTCTRL Register (offset = 0h) [reset = 1h]

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_ISP_CLKSTCTRL is shown in Figure 2-215 and described in Table 2-239.

**Figure 2-215. CM_ISP_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-239. CM_ISP_CLKSTCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-26 | Reserved | R | 0h | |
| 25-9 | Reserved | R | 0h | |
| 8 | Reserved | R | 0h | |
| 7-2 | Reserved | R | 0h | |
| 1-0 | CLKTRCTRL | R/W | 1h | Controls the clock state transition of the ISP clock domain in ISP power domain.<br>0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur.<br>1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain.<br>2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain.<br>3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions. |

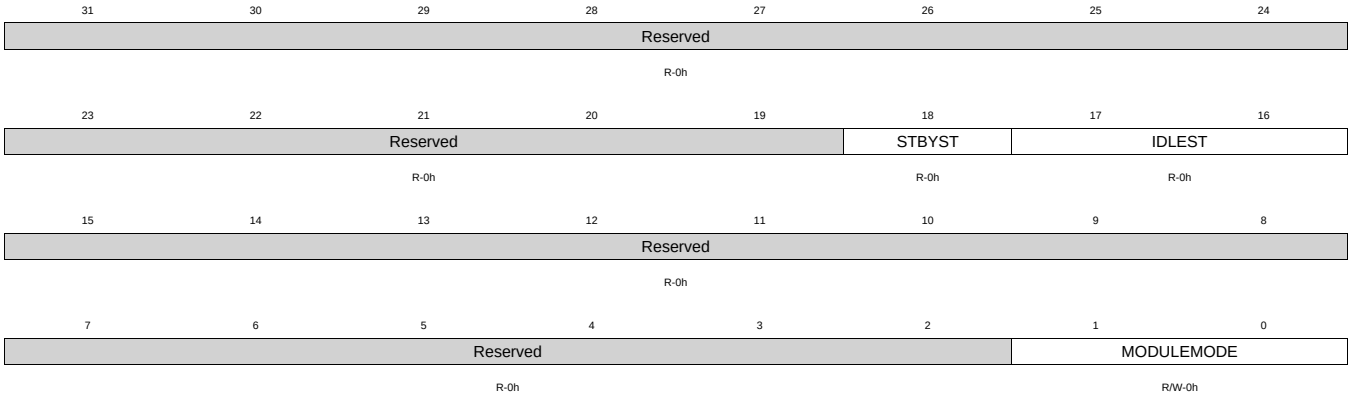
Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.9.2 CM_ISP_ISP_CLKCTRL Register (offset = 20h) [reset = 0h]

This register manages the ISP clocks.

CM_ISP_ISP_CLKCTRL is shown in Figure 2-216 and described in Table 2-240.

**Figure 2-216. CM_ISP_ISP_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-240. CM_ISP_ISP_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-19 | Reserved | R | 0h | |
| 18 | STBYST | R | 0h | Module standby status.<br>0 - Func: Module is functional (not in standby)<br>1 - Standby: Module is in standby |
| 17-16 | IDLEST | R | 0h | Module idle status.<br>0 - Func: Module is fully functional, including OCP<br>1 - Trans: Module is performing transition: wakeup, or sleep, or sleep abortion<br>2 - Idle: Module is in Idle mode (only OCP part). It is functional if using separate functional clock<br>3 - Disable: Module is disabled and cannot be accessed |
| 15-2 | Reserved | R | 0h | |
| 1-0 | MODULEMODE | R/W | 0h | Control the way mandatory clocks are managed.<br>0 - DISABLED: Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).<br>1 - RESERVED_1: Reserved<br>2 - ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.<br>3 - RESERVED: Reserved |

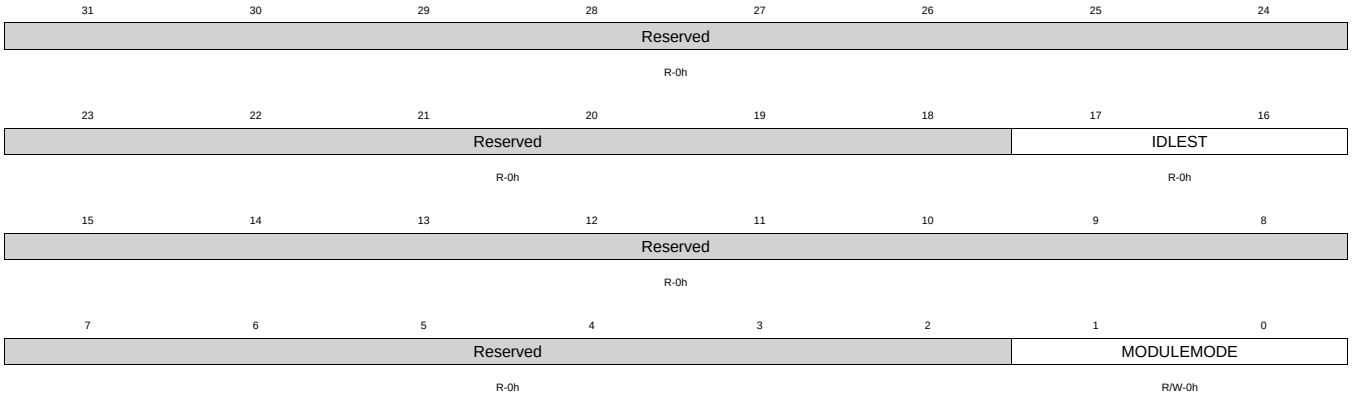
Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.9.3 CM_ISP_FDIF_CLKCTRL Register (offset = 24h) [reset = 0h]

This register manages the FDIF clocks.

CM_ISP_FDIF_CLKCTRL is shown in Figure 2-217 and described in Table 2-241.

**Figure 2-217. CM_ISP_FDIF_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-241. CM_ISP_FDIF_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

It is functional if using separate functional clock<br>3 - Disable: Module is disabled and cannot be accessed |
| 15-2 | Reserved | R | 0h | |
| 1-0 | MODULEMODE | R/W | 0h | Control the way mandatory clocks are managed.<br>0 - DISABLED: Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).<br>1 - RESERVED_1: Reserved<br>2 - ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.<br>3 - RESERVED: Reserved |

## *2.10.10 CM_DSS Registers*

Table 2-242 lists the memory-mapped registers for the CM_DSS. All register offset addresses not listed in Table 2-242 should be considered as reserved locations and the register contents should not be modified.

**Table 2-242. CM_DSS REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CM_DSS_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states.<br>It also hold one status bit per clock input of the domain. | Section 2.10.10.1 |
| 20h | CM_DSS_DSS_CLKCTRL | This register manages the DSS clocks. | Section 2.10.10.2 |
| 24h | CM_DSS_HDMI_CLKCTRL | This register manages the HDMI clocks. | Section 2.10.10.3 |

Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.10.1 CM_DSS_CLKSTCTRL Register (offset = 0h) [reset = 1h]

CM_DSS_CLKSTCTRL is shown in Figure 2-218 and described in Table 2-243.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-218. CM_DSS_CLKSTCTRL Register**

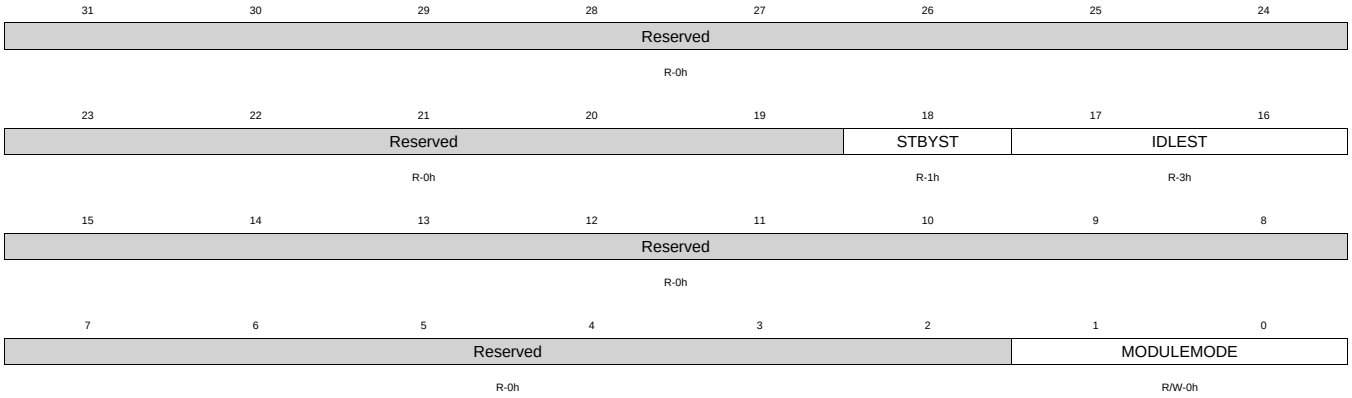
### 2.10.10.2 CM_DSS_DSS_CLKCTRL Register (offset = 20h) [reset = 70000h]

CM_DSS_DSS_CLKCTRL is shown in Figure 2-219 and described in Table 2-244.

This register manages the DSS clocks.

**Figure 2-219. CM_DSS_DSS_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

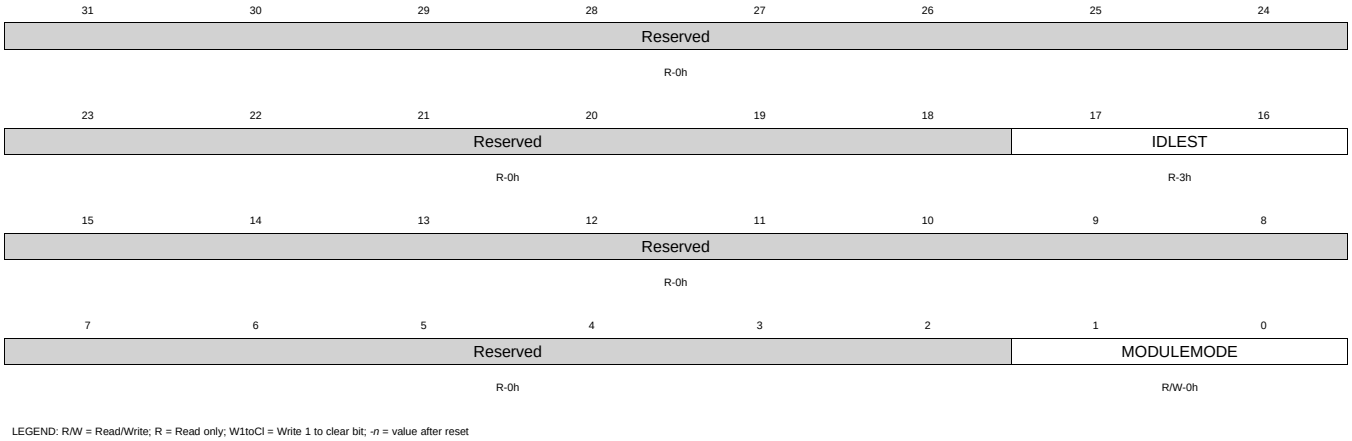
### 2.10.10.3 CM_DSS_HDMI_CLKCTRL Register (offset = 24h) [reset = 30000h]

CM_DSS_HDMI_CLKCTRL is shown in Figure 2-220 and described in Table 2-245.

This register manages the HDMI clocks.

**Figure 2-220. CM_DSS_HDMI_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-245. CM_DSS_HDMI_CLKCTRL Register Field Descriptions**

## *2.10.11 CM_SGX Registers*

Table 2-246 lists the memory-mapped registers for the CM_SGX. All register offset addresses not listed in Table 2-246 should be considered as reserved locations and the register contents should not be modified.

**Table 2-246. CM_SGX REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CM_SGX_CLKSTCTRL | This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states.<br>It also hold one status bit per clock input of the domain. | Section 2.10.11.1 |
| 20h | CM_SGX_SGX_CLKCTRL | This register manages the SGX clocks. | Section 2.10.11.2 |

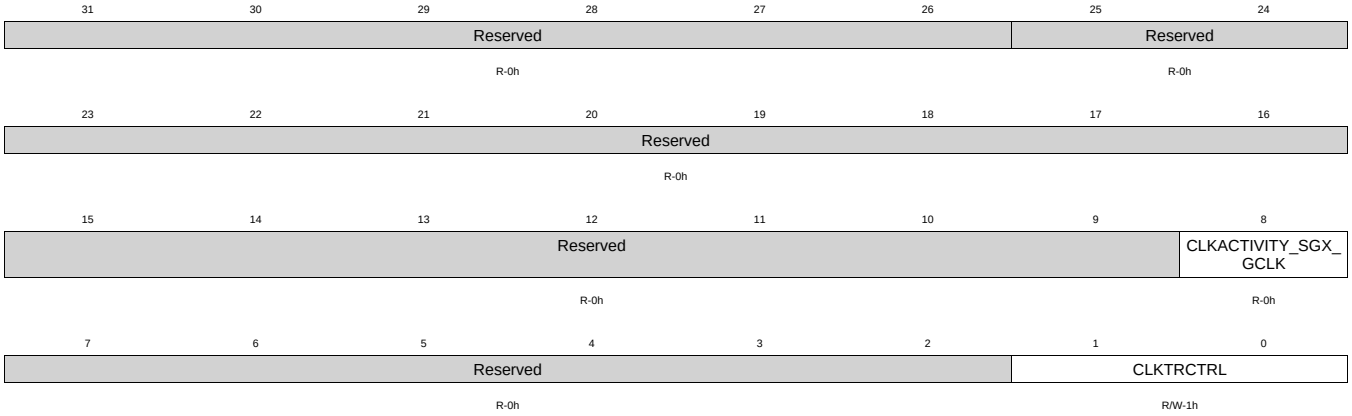
Copyright © 2011–2016, Texas Instruments Incorporated

### 2.10.11.1 CM_SGX_CLKSTCTRL Register (offset = 0h) [reset = 1h]

CM_SGX_CLKSTCTRL is shown in Figure 2-221 and described in Table 2-247.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-221. CM_SGX_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-247. CM_SGX_CLKSTCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-26 | Reserved | R | 0h | |
| 25-9 | Reserved | R | 0h | |
| 8 | CLKACTIVITY_SGX_GCLK | R | 0h | This field indicates the state of the SGX_GCLK clock in the domain.<br>0x0: Inact: Corresponding clock is gated<br>0x1: Act: Corresponding clock is active |
| 7-2 | Reserved | R | 0h | |
| 1-0 | CLKTRCTRL | R/W | 1h | Controls the clock state transition of the SGX clock domain in SGX power domain.<br>0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur.<br>0x1: SW_SLEEP: Start a software forced sleep transition on the domain.<br>0x2: SW_WKUP: Start a software forced wake-up transition on the domain.<br>0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions. |

### 2.10.12.4 RM_ACTIVE_RSTST Register (offset = 14h) [reset = 0h]

RM_ACTIVE_RSTST is shown in Figure 2-226 and described in Table 2-253.

This register logs the different reset sources of the ACTIVE domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

### 2.10.16.1 PM_DSS_PWRSTCTRL Register (offset = 0h) [reset = 30000h]

PM_DSS_PWRSTCTRL is shown in Figure 2-238 and described in Table 2-269.

This register controls the DSS power state to reach upon a domain sleep transition [warm reset insensitive]

**Figure 2-238. PM_DSS_PWRSTCTRL Register**

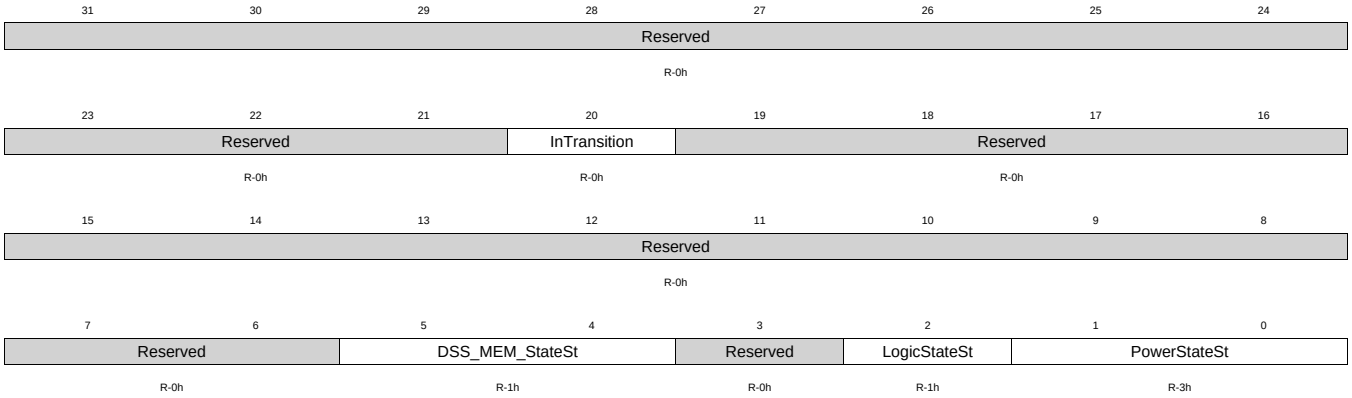
### 2.10.16.2 PM_DSS_PWRSTST Register (offset = 4h) [reset = 17h]

PM_DSS_PWRSTST is shown in Figure 2-239 and described in Table 2-270.

This register provides a status on the current DSS power domain state. [warm reset insensitive]

**Figure 2-239. PM_DSS_PWRSTST Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

### 2.10.16.3 RM_DSS_RSTCTRL Register (offset = 10h) [reset = 7h]

RM_DSS_RSTCTRL is shown in Figure 2-240 and described in Table 2-271.

This register controls the release of the DSS sub-system resets.

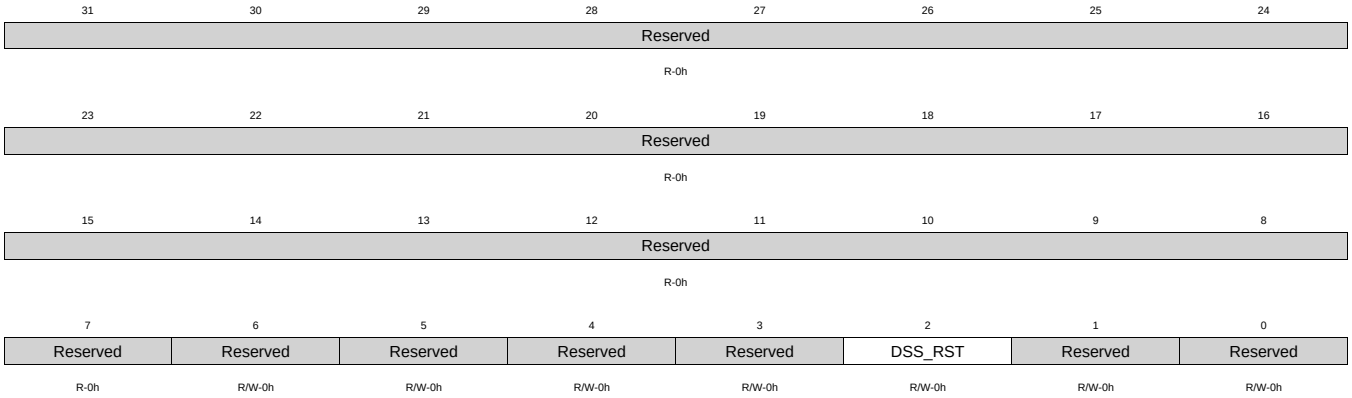
### 2.10.16.4 RM_DSS_RSTST Register (offset = 14h) [reset = 0h]

RM_DSS_RSTST is shown in Figure 2-241 and described in Table 2-272.

This register logs the different reset sources of the DSS domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

**Figure 2-241. RM_DSS_RSTST Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

### 2.10.18.1 CM_ALWON_L3_SLOW_CLKSTCTRL Register (offset = 0h) [reset = C002h]

CM_ALWON_L3_SLOW_CLKSTCTRL is shown in Figure 2-246 and described in Table 2-279.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-246. CM_ALWON_L3_SLOW_CLKSTCTRL Register**

### 2.10.18.2 CM_ETHERNET_CLKSTCTRL Register (offset = 4h) [reset = 1h]

CM_ETHERNET_CLKSTCTRL is shown in Figure 2-247 and described in Table 2-280.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-247. CM_ETHERNET_CLKSTCTRL Register**

### 2.10.18.4 CM_MMU_CLKSTCTRL Register (offset = Ch) [reset = 1h]

CM_MMU_CLKSTCTRL is shown in Figure 2-249 and described in Table 2-282.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-249. CM_MMU_CLKSTCTRL Register**

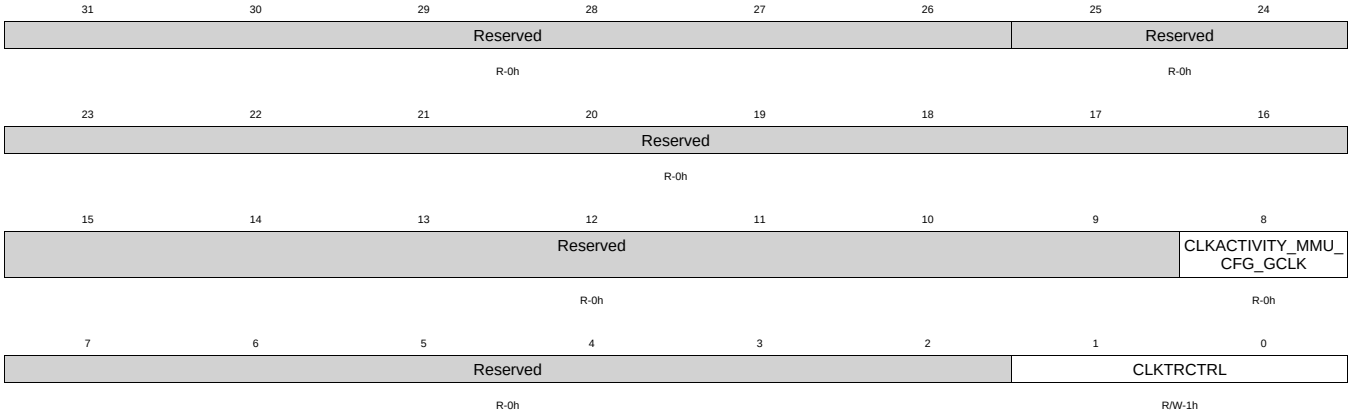
### 2.10.18.5 CM_MMUCFG_CLKSTCTRL Register (offset = 10h) [reset = 1h]

CM_MMUCFG_CLKSTCTRL is shown in Figure 2-250 and described in Table 2-283.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-250. CM_MMUCFG_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

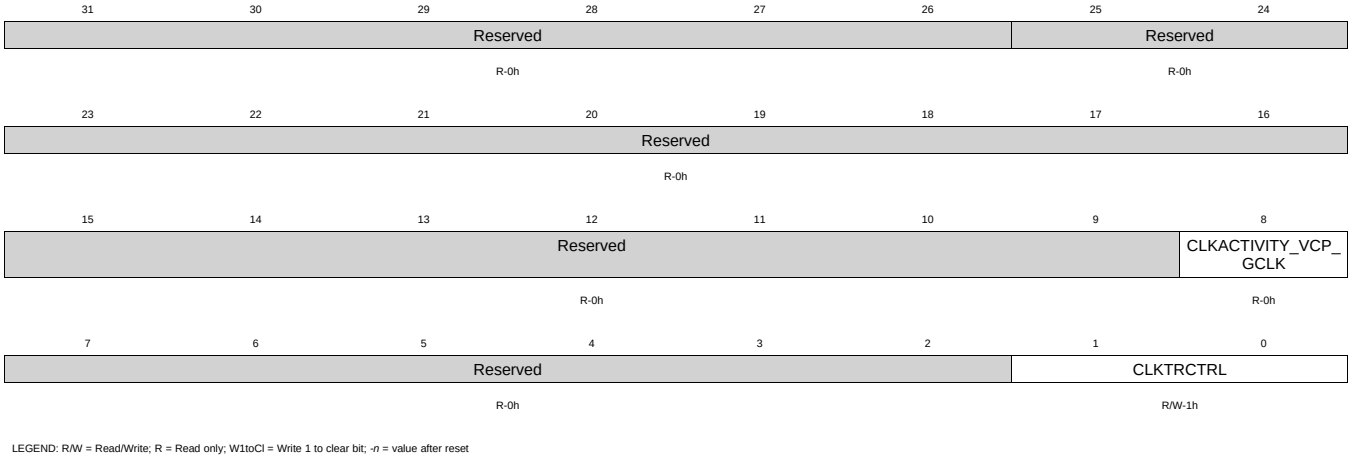
### 2.10.18.6 CM_ALWON_OCMC_0_CLKSTCTRL Register (offset = 14h) [reset = 1h]

CM_ALWON_OCMC_0_CLKSTCTRL is shown in Figure 2-251 and described in Table 2-284.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-251. CM_ALWON_OCMC_0_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

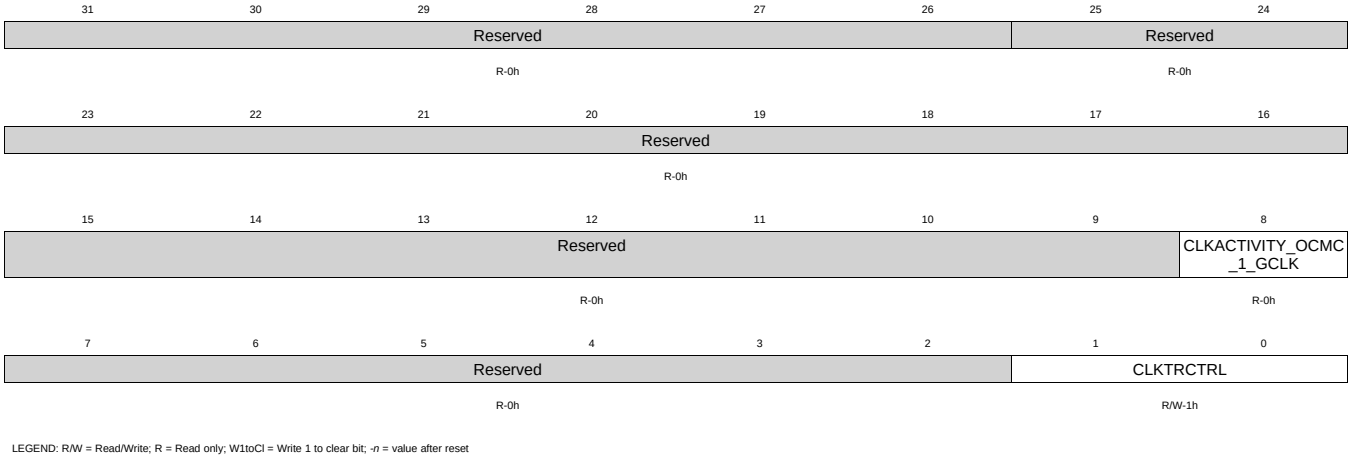
### 2.10.18.7 CM_ALWON_VCP_CLKSTCTRL Register (offset = 18h) [reset = 1h]

CM_ALWON_VCP_CLKSTCTRL is shown in Figure 2-252 and described in Table 2-285.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-252. CM_ALWON_VCP_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

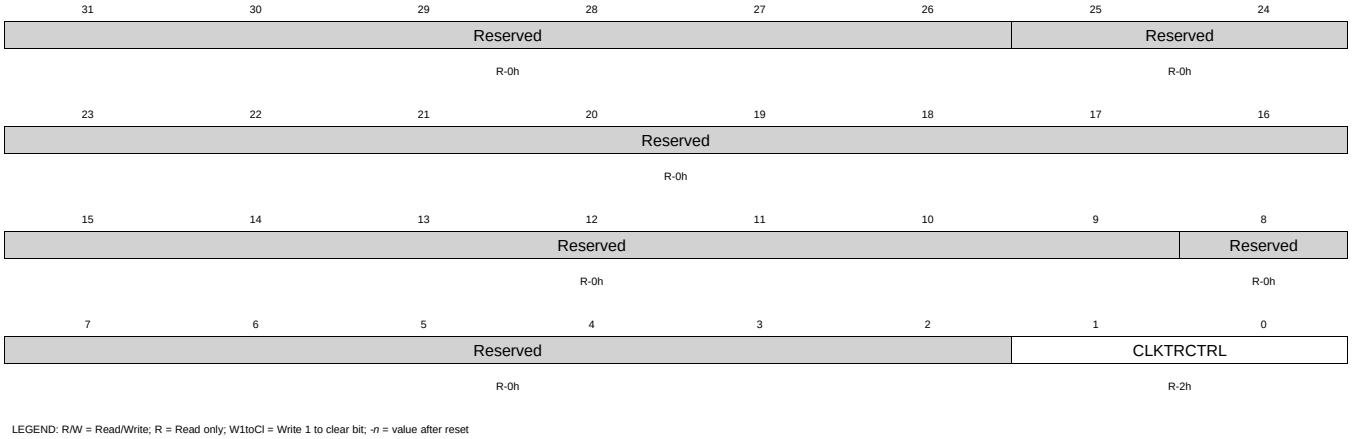
### 2.10.18.8 CM_ALWON_MPU_CLKSTCTRL Register (offset = 1Ch) [reset = 2h]

CM_ALWON_MPU_CLKSTCTRL is shown in Figure 2-253 and described in Table 2-286.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-253. CM_ALWON_MPU_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 2.10.18.9 CM_ALWON_SYSCLK4_CLKSTCTRL Register (offset = 20h) [reset = 2h]

CM_ALWON_SYSCLK4_CLKSTCTRL is shown in Figure 2-254 and described in Table 2-287.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

### 2.10.18.10 CM_ALWON_SYSCLK5_CLKSTCTRL Register (offset = 24h) [reset = 2h]

CM_ALWON_SYSCLK5_CLKSTCTRL is shown in Figure 2-255 and described in Table 2-288.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

### 2.10.18.11 CM_ALWON_SYSCLK6_CLKSTCTRL Register (offset = 28h) [reset = 2h]

CM_ALWON_SYSCLK6_CLKSTCTRL is shown in Figure 2-256 and described in Table 2-289.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

### 2.10.18.12 CM_ALWON_RTC_CLKSTCTRL Register (offset = 2Ch) [reset = 2h]

CM_ALWON_RTC_CLKSTCTRL is shown in Figure 2-257 and described in Table 2-290.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-257. CM_ALWON_RTC_CLKSTCTRL Register**

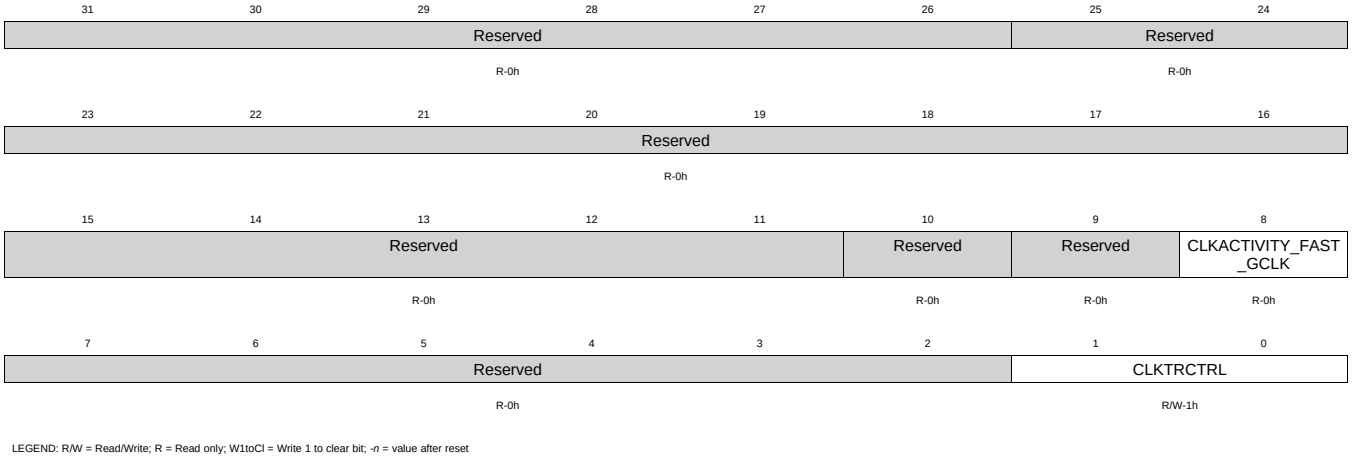
### 2.10.18.13 CM_ALWON_L3_FAST_CLKSTCTRL Register (offset = 30h) [reset = 1h]

CM_ALWON_L3_FAST_CLKSTCTRL is shown in Figure 2-258 and described in Table 2-291.

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 2-258. CM_ALWON_L3_FAST_CLKSTCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

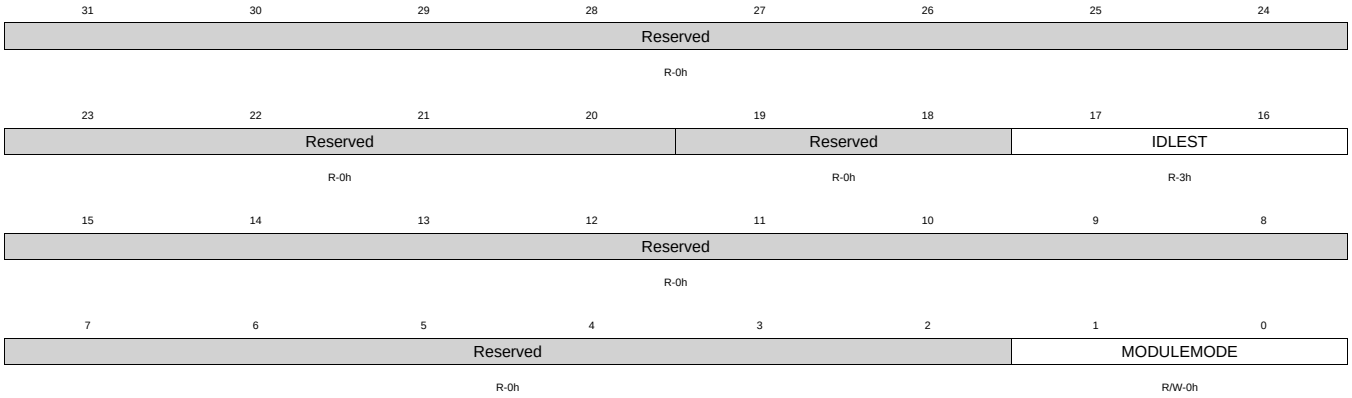
### 2.10.18.14 CM_ALWON_MCASP0_CLKCTRL Register (offset = 140h) [reset = 30000h]

CM_ALWON_MCASP0_CLKCTRL is shown in Figure 2-259 and described in Table 2-292.

This register manages the MCASP_0 clocks.

**Figure 2-259. CM_ALWON_MCASP0_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 2-292. CM_ALWON_MCASP0_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

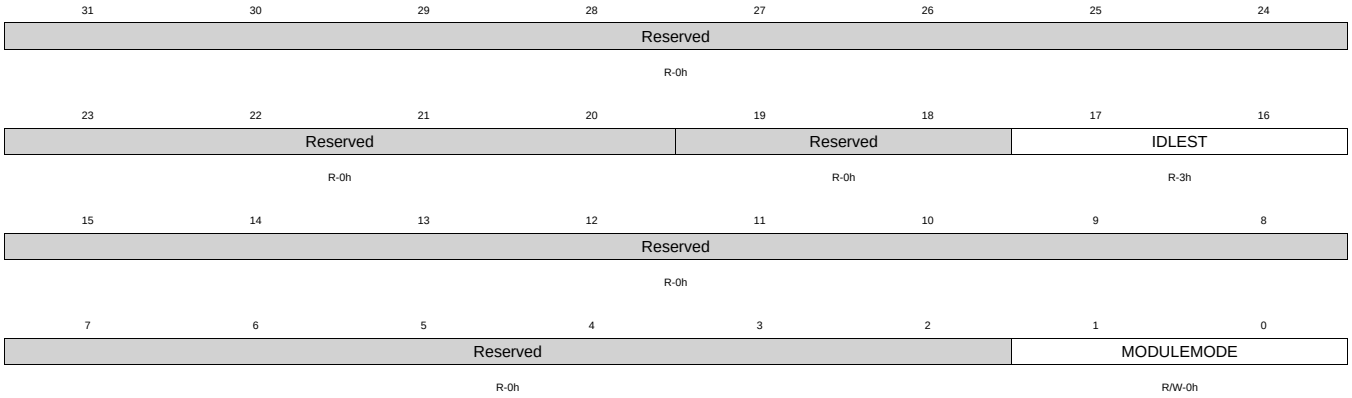
### 2.10.18.15 CM_ALWON_MCASP1_CLKCTRL Register (offset = 144h) [reset = 30000h]

CM_ALWON_MCASP1_CLKCTRL is shown in Figure 2-260 and described in Table 2-293.

This register manages the MCASP1 clocks.

**Figure 2-260. CM_ALWON_MCASP1_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 2-293. CM_ALWON_MCASP1_CLKCTRL Register Field Descriptions**

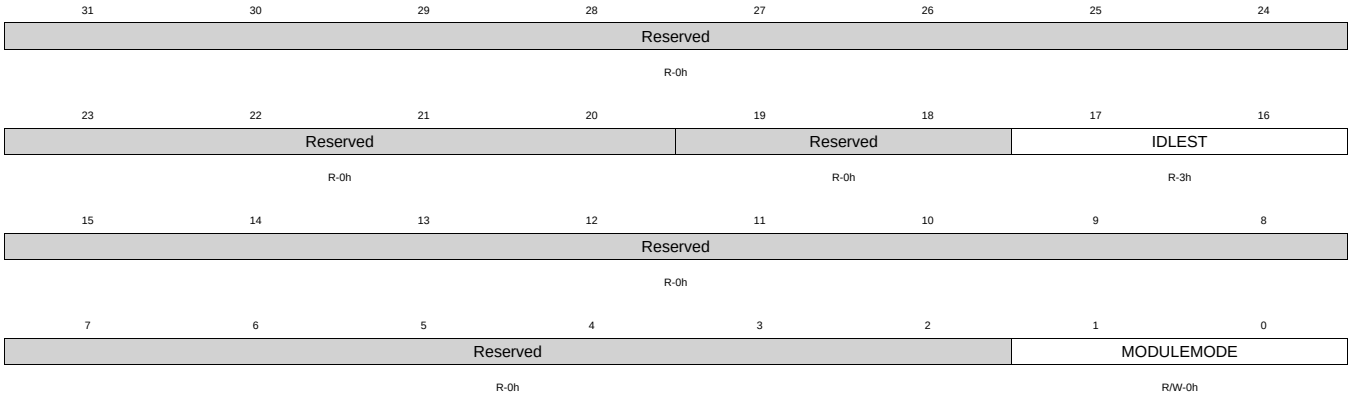
### 2.10.18.17 CM_ALWON_MCBSP_CLKCTRL Register (offset = 14Ch) [reset = 30000h]

CM_ALWON_MCBSP_CLKCTRL is shown in Figure 2-262 and described in Table 2-295.

This register manages the MCBSP clocks.

**Figure 2-262. CM_ALWON_MCBSP_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-295. CM_ALWON_MCBSP_CLKCTRL Register Field Descriptions**

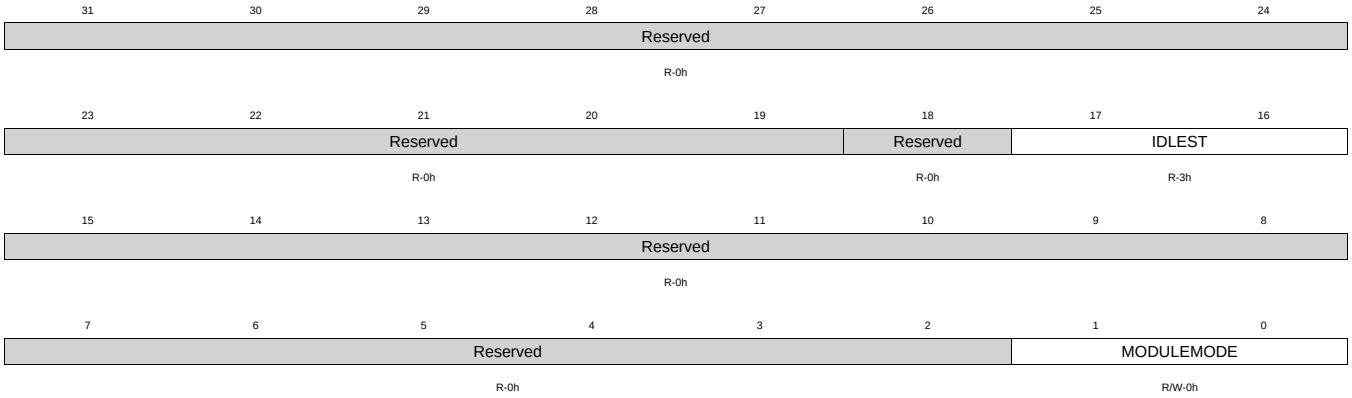
### 2.10.18.26 CM_ALWON_ATL_CLKCTRL Register (offset = 170h) [reset = 30000h]

CM_ALWON_ATL_CLKCTRL is shown in Figure 2-271 and described in Table 2-304.

This register manages the ATL clocks.

**Figure 2-271. CM_ALWON_ATL_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-304. CM_ALWON_ATL_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

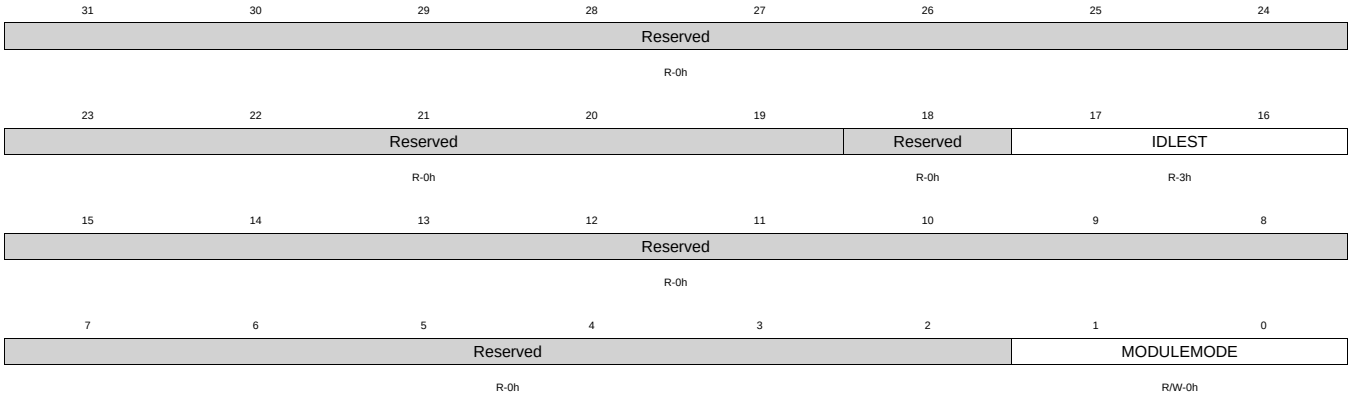
### 2.10.18.28 CM_ALWON_PATA_CLKCTRL Register (offset = 178h) [reset = 30000h]

CM_ALWON_PATA_CLKCTRL is shown in Figure 2-273 and described in Table 2-306.

This register manages the PATA clocks.

**Figure 2-273. CM_ALWON_PATA_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-306. CM_ALWON_PATA_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

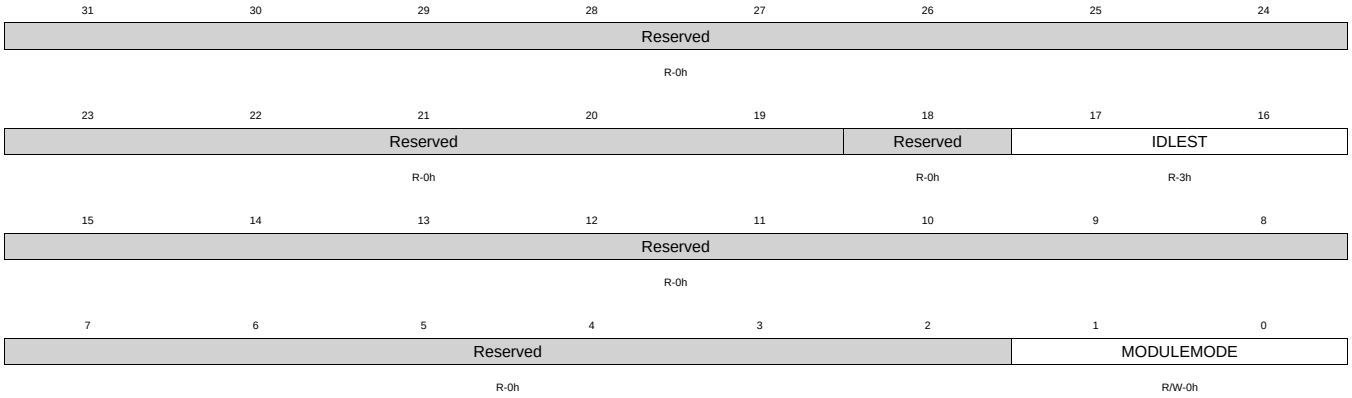
### 2.10.18.29 CM_ALWON_UART_3_CLKCTRL Register (offset = 180h) [reset = 30000h]

CM_ALWON_UART_3_CLKCTRL is shown in Figure 2-274 and described in Table 2-307.

This register manages the UART 3 clocks.

**Figure 2-274. CM_ALWON_UART_3_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-307. CM_ALWON_UART_3_CLKCTRL Register Field Descriptions**

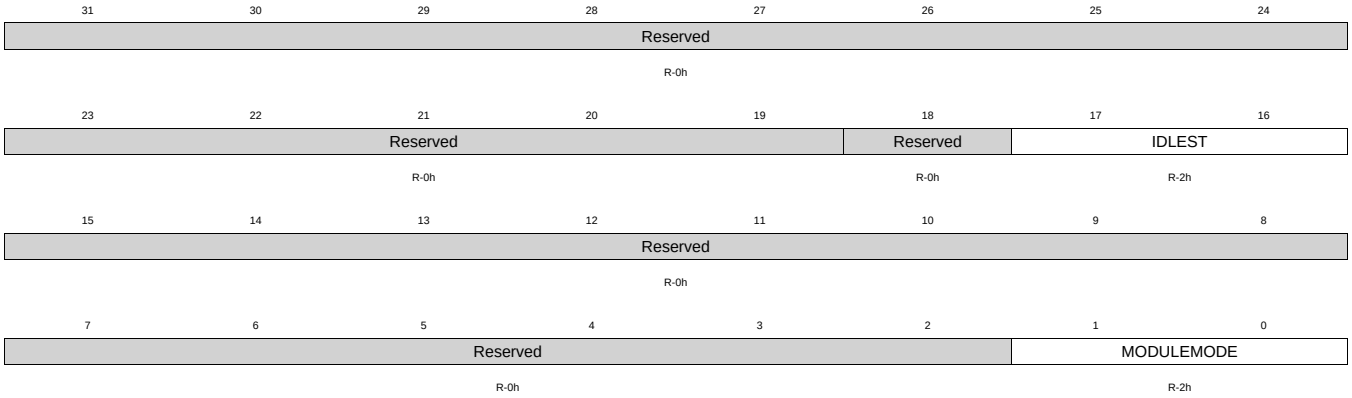
### 2.10.18.32 CM_ALWON_WDTIMER_CLKCTRL Register (offset = 18Ch) [reset = 20002h]

CM_ALWON_WDTIMER_CLKCTRL is shown in Figure 2-277 and described in Table 2-310.

This register manages the WDTIMER clocks.

**Figure 2-277. CM_ALWON_WDTIMER_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-310. CM_ALWON_WDTIMER_CLKCTRL Register Field Descriptions**

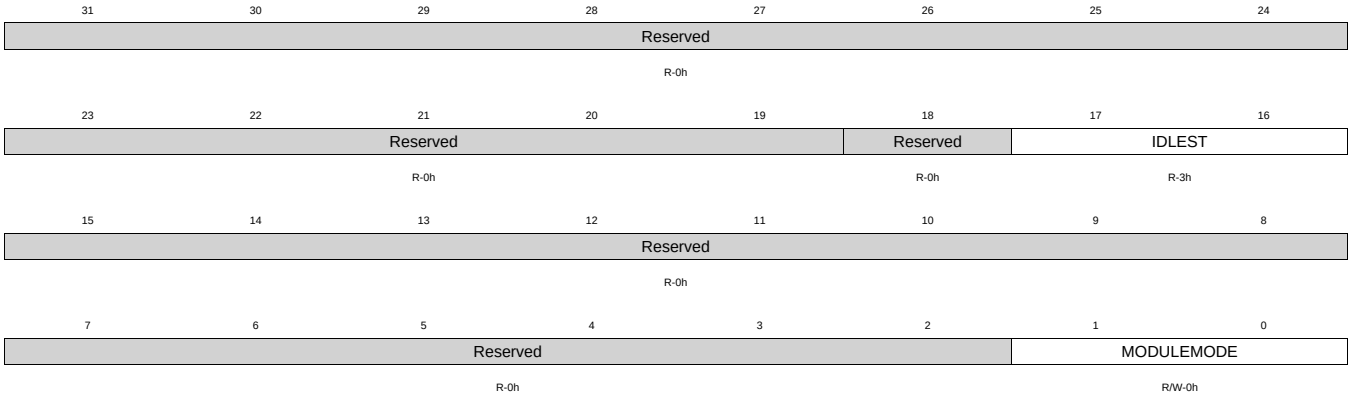
### 2.10.18.33 CM_ALWON_SPI_CLKCTRL Register (offset = 190h) [reset = 30000h]

CM_ALWON_SPI_CLKCTRL is shown in Figure 2-278 and described in Table 2-311.

This register manages the SPI0, SPI1, SPI2 and SPI3 clocks.

**Figure 2-278. CM_ALWON_SPI_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 2-311. CM_ALWON_SPI_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

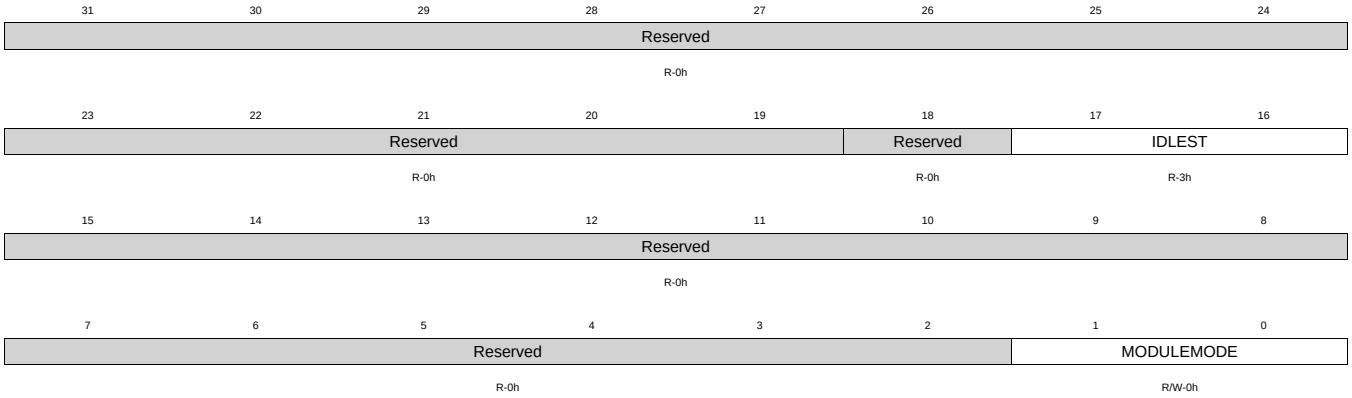
### 2.10.18.34 CM_ALWON_MAILBOX_CLKCTRL Register (offset = 194h) [reset = 30000h]

CM_ALWON_MAILBOX_CLKCTRL is shown in Figure 2-279 and described in Table 2-312.

This register manages the MAILBOX clocks.

**Figure 2-279. CM_ALWON_MAILBOX_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-312. CM_ALWON_MAILBOX_CLKCTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

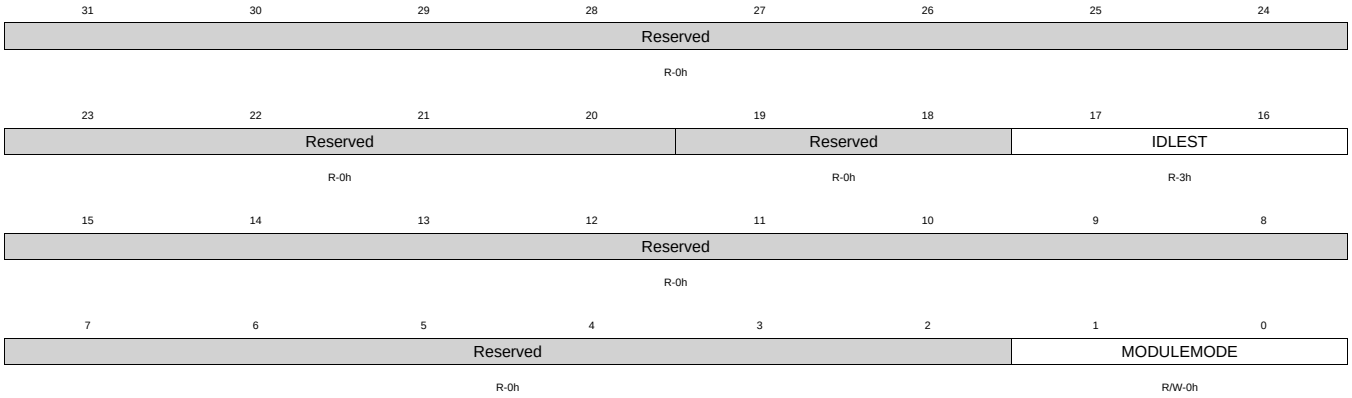
### 2.10.18.36 CM_ALWON_MMUDATA_CLKCTRL Register (offset = 19Ch) [reset = 30000h]

CM_ALWON_MMUDATA_CLKCTRL is shown in Figure 2-281 and described in Table 2-314.

This register manages the MMU data clocks.

**Figure 2-281. CM_ALWON_MMUDATA_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 2-314. CM_ALWON_MMUDATA_CLKCTRL Register Field Descriptions**

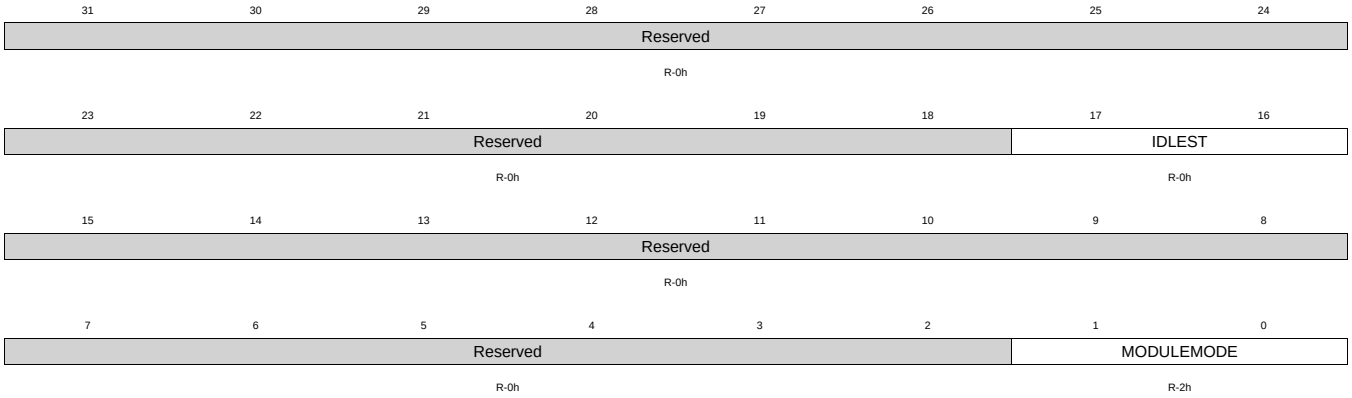
### 2.10.18.45 CM_ALWON_L3_CLKCTRL Register (offset = 1E4h) [reset = 2h]

CM_ALWON_L3_CLKCTRL is shown in Figure 2-290 and described in Table 2-323.

This register manages the L3 clocks.

**Figure 2-290. CM_ALWON_L3_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

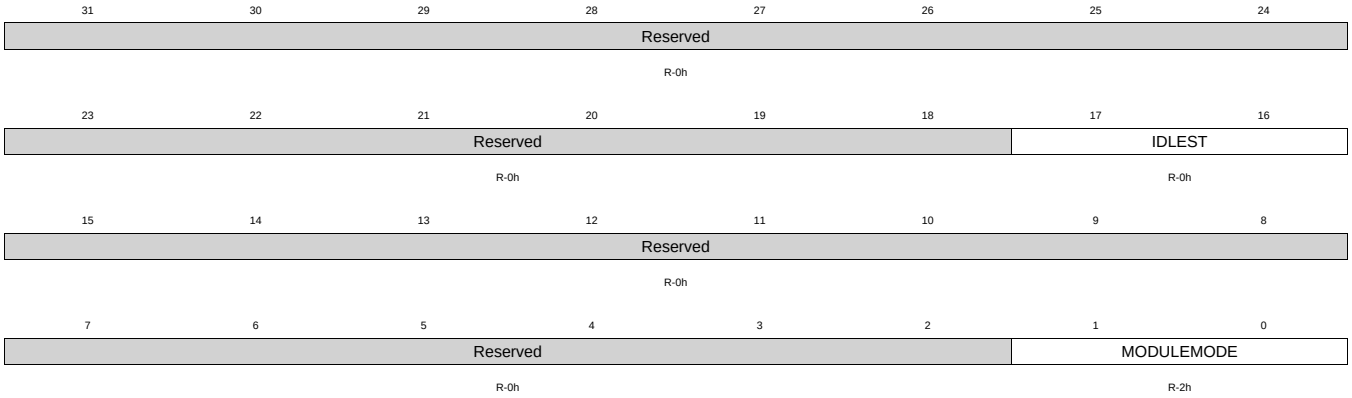
### 2.10.18.47 CM_ALWON_L4LS_CLKCTRL Register (offset = 1ECh) [reset = 2h]

CM_ALWON_L4LS_CLKCTRL is shown in Figure 2-292 and described in Table 2-325.

This register manages the L4LS clocks.

**Figure 2-292. CM_ALWON_L4LS_CLKCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

# Control Module

This chapter provides information about the control module.

**Topic** **Page**

**3.1 Control Module** ..... **852**
**3.2 CONTROL_MODULE Registers** ..... **856**

Copyright © 2011–2016, Texas Instruments Incorporated

## 3.1 Control Module

This device contains a system-level control logic block. The control module includes status and control logic not addressed within the peripherals or the rest of the device infrastructure.

This module is the primary point of control for the following areas of the device:

- Functional I/O multiplexing
- Device status
- Static device configuration
- Reset isolation logic inside the chip control module
- Lock/unlock mechanism for section of MMR inside the chip control module

The device control module primarily implements a bank of registers accessible (read/write) by the software along with some read-only registers carrying status information.

**Note:** The following operating systems and devices are used interchangeably throughout this chapter:

- DSP and C674x
- MPU and CORTEX-A8

The Control Module registers are documented in the section *CONTROL_MODULE Registers*. The following sections give an overview of the most important functionality provided by the Control Module.

**NOTE:** A processor (or other bus master) must be operating in the Supervisor privilege state in order to write to the control module registers. Registers are readable in either User or Supervisor privilege state.

### *3.1.1 MMR_LOCK Register (Locked/Unlocked States)*

The control module is segmented into 5 regions that are protected by a corresponding MMR_LOCKx register. The intent of the LOCK/UNLOCK mechanism is to prevent critical registers from being corrupted by undesired or malicious writes to the memory mapped addresses.

These regions default to LOCKED state, at which time the corresponding MMRs cannot be written. In order to write to the MMRs of the corresponding region, software must first UNLOCK the region by writing a specified 32-b value to the MMR_LOCKx register. At that point, the MMRs can be successfully written. Software should, in general, relock the registers after the necessary accesses have been done.

Table 3-1 summarizes the MMR_LOCKx registers including offset address range that is protected by each register.

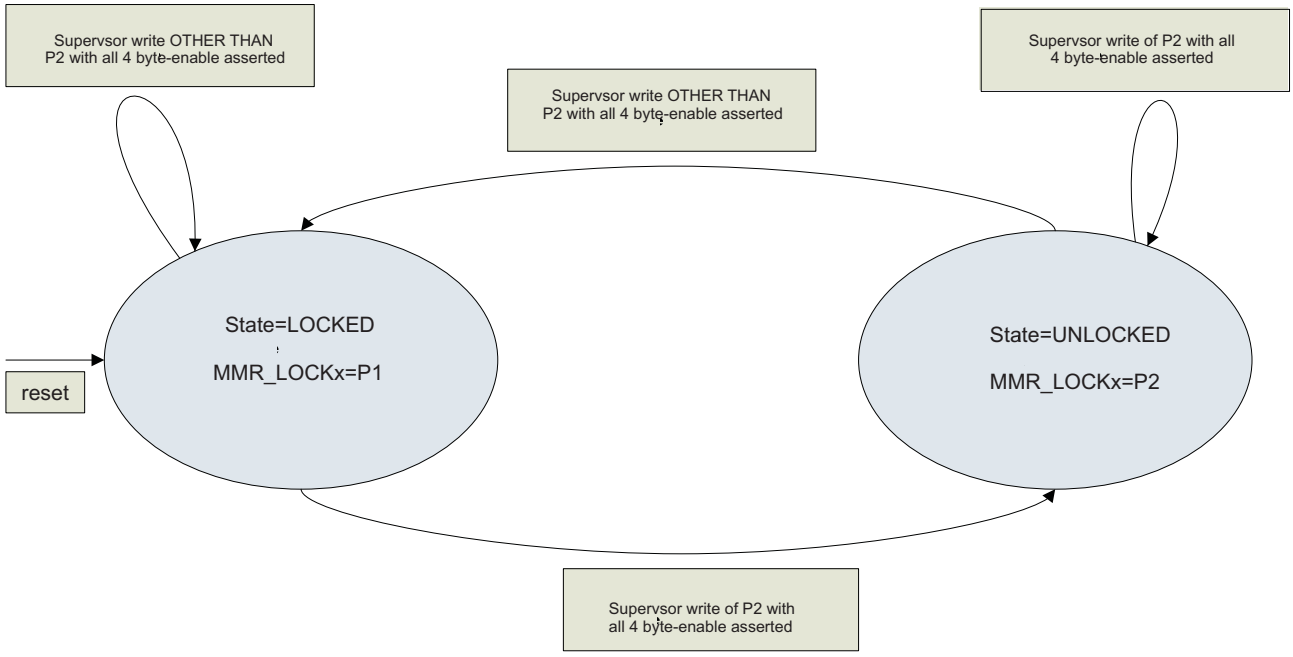
**Table 3-1. MMR_LOCKx Registers**

| Register Name | LOCKED State (register value=P1) | UNLOCKED State (register value=P2) | Start_Addess_x | End_Address_x |
|---|---|---|---|---|
| MMR_LOCK0 | 0x1A1C 8144 | 0x2FF1 AC2B | 0x0400 | 0x05FF |
| MMR_LOCK1 | 0xFDF4 5530 | 0xF757 FDC0 | 0x0600 | 0x07FF |
| MMR_LOCK2 | 0x1AE6 E320 | 0xE2BC 3A6D | 0x0800 | 0x0FFF |
| MMR_LOCK3 | 0x2FFA 927C | 0x1EBF 131D | 0x1000 | 0x12FF |
| MMR_LOCK4 | 0x143F 832C | 0x6F36 1E05 | 0x1300 | 0x17FF |

Copyright © 2011–2016, Texas Instruments Incorporated

Figure 3-1 shows the transition from locked to unlocked state for the MMR_LOCK register.

**Figure 3-1. MMR_LOCKx Transition from LOCKED/UNLOCKED State**



Note: Non-supervisor writes should not reach this register.
Reads should always return the value P1 or P2, depending on the state.

### 3.1.2 Pin Multiplexing (Pin Mux)

Many I/O pin can be internally routed to/from one of several peripheral modules within the device. This routing is referred to as Pin Multiplexing. Pin Multiplexing allows software to choose the subset of internal signals which will be mapped to balls of the device for a given application.

Device-level pin multiplexing is controlled on a pin-by-pin basis by the MUXMODE bits of the PINCNTL1 – PINCNTL270 registers in this control module. The PINCNTLx registers' descriptions and functions can be found in the device data manual, *Pin Multiplexing Control* section.

A second level of pin selection is provided via specific control module registers. The secondary control is described in the following sections.

#### 3.1.2.1 Other Pin Muxing Control

The GPIO_MUX register is used to select whether specific GPIO pins are sourced from device inputs or from internal interrupt sources. Refer to the register description for details.

The GMII_SEL register is used to select between GMII/MII, RMII, and RGMII modes of operation.

#### 3.1.2.2 Special Muxing of GPIO1[7:10] Signals

The GPIO1[7:10] signals can be mapped on the following device balls:

- GPIO1[7] - on device ball W1
- GPIO1[8] - on device ball W2
- GPIO1[9] - on device ball V1
- GPIO1[10] - on device ball V2

To ensure this mapping, the user must not only configure the PINCTNL[62:65] registers properly, but also make the following settings in the MLBP_SIG_IO_CTRL and MLBP_DAT_IO_CTRL registers:

- MLBP_SIG_IO_CTRL register:

Copyright © 2011–2016, Texas Instruments Incorporated

  - Set bit [2] ENLVCMOS to '1' to map GPIO1[7] on device ball W1 and GPIO1[8] on device ball W2.
  - Set bit [1] ENN to '0' to enable GPIO1[8] as output; or set this bit to '1' to enable GPIO1[8] as input.
  - Set bit [0] ENP to '0' to enable GPIO1[7] as output; or set this bit to '1' to enable GPIO1[7] as input.
- MLBP_DAT_IO_CTRL register:
  - Set bit [2] ENLVCMOS to '1' to map GPIO1[9] on device ball V1 and GPIO1[10] on device ball V2.
  - Set bit [1] ENN to '0' to enable GPIO1[10] as output; or set this bit to '1' to enable GPIO1[10] as input.
  - Set bit [0] ENP to '0' to enable GPIO1[9] as output; or set this bit to '1' to enable GPIO1[9] as input.

**NOTE:** The GPIO[7:10] signals can also be mapped on other device balls. The MLBP_SIG_IO_CTRL and MLBP_DAT_IO_CTRL settings are only necessary for mapping GPIO1[7:10] to the [W1, W2, V1, V2] device balls. For more information about device balls mapping, see device data manual.

### 3.1.3 BOOT Status

The Control Module CONTROL_STATUS and BOOTSTAT register allows the software to poll the status of the device boot to determine which boot sequence was detected and if any boot errors persist.

This register can be used by software for verification of a (un)successful boot and if necessary display error messages to the user.

### 3.1.4 DSP / EDMA Memory Management Unit Configuration

The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU, accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance. MMU_CFG Additional details are provided in the *System MMU* chapter.

### 3.1.5 Interrupt and DMA Controller Crossbars

The device contains a large number of system interrupts that are triggered by on chip events. Each CPU has an interrupt controller which allows a limited number of system events to trigger a CPU interrupt.

For the device DSP and Media Controller, to accommodate CPU interrupt generation by all system events, an Interrupt Event Crossbar precedes their corresponding interrupt controllers. To allow a multiple DMA request sources mapping versus each line of the device EDMA subsystem, a DMA Event Crossbar precedes the EDMA3CC controller. This allows a flexible mapping where any input to the Interrupt / DMA event Crossbar can be mapped to any of the interrupt/event outputs of the crossbar (which maps to inputs to the processor interrupt controller or device DMA controller).

This functionality is controlled by the DSP_INTMUX, Media_Controller_INTMUX and EDMA3CC_EVTMUX registers, which format is briefly described in below sections.

#### 3.1.5.1 DSP Interrupt Mux

Each DSP Interrupt mux is controlled by a MMR field which is 6 bit in length (of which only the 5 LSBs are used) .This field value descriptions are available in table *DSP INTC Interrupt Crossbar Mapping* of the section, *Interrupt Requests to DSP INTC*.

This MMR field DSP_INT_MUX_[#int_number], where #int_number is the interrupt number at GEM boundary.There is not interrupt mux for GEM interrupt number a) 0 to 14 and b) 96 to 127 so the range of #int_number is 15 to 95.

Copyright © 2011–2016, Texas Instruments Incorporated

After reset DSP_INT_MUX_[#int_number] defaults to 0b000000, which maps the interrupt from default mapping to interrupt_[#int_number], e.g. interrupt_15's default mapping is MMCHS0's SDINT, interrupt_16's default mapping is McSPI0's SPIINT etc. The mapping for other values of DSP_INT_MUX_[#int_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

#### 3.1.5.2 Media Controller Interrupt Mux

Each Media Controller interrupt mux is controlled by a MMR field which is 6 bit in length. This field value descriptions are available in table *Media Controller INTC Interrupt Crossbar Mapping* of the section, *Interrupt Requests to Media Controller*.

This MMR field Media_Controller_INT_MUX_[#int_number], where #int_number is the interrupt number at Media Controller boundary. The range of #int_number is 0 to 56.

After reset Media_Controller_INT_MUX_[#int_number] defaults to 0b000000, which maps the interrupt from default mapping to Media_Controller_interrupt_[#int_number], e.g. interrupt_0's default mapping is HDMI's HDMIINT, interrupt_2's default mapping is Timer1's TINT1, etc. The mapping for other values of Media_Controller_INT_MUX_[#int_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

#### 3.1.5.3 EDMA3CC Event Mux

Each EDMA3CC (TPCC) Event mux is controlled by a MMR field which is 6 bit in length (of which only the 5 LSBs are used). This field value descriptions are available in table *EDMA Multiplexed Synchronization Events* of the section, *EDMA Channel Synchronization Events*.

This MMR field EDMA3CC_MUX_[evt_number], where #evt_number is the event number at EDMA3CC boundary. The range of #evt_number is 0 to 63.

After reset EDMA3CC_MUX_[#evt_number] defaults to 0b000000, which maps the event from default mapping to event_[#evt_number], e.g. EDMA3CC event_0's default mapping is VCP's VCPREVT0, EDMA3CC event_1's default mapping is VCP's VCPXEVT0etc. The mapping for other values of EDMA3CC_MUX_[#evt_number] and additional details, including interrupt/event mapping, are provided in the *Device Interrupts and EDMA Events* section.

### 3.1.6 Device Level Peripheral Configuration

Various peripherals within the device contain various device level configuration that are not contained within the peripheral configuration registers. Device level configuration includes Power Management, MAC Address, USB Configuration / Status Registers, USB Product ID, Vendor ID Registers and PCIe Vendor ID, Product ID Registers.

### 3.1.7 Reset Isolation

The device supports reset isolation for the Ethernet Subsystem. For more information refer to the section *Reset Isolation* of the chapter, *Power, Reset, and Clock Management (PRCM) Module*.

Table 3-2 describes the subset of device pins and the corresponding PINCNTLx registers that can be reset-isolated. The specific combination of pins that are enabled for isolation is controlled by the RESET_ISO register and is detailed in the Register section of this chapter. In summary, the ISO_CONTROL field can enable/disable reset isolation. The GMII_ISO, RMII_ISO0, and RMII_ISO1 fields control which subset of the Pin Groups (and PINCNTL registers) are selected for reset isolation.

**Table 3-2. List of PINCNTLx Registers, reset affected by RESET_ISO.**

| RESET_ISO Pin Group | Associated PINCNTL Registers |
|---|---|
| MDIO/MDCLK | PINCNTL233 to PINCNTL234 |
| EMAC[1]_Mx/Other(1) | PINCNTL204 to PINCNTL227 |
| EMAC[0]_Mx/EMAC[1:0]_RGx | PINCNTL235 to PINCNTL258 |
| EMAC_RMREFCLK | PINCNTL232 |

(1) Several pins not related to the Ethernet Subsystem are included in this Pin Group for device compatibility.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 3-2. List of PINCNTLx Registers, reset affected by RESET_ISO. (continued)**

| RESET_ISO Pin Group | Associated PINCNTL Registers |
|---|---|
| EMAC[1]_RMx_MUX0 | PINCNTL252 to PINCNTL258 |
| EMAC[1]_RMx_MUX1 | PINCNTL157 to PINCNTL163 |
| EMAC[0]_RMx | PINCNTL236 to PINCNTL242 |

## 3.2 CONTROL_MODULE Registers

Table 3-3 lists the memory-mapped registers for the CONTROL_MODULE. All register offset addresses not listed in Table 3-3 should be considered as reserved locations and the register contents should not be modified.

All these registers can only be modified by SUPERVISR mode access.

**Table 3-3. CONTROL_MODULE REGISTERS**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 0h | CONTROL_REVISION | The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect. | Section 3.2.1 |
| 4h | CONTROL_HWINFO | The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any). | Section 3.2.2 |
| 10h | CONTROL_SYSCONFIG | The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the register implements various standby and emulation control bits. | Section 3.2.3 |
| 40h | CONTROL_STATUS | The CONTROL_STATUS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) or warm reset (RESETz) signal goes high. | Section 3.2.4 |
| 44h | BOOTSTAT | The Boot Status (BOOTSTAT) register indicates the status of the device boot process | Section 3.2.5 |
| 48h | DSPBOOTADDR | The DSP boot address defaults to 0x00800000 (C674x_DSP L2 space). The Host ARM must place DSP boot code into C674x_DSP L2 prior to releasing C674x_DSP reset or change the DSPBOOTADDR to point to the code location. The DSPBOOTADDR register is reset to its default value by a hard reset only and retains its current value over a soft reset. | Section 3.2.6 |
| 60h | MMR_LOCK0 | The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers. | Section 3.2.7 |
| 64h | MMR_LOCK1 | The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers. | Section 3.2.8 |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 3-3. CONTROL_MODULE REGISTERS (continued)**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 68h | MMR_LOCK2 | The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers. | Section 3.2.9 |
| 6Ch | MMR_LOCK3 | The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers. | Section 3.2.10 |
| 70h | MMR_LOCK4 | The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers. | Section 3.2.11 |
| 100h | CONTROL_SEC_CTRL | Security Control Register | Section 3.2.12 |
| 468h | DEVOSC | Oscillator 0 Control. Note for deepsleep: - 1st program bit16 (DSPOLARITY) of register DEEPSLEEP_CTRL to the desired polarity - To enter deepsleep mode, set bit 17 (DSENABLE) of DEEPSLEEP_CTRL to 1. - To exit, toggle the external pin DEEPSLEEPZ. | Section 3.2.13 |
| 46Ch | AUXOSC | Oscillator 1 Control | Section 3.2.14 |
| 480h | PCIE_CFG | 5.6.20. PCIE Configuration Register | Section 3.2.15 |
| 600h | DEVICE_ID | The DEVICE_ID register contains a software readable version of the device JTAG ID. Software can use this register to determine the version of the device on which it is executing. | Section 3.2.16 |
| 604h | DEV_FEATURE | The DEV_FEATURE register reflects the eFuse settings enabling or disabling certain device functions and capabilities. Note that DEV_FEATURE bits are all implemented as feature enabled bits. This may require inverting the value of those eFuses which are implemented as disable signals. | Section 3.2.17 |
| 608h | INIT_PRIORITY_0 | The INIT_PRIORITY_0 register configures the infrastructure pressure input for L3 initiators to provide dynamic priority escalation. | Section 3.2.18 |
| 60Ch | INIT_PRIORITY_1 | The INIT_PRIORITY_1 register configures the infrastructure pressure input for L3 initiators to provide dynamic priority escalation. | Section 3.2.19 |
| 610h | MMU_CFG | The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance. | Section 3.2.20 |
| 614h | TPTC_CFG | The TPTC_CFG register configures the default burst size for TPTC0, 1, 2, and 3. | Section 3.2.21 |

**Table 3-3. CONTROL_MODULE REGISTERS (continued)**

| Offset | Acronym | Register Name | Section |
|---|---|---|---|
| 61Ch | DSP_IDLE_CFG | The C674x_DSP_IDLE_CFG register controls the state manaC674x_DSPent of the C674x_DSP initiator and target port interfaces. | Section 3.2.22 |
| 620h | USB_CTRL0 | USB Control Register 0 controls the PHY, CM and OTG modules for USB0. | Section 3.2.23 |
| 624h | USB_STS0 | USB Status Register 0 reflects the status of the USB0. | Section 3.2.24 |
| 628h | USB_CTRL1 | USB Control Register 1 controls the PHY, CM and OTG modules for USB1. | Section 3.2.25 |
| 62Ch | USB_STS1 | USB Status Register 1 reflects the status of the USB0. | Section 3.2.26 |
| 630h | MAC_ID0_LO | The MAC_ID0_LO register contains the lower 2 bytes of the 48-bit ID for MAC0. | Section 3.2.27 |
| 634h | MAC_ID0_HI | The MAC_ID0_HI register contains the upper 4 bytes of the 48-bit ID for MAC0. | Section 3.2.28 |
| 638h | MAC_ID1_LO | The MAC_ID1_LO register contains the lower 2 bytes of the 48-bit ID for MAC1. | Section 3.2.29 |
| 63Ch | MAC_ID1_HI | The MAC_ID1_HI register contains the upper 4 bytes of the 48-bit ID for MAC1. | Section 3.2.30 |
| 640h | SW_REVISION | The SW_REVISION register reads the Paper Spin Variant 32bit efuse. The SW can read this bit and decide what to do with a specific SW package. | Section 3.2.31 |
| 644h | DCAN_RAMINIT | The DCAN_RAMINIT register is used to start/check status of the autoinitialization process of DCAN RAM. | Section 3.2.32 |
| 64Ch | AUD_CTRL | The register controls loopback of McBSP data for testing purposes. | Section 3.2.33 |
| 650h | GMII_SEL | Ethernet GMII Select | Section 3.2.34 |
| 654h | OCMEM_PWRDN | The OCMEM_PWRDN Register determines the powerdown behavior of the OCMC RAM memories. | Section 3.2.35 |
| 65Ch | MEDIA_CONTROLLER_MEM_PWRDN | The MEDIA_CONTROLLER_MEM_PWRDN Register determines the powerdown behavior of the Media Controller memories. | Section 3.2.36 |
| 670h | SD_DAC_CTRL | The SD_DAC_CTRL Register controls operation of the Standard Definition video DACs. | Section 3.2.37 |
| 674h | SD_DAC0_CAL | The SD_DAC0_CAL Register is used to calibrate the output level of SD DAC 0 (SD Y). Users can use this register to drive a known value to the DAC input for performing system video level calibration. | Section 3.2.38 |
| 678h | SD_DAC1_CAL | The SD_DAC1_CAL Register is used to calibrate the output level of SD DAC 1 (SD C). Users can use this register to drive a known value to the DAC input for performing system video level calibration. | Section 3.2.39 |
| 67Ch | SD_DAC0_REGCTRL | The SD_DAC0_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked). | Section 3.2.40 |
| 680h | SD_DAC0_REGSTATUS | The SD_DAC0_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked). | Section 3.2.41 |
| 684h | SD_DAC1_REGCTRL | The SD_DAC1_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked). | Section 3.2.42 |
| 688h | SD_DAC1_REGSTATUS | The SD_DAC1_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked). | Section 3.2.43 |
| 694h | EMIF_CLK_GATE | This register provides a mechanism to control clock gating of DDR PHYs and see status of Self Refresh. | Section 3.2.44 |

### 3.2.1 CONTROL_REVISION Register (offset = 0h) [reset = 40000000h]

CONTROL_REVISION is shown in Figure 3-2 and described in Table 3-4.

The CONTROL_REVISION register is a read only register containing the revision number of the Control module. A write to this register has no effect.

**Figure 3-2. CONTROL_REVISION Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

### 3.2.2 CONTROL_HWINFO Register (offset = 4h) [reset = 0h]

CONTROL_HWINFO is shown in Figure 3-3 and described in Table 3-5.

The CONTROL_HWINFO register contains information about the module hardware configuration (typically HDL generics, if any).

**Figure 3-3. CONTROL_HWINFO Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

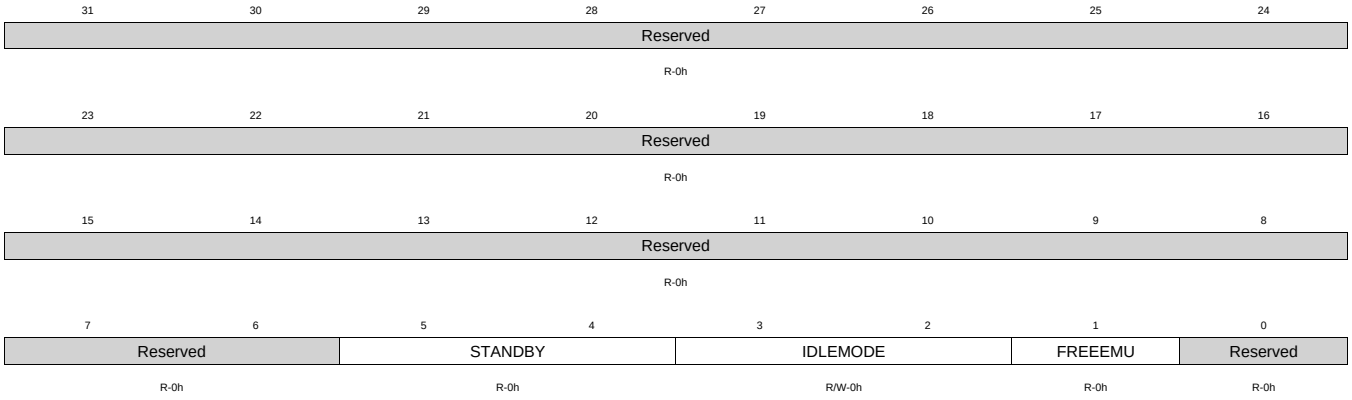
### 3.2.3 CONTROL_SYSCONFIG Register (offset = 10h) [reset = 0h]

CONTROL_SYSCONFIG is shown in Figure 3-4 and described in Table 3-6.

The CONTROL_SYSCONFIG register implements only a reduced set of the register defined in the register implements various standby and emulation control bits.

**Figure 3-4. CONTROL_SYSCONFIG Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 3.2.4 CONTROL_STATUS Register (offset = 40h) [reset = 0h]

CONTROL_STATUS is shown in Figure 3-5 and described in Table 3-7.

The CONTROL_STATUS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) or warm reset (RESETz) signal goes high.

**Figure 3-5. CONTROL_STATUS Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

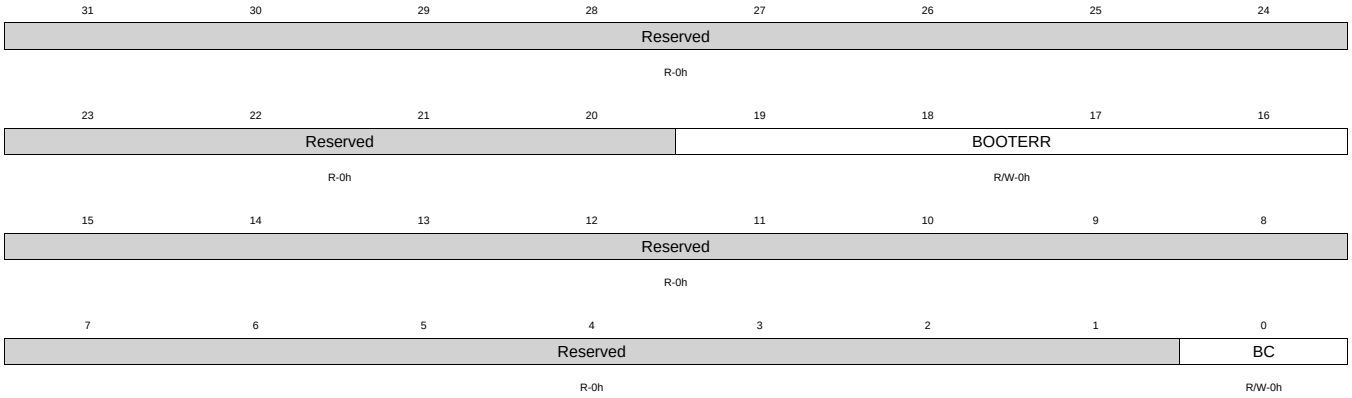
### 3.2.5 BOOTSTAT Register (offset = 44h) [reset = 0h]

BOOTSTAT is shown in Figure 3-6 and described in Table 3-8.

The Boot Status (BOOTSTAT) register indicates the status of the device boot process

**Figure 3-6. BOOTSTAT Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

### 3.2.6 DSPBOOTADDR Register (offset = 48h) [reset = 800000h]

DSPBOOTADDR is shown in Figure 3-7 and described in Table 3-9.

The DSP boot address defaults to 0x00800000 (C674x_DSP L2 space). The Host ARM must place DSP boot code into C674x_DSP L2 prior to releasing C674x_DSP reset or change the DSPBOOTADDR to point to the code location. The DSPBOOTADDR register is reset to its default value by a hard reset only and retains its current value over a soft reset.

### 3.2.7 MMR_LOCK0 Register (offset = 60h) [reset = 1A1C8144h]

MMR_LOCK0 is shown in Figure 3-8 and described in Table 3-10.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

**Figure 3-8. MMR_LOCK0 Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 3.2.8 MMR_LOCK1 Register (offset = 64h) [reset = FDF45530h]

MMR_LOCK1 is shown in Figure 3-9 and described in Table 3-11.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

**Figure 3-9. MMR_LOCK1 Register**

### 3.2.9 MMR_LOCK2 Register (offset = 68h) [reset = 1AE6E320h]

MMR_LOCK2 is shown in Figure 3-10 and described in Table 3-12.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

**Figure 3-10. MMR_LOCK2 Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

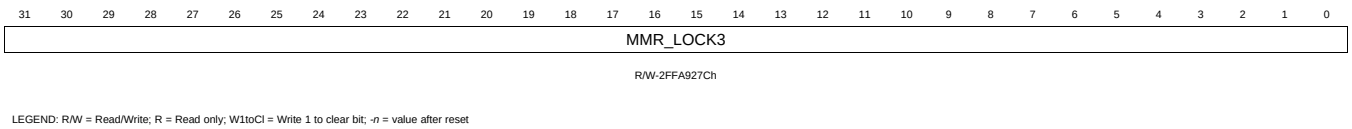
### 3.2.10 MMR_LOCK3 Register (offset = 6Ch) [reset = 2FFA927Ch]

MMR_LOCK3 is shown in Figure 3-11 and described in Table 3-13.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

**Figure 3-11. MMR_LOCK3 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

### 3.2.11 MMR_LOCK4 Register (offset = 70h) [reset = 143F832Ch]

MMR_LOCK4 is shown in Figure 3-12 and described in Table 3-14.

The MMR_LOCKx Register is used allow/block writes to the registers in address region Start_Addess_x - End_Address_x. This register has 2 states LOCKED and UNLOCKED When in LOCKED state all writes to Start_Addess_x -End_Address_x is blocked. When in UNLOCKED state all writes to Start_Addess_x - End_Address_x is allowed. All reads to Start_Addess_x -End_Address_x should not be blocked by the state of MMR_LOCKx registers.

### 3.2.13 DEVOSC Register (offset = 468h) [reset = 0h]

DEVOSC is shown in Figure 3-14 and described in Table 3-16.

Oscillator 0 Control. Note for deepsleep: - 1st program bit16 (DSPOLARITY) of register DEEPSLEEP_CTRL to the desired polarity - To enter deepsleep mode, set bit 17 (DSENABLE) of DEEPSLEEP_CTRL to 1. - To exit, toggle the external pin DEEPSLEEPZ.

**Figure 3-14. DEVOSC Register**

| 27-2 | Reserved | R | 0h | |
| 1-0 | PCIDEVTYPE | R/W | 0h | Directly controls the DEVTYPE ports on the PCIESS. Used to select PCI device type. Should be valid before releasing reset to PCIESS. Full definition in PCIESS IP spec. |

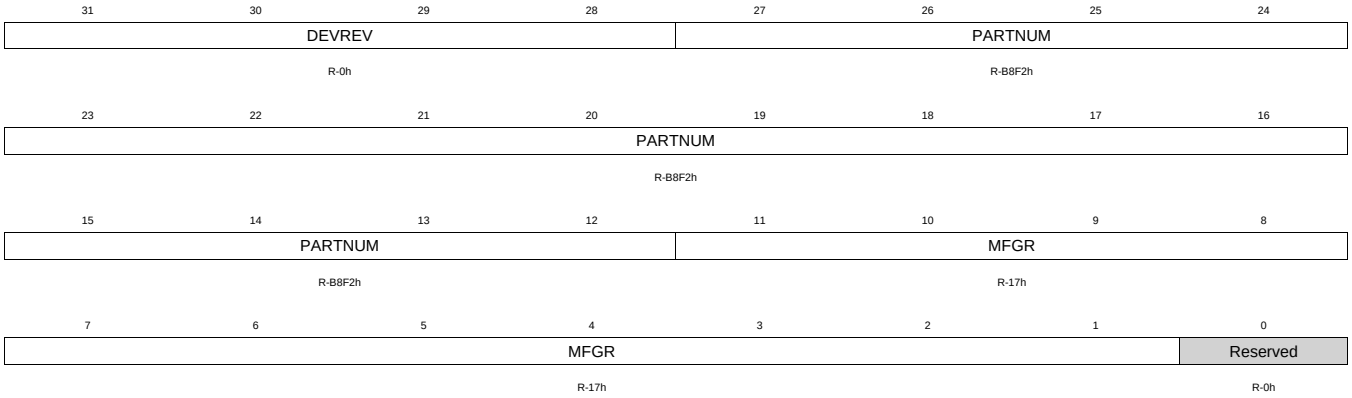
Copyright © 2011–2016, Texas Instruments Incorporated

### 3.2.16 DEVICE_ID Register (offset = 600h) [reset = B8F202Eh]

DEVICE_ID is shown in Figure 3-17 and described in Table 3-19.

The DEVICE_ID register contains a software readable version of the device JTAG ID. Software can use this register to determine the version of the device on which it is executing.

**Figure 3-17. DEVICE_ID Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 3-19. DEVICE_ID Register Field Descriptions**

### 3.2.17 DEV_FEATURE Register (offset = 604h) [reset = 0h]

DEV_FEATURE is shown in Figure 3-18 and described in Table 3-20.

The DEV_FEATURE register reflects the eFuse settings enabling or disabling certain device functions and capabilities. Note that DEV_FEATURE bits are all implemented as feature enabled bits. This may require inverting the value of those eFuses which are implemented as disable signals.

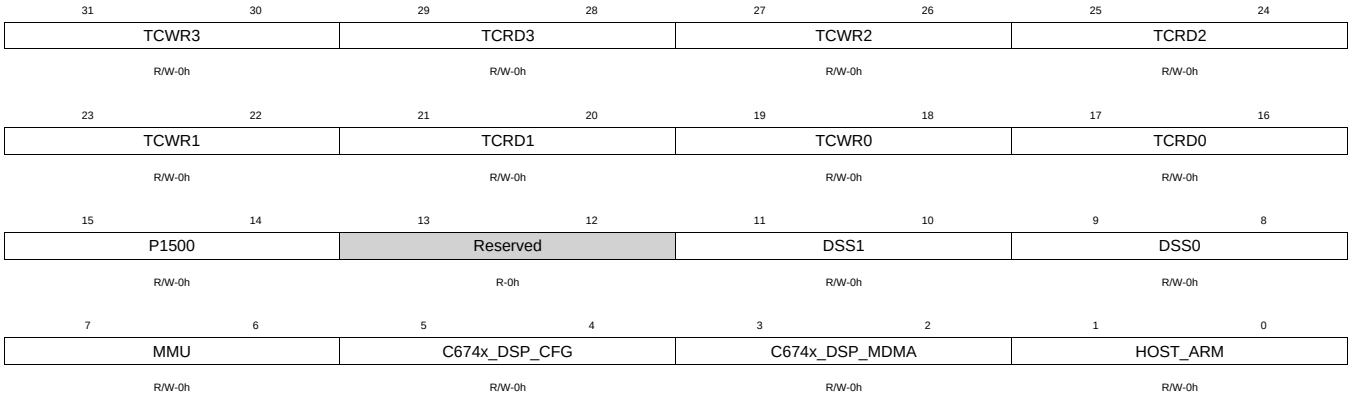
### 3.2.18 INIT_PRIORITY_0 Register (offset = 608h) [reset = 0h]

INIT_PRIORITY_0 is shown in Figure 3-19 and described in Table 3-21.

The INIT_PRIORITY_0 register configures the infrastructure pressure input for L3 initiators to provide dynamic priority escalation.

**Figure 3-19. INIT_PRIORITY_0 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 3.2.20 MMU_CFG Register (offset = 610h) [reset = 80h]

MMU_CFG is shown in Figure 3-21 and described in Table 3-23.

The MMU_CFG register is used to optionally route certain initiators through the System MMU. The C674x_DSP MDMA port accesses will always be routed through the System MMU so no configuration bit is instantiated for C674x_DSP. Note that when TPTC0 is routed through the MMU accesses to the C674x_DSP SDMA port will still by-pass the MMU for increased performance.

**Figure 3-21. MMU_CFG Register**

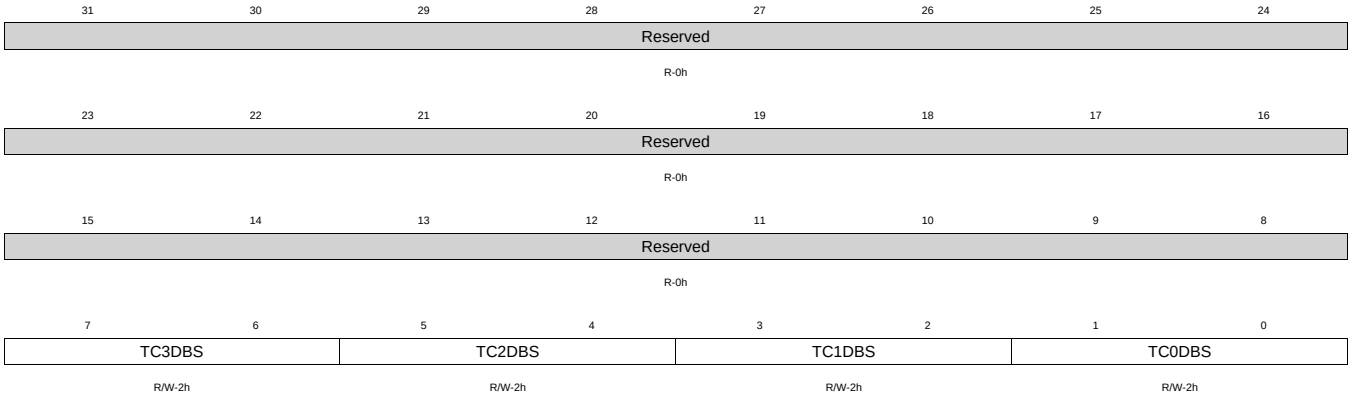
### 3.2.21 TPTC_CFG Register (offset = 614h) [reset = AAh]

TPTC_CFG is shown in Figure 3-22 and described in Table 3-24.

The TPTC_CFG register configures the default burst size for TPTC0, 1, 2, and 3.

**Figure 3-22. TPTC_CFG Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

### 3.2.27 MAC_ID0_LO Register (offset = 630h) [reset = 0h]

MAC_ID0_LO is shown in Figure 3-28 and described in Table 3-30.

The MAC_ID0_LO register contains the lower 2 bytes of the 48-bit ID for MAC0.

**Figure 3-28. MAC_ID0_LO Register**

### 3.2.28 MAC_ID0_HI Register (offset = 634h) [reset = 0h]

MAC_ID0_HI is shown in Figure 3-29 and described in Table 3-31.

The MAC_ID0_HI register contains the upper 4 bytes of the 48-bit ID for MAC0.

**Figure 3-29. MAC_ID0_HI Register**

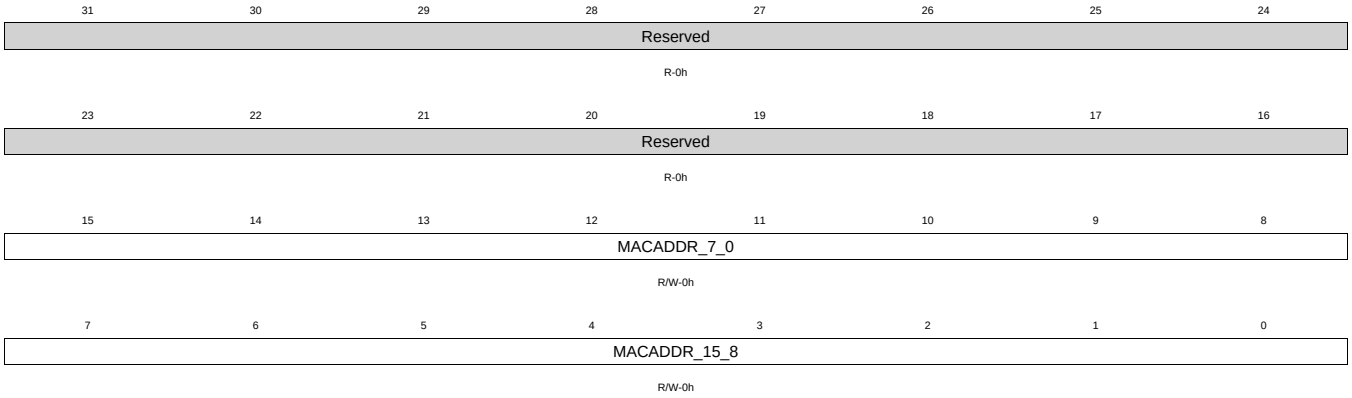
### 3.2.29 MAC_ID1_LO Register (offset = 638h) [reset = 0h]

MAC_ID1_LO is shown in Figure 3-30 and described in Table 3-32.

The MAC_ID1_LO register contains the lower 2 bytes of the 48-bit ID for MAC1.

**Figure 3-30. MAC_ID1_LO Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 3.2.31 SW_REVISION Register (offset = 640h) [reset = 0h]

SW_REVISION is shown in Figure 3-32 and described in Table 3-34.

The SW_REVISION register reads the Paper Spin Variant 32bit efuse. The SW can read this bit and decide what to do with a specific SW package.

**Figure 3-32. SW_REVISION Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 3.2.38 SD_DAC0_CAL Register (offset = 674h) [reset = 0h]

SD_DAC0_CAL is shown in Figure 3-39 and described in Table 3-41.

The SD_DAC0_CAL Register is used to calibrate the output level of SD DAC 0 (SD Y). Users can use this register to drive a known value to the DAC input for performing system video level calibration.

**Figure 3-39. SD_DAC0_CAL Register**

### 3.2.39 SD_DAC1_CAL Register (offset = 678h) [reset = 0h]

SD_DAC1_CAL is shown in Figure 3-40 and described in Table 3-42.

The SD_DAC1_CAL Register is used to calibrate the output level of SD DAC 1 (SD C). Users can use this register to drive a known value to the DAC input for performing system video level calibration.

**Figure 3-40. SD_DAC1_CAL Register**

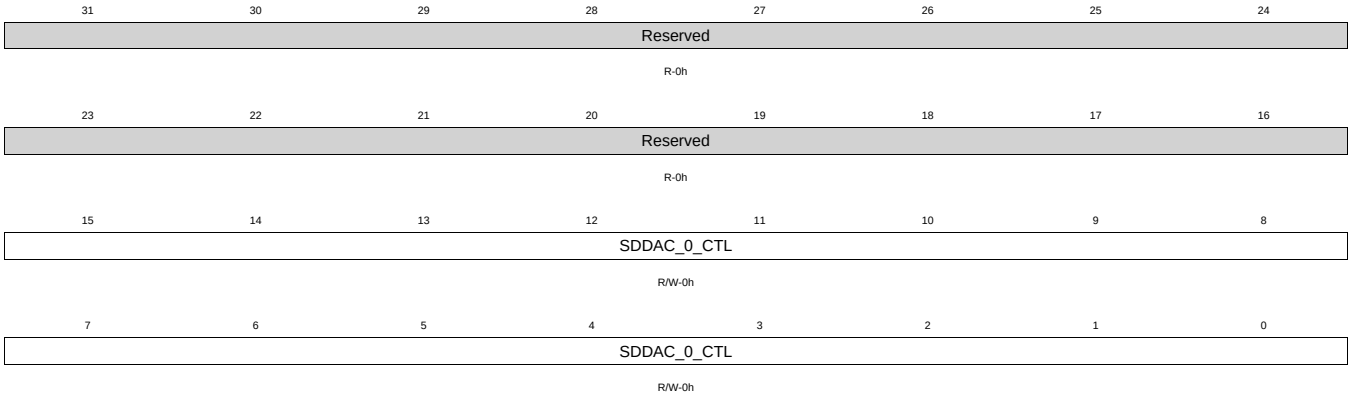
### 3.2.40 SD_DAC0_REGCTRL Register (offset = 67Ch) [reset = 0h]

SD_DAC0_REGCTRL is shown in Figure 3-41 and described in Table 3-43.

The SD_DAC0_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked).

**Figure 3-41. SD_DAC0_REGCTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

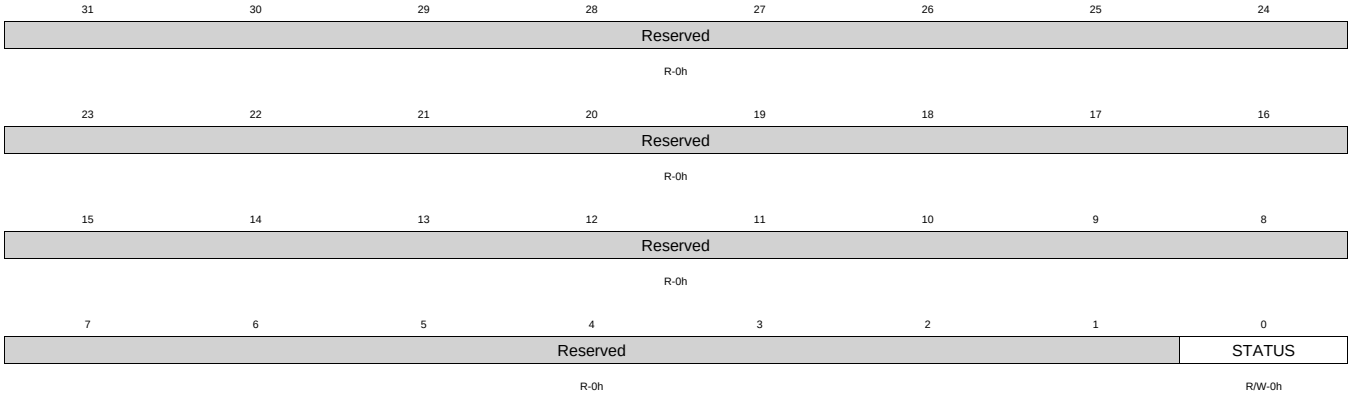
### 3.2.41 SD_DAC0_REGSTATUS Register (offset = 680h) [reset = 0h]

SD_DAC0_REGSTATUS is shown in Figure 3-42 and described in Table 3-44.

The SD_DAC0_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked).

**Figure 3-42. SD_DAC0_REGSTATUS Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 3.2.42 SD_DAC1_REGCTRL Register (offset = 684h) [reset = 0h]

SD_DAC1_REGCTRL is shown in Figure 3-43 and described in Table 3-45.

The SD_DAC1_REGCTRL Register is used to provide an alternate method to program the AVDAC s CTL interface (to be used only when the internal registers of the AVDAC needs to be tweaked).

**Figure 3-43. SD_DAC1_REGCTRL Register**

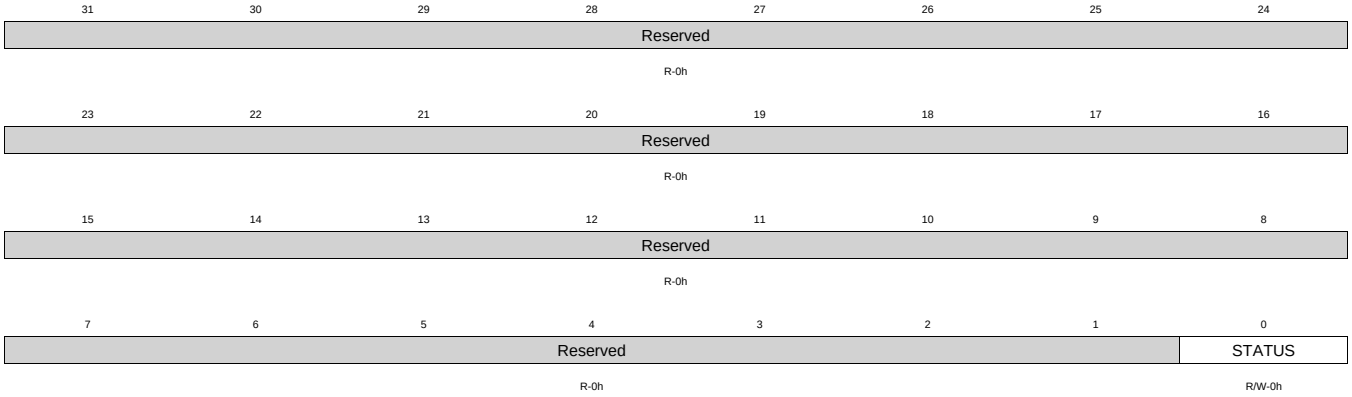
### 3.2.43 SD_DAC1_REGSTATUS Register (offset = 688h) [reset = 0h]

SD_DAC1_REGSTATUS is shown in Figure 3-44 and described in Table 3-46.

The SD_DAC1_REGSTATUS Register is used to provide to know the status of the last write to the AVDAC s internal registers (to be used only when the internal registers of the AVDAC needs to be tweaked).

**Figure 3-44. SD_DAC1_REGSTATUS Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

### 3.2.44 EMIF_CLK_GATE Register (offset = 694h) [reset = 0h]

EMIF_CLK_GATE is shown in Figure 3-45 and described in Table 3-47.

This register provides a mechanism to control clock gating of DDR PHYs and see status of Self Refresh.

**Figure 3-45. EMIF_CLK_GATE Register**

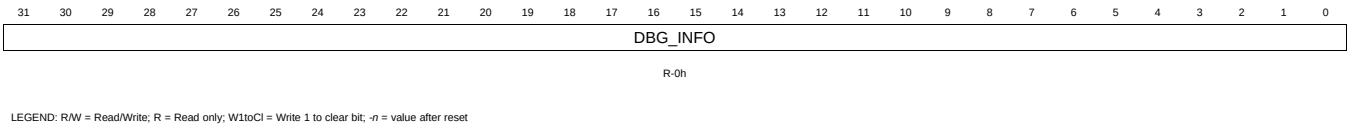
### 3.2.47 ARM_CORTEX_A8_HW_DBG_INFO Register (offset = 6A8h) [reset = 0h]

ARM_CORTEX_A8_HW_DBG_INFO is shown in Figure 3-48 and described in Table 3-50.

This register shows the debug info bus from ARM Cortex-A8. Please see below for definition. The selection bits are HW_DBG_SEL (3:0) in the MMR ARM_CORTEX_A8_HW_DBG_SEL

**Figure 3-48. ARM_CORTEX_A8_HW_DBG_INFO Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 3-50. ARM_CORTEX_A8_HW_DBG_INFO Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-0 | DBG_INFO | R | 0h | Debug info from ARM Cortex-A8. |

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-56. PCIE_PLLCFG3 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-28 | Reserved | R/W | 0h | Reserved for future use |
| 27 | DIGLDO_BYPASS | R/W | 0h | Digital signal when high puts the DIG LDO in bypass mode. Need to be careful while exercising this mode, the 1.8V external supply must be lowered before asserting this bit. |
| 26 | DIGLDO_PULLDOWNZ | R/W | 1h | Digital signal when high disables all the pull down paths for LDO output |
| 25 | DIGLDO_DIS_SC_PROT | R/W | 0h | Digital signal when high disables short circuit protection |
| 24 | DIGLDO_EN_SUB_REGULATION | R/W | 0h | Digital signal when high disables sub regulation |
| 23 | DIGLDO_EN_HP_CAPLESSMODE | R/W | 0h | Digital signal when high enables high performance Capless mode. In this mode, quiescent LDO current increases by 240uA |
| 22 | DIGLDO_EN_CAPLESSMODE | R/W | 0h | Digital signal when high enables Capless Mode. In particular: (1) The 800fF capacitor between VDDAR and the gate of the power FET is bypassed (2) The output of the error amplifier connects to a 30pF capacitor and the other terminal of the capacitor connects to a 40k resistor whose other terminal goes to VSSA. This resistor is also bypassed. |
| 21 | DIGLDO_EN_LP_CAPLESSMODE | R/W | 0h | Digital signal when high enables Low Power Capless Mode. Quiescent LDO current increases by 240uA typical when this bit is set to low. |

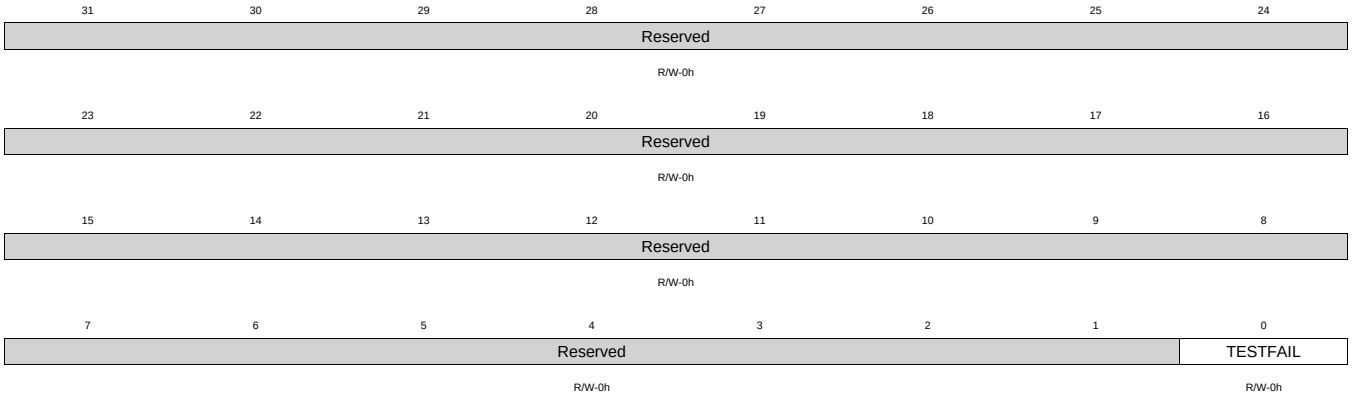
### 3.2.56 PCIE_RXSTATUS Register (offset = 6F0h) [reset = 0h]

PCIE_RXSTATUS is shown in Figure 3-57 and described in Table 3-59.

PCIE SerDes Receive Status register

**Figure 3-57. PCIE_RXSTATUS Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-59. PCIE_RXSTATUS Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-1 | Reserved | R/W | 0h | Reserved, driven low. |
| 0 | TESTFAIL | R/W | 0h | Test failure. Driven high when an error is encountered during a test sequence executed on channel i. Synchronous to RXBCLKIN[i]. |

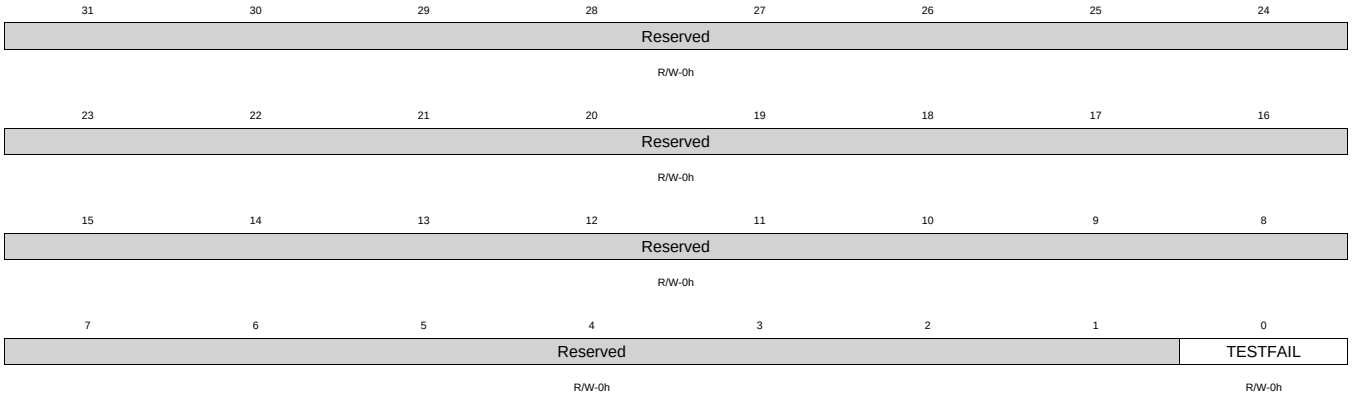
Copyright © 2011–2016, Texas Instruments Incorporated

### 3.2.57 PCIE_TXSTATUS Register (offset = 6F4h) [reset = 0h]

PCIE_TXSTATUS is shown in Figure 3-58 and described in Table 3-60.

This register reports PCIE SerDes Transmit Status.

**Figure 3-58. PCIE_TXSTATUS Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-60. PCIE_TXSTATUS Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-1 | Reserved | R/W | 0h | Reserved, driven low. |
| 0 | TESTFAIL | R/W | 0h | Test failure. Driven high when an error is encountered during a test sequence executed on channel i, or if an over or underflow occurs in the Tx serialiser when ENFTP = 0. Synchronous to TXBCLKIN[i]. |

**Table 3-64. SATA_PLLCFG3 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-28 | Reserved | R/W | 0h | Reserved |
| 27 | DIGLDO_BYPASS | R/W | 0h | Digital signal when high puts the DIG LDO in bypass mode. Caution Need to be careful while exercising this mode, the 1.8V external supply must be lowered before asserting this bit. |
| 26 | DIGLDO_PULLDOWNZ | R/W | 1h | Digital signal when high disables all the pull down paths for LDO output |
| 25 | DIGLDO_DIS_SC_PROT | R/W | 0h | Digital signal when high disables short circuit protection |
| 24 | DIGLDO_EN_SUB_REGULATION | R/W | 0h | Digital signal when high disables sub regulation |
| 23 | DIGLDO_EN_HP_CAPLESSMODE | R/W | 0h | Digital signal when high enables high performance Capless mode. In this mode, quiescent LDO current increases by 240uA |
| 22 | DIGLDO_EN_CAPLESSMODE | R/W | 0h | Digital signal when high enables Capless Mode. In particular: (1) The 800fF capacitor between VDDAR and the gate of the power FET is bypassed (2) The output of the error amplifier connects to a 30pF capacitor and the other terminal of the capacitor connects to a 40k resistor whose other terminal goes to VSSA. This resistor is also bypassed. |
| 21 | DIGLDO_EN_LP_CAPLESSMODE | R/W | 0h | Digital signal when high enables Low Power Capless Mode. Quiescent LDO current increases by 240uA typical when this bit is set to low. |

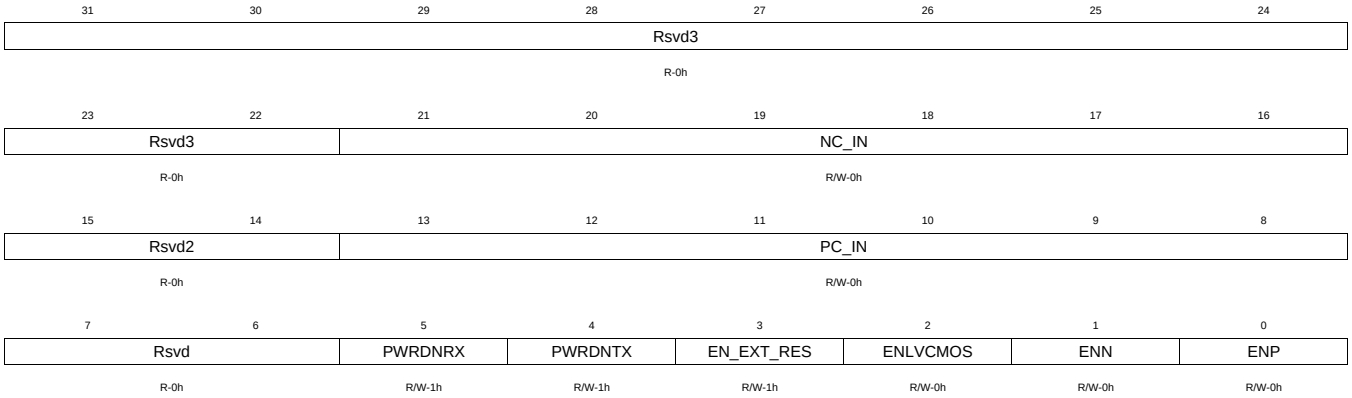
### 3.2.85 MLBP_SIG_IO_CTRL Register (offset = E18h) [reset = 38h]

MLBP_SIG_IO_CTRL is shown in Figure 3-86 and described in Table 3-88.

This register controls the MLBP SIG pins IO characteristics.

**Figure 3-86. MLBP_SIG_IO_CTRL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-88. MLBP_SIG_IO_CTRL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-22 | Rsvd3 | R | 0h | Reserved-read returns 0 |
| 21-16 | NC_IN | R/W | 0h | MLB LVDS Output Drive Trim value. If register defaults to state of 0x0, then it should be set to the recommended state of 0x1A. If the register defaults to non-zero, that implies it was set to optimal value during manufacturing. |
| 15-14 | Rsvd2 | R | 0h | Reserved-read returns 0 |
| 13-8 | PC_IN | R/W | 0h | MLB LVDS Output Drive Trim value. If register defaults to state of 0x0, then it should be set to the recommended state of 0x24. If the register defaults to non-zero, that implies it was set to optimal value during manufacturing. |
| 7-6 | Rsvd | R | 0h | Reserved-read returns 0 |
| 5 | PWRDNRX | R/W | 1h | Power down control for MLB LVDS receiver. A 1 written to this register will power down the receiver. A 0 written to this register will power on the receiver. By default, the receiver is in power down mode. |
| 4 | PWRDNTX | R/W | 1h | Power down control for MLB LVDS transmitter. A 1 written to this register will power down the transmitter. A 0 written to this register will power on the transmitter. By default, the transmitter is in power down mode. |
| 3 | EN_EXT_RES | R/W | 1h | Disables the internal resistors required for proper MLB LVDS operation. This register should always be programmed to 0x0 |
| 2 | ENLVCMOS | R/W | 0h | This registers is used to disable the MLB LVDS mode and program the pins as GPIO. Each pad acts as 50ohm LVCMOS TX and LVCMOS RX when this bit is set to 1. Each pad is MLB LVDS when this bit is set to zero. |
| 1 | ENN | R/W | 0h | Receiver enable for LVCMOS GPIO mode. Programming this register to 1 enables the MLBP_SIGN pad to be a GPIO input. Programming this register to 0 disables the input and MLBP_SIGN pad is only an output. |
| 0 | ENP | R/W | 0h | Receiver enable for LVCMOS GPIO mode. Programming this register to 1 enables the MLBP_SIGP pad to be a GPIO input. Programming this register to 0 disables the input and MLBP_SIGP pad is only an output. |

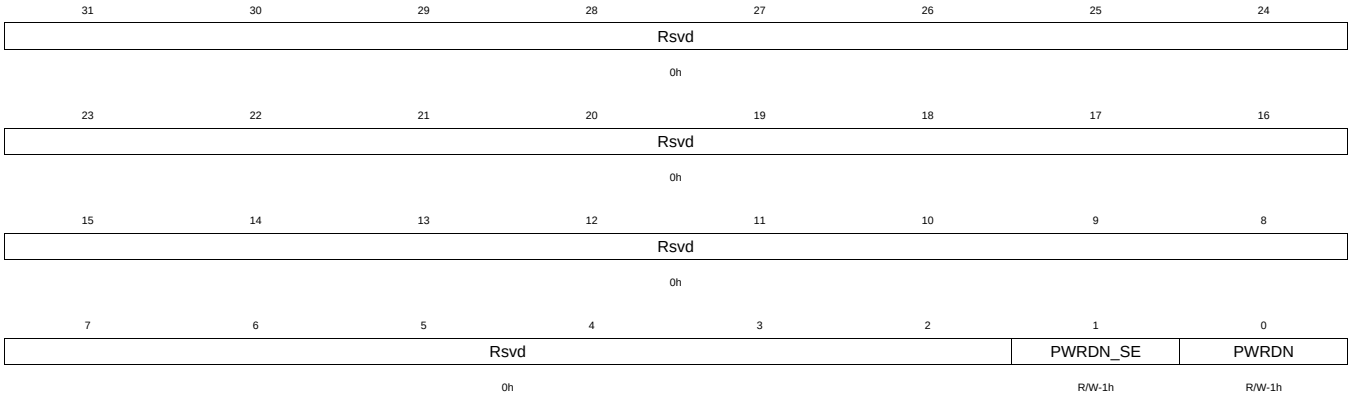
### 3.2.87 SERDES_REFCLK_CTL Register (offset = E24h) [reset = 3h]

SERDES_REFCLK_CTL is shown in Figure 3-88 and described in Table 3-90.

This register controls the refclk for the SerDes block s IO powerdown.

**Figure 3-88. SERDES_REFCLK_CTL Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-90. SERDES_REFCLK_CTL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-2 | Rsvd | | 0h | Reserved-read returns 0 |
| 1 | PWRDN_SE | R/W | 1h | Powerdown both refclkp/n single ended receiver |
| 0 | PWRDN | R/W | 1h | Powerdown both refclkp/n receiver |

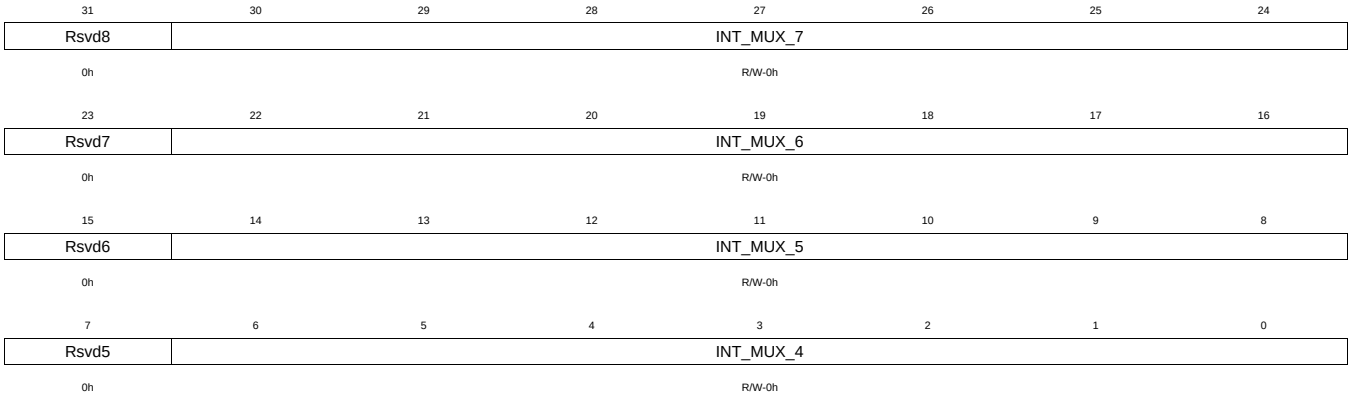
### 3.2.110 Media_Controller_INTMUX_4_7 Register (offset = F58h) [reset = 0h]

Media_Controller_INTMUX_4_7 is shown in Figure 3-111 and described in Table 3-113.

This register controls Media Controller interrupt assignment for interrupts through 4 to 7

**Figure 3-111. Media_Controller_INTMUX_4_7 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-113. Media_Controller_INTMUX_4_7 Register Field Descriptions**

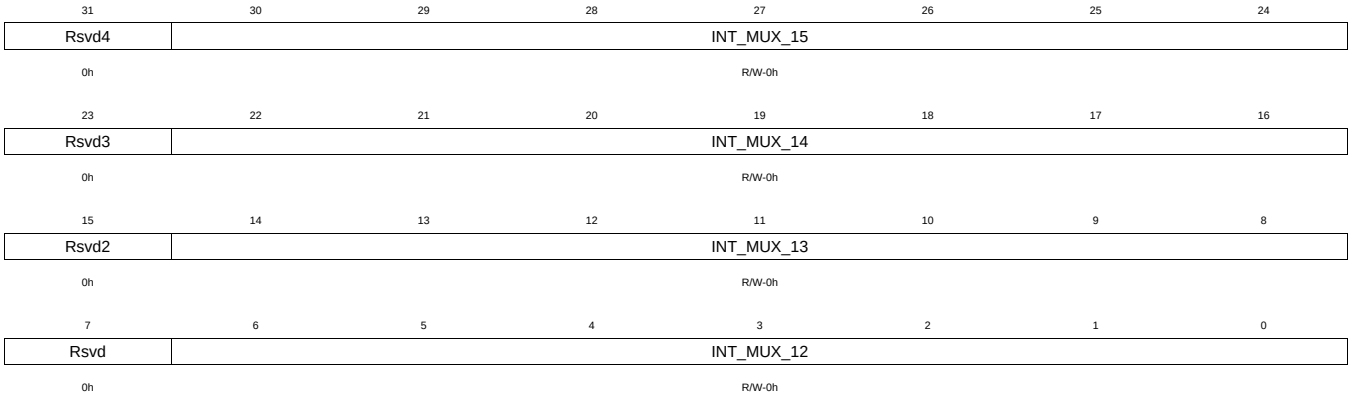
### 3.2.112 Media_Controller_INTMUX_12_15 Register (offset = F60h) [reset = 0h]

Media_Controller_INTMUX_12_15 is shown in Figure 3-113 and described in Table 3-115.

This register controls Media Controller interrupt assignment for interrupts through 12 to 15

**Figure 3-113. Media_Controller_INTMUX_12_15 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

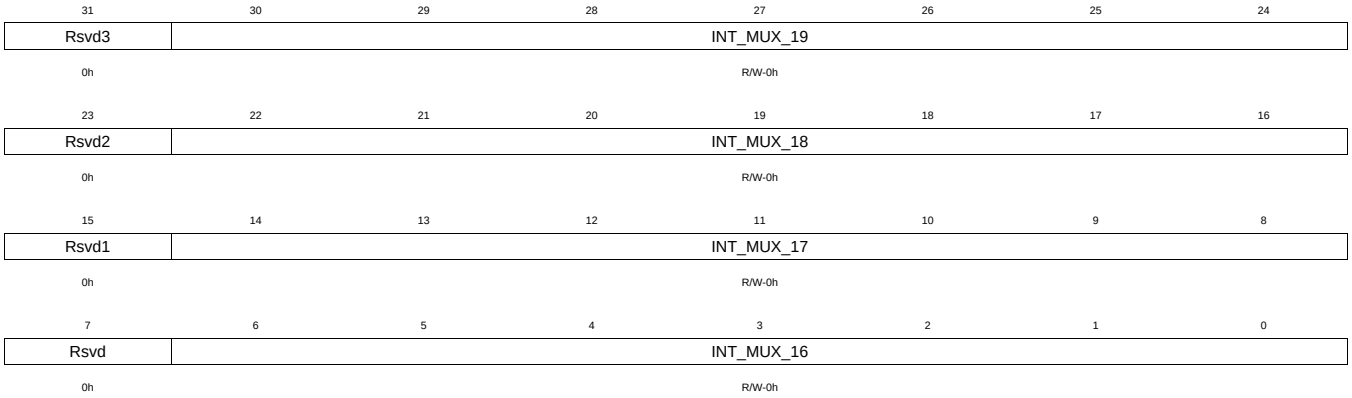
### 3.2.113 Media_Controller_INTMUX_16_19 Register (offset = F64h) [reset = 0h]

Media_Controller_INTMUX_16_19 is shown in Figure 3-114 and described in Table 3-116.

This register controls Media Controller interrupt assignment for interrupts through 16 to 19

**Figure 3-114. Media_Controller_INTMUX_16_19 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

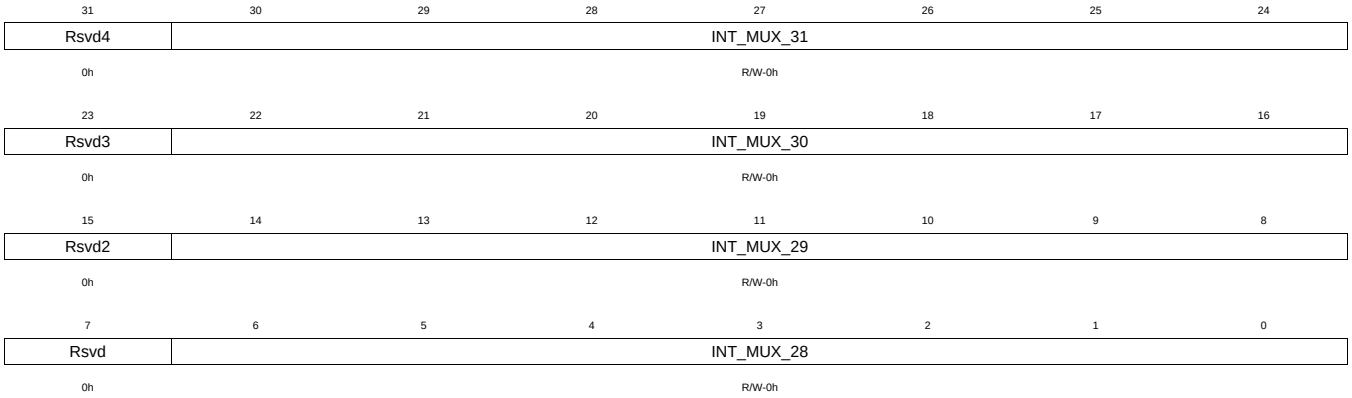
### 3.2.116 Media_Controller_INTMUX_28_31 Register (offset = F70h) [reset = 0h]

Media_Controller_INTMUX_28_31 is shown in Figure 3-117 and described in Table 3-119.

This register controls Media Controller interrupt assignment for interrupts through 28 to 31

**Figure 3-117. Media_Controller_INTMUX_28_31 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

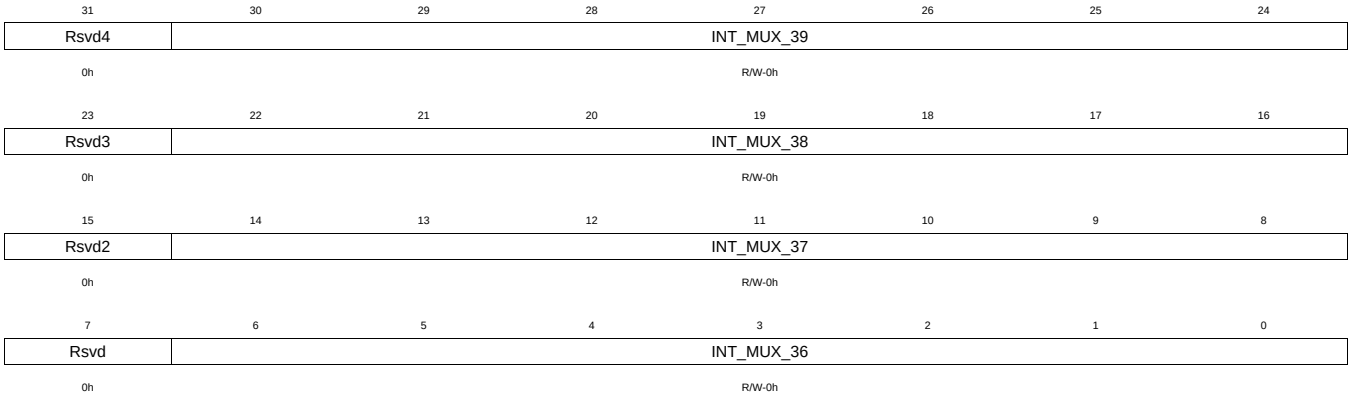
### 3.2.118 Media_Controller_INTMUX_36_39 Register (offset = F78h) [reset = 0h]

Media_Controller_INTMUX_36_39 is shown in Figure 3-119 and described in Table 3-121.

This register controls Media Controller interrupt assignment for interrupts through 36 to 39

**Figure 3-119. Media_Controller_INTMUX_36_39 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

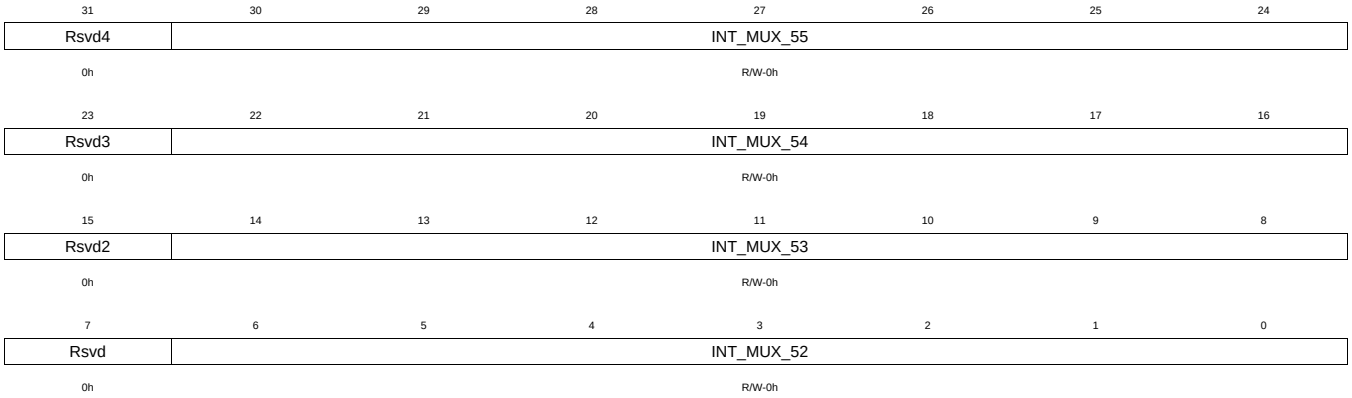
### 3.2.122 Media_Controller_INTMUX_52_55 Register (offset = F88h) [reset = 0h]

Media_Controller_INTMUX_52_55 is shown in Figure 3-123 and described in Table 3-125.

This register controls Media Controller interrupt assignment for interrupts through 52 to 55

**Figure 3-123. Media_Controller_INTMUX_52_55 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-125. Media_Controller_INTMUX_52_55 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |

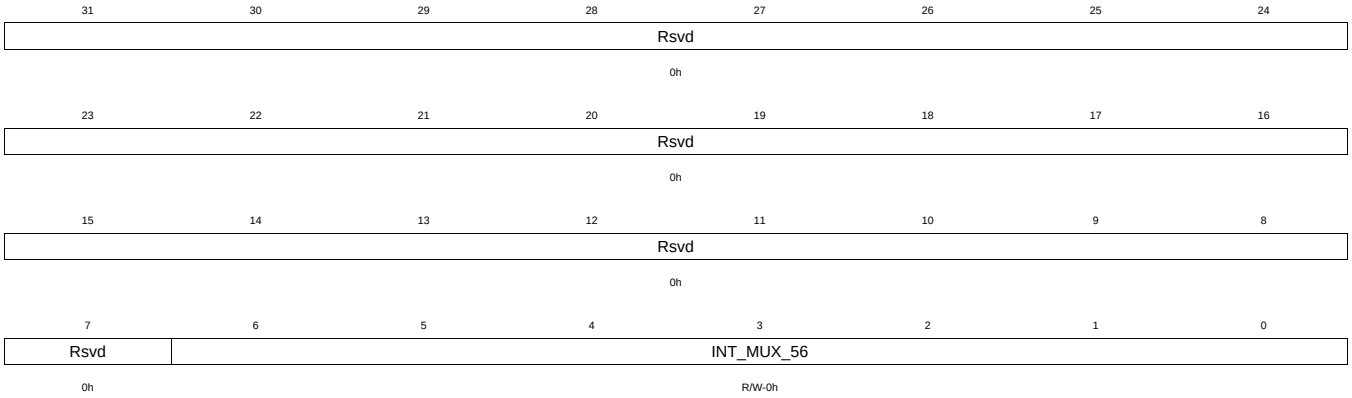
### 3.2.123 Media_Controller_INTMUX_56 Register (offset = F8Ch) [reset = 0h]

Media_Controller_INTMUX_56 is shown in Figure 3-124 and described in Table 3-126.

This register controls Media Controller interrupt assignment for interrupt number 56.

**Figure 3-124. Media_Controller_INTMUX_56 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

**Table 3-126. Media_Controller_INTMUX_56 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-7 | Rsvd | | 0h | Reserved- Read returns 0 |
| 6-0 | INT_MUX_56 | R/W | 0h | Interrupt mux 56 |

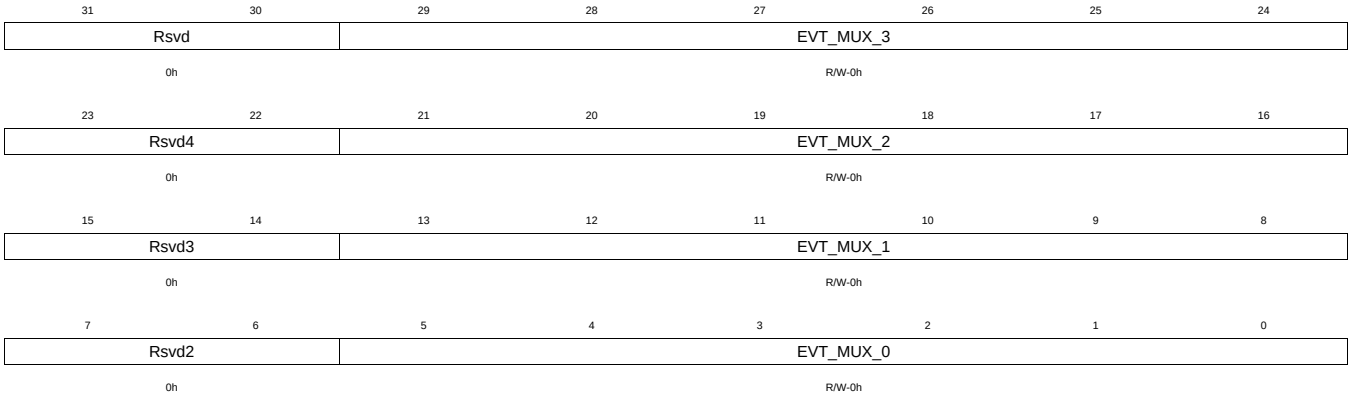
### 3.2.124 EDMA3CC_EVTMUX_0_3 Register (offset = F90h) [reset = 0h]

EDMA3CC_EVTMUX_0_3 is shown in Figure 3-125 and described in Table 3-127.

This register controls EDMA3CC Event mux assignment for event no 0 to 3

**Figure 3-125. EDMA3CC_EVTMUX_0_3 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 3-127. EDMA3CC_EVTMUX_0_3 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|

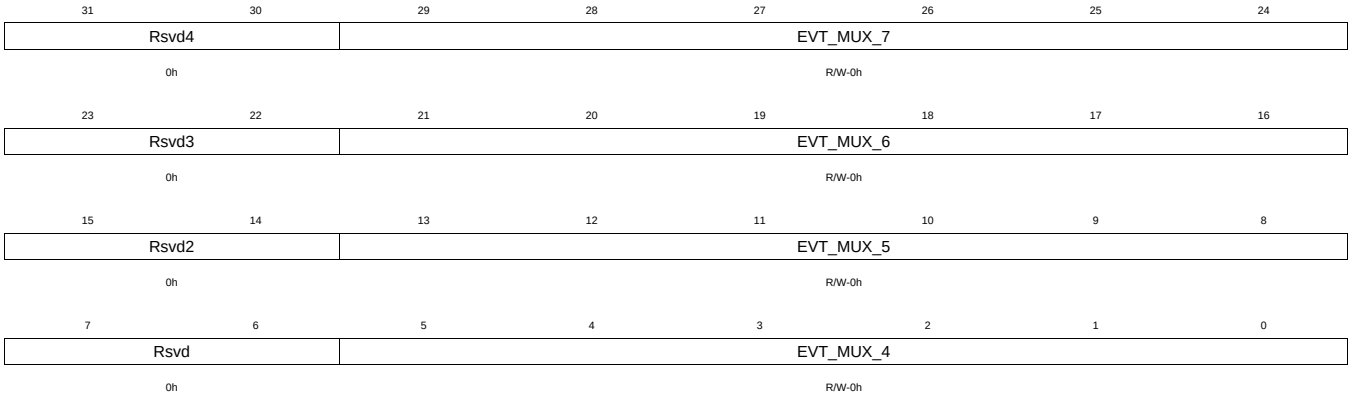
### 3.2.125 EDMA3CC_EVTMUX_4_7 Register (offset = F94h) [reset = 0h]

EDMA3CC_EVTMUX_4_7 is shown in Figure 3-126 and described in Table 3-128.

This register controls EDMA3CC Event mux assignment for event no 4 to 7

**Figure 3-126. EDMA3CC_EVTMUX_4_7 Register**



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

**Table 3-128. EDMA3CC_EVTMUX_4_7 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-30 | Rsvd4 | | 0h | Reserved-Read returns 0 |
| 29-24 | EVT_MUX_7 | R/W | 0h | Event mux for EDMA3CC event number 7 |
| 23-22 | Rsvd3 | | 0h | Reserved-Read returns 0 |
| 21-16 | EVT_MUX_6 | R/W | 0h | Event mux for EDMA3CC event number 6 |
| 15-14 | Rsvd2 | | 0h | Reserved-Read returns 0 |

### 3.2.136 EDMA3CC_EVTMUX_48_51 Register (offset = FC0h) [reset = 0h]

EDMA3CC_EVTMUX_48_51 is shown in Figure 3-137 and described in Table 3-139.

This register controls EDMA3CC Event mux assignment for event no 48 to 51

**Figure 3-137. EDMA3CC_EVTMUX_48_51 Register**

### 3.2.140 GPIO_MUX Register (offset = FD4h) [reset = 0h]

GPIO_MUX is shown in Figure 3-141 and described in Table 3-143.

This register controls the input source for GPIO1_0 to GPIO1_5 inputs. The input source can either come from the device pin (as a GPIO), or from an internal interrupt source.

**Figure 3-141. GPIO_MUX Register**

# ROM Code Memory and Peripheral Booting

This chapter describes the booting functionality of the public ROM code, referred hereafter as ROM Code. The booting functionality covers the following features:

- *Memory Booting* – booting the device by starting code stored on permanent memories like flash-memory or memory cards. This process is usually performed after either device cold or warm reset.
- *Peripheral Booting* – booting the device by downloading the executable code over a communication interface like UART or Ethernet. This process is intended for flashing a device.

The device always starts up in secure mode. The ROM Code takes care of early initialization. The ROM code switches the device into public mode; hence, the Public ROM Code provides run-time services for cache maintenance.

This chapter is intended for all who design systems based on this device, develop bootloader images and flashing tools.

## 4.1 Introduction

This chapter describes the booting functionality of the Public ROM Code.

### *4.1.1 Acronyms and Naming Conventions*

The following tables provides acronyms and abbreviations, as well as the naming conventions used in this document.

**Table 4-1. Acronyms and Abbreviations**

| Acronym/Abbreviation | Definition |
|---|---|
| ASIC | Application Specific Integrated Circuit |
| B | Byte (8 bits) |
| CS | Chip Select |
| CH | Configuration Header |
| DPLL | Digital PLL |
| EMIF | External Memory InterFace (SDRAM Controller) |
| FIQ | Fast Interrupt Request |
| FS USB | Full Speed USB |
| GPMC | General Purpose Memory Controller |
| HLOS | High Level Operating System |
| HS USB | High Speed USB |
| HW | Hardware |
| HWA | Hardware Accelerator |
| I2C | Inter-Integrated Circuit |
| IRQ | Interrupt |
| ISR | Interrupt Service Routine |
| JTAG | Joint Test Action Group. This term is used to refer to the Debugging and Testing interface. |
| Kbps | Kilobits per second |
| KB | Kilobyte, 1024 B |
| LPDDR2 | Low Power Double Data Rate rev. 2 |
| LPDDR2-NVM | Non volatile type of memory connected to EMIF interface |
| MB | Megabyte, 1024 KB |
| MMC | Multimedia Card. |
| MPU | Micro Processor Unit |
| OCM | On-Chip Memory |
| OneNAND™ | A type of Flash memory |
| PA | Protected Application (also see Table 4-2) |
| PLL | Phase Locked Loop |
| PK | Public Key |
| PPA | Primary Protected Application (also see Table 4-2) |
| POR | Power On Reset |
| PMU | Power Management Unit |
| PRCM | Power, Reset and Clock Management module |
| RAM | Random Access Memory. Refers to the OMAP internal static RAM |
| ROM | Read Only Memory |
| RSA | Rivest, Shamir, Adleman encryption algorithm |
| SAR | Save & Restore |
| SDRAM | Synchronous Dynamic Random Access Memory |
| SWI | Software Interrupt |
| TOC | Table Of Contents – a structure within an executable image |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-1. Acronyms and Abbreviations (continued)**

| Acronym/Abbreviation | Definition |
|---|---|
| UART | Universal Asynchronous Receiver/Transmitter |
| USB | Universal Serial Bus |
| XIP | Execute In Place |
| WDT | Watchdog timer |

**Table 4-2. Naming Conventions**

| Name | Definition |
|---|---|
| Bootstrap | Initial SW that is launched by the ROM Code during the Memory Booting phase |
| Downloaded SW | Initial SW that is downloaded into internal RAM by the ROM Code during peripheral booting phase. |
| E-Fuse | A one-time programmable memory location usually set at the factory |
| Flash Loader | Downloaded software launched by the ROM Code in Pre-Flashing and which programs an image into external memories. |
| Initial SW | Software which is executed by any of the ROM Code mechanisms (Memory Booting or Peripheral Booting). Initial software is a generic term for Bootstrap and Downloaded software. |
| Memory Booting | ROM Code mechanism that consists of executing an Initial SW from external memory. |
| Monitor Mode Manager | ROM Code software component in charge of handling all entry/exit to/from MPU Secure State. |
| Peripheral Booting | ROM Code mechanism that consists of polling selected interfaces, downloading and executing an Initial SW (in this case called Downloaded SW) in internal RAM. |
| Pre-Flashing | Specific case of peripheral booting, where the ROM Code mechanism is used to program external Flash memories. |

## 4.2 Overview

### *4.2.1 Architecture*

The architecture of the ROM code is shown in Figure 4-1. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower level layer through a unified interface.

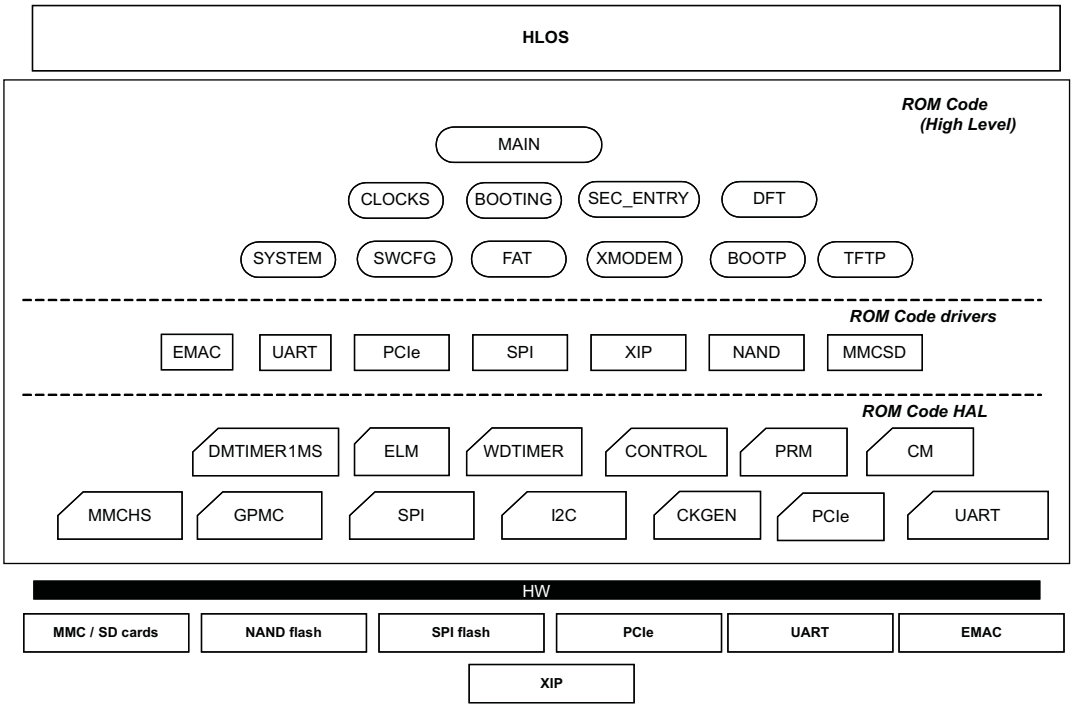
The high level layer is in charge of the main tasks of the ROM Code: watchdog and clocks configuration and main booting routine.

The drivers layer implements the logical and communication protocols for any booting device in accordance with the interface specification.

Finally the HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to device IO pads.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-1. ROM Code Architecture**



### 4.2.2 Functionality

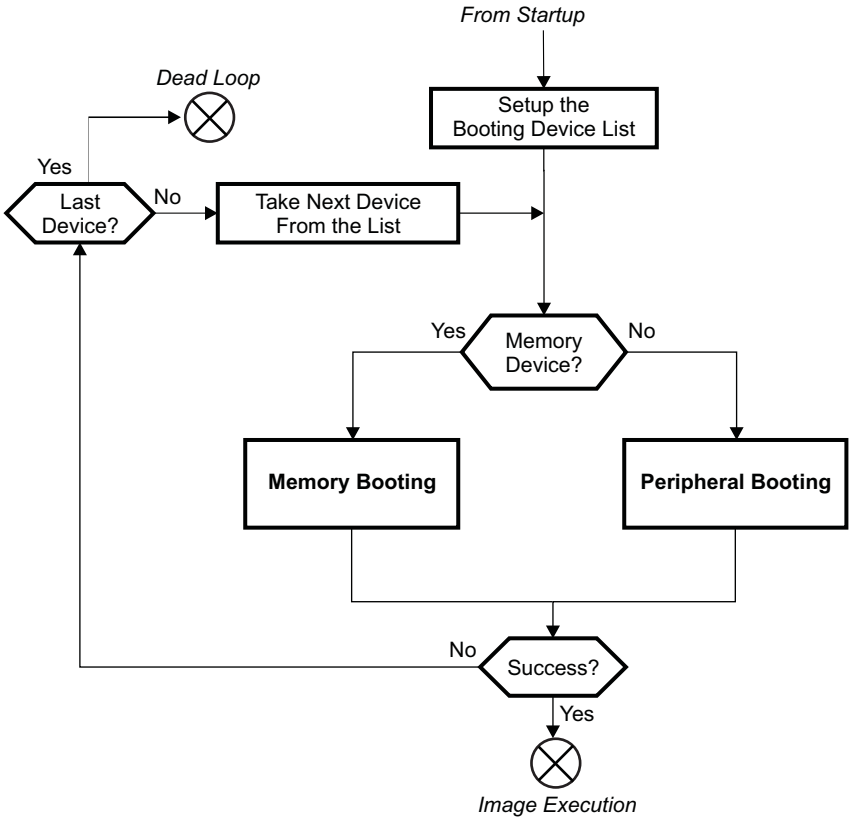
Figure 4-2 illustrates the high level flow for the Public ROM Code booting procedure. On the device, the Public ROM Code starts upon completion of the secure startup (performed by the Secure ROM Code). The ROM Code then performs platform configuration and initialization as part of the public start-up procedure.

The booting device list is created based on the MBOOT. A booting device can be a memory booting device (soldered flash memory or temporarily booting device like memory card) or a peripheral interface connected to a host.

The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-2. ROM Code Boot Procedure**



## 4.3 Memory Map

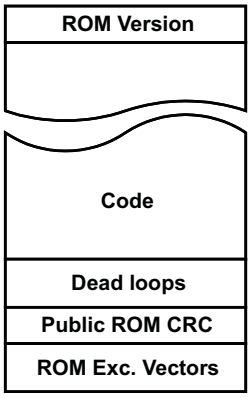
### *4.3.1 ROM Memory Map*

The on-chip ROM memory map is shown in Figure 4-3. The ROM Code mapping consists in the following:

- Exception vectors
- CRC
- Dead loops collection
- Code and const data sections
- API Table
- ROM Version

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-3. ROM Memory Map**



#### 4.3.1.1 ROM Exception Vectors

Table 4-3 lists the ROM exception vectors. The reset exception is redirected to the ROM Code startup. Other exceptions are redirected to their RAM handlers by loading appropriate addresses into the PC register.

**Table 4-3. ROM Exception Vectors**

| Address | Exception | Content |
|---|---|---|
| 20000h | Reset | Branch to the ROM Code startup |
| 20004h | Undefined | PC = 4030 D004h |
| 20008h | SWI | PC = 4030 D008h |
| 2000Ch | Pre-fetch abort | PC = 4030 D00Ch |
| 20010h | Data abort | PC = 4030 D010h |
| 20014h | Unused | PC = 4030 D014h |
| 20018h | IRQ | PC = 4030 D018h |
| 2001Ch | FIQ | PC = 4030 D01Ch |

#### 4.3.1.2 ROM Code CRC

The ROM Code CRC is calculated as 32 bit CRC code (CRC-32-IEEE 802.3) for the address range 20000h–2BFFFh. The four bytes CRC code is stored at location 20020h.

#### 4.3.1.3 Dead Loops

Built-in dead loops are used for different purposes as shown in Table 4-4. All dead loops are branch instructions coded in ARM mode. The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors. The dead loops might be called directly from the user code. However there exists a special function which can be called from ROM code in order to execute a dead loop. The function is an assembly code in ARM mode which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global SW reset before going to a dead loop. The function is located at address 200C0h. In addition the function clears global cold reset status upon issuing the global SW reset.

**Table 4-4. Dead Loops**

| Address | Purpose |
|---|---|
| 20080h | Undefined exception default handler |
| 20084h | SWI exception default handler |
| 20088h | Pre-fetch abort exception default handler |
| 2008Ch | Data abort exception default handler |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-4. Dead Loops (continued)**

| Address | Purpose |
|---|---|
| 20090h | Unused exception default handler |
| 20094h | IRQ exception default handler |
| 20098h | FIQ exception default handler |
| 2009Ch | Validation tests PASS |
| 200A0h | Validation tests FAIL |
| 200A4h | Reserved |
| 200A8h | Image not executed or returned. |
| 200ACh | Reserved |
| 200B0h | Reserved |
| 200B4h | Reserved |
| 200B8h | Reserved |
| 200BCh | Reserved |

#### 4.3.1.4 Code

This space is used to hold code and constant data.

#### 4.3.1.5 Public ROM Code Version

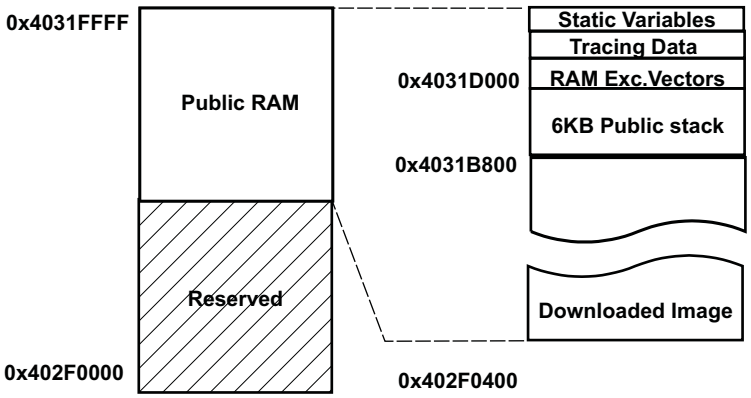
The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM Code release version burnt in a given IC (e.g., useful to identify an IC version). The ROM code version is a 32 bits hexadecimal value located at address 2BFFCh.

Copyright © 2011–2016, Texas Instruments Incorporated

### 4.3.2 RAM Memory Map

The ROM code makes use of the on chip RAM module connected to the L3 interconnect (further referred as L3 RAM in this document). Its usage is shown in Figure 4-4. The RAM memory map ranges from address 4020F000h to 4031FFFFh.

**Figure 4-4. Public RAM Memory Map**



#### 4.3.2.1 Downloaded Image

This area is used by the ROM code to store the downloaded boot image. It can be up to 173 KB.

#### 4.3.2.2 Public Stack

Space reserved for stack.

#### 4.3.2.3 RAM Exception Vectors

The RAM exception vectors enable a simple means for redirecting exceptions to custom handlers. Table 4-5 shows content of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load the value located in the subsequent seven addresses into the PC register. Theses instructions are executed when an exception occurs since they are called from the ROM exception vectors. Undefined, SWI, Unused and FIQ exceptions are redirected to a hardcoded dead loop. Pre-fetch abort, data abort, and IRQ exception are redirected to pre-defined ROM handlers. User code can redirect any exception to a custom handler either by writing its address to the appropriate location from 4031 D024h to 4031 D03Ch or by overriding the branch (load into PC) instruction between addresses from 4031 D004h to 4031 D01Ch.

**Table 4-5. RAM Exception Vectors**

| Address | Exception | Content |
|---|---|---|
| 4031 D000h | Reserved | Reserved |
| 4031 D004h | Undefined | PC = [4031 D024h] |
| 4031 D008h | SWI | PC = [4031 D028h] |
| 4031 D00Ch | Pre-fetch abort | PC = [4031 D02Ch] |
| 4031 D010h | Data abort | PC = [4031 D030h] |
| 4031 D014h | Unused | PC = [4031 D034h] |
| 4031 D018h | IRQ | PC = [4031 D038h] |
| 4031 D01Ch | FIQ | PC = [4031 D03Ch] |
| 4031 D020h | Reserved | 20090h |
| 4031 D024h | Undefined | 20080h |
| 4031 D028h | SWI | 20084h |
| 4031 D02Ch | Pre-fetch abort | Address of default pre-fetch abort handler (*) |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-5. RAM Exception Vectors (continued)**

| Address | Exception | Content |
|---|---|---|
| 4031 D030h | Data abort | Address of default data abort handler (*) |
| 4031 D034h | Unused | 20090h |
| 4031 D038h | IRQ | Address of default IRQ handler |
| 4031 D03Ch | FIQ | 20098h |

(*) the default handlers for pre-fetch and data abort are performing reads from CP15 debug registers to retrieve the reason of the abort:

- In case of pre-fetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM Code jumps to the pre-fetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM Code jumps to the data abort dead loop (2008Ch).

#### 4.3.2.4 Tracing Data

This section contains trace vectors reflecting the execution path of the public boot. Section 4.12 describes the usage of the different trace vectors and lists all the possible trace codes.

**Table 4-6. Tracing Data**

| Address | Size [bytes] | Description |
|---|---|---|
| 4031 D040h | 4 | Current tracing vector, word 1 |
| 4031 D044h | 4 | Current tracing vector, word 2 |
| 4031 D048h | 4 | Current tracing vector, word 3 |
| 4031 D04Ch | 4 | Current copy of the PRM_RSTST register (reset reasons) |
| 4031 D050h | 4 | Cold reset run tracing vector, word 1 |
| 4031 D054h | 4 | Cold reset run tracing vector, word 2 |
| 4031 D058h | 4 | Cold reset run tracing vector, word 3 |
| 4031 D05Ch | 4 | Reserved |
| 4031 D060h | 4 | Reserved |
| 4031 D064h | 4 | Reserved |

#### 4.3.2.5 Static Variables

This area contains the ROM code static variables used during boot time (and possibly during run-time, if calling the Public ROM API functions).

Copyright © 2011–2016, Texas Instruments Incorporated

## 4.4 Startup and Configuration

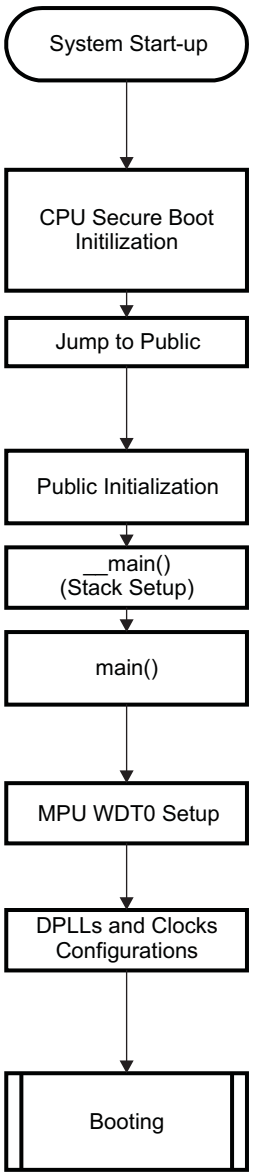
### 4.4.1 ROM Code Start-up

The main MPU subsystem always starts its execution in secure mode after reset due to the TrustZone architecture (the Secure ROM code implements the reset handler). The Public ROM code is physically located at the address 20000h that is immediately next to the Secure ROM code.

As shown at top of Figure 4-5, the CPU jumps to the Public ROM Code reset vector once it has completed the secure boot initialization.

Once in public mode the CPU performs the public-side initialization and stack setup (compiler auto generated C- initialization or “scatter loading”) as shown in left hand side of Figure 4-5. Then it configures the watchdog timer 2 (set to three minutes), and performs system clocks configuration. Finally it jumps to the booting routine.

**Figure 4-5. ROM Code Start-up Sequence**



Copyright © 2011–2016, Texas Instruments Incorporated

### 4.4.2 CPU State at Public Startup

The CPU L1 instruction cache and branch prediction mechanisms are not activated as part of the public boot process. The public vector base address is configured to the reset vector of Public ROM Code (20000h). MMU is left switched off during the public boot (hence L1 data cache off).

No specific configuration is performed for the slave CPU which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public vectors base address).

### 4.4.3 Clocking Configuration

The supported system clock frequencies are OSC0 = 20 MHz.

The ROM Code configures the clocks and DPLLs that are necessary for ROM Code execution:

- L3 DPLL locked to provide 220MHz clocks for peripheral blocks
- DDR DPLL locked to provide 400MHz
- ARM DPLL is locked to provide 600MHz for the A8
- USB DPLL is locked to provide 960MHz and 192MHz for peripheral blocks

Table 4-7 summarizes the ROM Code default settings for clocks. This default configuration enables all the ROM Code functionalities with minimized needs on power during boot.

The DPLLs and PRCM clock dividers are configured with the ROM Code default values after cold or warm reset in order to give the same working conditions to the Public ROM Code sequence

**Table 4-7. ROM Code Default Clock Settings**

| Clock | Frequency (MHz) | Source |
|---|---|---|
| PLL_ARM | 600 | OSC0 |
| PLL_L3 | 220 | OSC0 |
| PLL_USB | 960 | OSC0 |
| PLL_DDR | 400 | OSC0 |
| SYSCLK4 | 220 | PLL_L3/1 |
| SYSCLK8 | 192 | (PLL_USB/5)/1 |
| SYSCLK10 | 48 | (PLL_USB/5)/4 |
| SYSCLK18B | 32KHz | RTCDIVIDER |

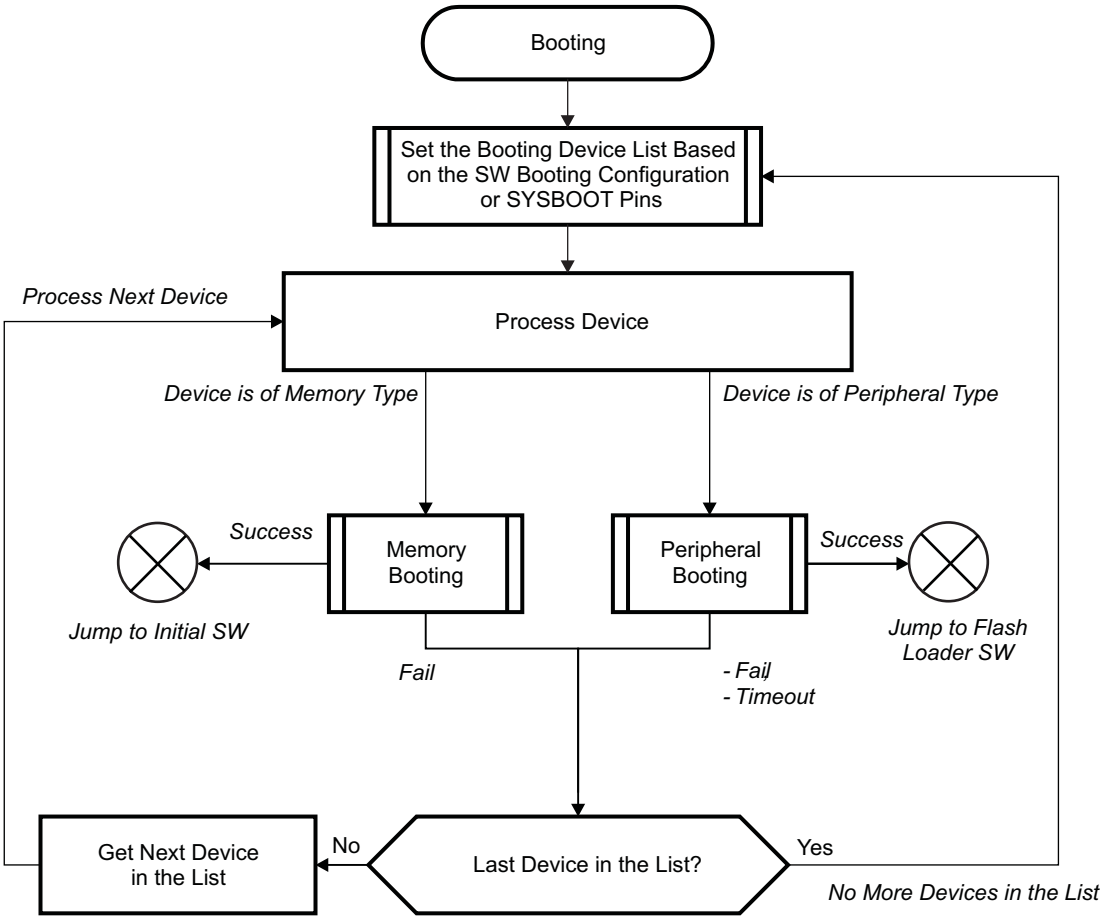
## 4.5 Booting

### 4.5.1 Overview

Figure 4-6 shows the booting procedure. First, a booting device list is created. The list consists of all devices which will be searched for a booting image. The list is filled in based on the SYSBOOT.

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-6. ROM Code Booting Procedure**



Once the booting device list is set up, the booting routine examines the devices enumerated in the list sequentially and either executes the memory booting or peripheral booting procedure depending on the booting device type. The memory booting procedure is executed when the booting device type is one of NOR, NAND, MMC, or SPI-EEPROM. The peripheral booting is executed when the booting device type is Ethernet, PCIe or UART.

The memory booting procedure reads data from a memory type device. If a valid booting image is found and successfully read from the external memory device, the initial SW is simply started.

The peripheral booting procedure downloads data from a host (commonly a PC) to the device by means of Ethernet, PCIe or UART links. The ROM Code uses a host-slave logical protocol for synchronization. Upon successful PCIe enumeration (or UART or Ethernet connection) the host sends the image binary contents. The peripheral booting procedure is described in detail in Section 4.8.

If the memory or peripheral booting fails for all devices enumerated in the device list, then the ROM Code gets back to the first device in the list. The device list is then processed again in a loop. This loop shall be further interrupted by the MPU or secure watchdog.

### 4.5.2 Device List

The ROM Code creates the device list based on information gathered from the SYSBOOT configuration pins sensed in the control module. The pins are used to index the device table from which the list of devices is extracted.

#### 4.5.2.1 BTMode[4-0] Configuration Pins

The following table describes the BTMode[4-0] configuration pins.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-8. BTMode[4-0] Configuration Pins**

| Boot Modes | | | | BTMODE[4:0] |
|---|---|---|---|---|
| 1st | 2nd | 3rd | 4th | |
| Reserved | Reserved | Reserved | Reserved | 00000 |
| UART | XIP w/ WAIT (MUX0) | MMC | SPI | 00001 |
| UART | SPI | NAND | NANDI2C | 00010 |
| UART | SPI | XIP (MUX0) | MMC | 00011 |
| EMAC | SPI | NAND | NANDI2C | 00100 |
| Reserved | Reserved | Reserved | Reserved | 00101 |
| Reserved | Reserved | Reserved | Reserved | 00110 |
| EMAC | MMC | SPI | XIP (MUX 1) | 00111 |
| PCIE_32 | Reserved | Reserved | Reserved | 01000 |
| PCIE_64 | Reserved | Reserved | Reserved | 01001 |
| Reserved | Reserved | Reserved | Reserved | 01010 |
| Reserved | Reserved | Reserved | Reserved | 01011 |
| Reserved | Reserved | Reserved | Reserved | 01100 |
| Reserved | Reserved | Reserved | Reserved | 01101 |
| Reserved | Reserved | Reserved | Reserved | 01110 |
| Fast External Boot | UART | EMAC | PCIE_64 | 01111 |
| XIP (MUX1) | UART | EMAC | MMC | 10000 |
| XIP w/WAIT (MUX1) | UART | EMAC | MMC | 10001 |
| NAND | NANDI2C | SPI | UART | 10010 |
| NAND | NANDI2C | MMC | UART | 10011 |
| NAND | NAND12C | SPI | EMAC | 10100 |
| NANDI2C | MMC | EMAC | UART | 10101 |
| SPI | MMC | UART | EMAC | 10110 |
| MMC | SPI | UART | EMAC | 10111 |
| SPI | MMC | PCIE_32 | Reserved | 11000 |
| SPI | MMC | PCIe_64 | Reserved | 11001 |
| XIP (MUX0) | UART | SPI | MMC | 11010 |
| XIP w/ WAIT (MUX0) | UART | SPI | MMC | 11011 |
| Reserved | Reserved | Reserved | Reserved | 11100 |
| Reserved | Reserved | Reserved | Reserved | 11101 |
| Reserved | Reserved | Reserved | Reserved | 11110 |
| Fast external Boot | EMAC | UART | PCIE_32 | 11111 |

The ROM Code uses the row pointed by the MBOOT configuration value .The device list is filled in with the 1st to 4th devices. is the decoding table for MBOOT configuration pins. The following shortcuts are used in the table:

| MMC | MMC or SD card (MMC port 1) |
|---|---|
| NAND / NANDI2C | NAND flash memory / read flash geometry from I2C EEPROM |
| XIP / XIP w/ WAIT | NOR or other XIP device with or without wait monitoring |
| UART | UART interface (UART port 0) |
| EMAC | Ethernet GMII0m RGMII and RMII interface (EMAC port 0) |
| SPI | SPI EEPROM (SPI 0, CS0) |
| PCIE_32 / PCIE_64 | PCI Express interface with 32 bit / 64 bit addressing |

Copyright © 2011–2016, Texas Instruments Incorporated

## 4.6 Fast External Booting

### 4.6.1 Overview

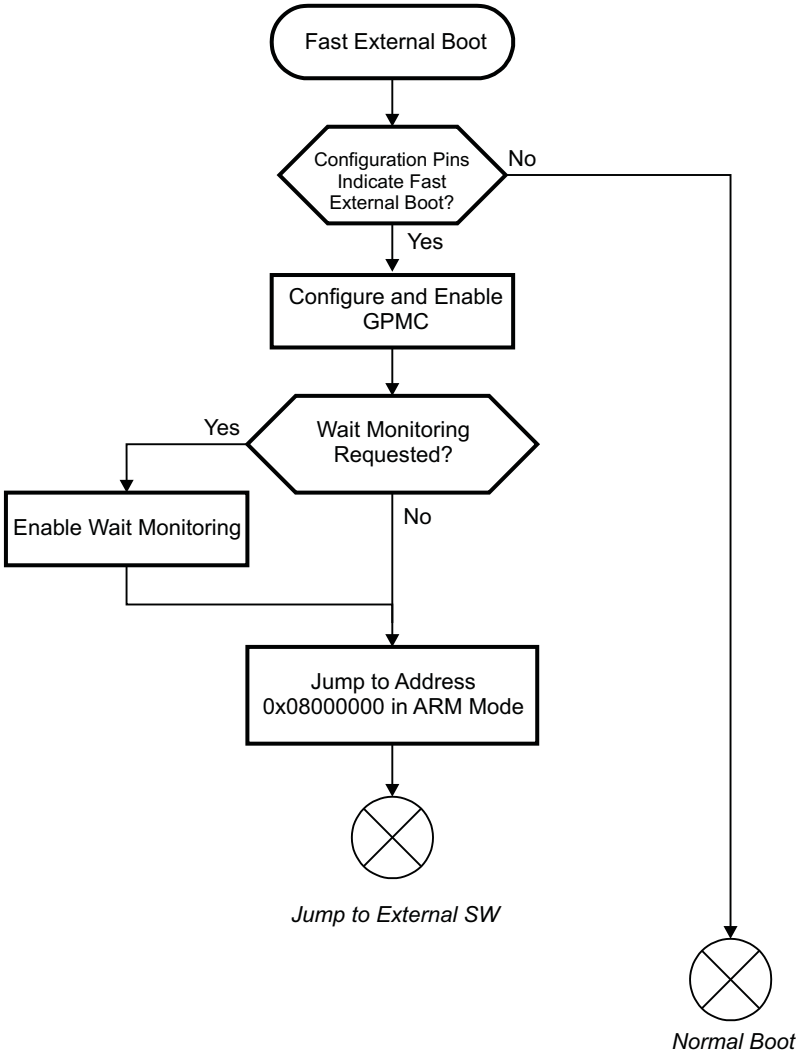
The fast external boot feature:

- Consists of a blind jump in ARM mode to a code located in an external XIP device connected to CS0
- The jump is performed with minimum on-chip ROM Code execution, without configuring any PLL
- Allows the customer to create its own booting code
- Is set up by means of the configuration pins, see Table 4-8

### 4.6.2 External Booting

Figure 4-7 shows the fast external boot procedure. The code does not make use of RAM and is designed for fast execution.

**Figure 4-7. Fast External Boot**



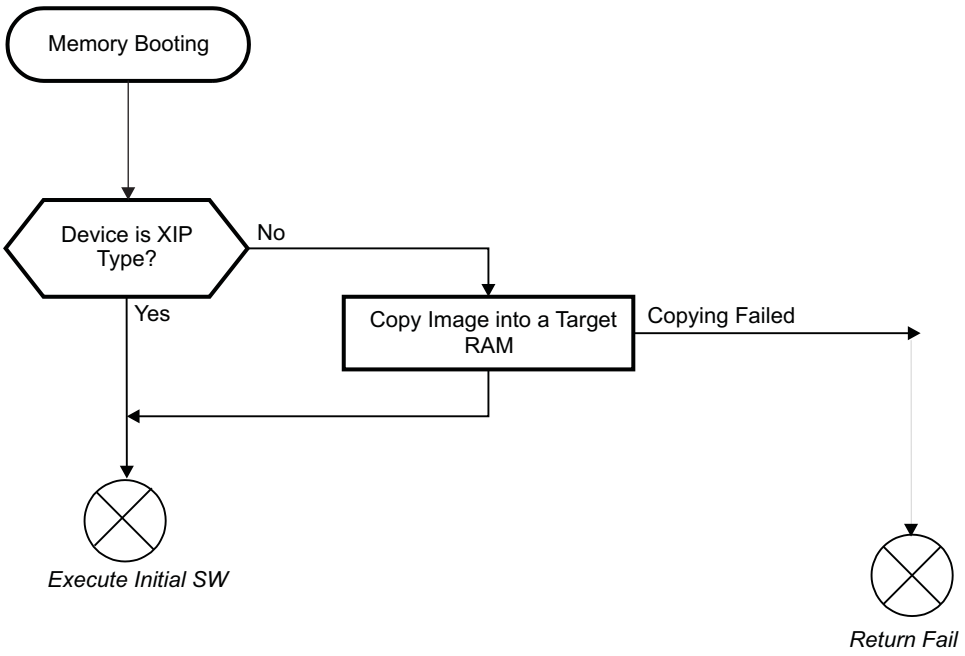
Copyright © 2011–2016, Texas Instruments Incorporated

## 4.7 Memory Booting

### 4.7.1 Overview

The memory booting procedure takes care of starting an external code located in memory device types. These devices are also called permanent booting devices since they are used in that manner.

**Figure 4-8. Memory Booting**



The permanent booting devices supported are:

- MMC/SD cards
- NOR flash
- NAND flash
- SPI EEPROMs

There are two groups of permanent booting devices distinguished by the need of code shadowing. The code shadowing means copying a code from a non-directly addressable device into a location (typically a RAM area) from where the code can be executed. Devices which are directly addressable are called eXecute In Place (XIP) devices.

Copyright © 2011–2016, Texas Instruments Incorporated

The memory booting flowchart is shown in Figure 4-8. The second step is about performing the shadowing of the image that is copying the image from external mass storage (non-XIP) into internal RAM. Failure in image copy results in memory booting returning to the main booting procedure which will select the next device for booting. The next sections detail procedures for device initialization & detection in addition to the description of the sector read routine for each supported device type. A sector is a logical unit of 512 bytes.

A valid image is considered to be present when the first 4 bytes word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector call, sectors are copied to a temporary RAM buffer. Once the image is found and a destination address is known, the content of the temporary buffer is moved to the target RAM location so it is needed to re-read the first image sector. The header is discarded; therefore, only executable code is located in RAM with the first executable instruction located at the destination address.

For more information about image formats and contents refer to Section 4.9.

MMC/SD cards and NAND devices can hold up to four copies of the booting image. Therefore the ROM Code searches for one valid image out of the four if present by walking over the first four blocks of the mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

### *4.7.2 XIP Memory*

The ROM Code can boot directly from XIP devices. A typical XIP device is a NOR flash memory. Support for XIP devices is performed under the following assumptions:

- Uses GPMC as the communication interface
- Can connect up to 1 Gbit (128 Mbytes) memories
- Uses both ×8 and ×16 data bus width
- Follows asynchronous protocol
- Supports address / data multiplexed mode and non-multiplexed mode
- GPMC clock is 55 MHz
- Device is connected to CS0 mapped to address 800 0000h
- Wait pin signal WAIT0 is monitored depending on the MBOOT configuration pins (XIP/XIPWAIT).

Depending on the MBOOT option the GPMC is configured to use the WAIT signal connected on the WAIT0 pin or not. Wait pin polarity is set to stall accessing memory when the WAIT0 pin is low. The wait monitoring is intended to be used with memories which require long time for initialization after reset or need to pause while reading data. The boot procedure from XIP device can be described as such:

1. Configure GPMC for XIP device access
2. Set the image location to 800 0000h
3. Verify if bootable image is present at the image location.
4. If the image has been found, start it.
5. If the image has not been found, return from XIP booting to the main booting loop.

#### 4.7.2.1 XIP Initialization and Detection

***GPMC Initialization***

Figure 4-9 and Table 4-9 describes the GPMC timing settings set for XIP boot and other address-data accessible devices (e.g., OneNAND).

Copyright © 2011–2016, Texas Instruments Incorporated

**Figure 4-9. GPMC XIP Timings**

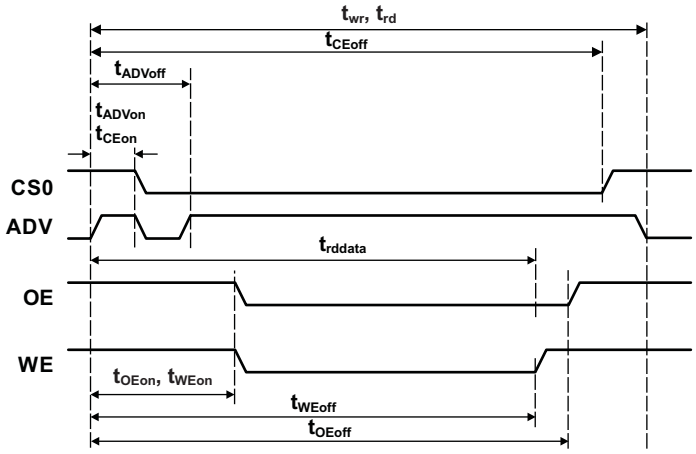


**Table 4-9. XIP Timings Parameters**

| Parameter | Description | Value [clock cycles] |
|---|---|---|
| twr | write cycle period | 17 |
| trd | read cycle period | 17 |
| tCEon | CE low time | 1 |
| tCEoff | CE high time | 16 |
| tADVon | ADV low time | 1 |
| tADVoff | ADV high time | 2 |
| tOEon | OE low time | 3 |
| tWEon | WE low time | 3 |
| trddata | data latch time | 15 |
| tOEoff | OE high time | 16 |
| tWEoff | WE high time | 15 |

The one clock cycle is 18.182 ns which corresponds to 55MHz frequency.

***Device Detection***

There is no specific identification routine executed prior to booting from an XIP device.

### 4.7.2.2 Pins Used for NOR Boot

The list of pins that are configured by the ROM in the case of NOR boot mode are listed in Table 4-10. Note that all the pins might not be driven at boot time. The decision as to which pins need to be driven is based on the type of NOR flash selected.

**Table 4-10. Pins Used for NOR Boot**

| Signal name | Pin used in XIP_MUX0 mode | Pin used in XIP_MUX1 mode |
|---|---|---|
| cs0 | gpmc_cs0 | gpmc_cs0 |
| advn_ale | gpmc_advn_ale | gpmc_advn_ale |
| oen_ren | gpmc_oen_ren | gpmc_oen_ren |
| be0n_cle | gpmc_be0n_cle | gpmc_be0n_cle |
| wen | gpmc_wen | gpmc_wen |
| wait | gpmc_wait | gpmc_wait |

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-10. Pins Used for NOR Boot (continued)**

| Signal name | Pin used in XIP_MUX0 mode | Pin used in XIP_MUX1 mode |
|---|---|---|
| clk | gpmc_clk | gpmc_clk |
| ad0 - ad15 | gpmc_ad0 - gpmc_ad15 | gpmc_ad0 - gpmc_ad15 |
| a0 | gmii0_rxd[3] | vout1_b_cb_c[2] |
| a1 | gmii0_rxd[4] | mmc2_dat[3] |
| a2 | gmii0_rxd[5] | mmc2_dat[2] |
| a3 | gmii0_rxd[6] | mmc2_dat[1] |
| a4 | gmii0_rxd[7] | mmc2_dat[0] |
| a5 | gmii0_rxdv | vout1_g_y_yc[1] |
| a6 | gmii0_gtxclk | vout1_g_y_yc[0] |
| a7 | gmii0_txd[0] | vout1_r_cr[1] |
| a8 | gmii0_txd[1] | vout1_r_cr[0] |
| a9 | gmii0_txd[2] | vout1_b_cb_c[1] |
| a10 | gmii0_txd[3] | vout1_b_cb_c[0] |
| a11 | gmii0_txd[4] | vout1_fid |
| a12 | gmii0_txd[5] | vout0_fid |

**Note:** The ROM code does not multiplex high order address lines gpmc_a[27:13] to their address functions, although the external memory device generally needs to see logic "0" on its higher order address bits to correctly address memory. Many of the high order address pads default to internal pull-down active; however, some pins will default to internal pull-up active and therefore will need to be driven or pulled low by external hardware for the duration of XIP boot operation. See the device data manual for specific details.

In PG2.0, if MBOOT[10] = 1b, the following changes come into effect. These override the pin configuration mentioned above.

- GPMC_CLK is not configured
- GPMC_BE0N_CLE is not configured
- GPMC_ADVN_ALE is configured only for multiplexed NOR boot
- GPMC_A0 configured pinmux in case of 8-bit wide data NOR boot ONLY.
- GPMC_WAIT0 is configured for NOR (muxed and Non-muxed) with default settings in case we use as WAIT , else do a PULL DOWN
- For the following Pins a PULL DOWN is done for both Muxed NOR and Non-Muxed NOR devices
  - GPMC_A[20]
  - GPMC_A[22]
  - SD2_DAT[7]
  - SD2_DAT[6]
  - SD2_DAT[5]
  - GPMC_WAIT[0] (UNLESS configured as WAIT per BOOTMODE)
- For the following Pins a PULL DOWN is done for Non-Muxed NOR devices only
  - VOUT[1]_G_Y_YC[2]
  - VOUT[1]_R_CR[3]

#### 4.7.2.3 Sysboot Pins

Some of the SYSBOOT pins have special meanings when NOR boot is selected.

Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-11. Special SYSBOOT Pins for NOR Boot**

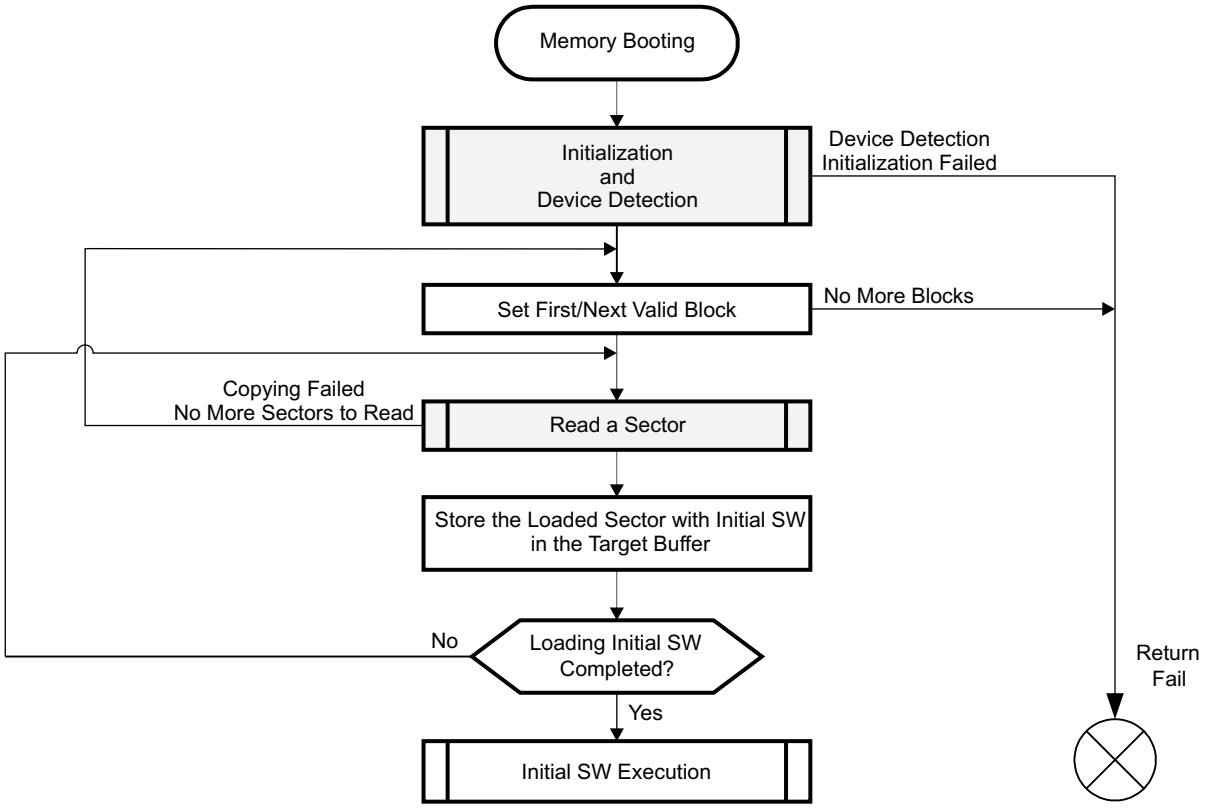
| SYSBOOT[n] | Description |
|---|---|
| [12] (CS0BW) | Must be 0 if 8-bit device is used<br>Must be 1 if 16-bit device is used |
| [15] (CS0WAIT) | Must be 0 if XIP WIAT if not used<br>Must be 1 if XIP WAIT is used |
| [14:13] (CS0MUX[1:0]) | 00b – Non-muxed device<br>01b – A/D muxed device<br>10b – AAD muxed device<br>11b – reserved. |

#### 4.7.2.4 Image Shadowing for non-XIP Memories

**Shadowing on the device**

Shadowing uses the following approach.

**Figure 4-10. Image Shadowing on the Device**



Copyright © 2011–2016, Texas Instruments Incorporated

### 4.7.3 NAND

The NAND flash memory is not XIP and requires shadowing before the code can be executed.

#### 4.7.3.1 NAND Features

The NAND features include:

- GPMC as the communication interface
- Device from 512Mbit (64 MByte)
- ×8 and ×16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128 / 218 spare bytes)
- CE don't care devices only
- Single Level Cell (SLC) and Multiple Level Cell (MLC) devices
- Device Identification based on ONFI or ROM table
- ECC correction : 8 bits/sector for most devices (16b/sector for devices with large spare area)
- GPMC timings adjusted for NAND access
- 55MHz GPMC clock
- Device connected to CS0
- Wait pin signal WAITPIN0 connected to NAND BUSY output
- Four physical blocks are searched for an image. The block size depends on device.

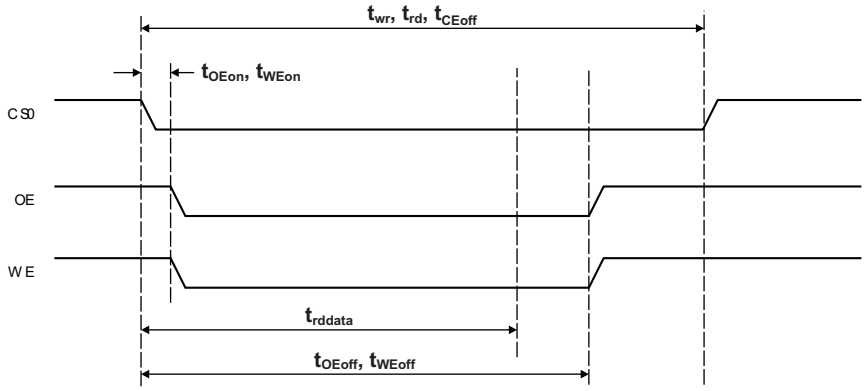
#### 4.7.3.2 Initialization and Detection

The initialization routine for NAND devices consists in three parts: GPMC initialization, device detection with parameters determination and finally bad block detection.

- **ONFI support.** The NAND identification starts with ONFI detection.
- **GPMC initialization.** The GPMC interface is configured such that it can be used for accessing NAND devices. The address bus is released since a NAND device does not use it. The data bus width is initially set to 8 bits; and changed to 16 bits if needed after device parameters determination. The following scheme is applied since NAND devices require different timings when compared to regular NOR devices:

Figure 4-11 and Table 4-12 describes the timings configured for NAND device access. The one clock cycle is 18.181 ns which correspond to 55 MHz frequency.

**Figure 4-11. GPMC NAND Timings**



Copyright © 2011–2016, Texas Instruments Incorporated

**Table 4-12. NAND Timings Parameters**

| Parameter | Description | Value [clock cycles] |
|---|---|---|
| twr | write cycle period | 30 |
| trd | read cycle period | 30 |
| tCEon | CE low (not marked on the figure) | 0 |
| tOEon | CE low to OE low time | 7 |
| tWEon | CE low to WE low time | 5 |
| trddata | CE low to data latch time | 21 |
| tOEoff | CE low to OE high time | 24 |
| tWEoff | CE low to WE high time | 22 |
